SCHOOL OF ATHENS

The fresco of "Philosophy" in the Camera delle Segnatura, Vatican Palace, Rome. Height to arched top 16 feet; width 36 feet 8 inches

This splendid fresco was painted by Raphael in 1511 to represent the "Triumph of Science," as a companion painting to the Dispute of the Sacrament, representing the "Triumph of Religion." Philosophy, implying an encyclopedic knowledge of the whole sphere of scientific learning and intellectual culture, is here symbolized. A vast portico is pictured, the arches of which are pierced with statuette-filled niches; the facing statues are Apollo and Minerva. The central figures are Plato and Aristotle. Grouped about them are all the philosophers, sages, and elders of antiquity discussing the problem of life. Diogenes is prone on the steps; Aristippus passes him talking to Protagoras; to the left, on the steps, Alcibiades, Xenophon and others are listening to Socrates. Below them are Pythagoras, with his wife Theano, his son Telauges, and his pupil Archytas; Anaxagoras is standing; Heraclitus sits alone; Democritus and Epicurus at the base of the pillar. To the right, on the steps are Pyrrho, Arcesilacus and others; below them Archimedes (a portrait of Bramante) teaches geometry, and Ptolemy and Zoroaster stand beside Raphael, Ii Sodoma, and Perugino. Vasari says the fresco represents the union of Theology and Philosophy through Astronomy, and points out Saint Matthew as Pythagoras. It has also been said to represent Saint Paul preaching at Athens, and in 1560 Giorgio Mantovano engraved it as Saint Paul disputing with the Stoics and Epicureans.

PREFACE TO THE NEW EDITION

To impartial critics and scholars, no less than to the thousands of its possessors among the general public, the first edition of The Americana commended itself as a useful work of reference. In many ways, both in its emphasis and in its treatments, it was a departure from the beaten track of earlier works, and experience has shown the wisdom of this departure. The characterization of the work in The Encyclopedia of Education: "Notable for its fullness in articles dealing with technical subjects, as mathematics, engineering, and the trades," is true, even if it fails to state the whole truth. In History, Political Economy, Religion, Philosophy, Astronomy, Education, Literature, as well as in topics of general interest, the first edition was not surpassed by any contemporary American work.

In view of the tremendous changes that the great world conflict has brought about in every department of human thought and activity, and the vital necessity for a new and up-to-date restatement of the world's knowledge, the publishers determined to issue this new edition, and ordered the work planned upon a scale to make it of still greater utility, retaining whatever features the experience of the past had shown to be excellent, and enlarging and improving wherever necessary to meet present conditions. New departments and thousands of new articles have therefore been added, and the whole work has been revised and reset and is printed from new plates. The maps have been prepared especially for this Encyclopedia by the Rand McNally Company of Chicago, and are late and accurate. The illustrations have been carefully selected and are far superior and more numerous than in the former edition. We are confident therefore that the new Americana will be recognized as the greatest repository of practical universal knowledge in one set of books that has ever appeared in the English language.

In the new edition, the Editor has endeavored to limit the work to its legitimate purpose — the presentation of knowledge with faithfulness and
with scholarly impartiality, avoiding the promotion of theories and such discussions and defenses as are entirely foreign to the character and nature of an encyclopedia. Every effort has been made to secure not only accuracy of statement but also fairness and correctness of view.

The "Americana idea" is not simply a reference "book of facts"—too brief to be of any special value to the intelligent reader; nor yet a series of "learned and splendid essays," showing an utter misconception of the idea which justifies the existence of a general work of reference. It is rather an endeavor to present, in an intelligent and informing way, the history and nature of the civilization, institutions, systems, activities and achievements of mankind with sufficient fullness to furnish the general reader a fair and adequate understanding of the development of man and his social life. In dealing with "the dead past and the living present" this Encyclopedia does not seek to dogmatize beyond the established facts. It is content to tell what is known so far as we know it, and leave it there. It knows no north or south—no national boundaries; it has no political, governmental, religious, or social proclivities or antipathies; it is neither pro nor anti; it is neither a maker nor an ultimate interpreter of history; it does not preach sermons, or inculcate morals, or prophesy future events; it neither eulogizes good men nor abuses the bad; but seeks to maintain in all things the spirit of fairness, and aims to avoid pedantry and intellectual cocksureness.

The prime object has been to give a clear, concrete, definite, truthful and up-to-date statement of every subject, without prejudice or bias of any kind; to present in the most intelligent, authoritative, impersonal and impartial manner the actual facts of knowledge so far as it is humanly possible to do so. True, analysis must be made; opinion must be offered; judgment must be passed; perhaps criticism and even condemnation may occasionally be necessary, but it must all be done in the spirit of true scholarship and high service.

The thousands of contributors are representative of the highest scholarship and authority in the United States and other countries, and the editorial staff is composed of men and women of wide knowledge and experience, possessing special encyclopedia training.

The Editor-in-Chief and his staff of co-workers are solely responsible for the literary development of this work. Appreciative acknowledgment, however, is due and is here made, to all the friends of this enterprise who have
encouraged its production, and especially to those who by their practical advice and scholarly assistance, as well as by their personal contributions, have rendered invaluable service, among whom may be mentioned:

To give an adequate statement of the civilization of the world to date, even thirty volumes have proved few enough, but it is the hope and belief of the Editor that the new edition of The Americana will prove an efficient aid to the educational and intellectual forces of America, and of especial value at this time to the general public of the whole English-speaking race.

George Edwin Rines
The first letter of every alphabet except the old German or Runic and the Ethiopian: the "futhark" of the former places it fourth, the latter makes it thirteenth. As all alphabets ultimately come through the Phoenician, (witness the name itself), this arrangement is natural. Our own is inherited from the Latin, which was derived from the Greek; and the latter in its alpha confirms its traditional derivation from the Phoenician where and in Hebrew it is called aleph, Aramaic alpha. The name is said to have meant ox, and so strongly resembles the root-element of elephant that there is little doubt the original meaning of both was the same. Hence formerly the shape of the lower-case a was derived by some from the rough outline of an ox-head with its horns; but in fact, as evidenced by a comparison of the gradual evolution of forms, the small letters in all cases are derived from the capitals, and the Greek capital A (see table under Alphabet) in its original shape was a somewhat more cursive form of the Phoenician aleph which itself was a conventionalized form of the Egyptian hieratic, and that in turn (the final step backward) was conventionalized from the picture of an ibis in the ancient Egyptian hieroglyphics or ideographs.

The sound of the letter has varied little more than the form—perhaps less—except in modern English, which owing to its composite character has made it a symbol of so many different vowel-sounds as to be well-nigh meaningless. Yet even here most of them have never quite lost connection with the earlier vocal efforts it stood for, and their fluctuations are fixed by the character of the vocal opening. The Phoenician sound represented by the letter aleph cannot have corresponded to the Greek alpha or any of its derivatives, as the former alphabet assumed that all syllables began with consonants, and aleph was in some sort consonantal; but the Greeks made it a pure vowel, the so-called Continental or broad a as in "ah." This is the simplest and most fundamental of all vowel-sounds, the earliest uttered by infants, whence many grotesque theories of its divine origin and its pronunciability for, if position—such as it results from opening the throat and mouth wide and emitting the tone from the larynx, with the least friction or interference possible from the other organs; and it is still the most general on the Continent of Europe. But even there it has been largely flattened by the French into the short sound as in "at"; at the end of words in all languages the dropping of the voice tends to set it toward the sound of u-in "but," which in English it quite attains; and with us it has become the representative of nine distinct sounds, seven of them each recognizably developed from one of the others, and all from the parent sound, while two are of a different order yet still explicable. The usual arrangement (&"fate, fat, far, fall," etc.) is entirely misleading, as it obliterates this evolution which the following makes clear:

1. ah, explained above.
2. all, a closer sound than (1), formed by drawing back the tongue, compressing the sides of the throat, and speaking more toward the diaphragm. In general utterance this is perhaps the first change from ah. It is almost universal among the Hindu and Persian masses (&"ghaut" for &"ghat," etc.), and was very common in England and America in the 18th century: witness pronunciations like &"spaw" for &"spa"; the curious aberrant &"vawz" for &"vahz" which has more curiously become accepted as a sort of social touchstone in a small group; family names like Raleigh, Decatur &"Toney," etc., in American pronunciation.

3. was, what. The same pronounced still deeper in the diaphragm, and cut short instead of prolonged.

4. oval. This is the neutral sound, corresponding to "short u"; used in Western languages only in unaccented syllables, and made by lazily opening the organs as little as possible and putting no stress on the expiration of the breath. It is the closest of the vowel-sounds, and the most diaphragmal, and therefore seemingly the antithesis of &"broad a"; it has in truth no special relation to that more than to e and o (&"silent," &"apron"), but is the common weakened form of all. In Hindu speech it is used stressed, as in the familiar &"Juggernaut" (Jagannath), &"Buckergunge" (Bakarganj), etc.

5. bare. A more open sound than (1), formed in precisely the same manner as (2) except by expanding instead of contracting the throat.

6. aT. Identical with (5) except being cut short instead of prolonged; in fact, its short sound.

7. ask. Always a different sound from
the others, but not always the same in itself. With the less cultivated speakers it is nearly identical with (5), even with (6). With others, anxious to avoid the flatness and exasperating in the opposite direction, it is made identical with (1). With the majority of good speakers it is akin to (1), but shorter and more diaphragmal, and with the organs rather closer together.

(8) any, many. This is not one of the group of a-sounds, but is "short e." The change was caused by assimilating the a-sound to the i-sound of the closing letter.

(9) ate. This, in usual order the first given, considered the typical English a-sound, and actually furnishing the pronunciation of that letter in its alphabetic position, is not merely not an a-sound at all, but not even a simple vowel-sound being nearly ē, sliding quickly from a closer and more diaphragmal "short e" to a vanishing sound of "short i." As in (8), the cause appears to have been originally assimilation of a final vowel (the sound e now so often silent but "lengthening" the a before it), and afterwards extended to words where this principle could not act.

A, in general, the first term of any series. The highest note of the scale of A, major minor; and A minor is the relative (or related) minor of (or belonging to) C major; the Continental la. The open second string of the violin sounds it, and the instruments of an orchestra are all tuned to it. As a fixed tone a' (435 vibrations) is the standard by which all instruments are tuned. In theoretical works A denotes the triad of A major and a the triad of A minor. In the score of works requiring more than one performer the letters of the alphabet are used as guides, to help find the places readily in case of repetition.

In logic, the universal affirmative ("all trade is barter"), distinguished from the particular affirmative ("some trade is barter"). See Logic.

In algebra, the first letters of the alphabet, a, b, c, etc., are used to denote known quantities, while the last, down to z, denote the unknown,—a and x being used first in all cases, the others being added according to need.

In mechanical diagrams, the capitals A, B, C, etc., are used to mark off points, lines, angles, and figures; in complicated diagrams, often supplemented by the small letters and accented, to indicate the closer relations of parts.

As an abbreviation, see Abbreviations.

As an adjective or attributive, shaped like the letter A; as an A tent.

Consult Petrie, W. M. F., "The Formation of the Alphabet" (1912); Rippmann, "Sounds of Spoken English" (London 1910); Stucken, "Das Alphabet und die Mundstationen" (1913); Sweet, "History of English Sounds" (Oxford 1908); Taylor, I., "The Alphabet" (London 1883).

A is also the first of the Dominical Letters. A, word. (1) The form of "an" used before consonants. (2) Broken-down form of "on," or ellipsis of "for a" ("twice a day"). (3) Old form of "ah," as a war-cry ("A Douglas!"").

A1, a-one (colloquially, "first-class"), the mark for highest-grade wooden vessels in Lloyd's (q.v.) Register of Shipping. A refers to hull, 1 to rigging and equipment. This rank is assigned by Lloyd's, surveyors to new ships for a term of years prefixed to the symbol, as 10A1) dependent on quality of materials and mode of building; but to retain it they must be periodically surveyed. Pilots are granted continuation for one to eight years, marked 10A1 Cont. SAI, etc. A in red means over-age, but still fit for any voyages which perishable goods can endure; B in black, fit for short trips with similar goods. In all cases the 1 is omitted if rigging, etc., are inferior. Iron and steel vessels have a Gothic A preceded by numerals from 100 down, 100A to 90A re-surveyed once in four years, 85A and below once in three; rigging, etc., marked same as on wooden ships. In the German Lloyd's A1 and A are the two best grades of wooden ships; B1, B, CL, and CK, lower ones; iron and steel ships are marked as in the English classification, but with the resurvey term marked under the A.

As, a ("water"): a general Indo-European word in various shapes,—Ger. ach or aach in Aachen, Biberach, etc.; Lat. aqua, pl. aquae, whence O.F. Aiges, Mod.F. Aix, in compounds; etc.), the name of some forty streams in northern and central Europe, among the chief, a French river rising in river rising in dept. Pas-de-Calais, flowing into dept. Nord, and reaching the Strait of Dover at Gravelines; about 50 miles long, navigable below St. Omer, and connected with Calais and Dunkirk by canals.

As, geographically, a Hawaiian term much in use to describe lava flows with rough, cindery surfaces.

AACHEN, ä’ten. See AIX-LA-CHEAPPE.

AAGESEN, Andrew, æ’gè-sen, Danish statesman and jurist: b. 1826; d. 1879. In early life he commanded a reserve battalion in the Schleswig war of 1848. He was appointed professor of jurisprudence in his alma mater, the University of Copenhagen in 1855, where he was distinguished by his learning and attractive personality. He was an expert in Roman law, in maritime and commercial legislation, and was the chief author of the navigation law of 1882. He was elected to the Lands thing in 1879.

AAMHES or AAMHES, æ’mess. (c. 1700 B.C.) the author of the hieratic papyrus from the Rhind collection, deciphered by Eisenlohr in 1877, which is the first extant mathematical document from Egypt, or indeed from anywhere. It contains crude approximations to the area of an isosceles triangle or trapezoid, and the fairly correct value of \( \pi \) for \( \pi \). It also contains the first trace of the notion of equation.

AAHMES I, the founder of the 18th dynasty in Egypt, c. 1600 B.C., and its final liberator from the Hyksos or Shepherd Kings, Asiatic nomads who had conquered the land a century or two before. Native kings had already recovered it in part; but Aahmes captured the last Hyksos fortress, Hatwaret (Awaris), expelled them from Egypt, and followed them into southern Palestine, besieged their army five years in "Sharureh" and captured it. He then penetrated farther into Palestine, levying tribute on it and on the seaboard. This began a long series of Egypt-
tian retaliatory expeditions into West Asia and a long dominance over it. He had an admiral of the same name, whose self-laudatory inscription on his tomb is a most valuable mine of knowledge on the military and naval operations of the time. As his queen; her mummy-case, one of the most magnificent ever discovered, is in the museum at Gizeh.

AAHMES II, the Amasis of Herodotus, fifth Pharaoh of the 26th dynasty, c. 570-526 B.C. An officer of Aries headed a revolt against him, and overthrew and killed him. Though he seems to have risen from the ranks, and to have loved roystering and disliked royal etiquette, he made a capable and judicious sovereign; saved Egypt from conquest by Nebuchadnezzar (who ravaged it, but retreated), and managed to preserve it from invasion by Cyrus the Great. He was on very friendly terms with the Greeks: lending his influence to promote their commerce and colonization; assigning them the excellent port of Naucratis, which soon grew into a flourishing city; contributing liberally toward the rebuilding of the burned temple at Delphi; and according to Greek story having cordial relations with several philosophers and princes — Pythagoras, Polycrates, etc. Under the reign of Aahmes Egypt enjoyed much prosperity.

AALBORG, ålb'borg (=eel-town), Denmark, the chief city of N. Jutland; on the south side of the Limfjord (a sea-arm which joins the Cattegat to the North Sea), and on the Danish State Ry., which crosses the fjord by an iron bridge 990 feet long, one of the finest pieces of engineering in the kingdom. An important commercial town as far back as the 11th century (Wallenstein sacked it in 1627, the Swedes in 1644 and 1657). Despite a shallow harbor it has much trade, by means of all vessels, with Scandinavia and England; and it manufactures liquors, leather, lumber, soap, cement, cotton goods, etc. A bishop's seat, it has a cathedral; also two old churches, an old castle, a museum, and a well equipped library. P. 33,500.

AALSEND. See ALESUND.

AALEN, a'len, Germany, town of Württemberg on the Kocher river, 46 miles by rail east of Stuttgart. It is situated in the foothills of the Swabian Alps, 1,400 feet above sea-level. It was the boyhood home of Christian Schubart the poet who is commemorated by a statue. Large iron works, woolen, linen, ribbon and leather manufactures are carried on. Aalen was a free imperial city from 1360 until its annexation to Württemberg in 1802. P. 11,400.

AALE PASHA, Mehemed Emin, a-i'le' pă-shă, mē-hēm'-ed' a-min', a Turkish statesman: b. Constantinople 1815; d. 6 Sept. 1871. Entering public life at 15, he was charged d'affaires at the ambassador to Great Britain 1841-44; chancellor of the divan 1845; thrice minister of foreign affairs in the troublous years 1846-52; grand vizier a short time in 1852 but soon displaced as not in political accord with his companions. Recalled as foreign minister in 1854 as Crimean Minister of 1854 in March 1855 he took part in the treaty of the four guarantees; in July again became grand vizier, and at the Treaty of Paris in 1856 showed great decision and cleverness in looking after Turkish interests, but without entire success. In November his political tone forced him to resign, but he remained minister without portfolio and member of the Great Council. After Reshid Pasha's death in 1858 he was again grand vizier, and soon again withdrawn; but in November 1861 he resumed the office of foreign minister. He was president of the convention on Rumanian affairs, in Paris 1864, and member of the Black Sea Conference in London 1871. During the Sultan's absence at the Paris Exposition in 1867 he was regent; and while the very soul of the reform movement energetically suppressed the Cretan rebellion and the movement for Egyptian independence. In the full tide of activity he suddenly died.—an excellent man and statesman who strove all his life, like Midhat Pasha, but with little success, to regenerate and modernize his country.

AAR or AARE, ar (*river*), the name of several German streams: chiefly, a Swiss river tributary to the Rhine, about 175 miles long, the largest in Switzerland and longest in Switzerland, the Rhone. Formed by torrents from the vast and famous Oberaar and Unteraar glaciers of the Bernese Alps in E. Bern, it flows northwest through the valley of Hasli over the Handeck Falls, 200 feet high, expands into Lake Brienz, and past Interlaken into Lake Thun becoming navigable, passes Bern, turns north and then northeast along the southern slopes of the Jura, past Solothurn and Aarau, and joining the Limmat, shortly after breaks through the ridge and empties into the Rhine at Waldshut. Chief affluents, the Saane, Zihl, and Emme, the Reuss feeding it from the lake of Lucerne and Zuger See, the Limmat from the lake of Zurich and the Lützschine from the two splendid Grindelwald glaciers. The chief cities on its banks are Bern, Solothurn, Aarau and Interlaken.

AARAU, (*Aar-meadow*), Switzerland, capital of the canton of Aargau; right bank of the Aar, 41 miles northeast of Bern, 1,100 feet above sea-level, in a fertile plain just south of the Jura, whose peaks close by are the Wasserfluh (2,850 feet) and Grossfluth (2,540 feet). It has famous manufactures of cannon, bells, and fine scientific instruments, besides cutlery, leather, silk, and cotton; and holds eight fairs yearly. There are also historic, scientific, and ethnographic museums, a cantonal library rich in volumes of Swiss history, and a bronze statue of the historian and novelist Heinrich Zschokke (q.v.), who lived here. Here, December 1797, the old Swiss confederacy held its last session; April to September 1798 it was the capital of the Helvetic Republic. P. 9,800.

AARDVARK, är'd-värk (Dutch, "earth-pig"), the Cape ant-eater (Orycteropus capensis). Also called ground-hog and ant-bear. A South African mammal measuring about five feet from end of tubular snout to tip of long naked tail. It lives in shallow burrows and is of timid, nocturnal habit; it feeds on ants and other insects, licking them up with its long tongue which secretes a sticky saliva. The head is slightly pig-like, with erect ears; the
stout body is sparsely covered with short stiff hairs; the limbs are short, with strong claws for digging; the flesh is edible and considered delicate, though of peculiar flavor. See Anteater.

AARDWOLF (Dutch, "earth-wolf"), a timid, nocturnal South African carnivore (Proteles lagandus), the only representative of the family Proteidae. It resembles the hyena, to which it is very closely related, but has a short strength of jaw and teeth. Its fur is coarse; color ash-gray irregularly striped with black; muzzle, black and nearly naked; ears, brown outside, gray within. It inhabits burrows, and being unable to kill vertebrates lives upon insects, larvae, and small carrion.

AARESTRUP, Emil, a're-stroop, Danish poet (1800-56). He was born in Copenhagen. He was not duly appreciated until after his death, but is now acknowledged one of the foremost lyric poets of Denmark, ranking next to Christian Winther. His 'Collected Poems,' with critical sketch by G. Randers, was published at Copenhagen in 1877.

AARGAU, ar'goov ("Aar-shire": Fr. Argovie, ar-go-vay), Switzerland, an extreme N. canton between Basel W., Zurich E., Lucerne S., and the Rhine and Baden N. Area 542 square miles; capital Aarau. It consists mainly of slopes of the Alps and Jura, nowhere over 3,000 feet above sea-level, with numerous fertile valleys watered by the Aar and its S.E. tributaries, the Limmat (or Linth) and Reuss (see Aar) being chief. The climate is moist and variable, and stock-farming and agriculture are advanced: fruit, vegetables, and vines abound, but the wines are inferior. Timber is plentiful. Manufactures: cottons, silks, ribbons, linens, hosier-y, straw-plait, etc., and important machine works. The boat traffic on the Aar and Rhine, and the active land and water transit trade, employ many. It has several picturesque ruined castles. Aargau, part of old Helvetia, then conquered by the Franks (5th century), a Hapsburg fief 1173-1415, then captured by the Cantonal League and driven out. Bern and Lucerne, was subjugated and a part made a member of the Helvetic Republic 1798. Its constitution was first fixed by the Congress of Vienna in 1815; in 1831 it gained a democratic one, and has ever since been a champion of liberalism. In 1841 it suppressed its eight monasteries, and this led to the formation of the Sonderbund (q.v.), or Secession League, of Catholic cantons in 1847. Legislative power is vested in the Great Council, one for every 1,100 people, which has to submit laws and decrees to a referendum; executive power in the Small Council of five, chosen by and from the Great one. Aargau sends 10 members to the National Council. Pop. (1913) 236,860, nearly all German. See Schweiz and Aargau.

AARHUS, är'hoos, Denmark. (1) District, the east central part of Jutland, divided into Aarhus and Randers amfs (or bailiwicks); area 727 square miles; pop. about 325,000, mainly employed in fishing industries. (2) City, the second largest of Denmark, capital of Aarhus amt, on a bay of the Cattegat and the Danish State Ry.; has a harbor made in 1883-90, with a breakwater and six feet of water, regular steamer lines to Copenhagen and England, and a large trade in grain, cattle, etc.; and much shipbuilding, iron founding, cotton-spinning, and other manufactures. It is a bishop's seat since 946, making it one of the oldest cities in Denmark. The cathedral, begun in 1201, is one of the largest and finest church buildings in the kingdom. It has a museum, banks and a stock exchange. Pop. about 62,000.

AARON, a'ron, a prominent but subordinate figure of the Exodus period in Jewish history, whose importance increases with the distance of the recorders from the early epochs, and with the remodeling of the early stories by the priesthood to support their later pretensions and their theocratic ideal of Judaism. In the earliest or Elohist (q.v.) portions of the Hexateuch, he is brother of Miriam (Ex. xii, 26); but it is Joshua who, as Moses' minister for religious rites and who keeps guard over the tent of meeting (Ex. xxiii, 11), the young men of Israel offer sacrifice, and Moses alone is the high-priest. Aaron, however, seems to be regarded as ancestor of one set of priests, those at the Hill of Pharaoh, and perhaps of those at Bethel. In a later portion it is he who yields to the demand for an idol, and fashions the golden calf—a evident genealogy of Baal-worship, accredited to the ancestor of rival priests, and perhaps Moses' older brother, but is brought upon the stage only to be ignored: Pharaoh sends for him and Moses to take away the plagues (Ex. vii), but he has no independent power and is merely Moses' agent in performing miracles, bringing down the plagues, etc. The supererogatory nature of his functions makes it probable that his rôle is introduced by the priestly redactor, under whose hands he becomes a mighty leader little inferior to Moses: he sometimes receives laws directly from Yahweh (Num. xxvii), he alone numbers the people; the Israelites rebel against him as well as Moses, though, when he criticizes Moses, curiously his inciter Miriam is punished, not himself (Num. xii); he and Moses jointly disobey Yahweh's command at Meribah; and he is punished by having his life close before entering Canaan. This magnifying connects itself clearly with the post-exile books, where he is the ancestor of all legitimate priests, consecrated high-priest by Moses, and alone permitted to enter the Holy of Holies yearly: he represents the tribe of Levi, and even within it his descendants alone are rightful priests, and interlopers (see Korah) are stricken dead by Yahweh. The pre-exilic prophets know nothing of this claim; Pielkiel traces the origin of the Jerusalem priesthood only to Zadok (q.v.). He belongs to the tribe of Joseph and its struggle to secure admission to the Jerusalem priesthood. Consult Meyer, Ed., 'Die Israeliten und ihre Nachbarstämme' (1906); Schmidt, N., 'Jewish and Christi an Doctrines' (in the Hibbert Journal 1906); Oort 'Die Aaroni eden' (in Theologisch Tijdschrift 1884).

AARON BEN ASHER, Jewish scholar: lived in Tiberias early in the 10th century. He
completed one of the two existing recensions of the vowels and accents of the Hebrew Bible. His rival Ben Naftali also completed a similar work, but the readings of the former are usually preferred.

AARON BEN ELIJAH, renowned Karaite theologian: b. Cairo, Egypt, 1300; d. Constantinople 1369. To distinguish him from his father, Aaron ben Joseph, also a famous scholar, he was often called "Aaron the Younger." By many he is considered the most logical reasoner of the Karaite school and in the proficiency of his learning the equal of Maimonides. In accordance with the doctrines of the Mutazilites, which influenced him early in his career, he emphasized the reason as the medium for salvation and enunciated a materialistic theory of the universe, though of divine origin. His first work was ‘Ez ha-Hayyim’ (‘The Tree of Life,’ 1346), which was followed by ‘Gan Eden’ (‘The Garden of Eden,’ a Karaite code, 1354) ‘Keter Torah’ (‘The Crown of the Law,’ a commentary on the Pentateuch, 1362). Most of his life he lived in Nicomedia, in Asia Minor, but later in life took up his residence in Constantinople.

AARON, Hill of, a lofty mountain range of Arabia Petraea, in the district of Shurah Seir, 15 miles southwest of Shobeck. On its highest pinnacle — called by the Arabs Nebi Haroun — is a small building supposed by the natives to inclose the tomb of Aaron; and it may be the Mount Hor of Num. xxxiii.

AARSENS, Frans Van, a’r sens, Dutch diplomat: b. The Hague, 1572; d. 1641. From 26 on he represented the States-General at the court of France for many years, first as agent and then as ambassador; and Richelieu ranked him one of the three greatest politicians of his time. He also held embassies to Venice, Germany, and England. The judicial murder of John of Barneveld by Maurice of Orange in 1619 was greatly helped on by Aarsens, who has gained a tardy popular opprobrium for it through Motley’s life of John.

AASEN, Ivar Andreas, a’ sen, é var å’ ndra’ as, Norwegian philologist and poet: b. Orsten, 1816; d. 1868. As first a botanist, he turned philologist and student of native dialects from motives of patriotic enthusiasm; his great aim was to construct from their older elements a new national language ("Landssmaal"), as a substitute for Danish, in pursuance of which he published several valuable philological works and set going the nationalistic movement called "maalstøve." As a poet he produced "Symra," a collection of lyrics, and "Ervingen," a drama.

AASVAR, a’ svir, Norwegian islands near the Arctic Circle, where the great Nordland herring are caught in December and January to the extent of sometimes 200,000 tons, and 10,000 men are employed, who live elsewhere the rest of the year.

AASVOGEL, a’ sf o-gel (‘carroion-bird’), the South African vulture, of several different species.

AB, the 11th month of the Hebrews’ civil year and the 5th of their ecclesiastical (which begins with Nisan), has 30 days, and answers to the July moon, or part of our July and August. The 9th day was a great fast in memory of the destruction of the first temple by Nebuchadnezzar, 586 B.C., and the second by Titus, 70 A.D.

ABA or ABU HANIFAH, or HANIFA, a’ba or a’bo hà-né’fa, or hàn’fa, a surname of Alnooma: b. in the 80th and d. in the 15th year of the Hegira (701–71) He is the most celebrated doctor of the orthodox Mussulmans, and his sect is the most esteemed of the four which they severally follow.

ABA, a’ba, a mountain in Armenia, part of Mount Taurus, where the rivers Araxes and Euphrates have their rise.

AABADA, a’bà-da, a wandering tribe of Hamitic Arabs found on the southern border of Egypt east of the Nile from Assuan to the Red Sea and north to Kena-Kosseir. They now number about 30,000, governed by an hereditary chief, but in ancient days were much more numerous. The more enterprising still carry on their old occupation of trade, guards, and others of trade carriers, and as dealers in herbs, drugs and gums. During the Mahdist wars of 1882–98 many enlisted in the Anglo-Egyptian troops. Under British rule they have advanced considerably, and now engage profitably in agricultural and fishing industries. Self-styled "sons of Jinns," they are claimed to be descendants of the Troglydytes and Blemmyes of classic ages, the Gebelid of Flioni, who inhabited the same region.

ABACO, a’ba-kò (or Lucaya), Great and Little, two Bahama islands 150 miles west of Florida. Great Abaco, the largest of the Bahamas, is about 80 miles long by 20 wide, with a lighthouse at its southeast point, at a natural perforation of the rock known to seamen as "The Hole-in-the-Wall." Little Abaco, 28 miles long, lies west of its north point. Area of both, 879 square miles; pop. 2,400.

ABACUS (Greek å’ bas, from the Semitic pza, abq, dust). In mathematics, a term applied to several forms of reckoning apparatus, and hence for some centuries to arithmetic in itself. The primitive form seems to have been a board covered with fine dust, whence the generic name. Among the Hindus this was a wooden tablet covered with pipe clay, upon which was sprinkled purple sand, the numerals being written with a stylus. (Consult Taylor, in the preface to his translation of the ‘Lilawati,’ Bombay 1816, p. 6). That this form was used by the ancient Greeks is evident from Iamblichus, who asserts that Pythagoras taught geometry as well as arithmetic upon an abacus. Its use among the Romans of the classical period is also well attested. Another form of the abacus, having many modifications, is a board with beads sliding in grooves or on wires in a frame. Herodotus tells us that this instrument was used by the Egyptians and the Greeks, and we have evidence that the Romans also knew it, although preferring a form described below. It is at present widely used in India and appears in the form of the swan în Chine, the sárōban in Japan, and the tschoty in Russia, the latter being the same as the modern Arabian abacus. In its simplest form, the beads or counters are stored at one end of the frame and the computation is done at the other end by moving the correct number of
beads over against that side of the frame. Usually on a decimal scale, the separate wires represent units, tens, hundreds, etc., "progressively, but a duodecimal scale is also in use, and among the Chinese there is a separate division horizontally across the frame below which units are counted up to five, and the fives transferred to the upper section where each bead stands for five units. In parts of India where English money is used the wires on the abacus represent pence, shillings, pounds, tens of pounds, hundreds of pounds, etc., there being 11 beads on the first wire, 19 on the second, and 9 on each one above. It is in this type of the abacus that prayer beads have their origin. The third form is a ruled table, upon which counters are placed, somewhat like checkers on a backgammon board, a game derived from this type of abacus. This was the favorite form among the Romans, whose numerals were not at all adapted to calculation, and it maintained its position throughout the Middle Ages and until the latter part of the 16th century. The Hindu-Arabic numerals (see NUMERALS) having then supplanted the Roman, such an aid to calculation was thought superfluous in Western Europe. The counters used were called ϕφοι by the Greeks, calculi (pebbles, whence calculate and our calculate) by the Romans, and in Cicero’s time aera because brass discs were used. In medieval times they were called projectiles because they were thrown upon the table, whence our expression to cast an account, and Shakespeare’s counter caster. The early French translated this as gettons, gectoirs, and jetons, whence our obsolete English jettons and the modern French jeton, meaning a medal, and also a counter for games. The Germans translated the late Latin denerarī supputarī (calculating pennies) as Rechenpfennige, the early printed books distinguishing between reckoning on the line (that is, on the ruled table) and with the pen. The Court of the Exchequer (q.v.) derives its name from this form of the abacus, about which the judges of the fiscal court sat. (Hall, ‘The Antiquities and Curiosities of the Exchequer,’ London 1891; Henderson, ‘Select Historical Documents of the Middle Ages,’ London 1892, p. 20.) Another form of the abacus, possibly introduced by Gerbert before he became Pope Sylvester II (q.v.), was arranged in columns and employed counters upon which the western Arab forms of the Hindu numerals (see NUMERALS) were written. The use of the term to designate an instrument of experts of India where the language of arithmetic itself, as in the ‘Liber abaci’ of Leonardo Fibonacci of Pisa (q.v.) and in the works of later writers.

DAVID EUGENE SMITH,
Professor of Mathematics, Teachers College, Columbia University, New York.

ABACUS. In architecture, the flat stone forming the highest member of a column, next under the architrave and bearing its first weight. In the Tuscan, Doric, and Ionic orders, its four sides are arched inward, with generally a rose in the centre. In Gothic architecture it was variously employed, according to the architect’s fancy.

ABAD (‘abode’), a suffix meaning town or city, common in Hindu and Persian names: as Allahabad, city of God; Hyderabad, city of Hyderabad; Secunderabad, city of Alexander.

ABAD’DON, in the Old Testament and the rabbinical literature, Sheol, the underworld, or the place of the lost in it: in Revelation (ix, 11) the King of the Abyss, Greek APOLLYON.

AB’ADIR, according to Augustine, the chief god of the Carthaginians; according to Priscian, a stone which Saturn swallowed by contrivance of his wife Ops, believing it to be his new-born son Jupiter, and hence worshipped with divine honors.

ABAKANSK’, a mountain range in Siberia, extending from the upper Yenisei to the Tom River, parallel to the Altai Mountains. Also a town founded by Peter the Great in 1707, near the Abakan River; now renamed Minusinsk (q.v.).

AB’ALONE (Sp., origin unknown). Any one of the several species of Haliotis (ear-shells or sea-ears) found along the California coast. The shell is a spiral so broadly flattened as to make an oval saucer, around the edge of which is a row of holes through which the tentacles pass when extended. The animal lives on rocks near the shore, feeding on seaweed; when frightened it withdraws entirely beneath its shell and clings with surprising force to the rock. The shell is lined with a bright mother-of-pearl much used in arts and crafts. The animal itself is used as food by the Chinese and Japanese; quantities of them are dried and exported from California to the Orient. The name ‘abalone’ is local, but marine gastropods of the same family are abundant in all seas not too cold, outside the western Atlantic. In the Channel Islands off the coast of France, a species known as ormers, Fr. ‘oreilles de mer,’ is used as food. See EAR-SHELL.

ABANAH, ā-bānā, or AMANAH (Gr. Chrysorrhoas, now Baradā, ‘The cold’), one of the two famous ‘rivers of Damascus’ mentioned in the Scripture: rising in the heart of the Anti-Lebanon, it flows through a narrow gorge and spreads fan-wise through the Damascus oasis, irrigating the land and supplying the city, by the canals or ‘rivers,’ with its clear sparkling water, so greatly superior to the Jordan in beauty that Naaman’s question is quite intelligible.
ABANCAY, ñ-bã-sí', Peru, capital of dept. Apurimac, 65 miles west of Cuzco, on the Abancay, an affluent of the upper Apurimac; in an East-Andean valley, the best sugar district in Peru, with large refineries and silver mines. Pop. about 3,000.

ABANDONMENT, the act of abandoning, giving up, or relinquishing. It is the relinquishment of an interest or claim. Thus, in certain circumstances, a person who has insured property on board a ship may relinquish to the insurers a remnant of it saved from a wreck, as a preliminary to calling upon them to pay the full amount of the insurance effected.

The principle is also applicable in fire insurance, and often under stipulations in life policies in favor of creditors. The chief object of abandonment being to recover the whole value of the subject of the insurance, it is necessary only where the subject itself, or portions of it, or claims on account of it, survive the peril which caused the loss. At once upon receiving information of a loss the assured must elect what he abandons, and not delay for the purpose of speculating on the state of the markets.

The English law is more restricted than the American, by not making the loss over half the value conclusive of the right to abandon, and by judging the right to abandon by the circumstances at the time of action brought, and not by the facts existing at the time of the abandonment. By commencing full repairs the right of abandonment is waived. An abandonment may be oral or in writing. When acted upon by another party, the effect of abandonment is to deprive all the owner's rights.

In criminal law abandonment is the intentional desertion of a dependent by one under a legal duty to maintain him. A parent or guardian of the person of an infant is guilty of a misdemeanor if the child is injured through the act of the guardian, and of murder if death results. The offense is now defined in nearly all States. Consult Bishop 'Commentaries on Criminal Law' (Boston 1895); Wharton, A. 'Treatise on Criminal Law' (San Francisco 1912).

ABANO, Pietro d’, ñ-bá-nó, pé-a-trò dè, known also as Petrus de Apono, one of the most celebrated physicians of the 13th century: b. in the Italian village from which he takes his name, in 1246 or 1250; d. 1316. He visited the East in order to acquire a thorough knowledge of Greek, and then completed his studies at the University of Paris. Returning to Italy he settled at Padua, where his reputation as a physician became so great that his rivals, envious of his fame, gave out that he was aided in his cures by evil spirits. It was known, too, that he practised astrology, and he was twice summoned before the Inquisition. On the first occasion he was acquitted, and he died before his case was tried to an end. Besides the work, 'Conciliorum Differentiarum Philosophorum et Praeclari Medicorum' (Mantua 1472), he wrote 'De Venenis eorumque Remediis' (1472); 'Geomantia', 'Questiones de Febribus,' and other works.

ABANO BAGNI, ñ-bá:no bá:ní, Italy, a hilly comune in the province of Padua, 29 miles from Venice by rail. Already in ancient times its hot sulphur springs were famous among the Romans as a cure for diseases of the skin, the town being known then as Fons Aponi. Pop. 5,500.

ABANTS, an ancient Greek people originally from Thrace, who settled in Phocis, and built a town called Abæ. Their name implies an ancestor or leader Abas.

ABAR' BANEL. See ABRAVANEL.

ABAR' IM ('the beyond,' sc. Jordan), the edge of the Moabite plateau overlooking the entire Jordan valley: a range of highlands forming its whole horizon, broken only by the valley mouths of the Yarmuk, the Zerka, and the Jabrok. Its highest elevation is Mount Nebo, whence Moses had his 'Pisgah view' of Palestine (see PISGAH), and whence Jericho is plainly visible. Ancient altars, perhaps Amorite, were discovered here in 1881.

ABARIS, the Hyperborean (fabled as from the Caucasus or thereabout), a legendary sage first mentioned by Pindar and Herodotus, 5th century B.C., but quite uncertain of date or existence. He had the power of prophecy and a magic arrow of Apollo on which he rode through the air; cured by incantations, rid the world of a great plague, etc. The Neo-Platonists made him Pythagoras' companion.

ABASCAL, José Fernando, ñ-bás-kál', hó-sá fér-nándo, Spanish soldier and statesman: b. Oviedo, 1743; d. Madrid, 1821. Entering service in 1762, he rose to brigadier-general in the French Revolutionary wars; in 1796 became viceroy of Cuba and defended Havana against the English fleet; then was commander in New Galicia, and last, viceregal of Peru, where he showed great ability and kindliness, and in recognition of his efforts to reconcile natives and Spanish was created Marqués de la Concordia. He defended Buenos Aires from the English, and suppressed revolts in Lima and Cuzco; but having a turn of ill success was recalled in 1816.

ABASOLO, Mariano, ñ-bás-so-lo, má-re-a-nó, Mexican patriot: b. Dolores, Guanajuato, about 1780; d. Cadiz, 1819. Joining Hidalgo's (q.v.) Mexican revolution in 1810, he rose to major-general, and was noted for his treatment of prisoners. After the final rout at Puente de Calderon, 17 Jan. 1811, he fled with his chief; with him was captured by the counter-revolutionists, tried at Chihuahua, and sentenced to imprisonment in Spain, where he died.

ABATEMENT. In law: (1) A removal, or putting down, as of a nuisance. (2) A quashing; a judicial defeat; the rendering abortive by law, as when a writ is overthrown by some fatal exception taken to it in court. A plea designed to effect this result is called a plea in abatement. All dilatory pleas are considered pleas in abatement, in contradistinction to pleas in bar, which consider the merits of the claim. (3) Forcible entry of a stranger into an inheritance when the person seized of it dies, and before the heir or devisee can take possession. (4) The termination of an action in a court of law, or the suspension of proceedings in a suit in equity, in consequence of the occurrence of some event, as for example the death of one of the litigants. In contracts, a reduction made by the creditor in consideration of the prompt payment of a debt due by the debtor. In mercantile law, a deduction from
duties imposed at the custom-house, on account of damages received by goods during importation or while in the custom-house.

A misnomer of plaintiff or defendant can be taken advantage of only by plea in abatement. A abattement was formerly an addition to a coat-of-arms, indicative of disgrace or inferiority; now it is confined to the bend sinister, marking illegitimate descent.

**ABATIS**, or **ABATTIS**, in military affairs, a defense made of felled trees. In sudden emergencies, the trees are merely laid lengthwise beside each other, with the branches pointed outward to prevent the approach of the enemy. When employed for the defense of a pass or entrance, the boughs of the trees are stripped of their leaves and pointed, the trunks are planted in the ground, and the branches interwoven with each other; and the abatis is laid in a depression in front of a trench, for protection from artillery fire.

**ABATOS**, Egypt, an island in Lake Moeris, famous as the sepulchre of Osiris, and for producing the papyrus of which the ancients made their paper.

**ABATTOIR** (Fr.), ab-at-war, a slaughterhouse, the name sometimes extended to include a great market of which the abattoir proper is only a part. The nuisance of blood, offal, etc., in crowded settlements, early forced ancient civilized governments to put the slaughter of the animals under restrictions. Our most definite information on this point is the system under the Roman empire: the slaughter-houses instead of being scattered about the streets were collected in one quarter, forming the public market, which in Nero's time was one of the most imposing structures in Rome. The system was introduced into Gaul, but the meat supply of Paris was in the hands of a clique of aristocratic families who balked all attempts at reform; and though asfar back as 1567 Charles IX had issued a decree on the subject, no improvement was made till Napoleon's time, when the nuisance was shocking—slaughterhouses abutted on the principal thoroughfares, herds of footsore and lamenting beasts impeded traffic, the gutters ran with blood, offal poured into the air, and the stench was a sewer for it. A commission was appointed to rectify these conditions in 1810, and the five great abattoirs which still exist were formally opened 15 Sept. 1818. They have been the models of the world, and for many years had no rivals; indeed, for symmetry of arrangement they have never been surpassed. But of late the vast American establishments at Chicago, at Kansas City, St. Louis, Mo., Brighton, Mass., and other places, have carried speed, economy, and cleanliness to an ideal point, and American inventiveness has built up an incredible number of subsidiary industries and products, so that literally not a hair of an animal's body nor a drop of its blood is wasted: foods, medicines, chemicals, manures, building materials, etc., produced from the refuse of the slaughterhouses are past numbering. The improved systems of the United States are of recent development and are due to the investigations of the methods followed in abattoirs in preparing meats and canned goods. These insanitary conditions, and unwholesome and unhealthy practices. On 30 June 1906 Congress provided for the inspection of all meats destined for interstate or foreign trade and of all establishments engaged in the industry, and appropriated $3,000,000 per annum for the maintenance of this supervision. Federal inspection is now required in all slaughter establishments located in 275 cities and towns. It reaches about 60 per cent of the total meat supply of the country, the remaining 40 per cent being under the supervision of State and local officers. In modern abattoirs great skill and speed are attained in the slaughtering and dressing of animals. The cattle are driven up to pens on a killing floor and are stunned by being struck between the eyes with a sledge hammer. The animal is then shackled, placed on the killing bed, and hoisted on a suspended tramway, and bled. It is next moved on to the "header", who skins and removes the head. The animal is then lowered and skinned, and passes through a row of butchers, each of whom performs some operation in trimming the dressed carcass. It is then in the cooling room and its place is at once taken by the next carcass on the run. By means of this specialization and division of labor a constant run is maintained, a force of less than 200 workers kill, dress and trim about 2,000 carcasses in a day of 10 hours. During the slaughtering, the carcasses are inspected by Federal meat inspectors, examining with care the viscera for indications of disease, or if animals are emaciated or in any way unsound the carcass is marked "U. S. Inspected and Condemned" and is turned into fertilizer. For hogs the process is different but the same subdivision and specialization of labor obtain; scalding vats and scraping machinery are added, and the carcasses are examined during the process as in the case of beef carcasses. The largest abattoirs in the United States, and in the world, are located at Chicago, Kansas City, St. Louis, Omaha, and Cincinnati. The Chicago Union Stock Yards is the largest concern of its kind in the world, covering an area of about 500 acres, and having an invested capital of about $70,000,000. About 8,000,000 hogs, 2,500,- 000 cattle, and 6,000,000 sheep are received and slaughtered annually. (See MEAT; PACKING INDUSTRY.)—Consult Macewen, 'Food Inspection' (1910).

**ABAUZIT, Firmin, ab-o-zit, far-mon**. French scholar of Arabian blood and Protestant parents; b. Uzès, 1679; d. Geneva, 1767. He lost his father when only two; in 1685, on the Revocation, the authorities tried to tutor him for a Catholic, but his mother contrived his flight with an elder brother to the Cevennes, where after two years as fugitives they gained Geneva, and the mother escaped from imprisonment and joined them. He early acquired great proficiency in languages, physics, and theology; traveled to Holland and made acquaintance with Bayle and others, and to England, where Newton admired him greatly, corrected through him an error in his 'Philosophy,' and wrote to him, "You are well worthy to judge between Leibnitz and me." William III wished him to settle in England, but he preferred to return to Geneva: assisted a society there in translating Newton's investigations; revealed to French, was offered but refused a chair in the university, but accepted a sinecure librarian-
ship, and died very aged. He was of wonderful versatility and universality, seeming to have made everything a specialty; Rousseau, jealous of every one, yet eulogised him warmly; and Voltaire, speaking of a stranger who said he had come to see a genius, whether he had seen Abazui. His heirs, through theological differences, destroyed his papers, so that little remains of his work; he wrote articles, however, for Rousseau's 'Dictionary of Music' and other works, and edited with valuable additions Spon's 'History of Geneva.' Collected works, Geneva, 1770; London, 1773. Translations by Dr. Harwood, 1770, 1774. For personal information, consult Senebier's 'Histoire Littéraire de Genève'; Harwood's 'Miscellanies'; Orme's 'Bibliotheca Biblica' (1834).

ABAZA, Alexander Agrelevich, á-grá-vich, abá-zá, Russian statesman: b. 1821; d. Nice, 1895. He was descended from a noble family of Moldavia, completed his education at the University of Petrograd and, in 1839, entered the Ministry of Finance in which he distinguished himself in the Caucasus, being wounded several times and being invested with the order of St. Vladimir. However he abandoned the service and joined the educational and humanitarian circles, presided over by Grand Duchess Helena Pavlovna. He soon was appointed master of ceremonies at the court of the princess. In 1865 he was elected a member of the council in the Ministry of Finance in which capacity he rendered important service to the financial and economic department of his vast country. He retired from public life in 1892 and, until his death, traveled extensively through Europe. He was not in favor of the reforms of Alexander II (q.v.), which were passed before he had any substantial power in his hands to oppose them effectively. But as Minister of Finance he suddenly changed and became one of the most fervent supporters of the reforms.

ABBA ARIKA, á-rě-ká, also known as *Rab,* a Jewish scholar of Babylonia and the son of a distinguished family. He studied at Sura, then went to Jerusalem where he founded the academy of that name. He was one of the leaders of Jewish thought in Babylonia.

ABBA MARI, mà-rí (correctly ABBA MARI ben MOSES ben JOSEPH DON ASTRUC of LUNEL), a French Hebrew who achieved fame as leader of the opposition to the growing rationalism of Maimonides, in the Montpellier controversy of 1303-06. He was born at Lunel near Montpellier, but the dates of his birth and death are unknown. His correspondence with Solomon ben Adret, rabbi of Barcelona, published under the title of Minhat Kenaot—Jealousy Offering—accentuates the three cardinal doctrines of orthodox Judaism, and throws much light on the question of the relation of religion to the philosophy of the age.

ABBA (same as papa, etc.), Aramaic form of Hebrew for 'father.' In the New Testament, used as an address to God; in the Talmud, a scholar's title of honor; also used as part of proper names; and at present the title of Syriac, Coptic, and Ethiopic bishops. See Pope.

ABBADIDES, a-bá’d-iz, a Mohammedan dynasty founded in Spain in 1023 by Abd-al-Kasim Mohammed and maintained by his son, Abbad, El Mataddid (1042-68) and his grandson, El Matamid (1068-91), all three men of remarkable personality. They were recognized as the leaders of the Moslems of Arabic or Spanish descent against the Berbers of Granada. They have been the subjects of many romances and even to-day they are the heroes of many legendary tales told among the Spanish peasants. After the capture of Toledo by Alphonso VI of Castile in 1085 El Matamid found himself in so desperate a position that he was obliged to call the Almoravides to his assistance. His duplicity soon caused a breach between himself and his allies, in 1091 Seville was captured and El Matamid was made a prisoner by the Spanish, thus bringing the Abbadides dynasty to an end. In 1095 he died in prison.

ABBADIE, Antoine Thomson and Arnaud Michel d', dab-ad-é, áhn-tn toh-soh and ar-nô mé-shel, French brothers and explorers: b. Dublin, Ireland, 3 Jan. 1810; and 24 July 1815; d. 1897 and 1893, respectively. In 1837-48 they explored Abyssinia and Upper Egypt, traveled up the White Nile, visited Darfur (regarded by the English in these places as French emissaries), and made a remarkably large collection of Ethiopic and Amharic manuscripts. Among other works Antoine published 'Geodesy of Part of Upper Ethiopia' (1860-73) and 'Dictionary of the Amarin Language' (1881); and Arnaud, 'Twelve Years in Upper Ethiopia' (1868).

ABBADIE, Jacques, ab-ad-é, zhak, or James, French-English divine: b. Nay, Bern, c. 1654-57; d. London, 1727. A poor boy, educated by friends, he took a degree of doctor in theology at Sedan at 17, was minister of a French Protestant church in Berlin some years, then in 1688 accompanied Marshal Schomberg to London for the second English Revolution, and became minister of the French church in the Savoy. He was strongly attached to William's cause, wrote an elaborate defense of it, and a history of the conspiracy of 1696 from materials furnished by the Government; and William made him dean of theKiln by then. A very able man and eloquent preacher, Abbudie is best known by his religious treatises in French, several of them translated into other languages: the most important are: 'On the Truth of the Christian Religion' with its sequel 'On the Divinity of Jesus Christ;' and 'The Art of Self-Knowledge.'

ABBAS (IBN ABD IL MUTTALIB, 'ibn ábd il moo-tä-leb), uncle of Mohammed; at first hostile to him, but ultimately—after the defeat at Bedr (see MOHAMMED)—the chief promoter of his religion. He was the founder of the Abbasside (q.v.) caliphate in Baghdad.

ABBAS I, of Persia, 'the Great,' 7th shah of the Safavid dynasty: b. 1557, acceded 1585; d. 27 Jan. 1628. Sent to Khorasan as nominal governor in childhood, at 18 he was proclaimed shah by its nobles,smarting under the oppression of his father Mohammed Khodacendeh's officers; the father was soon driven from the throne. At this time the Turks had invaded the western Persian provinces, and the Uzbek Tartars occupied and ravaged Khorasan. Abbas first transferred his residence from
Kasbin to Isphahan; he then by treaty confirmed to the Turks all their conquests, to gain time for his expected return, whom in 1592 he surprised and routed near Herat, and followed this by the conquest of Ghilan, Mazanderan, much of Tartary, and nearly all Afghanistan. He then declared war against the Turks; and in 1605, with 60,000 men, annihilated their army of five thousand at Basra (Busso- rah), recovering all the lost provinces, and not only securing complete immunity from Turk- ish aggression for the rest of his life, but ex- tending his empire beyond the Euphrates. In 1611 he concluded with Persia and Kurdistan. In 1618 he routed the united Turkish and Tartar armies near Sultanieh, securing more territory; and on the Turks renewing the war in 1623 he cap- tured Bagdad after a year's siege. The same year he took Omur from the Portuguese; and when he died his dominions reached from the Tigris to the Indus. His internal administra- tion was no less firm and beneficial. He en- couraged commerce, built highways, repressed vice, and left the country flourishing as it never has since. He was favorable to foreign- ers, and two Englishmen, Sir Anthony and Sir Robert Shirley, had much influence over him. He was like Herod in every respect: a jealous and cruel tyrant to his family— he slew his eldest son and blinded his other children,—his country alone felt his good side. (See Persia). Consult Markham, C. R., 'General Sketch of the History of Persia' (London 1874).

ABBAS, Kuli Khan (Nawaa), Persian diplomat: b. 1864. The son of Nawab Jafer Kuli Khan, educated in England and became interpreter to the British legation at Teheran in 1885. He was appointed third secretary in the British diplomatic service in 1901; was the Persian special envoy to King Edward's coronation, and on the Shah's visit to England in 1903 received the order of the C. M. G., and was a member of Viscount Downe's special mission to Persia. In 1908 he became head of the Oriental Chancery of the British Legation at Teheran.

ABBAS-MIRZA, Persian prince and warrior, favorite son of the shah Feth-Ali: b. 1783; d. 1834. He was early convinced of the ad- van tages of Western civilization, and with the help of European officers he first of all applied himself to the reform of the army. He led the Persian armies with great bravery, but with little success, in the war with Russia ended by the peace of Gulistan, when Persia lost her remaining Caucasus districts and ceded to Rus- sia the sovereignty of the Caspian; in that of 1826-28, ended by the peace of Turkmanchak, when she lost most of Persian Armenia. In 1829 he visited St. Petersburg, to ward off punishment for the murder of the Russian ambassador in a riot at Teheran; and was sent back to Persia loaded with presents. His eldest son acceded to the throne in 1834.

ABBAS PASHA I, viceroy of Egypt, grandson of the famous Mehmet Ali: b. 1813; d. July 1854. He happened to be born into public life, in 1841 he took an active part in his grand- father's Syrian war; in 1848 the death of his uncle Ibrahim Pasha called him to the vice- regal throne at Cairo. During his brief reign he did much to undo the progress made under Mehemet Ali: he dismissed all Europeans and fought Western ideas energetically. At the outbreak of the Crimean war he placed 15,000 men and his fleet at the Sultan's disposal; but was shortly after found dead, not without sus- picion of foul play.

ABBAS PASHA II, Hilimi, hel'meh, third Khedive of Egypt: b. 14 July 1874, the eldest son of the Khedive Mehemed Tewfik, better known as Tewfik Pasha, was educated with his brother at the Theresianum in Vienna. Abbas Hilmi was declared to be officially of age in 1891, and on the death of his father (7 Jan. 1892) was proclaimed Khedive of Egypt in accordance with the Sultan's firman of 8 June 1873, by which the succession was to fall from father to son instead of from brother to brother. Despite the British occupation of Egypt since 1882, that country was—at least nominally—under Turkish suzerainty down to December 1914. The activities of Abbas Hilmi as a ruler were limited to following the advice of Lord Cromer, Sir Eldon Gorst, and, later, of Lord Kitchener, successively British Consuls-General in Egypt. At the outbreak of the European War (1914) the Khedive was in Constantinople, the guest of the Sultan, and was credited with devoting his energies to plotting against the British rule in his country. Great Britain declared war on Turkey (5 Novem- ber) in consequence of hostile acts com- mitted by Turkish troops. On 18 December the British Foreign Office issued a statement to the effect that in view of the state of war arising out of the action of Turkey, *Egypt is placed under the protection of His Majesty and will hence- forth constitute a Protectorate. The suzerain- try of Turkey over Egypt is thus terminated and His Majesty's Government will adopt all measures necessary for the defense of Egypt and the protection of its inhabitants and in- terests.* A further announcement next day referred to Abbas Hilmi, "lately Khedive of Egypt," who had adhered to the King's enemies, and stated that he had been deposed. The title of Khedive was abolished for that of Sultan and conferred on the eldest living descendant of the family of Mehmet Ali, Prince Hussein Kamel Pasha who died 5 July 1914 and was succeeded by Prince Ahmed Fuad. Consult Cromer, Earl of, 'Abbas II' (London 1915).

ABBASSIDES, aabas’sids, The, 750-1517, caliphs at Bagdad and later in Egypt; nominal sovereigns of all Islam, but losing Spain at the outset, and never practically obeyed in Africa outside Egypt; the most famous dynasty of Saracen sovereigns. They took their name from Abbas (q.v.), the uncle of Mohammed. This descent had given the family great influence by a century after the Prophet's death; and Ibra- him, fourth in descent from Abbas, had gained several victories over the Om- miads (q.v.), supported by the province of Khorasan, when the Om- miad caliph Merwan defeated and put him to death in 747. His brother Abu l-Abbas, whom he had named his heir, as- sumed the title of caliph, crushed the Om- miads, and was only killed in his turn by the Abbasid Umayyads and acceded to their position. Its members and relatives were nearly all toled into one spot and exterminated, earning for Abu l-Abbas the nickname of As-Saffah, "the butcher"; but one of them, Abder-Rahman (q.v.),
escaped, and after picturesque adventures set up an independent emirate in Spain, which two years later took the title of caliphate. On Abu 'l-Abbas' death, his successor Al-Mansur removed the seat of royalty to Bagdad, and won successes against Turkomans and Greeks in Asia Minor; but by this time the warlike impulse had begun to decay, and the luxury and its literary and artistic attendants to come to the front. Means were found of evading the strictness of Mohammedan rules; and no courts of any age or country were gayer or more splendid than those of the great Harun al-Rashid, Charlemagne's contemporary (786-809), and Al-Mamun (813-33). The splendor of their palaces, their decorations, their equipages, and the seemingly exhaustionless treasures they possessed, gave them a world-wide celebrity — especially in contrast with the poverty-stricken barrenness and barbarism of most Christian sovereigns at that period — which is vivid even yet in literature and popular memory: Harun is the chief princely figure of the Caliphate of Bagdad the centre of picturesque and varied enjoyment. Al-Mamun is still more honorably remembered as the patron of arts and literature. What lay underneath this external gorgeousness — the corruption, the furies of jealousy and bloodshed, and the barbarous oppression of the many — is outside a notice like this. But external decay soon began to witness internal rottenness. The Aslabites, Edrisites, etc., carved out independent sovereignties in Africa; the Taherites in 820 set up a separate power in Khorasan, even under the great Al-Mamun. The Greeks, under the new life of the Byzantine empire brought in by Leo the Isaurian (q.v.), pushed them back in Asia Minor; and Al-Mamun's last years were contemporary with the philosopher, soldier, and statesman, the all-accomplished Emperor Theophilus. But the final stroke came from barbarians. The caliph Motassem (833-42), who had fought both Theophilus and the hordes of Turkestan successfully distrusting his subjects, formed bodyguarders out of his Turkish prisoners. They soon became what the Roman praetorians were — masters of the empire. Motassem's son Motawakkil was assassinated by them in his presence (861) and the succeeding caliphs were their puppets; and in 936 the caliph Radhi (934-41) was forced to give up the command of the army and other powers to his general and mayor of the palace, Mohammed ben Rayek. The provinces one after another flew off allegiance; the caliph held only Bagdad and its neighborhood; and at last Hulagu, prince of the Mongols, fired Bagdad and slew the reigning caliph Motassem in 1258. The Abbassides retained a nominal caliphate in Egypt under the egists of the Mamelukes, and neither gave up the claim or the hope of their old position and seat; but in 1517 the Turkish Sultan Selim I, the conqueror of Egypt, bore the last of them, Motawakkil III, a prisoner to Constantinople, finally allowing him to reunite Egypt, when he had a Turkish prisoner in 1538. Consult Muir's 'Caliphate' for the best English account; the monumental treasure-house of information for scholars is Weil's great 'Geschichte der Chalifen' (Mannheim and Stuttgart 1846-62). Consult also Muller 'Der Islam in Morgen-und Algland' (1887).

ABBATE, ab-a'te, or ABATI, a-ba'te, Ncolo, ne'ko-lo, Italian painter; follower of Raphael and Correggio: d. 1512 at Modena, where his earlier works are exhibited; d. 1571 at Fontainebleau — his frescoes in which palace are his best-known productions. His finest piece, however, is regarded as 'The Adoration of the Shepherds,' at Bologna, where his later work mostly exists. He has another in the Dresden gallery.

ABBAYE, a military prison near St. Germain des Prés, Paris, where 164 prisoners were murdered by infuriated republicans led by Maillard 2-3 Sept. 1792.

ABBIZA, a-ba-tz'a, a popular health resort on the Adriatic, in Austria, nine miles northwest from Triume. On account of its sheltered situation it has an equable climate, the temperature seldom dropping below 50° F. in winter or rising above 77° F. in summer. It is frequented by over 40,000 visitors annually and is a favorite resort for yachtsmen. One of its most prominent features is the Carol Promenade, built in 1896 by the King of Rumania. Resident population, 3,000.

ABBE, Cleveland, American meteorologist: b. New York City, 3 Dec. 1838; d. Chevi Chase, Md., 28 Oct. 1916. His education was received at the New York Free Academy, now the College of the City of New York, where he made a record in mathematical and mathematico-physical science. He was graduated in 1857 and then taught mathematics at the Trinity Latin School for a year. Later he studied astronomy under Professor Brunnow at the University of Michigan. A year afterward he removed to Cambridge where he spent four years with Dr. B. A. Gould and did telegraphic longitude work for the United States Coast Survey. During 1865-66 Professor Abbe studied at the Observatory of Poulkova, Russia, then under the direction of the illustrious Otto Struve, and finally, in 1867, he returned to the U.S.S.R. and became connected with the National Observatory in Washington. He was immediately appointed Director of the Cincinnati Observatory. Professor Abbe took charge there in May 1868 and immediately became prominent through his offer to the Chamber of Commerce to make daily predictions of the weather for the benefit of the citizens. From a scientific standpoint this was then unheard of. However, it was soon seen that he had inside information on the all-important subject, the weather, and during September 1869 his offer was accepted, and the daily publication of weather bulletins and probabilities began.

His weather service met with instant success, and soon his friends had a resolution introduced into Congress providing for the establishment of a national bureau of storm warnings for the benefit of commerce, which bureau was opened in February 1870 with Gen. A. J. Myer, Chief Signal Officer of the Army, in charge. He immediately adopted all Professor Abbe's systems and ideas, and in January 1871 invited him to come to Washington as his scientific assistant. A month later Professor Abbe commenced the regular tri-daily issue of probabilities, which he kept
up himself until he could train others to do the work correctly. These forecasts were published all over the country anonymously as official documents, and it caused for Professor Abbe the cognomen of "OldProb.* From that time the weather service was extended each year until the United States Weather Bureau came to rank first among such services the world over. Professor Abbe came to be regarded as the world's foremost meteorologist. It was largely due to his initiative that several successful advances were made in the service, such as ocean meteorology, the introduction of uniform standard time, and a great many other steps were taken. Professor Abbe continued in the Government service even when well past 70 years of age. He continued to edit the *Monthly Weather Review* and made many other contributions to meteorological science. In addition, he was editor of the *Bulletin of the Mount Weather Observatory* from 1909, professor of meteorology at Washington University from 1886, and lecturer on meteorology at Johns Hopkins University from 1896. He was a member of the National Academy of Sciences and of many other foreign and domestic scientific bodies.

One of Professor Abbe's most noteworthy achievements was his "Report on Standard Time" (1879), which started the agitation that resulted in the establishment of the modern standard hour meridians from Greenwich. He was the author of a number of books on meteorological subjects, including *Meteorological Apparatus and Methods* (1887); *Studien für den Sturm und Weather Predictions* (1889); *Mechanics of the Earth's Atmosphere* (Vol. I, 1891; Vol II, 1909); *The Altitude of the Aurora* (1896); *Physical Basis of Long-Range Forecasting* (1902); *Solar Spots and Terrestrial Temperature,* and *Atmospheric Radiation.*

**ABBE, Cleveland, Jr.,** American geographer and geologist, son of Cleveland Abbe: b. Washington, D. C., 25 March 1872. After graduating from Harvard University in 1894 he took up a post-graduate course at Johns Hopkins University, receiving his degree of Ph.D. in 1898. In 1894, on graduating from Harvard, he was appointed instructor in physiography at the Corcoran Scientific School of Columbian, now George Washington University, which position he held until 1897. From 1896 until 1901 he was an assistant in the Maryland Geological Survey and, at various times during this period, taught geology and biology in the Western Maryland College. In 1899 he was appointed acting professor of natural sciences in the Winthrop Normal and Industrial College in South Carolina. In 1901, he took this position to follow a two-year special course in geography at the Imperial University, Vienna. Upon his return, two years later, he was appointed aid in the United States Geological Survey and, in 1906, he became research observer in the Weather Bureau. From 1908 to 1910 he was assistant editor of the *Monthly Weather Review,* after which he was appointed assistant librarian of the Weather Bureau.

**ABBE, Ernst,** German physicist: b. Eismann, 1840; d. Jena, 1905. Studied at Jena and Gottingen; became assistant at the latter's observatory, and lecturer before the Frankfort-on-the-Main Physical Society; 1863-70 lecturer at Jena, and 1870 professor there; 1878 director of its observatory; in 1891 he resigned professorship. He became distinguished for his work in perfecting optical instruments, especially photographic and microscope lenses, having for a long time been connected with the highly reputed firm of Carl Zeiss. In 1891 he invented the Abbe refractometer. He wrote a work in German on the "Refracting and Dispersing Power of Solid and Fluid Bodies."

**ABBE, Truman,** American surgeon, son of Cleveland Abbe and brother of Cleveland Abbe, Jr.: b. Washington, D. C., 1 Nov. 1873. After his graduation from Harvard University in 1893, he studied medicine at the College of Physicians and Surgeons, at Columbia University, New York, gaining his degree of M.D. in 1899. After a year's post-graduate course at the University of Berlin he served for two years in several hospitals in New York. In 1902 he was appointed instructor of physics and physiology at Georgetown University and in the following year surgery was added to his subjects. In 1905 he became instructor in physiology at George Washington University and in 1906 he became also instructor in surgery at the same institution. From 1906 to 1910 he was chief surgeon of the Garfield Surgical Dispensary. In 1907 he was awarded a silver medal at the Jamestown Exposition for his researches into the use of radium as applied to medicine. Besides his many articles on radium in medical journals he contributed to Vol. III of Wharton and Stillier's *Medical Jurisprudence* (1905), and (with F. H. Bowlby) wrote *Physical Conditions and Treatment.*

**ABBE, ab-ä, originally the French name for an abbot, but later used in the general sense of a priest or clergyman.** By a concordat between Pope Leo X and Francis I in 1516, the French king had the right to nominate upward of 200 abbés commissaires, who drew a third of the revenues of the monasteries without having any duty to perform. They were not necessarily clergy, but were expected to take orders unless exempted by a dispensation. The hope of obtaining one of these distinguished emoluments was the chief end of many young men, many of them of noble birth, to enter the clerical career, which however seldom went further than taking the inferior orders; and it became customary to call such aspirants abbés, jocularly, Abbés of St. Hope. They formed a considerable and influential class in society; and an abbé, distinguished by a short violet-colored robe, was often found as chaplain or tutor in noble households, or engaged in literary work. This class of nominal clergy disappeared at the Revolution. In Italy they are called *abbate.*

**ABBESS, the female superior of some convents of nuns, corresponding to the abbot over monks.** She was elected from the monastery by secret votes, induct by a bishop's consecration, and held office three years or even for life unless deprived for misconduct. The Council of Trent fixed the required age of 40, with eight years of professed membership in the monastery. She could discipline and even expel the nuns, subject to the bishop; but, being a female, could exercise only certain functions, such as
ABBEVILLE—ABBO OF FLEURY

giving religious counsel and administering the rule, but no spiritual jurisdiction, as ordaining, conferring the veil, or excommunicating.

ABBEVILLE, France, ab-vêl ("abbey-town," of St. Riquier's), capital of Abbéville arrondissement, dept. Somme; 25 miles north-west of Amiens on both banks of the Somme and an island in it, 12 miles from its mouth and head of navigation (at high tide vessels of 150 to 200 tons can reach it) connected by canals with Amiens (25 miles distant), Paris, and Belgium; on the Northern Ry. It is an old, narrow-streeted, picturesque town, with strong fortifications on Vauban's system; has a wonderfully fine church of the flamboyant ordre. St. Wolfran's, begun under Louis XII (1462-1515), a very interesting city hall built in 1209, and a library of 1690 now containing 45,000 volumes. It manufactures jewelry, soap, glassware, and various fabrics, as velvets, cottons, linens, etc. But its chief interest to the foreign world is for the relics and implements of primitive man (the cave-dweller) and the fossils of extinct animals found in its neighborhood. Pop. (1914) 20,372.

ABBEVILLE, S. C., county seat of Abbeville County; on the Southern and Seaboard A. L. railways; 105 miles west of Columbia. It is in a rich cotton-growing region; is noted for its fine climate, which makes it a popular resort for Northern invalids, and has a national bank, excellent public schools, several large manufactories connected with the cotton industry, railroad repair shops, flour and feed mills, brickyards, etc. Property valuation over $500,000; bonded debt less than $55,000. Pop. (1913) 4,459; (1917) 5,000.

ABBEVILLE TREATIES, (1) A treaty in 1259 between Louis IX of France ("St. Louis") and Henry III of England, to settle definitely the territorial rights of the two crowns, Louis fearing that his title to some possessions was liable to dispute, and having sought a settlement for many years. It was negotiated at Paris with Simon de Montfort, Earl of Leicester, and signed by the two kings at Abbeville during Henry's visit to France, 1259-60, but dated May 4, 1260. Henry resigned all title to Normandy, Maine, Anjou, Touraine, and North Saintonge. Louis turned over Périgord, Limousin, South Saintonge, and some districts south of the Loire, to be held by Henry in fief, —a surrender which so enraged the inhabitants that they refused to celebrate Louis' birthday. Henry resigned the titles of Duke of Normandy and Count of Anjou, and agreed to do homage at Paris for those of Duke of Guienne and peer of France. (2) Between Henry VIII and Francis I in 1527, Wolsey representing England.

ABBEY, Edwin Austin, American artist: b. Philadelphia, 3 April 1852; d. London, 1 Aug. 1911; studied at the National Academy of Design; lived in New York and drew illustrations of a high order for periodicals, also painting water-colors, till 1883, when he moved to England. His two most individual qualities have been his love for English country life and scenery and for the old English poets and dramatists, both of which have resulted in notable illustrations (as of Shakespeare, Goldsmith, etc.) and paintings; and his ability as a colorist, though much of his work has been done without color. He had also deep intellectual and spiritual qualities; and all these faculties and tastes together combine in the famous panels of the 'Search for the Holy Grail' on the upper walls of the delivery room in the Boston Public Library. He was elected member of the Royal Academy July 1898; was one of the American jurors on paintings in the Paris Exposition of 1900; and was commissioned by Edward VII to paint the coronation scene in Westminster Abbey. He moved to the Mary Mead of New York. Though many years resident in England Abbey never abandoned his American nationality. Consult Radicliffe, 'Schools and Masters of Painting' (1898), Müller, 'History of Modern Painting' (1896).

ABBEY, Henry, poet and journalist: b. Rondout, N. Y., 11 July 1842; d. 1911. He published several collections of pleasing verse: 'May Dreams' (1862); 'Ralph, and Others Poems' (1866); 'Ballads of Good Deeds' (1872); 'Collected Works' (1885; 3d ed. 1895); 'Phaethon' (1901); 'Poems' (1904).

ABBEY, Henry Eugene, American operatic manager: b. Akron, Ohio, 27 June 1846; d. 1896. He was engaged for several years in theatrical, and from 1883 in operatic management, producing Italian and German operas with the most distinguished singers of the day. Under his management Madame Adelina Patti made a tour of the United States in 1889-90.

ABBEY, a monastery or religious community of the highest class, governed by an abbot, assisted generally by a prior, sub-prior, and other subordinate functionaries; or, in the case of a female community, superintended by an abbess. A priory differed from an abbey only in being on a smaller scale, and governed by a superior named a prior. Abbeys or monasteries first rose in the East. Among the most famous abbeys on the European continent were those of Cluny, Clairvaux, and Citeaux in France; of St. Gall in Switzerland, and of Fulda in Germany; in England, those of Westminster, St. Mary's of York, Fountains, Kirkstall, Tintern, Rievaulx, Netley, Paisley, and Arbroath. The English abbeys were wholly abolished by Henry VIII at the Reformation. Westminster Abbey is strongly built, with walls which served as a defense against enemies and within which were large buildings in which the occupants carried on the work to which they had been assigned. See ABBO; MONASTERY.

ABBIT, BI, a river, a lake, and a former important trading-post of the Hudson Bay Company in the Northwest Territories of Canada. The river is the outlet of the lake, about 49° N. lat., and flows into James Bay; the post is on the shore of the lake.

ABBO OF FLEURY, fle-rê, French theologian: b. near Orleans about 945; d. 1004. He studied at Rheims and Paris, and rose to great repute as a scholar and scientist (of the time). Oswald, Archbishop of York, induced him to teach for two years in the abbey of Ramsey and aid in restoring the monastic system; on his return to France he became abbot of Fleury and built up an English-style grammar school by Robert II (son of Hugh Caper) on two missions to Rome, 986 and 996, and each time succeeded in warding off a papal interdict. Later, while trying to reform the discipline of
the priory of La Réole, Gascony, he was killed. He wrote lives of the early popes down to Gregory I. Consult Life by his pupil Aimoyn, in Latin, "Vita Abbonis abbatis Floriacensis,"

ABBOT, Benjamin, American educator: b. New England, about 1762; d. Exeter, N. H. 22. He was a graduate of Harvard College, then became head of the Phillips Academy at Exeter, N. H., a position which he held for nearly 50 years, until 1838. Among his pupils were many who later became prominent figures in American history, notably Daniel Webster, George Bancroft, Edward Everett and Jared Sparks.

ABBOT, Charles, first Baron of Colchester, speaker of the British House of Commons: b. Abingdon, Berkshire, 14 Oct. 1757; d. 1829. After finishing his studies at Christ Church he entered government service and, after several positions, finally became Speaker of the House in 1802, retaining this position for 15 years, when he was compelled to resign on account of ill health. He was also one of the trustees of the British Museum. His "Diary and Correspondence" (1861) is of considerable historical value.

ABBOT, Charles Greeley, American astrophysicist: b. Wilton, N. H., 31 May 1872. After graduating from the Massachusetts Institute of Technology, in 1894, he was appointed assistant at the Smithsonian Astrophysical Observatory. In 1907 he was advanced to the position of acting director, becoming director a few months later. During this period he attracted much attention by his researches in solar radiation. In collaboration with S. P. Langley he completed and published the mapping of the infra-red solar spectrum, described in Vol. I of the "Annals" of the Astrophysical Laboratory. More recently his studies have been of the total amount and variability of solar radiation, its absorption in the solar and terrestrial gaseous envelopes and its effects on climatic conditions. He has written numerous articles on the apparatus, methods and results of solar research, but his chief work is "The Sun" (1911).

ABBOT, Ezra, American Biblical scholar: b. Jackson, Me., 28 April 1819; d. 21 March 1884. He studied at Phillips Exeter Academy, graduated at Bowdoin 1840, and after teaching in Maine and Cambridge, Mass., became in 1856 assistant librarian of Harvard. In 1872 he received a D.D. from Harvard, though a layman, and thence till death was professor of New Testament criticism and interpretation in the Cambridge Divinity School. His wide reading and wonderful verbal memory made him one of the foremost of textual critics and bibliographers; his mastery of the Greek New Testament text placed him beside the leading scholars of the world; and on the American New Testament Revision Committee, 1871–81, he was a chief agent in putting its work on an even level of authority with the English, in minute accuracy of scholarship as well as broad, acute judgment. Indifferent to fame, he gave his best work to collaborations or private assistance mostly unacknowledged and unrealized except by scholars. His most important individual book was on the "Authorship of the Fourth Gospel" (1880), in which he announced the important discovery of Tatian's "Diatessaron." Of his other critical work, besides the great Revision, his half of the prolegomena to Tischendorf's Greek New Testament (1884–94), his additions to Mitchell's "Critical Handbook of the New Testament" (1880), and his revision of Schaff's "Companion to the New Testament" (1883), should be mentioned. As a bibliographer, his greatest fame was for the curious and exhaustive catalogue of relevant books he furnished for Alger's "Critical and Historical Development of a Future Life" (1864), and his notes to Smith's "Bible Dictionary" (Am. ed. 1867–70). He also wrote many papers for periodicals. His monographs were collected by J. H. Thayer and published under the title "Critical Essays" (Boston 1888). Consult Barrow "Ezra Abbot" (Boston 1884).

ABBOT, Francis Ellingwood, American religious radical: b. Boston, 1836; d. 1903. He was graduated at Harvard 1859 and Meadville (Pa.) Theological School 1863. A Unitarian minister 1863–58, he started in 1872 the "Index," an ultra-radical and highly-radical, devoted to religious and philosophical topics; and wrote "Scientific Theism" (1886), and "The Way Out of Agnosticism" (1890), besides notable magazine articles.

ABBOT, George, Archbishop of Canterbury: b. Guildford, Surrey, 19 Oct. 1562; d. 5 Aug. 1633. A cloth-worker's son, he studied at Balliol, Oxford, was chosen Master of University College 1597, and three times was vice-chancellor of Oxford. Dr. Abbot's name was second on the list of eight divines ordered in 1604 to prepare the present (King James) version of the Bible. In 1608 he went to Scotland with the Earl of Dunbar to arrange for a union of the English and Scotch churches. James took a great fancy to him, and, though Abbot had never held a parish, made him bishop of Lichfield and Coventry in 1609, transferred him to the see of London a month later, and less than a year afterward appointed him Archbishop of Canterbury. Flattery of the king is accredited as the cause of this astonishing rapidity of preferment; but his son, at least, Abbot felt no need of such tactics. He opposed the scandalous divorce suit of Lady Frances Howard against the Earl of Essex, though the court favored and carried it. In 1618 he forbade the reading, in the Croydon church where he was, of the king's declaration permitting games and sports on Sunday, which the Puritans (to whom Abbot belonged) regarded as a permit to break the Sabbath, and the order to read it as a command to commit blasphemy. He promoted the marriage between the Princess Elizabeth and the Protestant Elector Palatine, and opposed the disastrous Spanish-marriage project of Prince Charles, and thereby won Charles', Laud's, and Buckingham's hatred. The king, however, remained his friend. In 1622 he accidentally killed a keeper while deer-hunting, and his enemies tried to have him disqualified for the involuntary manslaughter. The king made light of the matter, but had to refer it to a commission, which decided in his favor, and he was finally absolved and reappointed. He attended James in his last sickness, and crowned Charles. The latter, on Abbot's refusing to license a fanatical divine-right sermon, deprived him of his func-
ABBOT

ABBOT, Henry Larcom, American military engineer: b. Beverly, Mass., 13 Aug. 1831; graduated at West Point 1854, and entered the engineer corps. Took part in the survey for a Pacific railroad and of the Mississippi River delta, served through the Civil War as engineer and artilleryist, was wounded at Bull Run, and commanded the siege artillery before Richmond, an account of which he published in 1867. He was brevetted brigadier-general U. S. Army and major-general U. S. Volunteers. He long commanded the engineers' garrison at Willet's Point, N. Y., established an engineers' school, worked out the submarine defenses of the United States sea coast, and accomplished much in the improvement of mortar batteries and engineering equipment, etc.; was a member of the Gun Foundry Board and the Board of Fortifications and Defense, of that for the protection of the Mississippi basin, of that on the proposed canal from Pittsburg to Lake Erie, and of the technical Committee of the new Panama Canal Company. He drew the plans for the interior harbor at Manitowoc, Wis. He was retired in 1895. He has written besides "Physics and Hydraulics of the Mississippi" (1861); "Problems of the Panama Canal in 1905 and 1907." He is a member of the Committee of the National Academy of Sciences to report on the slides obstructing the Panama Canal, appointed at the request of President Wilson in 1915.

ABBOT, Joseph Hale, American educator: b. Wilton, N. H., 26 Sept. 1802; d. 7 April 1873. He was graduated at Bowdoin in 1822, was tutor there 1825-27; and professor of mathematics in the Exeter Academy 1827-33; then taught a ladies' school in Boston; subsequently was principal of the Beverley, Mass., high school. He was for some years recording secretary of the American Academy of Arts and Sciences, and published valuable scientific papers in its "Transactions," besides writing on pneumatic and hydraulic problems, in which he made ingenious investigations. He was associate editor of Worcester's "Dictionary of the English Language" (1860).

ABBOT, Samuel, American philanthropist: b. Andover, Mass., 25 Feb. 1772; d. 12 April 1812. He was a merchant and gave $20,000 in 1807 toward founding Andover Seminary, with $100,000 more by will.

ABBOT, Willis John, American author and editor, grandson of John S. C. Abbot: b. New Haven, Conn., 16 March 1863. He was graduated from the University of Michigan in 1884. In 1892 he became managing editor of the Chicago Times, holding this position for about a year. From 1896 to 1898 he was on the editorial staff of the New York Journal. His chief works are: "Blue Jackets of '61"; "Blue Jackets of 1812"; "Battle Fields of 1861"; "The American Merchant Ships and Sailors" (1902); "A Story of Our Navy for Young Americans" (1910); "Panama and the Canal in Picture and Prose" (1913).

ABBOT ("father"), originally the head and ruler of a community of monks; in the Greek Church hegumenos, "leader," or archimandrite, "ruler of the fold," though the latter is oftener an abbot-general with hegumenos under him. Among the Dominicans the head of a convent was called propositus, a "provost," or "prior;" among the Franciscans custos, "guardian;" among the Camaldulenses major. The name survives in the orders derived from the Benedictines, as the Cistercians, Bernardines and Trappists. The term "abbot" originated in the East, and was first applied to any monk noted for piety, but at length restricted to the superior. The first abbots were laymen like the rest of the monks in general; the lowest clergy took precedence of them, and for sacraments they had to attend the nearest church: but the extreme inconvenience or even impossibility of this when the monastery was in a desert or far from a town forced the ordination of the abbots. Abbots could attend councils, and the second Council of Nica, 707, allowed them to ordain monks to the inferior orders; and ultimately nearly all monks were ordained to some grade of the ministry. To this elevation was added that of allowing pluralities of abbeies, originally forbidden, and even in the 6th century allowed only in special cases; but it increased till early in the 10th century one German prelate had 12 abbeys under him, corresponding to the archimandrites of the East. Thus, and by the increase of numbers and corporate wealth in the great abbeys, the abbots themselves became prelates of vast power. Still another cause developed this,—the exemption of abbies from control of the bishops. They were originally all subject to episcopal jurisdiction, and in the West generally continued so till the 11th century; this is expressly ordered in Justinian's code. The exactions of the bishops, however, rendered the exemption increasingly frequent; beginning in 56 the practice grew, and was much helped forward by Gregory the Great, who ordained many abbots from episcopal control and made them responsible directly to the Pope. By the 12th century this had become an evil of the first order in ecclesiastical government, the bishop usually having no authority whatever over the chief centres of religious and often secular power in his diocese; and one abbot, of Fulda in Germany, claimed precedence over the Archbishop of Cologne. Next came an encroachment on the functions of the bishops: from conferring the tonsure and the office of reader they came to be equally associated with the bishops in consecrations; and while originally the bishop chose the abbot from the monks of the house, and then the right of election was transferred to the monks, the abbots came sometimes to choose their own successors. This, however, was stopped in some countries by a counter-process; the popes in Italy and the kings in France assuming to themselves the right of appointment.

Otherwhere the choice was by secret election of and from the monks of the house, unless it furnished no fit candidate, when choice might
be made from another monastery of one well instructed himself and competent to instruct others, of legitimate birth and at least 25 years of age. His "ordination was for life. His power was absolute except as restricted by the canons of the Church. His exaction of deference in the routine of life was royal; all rose and bowed when he entered the church or chapter, his letters were received kneeling, and no monk could sit in his presence or leave it without permission. They had immense political power, and were on equal terms of intimacy with the greatest in the realm. Many of the abbots were an honor to their countries, and their schools were seminaries of learning and virtue.

In time the title was improperly conferred on others who had no connection with monastic life, or sometimes even with the Church,—on the principal of a body of parochial clergy or on the king. The representative of the chief magistrate of Genoa was called "Abbot of the People." Lay abbots, so called, originated in temporarily handing over the revenues of an abbey to some noble, or even the king, for a great public event, or, in the boyish days of the abbot, for the help of the abbey, and the excess of the revenues being reserved from sequestration to support the house. Once in lay hands they usually remained there, and most of the Frankish and Burgundian sovereigns and chief nobles in the 9th and 10th centuries were titular abbots of great monasteries, whose revenues they applied to their own uses. This often happened from the monastery's voluntarily placing itself under the "commendation" of some noble for protection; and there were sometimes two lines of abbots,—one lay, taking the major part of the income without service, the other clerical, doing the work. This was mostly reformed during the latter part of the 10th century. The Council of Trent restored to the monasteries the right of electing their abbots. The newly elected abbot is then confirmed by the bishop or in certain cases by the pope.

In convent cathedrals, where the bishop filled the place of the abbot, the superior's duties were performed by a prior. In other convents the prior was the vice-abbot. The superiors of cells, or small monastic establishments dependent on the larger ones, were also called priors; they were appointed by the abbott and held office at his pleasure. There were three classes of abbots: mitred abbots, crosiered abbots, or those allowed to bear a crosier, and secular abbots, ruling the houses of a province or a country. Abbots hold a rank immediately after bishops. Their duties must be less costly than those of bishops; and they are largely a temporal throne. There are now 17 mitred abbots in the United States, two in Canada, 10 in England, two in Ireland and one in Scotland. Consult Feazey, H. J., "Monasticism"; Montalbetti, "Monks of the West" (ed. 1866, Vol. 1); Blainville-Patton, "Rites of the Ancient Monasteries"; Gasquet (Cardinal), "English Monastic Life" (London 1904); Taunt, "English Black Monks of St. Benedict" (London 1898).

ABBOT OF JOY, from the French "Abbé de Lisse," a title conferred upon the head of a fraternity founded in Lille. He presided over the games that took place during the carnival at Arras and the neighboring communities, popularly known as the "Feast of the Ass."

ABBOTT, The, by Sir Walter Scott. A sequel to "The Monastery," but dealing with more stirring situations. The time of the action is 1557-68. While the action goes on partly at Avenel Castel, and Halbert Gledinning of "The Monastery," as well as his brother Edward (now an abbot) figure prominently in the story, the reader finds that he has exchanged the humble events of the little border vale by Melrose for thrilling and romantic adventures at Lochleven Castle on its island in the lake, north of Edinburgh, where Mary Queen of Scots is imprisoned. The chief interest centres around the unfortunate queen. The framework of the tale it is claimed is historically true.

ABBOTSFORD, a fording-place of the Tweed near its confluence with the Yarrow; the name given by Sir Walter Scott to his property there bought in 1811, in memory of its use by the monks of Melrose Abbey, it being at the time known as the Clary [Filthy] Hole. The site is a low hillside on the southern bank, overlooked by the house. It is not a castle, but an old house, the west wing of the pile, being seized with the idea of founding a great feudal family of the old Scotch pattern, with this for a baronial seat; and gradually added other sections, copying old Scotch mansions or ruins, or special features of them, making an irregular, rambling, picturesque abode, *a romance in stone and time.* It remained in Scott's family for four generations, but has in recent years been leased to Americans. Consult Irving's "Abbotsford" (London 1850); Lockhart's "Life of Scott" (Edinburgh 1838); Scott, Mary "Abbotsford" (New York 1893); Smith and Crockett "Abbotsford" (ib., 1905).

ABBOTT, Alexander Crever, American hygienist: b. Baltimore, Md., 26 Feb. 1860. He was educated at Johns Hopkins University and at the universities of Maryland, Munich, and Berlin. He is a fellow of the College of Physicians in Philadelphia, and a member of numerous scientific societies; in 1900 was professor of hygiene and director of the laboratory of hygiene in the University of Pennsylvania. His publications include "The History of Bacteriology" (1892, 1915); "The Hygiene of Transmissive Diseases" (1899–1902), and numerous papers on bacteriology and hygiene.

ABBOTT, Austin, American law-writer, son of Jacob: b. Boston, 18 Dec. 1831; d. 1896. He was graduated at the University of the City of New York in 1851, and entered the practice of law. In 1865 he received Benjamin in valuable legal compilations, digests, textbooks, etc.; was an able law lecturer, and dean of his alma mater's law school 1891–96. He was counsel for Theodore Tilton in the Beecher trial. With his brothers Benjamin and Lyman he wrote two novels, "Come Cut Corners" (1885) and "Matthew Caraby" (1888).

ABBOTT, Benjamin, American revivalist: b. Long Island 1732; d. Salem, N. J., 14 Aug. 1796. A hetero's and then a farmer's apprentice, somewhat dissipated but a kind husband and father and a church-goer (whence his accounts of the pit from which he was rescued are probably dialectic), he was roused to intense
ABBOTT, Edward, American clergyman, son of Jacob: b. Farmington, Me., 15 July 1841; d. Boston, Mass., 5 April 1908. He was graduated at the University of the City of New York 1860, and at Andover Theological Seminary 1862; in 1863 was with the United States Sanitary Commission at Washington and in the field. He was zealous in Congregationalism, and in 1863, and 1865-69 was pastor of the Pilgrim Church, Cambridge, Mass.; in 1879 was ordained Episcopal priest and was rector of St. James', Cambridge, till 1906; in 1889 he was elected missionary bishop of Japan, but declined. He was a taste ednyer of the Congregationalists and of the American Revolution; a Long Look Series, 1877-80; memorial of his father (1882); and Phillips Brooks' (1900).

ABBOTT, Edwin Abbott, English theologian and Shakespearean scholar: b. London, 20 Dec. 1838; graduated at St. John's College, Cambridge; son of the Cambridge Chaucer medalist (1861). He was master at King Edward's School, Birmingham, 1862-64, and at Clifton College; and head-master of the City of London School, 1865-69, raising it to a foremost rank in England. In the latter year he retired. He has been select preacher at Cambridge and Oxford. His works include the well-known 'Shakespearean Grammar' (1869, enlarged 1870), still a classic; 'Bacon and Essex' (1877); 'Philochristus' (1878), and 'Onesimus' (1882), two annals of the first age of the Church; 'Francis Bacon' (1885); 'Anglican Career of Cardinal Newman' (1892); 'St. Thomas of Canterbury' (1898); 'From Letter to Spirit' (1903); 'Johann the Vocabulary' (1905); 'The Son of Man' or 'Contributions to the Study of the Thoughts of Jesus' (1910); 'Light on the Gospel' (Eng. ed. 1912; Am. ed. 1913); 'The Fourfold Gospel' (1913).

ABBOTT, Emma (Wetherell), American dramatic soprano: b. Chicago, Ill., December 1849; d. Salt Lake City, 1885. She began her musical career in Plymouth Church choir, Brooklyn, N. Y., where she studied abroad with Sangiovanni at Milan and with Delled Sedie, Wartel, and James at Paris; then joined Mapleson's troupe, made her début at Covent Garden, London, toured three years in Great Britain, and returning to the United States joined the Emma Abbott English Opera Company. She sang in 'Martha,' 'The Chimes of Normandy,' 'Faust,' and other popular operas and was one of the best known singers in America in her day. Consult Lahee, H. C., 'Famous Singers of To-day and Yesterday' (Boston 1898).

ABBOTT, Frank Frost, American Latinist: b. Redding, Conn., 27 March 1860; graduated at Yale 1882; Latin tutor at Yale 1883-91; associate professor 1892-1902 of Latin in the University of Chicago; 1901-02 annual professor of the American school of classical studies in Rome; becoming associate chairman of the managing committee; 1908, professor of classics in Princeton University; a frequent contributor to classical periodicals.
and associate editor of *Classical Philology*. He has written 'A History of Roman Political Institutions' (1901); 'The Toledo Manuscript of the Germania of Tacitus' (1903); 'A History of Rome' (1906); 'Society and Politics in the Ancient Roman World' (1909); 'The Cambro-Norman People of Ancient Rome' (1911); etc. He is vice-president of the American Philological Association.

**ABBOTT, Gorham Dummer, American educator, brother of Jacob and J. S. C.: b. Hallowell, Me., 3 Sept. 1807; d. 31 July 1874. He was graduated at Bowdoin in 1826, and at Andover 1831. Ordained a Congregational clergyman, he became a teacher in New York; in 1845 with his brothers he established the Abbott Institute for females in New York city and in 1847 the Spangler Institute,—pioneers in women's higher education; the latter held a foremost rank in the United States for 30 years, and he left it in 1869 a rich man. He wrote didactic works, as 'The Family at Home,' 'Nathan W. Dickerman,' 'Pleasure and Profit'; also 'Maiden and Youth' and 'In the United States.'

**ABBOTT, Jacob, American juvenile writer and educator:** b. Hallowell, Me., 14 Nov. 1803; d. 31 Oct. 1879. He was graduated at Bowdoin 1820, studied at Andover, and was ordained a Congregational minister; professor of mathematics and natural philosophy at Amherst 1825–29; then established the Mt. Vernon girls' school in Boston, and in 1834 organized and was pastor of the Eliot Church in Roxbury. In 1839 he removed permanently to Farmington, Me., and devoted himself to literary work there and in New York, assisting also in female education (see the preceding title), writing extensively for the early *Harper's Monthly*, of which he was one of the chief bulwarks, traveling widely abroad, and writing the classic juveniles of which the 'Rollo Books' are the best known type,—neither their usefulness, their popularity, nor their charm, has yet vanished. He had an excellent dramatic sense, a healthy balance, a sound business practicality and a true understanding of and sincere sympathy with children, which makes his didactic works charming to rightly constituted children; no boys and girls were ever less priggish than those in 'Rollo,' the conventional burlesques of which merely prove that the authors have not read the books, and even so are a testimony to their vitality. The chief of his more than 200 volumes are the 'Rollo Books' (28 vols.), the 'Lucy Books' (6 vols.), the 'Jonas Books' (6 vols.), the 'Franconia Stories' (10 vols.), the 'Marco Paul Series' (6 vols.), the 'Gray Family' series (12 vols.), the 'Junior Books' (6 vols.), the 'Rainbow Series' (5 vols.), and several other series of science and travel for the young; more than 20 of the series of illustrated histories to which his brother J. S. C. contributed, and 8 vols. of American history. He also edited historical text-books and compiled school readers.

**ABBOTT, Sir John Joseph Caldwell, Canadian statesman:** b. St. Andrews, Quebec, 12 March 1821; d. 1893. Graduated at McGill College, Montreal, he became a lawyer, and was regarded as among the best Canadian authorities on judicial law, but he devoted himself to the editorial work of the *Christian Union*, now the *Outlook*, of which he became chief editor on Mr. Beecher's death in 1887, succeeding him also in the Plymouth Church pulpit, which he resigned in 1899 to devote himself wholly to literary work. Since that time he has devoted himself to the editorship of the *Outlook*, other occasional contributions to literature, and to preaching in various pulpits during seven or eight months of the year, generally in colleges. He has taken an active part in social and religious reform and in the religious and theological movements of the time. His earliest works were two novels written in collaboration with his brothers Benjamin and Austin Abbott (see ABBOTT, AUSTIN) published under the nom-de-plume, composed of the first four syllables of their names, 'Rof.' The following is a list of his published volumes: 'Commentary on the New Testament. Mathew to Romans.'
ABBOTT — ABBREVIATIONS

(1875); 'In Aid of Faith' (1886); 'Evolution of Christianity' (1892); 'Plymouth Hymnal' (1893); 'Christianity and Social Problems' (1896); 'The Theology of an Evolutionist' (1897); 'Life and Letters of Paul' (1898); 'Life and Literature of the Ancient Hebrews' (1901); 'The Rights of Man' (1901); 'The Other Rock, the Church of Henry Ward Beecher' (1903); 'The Great Companion' (1904); 'The Christian Ministry' (1905); 'The Home Builder' (1908).

ABBOTT, Nathan, American jurist and educator, son of Abiel Abbott: b. Norridgewock, Me., 11 July 1854. He was graduated from Yale College in 1877, then studied law in Boston University. For some years he applied himself to his private law practice in Boston, after which he became Tappan Professor of Law in the University of Michigan. In 1893 he was appointed professor of law in Northwestern University. In 1895 he became professor of law and Dean of the Law School and Leland Stanford University. After holding this position for 12 years he became, in 1907, professor of law at Columbia University, New York City. He is recognized as one of the leading authorities on the English and American law of real property.

ABBOTT, Thomas Kingsmill, Irish educator: b. Dublin, 26 March 1829; d. 1913. He was a graduate of Trinity College. In 1867 he was appointed to fill the chair of moral philosophy at the same institution, which position he held until 1872. From 1873 to 1888 he was professor of biblical Greek and from 1877 until 1900 he was professor of Hebrew. His works are: a translation of Kant's 'Introduction to Logic' (1878), and Kant's 'Ethics' (1900); 'Essays' (1892); 'The Elements of Logic' (1895); 'Commentary on Ephesians and Colossians' (1897); 'Elementary Theory of the Tides' (1901); 'Catalogue of 15th Century Books in the Library of Trinity College' (1905).

ABBOTT, Wilbur Cortez, American educator: b. Kokoma, Ind., 28 Dec. 1869. After graduating from Wabash College in 1892 he took a post-graduate course at Cornell University, then studied at Oxford, where he received a degree of B.L. in 1895. In 1893 to 1895 he was instructor in history at Cornell. In 1897 he became instructor in history at the University of Michigan. Two years later he was appointed assistant professor of history in Dartmouth College; in 1902 professor of history in the University of Kansas, and in 1908 he was appointed professor of history at the Sheffield Scientific School, at Yale University. He is the author of 'Colonel Blood, Crown Stealer' (1911).

ABBREVIATIONS or "shortenings" are used in writing to save time and space, or it may be to ensure secrecy. They are of two kinds, consisting either in the omission of some letter or letters, or in the substitution of some arbitrary sign. In the earliest times, when uncial or lapidary characters were used, abbreviations by omission prevailed, such as we find in the inscriptions on monuments, coins, etc. The ancient copiers of MSS. invented many contractions to facilitate their labor. Greek MSS. abound in such, and hence often cannot be read without a previous regular study of Greek palaeography. From MSS. these contractions were transferred to the printed editions of Greek authors, and have only been wholly disused within the past century; hence regular lists of them were given in the earlier Greek grammars, because the knowledge of them was absolutely essential to the student. Some of the commoner are still given in some grammars, as many Greek works are accessible only in editions full of them. Among the Romans the marks of abbreviation, called notae or compendia scribendi, were so numerous that, in a classification by L. Annæus Seneca, they amount to 5,000. With the Latin language the ancient Roman abbreviations passed to the Middle Ages, appearing first on inscriptions and coins, then in manuscripts, and, more especially after the 11th century, in charters and other legal documents, and the practice continued in these long after the invention of printing had made it unnecessary in books. The use of them in legal documents was forbidden by an act of Parliament passed in the reign of George II. In ordinary writing and printing few abbreviations are now employed. The abbreviations by using the initials of words are chiefly confined to titles, dates, and a few phrases: A.M.—Magister Artium; Master of Arts; A.D.—Anno Domini, in the year of our Lord; F.R.G.S.—Fellow of the Royal Geographical Society. In the following list most of the abbreviations that are likely to be met with by modern readers are alphabetically arranged, save chemical elements, for which see table of Atomic Weights. The standard abbreviations used in library catalogues are also given. For Latin abbreviations see Campbell's 'Dizionario di Abbreviazioni' (Milan, 1899); Dobbs' 'Abbreviations, British and Foreign' (1911).

A.A.—Associate of Arts.
A.A.A.—Amateur Athletic Association (Brit.).
A.A.A.S.—American Association for the Advancement of Science.
A.A.P.S.—American Association for the Promotion of Science.
A.A.S.—Academia Americana Socius, Fellow of the American Academy (of Arts and Sciences); American Automobile Association.
A.A.S.S.—American Antiquarian Societatis Socius, Member of the American Antiquarian Society.
A.B.—Artium Baccalauraeus, Bachelor of Arts.
A.B.C.F.M.—American Board of Commissioners for Foreign Missions.
Abp.—Archbishop.
Abr.—Abridgement, or Abridged.
a/c.—Account.
A.C.—Ante Christum, before the birth of Christ.
Acad. Nat. Sci.—Academy of Natural Sciences.
Accel.—accelerando, In music, more quickly.
A.D.—Anno Domini, in the year of the Lord.
A.D.C.—Aide-de-camp.
Adjt.—Adjudant.
Adjt.-Gen.—Adjutant-General.
Ad lib.—Ad libitum, at pleasure.
Adm.—Admiral.
Admrx.—Admiratrix.
Advs.—Ad sectam, at the suit [of].
Ad v.—Ad valorum, at (or on) the value.
Æt.—Ætatis, of age; aged.
ABBREVIATIONS

A.F.B.S.—American and Foreign Bible Society.

Avdp. or Avoir.—Avoirdupois.
B.—Born.
B.A.—Bachelor of Arts.
Bal.—Balance.
Bapt.—Baptist.
Bart. or Bt.—Baronet.
Bbl.—Barrel.
B.C.—Before Christ; British Columbia.
B.C.L.—Bachelor of Civil Law.
B.D.—Baccalaureus Divinitatis, Bachelor of Divinity.
Bds.—Boards; Bonds.
Beau. & Fl.—Beaumont and Fletcher.
Belg.—Belgian; Belgium.
Ben.—Benjamin.
B.S.—Bachelor of Science (Fr.).
Bib.—Bible; Biblical.
Bibl.—Biblical; Bibliography.
Biog.—Biography; Biographical.
Bk.—Book.
B.L.—Bachelor of Letters.
B.Litt.—Bachelor of Literature in Journalism.
B.L.L.—Baccalaureus Legum, Bachelor of Laws.
B.M.—Baccalaureus Medicina, Bachelor of Medicine.
B.Mus.—Bachelor of Music.
Bot.—Botany.
Bp.—Bishop.
B.P.—Bachelor of Philosophy.
Br.—Brig.; British; Brother.
Brig.—Brigade; Brigadier.
Brig.-Gen.—Brigadier-General.
Brit. Mus.—British Museum.
Bro.—Brother.
B.S. or B.Sc.—Bachelor in the Sciences.
Bt.—Baronet.
B.V.—Beatæ Virgo, Blessed Virgin; B. V. sale, farewell.
C.—Caput or capitulum, chapter; Celsus; Cent.; Centigrade; Cents; Centum, a hundred; Century; Circa or circiter, about; Consul.
C.A.—Chief Accountant; Commissioner of Accounts.
Cam., Camb.—Cambridge.
Can.—Canon.
Cant.—Canticles.
Cantab.—Cantabrigiæ, Cantabrigiensis, or Cambridge. In music cantabile, singing tone.
Cantuar.—Cantuariorum, Canturienis, of Canterbury.
Cap.—Caput, capitulum, chapter.
Capt.—Captain.
Capt.-Gen.—Captain-General.
Card.—Cardinal.
Cath.—Catherine, Catholic, Cathedral.
C.B.—Cape Breton; Communis Buncus, Common Bench; Companion of the Bath.
C.C.—Caius College; Comptæ courtante, account current; Circuit Court; County Commissioner; County Court; Cubic centimeter.
C.E.—Civil Engineer; Church of England; Christian Endeavor Society.
Celt.—Celtic.
Cent.—Centigrade, a scale of 100° from freezing to boiling; Central; Centum, a hundred; Century.
Cf.—Confer, compare.
C.G.—Commissary-General; Consul-General.
C.G.H.—Cape of Good Hope.
Chap.—Chapter.
Ch.—Chief Justice.
Ch.—Chief Justice.
Ch.—Christ; Christian; Christopher.
Chronic.—Chronicles.
Cic.—Cicero.
Circ.—Circa, or circiter, about; Circuit.
Cit.—Citation; Cited; Citizen.
Civ.—Civil.
C.J.—Chief Justice.
C.M.—Compagnon of the Order of St. Michael and St. George.
C.o.—Company; county.
c/o.—In care of.
Coch., or Coch.—Cochlear, a spoonful. C. amp. (amphium), a tablespoonful. C. mag. (magnum), a large spoonful. C. med. (medium), a dessert-spoonful. C. parv. (parvum), a small spoonful or teaspoonful.
ABBREVIATIONS

C.O.D.—Cash (or collect) on delivery.
Coll.—College.
Com.—Commerce; Committee; Commissioner; Commercial.
Com. Ver.—Common Version (of the Bible).
Con.—Contra, against; in opposition.

d.—Denarius, penny, pence; Died.
D.C.—Da capo, from the beginning; District of Columbia.
D.l.—Dean of Civil Law.
Dec.—Decennal; Deacon.
Dec. of Ind.—Declaration of Independence.
Def.—Defendant.
Deg.—Degree; degrees.
Dem.—Democrat; Democratic.
Dep.—Deputy.
Deut.—Deuteronomy.
D.F.—Defender of the Faith.
D.G.—Dei gratia, by the grace of God; Deo gratias, thanks to God.
Disc.—Discount.
Dist.—District.
D.M.—Doctor of Music.
D.M.D.—Doctor of Medical Dentistry.
D.O.—Doctor of Osteopathy.
Do.—Ditto, the same.
Doc.—Document.
D.O.M.—Deo optimo maximo, to God, the best, the greatest.
D.P. or D.Ph.—Doctor of Philosophy.
Dpt.—Department.
Dr.—Debtor; Doctor.
D.Sc.—Doctor of Science.
D. Th.—Doctor of Theology; Doctor of Theology.
D.V.—Deo valente, God willing.
D.V.M.—Doctor of Veterinary Medicine.
Dwt.—Pennyweight.
Dyn.—Dynamics.
E.—East.
Ebor.—Eboracum, York.
Ecl.—Ecclesiastes.

Eccles.—Ecclesiastus.
Ed.—Editor; Edition.
Edin.—Edinburgh.
E.E.—Electrical Engineer.
e.g.—Exempli gratia, for example; Ex grege, among the rest.
E. I.—East Indies or East India.
E. Lon.—East longitude.
E.M.—Mining Engineer.
Encyc.—Encyclopedia.
Encyc. Amer.—Encyclopedia Americana.
Eng.—Engineering; Engineers; England; English.
Env. Ext.—Envoy Extraordinary.
Ep.—Epistle.
Epis.—Episcopal.
Esq.—Esquire.
Et al.—Et aliis, and others.
Etc., or &c.—Et cetera, et cetera, et cetera, and others; and so forth.
Et seq.—Et sequentes, et sequentia, and what follows.
Etym.—Etymological; Etymology.
E.U.—États Unis, United States; Evangelical Union.
Ex.—Example; Exodus.
Exch.—Exchange.
Exec.—Executive; Executor.
Execl.—Executors.
Exon.—Exonia, Exeter; Exonia, Exoniensis, of Exeter.
Ex parte.—Ex parte, in behalf of.
F.—Fahrenheit; Franc; Francs.
Fahr.—Fahrenheit.
F. A.M.—Free and Accepted Masons.
F.A.S.—Fellow of the Antiquarian Society.
F.B.S.—Fellow of the Botanical Society.
Foolscap, or fcp.—Foolscap.
F.C.P.S.—Fellow of the Cambridge Philosophical Society.
F.C.S.—Fellow of the Chemical Society.
F.D.—Fidei Defensor, Defender of the Faith.
Fecit, or he did or made it.
Fed.—Federal.
F.E.S.—Fellow of the Entomological Society; Fellow of the Ethnographical Society.
Ff.—Fecerrunt, they did or made it; Folios; Following; Forthiissimo.
P.G.S.—Fellow of the Geologica Society.
P.H.S.—Fellow of the Horticultural Society.
Fid. Def.—Fidei Defensor, Defender of the Faith.
Fig.—Figure.
Fin.—Finland.
Finns.—Finnish.
Fir.—Firkin.
Fl.—Florin; Florins; Flourished.
F.L.S.—Fellow of the Linnean Society.
F.M.—Field-Marshal.
F. o. b.—Free on board.
Fol.—Folio.
For.—Foreign.
F.P.S.—Fellow of the Philological Society.
Fr.—Fragmentum, fragment; Franc; France; Frans; Frans; French.
F.R.C.P.—Fellow of the Royal College of Physicians.
F.R.C.S. (E.I. or L.)—Fellow of the Royal College of Surgeons (Edinburgh, Ireland, or London).
ABBREVIATIONS

F.R.S.—Fellow of the Royal Society.
F.R.S.E.—Fellow of the Royal Society, Edinburgh.
F.R.S.S.A.—Fellow of the Royal Scottish Society of Arts.
F.S.A.—Fellow of the Society of Arts, or of Antiquaries.
F.S.A. Scot.—Fellow of the Society of Antiquaries of Scotland.
F.S.S.—Fellow of the Statistical Society.
Ft.—Foot; feet; Fort.
Fur.—Furlong.
F.Z.S.—Fellow of the Zoological Society.
G.—Guineas.
G. B.—Great Britain.
G.B. & I.—Great Britain and Ireland.
G.C.K.—Grand Cross of the Knights of St. Patrick.
G.C.L.—Grand Cross of the Legion of Honour.
G.C.M.—Grand Cross of St. Michael and St. George.
G.C.S.I.—Grand Commander of the Star of India.
Gen.—Genealogy; Genera; General; Genesis; Genius.
Gl. or Gloss.—Glossary.
G.L.—Grand Lodge.
G.M.—Grand Master.
G.M.K.—Grand Master of the Knights of St. Patrick.
G.M.S.I.—Grand Master of the Star of India.
G.O.—General Order.
Goth.—Gothic.
G.P.O.—General Post-Office.
Gr.—Greek.
G. R.—Georgius Rex, King George.
Gr., Grs.—Grain; Grains.
G.S.—Grand Secretary; Grand Sentinel; Grand Scribe.
Gtt.—Gutta or gutta, drop; drops.
H.—Hour.
Hab.—Habakkuk.
Hab. corp.—Habemus corpus, that you have the body.
Hab. fa. poss.—Habere facias possessionem, that you cause to have possession,—a legal writ.
Hab. fa. seis.—Habere facias seisinam, that you cause to have seisin,—a legal writ.
H.B.M.—His or Her Britannic Majesty.
H.M.—His or Her Majesty's Ship.
H.C.M.—His or Her Catholic Majesty.
H.E.—His Excellency, or His Eminence.
Heb.—Hebrew; Hebrews.
Her.—Heraldry.
H.H.—His or Her Highness; His Holiness (the Pope).
H.I.—Hawaiian Islands.
Hier.—Hierosolyma, Jerusalem.
H.I.H.—His or Her Imperial Highness.
Hind.—Hindu; Hindustan; Hindustani.
H.I.S.—Hic jacet sepulsus, here lies buried.
H.L.—House of Lords.
H.M.—His or Her Majesty.
H.M.P.—Hoc monumentum posuit, erected this monument.
H.M.S.—His or Her Majesty's Ship or Service.
Hon.—Honorable.
Hort.—Horticulture.
Hos.—Hosea.
H.R.—House of Representatives.
H.R.H.—His or Her Royal Highness.
H.R.I.P.—Hic requiescit in pace, Here rests in peace.
H.S.—Hic situs, Here lies.
H.S.H.—His or Her Serene Highness.
Hypoth.—Hypothesis; Hypothetical.
I.—Imperator or Imperatrix, Emperor or Empress.
Ib., or ibid.—Ibidem, in the same place.
Ich., or Ichth.—Ichthyology.
Icon. Encyc.—Iconographic Encyclopaedia.
I. Ch. Th. U. S.—Τ(γάνος)Χ(προτός)Θ(εος)Υ(λος) Σ(ωματος) (Iesous Christos, Theou Uios, Soter), Jesus Christ, the Son of God, the Saviour; also written Ιχθυς = a fish; whence the symbol of a fish for the sacred name.
Id.—Idem, the same.
I.e.—In est, that is.
I.H.S.—(Corrupted from Gr. ΙΗΣΩΥΣ, abbrev. of ΙΗΣΟΥΣ, Jesus). Now read Jesus Hominum Salvator, Jesus the Saviour of Men.
Imp.—Imperative; Imperator, emperor; Imperial.
In.—Inch; inches.
Inc. or Incor.—Incorporated.
Incog.—Inognito, unknown.
I.H.P.—Indicated horse-power.
I.N.D.—In nomine Dei, in the name of God.
Inf.—Infræ, beneath, or below.
In f.—In fine, at the end.
In lim.—Inlimine, at the outset.
In loc.—In loco, in the place.
In pr.—In principio, in the beginning.
I.N.R.I.—Jesus Nazarensus, Rex Judæorum, Jesus of Nazareth, King of the Jews.
Inst.—Instant; Institute; Institutes; Institution.
In transit.—In transitu, in transit.
Int. Rev.—Internal Revenue.
Ion.—Ionic.
I.O.S.M.—Independent Order of the Sons of Malta.
I.O.U.—I owe you.
Ipecac.—Ipecacuanha.
I.R.—Imperator, Rex.
Ital.—Italian; Italian.
J.—Justice, or Judge.
J.A.—Judge-Advocate.
J.C.—Jurisconsultus, jurisconsult.
J.D.—Juris Doctor, Doctor of Law.
J.P.—Justice of the Peace.
J. Prob.—Judge of Probate.
Jud.—Judicial; Judith.
J.U.D., or J.V.D.—Juris utriusque Doctor, Doctor of both laws (of the Canon and the Civil Law).
Judge-Adv.—Judge-Advocate.
K.—Karat; Karats; King.
K.A.—Knight of St. Andrew, in Russia.
ABBREVIATIONS

Kal.—Kalenda, the Kalends.
K.B.—King's Bench; Knight of the Bath.
K.B.A.—Knight of St. Bento d'AVIS, in Portugal.
K.B.E.—Knight of the Black Eagle, in Russia.
K.C.—King's Counsel; Knight of the Crescent, in Turkey.
K.C.B.—Knight Commander of the Bath.
K.C.H.—Knight Commander of Hanover.
K.E.—Knight of the Elephant, in Denmark.
K.F.—Knight of Ferdinand, in Spain.
K.F.M.—Knight of St. Ferdinand and Merit, in Sicily.
K.G.—Knight of the Garter.
K.G.H.—Knight of the Guelphs of Hanover.
K.H.—Knight of Hanover.
Kilo, Kilog.—Kilogram.
Kilol, Kilom.—Kilometer.
K.L.—Knights of Labor.
K.L., or K.L.A.—Knight of Leopold of Austria.
K.L.H.—Knight of the Legion of Honor.
K.M.—Knight of Malta.
K.M.H.—Knight of Merit of Holstein.
K.M.T.—Knight of Maria Theresa, in Austria.
K.N.S.—Knight of the North Star, in Sweden.
Knt. or Kt.—Knight.
K.P.—Knight of St. Patrick; Knight of Pythias.
K.R.C.—Knight of the Red Cross.
K.S.—Knight of the Sword, in Sweden.
K.S.A.—Knight of St. Anne, in Russia.
K.S.E.—Knight of St. Esprit, in France.
K.S.F.—Knight of St. Ferdinand, in Spain.
K.S.F.M.—Knight of St. Ferdinand and Merit, in Naples.
K.S.G.—Knight of St. George, in Russia.
K.S.H.—Knight of St. Hubert, in Bavaria.
K.S.J.—Knight of St. Januarius, in Naples.
K.S.L.—Knight of the Sun and Lion, in Persia.
K.S.P.—Knight of St. Stanislaus of Poland.
K.S.S.—Knight of the Southern Star, in Brazil; Knight of the Sword of Sweden.
K.S.V.—Knight of St. Vladimir, in Russia.
Kt.—Knight.
K.T.—Knight of the Thistle; Knight Templar.
K.t.l. (Gr.:K.t.l.)—Κατ' ης των εργων (kat' ta leip- pseis), or ἡσυχα (lespa), and so forth; and the rest; same as etce.
K.T.S.—Knight of the Tower and Sword, in Portugal.
K.W.—Knight of William, in the Netherlands.
K.W.E.—Knight of the White Eagle, in Poland.
L.—Lake; Liber, book; Libra, libra, pound, pounds.
L.A.—Licentiate of the Apothecaries' Company.
Lappish.
Lat.—Latitude.
Lb., or lbs.—Libra or libra, pound or pounds in weight.
L.C.—Loco citato, in the place cited; Lord Chamberlain; Lord Chancellor; Lower Canada; Lower case.
Leg.—Legal; Legate.
Legis.—Legislature.
Lev.—Leviticus.
Lex.—Lexicon.
L.H.A.—Lord High Admiral.
L.H.C.—Lord High Chancellor.
L.H.T.—Lord High Treasurer.
Lib.—Liber, book.
Lieu.-Col.—Lieutenant-Colonel.
Lieu.-Gen.—Lieutenant-General.
Lieu.-Gov.—Lieutenant-Governor.
Linn.—Linnaeus; Linnaean.
Lit.—Liquid; Liquidation; Liquor.
Lit.—Literally; Literature.
Lith.—Lithuanian.
Litt.—Bachelor of Letters.
L.L.—Loco laudato, in the place praised (quoted); Lord Lieutenant.
L.Lat.—Low Latin; Law Latin.
L.L.B.—Legum Baccalauraeus, Bachelor of Laws.
L.L.D.—Legum Doctor, Doctor of Laws.
L.L.M.—Legum Magister, Master of Laws.
Loc. cit.—Loco citato, in the place cited.
Long.—Longitude.
L.R.C.P.—Licentiate of the Royal College of Physicians.
L.R.C.S.—Licentiate of the Royal College of Surgeons.
L.S.—Locus sigilli, place of the seal.
L.S.A.—Licentiate of the Society of Apothecaries.
L.S.D.—Pounds, shillings, and pence.
M.—Married; Meridies, noon; Mille; Mille, a thousand; Minute, minutes; Monsieur, mister.
M.A.—Master of Arts.
M. Am. Soc. C.E.—Member American Society Civil Engineers.
Maj.-Gen.—Major-General.
M.B.—Mathematics; Mathematician.
M.B.—Medicina Baccalauraeus, Bachelor of Medicine; Musica Baccalauraeus, Bachelor of Music.
M.C.—Member of Congress; Master of Ceremonies; Master Commandant.
M.C.E.—Master of Civil Engineering.
Mch.—March.
M.D.—Medicinae Doctor, Doctor of Medicine.
Mdlle.—Mademoiselle.
Mdlse.—Merchandise.
M.E.—Methodist Episcopal; Military or Mechanical Engineer.
Mech.—Mechanic; Mechanical.
M.E.G.H.—Most Excellent Grand High Priest.
Mem.—Memento, remember; Memorandum.
M.E.S.—Methodist Episcopal, South.
Met.—Metallurgy.
Meteor.—Meteorology.
Meth.—Methodist.
Mex.—Mexico, or Mexican.
M.F.A.—Minister of Foreign Affairs; Master of the Fox Hounds (Eng.).
M. Goth.—Méeso-Gothic.
ABBREVIATIONS

Mic.—Micah.
M.I.C.E.—Member of the Institution of Civil Engineers.
Mich.—Michael; Michaelmas.
Mil.—Military.
Min.—Mining; Minute, minutes.
M.L.A.—Master of Laws.
M.L.A.—Mercantile Library Association; Member of the Legislative Assembly (S. Africa).
Mlle.—Mademoiselle.
MM.—Messieurs, Gentlemen; (Their) Majesties.
M.W.—Master of Masons.
M.M.—Master of Mining Engineering.
Mme.—Madame, Madam.
M.M.S.—Moravian Missionary Society.
M.M.S.S.—Massachusetts Medical Society; Fellow of the Massachusetts Medical Society.
M.N.A.—Member of the National Academy of Sciences.
M.P.—Member of Parliament; Metropolitan Police; Methodist Protestant.
M.P.—Member of Provincial Parliament.
M.P.—Member of the Philological Society; Member of the Pharmaceutical Society.
M.R.A.—Member of the Royal Asiatic Society; Member of the Royal Academy of Science.
M.R.C.C.—Member of the Royal College of Chemistry.
M.R.C.P.—Member of the Royal College of Physicians.
M.R.C.S.—Member of the Royal College of Surgeons.
M.R.C.V.S.—Member of the Royal College of Veterinary Surgeons.
M.R.G.—Member of the Royal Geographical Society.
M.R.I.—Member of the Royal Institution.
M.R.I.A.—Member of the Royal Irish Academy.
M.R.S.L.—Member of the Royal Society of Literature.
M.S.—Master of Science; Memoria sacra, to the memory.
M.S.A.—Master of Science in Agriculture.
Mus.B.—Musica Bacalauraeus, Bachelor of Music.
M.W.G.C.P.—Most Worshipful Grand Chief Patriarch.
M.W.G.M.—Most Worthy Grand Master; Most Worshipful Grand Master.
Myth.—Mythology.
N.—Neuter; North; Note; Noun; Number.
N.A.—National Academician; North America; North.
Nat.—Natural; National.
Nath.—Nathanael, or Nathaniel.
Naut.—Nautical.
Naut. Alm.—Nautical Almanac.
Neb.—New Brunswick; North Britain (i.e. Scotland); North British (i.e. Scottish); Nota bene, mark well; take notice.
N.D.—No date; Not dated; North Dakota.
Neh.—Nehemiah.
N. e. i.—Non est inventus, he is not found.
Nem. con. or nem. diss.—Nemine convirradicente, or nemine dissentiente, no one opposing or dissenting; unanimously.
N. I.—Non liquet, it does not appear.
N. lat.—North latitude.
N. M.—New measurement; New Mexico.
NoL. pros.—Nolle prosequi, unwilling to proceed.
Non-com.—Non-commissioned (officer).
Non cul.—Non culpabilis, not guilty.
Non obst.—Non obstante, notwithstanding.
Non pros.—Non prosequitur, he does not prosecute.
Non seq.—Non sequitur, it does not follow.
Notts.—Nottinghamshire.
N.P.—Nisi Prius; Notary Public.
N.P.D.—North Polar Distance.
N.S.—New Series; New Style (after 1752); Nova Scotia.
N.S.J.C.—Noster Salvator Jesus Christus, Our Savious Jesus Christ.
N.S.W.—New South Wales.
Num.—Numbers (Book of).
N.V.—New Version.
N.Z.—New Zealand.
Ob.—Obit, he or she died.
Obs.—Obsolete; Observatory; Observation.
Oct.—or 8vo.—Octavo.
O.F.—Odd Fellow, or Odd Fellows.
O.G.—Outside Guardian.
O.H.M.S.—On His or Her Majesty's Service.
Olym.—Olympiad.
O.M.—Old Measurement; Order of Merit.
Opt.—Optics.
O.S.—Old Series; Old Style; Outside Sentinel.
O.U.A.—Order of United Americans.
Oxon.—Oxonia, Oxford; Oxonia, Oxoniensis, of Oxford.
Oz.—Onza, ounce.
P.—Page; Part; Particle; Pondere, by weight.
Pal.—Palaeontology.
Parl.—Parliament.
Pathol.—Pathology.
Pay.—Gen.—Paymaster-General.
P.B.—Philosophiae Baccalauraeus, Bachelor of Philosophy; Primitive Baptist.
P.C.—Pater Conscript, Conscript Fathers, Senators; Postal card; Privy Council; Privy Councillor.
P.C.P.—Past Chief Patriarch.
P.C.S.—Principal Clerk of Sessions.
Per.—Paid.
P.D.—Philosophiae Doctor, Doctor of Philosophy.
P.E.—Protestant Episcopal.
P.E.I.—Prince Edward Island.
Per.—Persia; Persian.
Per ann.—Per annum, by the year.
Per cent.—Per centum, by the hundred.
Per.—Perige.
Per proc.—Per procurationem, by procurement, or by power of attorney.
Phar.—Pharmacy.
Ph.B.—Philosophiae Baccalauraeus, Bachelor of Philosophy.
Ph.B.—Philosophiae Doctor, Doctor of Philosophy.
Ph.G.—Graduate in Pharmacy.
Phil.—Philadelphia; Philomen; Philip; Philippians; Philosophical; Philosophy.
Philem.—Philemon.
Philol.—Philomathes, a lover of learning.
Phren.—Phrenology.
P.I.—Philippine Islands.
Pinx., or pxt.—Pinxit, he (she) painted it.
P.M.—Passed Midshipman; Post meridiem, afternoon, evening; Postmaster; Past Master.
P.M.G.—Postmaster-General.
P.O.—Post Office; Province of Ontario.
P. of H.—Patrons of Husbandry.
P-O-O.—Post-Office order.
P.P.—Parent, Fathers.
P.P.—Parish priest; Per proctionem, by procuration, or by power of attorney.
P.P.C.—Pour prendre congé, to take leave.
P.Q.—Previous Question; Province of Quebec.
P:—Per by, or by the.
P.R.—Populus Romæns, the Roman people; Porto Rico.
P.R.A.—President of the Royal Academy.
P.R.C.—Post Romanum condom, from the building of Rome.
Presb.—Presbyterian.
Pro tem.—Pro tempore, for the time being.
Prov.—Proverbs; Province; Provost.
Pr.—Proximo, next (month).
P.R.S.—President of the Royal Society.
Prus.—Prussia; Prussian.
Ps.—Psalms, or Psalms.
F.S.—Post scriptum, postscript; Privy Seal.
Psych.—Psychic; Psychological.
Pt.—Part; Pint; Payment; Point; Port.
P.T.O.—Please turn over.
P.W.P.—Past Worthy Patriarch.
Pwt.—Pennyweight; pennyweight.
Q.—Quadrans, farthing; Quasi, as it were, almost; Queen; Query, or question.
Q.B.—Queen’s Bench.
Q.C.—Queen’s College; Queen’s Counsel.
Q. d.—Quasi dicit, as if he should say; quasi dicitum, as if he had said.
Q. e.—Quod est, which is.
Q. e. d.—Quod erat demonstrandum, which was to be proved.
Q. e. f.—Quod erat faciendum, which was to be done.
Q. e. i.—Quod erat inveniendum, which was to be found out.
Q. i.—Quantum libet, as much as you please.
Qm.—Quoniam, how; by what means.
Q. m.—Quartermaster-General.
Q. p. or q. pl.—Quantum placet, as much as you please.
Q. s.—Quantum sufficient, as much as may suffice; Quarter Sessions.
Q.—Quart.
Qu, or qu.—Quære, inquire; query.
Quadr.—Quadrant; Quadrate.
Qua.—Quod vide, which see; Quantum vis, as much as you will.
R.—Railroad; Railway; Receipt, take; Regina, Queen; River.
R.A.—Royal Academician; Royal Academy.
R.C.—Recreation, a counterpart.
R.C.—Roman Catholic.
R.C.S.—Royal College of Surgeons.
R.C.P.—Royal College of Physicians.
R.D.—Rural Dean.
R.E.—Reformed Episcopal; Royal Engineers.
Rec.—Recipe; Record; Recorder; Recording.
Recd.—Received.
Rect.—Rector; Receipt.
Ref.—Reformed; Reformation; Reference.
Reg.—Regiment; Register; Registrar; Regular.
Reg. Prof.—Regius Professor, Royal Professor.
Rev.—Reverend; Revelation (Book of); Review; Revenue; Revise.
R.H.S.—Royal Humane Society; Royal Historical Society.
R.I.—Requiescat in pace, Let him (her) rest in peace.
R.M.—Royal Marines; Royal Mail.
R.M.S.—Railway Mail Service; Royal Mail Service; Royal Mail Steamer.
R.N.—Royal Navy.
R.N.R.—Royal Naval Reserve.
Rom.—Roman; Romans.
R.P.—Reformed Presbyterian; Regius Professor, Royal Professor.
R.S.A.—Royal Society of Antiquaries; Royal Scottish Academy.
R.S.V.P.—Répondez, s’il vous plaît, answer, if you please.
Rt. Hon.—Right Honorable.
Rt. Rev.—Right Reverend.
Rt. Wpful.—Right Worshipful.
R.U.E.—Right upper entrance.
R.V.—Revised Version.
R.W.D.G.M.—Right Worshipful Deputy Grand Master.
R.W.G.S.—Right Worshipful Grand Secretary.
R.W.G.T.—Right Worshipful Grand Treasurer; Right Worshipful Grand Templar.
R.W.S.G.W.—Right Worshipful Senior Grand Warden.
Rxs.—Rupees.
S.—Saint; Scribe; Second; Series; Solidus, a shilling; South; Sun; Sunday.
S.A.—Secundum artem, according to art; South America; South Australia.
S.A.S.—Societatis Antiquariarum Socius, Fellow of the Society of Antiquaries.
S.C.—Senatus Consultum, a decree of the Senate; Small capitals; South Carolina; Staff Corps; Supreme Court.
Sc.—Scene; Scilicet, namely, to wit; Scruple; Sculpt, he (or she) engraved it.
Scan. Mag.—Scandalum magnatum, scandal of the great.
Sc. B.—Scientia Baccalauraeus, Bachelor of Science.
Scho—Scholium, a note.
Scri.—Scruple.
Scrip.—Scripture.
Sculp.—Sculpt, he (or she) engraved it.
Sec.—Secretary; Second; Section.
Sec. Leg.—Secretary of Legation; Secundum legem, according to law.
Sec. Reg.—Secundum regulum, according to rule.
Sem.—Semble, it seems; Seminary.
Seq.—Sequentia, following; Sequitur, it follows.
Serg.-Maj.—Sergeant-Major.
Sess.—Session.
S.—G.—Solicitor-General.
S.H.S.—Societatis Historiae Socius, Fellow of the Historical Society.
S.I.M.—Society for Increase of the Ministry.
S.J.—Society of Jesus; a Jesuit.
S.M.—State Militia; Short Meter; Sergeant-Major; Sons of Malta.
S.M. Lond. Soc.—Societatis Medicæ Londinensis Socius, Member of the London Medical Society.
Soc. Isl.—Society Islands.
Sol.-Gen.— Solicitor-General.
S.P.—Sine prole, without issue.
ABBREVIATORS

S.P.A.S.—Societatis Philosophica Americana Socius, Member of the American Philosophical Society.
Sp. gr.—Specific gravity.
S.P.M.—Short particular metre.
S.P.Q.R.—Senatus Populus Romanus, the Senate and people of Rome.
S.P.R.L.—Society for the Promotion of Religion and Learning.
Sq.—Sequent, following; usually et seq., and following (pages); Square.
Sqq.—Sequentibus, the following (pages or places).
S.R.I.—Sacrum Romanum Imperium, Holy Roman Empire.
S.R.S.—Societatis Regia Socius, Fellow of the Royal Society.
S.S.—Saints; Scilicet, to wit; Semis, half; Sessions.
S.S.—Steamship; Sunday-school.
S.S.E.—South-southeast.
S.S.W.—South-southwest.
S.S.—Saint; Street.
S.T.B.—Sacra Theologia Baccalaureus, Bachelor of Sacred Theology.
S.T.D.—Sacra Theologia Doctor, Doctor of Sacred Theology.
Ster., or Sig.—Sterling.
S.T.P.—Sacra Theologia Professor, Professor of Sacred Theology.
Su.- Goth.—Suo-Gothic.
Sup.—Superfine; Supplement; Supra, above; Supreme.
Surg.—Surgeon; Surgery.
Surg.-Gen.—Surgeon-General.
S.V.—Sub voce, under the word or title.
Syn.—Synonym; Synonymous.
Syriac.
Tang.—Tangent.
T.E.—Topographical Engineers.
Tel.—Telegraph or Telephone.
Text. Rec.—Textus Receptus, Received Text.
Thess.—Thessalonians.
Tob.—Tobit.
Tome.—Volume.
Top.—Topography; Topographical.
Tr.—Transpose; Translator; Translation; Trustee.
Trans.—Translator; Translation; Transactions; Transpose.
Tr. —Turkey.
Typ.—Typical; Typographer; Typographical.
U.—Union.
U.B.—United Brethren.
U.C.—Upper Canada; Urbe condita, year of the founding of Rome.
U.J.D.—Utriusque Juris Doctor, Doctor of both Laws (Canon and Civil).
U.K.—United Kingdom.
U.K.A.—Ulster King-at-Arms; United Kingdom Alliance.
U.L.—University last; of the last month.
U.P.—United Presbyterian.
U.S.—United States.
U.S.A.—United States of America; United States Army.
U.S.M.—United States Mail; United States Marines.
U.S.M.A.—United States Military Academy.
U.S.M.C.—United States Marine Corps.
U.S.M.H.S.—United States Marine Hospital Service.
U.S.N.—United States Navy.
U.S.N.A.—United States Naval Academy.
U.S.S.—United States Senate; United States Ship.
U.s.w.—Und so weiter, and so further; same as "et al."
V.—Versus, against; Versiculo, in such a verse; Vide, see.
Val.—Valorem; Value.
Vat.—Vatican.
V.C.—Victoria Cross; Vice-Chairman; Vice-Chancellor.
V.D.M.—Verbi Dei Minister, Minister of God’s word.
V.G.—Vicar-General.
V.g.—Verbi gratia, as for example.
Vid.—Vide, see.
Visc.—Viscount.
Viz., or vl.—Videlicit, to wit; namely; that is to say.
V.o.—Verso, left-hand page.
Vols.—Volunteers; Volumes.
V.P.—Vice-President.
V.R.—Victoria Regina, Queen Victoria.
Vs.—Versus, against; Versiculo, in such a verse.
V.S.—Veterinary Surgeon.
Vul.—Vulgate.
W.B.M.—Woman’s Board of Missions.
W.C.A.—Woman’s Christian Association.
W.F.—Wrong font.
W.F.M.S.—Woman’s Foreign Missionary Society.
W.M.—Worshipful Master.
W.M.S.—Wesleyan Missionary Society.
W.S.—Writer to the Signet.
X.—Xmas, Christmas.
X.—Xmas, or Xm.,—Christmas.
X., or Xt.—Christ. (X in this and the following abbreviations is the Greek chi.)
Xmas, or Xm.—Christmas.
Xn., or Xian.—Christian.
Xnty., or Xty.—Christianity.
Xper., or X.—Christopher.
Y.M.C.U.—Young Men’s Christian Union.
Y.P.S.C.E.—Young People’s Society of Christian Endeavor.
Y.W.C.A.—Young Women’s Christian Association.
Zach.—Zachary.
Zech.—Zachariah.
Zeph.—Zephaniah.

ABBREVIATORS, a body of 72 writers in the Papal Chancery who have charge of sketching and putting in shape papal bulls, briefs, and consistorial decrees, and signing them in the name of the Cardinal Vice-Chancellor. This body receives its name from the fact of their taking short-hand notes of the decisions to be later expanded. They have existed at least since 1400.
ABD ALLAH IBN ZUBAIR, b'n'zoo'b'er, Moslem Caliph: b. 622: d. 692. He was the son of Zubair, nephew of Mohammed, the Prophet, and the grandson of Abu Bekr. After the death of Husain he had himself proclaimed caliph by the people of Mecca; 681, taking the title of Amir al Muminin. Soon he was attacked by the armies of Yazid and was besieged in Mecca. Yazid's death, however, in 683, put an end to the siege, and Iraq, Arabia and the greater part of Syria recognized Abd Allah as caliph. But presently Abd al Malik renewed the war and again laid siege to Mecca. After a long resistance the city finally fell in 692, and Abd Allah was slain.

ABD AL LATIF, là-téf, Arabian writer and physician: b. Bagdad, 1160; d. while on a pilgrimage to Mecca, 1231. Amite his early studies, which consisted, after the custom of the time and the people, of memorizing the Koran and other literary works, he went to Damascus, which was then the centre of learning of the Moslem world. While in Egypt Abd al Latif became acquainted with Maimonides, the great Jewish philosopher. At Cairo he became a teacher of medicine, though he also devoted much time to traveling. Abd al Latif is supposed to have written many works, but of these only his 'Account of Egypt' is preserved. This work was translated into Latin by White (1800), and into French by De Sacy (1810).

ABDALWADIDS, āb'dal-wā'didz, a Berber dynasty of Tlemcen, sometimes referred to as Banu Zayyan, after the father of the first independent king, whose reign began in 1239. Of the early origin of the family little is known, but there are ample records to prove that the Abdalwadids reigned wisely for more than three centuries over the western part of Alger, the dynasty terminating in 1554.

ABD EL AZIZ, āb'dool-a'z'ēz, Sultan of Morocco, son of Sultan Mulai Hassan: b. Marrakesh, 1880. In 1912 he succeeded his father as Sultan. So progressive was he in his tendencies and so friendly toward Europeans that he aroused thereby the fanaticism of his people. Taking advantage of this, a prophet, Bu Hamara, precipitated a formidable rebellion in 1902, bringing about the intervention of France. This was finally followed by the Algeciras Conference, in 1906, by which France and Spain undertook to maintain law and order along the Moroccan Coast, Abd el Aziz agreeing to co-operate with these two European nations. But this was difficult in keeping on account of his growing unpopularity. The following year Mulai Hafid, elder brother of the Sultan, headed a rebellion of the southern tribes and Abd el Aziz was obliged to remove his capital from Fez to Rabat. In spite of the support of France, both moral and financial, he was unable to maintain his authority, and in January 1908 the throne was declared vacant by the priesthood of Fez and immediately offered to Mulai Hafid. Realizing that his attempt to maintain his authority by force would prove futile, Abd el Aziz compromised with his brother and retired to private life in Tangier.

shortly after his birth. Aside from these bare facts little of any certainty is known of the father of the Prophet.

ABD ALLAH IBN ZUBAIR, 'bn'zoo'b'er, Moslem Caliph: b. 622: d. 692. He was the son of Zubair, nephew of Mohammed, the Prophet, and the grandson of Abu Bekr. In spite of the support of France, both moral and financial, he was unable to maintain his authority, and in January 1908 the throne was declared vacant by the priesthood of Fez and immediately offered to Mulai Hafid. Realizing that his attempt to maintain his authority by force would prove futile, Abd el Aziz compromised with his brother and retired to private life in Tangier.
ABD EL KADER IBN MOUHI AD DIN, abdelkader ibn mouhid ad-din, noted Arab chief: b. near Mascara, 1807; d. Damascus, Egypt, 26 May 1883. He was educated at Ghetna in an institution maintained by the Marabouts. When only eight years of age he went with his father on a pilgrimage to Mecca. In 1827, while 20 years of age, he visited Egypt, where he came in first contact with Europeans. His first entry into the affairs of public life was when Algiers was conquered by the French. On the defeat of the Turks, Abd el Kader placed himself at the head of the Arab tribes of the province of Oran and declared himself an independent ruler. On 3 Dec. 1833 he fought a bloody battle with the French, in which the French were decidedly beaten. A month later he again attacked the French under General Desmichels, commanding all the forces of France in Oran, and compelled him to recognize his authority. The result was that his power increased rapidly and he was proclaimed sultan by all the surrounding peoples. The truce with the French was only temporary, however, and in 1841 Abd el Kader was completely defeated and driven into Morocco. Here he appealed to the people in the name of Islam and declared a religious war. France then turned her attention to Morocco, her possessions finally terminating in the Battle Isly, in 1844, after which the Sultan of Morocco repudiated Abd el Kader. The latter attacked the Moors on the night of 11 Dec. 1847, but was heavily defeated and obliged to flee to Algeria, where he was compelled to surrender to the French. Abd el Kader was now taken a prisoner to France. For five years he was held in France, though allowed an annuity of 100,000 francs. Finally, in 1852, Napoleon III liberated him, whereupon he retired to Brussa, Asia Minor, later removing to Damascus. During the massacres in Syria, in 1860, he rendered the Christians such services that Napoleon III awarded him the Grand Cross of the Legion of Honor. In 1865 he went to Europe again and was present at the Paris Exposition in 1867. During his later years he engaged in literary labors, writing a religious work, which was later translated into French (1858), under the title "Rappel à l'intelligent: avis à l'indifferent.

ABD EL MUHIN ABU MOHAMMED, abdelmoumen abou mouhamed, Moorish ruler, founder of the Almohades dynasty: b. Tajira, North Africa, 1094; d. 1163. He was a member of the Kumiya, a Berber tribe. He became a close friend of Ibn Tumart, founder of the Almohadea sect, and when that leader died he was chosen his successor. Announcing himself as a caliph, he met the Almoravides in battle, put them to flight and then began a campaign of conquest that did not cease until he had subdued the cities of Oran, Tiemcen, Fez, and finally Morocco. Having established himself firmly in Africa he crossed over into Spain and conquered Cordova in 1148, Almeria in 1151, and Granada in 1154, until the greater portion of Mohammed Spain was under his control.

ABD-ER-RAHMAN I, abderrahman, founder of the Murabit emirate (later caliphate) of Cordova (q.v.): b. Damascus, 731; d. 788. He was a grandson of the Ommiad caliph Hisham, and having fled to Africa escaped the frightful massacre of his family (see OMMIADS and ABBASIDES) by Abu 'l-Abbas; a hunted fugitive in the desert, but faithfully protected by the tribesmen, who respected his blood and pitied his misfortunes. Meanwhile Spain was seething with anarchy; each new caliph attempted to establish an emir there; the governor of Africa claimed the right to interfere on the ground that the African governors had captured it; the native chiefs were unwilling to submit to a constant succession of interlopers with no interest but their own, and at last the situation became so intolerable that the Spanish Arabs determined to choose a ruler with his residence in Spain. They selected the wandering heir of the overthrown house, and seeking him out in Africa offered him the place. He landed in Spain 23 Sept. 755, and fixed his royal seat at Cordova. His reign was one of incessant warfare. Hosein ben-Yahya, the Abbasside emir, driven from Spain, fled to Charlemagne and implored his assistance; it was granted and Hosein was re-enthroned at Saragossa, but while the French were returning through the Pyrenees, the Basque mountaineers fell upon the rear-guard and annihilated it in the pass of Roncesvalles, with its commander Roland. Saragossa was taken after two years' siege. Hosein put to death as a rebel, and Spain to the Pyrenees subdued. A formidable rising in 786 was crushed, and Abd-er-Rahman had two years of life to devote to the arts of peace and the building of his famous mosque at Cordova (now used as a cathedral), with its rows of cupolas supported by 850 pillars of jasper.

ABD-ER-RAHMAN III, the greatest of the caliphs of Cordova, and the first under whom the emirate assumed the title of caliphate: b. 891, acceded 912; d. 961. Measured by what he found and what he left, he must be counted among the ablest rulers of history. The former was a throne handed down to him. Most of the provincial governors had thrown off allegiance, and the rest rendered such obedience as suited them; a country in a state of permanent anarchy and civil war, perishing of racial, religious, and factional quarrels between the Moors; the Fatimite dynasty establishing a great empire in Africa, and looking for a speedy succession to the heritage of Spain; on the north, the new Christian states rapidly growing,—Alfonso III had recently moved his capital across the mountains to Leon, and Sancho had founded the kingdom of Navarre,—so that what escaped the Africans would probably fall into the hands of the Christians. Abd-er-Rahman first put down the worst internal revolt; that of the rebellious old brigand Omar ben Hafsun, whose stronghold in the mountains of Andalusia had become a centre for all the renegades, Christians, and rebels of the south. He tied the hands of the Fatimites by subsidizing the native princes who held out against them. The northern danger was the worst. Ordoño II in 914 RAIDED the territory of Merida; and though Merida had thrown off allegiance to Cordova, Abd-er-Rahman wished the more to show them that he was their protector. Gathering an army of a splendid army, in 918 he gained a great victory over the combined forces of Leon and
Navarre, following it up with several campaigns in which he penetrated to Pamplona, the capital of Navarre. These victories were not final: his fortunes were checked on the Christian side, and he suffered some decisive defeats. But his suzerainty over Navarre was recognised, and in 960 a deposed king was reseated on the throne of Leon by Abd-er-Rahman's troops. Internally his success and glory were unqualified. At his death he left a consolidated kingdom, a rich treasury invested with an emulated one, internal order kept by a vigilant police, flourishing agriculture based on scientific irrigation, prosperous industries, commerce whose customs dues furnished the majority of the revenue, an income of which one-third paid the current expenses and another third was used for building, and the rest kept for a reserve, the best army in Europe, a superb navy which made him lord of the gates of the Mediterranean, and equality in diplomatic rank with the proudest sovereigns of the world.

**ABD-ER-RAHMAN.** Saracen chieftain who led an army of nearly 90,000 into Gaul, and was defeated and slain near Poitiers (usually known as the battle of Tours) by Charles Martel (q.v.).

**ABD-ER-RAHMAN.** See also **ABD-UR-RAHMAN.**

**ABDICATION,** in strictness, the renunciation of any office by the holder before the expiration of its term; in actual use, applied only to sovereign rulers, *de jure or de facto,* who resign the crown in their lifetimes. The motives for this are as various as human fate, character, policy, or necessity, or the events of history. It may be compulsory—in which case it is really not abdication but deposition—or voluntary. Compulsion may come from foreign conquest; from foreign commands when the king is a puppet, as with the later Polish kings, or Napoleon's shifting his brothers from throne to throne; from the commands of *de facto* controllers of the state within, as with the puppet Roman emperors under the barbarian commanders-in-chief of the army, or frequent fractional insurrections. If voluntary, it may be from desire to let a constitutional machine have a fair chance to work alone, as with Sulla and Diocletian; from satiety with royal power and weariness of royal burdens, as with Murad II of Turkey; from physical ailments and discouragement, as with the Emperor Charles V; from penitence and desire to live a religious life, as with more than one mediæval prince who furnished real models for Shakespeare's usurper in *As You Like It*; from weariness of the restraints of royal etiquette, as with Christina of Sweden,—perhaps also sincere conversion to Catholicism and unwillingness to enforce a Protestant establishment; from unwillingness to obey an overlord to the harm of his kingdom, as with Louis Bonaparte of Holland; from inability to face the results of crushing defeat, as with Charles Albert of Sardinia; from acceding to a higher throne, as with Charles of Naples; from results of the results of the same policy, as with William I of the Netherlands; from the willingness to retain a throne against the popular will, as with Louis Philippe—for his resignation was not enforced; or other reasons. In monarchies as a whole, the sovereign can abdicate at will; in England, only by consent of Parliament—which however, as in the case of James II, can assume an implied abdication which the monarch had no intention of executing, the term being a euphemism for deposition.

The following is a list of some of the chief historical abdications, with their dates:

- Sulla the Dictator: B.C. 70
- Diocletian the Emperor: A.D. 305
- Louis XI of France: 1515
- Stephen II of Hungary: 1131
- Ladislas III, Duke of Poland: 1206
- Albert the Bear of Brandenburg: 1219
- Celestine V, Pope: 1294
- John Balliol of Scotland: 1296
- Richard II of England: 1399
- Richard III, Pope: 1399
- Philip V, Emperor (Netherlands): 1439
- (Spain, Sicily and the Empire): 1520
- Christina of Sweden: 1654
- John Casimir of Poland: 1668
- James II of England: 1688
- Frederick Augustus of Poland: 1707
- Philip V of Spain: 1724
- Victor Amadeus II of Savoy: 1730
- Mehmed III, Ottoman Emperor: 1732
- Charles of Naples (on accession to throne of Spain): 1759
- Stanislaus II of Poland: 1795
- Charles Emmanuel IV of Sardinia: 4 June 1820
- Charles IV of Spain: 6 June 1808
- Joseph Bonaparte of Naples (transferred to Spain by Napoleon): 6 June 1808
- Gustave IV of Sweden: 25 Mar. 1809
- Louis Bonaparte of Holland: 2 July 1810
- Napoleon I of France: 4 April 1814 and 22 June 1815
- Victor Emmanuel of Sardinia: 13 Mar. 1821
- Charles X of France: 2 Aug. 1830
- Pedro of Brazil: 7 April 1831

(Also abdicated the throne of Portugal in favor of his daughter, at once on his accession in 1826.)

- Miguel of Portugal: 26 May 1834
- William I of Holland: 19 Mar. 1840

**ABDIEL,** ábdi-él ("servant of God"), the one loyal spear in heaven, according to *Paradise Lost,* "among the faithless, faithful only he," who withstands Satan when the latter is inciting revolt against God for promoting his Son over the heads of the angel peers. Milton took the name from the Jewish cabalists.

**ABDOMEN,** áb-dó'men, in human anatomy, that portion of the body bounded above by the diaphragm, below by the pelvis, behind by the lumbar vertebræ, and in front by a thin layer of muscles, the abdominal muscles. This abdominal cavity contains the chief organs of digestion, respiration, and the genito-urinary system. By reason of the movements of the diaphragm it is rhythmically changing its size, and the movements of the intestines somewhat modify its internal contour. For purposes of description and for localization, the abdomen is divided by a tit-tat-toe figure into nine regions; the upper and lower horizontal lines passing at the lower level of the ribs and the upper borders of the pelvis. From above downward
the middle squares are termed the epigastric, the umbilical, and hypogastric; to the sides of the epigastric regions are the right and left hypochondrium (under the ribs); the right and left lumbar flank, the central umbilical region, and the right and left iliac regions lie down in the pelvis on either side of the hypogastric area. The general location of the abdominal viscera in the various areas thought to be involved is as follows: The liver lies under the ribs in the right hypochondrium, stretching over the upper part of the epigastrium into the left hypochondrium; the stomach lies mostly in the left hypochondrium and reaches into the epigastrium just below the sternum; the large intestine starts in the right iliac region, the appendix being there also, goes up the right lumbar into the lower portion of the right hypochondrium, crosses straight over, dipping slightly into the umbilical region, from the left hypochondrium it descends into the left iliac region and then turns back into the centre and ends at the rectum. The small intestine occupies most of the umbilical region, extending out into the others. The pancreas lies just below the lower end of the stomach in the epigastrium. The spleen lies higher up on the left side behind, resting on the 10th and 11th ribs; the kidneys are behind high up, in the hypochondriac lumbar region, just coming below the free borders of the ribs; most pains in the small of the back or in the epigastric are kidney pains are pains from constipated bowels; kidney pains are high up under the ribs behind. The genital organs lie in the hypogastric and right and left iliac regions, the bladder low in front in the centre, the uterus slightly above in the centre, the ovaries to the right and left in the right and left iliac fossae.

In entomology, the whole body of an insect behind the thorax. It usually consists of rings or short hollow cylinders, which are united by a joint or membrane, and in some cases, as in the grub of the chameleon fly, slide upon one another like the tubes of a telescope. Sometimes it bears a sting or an ovi- position organ in the perfect insect no appendages are found.

An abdominal ring is one of two oblong tendinous openings or rings* existing in either groin, or in the right and left inguinal regions. Through these rings pass the spermatic cord in the one sex, and the circular ligament of the uterus in the other. Consult Taussig. F. J., 'Surgical Diseases of Abdomen' (1910); Gray, 'Human Anatomy' (1916).

**ABDUCTION**, the act of abducting or abducting; a taking or drawing away, and specifically an unlawful taking. In the United States the word abduction is ordinarily applied to the illegal seizure and detention of a female for the purpose of concubinage, prostitution or marriage. The punishment for abduction varies in the different States of the Union. The tendency of American legislation is to extend the scope of the term beyond its common law limits. In many States the statutes in express terms look to the punishment and suppression of the vices which are involved in the sexual acts usually contemplated in the unlawful taking or enticing of females. They are variously directed against the taking of a woman against her will for the purpose of compelling her by force, menace, etc., to marry; against the taking of a female under a designated age, without the consent of her lawful custodian, for the purpose of marriage; against the taking and detaining of any woman against her will, with intent to have carnal knowledge of her, or that another shall have such knowledge; against the inveigling of an unmarried female of previous chaste character into a house of ill fame, assignation or elsewhere, for the purpose of prostitution or sexual intercourse, or against the taking and seduction of a girl under a designated age.

In common and English law this offense is of three kinds: (1) If any person shall maliciously, either by force or fraud, lead, or take away, or detain, any child under the age of 10 years, with intent to deprive the parents or other person having the lawful charge of such child, or with intent to steal any article of its person; or shall receive or harbor such child, knowing the same to have been so stolen or enticed, every such offender shall be guilty of felony, and shall be liable to penal servitude for not more than three years, or imprisoned, with or without hard labor, for any term not more than two years. (2) If the girl is under the age of 16 years, the offender shall be guilty of misdemeanor, and being convicted thereof, shall be liable to suffer such punishment, by fine or imprisonment, or both, as the court shall award. (3) If any person shall, from motives of lucre, take away or detain against her will, any woman having any interest, present or future, in any real or personal estate, with intent to marry or defile her, or to cause her to be married or defiled by any other person, every such offender, and every person counseling, aiding, or abetting such offender, shall be guilty of felony, and liable to penal servitude for life, or for any time not less than three years, or imprisoned, with or without hard labor, for any term not exceeding five years. If the woman first consent to be taken away, and afterward refuse to continue with the offender, and he forcibly detain her; if she be forcibly taken away and she afterward consent to her marriage or deflement; or if she be taken away with her own consent, obtained by fraud or imposition, the offense is the same. But if a man, without fraud, deceit, or violence, marries a woman under age, without the consent of her father or guardian, that act is not indictable at common law.

In logic, abduction is a form of reasoning in which the greater extreme is contained in the medium; but the medium is evidently in the lesser extreme. Example: Whatever God has revealed is certainly true; now God has revealed a future retribution; therefore a future retribution is certainly true.* In the use of this kind of reasoning the minor proposition must be proved to be contained in the major.

**ABDUCTOR**, a muscle, the office of which is to draw a limb or portion of a limb to which it is attached away from the centre of that limb. Abductor of the thigh, for example, raises the thigh away from the centre of the body.

In law, a person guilty of abduction.
From the text provided, it appears to be a historical narrative discussing the lives and events of various figures, including Abd-al-Akhd Khan and Abdul Baha. The document mentions the founding of the Universal House of Justice and details the activities of Abdul Baha, including his efforts to promote the Bahá'í faith and his international correspondence. The text also touches on the historical context of the Ottoman Empire and the Ottoman-Azerbaijan peoples. It highlights the challenges and achievements of Abdul Baha in promoting social justice and unity. The narrative is rich in historical detail, providing insights into the socio-political landscape of the late 19th and early 20th centuries.
ABD-UL-HAMID I — ABD-UL-HAMID II

ABD-UL-HAMID I, abd-oel-ha-mid', 27th Sultan of Turkey, son of Ahmed III: b. 1725; d. 19 April 1789. He succeeded his brother Mustapha III in 1774. He was involved in two wars with Russia, and the treaty of Kuchuk-Kainardji in 1774 compelled him to relinquish Kars, Erzerum, and Kiakinburg. He was also forced to grant free navigation in the Black Sea, the protectorate of Russia over the provinces of Wallachia and Moldavia, guarantee the partition of Poland, and independence of the Crimean Tartars. This Sultan succeeded in quelling the rebellions instigated by several of his pashas and, recognizing the superiority of the European military system, invited French officers for the purpose of fortifying the fortresses of his empire. In 1787 a war broke out between Turkey and Russia and the latter's ally, Austria which ended in the disaster of the Ottoman fleet at Kimburn (30 Dec. 1788) and the loss of Ochakov. In the last years of his reign Abd-ul Hamid suffered from mental and physical disorders and died 19 April 1789, just when he was preparing for a formidable invasion to the north of his empire. He was succeeded by his nephew Selim III. Consult Azim-Tarsich, 'History of Abd-ul-Hamid and Selim III' (Constantinople 1867).

ABD-UL-HAMID II, 34th Sultan of the Ottoman Empire: b. 22 Sept. 1842, second son of Abdul-Medjid, reigned from 1876 to 1909, when he was deposed and made a state prisoner for life. His uncle, Abdul-Aziz, a profligate debauche, was dechekoned by Midhat Pasha (q.v.) in 1876, and was found shortly after with the reins of his wrists cut open with a pair of scissors. Whether it was a case of suicide or murder has never been decided. Abdul-Hamid's brother Murad V ascended the throne, but was deposed again in a few months' time owing, it was said, to a disordered mental condition, and Abdul-Hamid reigned in his stead. Up to that time he was known as a debauched weakling, brought up in the luxurious atmosphere of the harem. No sooner, however, had he grasped the reins of power than he proved himself a despotic ruler of the strongest type, and developed into one of the cleverest and most unscrupulous diplomatists of his age. At the time of his accession, the country was in a deplorable condition. Torn by revolution, corruption, and bankruptcy, within its borders, Turkey was threatened with war outside by her hereditary enemy, Russia. Even the European powers who had labored and fought to keep the "Sick Man of Europe" alive, were clamorously demanding the introduction of long-promised and necessary reforms. By a skilful policy of apparent acquiescence in every demand made upon him, the new ruler managed for a time to relieve the external pressure and devote his immense energy to the reorganization of the army and finances of the state. He speedily crushed the insurrection in Herzegovina and Bosnia; by galvanizing his tottering empire with new life and vigor, he showed an astonished world that the Turk was not so "sick" as his numerous doctors maintained. A rejuvenated Turkey was the last thing that Russia desired, and Alexander II lost no time in declaring war. Abdul Hamid accepted the challenge and conducted the war with remarkable ability. But his enemy was too strong for him, and he committed the fatal error of interfering too much with his generals. The surrender of Osman Pasha at Plevna (q.v.) to the Russians opened a clear passage for the victors to Constantinople. As before in the Crimean War, Great Britain again came to the rescue. Disraeli ordered the British Fleet to the Dardanelles and mobilized the fighting forces of the whole British Empire. The unexpected move checked the Russian advance; the Treaty of San Stefano (q.v.) was nullified by the Berlin Congress, and a totally undeserved new lease of life was granted to the worst-ordered state in modern history.

The Treaty of Berlin deprived Turkey of her Balkan principalities: Herzegovina, Bosnia, Kars and Batum, but she was still permitted to retain her suzerainty over Eastern Rumelia.

The gloom of the Hamidian era settled like a pall over the land of the Osmanli. The constitution and parliament inaugurated by Midhat were abolished; the control of every department of state was centralized in the hands of the Sultan, and the liberal Hadji Midhat Pasha, was exiled to Arabia and strangled. He was too honest and too democratic to please his imperial master. European jealousy had hindered Russia from wiping out the plague spot of Europe, and Abdul Hamid was clever enough to utilize that jealousy by playing one power off against the other. His one aim was to maintain absolute autocracy at home and to evade the demands of the "infields" abroad. The methods he employed in the process were truly Oriental: espionage, bribery, murder and terrorism. Many powerful persons who disagreed with him were quietly removed and never heard of again. High positions were conferred upon unscrupulous tools or sold to the highest bidder. The governors of provinces were permitted to squeeze and tyrannize over the unhappy people they were supposed to govern; wholesale massacres of Christian subjects were encouraged—or at least tolerated. Hordes of savage Kurds were permitted to burn a thousand; unspeakable atrocities sent many a thrill of horror throughout the civilized world; international representations and diplomatic "Notes" were simply showered upon the hermit Sultan, who smilingly accepted them all and calmly pursued the uneven tenor of his way. Nemesis, however, prepared a belated instrument of vengeance to compass his downfall—the Young Turk Party. Persecuted, imprisoned and judicially murdered at home, the survivors of the party carried on their propaganda as the "Committee of Union and Progress" in Paris, Geneva and London, whilst secret agents canvassed among those without whose help nothing could be done—the Turkish army officers. The Albanians, the finest soldiers in that army, went over in a body to the revolutionary movement. The hour struck on 22 July 1908, when Majors Niazi Bey and Enver Bey raised the flag of military revolt at Reina, in Macedonia, where they were stationed in command of the troops. They proclaimed the Constitution and threatened to march on Constantinople. Seeing that he could no longer count on the loyalty of his soldiers, Abdul Hamid became thoroughly alarmed and capit-
lated at once. Making a virtue of necessity, he immediately restored the Constitution he had abrogated in 1878. Great rejoicing prevailed, especially when, on 1 August the Sultan issued a Hatti-i-Humayun assuring to the people those elementary principles of freedom and justice they had never before enjoyed. The revived Turkish Parliament opened on 15 Jan. 1909. Kiamil Pasha, the aged grand vizier, referred to the "wise and prudent policy" of the Sultan in putting himself at the head of the revolution. The Government soon resigned, however, owing to internal dissensions. Serious disturbances broke in the provinces; in Ardana, Asia Minor, thousands of Armenians and two American missionaries were massacred. The spirit of Abdul-Hamid inspired his followers to restore the old order of things, and there is no reason to doubt that he instigated the mutiny that broke out (14 April 1909) among the troops still loyal to him. They seized the Parliament House, telegraph offices and bridges of the city. Two members of the Committee were murdered and several arrested. The minister of justice was killed and the minister of marine wounded. For the moment it seemed that Abdul-Hamid would emerge victorious from the crisis, but the Committee of Union and Progress sent troops to Constantinople to crush the counter-revolution. On 24 April Gen. Mahmod Shefket Pasha entered the city with a constitutional army. Considerable street fighting developed with the "loyalists," who were easily overcome by the Young Turkish leaders. It was decided to depose the Sultan and replace him by his younger brother Mohammed Reshad Effendi, who had for many years been kept in isolation to prevent the very event which was now to happen. (See Mohammed V.) The ring leaders of the counter-revolution were court-martialled and 40 of them hanged in the principal public squares of the city. Abdul-Hamid was banished to Salonica with his dogs, birds, carpenter's tools, and a few members of his harem. As a cabinet-maker he frequently presented desks of his own make to foreign diplomats. Many uncomplimentary epithets were applied to him during his dark reign, such as "The Great Assassin," "Abdul the Damned," and "the Lame Turk." Conant Pears (Sir) E., Abdul Hamid? (in Makers of the Nineteenth Century Series, New York 1917).

ABDULLAH. See KHALIFA, THE.

ABD-UL-MEDJID, "abd-ool-me-jid," 31st Sultan of the Ottoman Turks, son of Mahmoud II; b. 23 April or 6 May 1823; acceded 1 July 1839; d. 25 June 1861. He received the usual enfeoffing harem education, his father failing in his efforts to rescue his children from the system. On his accession Turkish affairs were critical. The great vicrory of Egypt, Mehemet Ali, had a second time revolted; 10 days previously the Turkish admiral had turned traitor and put the entire fleet in his hands; and three days afterward Mehemet's son Ibrahim, the greatest Moslem soldier of the century, had routed the Turkish army at Nizib, and was marching straight on Constantinople, where the orthodox party, enraged at Mahmoud's reforms, had conspired to place Mehemet Ali on the throne. But the Europeans interfered, and the treaties of 27 Nov. 1840 and July 1841 confined Mehemet to Egypt again. Abd-ul-Medjid at once set about complying with his father's express instructions and carrying out his reforms: 3 Nov. 1839, he promulgated the "Hatti-sherif of Gulhané," placing all his subjects on full religious and civil equality, and providing for security of life and property to all, with just and equal taxation, administration of laws, and conscription; February 1856, after the Crimean War, it was supplemented by another to the same purport. But the Mussulman aristocracy and the educated classes (Ulema) regarded it as an anti-Mussulman revolution to do no profit but that of the infidels, and fought it so furiously that it remained practically inoperative, and rather sharpened the edge of their ill-treatment of the Christians; and repeated conspiracies were formed against his life, whose members however the kindly Sultan would not put to death. His right hand in reform work was the able and humane Reshid Pasha, a Mussulman educated in France: through him the army was reorganized 1843-44; a board of education established, a navy re-formed, with military, medical, and agricultural colleges; a hateful capitation tax abolished, slave-trading repressed, and commerce advanced. Nothing can better prove the intrinsic and hopeless rottenness of the Mussulman system under modern conditions than the fact that the men who were written in water and died almost with their birth; their main fruit was bloody insurrections in various parts of the empire, of which the great Syrian massacres of 1860 (see Syria) were the worst. In 1849 Abd-ul-Medjid honored himself by boldly refusing to surrender Kossuth and the other Hungarian refugees, after the failure of the Hungarian revolution, at the joint demand of Russia and Austria. For the Crimean War, and its antecedents and results, see that head. In later life he sank into extravagance and sensuality; but he was essentially a good-hearted and honorable man, powerless against fate. He was succeeded not by one of his seven sons, but by his brother Abdul-Aziz, the oldest living member of the house of Othman.

ABD-UR-RAHMAN, abd-oor-rá'man, Sultan of Fez and Morocco: b. 1778; succeeded his uncle 1823; d. 1859. His first four years of rule were occupied in quelling insurrections. Next, Austria refused to pay the tribute for safety against pirates levied by Morocco on European ships in the Mediterranean: the Sultan wisely adjusted the dispute by relinquishing this blackmail. (See Morocco.) The religious war under Abd-el-Kader against the French in Algeria involved Morocco in its movements: the defeat of the French in 1844 compelled the Sultan to order Abd-el-Kader to quit the country, which, however, he did not for three years longer. The piratical habits of the Moroccans brought him to the brink of war with more than one European state. He was succeeded by his eldest son, Sidi-Mohammed (1859-73).

ABD-UR-RAHMAN-KHAN, abd-oor-rá'man-kan, amir of Afghanistan, son of Afzul (uf-zool) Kahn, nephew of the amir Shere Ali, grandson of Dost Mohammed: b. Kabul, 1844; d. 3 Oct. 1901. During the civil war of 1864 in Afghanistan (q.v.) between Dost Mohammed's sons, he played a leading part on his father's.
side against his uncle, won several battles,—the important victories of Shaikhabad and Khelat-i-Ghilzai were mainly due to his ability—and for a time his father seemed secure of the emirate. Abd-ur-Rahman was made governor of Balkh, and won great popularity by his moderation and by marrying the daughter of the chief of Badakh-shan. In 1868, however, Shere Ali gained the mastery, and the English government decided to put forward further resistance for order's sake. Yakub-Khan drove out his cousin Abd-ur-Rahman, who after hunting wanderings reached Russian territory, and General Kaufman allowed him to live at Samarcand with a pension of 25,000 rubles a year. Here he remained till 1879, when Shere Ali's death, and the weakness of Yakub, whom the English had recognized as amir, gave him a chance to return to Bakh, where he was welcomed. The murder of the British Resident at Kabul and Yakub's deposition followed; Abd-ur-Rahman came forward once more, and was acknowledged by the principal chiefs and the English government, which gave him a subsidy of £100,-000 a year, and large gifts of artillery, rifles, ammunition, etc. In 1893 the Indian government turned over to him Kafiristan, in the Hindu-Kush mountains, and he brought its savage tribes under control in 1896. The English government showed him great honor, as he deserved; and made him G.C.B. and G.C.I.E. He was succeeded by his eldest son, Habibullah-Khan, who had been associated with him in the government for some time.

A BECKET, Thomas. See BECKET, THOMAS A.

A BECKETT, Arthur William, English novelist and dramatist, son of Gilbert Abbott A. Beckett, b. London, 25 Oct. 1844; d. 1909. From 1865 to 1868 he was editor of The Glitter, after which he edited the Britannia Magazine until 1870. When the Franco-Prussian War broke out he was sent to the front as a special correspondent by the London Standard and Globe. In 1874 he became a member of the editorial staff of Punch, a position which he retained continuously until 1902, when he resigned to become editor of John Bull. Among his works are: Nightingales (1888); London, at the End of a Century (1900); The A'Becketts of Punch (1903); 'Recollections of a Humorist' (1907).

A BECKETT, Gilbert Abbott, English humorist: b. London, 9 Jan. 1811; d. Boulogne, 30 Aug. 1856. He began life as a lawyer and later became a police magistrate, but he became famous as a playwright, writing over 60 plays. In collaboration with Mark Lemon he dramatized 'The Chimes' and several other works by Dickens. He was the founder of Figaro London, which was later transformed into Punch, of whose original staff A'Beckett was a member. Among his most important works are: 'Comic History of England' (new ed. 1907); 'Comic History of Rome' (1852); 'Comic Blackstone' (1869).

ABEEL, David, American missionary: b. New Albany, Ind., 1844; d. Albany, N. Y., 4 Sept. 1846. He studied at Rutgers College and at the Theological Seminary of the Reformed Dutch Church and in 1827 was ordained to the ministry. For two years he was pastor of a church at Athens, N. Y., leaving there in 1829 for Canton, China, as a missionary. While in that country and in Java, Singapore, and Siam he did much good work in spreading Christianity. He returned to America in 1845, broken down in health. His published works include: 'The Claims of the World to the Gospel,' 'Residence in China,' and 'The Missionary Convention at Jerusalem.' An account of his life has been written by Rev. J. S. Williams.

ABEKEN, a-beck-en, Heinrich, German divine and diplomat: b. Berlin, 8 Aug. 1809; d. 1872. He was chaplain to the Prussian embassy in Rome in 1834, and in 1841 visited England to arrange for the establishment of a Protestant episcopate at Jerusalem. He was a member of the Prussian ministry for foreign affairs in 1848, and in 1853 became privy councillor of legation. Associated officially with Bismarck and with King William II during the campaigns of 1866 and 1870-71. Heinrich Abecken, ein schönes Leben in bewegter Zeit (Berlin 1898) published by his widow, has much historic value. See EM'S DISPATCH.

ABEL, second son of Adam and Eve, the first born being Cain. Abel became a shepherd, while Cain became an agriculturalist. At the end of the first season both went to the Deity, Abel bringing the firstlings of his flock while Cain offered the first fruits of his labor. Abel's offerings were accepted but Cain's ignored, which so aroused the jealousy of the latter that he killed his brother. It is not said in Genesis why Jehovah rejected the sacrifice of Cain and accepted that of Abel; but the Saviour, in the New Testament, speaks of "righteous Abel," from which it is concluded that there dwelt in him a spirit of righteousness, which was absent in his brother. The story is generally regarded as reflecting the ancient belief of the early nomadic tribes that the herding of animals is more pleasing to the Deity than the more settled life of the grower of food plants.

ABEL, Carl, German philologist: b. Berlin, 1837; d. 26 Nov. 1906. After finishing his studies at the universities of Berlin, Munich and Tübingen, he specialized in European and Oriental languages. He was, at various times, teacher of philosophical and comparative linguistics at the Humboldt Academy of Science at Berlin, lecturer at Oxford and linguistic assistant in the German Foreign Office. Among his many works, published in German, French and English, are: 'Linguistic Essays' (1880); 'Slavic and Latin' lectures on comparative lexicography, delivered at Oxford (1883); 'Russland und die Lage' (1888); 'Letters on International Relations before and during the War of 1870' (London 1871).

ABEL, John Jacob, American pharmacologist and physiological chemist: b. Cleveland, Ohio, 19 May 1857. He was graduated at the University of Michigan in 1883, took advanced work in physiology in the Johns Hopkins University 1883-84, studied chemistry and medicine at Leipzig, Strassburg, Heidelberg, Vienna, Berne, Würzburg and Berlin 1884-91, settling in New York in 1888. His devoted himself to the study of chemical composition of animal tissues and fluids and to the toxic and therapeutic action of various substances and made numerous discoveries in these
fields. He has held the chair of pharmacology in the Medical School of the Johns Hopkins University at Baltimore, since 1893.

ABEL. Sir Frederick Augustus, English chemist: b. London, 17 July 1827; d. there 6 Sept. 1902. As a specialist in explosives he was consulting chemist in the British War Department, from 1854 until 1888, improving considerably the processes of manufacture of gun cotton and blasting gelatine. In collaboration with James Dewar he invented cordite. His most important works are: 'Gun Cotton' (1884); 'Explosive Powders' (1872); 'Researches in Explosives' (1875); 'Electricity Applied to Explosive Purposes' (1884); 'Handbook of Chemistry' (with Colonel Blexam, 1854).

ABEL. Karl Friedrich, German musician and composer: b. Göthen, 1723; d. London, 20 June 1787. He was a pupil of Bach and for some years a member of the famous Dresden band of the Elector of Saxony, King of Poland. In 1758 he went to England in a state of great destitution and some years later was appointed chamber musician to Charlotte, the queen of George III. He and John Christian Bach, the son of his old teacher, directed the subscription concerts, known as the Bach–Abel Concerts, from 1765 until 1782. His works include many symphonies, string quartets, trios and piano sonatas.

ABEL. Niels Henrik, Norwegian mathematician: b. Findöe, 5 Aug. 1802; d. Arendal, 6 April 1829. Having finished his studies in the University of Christiania, in 1825, he spent two years in Paris and Berlin. In 1828 he was appointed instructor at the University and at the military school at Christiania. He demonstrated for the first time the impossibility of solving general equations of any degree higher than the fourth by the elementary processes of algebra. He was one of the originators of the theory of functions, an important class of transcendental functions being known as "Abelian," after him. The binomial theorem, proved by Newton and Euler, were more widely generalized by Abel, including the cases of irrational and imaginary exponents. The results of his labors, in two volumes, were published by the Norwegian government (Christiania 1839).

ABELARD, ãb-ã-lãr (Fr. Abélard, ãb-ã-lãr), Pierre, pé-ar, a distinguished philosopher, and lover of Héloïse. His real name was Pierre de Palais, the other being a nickname spelled in many other ways, but originally Bajolardus, *baco-licker,* from a school joke, which he changed to Habelardus, *baco-haver,* as a retort: b. 1079 near Nantes, in the little village of Pallet, the property of his father Berengar; d. Chalon-sur-Saône, 21 April 1142. Full of intellectual enthusiasm, he gave up his patrimony to his younger brothers to devote himself to a life of study. Those studies were very wide, though the usual inclusion of Greek and Hebrew is an error; but his chief passion was philosophy, and its great implement, the scholastic logic, in which he soon became the most eminent master of his age. Having learned all that Brittany could teach him, he went to Paris, the university of which attracted students from all parts of Europe. Guillaume de Champeaux, a follower of Anselm and an extreme Realist, was the most skilful disputant of his time, and Abelard, profiting by his instructions, was often victorious over his master in contests of wit and logical acumen. The friendship of Champeaux was soon succeeded by enmity; and Abelard, who had not yet completed his 22d year, removed to Melun, whither he was soon followed by a multitude of young men, attracted from Paris by his great reputation. Hostility still pursued him, but he left Melun for Corbeil, nearer the capital, where he was still more admired and persecuted. Soon after he ceased teaching to recruit his strength and after two years returned to Paris and found that his former teacher had removed to a monastery outside the city.

He again joined issue with him and gained so complete a triumph that he opened in Paris a school of rhetoric, the fame of which soon deprived all the others of their pupils. Shortly afterward he was appointed to his rival's chair in the cathedral school of Notre Dame, where he educated many distinguished scholars, among whom were the future Popes Celestine II and Urban IV, Peter of Lombardy, bishop of Paris, Berenger, bishop of Poitiers, Arnold of Brescia.

At this time there resided close to Notre Dame, a young lady, by name Héloïse, niece to the canon Fulbert, then of the age of 17, and remarkable for her beauty, and varied accomplishments. Abelard became inspired with such violent love for Héloïse as to forget his duty, his lectures, and his fame. Héloïse was no less susceptible. Under the pretext of finishing her education he obtained Fulbert's permission to visit her, and finally became a resident in his house. His conduct in abusing the confidence which had been placed in him opened the eyes of Fulbert. He separated the lovers, but too late. Abelard fled with her to Brittany, where she was delivered of a son, who died early. Abelard now resolved to marry her secretly. Fulbert gave his consent, the marriage was performed, and in order to keep it secret Héloïse remained with her uncle, while Abelard retained his former lodgings and continued his lectures. Abelard, however, carried her off a second time and placed her in the convent of Argenteuil.

Fulbert erroneously believed it was intended to force her to take the veil and under the influence of rage subjected Abelard to mutilation. He became, in consequence, a monk in the abbey of St. Denis, and Héloïse took the veil at St. Argenteuil. After time had somewhat moderated his grief he resumed teaching. At the Council of Soissons (1121), no defense being permitted him, his "Essay on the Trinity" was declared heretical, and he was condemned to burn it with his own hands. Continued persecutions obliged him at last to leave the abbey of St. Denis and to retire to a place near Nogent-sur-Seine, where he built a rude hut in which he determined to live a hermit's life. Even here, however, students flocked to him, and they built him an oratory, which he dedicated to the Holy Ghost and hence called Paraclete. Being subsequently appointed abbot of St. Gildas de Ruys, in Brittany, he invited, from the sisterhood, on the dissolution of their monastery at Argenteuil, to reside at the above oratory, and received them there. He lived for some 10 years at St. Gildas. Ultimately, however, he fled from it and lived for a time in other parts of Brittany.
Saint Bernard of Clairvaux, the leading opponent of the rationalistic school of Abelard, laid his doctrines before the Council of Sens in 1140, had them condemned by the Pope, and obtained an order for his imprisonment. Abelard appealed to the Pope, publishing his defense, and went to Rome. Passing through Cluny he visited Peter the Venerable, who was abbot there. This humane and enlightened divine effected a reconciliation between him and his enemies, but Abelard resolved to end his days in retirement. The Pope, satisfied with what he imposed on himself, together with the grief which never left his heart, gradually consumed his strength, and he died, a pattern of monastic discipline, in 1142, at the abbey of St. Marcel, near Châlons-sur-Saône. Héloïse begged his body and had him buried in the Paraclete, of which she was at that time the abbess, with the view of reposing in death by his side. Héloïse died there 16 May 1164. In 1800 the ashes of both were carried to the Museum of French Monuments at Paris, and in November 1817 they were deposited under the altar of the precincts of the church of Monamy. The small chapel, in the form of a beautiful marble monument, in which the figures of the ill-fated pair are seen reposing side by side, is now one of the most interesting objects in the Parisian cemetery of Père la Chaise.

Abelard was distinguished as a grammarian, orator, logician, poet, musician, philosopher, theologian, and mathematician. As a philosopher he founded an eclectic system commonly but erroneously termed Conceptualism, which lay midway between the prevalent Realism, represented in its most advanced form by William of Champeaux, and extreme Nominalism, represented in the teaching of his other master, Roscellin, and largely approached the Aristotelian philosophy. In ethics Abelard placed much emphasis on the subjective intention, which he held to determine the moral value as well as the moral character of man's action. Along this line his work is notable, owing to the fact that his successors did little in connection with morals, for they did not regard the rules of human conduct as within the field of philosophic discussion. His love and his misfortunes have secured his name from oblivion; and the man whom his century admired as a profound dialectician is now celebrated as the martyr of love. Abelard's works were all written in Latin. They were first printed at Paris in 1616, are to be found in Migne, 'Patrologia Latina' (Vol. CLXXVIII, Paris 1855). Other editions of special works are: 'Ouvrages inédits d'Abélard,' edited by Victor Cousin (ib., 1836); 'Opera' (2 vols., 1849–59); 'Sic et Non,' edited by E. L. T. Henke and G. L. Lindenkohler (Marburg 1851); 'Plancts Virginum Israel super filia Jepet Galadite,' edited by W. Meyer and W. Brandt (Munich 1886); 'Tractatus de Unitate et Trinitate,' discovered, edited, and published by R. Stölzle under the title, 'Abélards 1121 zu Soissons verurtheilter Tractatus, etc.' (Freiburg-im-Breisgau 1891); 'Hymnarii Paraclitensis,' edited by G. M. Drews (Paderborn 1890). The letters of Abelard and Héloïse have been often published in the original and translations. Pope's epistle 'Eléosa à Abelard' is founded upon them. There is a complete English translation by J. Berington, with the Latin text, 'The History of the Lives of Abelard and Héloïse' (Birmingham 1878), edited by H. Mills (London 1850). Consult also Wight, O. W., 'Lives and Letters of Abélard and Héloïse' (New York 1861); Morton, H., 'Love Letters of Abélard and Héloïse' (ib., 1891); Richardson, A. S., 'Abélard and Héloïse' (ib., 1894). Concerning C. de Bérenger Abelard and the Origin and Early History of Universities (New York 1893) Deutsch, S. M., 'Abalards Verurtheilung zu Sens, 1141, nach den Quellen kritisch dargestellt' (Berlin 1880); McCabe, J., 'Peter Abélard' (ib., 1893); Henderson, R. L., 'Illustrations of the History of Mediæval Thought' (London 1884); Rashdall, 'Universities in the Middle Ages' (Oxford 1895); Quiumat, C. de, 'L' vie Pierre Abélard' (Paris 1855), the standard biography of Abélard; ibid., 'Abèlard, a Description' (Paris 1877); Sauerland, H. V., 'Abalard und Héloïse' (Frankfort 1879); Thaner, F., 'Abalard und das canonische Recht' (Gratz 1900); Tiba, P., 'Deux conus au moyen âge, ou l'abbaye de Saint Gildas et le Paraclete au temps d'Abélard et d'Héloïse' (Paris 1851); Vercandard, E., 'Abélard, sa lutte avec Saint Bernad, sa doctrine, sa méthode' (Paris 1881); Wilken, C. A., 'Peter Abélard' (Bremen 1851).

ABELIN, Johann Philipp, a'bè-len, German historian: d. about 1637 at Strasbourg; was also known as John Lubwur Gottfried or Gorofredus under which name he wrote 'Theatra Europaeum,' a history of the world down to 1619, illustrated with Merian's beautiful copperplate engravings (21 vols., Frankfort 1633–1738); 'Historia Antipodum' (Frankfort 1635); and other works.

ABEN ESRA, a'bèn ̀ez-ra', or ibn Esra, properly Abraham ben Meir ibn Esra, Jewish scholar: b. Toledo, Spain, between 1093 and 1097; d. 23 Jan. 1167. While still a young man he traveled extensively and visited Italy, France, England and Egypt, but spent his later life in Rome. He was a profound master of the Hebrew, Arabic and Aramaic languages, as well as of mathematics, medicine, astronomy and philosophy, besides being a poet of no mean order. His most important work is his 'Commentaries on the Old Testament,' but he also wrote extensively on astronomy, some of his treatises on that subject being published in Latin. His 'Isaiah' has been translated into English (London 1873), while his 'Canticles' appear in 'Miscellany of Hebrew Literature' (Vol. II, London 1877).

ABENSBERG, a'bëns-bërk, Germany, town in Bavaria, situated on the Abens, a branch of the Danube, 18 miles southwest of Ratisbon, with a population of 2,300. Its warm mineral springs have made it a health resort to a limited extent. On 20 April 1809 it was the scene of a battle between the French under Napoleon and the Austrians, whereby the former gained such advantages as lead up to their final victory at Eckmühl.

ABEOKUTA, a'bë-ô-koo-ta, city in Egba-land, a division of Yoruba, on the Slave Coast, north of Lagos, with which it is connected by rail. The population is estimated at consider-
ABERAVON—ABERDARE

ably over a quarter of a million. It was founded some time in the third decade of last century by a combination of various local tribes as a mutual protection against the slavers. They raided this region extensively. The inhabitants are an industrious people, expert in various crafts, especially in building and textiles. A considerable trade is done between them and European traders, who exchange their goods for the products of the region, of which cotton is the most important.

ABERAVON, åber-åvôn, Wales, seaport town of Glamorganshire, near the mouth of the Avon on Swansea Bay, 11 miles by rail south-east of Swansea. It is the seat of the important metal industry of the Vale of Avon with iron, steel, tin-plate, copper melting and engineering works. Pop. 11,000.

ABERCARN, åber-kärn, England, a town of Monmouthshire, on the Great Western Ry. 10 miles northwest of Newport, with important coal and iron mines and allied manufactures. Pop. 2,500.

ABERCROMBIE, John, åber-krûm'bi, Scottish physician: b. Aberdeen, 10 Oct. 1780; d. 14 Nov. 1844. After graduating from the medical school in Edinburgh University, in 1803, he began a private practice in the city and soon was regarded as one of the leading consulting physicians of the country. His fame, however, rested mostly on his writings, and especially on his 'The Intellectual Powers and the Moral Feelings' (London 1833). Though possessed of no scientific value, his works were immensely popular on account of their readable qualities, their highly religious tone being especially acceptable to the people of his time. The estimation in which he was held by the nation may be judged by the many honors that were bestowed on him, among them being the degree of M.D. from Oxford, the rectorship of Marischal College, the vice-presidency of the Royal Society of Edinburgh and the office of physician in ordinary to the King for Scotland.

ABERCROMBIE, John William, American educator and congressman: b. Kelly's Creek, Ala., 17 May 1866. In 1888 he was graduated from Oxford and from Harvard College and, two years later, from the law school of the University of Alabama. He was appointed president of Ashland College after graduating from college and on completing his legal studies he became principal of Cullman Institute, both Alabama institutions. For two years, from 1890 until 1892, he was president of Bowdon College, Georgia, after which he was for six years superintendent of schools in Anniston, Ala. For a while, during 1897, he was president of the Southern Female Seminary, now the Anniston College for Young Ladies, after which he was, for four years, superintendent of education for his native State. In 1902 he became president of the University of Alabama. From 1896 to 1898 he was a member of the slaves in the Senate, where he was chairman of the committee on education. From 1900 to 1904 he was a director of the National Education Association and from 1905 to 1906 he was president of the Southern Educational Association. In 1912 he was elected to Congress.

ABERCROMBY, David, Scottish philosopher: d. about 1702. His chief work is entitled 'A Discourse of Wit' (1686). He also wrote many treatises and his work is said to antedate the so-called Scottish School of Philosophy.

ABERCROMBY, or ABERCROMBIE, James, British soldier: b. Glasshau, Scotland, 1706; d. 1781. He is especially known as the commander of the 15,000 British troops who attacked Ticonderoga, 8 July 1758, being repulsed with a loss of 2,000 men. He obtained his commission in the British Army as major in 1742 and in 1756 was posted to Canada as a colonel, and then a major-general. In September 1758, following his disastrous defeat at Ticonderoga, he was superseded in command by Sir Jeffery Amherst, wherupon he returned to England, became a member of Parliament and a firm supporter of the King's colonial policy. A full account of his career in America is given in Parkman's 'Montcalm and Wolfe' (Boston 1884).

ABERCROMBY, Sir Ralph, distinguished British soldier: b. Mensity, Scotland, October 1724; d. 28 March 1801. He was educated at Eton and in the bar by his father and studied from 1752 to 1755 at the University of Edinburgh and the University of Leipsic. His natural inclination, however, was toward a military career, so in 1758 a cornet's commission was procured for him in the 3rd Dragoon Guards, with which regiment he went to Germany and saw some active service, as well as gained his first experience. After peace was concluded he was stationed in Ireland for some years, but in 1762 he married and retired to private life. In 1793 he accompanied the Duke of York to Holland, in which unfortunate campaign he was one of the few to distinguish themselves. On his return to England he was appointed chief-in-command of an expedition to the West Indies, which he conducted with marked success, capturing Demerara, Grenada, Essequibo and Trinidad. Soon after he was made commander-in-chief of the British forces in Ireland, but so obviously was he not in sympathy with the Government's policy of repression in that country that he was transferred to Scotland. In 1799 he was appointed second in command to the Duke of York in the expedition to Holland, another ignominious campaign, where Abercromby was the only general who distinguished himself with distinction. On his return he was appointed to command the expedition to the Mediterranean. The fleet anchored in Aboukir Bay, 2 March 1801. On the 7th Abercromby reconnoitered the shore in person. The next day a landing was effected in spite of a heavy fire and within a few days the enemy was driven within his lines around Alexandria. On 21 March Menou attempted to surprise the British camp; a terrible battle followed, in which the British forces were completely victorious, but Abercromby had been mortally wounded by a musket ball which caused his death some days later. The gratitude of the nation for his services took the form of a peereage, granted to his widow and afterwards enjoyed by his son, with the title of Baron Abercromby.

ABERDARE, åber-där', Wales, a town of Glamorganshire, at the junction of the rivers Cynon and Dâr, and on the Great Western Railway, four miles southwest of Merthyr Tydfil. It is an important coal-mining centre.
with iron and tin-plate works, brickworks and breweries. Pop. 51,000.

**ABERDEEN**, 4th Earl of (George Hamilton Gordon), British statesman and premier: b. Edinburgh, 28 Jan. 1784; succeeded to title in 1801; d. London, 14 Dec. 1860. He was educated at Harrow and St. John's College, Cambridge. Shortly after returning from a Continental and Grecian tour, full of classical enthusiasm, he established the Athenian Society; whence Byron's sneer

"First in the oat-fed phalanx shall be seen
The traveled Dane, Athenian Aberdeen."  

He severely criticized Gell in the *Edinburgh Review* and wrote an introduction to Wilkins' translation of Vitruvius, published separately in 1822 as 'An Inquiry into the Principles of Beauty in Athenian Architecture.' In 1806 he entered Parliament as a Scottish representative peer, and was twice re-elected. In 1813 he was sent to Austria to bring it into the coalition against Napoleon, and in 1814 was a signatory of the Treaty of Paris; he won credit in diplomacy, and the same year was made Viscount Gordon in the British peerage. During 1815-28 he devoted himself to his estates. In 1828 he became chancellor of the Duchy of Lancaster, and a few months later foreign secretary in Wellington's Cabinet, and had the satisfaction of seeing Greek independence recognized. He warmly supported repeal of the Test and Corporation Acts, and Catholic Emancipation. Peel had him in both his Cabinets, 1834-35 as Colonial secretary, 1841-46 as foreign secretary. In 1846, during the struggle which rent the Established Church of Scotland in twain, he brought in a compromise bill which was denounced by both halves; and after the Disruption in 1843 again attempted conciliatory measures without result. On Peel's death in 1850 he became the leader of the free-trade Conservatives. The Derby administration being unable to stand, Lord Aberdeen in 1853 formed a coalition ministry. In it were such men as Russell, Palmerston and Gladstone. For a time it was very popular; unfortunately the Crimean War superseded. Aberdeen's readiness of action and reluctance to enter on hostilities, the result of a constitutional aversion to war, irritated the country, which was in one of its periodical anti-Russian frenzies, and bent on fighting. Moreover, the early portion of the war was shockingly mismanaged, as those of commercial countries always are; and on the appointment of a committee of inquiry, the ministry, which had uniformly resisted the motion, resigned, and Palmerston's succeeded it. This closed Aberdeen's dislike to "spirited foreign policies and interference with other countries, and his sympathy with the Holy Alliance, gave him the name of an enemy to liberty; but the above detail shows its injustice. Consult Gordon 'Earl of Aberdeen' (London 1893).

**ABERDEEN**, John Campbell Hamilton Gordon, 1st Marquis of: b. 3 Aug. 1847. He succeeded his brother, as 7th Earl of Aberdeen, in 1870; was lord-lieutenant of Ireland, 1886, 1905-15; and governor-general of Canada, 1893-98. He was created a Marquis in 1915. Isabel Maria, Marchioness of Aberdeen, wife of above, is the youngest daughter of Dudley Coutts Majoribanks, 1st Baron Tweedmouth and a prominent banker. She was b. Inverness-shire, Scotland, 1857. At an early age she became interested in social and political work, has been especially prominent in organizations which have as their object the raising of the status of women, and has held the office of president of the International Council of Women. Her literary works are: Through Canada with a Kodak; 'Our Lady of the Sunshine' (1910); 'Ireland's Crusade against Tuberculosis' (1908).

**ABERDEEN**, Miss, city and county-seat of Monroe County; on the Tombigbee River, and the Illinois Cent., the St. L. & San F., and the Mobile & O. railroads; 130 miles southeast of Memphis, Tenn. Its chief trade and manufacture are cotton and cotton products, lumber coming next. There are also oil and grist mills and manufactures of clothing, buttons, barreloves, wagon spokes, etc. The waterworks and electric light plant are owned by the city. Pop. (1910) 3,708; (1917) 4,500.

**ABERDEEN**, S. D., city and county-seat of Brown County, on the Chicago & N. W., Chicago, Milwaukee & St. Paul, the Minn. & St. L., and Great Northern railroads; 280 miles west of Minneapolis, 125 miles northeast of Pierre. It is the farming and lumber trade centre of a large section; manufactures boots and shoes, flour and feed, soap, plows, machinery, chemicals, soft and pressed brick, clothing, candy, and artesian well supplies, etc, and has 10 grain elevators, granite and marble works and creameries. Its factories are supplied with abundant water power furnished by artesian wells. It has Federal and municipal buildings, a court house, an opera house, five inside parks, national banks, several daily, weekly and monthly periodicals, a system of graded public schools and a State normal and industrial school, a Carnegie library. The value of taxable property is $13,669,100. Aberdeen was settled in 1880, inc. 1882 and was one of the first cities to adopt commission government. Pop. (1910) 10,753; (1917) 14,760.

**ABERDEEN**, town, in Chehalis County, at the head of Grays Harbor, on the Chehalis River, 50 miles west of Olympia, and on the Northern Pacific, the Chicago, Milwaukee and St. Paul, and other railroads. It is a lumber and dairy centre. The city has logging, lumber and shingle mills, cooperages, shipyards and fish-curing houses. There is steamship communication with the Pacific ports. The waterworks are the property of the city. Pop. (1910), 13,660; (1917) 18,300.

**ABERDEEN**, Scotland, the chief city and seaport in N. Scotland, fourth largest in all Scotland; lies in Aberdeenshire, of which it is the county town, between the mouths of the Dee and Don rivers, 130¼ miles northeast of Edinburgh by the N. British Railway, also on the Caledonian N. Scotland Railway. William the Lion gave it a charter in 1179; and its privileges were subsequently extended by Robert Bruce. The English burned it in 1336, but it was soon rebuilt; within the same parliamentary boundary is a small town a mile north near the Don mouth, formerly called Old Aberdeen, the seat of St. Machar's Cathedral (1357-1527),
now represented by the granite nave, which, as restored since 1869, is used as a parish church. King’s College and University, founded by Bishop Elphinstone in Old Aberdeen in 1494, and Marischal College and University founded by the Earl Marischal in New Aberdeen in 1593, were in 1858 united into one institution, the University of Aberdeen (q.v.). With Glasgow University it sends one member to Parliament. Marischal College was rebuilt in 1818 and additions were made in 1895 and 1914. King’s College is a stately fabric, its chapel, dating from 1500, is adorned with exquisite wood-carvings. The university is richly endowed by the State and private bequests and is a beneficiary of the Carnegie Trust Fund.

In the 17th century Aberdeen had become an important place, but it suffered much from both parties in the civil wars. It has a flourishing trade and thriving manufactures; and having been largely rebuilt of granite and extended since that industry, of Union Street in 1800, the *Granite City* now offers a handsome and regular aspect. Among the chief public edifices are the Municipal and County buildings, the post-office, Market Hall, Trades Hall, the Royal Infirmary, the lunatic asylum, the Grammar school, the girls’ school, the art school, the music hall, public library, College of Agriculture and Gordon’s College. The last has been much extended as a technical school, the foundationers being no longer resident; while the infirmary was reconstructed and modernized to celebrate the Queen’s Jubilee (1887). Of more than 60 places of worship those of most interest are built on the site of the ancient church of St. Nicholas, connected by a granite tower where a fine carillon of 37 bells was placed in 1887, and a Roman Catholic Cathedral built in 1859, with a spire 200 feet high. One may also notice the Market-cross (1686), the Wallace, Gordon Pasha, and three other statues, the Duthie public park of 47 acres, Victoria Park, Union Terrace, and the four bridges spanning the River Dee, one of which is said to date from 1320. It has a fine harbor and docks, good steamship and railway facilities and does a large import and export trade, being the last port for the White Sea and Baltic trades. The chief exports are woollens, linens, cotton yarns, paper, combs, granite (hewn and polished), cattle, grain, preserved provisions and fish.

Aberdeen is one of the most important fish-trading centres and has the largest granite polishing works in the kingdom, the art of granite polishing having been revived here in 1818 by Alexander McDonald. There are also several large paper works nearby. Shipbuilding was formerly a prominent industry, the Aberdeen clipper-boat ships being celebrated as fast sailors, but now is greatly contracted. The city sends two members to Parliament and is under the jurisdiction of a council with lord provost, bailies, treasurer and dean of guild. Pop. (1901) 153,503; (1911) 163,084.

Aberdeen, University of, Scotland, situated in the city of Aberdeen, and consisting of King’s and Marischal Colleges. The former was at one time known as St. Mary and was founded in 1494 by William Elphinstone, Bishop of Aberdeen. Marischal College was founded in 1593 by George Keith, Earl Marischal of Scotland. Until 1858 the two institutions were under separate government, when they were united into the University of Aberdeen by an act of Parliament. The students number from 1,200 to 1,300 and include both sexes. The faculties, five in number, covering arts, law, science, theology and medicine, number fully 30 professors and as many instructors. Endowments are both state and private, beside which the institution is also a beneficiary of the Carnegie Trust Fund. Its library has over 140,000 volumes.

Aberdeen Act (Brit.), introduced by the Earl of Aberdeen, and passed in 1845, to enforce the observance of a convention made with Brazil in 1826 to put down the slave trade. The act was repealed in April 1869.

Aberdeenshire, Scotland, the north-easternmost county, on the North Sea, drained by the rivers Don, Ythan and Dee. Aberdeen, the capital, Peterhead and Fraserburgh are the chief towns. Area, 1,971 square miles; pop., 312,200.

Abernethy, John, Irish dissenting clergyman and pioneer of toleration: b. Colesa, 19 Oct. 1680; d. 1740. The son of a Non-conformist minister, he graduated successively from Glasgow and Edinburgh universities, was licensed to preach before coming of age, urged to take an important charge in Antrim at 21, and two years later was ordained there. The work he did there for many years was of the most remarkable kind, in drafts on body, brain, soul and will; and he was eminent in all. In 1717 he was invited at once to Dublin and Belfast; the Synod assigned him to Dublin; he refused to leave Antrim and was considered a Church mutineer; a furious quarrel followed, developing into the fight in the Irish Presbyterian Church between ‘subscribers’ and ‘non-subscribers’ (Abernethy’s party), the latter being formally barred out in 1726. The real question at issue was of old, the liberalizing opinions which he disclaimed holding, but which have of course long since left his position far behind. In 1730 he was nevertheless called to Dublin. The next year came up the question of the Test Act, really involving the whole subject of religious tests in civil life; and Abernethy took a firm stand against ‘all laws that, upon account of mere differences of religious opinion and forms of worship, excluded men of integrity and ability from serving their country’, a century ahead of his time that a Roman Catholic could be such. His ‘Tracts’ were later collected, and did good service in the Catholic Emancipation fight of the next century. Abernethy was the bravest of the brave, not only in advocating unpopular truths to his own harm, but in resisting the highest dignitaries in the cause of right. Consult ‘Diary,’ 6 vols.; Duchi’s ‘Life,’ ‘History of Irish Presbyterian Church.’

Abernethy, John, English surgeon, grandson of the preceding: b. London, 3 April 1764; d. 20 April 1831. Educated at Wolver-
ABERRATION.—ABHEDANANDA

Hampton grammar school, he was apprenticed at 15 to Sir Charles Blicke, a leading London surgeon-assistant surgeon at St. Bartholomew's Hospital; he also attended the lectures of Pott, the chief surgeon there, of John Hunter, and the anatomical lectures at London Hospital of Sir William Blizzard, who early employed him as demonstrator. Pott resigning, Blicke took his place, and made Abernethy assistant surgeon in 1787. His lectures, illustrated by apt anecdotes, drew such crowds that a special building was erected, now the celebrated St. Bartholomew's School. In 1813 he was appointed surgeon to Christ's Hospital, in 1814 professor of anatomy and surgery to the College of Surgeons, and in 1815 full surgeon to St. Bartholomew's, a post which he resigned in 1829. Of his numerous medical works the most important is 'Surgeons Observations on the Constitutional Origin and Treatment of Local Diseases' (1806), which, from his frequent references to it, became known as 'My Book.' He was one of the first to prove that topical symptoms should be treated by general remedies, especially for the stomach and bowels; and he was a persuasive and influential lecturer, though over-dogmatic. He was the first to introduce the capital surgical improvement of tying the great arteries in operations for aneurism, etc. (Works, 5 vols., 1820). 'Memoirs' by Macilwain (1853), not highly esteemed.

ABERRATION. In physics, (1) that property of a lens or curved mirror in virtue of which it does not form a sharp, flat image devoid of false color fringes. Spherical aberration, or local distortion of the image due to the fact that the surface of the lens or mirror is spherical instead of having the theoretically best form. It is easy to grind a spherical surface, and more difficult to grind those in the practical manufacture of a high-grade lens the curvatures are carefully calculated, so that spherical surfaces may be used, while the spherical aberration is still kept within limits that are consistent with the use of the lens. (See Lens.) Chromatic aberration is the defect in virtue of which the focal length of the lens is not the same for all colors. A lens possessing chromatic aberration gives an image that is blurred with rainbow-like fringes; one that is devoid of chromatic aberration is said to be achromatic (see LIGHT). Mirrors, whether concave or convex, have no chromatic aberration.

(2) The slight displacement of the apparent position of a star or other celestial object, due to the fact that although the velocity of light is very great it is not infinite. In recent years much attention has been paid to aberration phenomena, because the observed amount of the displacement of a star indicates that the ether of space is stationary and that the earth passes through it like a fish through stagnant water; while direct experiments indicate, on the contrary, that the ether is dragged along with the earth to a considerable extent. See Ether; Relativity, Theory of.

ABERT, Herman Joseph, German authority on music: b. Stuttgart, 25 March 1871. His first musical education came from his father, who was director of the court opera, but later he studied in the Stuttgart conservatory. From 1890 to 1895 he was a student in the University of Tübingen, where he specialized in classical philology, thereby earning his degree of Ph.D. In 1897 he entered the Gewandhaus orchestra of Leipzig and for four years there devoted himself to research work into the history of music. In 1902 he was appointed lecturer of music at the University of Halle, where he was appointed professor in 1913. His works are 'Die Kirchenmusik und die Musikschule von Ethos in der griechischen Musik' (1899); a biography of Schumann in Reimann's series 'Berühmte Musiker' (1903); 'Die Musikschau des Mittelalters und ihre Grundlagen' (1905); 'Jommell als Opernkomponist' (1908).

ABERT, John James, American military engineer: b. Shepherdstown, Va., 17 Sept. 1788; d. 1863. He was graduated at West Point in 1811, was admitted to the bar; served in the War of 1812, becoming topographical engineer with the rank of major; was made chief and colonel of topographical engineers in 1838, and assistant in developing important canals and other works. His engineering reports are considered standard, and he was a founder of the National Institute of Science, since merged in the Smithsonian. He was retired in 1861 and was an important factor in the development of governmental engineerings in the earlier half of the 19th century.

ABERYSTWITH, 'ab'er-ist'with, Wales, a popular seaside resort of Cardiganshire, on Cardigan Bay 50 miles by rail northeast of Swansea. The pier and attractive sea front promenade and the buildings of the University College of Wales on Castle hill near the picturesque ruins of the 11th century Norman castle are prominent features. Pop. 8,500.

ABEYANCE, meaning expectancy; probably derived from the French bayer, to gape after. When real or personal properties are in expectation, or the intention of the law, they are said to be in abeyance, or not actually possessed. The word is often used in the Church of England, a living being known as 4in abeyance4 when it is left vacant owing to the unwillingness of the patron to declare himself in favor of any particular applicant for the office.

AB'GAR, Kings of Edessa, northern Meso- potamia, chiefly remembered from the 3d century account by Eusebius Pamphilus of one of them, Ouchama—"the black," probably Abgar V, who, suffering from leprosy, wrote a letter to Jesus asking him to come to Mesopotamia to heal him. Eusebius states that Jesus wrote a letter in reply that he was unable to make the journey, but that after his ascension he would send a disciple. Eusebius says that he both saw and transcribed his account from the original letters at Edessa and that Judas, son of Thaddeus, one of the 70 disciples was sent, A.D. 29. Moses of Chorene further states that Jesus sent his portrait to Abgar. Portraits now exhibited both at Rome and Genoa are claimed to be this original portrait, known as 'The Holy Face of Edessa.'

ABHEDANANDA, Swâmi, āb'-ha-da’nandâ, Hindu author and lecturer: b. Calcutta, India, 21 Nov. 1866. He was graduated from the University of Calcutta and afterward became a disciple of Ramkrishna Paramahansa and a member of the Order of the Sâstras and a very ancient priesthood. He came to this country in 1897 to lecture on the Vedanta philosophy, organizing and becoming head of
the Vedanta Society in New York city. He has lectured extensively before educational institutions and societies throughout the United States and is considered the best authority on Monistic Vedanta. His chief works are: 'Reincarnation' (1899); 'Spiritual Unfoldment' (1902); 'Philosophy of Work' (1902); 'Health, Wisdom, and Power' (1903); 'Divine Heritage of Man' (1903); 'Self-Knowledge' (1905); 'India and Her People' (1906); 'Human Affection and Divine Love' (1911); 'Great Saviours of the World' (1911).

ABHORRERS, a term applied in English history by the Puritans, their opponents, to those Tories who expressed abhorrence of the petitions to Charles II in 1679 to reassemble Parliament, and upheld him in his autocratic efforts to control public opinion.

ABIAHAR, high priest of the Jews, son of Abimelech who was killed by Saul's command because he had assisted David. Abiahar also became one of David's most loyal adherents and supported him during the rebellion of Absalom. Solomon cast him out of the priesthood when he supported Adonijah and brought him to Athaliah.

ABIB, first month of the Jewish ecclesiastical year and the seventh of the civil year, the month in which the Passover is celebrated. This month is now called Nisan, a name which was adopted during the Babylonian period of the history of the Jewish people and as such it is now known in the official calendar of the Jewish Church.

ABICH, Wilhelm Herman, German mineralogist and naturalist: b. Berlin, 11 Dec. 1806; d. Graz, 2 July 1886. After completing a course of study in the natural sciences at the University of Berlin, he traveled in Italy and Sicily. In 1842 he was appointed to the chair of mineralogy in the university at Dorpat, and in 1853 was elected a member of the Academy of Sciences in St. Petersburg, for whom he wrote exhaustive accounts of the explorations with which he had made in the Caucasus, Russian Armenia and northern Persia. He also published several books descriptive of the minerals found in the different countries where he had traveled, the most important of which are: 'Erlauterungen über die mineralischen Erscheinungen, beobachtet am Vesuv und Acta 1833 und 1834' (1837); 'Ueber die Natur und den Zusammenhang der vulkanischen Bildungen' (1841); 'Ueber die geologische Natur des armenischen Hochlandes' (1843); 'Ueber die Natronseen auf der Araxesenge' (1846-49); 'Vergleichende geologische Grundzüge der kaukas-armenischen und nordpersischen Gebirge' (1858); 'Sur la Structure et la Geologie de Kabasthan' (1862).

ABIGAI or ABIGAL, wife of King David, but previously the wife of Nahash. She offered food to David while he was fleeing from Saul, after her husband had refused to do so. When Nahash died, some 10 days later, David took her to wife. During a foray of the Ammonites to Ziklag, Abigail was carried off, but David recovered her. She bore him a son, Chileab, or Daniel. Another Abigail was daughter of Nahash, sister of Zemiam, Joab's mother, wife of Ithra, the Ishmaelite, mother of Amasa. The name is also employed as a general name for waiting maids.

ABIJAH, or A比亚, also Abijam, the name of nine different persons mentioned in the Old Testament. (1) The second King of Judah, son and successor of Rehoboam. He was presumably a great-grandson of David on his mother's side, for she is described as a daughter of Absalom, though there is some confusion regarding his father and son in the text. In the books of Kings and Chronicles she is variously given as Maacah, daughter of Abishalom, and Micaiah, daughter of Uriel of Gibeah. It may be noted that Maacah was also the name of Asa's mother. All we can gather is that Abijah reigned three years, that he walked in all the sins of his fathers, and was at war with the King of Israel, Jero- boam. (2) The second son of Samuel bore the name of Abijah or Abiah, likewise (3) a young son of Jeroboam I, while another Abijah was one of the "heads of fathers' houses" of the sons of Eleazar, eponymist of the 8th course of priests, to which Zacharias, the father of John the Baptist, belonged. In the lists of priests the name Abijah occurs in Nehemiah x and xii; in 1 Chron. it appears as son of Hezon, eldest son of Perez; a son of Becher, son of Benjamin; and the mother of Hezekiah, also called Abi.

ABILDGAARD, a·bil-górd, Nikolai Abra-ham, Danish painter: b. Copenhagen, 4 Sept. 1744; d. Frederiksdal, 4 June 1808. He studied for some time at the academy in Copenhagen, but in 1772 went to Rome to study under the masters. After his return he was appointed to a professorship at the academy in 1786, and in 1789 was elected a director. The greater number of his pictures display the historical nature and he had much to do with the founding of the Danish school of historical painting. A series of 10 pictures in the castle of Christiansborg, which burned in 1794, and scenes from Shakespeare and Ossian were his most important works.

ABILENE, ab·i-lé·n, Kan., city, county-seat of Dickinson County 163 miles west of Kansas City, on the Smoky Hill River and Union Pacific, Chicago, R. I. & P. and Atchison, T. S. F., railroads. For many years it has been one of the great agricultural market centres of the State, the focus of a large farm loan business, and the sales-ground and shipping point for large droves of cattle that are annually brought from Texas. It has also large manufacturing interests, including several flour-mills and creameries, as well as manufacturers of iron bridges, carriages, etc. Mineral water from sand springs four miles distant is bottled for export. These springs also supply the water works which are owned by the city. There are four banks, with a combined capital of $175,000; one high school and three ward schools, many fine private residences, a city hall, court house, Government building and Carnegie library. The value of taxable property is $4,718,628. Abilene was settled in 1856, incorporated in 1869, the original charter remaining in force until 1911 when the commission form of government was adopted. Pop. (1910) 4,118; (1917) 5,000.

ABILENE, Tex., city and county-seat of Taylor county 160 miles southwest of Fort Worth, on the Texas & P., Wichita Valley and Abilene & S. railroads. It is the centre
of a farming, cotton, fruit and stock-raising district and its chief interests lie in its cotton gins, oil mills, flouring mills and oil refineries. It has three national banks, with deposits amounting to about $3,000,000; four ward schools and one high school, and is the seat of Christian College (Baptist), Simmons College and the State Epileptic Colony. There are two pharmaceutical and one manufacturing college, the chief industries being the making of boots and shoes, shoe findings, lasts, textile machinery, window shades and dry plates. Strawberry growing is also practised and there are good nurseries. Abington has three banks with a combined capital of $3,924,866; commodious and well-kept elementary and high schools, for which an annual appropriation of $57,200 is made, a good fire department, municipal owned water works and a fine park with an arch to Civil War veterans. The value of taxable property is $3,763,645. The government is by town meeting. In 1915 the treasurer’s reports totaled $240,035. The Abolitionist movement was started and encouraged by meetings in Island Grove in this town. Pop. (1910) 5,455; (1915) 5,646. Consult Hobart, B., ‘History of the Town of Abington’ (Boston 1866).

ABIOGENESIS. See Biogenesis.

ABIPONE, a-bí-bë-pönë, an Indian tribe, formerly inhabiting the Gran Chaco region of Paraguay, the headwaters of the Río Grande in Bolivia and the Vermejo in Argentina. They were daring riders and fierce and formidable antagonists of the Spaniards, their weapons being the bow and the lance. In 1780 the tribe numbered about 5,000, but owing to a peculiar custom prevalent among them, whereby all but two children of a family were killed off, as well as to the constant wars with the Spaniards, this whole people has become extinct. Consult Dobrizhoffer, ‘An Account of the Abipones’ (London 1822); Church, Aborigines of South America (London 1912).

ABITIBI, a-bët-i-bë, Canadian river and lake, the latter being situated in latitude 48° 24’ N. at an elevation of 830 feet. Out of the lake flows the river of the same name, northward to James Bay, in Hudson Bay.

ABJURATION, the act of forsaying, abjuring or renouncing upon oath; a denial upon oath; a renunciation upon oath. Chiefly a law term and used in the following sense:

1. In the United States when an alien wishes to become a citizen he must declare, among other things, that he doth absolutely and entirely renounce and abjure all allegiance and fidelity which he owes to any foreign sovereign, etc., and especially by name the sovereign, etc., whereof he was before a citizen or subject.

2. An abjuration of the realm. During the Middle Ages the right of sanctuary was conceded to criminals. A person fleeing to a church or churchyard might permanently escape trial if, after confessing himself guilty before the coroner, he took an oath abjuring the kingdom: promising to embark, at an assigned port, for a foreign land, and never to return unless by the king’s permission; but this, however, he forfeited his goods and chattels.

3. Special. An abjuration or renunciation of all imagined allegiance to the Jacobite line of rulers, after the English nation had given its verdict in favor of William and Mary.

The oath of abjuration was fixed by 13 Wm. III c. 16. By the 21 & 22 Vict. c. 48, one form of oath was substituted for the oaths of
allegiance, supremacy and abjuration. For this form another was substituted by the Act 30 & 31 Vict. c. 75, § 5. This has in turn been superseded by the Promissory Oaths Act, 31 & 32 Vict. c. 72.

4. An abjuration, renunciation or retraction of real or imagined heresy, or false doctrine. Thus, for example, 25 Chas. II. 2 enacted that certain tenets of the Church of Rome were to be solemnly renounced.

ABKHASIA, ăb-kā'sē-a, or ABASIA, a district of European Russia, in the government of Kutais, Trans-Caucasia. It extends down the southern slopes of the Caucasus Mountains to the Black Sea. The country is extremely mountainous and heavily timbered, mostly with oak and walnut. The inhabitants, numbering 136,500 in 1917, are mostly Mingrelians and Abkhazians and are engaged mainly in agriculture and stock-rearing, as well as in the cutting of lumber. The district, which is about 2,500 square miles in area, has been successively under the dominion of the ancient Persians, the Georgians and the Turks, the latter establishing Islam among the people. After the Treaty of Adrianople, in 1829, the Russians began establishing themselves there, but they did not gain full possession until 1864. The chief town is Sukhum Kale.

ABLATIVE CASE, one of a number of cases comprising a system of modifications which nouns, pronouns and adjectives undergo in many languages, the number of cases being very different in different languages. The further back we go in the history of the Indo-European languages, the richer we find these modifications. Sanskrit has eight cases, Latin six and Greek five. The Latin cases, often used in regard to the English language, are: the Nominative, which names the subject; the Genitive, expressing the source whence something proceeds; the Dative, to which something is given to; the Accusative, the object toward which an action is directed; the Vocative, the person addressed, or called; and the Ablative, that from which something is taken, denoted in English by means of the prepositions in, with, by, from, etc.

ABLEGATE, papal envoy, or special commissioner, representing the papal court at Rome in conveying the hat and the red biretta to a newly appointed cardinal. Upon delivering the insignia of office his mission is completed. There are two ranks of ablegates: the apostolic and the pontifical, the former out-ranking the latter.

ABLUTION, or the ceremonial act of washing to symbolize purification from uncleanness, is a rite which has been observed by many races of people from the early Mosaic days down to our own time. Under the Mosiacal dispensation the act of ablation had four purposes: (1) To cleanse from the taint of an inferior position before initiation into a higher state, as when Aaron and his sons, having been chosen for the priesthood, were washed with water before they were invested with their robes of office; (2) to cleanse in order to fit one for special acts of religious ceremony, as when the priests were required, under the penalty of death, to wash both their hands and feet before approaching the altar; (3) to cleanse from defilement contracted by some particular circumstance which prevented one from enjoying the privileges of ordinary life, of which there were no less than 11 species of uncleanness recognized by the law; and (4) to cleanse or absolve oneself from the guilt of a particular act, as when, in expiation for an unknown murder, the thief washed his hands over the slaughtered heifer, saying, "Our hands have not shed this blood, neither have our eyes seen it" (Deut. xxii). This practice was also common both among the Greeks and Romans, and it is undoubtedly in accordance with this practice that Pilate called for water and washed his hands to signify that he held himself innocent of the blood of Jesus Christ (Matt. xxvii, 24).

Ablution by the priests before the performance of sacred ceremonies was common even among the heathen, while the Egyptian priests carried the practice to such an extent that they shaved their entire bodies every third day and then washed themselves in cold water twice every day and twice each Sabbath. All filth might even rest upon them. Such an act corresponds somewhat to the more simple wadu of the Mohammedans, a ceremonial washing which they are compelled to observe five times daily before the immediate prayers, and these do not begin to represent the formal acts of cleansing required by the Moslem law. For example, the ablution for positive defilement required by Moses has its counterpart in the Mohammedan ghoul, and yet again, under the Moslem law, the causes of such defilement are specified so minutely that they greatly exceed those of the ancient Jews. So strict was the law upon this point, however, that, when water could not be obtained, it was required that the purification should be made with something that might represent the water. In times of drought, therefore, or on occasions of sickness, the act of purification might be performed by rinsing, or rubbing the hands and face with dry sand. This form of cleansing was called fayemum.

The ceremony of ablation at communion was adopted by the early Christian Church, and has been retained both in the Eastern and Roman Catholic churches. In the Roman Catholic Church it has become, in the Latin term, denoting the two acts of cleansing performed during the mass: (1) When wine is poured into the chalice to disengage any particles which may be left in the vessel; and (2) when both wine and water are poured over the priest's fingers into the chalice. In the Greek Church the word "ablation" is applied to a ceremony performed seven days after baptism, when theunction of the chrism is formally washed off from those who have been baptized.

ABNAKI, ăb-nâ'kē, a federation of the Algonquin Indians, including the early missionaries, the Penobschts, Norridgewocks and other minor tribes, formerly occupying a territory now included in Maine and southern New Brunswick. As a result of King Philip's war they assisted the French colonists against the English, until the latter destroyed their principal town at Norridgewock and killed their missionary, Rasle, in 1724. Thereafter the greater portion of them removed to Saint Francis, Canada. Those who remained behind made peace terms with the English and
were allowed to retain a smaller portion of their old territory. Their descendants, now numbering only about 1,500, are found in the Malecites on the Saint John River, New Brunswick, the Passamaquoddies on the bay bearing their name, in Maine, the Penobscots, at Oldtown, Me., and the Abnakis at Saint Francis and Saint John, N. B.

**ABNER** son of Ner and cousin of Saul and commander of the latter's army. When the tribe of Judah recognized David after Saul's death, Abner prevailed upon the other tribes to recognize Saul's son, Ishbaal. Whereupon David sent his forces, under the command of Joab, into the field. Abner met them at the pool of Gibeon and attempted to terrify Joab's men by a ruse. He proposed that 12 champions from each army should engage in a competitive trial of strength. Abner's 12 men were Benjaminites and left-handed, so that they could conceal short swords at their right sides. By this trick the Judeans were killed. Whereupon the angry soldiers of Joab fell on Abner's men and drove them from the field, but being closely pursued by Asahel, he turned and slew him. Later Abner quarreled with Ishbaal and went over to David. But Joab had not forgotten the death of Asahel, his brother, and while Abner was peacefully dining with David he killed him. The murder caused general indignation, but Joab's high position as commander of the army saved him from punishment.

**ABNEY, Sir William de Wiveleslie**, English astronomer and physicist: b. Derby, 24 July 1844. He was graduated from the mineralogy school at Woolwich in 1861 and entered the Royal Engineers as a lieutenant, reaching the rank of captain within 10 years. From 1893 to 1895 he was president of the Royal Astronomical Society, after which, for two years, he was president of the Physical Society of London. In 1903 he became adviser to the Science and Art Department of the Board of Education. In the same year he became a member of the Advisory Council for Education to the War Office. His reputation rests largely on his researches in photography and spectroscopy, on which he has written many works, the most important of which are: *Instruction in Photography* (1870); *Treatise on Photography* (1875); *Color Vision, Color Measurement and Mixture* (1893); *The Pioneers of the Alps* (with C. D. Cunningham, 1888). In 1900 he was awarded a knighthood.

**ABNORMAL PSYCHOLOGY.** See **PSYCHOLOGY OF THE ABNORMAL.**

**ABO, å'boo**, former capital and the oldest city of Finland, now the chief town of the government of Abo-Björneborg. It is situated on the Aurajoki River and near the Gulf of Bothnia, 128 miles in a westerly direction from Helsingfors. It was founded by the Swedes in 1157 and remained the capital of Finland until 1819. It contains a fine sarcophagus which was erected in 1865 in memory of the Queen Catharine. Another monument was erected in 1512. In one of the suburbs is an old spring in which, according to traditions prevalent among the people, the Finns were first baptized into Christianity. It is in direct steamship communication with Stockholm, Copenhagen and Petrograd. Its harbor is too shallow to allow shipping of more than 10 feet draught, so large vessels dock at Bornholm, where some 700 ships touch annually. Many Russian warships have been built in the shipyards near the city, the great Crayton works there supplying the Russian fleet with torpedo boats. It has a number of tobacco factories, cotton mills, sugar refineries and other industrial plants. The School of Navigation and the School for Deaf-Mutes are notable among its public educational institutions, besides which there are a number of technical, normal, commercial and commercial college and a normal training school.

In 1910 the population was 49,691, the people being mixed Finns and Swedes, with the Finns predominating. In 1827 a large portion of the city was destroyed by a conflagration, including the University buildings. Since then the University has been removed to Helsingfors.

**ABOLITIONISTS**, the extreme section of the anti-slavery party in the United States, who advocated immediate sweeping away by the national government of Southern slavery, without regard to constituencies, vested interests, or political facts; this section and its nickname date from about 1835. Gradual abolition had been the desire of many of the best men even of the South; and till after the War of 1812 there was no prejudice against the trest expression of opinion on the subject. But the effects of Whitney's cotton-gin were now beginning to be felt in the slave system for the time enormously profitable; and the Missouri Compromise, with the insistence of the South thereafter that States should be admitted only in pairs, one slave and one free, showed that the time of apathy had gone by. The new zeal of the South in upholding, increasing and justifying the system was met by a new intensity of the North in opposing it, though for a long time confined to a small band of agitators. In 1833 the National Anti-Slavery Society was formed in Philadelphia; in 1831 William Lloyd Garrison had founded the *Liberator*, a weekly continued till 1866, filled from the first with denunciation not only of the system but of all connected with it; and a brilliant band of orators, philanthropists and growing political forces,—Wendell Phillips, Charles Sumner, Gerrit Smith and women like Lucretia Mott,—kept the public mind on the alert and furnished a monotonous moral to the course of political events which the people might not otherwise have drawn so readily. There were grades even among these; and the extremists denied the duty of obeying the United States Constitution, since it contained the clause warranting the Fugitive Slave Law, which was denounced as "a covenant with death and an agreement with hell." In practice they violated it systematically by assisting in the escape of runaway slaves, through the machinery known as the "Underground Railroad," concealing them from pursuit and forwarding them from stage to stage till they reached Canada. But in 1840 the abolitionists divided on the question of the formation of a political anti-slavery party, and the two wings remained active on separate lines to the end. It was largely due to the abolitionists that the Civil War, when it came, was regarded by the North chiefly as an anti-slavery conflict, and they looked upon the
Emancipation Proclamation as a vindication of this view. See Anti-Slavery Society; Liberty Party; Slavery; United States — Causes of the Civil War.

ABOMEN, a-bó-mén French West Africa, city of Dahomey, 70 miles inland, north of the port of Kotonu, with which it was connected by rail in 1905. The town is modern and has a good artesian water supply. Before its occupation November 1892 by the French, Abomey was the capital of the native kingdom of Dahomey, a typical African city surrounded by mud walls and protecting ditches, its royal palaces and market square the scene frequently of barbaric festivals attended by human sacrifices. Pop. 10,000.

ABORIGINAL ART. Strictly speaking, the art of the aborigines, that is, of the original inhabitants of any region; and hence by extension, any primitive or savage art unaffected by the contact of a foreign and superior culture. In this sense the term is used without regard to the question of whether the people producing the art are true aborigines or not. The art of the savage tribes of our own time is included under this designation, and is studied carefully for the light it throws on primitive conditions, industries and conceptions. Yet the art of modern savage tribes must be considered as representing rather an early-arrested development than a truly primitive culture. The oldest known products of human industry are the flint and bone implements and the paintings of the prehistoric cave-dwellers of Western Europe, which in many respects, especially in the fine arts of drawing and painting, far surpass the most advanced works of modern savages. These works date from an antiquity estimated at 25,000 to 30,000 years. While in delineation of animal life they are thus superior to modern savage fine art, they reveal nothing of proficiency in the industrial arts of pottery and weaving or basketry, which are prominent in modern savage art. Indeed, basketry and pottery and the applied arts of carving and stamping constitute the chief artistic activities of modern savages. Of these pottery represents the more advanced development culturally. Primitive metal-working is met with in aboriginal regions. The ancient art of Central America, Mexico, Bolivia and Peru is aboriginal only in the sense of belonging to the most ancient inhabitants of whom we have exact knowledge in those countries; it exhibits many evidences of a civilization many stages removed from primitive savagery.

The primitive origins of art have been much discussed by anthropologists and philosophers. The earliest human works known, found in caves in the provinces of Dordogne, France, and Santander, Spain, include artistically shaped flint tools, ivory bone handles, pictures engraved on bone, and paintings of animals on cave walls and roofs. But between this vividly realistic prehistoric art of 30 millennia ago and modern savage art there is a great gulf, in kind as well as time. Modern savage art is almost wholly decorative, sedentary and realistic. It is so largely fetishistic that some writers derive the primitive artistic instinct wholly from animism — the ascribing of animate magic powers to inanimate objects, and to representations of them and of animals. (See Animism.) Others think it is first awakened by the processes of basketry, weaving, string-lashing, etc., which produce certain regularly recurring motives or patterns. Others again find its root in personal adornment by tattooing, smearing with color, etc. Probably all three origins are in a measure correct. The decorative instinct once awakened develops more and more intricate combinations, and this development continues until arrested by the cultural limitations of the people or region. Besides these forms of decorative plastic art, certain "savage" cultures have developed the art-instant in other directions, such as primitive forms of poetry and drama, music (songs or chants), and the dance. In all these the idea of rhythmic form predominates over substance or content, and it is rhythmical repetition, with or without alternation, that characterizes also all savage ornament, which is never realistic except, perhaps, in certain Australian rock-pictures and bushmen's drawings. Savage decoration, especially that of New Zealand and some other Polynesian islands, displays a keen sense of decorative values in space-filling, and infinite patience of execution. See Art; Decorative Art.

Alfred D. F. Hamlin, Professor History of Architecture, Columbia University.

ABORIGINES (Lat. "from the origin"); the Greek name was autochthonoi), the earliest inhabitants of a country discoverable by civilized investigation. Their relation to the animal world as a whole comes under the head of Anthropology; to other races, under Ethnology; their culture and conditions, under Archaeology; of special countries, under their names, or those of particular tribes. Specifically, in Roman writers, a race traditionally said to have been driven by the Sabines from their homes in the mountains around Reate (Rieti), invaded Latium, subjugated the native Siculi and occupied the land, along with a tribe of Pelasgii, the two thenceforth taking the name of Latini. If true, these Aborigines would be of Oscan stock and form the non-Pelasgian element in the Romans.

ABORTION, the expulsion of a fetus from the uterus before it is capable of carrying on its own life. A variety of different terms have been applied to indicate variations in the character of this process; thus: accidental, when brought about by purely accidental means; artificial or induced, when caused for medical therapeutic reasons; criminal, when induced for purely selfish reasons; tubal, when rupture of the Fallopian tube occurs, discharging the fetus into the abdominal cavity, the pregnancy thus being extra-uterine.

The causes for this accident, apart from induced abortion, may be due to paternal, maternal or fetal defects. The proportion of abortions to full-time pregnancies is about 1 to 7 or 10. Of the paternal causes, alcoholism,
ABORTION IN PLANTS — ABRACADABRA

syphilis, old age or physical weakness may be cited. The most frequent causes, however, are of fetal and maternal causes. Death of the fetus is the most frequent fetal cause; maternal causes may be local or constitutional. Inflammation of the membranes of the uterus, tumors or new growths of the uterus, disease of the ovary, and inflammatory adhesions of the closely associated organs, act as local causes. Alcoholism, starvation, as in times of famines, syphilis, lead poisoning, coal-gas poisoning, acute diseases, as typhoid, pneumonia, and sudden severe shock, are the most common agents acting on the mother that bring about the death of the fetus and its subsequent expulsion. With certain women abortion, or miscarriage, happens very readily.

The symptoms are hemorrhage, discharge of the amniotic fluid and pain. The treatment is always medical. The dangers are mostly those of hemorrhage and infection.

In law, when abortion is produced with a malicious design, it becomes a misdemeanor, and the party causing it may be indicted and punished. When, in consequence of the means used to induce abortion, the death of the woman ensues the crime is designated as murder. In all cases of abortion the body of the offense must first be proven. The fact of the pregnancy, the use of the instruments and the administering of the drugs must be established beyond a doubt. The evidence of the woman upon whom the abortion was committed is admissible but her dying declarations are not admissible unless homicide is charged. A person who sells a drug or instrument, knowing that it is to be used for the purpose of causing a miscarriage, is guilty of a misdemeanor.

ABORTION IN PLANTS. This term is applied to the arrest of development which occasionally occurs in otherwise normal organs of plants, being sometimes contrasted with degeneracy, where we not only find an arrested development but a portion of form. Abortion may take the form of an inordinate abbreviation of the stem or flower-stalk as in the cauliflower, of irregular development of any part of the leaf, which is sometimes reduced to a mere midrib, of great reduction in the size of the flowers or for all the petals of a flower, of indefinite stature in the anther, of abnormal want of succulence in the fruit, or of many other failures of development. Abortion of the sexual organs and sexual cells is probably one of the most common causes for the sterility of many hybrids. Abortion is sometimes due to defective nutrition, sometimes to the intrinsic defect of the organization of the plant. For further information on this subject consult Masters, M. T., 'Vegetable Teratology' (London 1869), and Ward, H. N., 'Disease in Plants' (London 1901).

ABOU BEN ADHEM AND THE ANGEL, á·boo bén ád·hem, title of a poem of which Leigh Hunt was the author. The following line in it is frequently quoted:

"Write me as one who loves his fellow men."

ABOUKIR or ABUKIR, á·boo-ker, Egypt, a spacious bay with a small village of the same name, 14 miles northeast by rail of Alexandria. It is noted as the scene of the battle of the Nile, 1-2 Aug. 1798, when Nelson defeated the French fleet; of a battle on its shores 25 July 1799 when Napoleon defeated the Arabs; and of the battle of Alexandria 21 March 1801, when Sir Ralph Abercromby defeated theTurks.

ABOUT, á·boo, Edmond François, French journalist and novelist: b. Dieuze, 14 Feb. 1828; d. 17 Jan. 1885. In 1851 he was sent to the French school in Athens, Greece, after having completed his studies in Paris. After spending two years in Greece he returned to France. In 1856 he attempted to become an actor, without success. He was especially favored by the court of the Second Empire. After the fall of the Empire he ceased writing fiction and devoted himself to the editorship of Le XIXe Siècle. In 1884 he was elected to the Academy, but died before his formal admission. It is generally admitted that had he taken his talents more seriously he could have become a really great writer, but he was by nature flighty and somewhat shallow. Among his many works are: 'La Grèce contemporaine' (1854); 'Le roi des montagnes' (1856); 'Les mariages de Paris' (1856); 'Trente et quarante' (1858); 'L'homme à l'oreille cassée' (1861); 'Le nez du motaire' (1861); 'Madelon' (1863); 'L'inéfable' (1867); 'Le Roman d'un brave homme' (1880). Consult Wells, 'A Century of French Fiction.'

ABRA, á·bra, a province and a river in the north of Luzon, Philippine Islands. The province contains numerous deposits of placer gold, and the river gravel is auriferous. Other minerals, such as coal, copper, lead, zinc are believed to exist in paying quantities. For its head-hunting tribes, see IROBOTE; PHILIPPINES.

ABRABANEL. See Abravanel.

ABRACADABRA, a magic word supposed to be derived from Abrasac, used as an incantation against inflammation, fevers, or agues, according to the earlier Jewish authority Serenus Sammonicus, a Gnostic, and physician in the 2d century, to the Emperor Caracalla. In his work "De Medicina Praecipia," which was admired by the Emperors Septimius Severus and Alexander Severus, he prescribes that the word be written in the shape of a cone, as shown in the diagram herewith, folded in the form of a cross, worn on linen as an amulet for nine days, and then before sunrise thrown backward into a stream, flowing eastward. The formula was supposed to make the spirit of the disease gradually loosen its hold upon the patient.

The letters are usually arranged as follows:

| A | B | R | C | A | D | A | B | R | A |

-Thou shalt on paper write the spell divine,

A BRACADABRA called, in many a line:

Each under each in even order place,
But the last letter in each line efface.
As by degrees the elements shall take away, but fix the residue.
Till at the last one letter stands alone
And the whole dwindles to a tapering cone.
Tie this about the neck with flaxen string,
Mighty the good 'twill to the patient bring.
Its wondrous potency shall guard his head.
And drive disease and death far from his bed.
ABRAHAM or ABRAM, the progenitor of the Hebrews and the Arab Bedouin. After deriving his genealogy through Shem to his father Terah and his brothers Nahor and Haran (Gen. xi. xxxv) proceeds as follows,—each step in the pilgrimage being by express direction of Yahwe to his purpose of founding the Hebrew nation:—

After Haran's death Terah removes with his family from his native Ur of the Chaldees (Mugheir in southern Babylonia), north to Haran, where he dies. Abram then (at 75) takes his wife Sarai and his nephew Lot, Haran's son, and makes his way north by way of Damascus (stopping to build altars to Yahwe at Shechem and Bethel) to Canaan, where he receives the promise that he shall become the founder of a great nation, and all the families of the earth shall be blessed in him. Being a pastoral nomad, a drouth in Canaan forces him to seek food for his flocks in the fertile region of Egypt; where he passes off Sarai as his sister, in fear that her beauty will lead to his murder to possess her, and she is taken by Pharaoh, who, on discovering the deception, restores her, but orders Abram out of Egypt. Accompanied by Lot, he returns to a foundation settlement between Bethel and Ai. The clans of the two kinsmen quarrel over the limited pasturage, as usual with nomad tribes, and Abram proposes that each follow his own fortune. Lot, wishing to quit nomad life, chooses the fertile Jordan plain; Abram pitches his tent among the oak groves of Mamre, close to Hebron, and the previous promise of his posthumous glory is repeated and solemnly covenanted. Lot is captured in a raid of the Babylonian king, with his Syrian and other allies, against his revolted vassals of the Dead Sea and Jordan valleys, including the kings of Sodom and Gomorrah, who are overthrown; Abram sallies out to his rescue with a band of tribesmen, defeats the confederacy and chases them near to Damascus, and not only recovers his nephew but restores the above kings to their thrones, refusing any reward. The property of the childless Abraham is to descend to his trusted servant Eliezer, and Sarai suggests that he may have a child by having a child from a concubine, a common enough arrangement; accordingly he has Ishmael by Sarai's maid Hagar, at 86. Four years later it is revealed by Yahwe in person to Abraham that he shall have a legitimate son by Sarai, whose name is then forth to be Isaac (plain Isaac) and his own to be Abraham (father of peoples); the promise is afterward repeated by Yahwe and two angels, who visit Abram's tent in human form, the latter going on to destroy Sodom and Gomorrah and its wickedness, and the former staying behind to inform Abram of it. Abram's plea wins a promise of mercy contingent on 10 righteous men being found there, but they are not forthcoming, and only Lot and his family escape. Abram goes to Gerar (Negeb) in southern Palestine, repeats precisely the same performance with the nonagenarian Sarai as before, and the king Abimelech repeats the part of Pharaoh, with the same apologies and reproaches. Isaac is born, Sarah being 90, and Hagar being banished into the desert by Sarah's jealous fears, where Ishmael becomes ancestor of the Bedouin. Isaac is circumcised at eight days old, as a token of Yahwe's covenant with Abraham. Some time in Isaac's boyhood Abraham is commanded by Yahwe to make a burnt-offering of him, and proceeds to obey, but is spared the sacrifice by Yahwe, who accepts a stray ram instead and blesses him for his faith. Sarah dies in Hebron and is buried in the cave of Machpelah, which Abraham buys of Ephron the Hittite. He later marries Keturah, has six sons by her, dies at 175, and is buried beside Sarah. Isaac has previously married Rebekah, so that the succession is assured.

The Jewish stories of Abraham were by no means confined to this account in our canonical book; they had many others, associating him with Nimrod, etc., which are collected in the Talmud; and the Mohammedans invented or preserved many more. The critical view is that there was a real Abram or Abraham (the traditions existing in both forms), with his home at Hebron, probably a considerable man from the number and persistence of the legends about him; but that this is all we know. The names of his brothers and ancestry are not perserved but Arab clans, and their relations and movements represent what was handed down or believed concerning the North-Arab league that grew into the Hebrew nation, or its original elements. The path of the 'real Terah' from the southern Euphrates valley into Palestine and elsewhere is certainly a correct type of the actual course, as revealed to us by archaeology, of the Semitic tribes who century after century poured out of the Arabian deserts, into and up through western Mesopotamia, to plunder or share the rich Babylonian civilization and wealth, as the barbarians did that of the Roman empire; according to the resistance they found they stayed in the Moabite district, turned west to overrun the Jordan valley, or moved north into Syria. For the archaeological results consult the chapters on early times in various histories of the Hebrews, Kittel's, Stade's, Guthe's, etc.; Sayce's 'Patriarchal Palestine' and 'Early History of the Hebrews,' reverence in tone; Tompkin's 'Studies on the Times of Abraham.' Critical commentaries on Genesis are also serviceable. For the rabbinical legends, the sources — in German — are Beer on the life of Abraham, and Grimm on the 'Semites of the East,' which gives the Mohammedan legends likewise. Consult Commentaries on Genesis by Driver, Gunckel, Dillman, Delitzsch, Holzinger, Strack. Histories of the Hebrews by Stade, Kittel, Gunckel, Piepenbring. also Duhm, in Reise Biblique (1908); Gunckel, 'Abraham' (in Die Religion in Geschichte und Gegenwart (1908); Proksch, 'Das nordhebräische Sagenbuch' (1906); Tomkins, 'Studies on the Times of Abraham' (London 1878).

ABRAHAM, Ladislav, Polish educator and author: b. Sambor, Galicia, 10 Oct. 1860. He was educated at the universities of Cracow and Berlin; began his career in a solicitor's office in Cracow and in 1886 was appointed lecturer in canon law at the University of Cracow. Two years later he was appointed professor of canon law in the University of Lemberg, becoming dean of the law faculty in 1895 and rector of the university in 1900. He is director of the Polish scientific expedition of the Academy of Cracow at Rome and member of the Cracow Academy of Science and of
ABRAHAM A SANTA CLARA — ABRANTES

other scientific associations in Austria. He was nominated Austrian crown councillor, knight of the Order of the Iron Crown, and commander of the Papal Order of Saint Gregory. He is a contributor to the 'Catholic Encyclopedia' and has written numerous treatises and books on canon law and the ecclesiastical history of Poland and Russia. Mrs. Albertus' 'The Church in Poland up to the Twelfth Century' (Lemberg 1893); 'The Commencement of the Organization of the Roman Church in Russia' (ib. 1904); and 'Forms of Engagement and Marriage in Canon Law.'

ABRAHAM A SANTA CLARA, á-brǎ-hám á sánkˈtRa klaˈtRa, Austrian priest, author and evangelist: b. Kreineinsittten, 1644; d. Vienna, 1709. He joined the order of barefoot Augustinians in 1662, when he abandoned his real name of Ulrich Mejerie. He became the prior of its province, and in 1669 was appointed court preacher at Vienna. Distinguished by exuberant eloquence, in which loftiness and dignity of thought were mingled with grotesque humor, coarse language, puns, slang, and utter fearlessness in attacking the vices of courtiers and the follies of all classes of society, he attracted crowded congregations. His self-sacrifice during the plague of 1679 exhibited his qualities as a faithful and devoted priest. He was a prolific author, his didactic sermons, 'Praxis der Gerechtigkeit' (4 vols., Salzburg, 1686–95), being his best known work. His collected writings were published in 21 volumes (1835–54).

ABRAHAM IBN DAUD (DAVID) HALEVI, ibn 'dowd ha-laˈve, Jewish astronomer, historian and philosopher: b. Toledo, Spain, about 1100; d. according to report a martyr, 1180. He was the first to introduce to Judaism that phase of philosophy which is derived from Aristotelian sources, and to his 'Emunah Ramah — Sublime Faith,' Maimonides was largely indebted for many valuable suggestions. His chief historical work is 'Sel'ah ha-Kaballah — Book of Tradition,' translated into Latin by Générard (1510).

ABRAHAM, Plains of. See Plains of Abraham.

ABRAHAM THE JEW AND THE MERCHANT THEODORE, a tale which was popular in the Middle Ages, in which figure prominently the miracle-working powers of the Saviour in Constantinople. Theodore, the merchant, being sorely pressed by the need of money, accepts two loans from the Jewish money-lender, Abraham, his only security being the oath he takes before the statue. But difficulties continue to beset Theodore for some time, and when finally he is able to repay the loans, he finds himself away in a distant country. Unable to find any means of transmitting the money to Abraham, Theodore casts his money box out into the sea. The currents carry the box to Constantinople where it is recovered by Abraham. When Theodore returns, however, he denies that he has received it. Theodore prays before the statue in whose presence he took the oath, and the result is that Abraham is converted to Christianity.

ABRAHAMITES. (1) A 9th-century sect of Syrian deists, denying the divinity of Christ. (2) In modern use, the Bohemian deists of the later 18th century, who called themselves followers of Huss, but accepted no religious doctrine beyond the unity of God, and nothing of the Bible but the Lord's Prayer. They avowed this creed in 1782 on Joseph II's promise of toleration; but as they would join neither Jewish nor Christian forces, he expelled them from Bohemia the next year and sent them through Hungary, Transylvania and Slavonia. Many were martyred, others turned Catholic.

ABRAHAMS, Israel, English-Jewish author: b. London, 26 Nov. 1858. His early education was in Jews' College, London, after which he studied in the University of London. After serving for a short period as tutor at Jews' College, he was appointed reader in Talmudic and Rabbinic Literature in Cambridge University. In 1905 he became the president of the Jewish Historical Society of England and he was also the first president of the Union of Jewish Literary Societies. In 1907 he was made honorary president of the Theological Society of the University of Glasgow. From 1889 to 1908 he was editor of the 'Jewish Quarterly Review. His chief work in this field is 'History of Judaism' (1895); 'Jewish Life in the Middle Ages' (1896); 'Chapters on Jewish Literature' (1899); 'Maimonides' (1903); 'Festival Studies' (1905); 'A Short History of Jewish Literature' (1906); 'Rabbinic Aids to Exegesis' (1910); 'The Talmud and Other Papers' (1913); 'Annotated Hebrew Prayer Book' (1914); 'Jews' (in Hutchinson's 'History of the Nations,' 1915).

ABRAHAM'S BOSOM, an old Hebrew term, later adopted by the Christians as well, signifying the home of the blessed, symbolized in the art of Byzantium, in which the blessed are pictured as little children being taken into the bosom of Abraham.

ABRAM. See Abraham.

ABRAMS, Albert, American physician: b. San Francisco, Cal., 8 Dec. 1863. After taking his degree of M.D. at Heidelberg University, in 1882, he continued his post-graduate studies in Vienna, Berlin, London and Paris. In 1893 he was appointed professor of Anatomy in the Cooper Medical College, in which position he continued for five years. In 1904 he became president of the Emmanuel Poly clinic in San Francisco. He is now president of the American Society for Psycho-Physical Research. Among his important works are: 'Synopsis of Morbid Renal Secretions' (1892); 'Manual of Clinical Diagnosis' (1894); 'Consumption — Its Causes and Prevention' (1895); 'Scattered Leaves from a Physician's Diary' (1900); 'Diseases of the Heart' (1901); 'Nervous Breakdown' (1901); 'Hygiene, in a System of Physiologic Therapeutics' (1901); 'The Blues' (1904); 'Diseases of the Lungs' (1905); 'Self-Poisoning; Diagnostic Therapeutics' (1909); 'Spinal Therapeutics' (1909); 'Spondylotherapy' (1910).

ABRANTES, á-brǎnˈtēs, Portugal, a town of Santarem district, Estremadura; on the Tagus, and a junction on the Madrid-Lisbon Railway with the Guarda-Abrantes line, 70 miles northeast of Lisbon. It is a strategic fortified position, founded about 300 B.C., and named by the Romans, A unrantes. An active
river trade was carried on in olive oil, wine, grain and fruit. Abrantes was occupied by the French, 24 Nov. 1807, Marshall June the victor later receiving the title of Duke of Abrantes. Pop. 7,000.

ABRASIVES, or those substances used in grinding or polishing, include (1) mineral substances, such as grindstones, millstones and whetstones, which are used by simply shaping up the material found in nature; (2) mineral substances—occurs disseminated in the rocks or which must first be freed from impurities and are prepared for use by an initial granulation; (3) artificial abrasivants. The history of abrasives shows that in ancient times the first class was used, the artificial abrasives now so extensively employed being unknown until quite recently.

Grindstones are manufactured from a tough, gritty sandstone, found chiefly in Ohio, though Michigan, Colorado and West Virginia add to the output, and England, Scotland and Bavaria are also producers. The Ohio and Michigan limestones are quarried from the Berea grit (q.v.) of Mississippian age. The production of grindstones in the United States in 1915 amounted to $65,479. Millstones and Whetstones are far less used now than before the introduction of the roller process of making flour, for while the American production in 1880 amounted to $200,000 it fell in 1894 to $13,887. Since 1894 it has steadily increased till in 1912 it was $71,414. The 1915 output was valued at $53,480. This is owing to the increased demand for whetstones for grinding the coarser cereals, fertilizers, cement rock and various minerals. Millstones are finer grained and more compact than grindstones. They are usually made from sandstone or a quartz conglomerate. The whetstone (q.v.) from France is the best, but the stones from New York and Virginia meet most of the requirements of the trade. A few are made in Pennsylvania and North Carolina. There are whetstone deposits in Vermont, Ohio and Alabama which have not been worked of late years; also a newly discovered deposit in California of stone equal to the French. The New York stones come from the Shawangunk grit of Silurian age.

Oilstones, Whetstones and Scythestones are to a large extent American products. For nearly a century New Hampshire was the headquarters of the whetstone industry, but Arkansas has held the lead for some years. Whetstone rock is also found in Vermont, Ohio, Kentucky, Pennsylvania and Indiana. The best oilstones from New Hampshire are inferior to those of Garfield County, Ark., in which region there are extensive beds of a remarkably compact, white metamorphic quartz rock, called Newacuitite. Griswold in 1890 announced that this material is a sedimentary deposit of fine-grained quartz and not a chemically precipitated deposit as had been previously supposed. The quarries were largely worked for implements in prehistoric times and since 1840 they have yielded the finest oilstones known. These are sold under the names of "Washita" and "Arkansas" oilstones. The production of oilstones and whetstones in the United States during 1915 amounted to $115,175. The imports, chiefly of razor bones from Belgium and Germany, and of "Turkey" oilstones from Italy and France amounted to $14,247—about one-third the normal value. Ohio leads in the production of scythestones, New Hampshire, Vermont and Michigan contributing important shares.

Pumice (q.v.), a spongy lava, or a volcanic ash, is used in scouring powders and soaps. It comes chiefly from the Lipari Islands, but is also produced in Utah and Nebraska. The production of the United States in 1915 was valued at $63,185; the imported pumice at $65,691. Infusorial or diatomaceous earth (Kieselguhr) occurs in beds often miles in extent. It is formed of the siliceous shells of infusorians and diatoms, and is used in scouring soaps and polishing powders. The chief American localities are in Maryland, Virginia, New Hampshire and California. The United States production for 1915 was 4,593 tons, valued at $38,517; but these figures cover not only that used as abrasive, but also a much larger quantity used by sugar refiners and to insulate boilers, etc. Tripoli is a similar variety of opal, but formed from a siliceous limestone by the leaching out of the calcium carbonate. It is used as an abrasive is as a polishing powder for metals, etc., but it is also extensively manufactured into filters, for which it is admirably adapted. Extensive deposits are worked at Seneca, Mo., and in Illinois, but the chief supply is imported from Tripoli. The United States production for 1915 was 30,711 tons, valued at $572,504—four times the output in 1911. The 1915 importation of tripoli was valued at $27,333. Crystaline quartz, of which 112,575 tons were mined in Connecticut and Pennsylvania in 1915, is used as a wood finisher, in the manufacture of sandpaper, in the sawing of marble, for cleaning castings, etc. Garnet (q.v.) occurs in many of the crystalline rocks, especially in pegmatite and mica schist. Many varieties are recognized by the mineralogist; but the value of garnet as an abrasive, aside from its great hardness, is dependent not on its composition, but on its structure. If this is distinctly lamellar, the material will continuously present the sharp edges which are so essential to a good abrasive. Garnet which lacks this lamellar structure is of comparatively little efficiency for grinding and smoothing. Garnet is of little value for grading metals but is of great utility in working certain materials. Its high melting point prevents its bonding with refractory materials. Garnet-paper is much superior to sandpaper and is extensively used in woodworking and finishing the soles and heels of shoes. The most important localities are in New York and New Hampshire. The output for 1915 amounted to 4,301 tons, valued at $139,584. Corundum (q.v.), being the hardest mineral known, except the diamond, ranks next to it among the natural abrasives. It occurs in enormous quantities in Ontario, which since 1901 has been the leading producer. It was at one time extensively mined in Montana, North Carolina and Georgia which furnished nearly all of the domestic supply, but since 1906 no corundum has been produced in the United States. Small quantities of corundum are produced in India which go chiefly to the English market. The chief deposits of corundum are of magmatic segregation origin, having solidified from a fluid state during the crystallization of very basic igneous rocks. The value
of any sample of corundum depends largely upon its fracture, the crystals which break smooth are of very high quality. *Erdkristall* (q.v.) is a natural mixture of corundum with magnetite or hematite. It has been largely mined at Chester, Mass., and Peekskill, N. Y., but the Massachusetts mines have not been operated of late years. The chief supply, however, comes from the Island of Naxos, Greece, and from Asia Minor. The material is brought to this country as ballast and owing to the low prices at which it is marketed, the sale for the American mineral is much reduced. The United States production for 1915 was 3,063 tons valued at $31,131 — five times the usual output. The Canadian output of corundum in 1915 was $37,798 — about one-sixth the usual production. The importation of emery and corundum was valued at $271,649 — about 55 per cent of the average. *Diamond* (q.v.), owing to its far greater hardness, brings many times the price per carat which any other abrasive brings per pound. The black amorphous *carbonado* found in Brazil is much harder than the crystalized diamond, but it is almost exclusively used for diamond drills, while the dust of the South African *boring* is the material commonly employed as an abrasive in the cutting of diamonds and other precious stones. In 1915 the importation was valued at $75,944. A large division of natural grinding material in the form of quartz pebbles may properly be included under abrasives. Formerly imported altogether, from Denmark, France, Sweden, Labrador and Newfoundland, the war cut off the supply and led to the development of American deposits, chiefly in Nevada, though in many instances hardened steel balls have been found an effective substitute.

Artificial abrasives belong to two principal groups: (1) The aluminous group, comprising alundum and aloxite; and (2) the silicon-carbide group, comprising carborundum and crystolon. Alundum is crystalline aluminum oxide and is the most efficient of all abrasives for steel. The possibility of determining the degree of toughness in the manufacture of this substance leads to a line of special alundum abrasives made purposely for grinding special hardened and toughened steels. Aloxite is of the same general composition as alundum, but with different qualities and adaptations. Its specific use is on malleable iron. Carbide of silicon, called in the United States *carborundum,* is the hardest of all abrasives but lacks the toughness of alundum. It is so hard that carborundum wheels have to be trued up with a diamond; no other known substance will cut them. Carborundum is the most effective abrasive for cast iron, chilled iron and brass. Crystolon is a very similar carbide, useful especially on copper, zinc, gold, tin and aluminum. Electride is still newer abrasive, with a composition between alundum and carborundum. It is extremely tough, and amorphous in structure, breaking with a sharp fracture, which is durable under heavy work. The production of artificial abrasives in the United States in 1915 amounted to 37,684,000 pounds, valued at $2,248,778. Abrasives are graded by the size of their fragments. After being crushed, the material is sifted through a series of screens, the number of the smallest screen through which the fragments will pass being given them. For mechanical use abrasives are commonly mixed with a bonding material and formed into wheels. The United uses four varieties — vitrified, silicate, elastic and hard rubber. The first is made of fused clays, and can be produced of varying degrees of hardness. This bond does not completely envelop the grains of the abrasive, and thus affords a larger clearance than the other bonds. However, it is entirely without elasticity. The silicate bond is of clay fluxed with sodium silicate at a low temperature. It is affected by dampness and cannot be made into a thin wheel. The elastic bond is made of shellac and other resins. It has a high degree of elasticity and can be formed into very thin wheels. The rubber bond is of vulcanite, also very elastic. By adapting the bond and the abrasive to the work to be done, almost any desired result may be attained. Another thing to be considered is the speed at which the wheel is to be run. With the artificial abrasives a piece of work may be done in a fraction of the time required by the best emery. It is common practice for wheel manufacturers to cut 1,000,000 cutting strokes per minute, and twice that speed is not unusual. On special work the speed is sometimes equal to 2,000,000,000 cuts per minute. Crushed steel is extensively used in sawing, grinding, rubbing and polishing granite, marble and other stone. The finer grades of this abrasive, known as *steel emery* and *steel rouge,* are used for working glass. See special articles under the names of the different abrasives for further particulars. Consult Hardy, A. E., *Roughing and the Emery Industry* (London 1912); *Grits and Grinds* (monthly, Worcester Mass.); United States Geological Survey, *Mineral Resources of the United States* (chapter *Abrasives* annually); Ries, H., *Economic Geography* (4th ed., New York 1916).

**ABRAVANEL, á-brává·nél, Isaac ben Jehuda.** Jewish statesman and Bible commentator: b. Lisbon, 1437; d. Venice, 1508. He was the son of the Portuguese treasurer, Dom Judah, and came of an old and distinguished family which traces its origin from King David. He became treasurer to King Ferreira of Portugal; was banished on the King's death; retrieved his fortunes in Spain where he gained royal favor; was ruined again on the decree of expulsion banishing all Jews in 1492; went to Naples where he again achieved high rank; lost all, his possessions when the French took the city in 1495; and finally settled in Venice where he negotiated a commercial treaty between Portugal and the Venetian Republic. His fame rests on his sound scholarship and exegetical writings, illuminated by a clear and keen mind. The chief of these are *Sources of Salvation* (1496); *Salvation of His Anointed* (1497); *Proclaiming Salvation* (1498), which attracted the attention of eminent Christian writers, among them the Frenchman Buxtorf, Judaeus and Carpio, who condensed and translated them, and introduced them to the world of Christian scholarship.

**ABRA'XAS, or ABRA'XAX,** a word used by the Basilidians, a sect of Christians who existed until the 4th century, to designate the many emanations from the Supreme Power. When the word is written in Greek letters, these
ABRUZZI — ABSCESS

letters, computed numerically, have the value of 365, the mystic number so often inscribed on the stones in the Gnostic schools of the Bassanesi, the elevation being 9,584 feet above sea level. Cattle and swine form an important part of the produce, but in the smaller valleys nestling in among the mountain forests there are many olive orchards, vineyards and grain fields. Here too, the silk worm is reared and silk is one of the important products. The population is about 1,500,000.

ABSAŁOM, third son of King David (2 Sam. xiii–xv, xviii; 1 Chron. iii, 2). He revenged his brother Amnon’s outrage of his sister Tamar by killing him, and was banished from his father’s court for five years. The murderous retribution probably led him to dethrone his father, which took David unaware and forced him to fly east of the Jordan with Absalom. In the fighting, while Absalom gained possession of Jerusalem and the court, with this enormous advantage he might easily have maintained his seat; but according to the story, he was betrayed into deserting David, ingratiated himself with Absalom, and by cunning and flattery persuaded him to a policy of delay, while Ahithophel urged him to strike quick and hard, the obviously sensible course. David with this breathing-space collected an army, and his veteran captain Joab, with the superior qualities of a soldier, routed Absalom’s forces in the Defile of Ephraim; and on report that Absalom had been caught by his long hair in the branches he was riding under, and refusal of the messenger to lay hands on the king’s son, Joab himself dispatched him with his spear (about 980 B.C.). David could not have suffered the rebel to live; but the statement that he held a grudge against Joab for killing him and ordered public mourning for his son has nothing intrinsically improbable in it. Absalom is represented as a very handsome and charming prince and the chronicler plainly has much sympathy with him.

ABSALON, ābˈsā-lon, Danish prelate, statesman and military commander: b. 1128; d. 1201; the great historic figure who contributed most to Denmark’s rise as an independent nation. He was educated at the University of Paris; became bishop of Præstø in 1158 and chief counsellor to his boyhood friend, King Valdemar 1. In 1168 he rooted out piracy in the Baltic and idolatry in Rügen. In 1184 he destroyed the Pomeranian fleet which had attacked Rügen. He had previously been appointed archbishop of Lund in 1178.

ABSCESS, a local focus of infection by some bacteria which has progressed to the point of formation of pus, which is a collection of broken-down blood cells and of the tissue in which the abscess may occur. As a rule the infecting agent is brought to the tissues by the blood or lymph stream. Abscesses may occur in any tissue or organ. The usual micro-organisms of acute abscesses are various streptococci and staphylococci. Chronic or cold abscesses are chiefly tuberculous in origin. Abscesses are always best
treated surgically. The old-fashioned way of letting an abscess "come to a head" is more dangerous, time-consuming and usually disfiguring. Dispensing an abscess is a delusion.

ABSCHATZ, āps'ḥats, Hans Assmann, Freiherr von, poet: b. Würzbiz, 4 Feb. 1646; d. ibid., 22 April 1699. A lyric poet of his day, whose poems were in great part called forth by his indignation at the predatory wars of the French. They are simple and without bombast, and show sincere feeling, pure sentiment and a sturdy, patriotic mind entirely free from class prejudices. His 'Poems and Translations' (1704) include a German translation of Guarini's 'Pastor Fido.' Selections from them were edited by W. Müller in 1824.

ABSECON, or ABSECM, a bay and an inlet on the coast of New Jersey, northeast of Atlantic City.

ABSCLUDING, the going clandestinely or secretly out of the jurisdiction of the courts, or lying concealed, in order to avoid their process. A person living in a State only transiently or has come into it without any intention of settling therein cannot be treated as an absconding debtor (15 Johns. N. Y. 196), nor can one who openly changes his residence (3 Yer. Tenn. 414). It is not necessary that the debtor should actually leave the State.

ABSENTEEISM, a term applied to the owners of estates in a country who habitually absent themselves from that country and spend the income of their estates in it in another; in current use, referring almost wholly to the Irish nobility whose fixed residence is outside of Ireland. Much of the poverty and many of the disturbances in Ireland have been charged directly to it, and the Irish people have protested against it since 1380. While an Irish Parliament existed, there seemed hope for its gradual dwindling, careers being opened for ambitious men in Ireland; but with its abolition the evil is almost incurable. Hungary suffered heavily from the same cause — its aristocracy looking on their native country's language and life as badges of barbarism, priding themselves on being Germans and living in Vienna — till the great national movement set going by Szchenyi and his companions early in the 19th century. Despite the defense of the system by some economists and the good theoretical arguments that may be made for it, in practice its economic, social, personal and political mischiefs are obvious. Not only is the absent landowner and property-owner, collecting his rents by agents, inaccessible to complaints, representations, appeals for help in upbuilding local institutions, etc., and unwilling to acknowledge rackrenting he does not personally see to be such (even a generous and kindly agent dares not be as lenient as he would, in fear of his master); but he should be the leader of his section of careers, furnishing it employment, having his own success depend on its prosperity, and the active defender of its interests and rights and susceptibilities. The estate of an absentee owner, in fact, is essentially like a colony in the old conception — a mine to exploit for outsiders who cared nothing for it; but the colonists of a distant province have a collective power much greater than that of the tenants of an absent landlord. Furthermore, it makes social co-operation for general needs almost impossible. The literature on the subject is nearly coincident with that of the Irish question as a whole; and the debates in Hansard's 'Parliamentary Reports' abound in its discussion.

AB'SIMARUS, a soldier of fortune who raised, against the Byzantine emperor Leon-tius, an army which proclaimed him emperor; A.D. 698. He slit Leontius' ears and nose and threw him into a convent. He was taken in 705 by Justinian II, who, after having used him as a footstool at the hippodrome, ordered him to be beheaded.

ABSINTHE, āb'sōnθ, a drink prepared from alcohol, the active principle of Artemisia absinthium, and other aromatics, notably the volatile oil of anise. Its frequent and protracted use leads to a diseased condition known as absinthism which is a product of chronic alcoholism to which the effects of the volatile oil of Absinthium has had a bearing. Other volatile oils probably contribute somewhat to the general result. Absinthism, in the main, is characterized by a greater amount of affetion of the brain than simple alcoholism. The action of the volatile oils is to heighten cerebral excitement, and absinthis-mania is a frequent result of this form of intoxication. On 15 Jan. 1915 its sale was forbidden in France during the duration of the Great War. See WORMWOOD.

ABSiT ÖMEN (Lat. may the omen be absent); God forbid!

ABSOLOM AND ACHITOPHEL. Dryden's 'Absalom and Achitophel,' perhaps the greatest verse-satire in English, was the direct outgrowth of political conditions. The Popish Plot of 1678-79, followed by the rebellion of Monmouth, illegitimate son of Charles II, against his father, had disorganized the kingdom; and the Exclusion Bill, which provided that the succession of James, Duke of York, brother to the king, and a Catholic, should be set aside in favor of the King's Protestant successors, was again being fiercely debated in Parliament. The state of affairs was a source of great doubt; Monmouth, though outwardly reconciled to the King, might again rebel; Shaftsbury, implacable enemy of James and instigator of Monmouth's rebellion, though being tried for high treason, might yet be acquitted and live to do further mischief. Amid such conditions, in 1681, Dryden, as poet laureate, was called upon to defend the throne. He answered with a satire that for brilliant characterization, cogent political reasoning, and mastery of form, has at least never been surpassed in English. His object was to expose the characters and motives of the King's opponents and to exhibit Monmouth as their dupe; and by so doing to kill the Exclusion Bill and confirm James in his succession. Taking a part of the story of Absalom's rebellion against his father David (2 Samuel, xv-xviii), he ingeniously adapts it to contemporary characters and conditions. The story of 'Absalom and Achitophel' is slight and unimportant, but from this digression and political reasoning amply alone. The characters are not merely impersonal types, nor, unlike most of Pope's, are they too sharply
individualized. Furthermore, they seemingly are drawn without personal animus; the satirist has the air of pronouncing judgment like a sage. The portraits of Achiropel (Shaftesbury), Zimri (Buckingham), Shemee (Slingby Bethel), deserve the place that they have for two centuries occupied in the picture gallery of great satire. Scarcely less remarkable is the cogent political philosophy of the poem, which minglesthe specious with the plain. In the mouth of Achiropel, whose reasoning he seems to condemn, the poet puts arguments that are now generally accepted as valid by the greater part of mankind. It is hard to tell just what Dryden really believed. The verse shows mastery of that heroic couplet which Dryden perfected and which is, all things considered, the best vehicle that English satire has discovered. Each couplet, its sense condensed to the last degree, is at the same time "a slap in the face and a stride forwards toward the goal." With such qualities, added to its timeliness, Achiropel is immediate and universal popularity and made literature for the first time in England a poem. Although the many replies which it evoked are long since forgotten, it remains great literature in spite of the fact that its political issues are dead and that the world in general has come around to Achitophel's point of view. A second part of Achiropel was written by Nahum Tate. To this Dryden contributed only 200 lines (310-509) of satire on the poets Shadwell and Settle, which are in his best vein and which form the only readable portion of the poem.

Marion Tucker,
Professor of English Literature, Polytechnic Institute of Brooklyn.

**Absolute**, opposed to relative; means that the thing is considered in itself and without reference to other things.

**Absolute Logic**.—(1) Absolute or non-connotative, according to Whately, is opposed to attributive or connotative. The former does not take note of an attribute connected with the object, which the latter does. Thus "Rome" and "sky" are absolute terms; but "Roman" and "sky" are attributive or connotative. (Consult Whately 'Logic,' bk ii, ch. v, §§ 1, 2-5). (2) According to J. S. Mill, it is incorrect to regard non-connotative and absolute as synonymous terms. He considers absolute to mean non-relative and to be opposed to relative. It implies that the object is to be considered as a whole, without reference to anything of which it is a part or to any other object distinguished from it. Thus "man" is an absolute term, but "father" is not, for the implication of existence of sons and is therefore relative. (J. S. Mill's 'Logic,' bk i, ch. ii).

**In Grammar**, a case absolute is one consisting essentially of a substantive and a participle, which form a clause not agreeing with or governed by any word in the remainder of the sentence. In Greek the absolute case is the genitive; in Latin the ablative; in English it is considered to be the nominative. In Latin the words *sole stantem* in the expression *sole stantem terra vertit* (the earth turned, the sun standing still—that is, while the sun is standing still) are in the ablative absolute. In English, thou leading, in the following familiar quotation—

"I shall not lag behind, nor err.
The way, thou guiding—" (Milton) is in the nominative absolute. So also is I rapt in the line—

"And, I all rapt in this, 'Come out,' he said."

—Tennyson's 'Princess,' Prol. 50.

**In Law.**—(1) Personal rights are divided into absolute and relative—absolute, which pertain to men as individuals; and relative, which are incident to the individual in his capacity as a member of society, standing in various relations to each other. The three chief rights of an absolute kind are the right of personal security, the right of personal liberty and the right of private property. (Blackstone's 'Commentaries,' bk i, ch. i). Similarly there are absolute and relative duties. Public sobriety is a relative duty, while sobriety, even when no human eye is looking on, is an absolute duty. (Ibid.). Property in a man's possession is described under two categories, absolute and relative property. His chairs, tables, spoons, horses, cows, etc., are his absolute property, while the term "qualified property" is applied to the wild animals on his estate. (2) An absolute decision is one which can at once be enforced. It is opposed to a rule writ, which cannot be acted on until cause be shown, unless, indeed, the opposite party fail to appear. (3) Absolute law: The true and proper law of nature. (4) Absolute warrantice (Scotch conveyancing): A warranting or assuring against all mankind. As this relativity may be of many kinds, various shades of meaning arise; thus:—

(1) Absolute or real expansion of a liquid, as opposed to its apparent expansion, the expansion which would arise when the liquid is heated; (2) Absolute gravity is the gravity of a body viewed apart from all modifying influences, as, for instance, of the atmosphere. To ascertain its amount, therefore, the body must be weighed in vacuo. (3) Absolute motion is the change of place on a body produced by the motion so designated, viewed apart from the modifying influence arising from disturbing elements of another kind. (4) Absolute force exercised by a centre of force; strength of a centre. (5) Absolute zero is that temperature at which bodies are absolutely devoid of heat. It is situated at 473.10 C. Absolute temperature is temperature measured in centigrade units from absolute zero. See Thermodynamics; Zero.

**In Astronomy**, the absolute equation is the aggregate of the optic and eccentric equations. In Algebra, (x), the absolute value of x, is x if x is real and positive, —x if x is real and negative, and +√a² + b² if x is a complex number of the form a + ib, where a and b are real.

**In Geometry**, the absolute is the region of a projective space which becomes the points at infinity when a Euclidean or non-Euclidean space is constructed from the elements of the projective space. In a Euclidean plane, as a locus, the absolute is a line, and as an envelope a pair of points on the line. In a non-Euclidean plane it is a conic.
In Ethics, absolute ethics are those that are based on a fixed standard, independent of time and of society.

In Metaphysics and Theology, the absolute is a being, often identified with God, which is (a) unrelated, (b) immediately presented to our consciousness and (c) all-inclusive. An unrelated being cannot of course be the subject of the cognitive relation, so that it known must be known in a manner involving no relatedness. This is why the absolute is supposed to be known immediately. This conception of knowledge without relation is one which it is very difficult to maintain consistently, and almost inevitably leads the absolutist (as the adherent of the doctrine of the absolute is known), to one or the other of the many forms of mysticism. It must be supposed that the mind in some way becomes the absolute by virtue of its act of knowledge. Furthermore, the third property of the absolute, that of being all-inclusive, follows directly from its unrelatedness. However, the desire for a finished philosophical system which contains an all-inclusive whole is probably one of the chief motives leading to the selection of an absolutistic standpoint. Consult Spinoza's 'Ethics,' Bradley's 'Logic,' or Bosanquet's 'Logic' for expressions of the absolutistic standpoint.

Space and Time are space and time viewed apart from their contents. Absolute rest is rest which possesses some intrinsic criterion that differentiates it from motion. The absolute position of a body is its position with respect to a set of axes at absolute rest. Absolute motion and velocity are motion and velocity with reference to a body at absolute rest.

**ABSOLUTE, Sir Anthony,** a character in 'The Rivals,' a comedy by R. B. Sheridan. He is a hot-headed, fiery-tempered, generous old man, always in a towering passion, even while he commends his own mildness of manner. His son, Captain Absolute, is the hero of the play.

**ABSOLUTE MONARCHY.** See Monarchy.

**ABSOLUTE PERMISSIVE BLOCK SYSTEM.** See Block Signal System.

**ABSOLUTION,** in ecclesiastical usage, the freeing from sin or its penalties. In the Catholic Church absolution has two important and distinctive bearings: (1) Absolution from sin; (2) Absolution from censures. The first is defined as the remission of sin, and can only be given by a duly ordained priest in the Sacrament of Penance, which requires, on the part of the penitent, a sincere confession of all his sins, contrition and a firm purpose of amendment. The basis of the doctrine is the authority of the Church and the commission in John xx. 23. In circumstances, where the conditions of the Sacrament of Penance cannot be fulfilled, absolution may be given on the ground of the moral conviction of the penitent's virtual desire to comply with all the necessary conditions. The Councils of Florence and Florence defined the form of absolution to be used: "If absolve thee from thy sins, etc." In the Greek or Eastern Church the deprecatory form is used: "May Christ absolve thee, etc." Absolution from censures merely removes penalties imposed by the Church. It may be given either in the Sacrament of Penance, or in the external form, that is, in the courts of the Church. It is not necessary for the person to be absolved from censures to be present or even living. Absolution for sins is a form of prayer imploring eternal rest and the remission of the temporal penalties of sin over a dead body. In the Protestant Churches in general absorption is simply a declarative power of the minister imploring the divine forgiveness. Consult 'Decrees of Council of Trent,' Denis de St. Martin, 'Traite de la Confession.'

**ABSOLUTISM.** A term used in political science to denote that system of government wherein the supreme power is vested in a single authority—individual or collective—unchecked by any constitution or laws. Since absolute power may be exercised under a monarchy, an aristocracy or even a democracy, the term, strictly speaking, does not apply to any particular form of government, though it is usually employed in describing monarchies, as they furnish the most archetypal form of absolutism. United sovereignty is an essential condition of absolutism, since the distribution of the functions of government places that government under restraints. Absolutism characterized all ancient monarchies and has prevailed in all Oriental monarchies, down to Japan of a few years ago. When the barbarians overran western Europe feudalism replaced the absolute monarchy, but the growth of towns and the rise of commercial classes made necessary a strongly centralized state to protect the nation against the feudalistic lords, and the absolute monarch again came into power, uniting in himself the various functions of national life, both political and religious. The Tudors and Stuarts in England, Frederick the Great of Prussia, and Louis XIV of France, with his famous assertion "L'état c'est moi" ("I am the State") are examples of absolute monarchs, though their absolutism was mainly limited to the central government. There are no absolute monarchies in Europe since 1908, when the government of Turkey was overthrown and a constitution adopted later, the term has not been applicable even to the Ottoman Empire.

The most common method of checking absolutism is to separate the governmental functions. The legislative functions in most states of western Europe and England are exercised by two chambers; in the United States the national and state governments share the powers of sovereignty itself, while in each of these governments the authority is again divided among the legislative, executive and judicial departments. The written constitution or fundamental law made by the people or their representatives is another method of preventing absolutism, since the fundamental purpose of a written constitution is not only to lay down the plan of government but also to regulate the powers and conduct of those who govern. From the standpoint of the citizen or subject no government, whatever its nature or form, can hold absolute sway in the midst of manifestations of human activity, since, being political in character, absolutism is subject to the limitations of human nature and is limited by local government, and, in some countries, by common law;
by international law which restrains sovereign states from acts prejudicial to the interests or injuries of the various states; and by the church, the religious authority of which is usually independent of the state. (See Monarchy; Feudal System; Despot.) Consult Brougham, H. P., Political Philosophy (1842–46); Baldwin, S. E., Modern Political Institutions (2d ed. 1892); Lieber, P., 'Civil Liberty' (3d ed., 1891).

**ABSORPTION,** in chemistry, absorption is the taking up of a gas by a liquid or by a porous solid; and in natural philosophy it is the taking up of rays of light and heat by certain bodies through which they are passing. Absorption of light is the retention of some rays and the reflection of others when they pass into an imperfectly transparent body. If all were absorbed, the body would be black; if none, it would be white; but when some rays are absorbed, and others reflected, the body is then of one of the bright and lively colors.

In chemistry the coefficient of absorption of a gas is the volume of the gas reduced to 0° Cent. and 760 m.m. pressure, which is absorbed by 1 cm. of a column of 1 cm. of any liquid. Absorption of heat is the retention and consequent disappearance of rays of heat in passing into or through a body colder than themselves. Absorption of the earth is a term used by Kircher and others for the subsidence of tracts of land caused by earthquakes.

In physiology absorption consists of a series of complicated processes by which the necessary constituents of the body are taken in at certain parts to be distributed to the places of need. The chief substances are water and salts, mainly absorbed in the small intestines; fat chiefly taken in the cells of the intestinal mucosa after a complicated series of chemical changes; carbohydrates chiefly absorbed at various parts of the intestinal canal after conversion into monosaccharids and proteins which are chiefly taken up by the bloodvessels after passing through the epithelial cells of the intestinal mucosa as peptones, proteoses, or amino-acids. Proteids are not absorbed in the stomach. (See Digestion: Gases, General Properties of Liquids; Occclusion; Spectroscopy.) Consult Bayliss, 'Principles of General Physiology'; Starling, 'Human Physiology.'

**ABSTRACT OF TITLE,** a synopsis, or brief statement, of the evidences of ownership of real estate. An abstract should set forth briefly but clearly every deed, will or other instrument, together with every fact relating in any way to the title, in order to enable the party in interest to form an opinion as to the exact state of the title. The vendor of land, in England, usually furnishes the purchaser with an abstract of title. The vendor is not compelled to furnish an abstract of title in the United States. He usually undertakes to give only a marketable title. Plans and sketches of the premises are generally inserted in abstracts of title.

**ABSTRACTION,** in logic, the formation of a general concept on the basis of individual entities exemplifying the concept, or of concepts of greater intensity and less extensity. The word is also used to refer to the concept thus formed. For example, when I single out the redness of an apple and recognize it as a separate quality, I am abstracting from the size, taste, smell, etc., of the apple. While the relation of the abstracted concept to the concept from which it is abstracted is altogether a logical one, our tendency to make abstraction is greatly enhanced by our innate psychological tendency to attend to certain striking portions of a sense-datum, while the less impressive aspects of the datum are only vaguely and blurrily noticed. This process of abstraction for the child begins in his noticing differences in familiar objects. Within certain groups some differences are found to be unimportant. These qualities which are found to be of less importance are then abstracted or removed from the complex idea for which the word denoting this group of objects stands. As this process develops it becomes deliberate, and the attention may be directed upon resemblances instead of differences. At this stage the grouping of objects according to likenesses results in classification. Consult any general work on logic or psychology.

**ABSYRTUS.** See Argonauts.

**ABT,** āpt, Franz, German song-writer and conductor: b. Wiesbaden, 22 Dec. 1819; d. 31 March 1885. He studied theology at Leipzig, but abandoned it for music at Mendelssohn's instance. In 1841 he became kapellmeister at the court theatre at Bernburg; shortly afterward relinquishing the post for a similar one in Zürich, where he remained till 1852. He was then called to Brunswick as chief conductor of the orchestra in the royal theatre, and made court kapellmeister in 1855. In 1872 he came to the United States at the invitation of a number of choral societies, and was very favorably received; he conducted at the famous Peace Jubilee in Boston in that year. In 1881 he retired to Wiesbaden on a pension. Many of his songs (for example, 'When the Swallows Homeward Fly,' 'Good Night, Thou Child of My Heart,' 'O Ye Tears,' etc.), have endeared themselves to the heart of the people all over the world.

**ABU-BEKKR, āboo-bék'ër,** his original name being Abd al Kahab ibn Abi Kuhlajah al Atik, also Abd Allah, father-in-law of Mohammed, being the father of the Prophet's wife: b. Mecca, 573; d. 23 Aug. 634. On the death of Mohammed, in 632, he was chosen as his successor and the first caliph of Islam. He began waging a successful warfare against his enemies in Arabia, Persia and the Byzantine Emperor Heraclius, but two years later died at the age of 63 and was buried in Medina, near the tomb of Mohammed and Ayesha, the Prophet's wife and his daughter.

**ABU-HASSAN, ā’boo-hās’ān,** surnamed 'The Wag,' hero of one of the 'Arabian Nights' Tales, entitled 'The Sleeper Awakened.' Unaware he entertains the caliph and later becomes the monarch's friend and trusted adviser.

**ABU KLEA** (Abuklea Wells), a place in the eastern Sudan, west of the Nile, on the desert route from Korti to Metemmeh, 23 miles north northwest of Khartum and about 120 miles from Khartum. Here a battle was fought 17 Jan. 1885 between a British force of 1,500 under Gen. Sir Herbert Stewart and 12,000 Mahdists, of whom 5,000 actually attacked.
ABU-SIMBEL, a'boor-sim-bell, or IPSAM-
BUL, site of two remarkable Egyptian temples, 
situated on the left bank of the Nile, in Nubia, 
south of Assuan, in latitude 22° 22' N. Both 
the temples are ancient, Egypt: were built 
by Rameses II, 1388–22 B.C., the smaller one 
being dedicated to the goddess Hathor while 
the larger one was dedicated to Ammon of 
Thebes, Harmachis of Heliopolis and Ptah of 
Memphis. The façade of the latter measures 
119 feet across and stands over 100 feet in 
height, before which are four sitting colossi, 
each over 65 feet in height, each representing 
the Pharaoh. The interior, divided into two 
large halls and 12 minor chambers and corridors, 
is fully 150 feet in depth, and the walls are 
decorated with some of the finest and best pres-
served examples of ancient Egyptian mural 
artistic decoration. The vast outer hall, 54 by 58 
feet, is supported by two rows of square pillars, 
to each of which is attached a statue of the 
Pharaoh reaching up to the roof. In front 
of the smaller temple are six statues, 
each three feet in height, representing Rameses 
and his consort. Both temples were discovered 
by Burckhardt in 1817. In 1912 the great colossi 
of the temple façade were repaired by filling 
them with cement.

ABU TAMMAM, a'boo-taam-mam, Arabian 
poet: b. near Lake of Galilee, Syria, about 807; 
d. Mosul 842. It is said that he was born a 
Christian and that he later became a Moham-
medan, but, like most of the Arabian scholars 
of his time, he was strongly inclined to 
scepticism. While still a mere youth he went 
to Egypt. For the songs he wrote glorifying 
the campaigns of Al Mutasim against Amorium, 
in which he accompanied him, he was openly 
rewarded. He traveled extensively, visiting 
Armenia and Khorasan. During one of his 
journeys he was obliged to seek refuge from 
a snowstorm with Abul Wafa ibn Salama, in 
Hamadan, whose extensive library was placed 
at his disposal. It was there that he compiled 
four collections of Arabic poems, the most 
famous of which is known as the 'Hamasa.' 
It is on this anthology that his fame rests most 
firmly, though he did compose many original 
poems. The Arabic text of the 'Hamasa' was 
published (Bonn 1828–47) by G. W. Freytag 
in two volumes; another edition was published 
in Bulak (1869) and Calcutta (1856). A Ger-
man translation, by Friedrich Rückert, has also 
been published (Stuttgart 1846). Consult 
Brockelmann, 'Geschichte der arabischen Litera-
tur' (Vol I, 1898).

ABU AL ALA, AL MA'ARRI, a'boo al-lah al 
ma-ar-ree, Arab poet and philosopher: b. Ma'arra 
ib Al Nu'man, northern Syria, 973; d. 1058. When 
only four years of age he became totally blind. 
His early schooling was obtained at Aleppo, 
Tripoli and Antioch. In 1010 he went to Bag-
dad, apparently to seek his fortune, but met 
with so little success that he finally returned to 
Maarrat, where he remained for the rest of 
his life. He soon attracted wide attention as 
a poet and a writer of songs, a collection of 
them being preserved under the title 'Sikt al 
Zand.' Later he ventured into philosophical 
writing, in which he criticized many of the 
tories of the time and people. In his Risalat al 
Ghufran,' 'Letters of the Forgiven,' he 
satirized the lives of the forgiven heretics of 
the past in the other world. He was, in fact, 
far ahead of his time in his religious ideas, 
adhering to neither Mohammedan nor Christian 
creeds, but advocated only the ethical teachings 
of both religions. Consult Kremer, 'Uber die 
philosophischen Gedichte des Abul' Ala al 
Marri' (1888); Nicholson, 'A Literary History 
of the Arabs' (1907, p. 313); Margoliouth, 
'The Letters of Abul' Ala' (1906).

ABUL ABBAS, a'boo-ool-bas, founder of 
the Abbasid dynasty of Caliphs. His name 
was properly 'Abd Allah, but by the other he 
was more generally known, to which was added 
the surname 'kunya,' the shedder of blood. 
His claim to the caliphate was based on the 
fact that his father, Mohammed ibn Ali, was 
the grandson of the first cousin of the Prophet, 
or, the great-grandson of the Prophet's uncle. 
With this foundation to his pretensions, Abul' 
Abbas began his career of conquest in Khorasan 
in 747, captured Kufa and there, two years 
later, proclaimed himself caliph. The follow-
ing year Marwan II was defeated and killed 
and Abul' Abbas began a course of systematic 
massacre of the whole family of the Banu 
Umeya. He died in 754, being succeeded by his 
brother Abul Ja'far al Mansur. Consult 
Turbuhi, 'The Caliphs' (3d ed., 1889, p. 426); 
Weilhausen, 'Das arabisch Reich' (1902, p. 
338).

ABUL ATAHIYA, a'boo-ool-ata-heit-ya, or 
ISMAIL IBN AL KASIM, Arab. poet: b. 
Anbar, on the Euphrates, 748; d. 825. He 
lived in Kufa, Hira and Bagdad, leading an 
ascetic life of extreme simplicity, writing 
against the religious fanaticism of his time. 
His poetry reflects his own simplicity in its 
simple, direct style. A good edition of a 
collection of his poems was published in Beirut 
in 1887. Consult Brockelmann, 'Geschichte der 

ABUL FARAJ, a'boo-ool-faa-raj, or ALI IBN 
AL HUSAIN IBN MOHAMMED IBN 
AHMED AL KURASHI AL ISFAHANI, 
Arabic historian: b. Isphahan, Persia, 897; d. 
967. He was a descendant of the Umayyads. 
Early in life he traveled extensively. His chief 
work is 'Kitab al aghani' ('The Book of 
Songs'), through which most of the modern 
knowledge of early Arabic literature is handed 
down. It includes a large collection of songs, 
to many of which are appended notes of 
the writers and anecdotes illustrative of their 
personalities. The latest edition of the text 
was published in Cairo (21 vols., 1905).

ABULFAZL, a'boo-ool-faa-zel, MUBARAK I 
ALLAMI, historian and victor of the 
Great Emperor of the Mongols: b. 1551; d. 1602. 
His chief work is a history of Akbar's reign, 
in two parts. The first, 'Akbar Nama,' or 
'Book of Akbar,' is an historical narrative, 
while the second part, 'Ayin-i-Akbar,' or 
'Institute of Akbar,' describes the religious 
and political constitution of the empire. The 
Persian text of the first part is edited in the 
'Bibliotheca Indica' (1867–87), and a transla-
tion by Beveridge may be found in the same collection. A translation of the second part begins and the text may be found in the same work. Abulfazl initiated that great literary movement through which has been handed down the Persian translations of many Sanskrit, Arabic and Hindu works. He was murdered while on a mission to the Deccan.

**ABULPEDA,** a’bool-fé’da’, ISMAIL IBN ALI, Arabian prince and scholar: b. Damascenus, 1273. In 1310 he became ruler of the principality of Hama, the throne being granted to him by the Sultan for distinguished military services, part of which were against the Crusaders. In 1320 he was granted the dignity of “sultan” with the right to transmit his powers to his heirs. During his entire reign he patronized arts and letters and traveled to Egypt and Arabia. One of his chief works is *An Abridgement of the History of the Human Race,* beginning with the creation and ending with the year 1329. The text was published in Constantinople in 1870 and several translations have been made. The period covering the Crusades is especially important and has been extensively quoted by Western historians. He found in the first volume of Muratori’s *Scriptores Rerum Italicarum.* The part preceding the Mohammedan era was translated into Latin by Fleischer as *Abulfedae Historia ante-Islamitica* (Leipzig 1831). The part dealing with the life of Mohammed has been rendered into English by W. Murray and published in London, and the later parts by Reiske and Adler in *Annales Moslemici* (5 vols., Copenhagen 1789–94). Abulfeda also contributed richly to modern knowledge of the Moslem world of the time through his geographical writings. A complete edition of this phase of his work was published by Reinaud de Slane in Paris (1840) and a French translation was published by Reynaud (first part, 1845) and Guyad (second part, 1883).

**ABY’DOS,** Greece, town and castle of Asia Minor; on the Hellespont or Straits of Gallipoli near Byzantium. It is the port from which Xerxes made his celebrated crossing of the Hellespont on the bridge of boats; and, also, as being the scene of the loves of Hero (q.v.) and Leander (see MUSAEUS). Byron adopts the name in his *Bride of Abydos* (1813), characterizing it as a clime where “All, save the spirit of man is divine.” It is thought originally to have been a Thracian town, which subsequently became a Milesian colony. In 411 B.C. Abydos revolted from Athens and went over to Dercyllidas the Spartan. Subsequently the city was captured by Philip II of Macedonia, but in 196 B.C. it was declared free by the Romans. (2) Another Abydos was situated in Egypt on the upper Nile, and in the Thebaid was second in importance only to Thebes. It has important ruins of the Palace of Memnon and the tomb of Osiris. Here also were found the famous Tablets of Abydos.

**ABYSMAL DEPOSITS** are accumulations at the bottom of the ocean at great depths known as abysmal depths. They consist chiefly of red and gray clays and oozes or combinations of clay with various shells and animals, such as *Dictyon, Foraminifera* and *Radiolarians*. These deposits constitute the larger part of the deep-sea bottoms. Although there is a vast amount of life found at these abyssal depths this life is confined, so far as definitely known, to a few species. The deposits are made up of the remains of surface and abyssal animals, the latter of which are born, live and die on the bottom of the ocean. Most of the shells of these animals decompose rapidly at great depths of the ocean, and many of them disintegrate under the pressure of the salt water before they reach the bottom, where they are constantly being added to the deposits. There are various kinds of deposits, classified according to the depths at which they are found and the local influences under which they have been formed; but only a comparatively few of them can be classed as abysmal. One of these abyssal depths exists in the deep bed of the Gulf of Mexico and along nearly the whole course of the Gulf stream. Very little, if any, of the deposits of these great ocean depths is derived from the shores of the bordering continents. Many of the formations going on there seem to be a thing apart from the debris of all except that of the surface animals that pass over them or live above them. As all the abysmal deposits merge into one another geologists have found great difficulty in determining their character in given areas. The 20 or more species of pelagic *Foraminifera* constitute over 90 per cent of the vast quantities of carbonate of lime present in the calcareous oozes of the abysmal depths of the oceans. This animal life, thus wonderfully abundant to-day, is present in a like plentitude in other geological formations and periods. Living as they do at such a great depth below the surface and being subject to a more or less uniform pressure, the shells of these animals are very much alike in appearance and thickness in all the abysmal deposits and zones. See CONTINENTAL SHELF.

**ABYSSINIA** (officially Ethiopia), an ancient kingdom of East Africa, now under a monarch who claims the title of Emperor; pop. 8,000,000. Abyssinia may be said to extend between lat. 5° and 15° N., and long. 35° and 43° E. It is bounded on the north by the Italian colony Eritrea, on the west by the Anglo-Egyptian Sudan, on the south by British East Africa and on the southeast and east by British, French and Italian Somaliland and Red Sea colonies. Its frontiers have been frequently changed, but in 1906 England, France and Italy agreed to preserve so far as possible the integrity of Abyssinia as it then existed. The country is divided into nine provinces which comprise the kingdoms of Shoa in the south (including Efat), the strongest and best organized state in Abyssinia, — capital, Addis Ababa, former capital Ankober, with some 2,000 inhabitants, 8,000 people, with a salubrious climate; Amhara in the centre (including Gojam), capital, Gondar, situated on the Gondar plateau, 7,500 feet above the sea; and Tigré in the north, chief places, Antalo, Adwa or Adowa and Axum, ancient capital of Ethiopia, the two latter with about 5,000 inhabitants. There are besides territories and dependencies extending to Kaffa and...
Harrar in the south and southeast, including large portions of Gallia and Somali Lands. Addis Ababa, capital of Shoa, was founded in 1886 by King Menelik of Abyssinia. It consists of villages and suburbs scattered round the palace over an area of three square miles, and has between 50,000 and 60,000 inhabitants.

Topography. The more marked physical features of the country may be described generally as consisting of a vast series of tablelands of various and often of great elevations, and of numerous ranges of high and rugged mountains, some of them of very singular forms, dispersed over the surface in apparently the wildest confusion. From these mountains flow inexhaustible supplies of water, which, pouring down by the deep and tremendous ravines that everywhere intersect them, impart an extraordinary fertility to the plains and valleys below.

The loftiest and most remarkable mountain summits occur in the Simen range in the centre of the northern part of the kingdom, immediately west of the Tacazze River. Among the highest of these (so far as known) is Ras Dashan, calculated at 15,160 feet and capped with perpetual snow. Abba Yared and Biuat are slightly lower. Along the eastern side of the country extends a mountain range or escarpment forming a natural rampart, with a mean elevation of 7,000 or 8,000 feet for some 600 miles. No volcanoes are known to exist at present, but almost everywhere are numerous evidences of past volcanic action. Perhaps the principal river of Abyssinia is the Tacazze, rising in the mountains of Lasta, about lat. 12° N.; long. 39° 20' E. It runs north and then west, and after leaving the bounds of Abyssinia takes the name of Atbara, and finally joins the Nile. The chief of the other rivers—if not indeed the chief of all—is the Abay or Abai in the centre which, after flowing through Lake Dembera, or Tsana, the largest lake in Abyssinia, runs south and then northwest, and later becomes the Bahr-el-Azrek or Blue Nile, of which it is in fact the upper portion. The Hawash is the principal river flowing east.

Fauna. The domestic animals consist of horses, cattle, sheep, goats, camels, mules and asses. Mules, camels and asses are the usual beasts of burden, the horses being generally reserved for war and the chase. Vast herds of oxen are met with throughout the country. The wild animals are the lion (rare), elephant, hippopotamus, rhinoceros, crocodile, buffalo, hyena, leopard, boar, antelope, zebra, quagga, giraffe, gazelle and civet. The hippopotamus abounds in Lake Tsana, and great numbers are killed annually for their flesh and hides. The rhinoceros, like the elephant, inhabits the low, moist grounds, and is numerous in certain districts. Crocodiles are found in various rivers, but the largest and most dreaded are those that inhabit the Tacazze. The buffalo, a comparatively harmless animal in other countries, is here extremely ferocious. Serpents are not numerous but several poisonous species are to be found as well as the cobra, which often attains a length of 20 feet. There are many birds of beautiful plumage; bees are numerous, honey being a general article of food; locusts often lay the land waste, and the tsetse fly is destructive to cattle during the rainy season. The flora is very varied and in the low lands and valleys extremely luxuriant. Cotton, sugar-cane, date palm, coffee, vine, bananas and other fruits would all probably be cultivated. A wild coffee plant runs riot in southern and western Abyssinia, and there are many valuable timber and rubber trees in the forests. Agriculture is the chief industry but is still in a primitive state, the soil belonging theoretically to the imperial government and the idea of landed property being little understood by the natives. Manufacturing industries are very backward, but cattle, sheep, goats, small hardy horses, donkeys and mules are extensively raised. The chief native products are hides, skins, millet, wheat, barley, tobacco and an excellent Mocha coffee known as Harirji coffee.

Productions. The chief mineral products of Abyssinia are iron, sulphur, coal and salt, but they are as yet undeveloped. Coal beds extend along the whole of the eastern frontier of Shoa, but as a combustible coal is scarce known in the country. Salt is obtained in various places. Aponal is obtained from the southeastern border of Tigré. Gold is obtained from alluvial deposits, but not in great quantity. In some parts of the country iron is abundant and is manufactured into implements. A few hot mineral springs are known and used.

Climate. The climate of Abyssinia is as various as its surface. In the valleys it is delightful, but on the mountains often cold. The light rains commence in April or May, the heavy rains in June and continue till September (or even longer in parts); during which period they are often so violent as to put a stop to agricultural labor.

Commerce. The foreign trade is chiefly carried on through Jibuti in French Somaliland and other non-Abyssinian ports on the Red Sea and Gulf of Aden and through Gambela and western Abyssinia to the Sudan; but the external traffic has never been of great importance, as the nature of the country is adverse to an extensive trade, and there are relatively few commodities suited for export; moreover, till recently the natives dared not trust their treasures out of their secret hoards, and the royal court was the chief buyer. Menelek's firm administration, however, with its better security for life and property, extended Abyssinian trade considerably, the United States and Great Britain being the chief beneficiaries, France, Italy, India and Germany ranking next. In 1913 the value of exports and imports through Jibuti was about $3,684,240, through Gambela and West Abyssinia $638,235 and through Somaliland $308,500. The chief exports were hides and skins, coffee, wool, ivory and rhinoceros horns, honey, wax, civet; the chief imports, cotton goods, in which American manufactures take the lead, firearms, ammunition, provisions, liquors, railway material, sugar and petroleum. Trade is greatly hampered by the primitive methods of communication, which is carried on by mules and pack-horses; the distance traversed being not above six to eight miles a day as well as the taboo of going out of doors longer than a month at a time. The line now under construction was opened between Jibuti and Diré Dawa, 25 miles from Harar; in 1909 a new company was formed to extend the line to Addis Ababa. In 1912 it reached the Hawash River, and was expected
to be about 30 miles from Addis Abeba in 1915. There are 1,056 miles of telegraph lines. The bank of Abyssinia, chartered in 1905 with a capital of $2,500,000, mainly provided by the Nations Bank of Egypt, the Catholic dean of which is its president, has its headquarters at Addis Abeba. The current coin of Abyssinia is the Maria Theresa dollar, but in recent years an effort had been made to introduce a new currency with the Menelek dollar (worth about 50 cents) as the standard. Silver ingots and cartridges are also accepted as currency.

Population.—The native population consists of Semitic Abyssinians, Gallas and Somalis, negroes (in southwest) and Falashas (of Jewish religion). The non-natives are Indians, Arabs, Greeks, Armenians, and a few Europeans. Up to 1907 education was solely in the hands of the clergy. In October of that year compulsory education was decreed for boys over 12, but the edict remained a dead letter. One day in early 1908 a boy of 10 and his existence in Addis Abeba. Justice is administered by the provincial governors and petty chiefs with right of appeal to the Emperor. The legal system is supposed to be based on the Justinian Code.

Government.—The government of Abyssinia is feudal in character. Each of the nine provinces has its governor, supposedly under the authority of the Emperor or Negus, and having their retainers, or professional warriors. There is a vague state council composed of the most important *basses*, or chiefs, and a ministerial council constituted by Emperor Menelek in 1908. The regular army numbers about 25,000 men, mostly cavalry, and is supplemented by irregulars and territorial troops in time of war.

History.—Northern Abyssinia corresponds to ancient Ethiopia (see ETHIOPIA), which is still the official name of the country. Abyssinia being a Portuguese form of the Abrahamic Habesh, signifying "mixture of the West, the East, and the desert". Christianity was introduced in the 4th century. In the 6th century the Abyssinians conquered the rich province of Yemen in Arabia and were in constant communication with the outside world for over a thousand years. The Moslems took Egypt in the 7th century completely isolated them however, and for centuries afterward the kingdom continued in a distracted state, now torn by internal commotions, and now invaded by external enemies (Mohammedans and Gallas). To protect himself from the former the Emperor of Abyssinia, about the end of the 16th century, applied for assistance to the King of Portugal. The solicited aid was sent, and the empire saved. The Jesuit priests, having now ingrained themselves with the Emperor and his family, endeavored to induce them to renounce the tenets and rites of the Coptic Church and adopt those of Rome. This attempt, however, was resisted by the ecclesiastics and the people, and finally ended, after a long struggle, in the expulsion of the Roman Catholic bishop in 1633. The kingdom gradually fell into a state of anarchy, which about the middle of the 18th century was complete. The Negus received no obedience from the provincial governors, who were feud, fought with another and severally assumed the royal title. Abyssinia thus became divided into a number of petty independent states and, save for visits from occasional explorers such as James Bruce in 1769, remained shut off from the world until the 19th century. A remarkable, but, as it proved, quite futile attempt to resuscitate the unity and power of the ancient kingdom was begun about the middle of the 19th century by King Theodore, who aimed at the restoration of the ancient kingdom of Ethiopia, with himself for its sovereign. He introduced European artisans, and went to work wisely in many ways, but his cruelty and tyranny counteracted his political measures. In consequence of a slight, real or fancied, which he had received at the hands of the British government, he threw Consul Cameron and a number of other British subjects into prison in 1864, and refused to give them up. To effect their release an army of about 16,000 men under Sir Robert Napier was dispatched from Bombay in 1867; it landed at Zulla on the Gulf of Aden in January 1868, and after marching 400 miles besieged Magdala, Theodore's capital, about May 1, 1869. After a siege of 27 days the place was taken by storm 13 April. Theodore was found among the slain, the general opinion being that he had fallen by his own hand.

After the withdrawal of the English, fighting began among the chiefs of the different provinces, the three most powerful, Kassa of Tigré, Gobasie and Menelek, struggling for the supremacy. This state of matters continued for some time, but at last the country was divided between Kassa, who secured the northern and larger portion and assumed the name of Johannes, and Menelek, who gained possession of Shoa. In 1872 Johannes made himself supreme ruler, with the title of emperor, or king of kings (Negus Negusti). Taking advantage of the troubles in Abyssinia the Egyptians annexed Massowa and adjoining territory on the Red Sea, and hostilities were repeatedly carried on between them and Johannes. In 1885 the Egyptian forces were withdrawn, and Italy, with the consent of Great Britain, declared a protectorate over Massowa and the strip of territory along the coast of the Red Sea. In the following year the Italians pushed inward to Saati, a few miles west of Massowa, an action which led to war with Johannes. An Abyssinian force under Menelek, in 1887 to recover Saati; but though a small Italian force was cut to pieces at Dogali the Italians maintained their position.

On the death of Johannes in 1889, while fighting against the Mahdists, Menelek, who had concluded an alliance with Italy, known as the treaty of Nchali, raised himself to the imperial throne. The result of this was the strengthening of the Italian hold on the country. The Italians regarded their treaty with Menelek as giving them a protectorate over Abyssinia, and by 1892 the whole of Ethiopia was generally recognized as within the Italian sphere. Proceeding to extend and strengthen their position, the Italians in 1889 occupied Keren, capital of the Gogos country, situated 60 miles west of Massowa, and also fortified Asmara, southwest of Massowa. Adowa, the capital of Tigré, and the centre of opposition to Menelek, was occupied in the following year. The Mahdists were also defeated, and Kassala in the Sudan was occupied by the Italians. Menelek, however, later repudiated the Italian protectorate, broke with his former allies, and in 1896 his troops inflicted on them such a defeat at Adowa
as gave a death-blow to their claim of a protectorate over all Abyssinia.

The treaty of Addis Ababa concluded in that year between Menelik and the Italians practically abrogated the treaty of seven years before, but left Italy in possession of a strip along the Red Sea coast from the French colony of Obok on the south to Ras Kasar on the north, known officially as Eritrea (Erythraea), the frontiers of which were definitely settled in 1908. A British mission in 1897 was favorably received by the Emperor, a treaty of commerce was concluded and the boundaries of Abyssinia and the British Somali protectorate were arranged. In 1908 a further agreement with Great Britain regulated the boundary between Abyssinia and the Sudan down to 6° N. lat. Abyssinia also has her comprehensive commercial treaties with the United States (1903), Germany and Austria-Hungary (1905), and France (1908). Each of these treaties was to remain in force for a period of 10 years, when it could be terminated at a year's notice. Menelik (b. 1842) died in December 1913 and was succeeded by his grandson Lidi Yasu (b. 1896), who on account of the illness of the Emperor had been virtually ruler, under regents, since 1909.

On 27 Sept. 1916, during the Emperor Lidi Yasu's absence at Hararr, the Metropolitan Abuna Mathaeos released the people and chiefs from their allegiance and deposed the Emperor. In his stead they elected Waizern Zauditu, daughter of the late Emperor Menelik, as Empress of Abyssinia, and designated Degag Tacassi Makonnen as heir to the throne. The deposed monarch, who is a Knight Grand Cross of the Royal Victorian Order (G.C.V.O.), is a son of Menelik's second daughter. The young emperor had received an excellent European education, and at the age of 14 could speak fluently English, French and German. In May 1909, when 13 years old, Lidi Yasu was married to Princess Romani, a granddaughter of the late Emperor John, who had fought against and defeated Menelik (when King of Sho) in 1877. The young emperor or favoritism found its part in Menelik's nature; the welfare of his country was his first preoccupation, and it was a well-known fact in Abyssinia that he had carefully studied the nature and character of the youth which he took the step of appointing him as his successor. During the World War, Abyssinian troops were allied with the British in the East African campaign.

CHALIES LEONARD-STUART, Staff of the Americana.

ABYSSINIAN CHURCH. The Church founded by Frumentius, the first bishop of Ethiopia, about 330 A.D. About 470 a great company of monks established itself in the country, completely changing the doctrines and affairs of the Church, but was a few years later expelled. From 1526 to 1540, the country was overrun by Mohammedans, followed at the end of the 15th century by the Portuguese Jesuit missions, which remained till 1633, when the Abyssinians resumed allegiance to the Church at Alexandria. The metropolitan (called Abuna) or bishop of the Church is appointed by the patriarch of Alexandria, and is always a foreigner. The Abyssinians are monophysites, generally agreeing with the Copts in ritual and practice. The fasts are long and rigid; confession and absolution are strictly enforced and the Sabbath and the Levirate law are generally observed. Graven images, purgatory, extreme unction, crucifixes, etc., are prohibited. The priests must marry, but only once. The liturgy is celebrated on the ark in the King's palace at Christmas, Epiphany or Easter and the Sunday of the Cross. The Scriptures are read in Geez, the literary language, which is used for all services. Consult Dowling, 'The Abyssinian Church' (London 1909).

ACACIA, ak′-차, (Gr. ακή, spine, from their spiny stalks), a genus of plants, family Mimosaceae. They are trees or shrubs with compound pinnate leaves and small leaflets,—in some species wholly or partially undeveloped, when the petiole or leaf-stalk expands into a blade resembling a leaf, hence called phyllocladum. Certain species yield gum senegal and other gums; some have astringent barks and pods, used in tanning. Some of the Australian species contain considerable tannin, and hence are exported to a large extent. An Indian species yields an astringent called catechu. Some of the species of tropical America, known as bullet-nut Acacias, are interesting because of their large hollow spines which are penetrated and inhabited by ants.

ACACIUS, a-ká′-치우스, bishop of Cesarea 340–365 A.D. He founded a curious Egyptian sect called Acastians, and that he be termed homoioathelites, as they held that the Son was like the Father in will, but not of the same or similar substance; thus differing from the Arians. He induced a synod at Constantinople in 359 to accept the doctrine, whereas St. Jerome said that "the world groaned and wondered to find itself Arian." It was finally condemned, however, and he was banished.

ACACIUS, SAINT, bishop of Amida in Mesopotamia, early in the 5th century. He sold the church plate to redeem 7,000 starving Persian slaves. Vararanes (Babylon), the king is said to have been so affected by this noble action that he sought an interview with the bishop, which resulted in a peace between that prince and Theodosius II, A.D. 422, and a hundred years' peace was sworn between Rome and Persia.

ACADEMIC COSTUME. See Costume, Academic.

ACADEMIC DEGREES. Academic degrees, whether earned or honorary, are titles conferred by colleges, universities and professional schools upon persons in the opinion of the authorities of these institutions,
have exhibited special proficiency in any branch of knowledge. (See Degree). The difference between earned and honorary degrees is that the former are conferred upon students who have completed a certain prescribed course of study and all other requirements of the institution granting such degrees, whereas the latter are conferred upon individuals selected, without examination or other requirement, because they have attained eminence in some line of endeavor.

There is a woful lack of uniformity in the methods used in granting degrees by the educational institutions of the United States. Academic degrees are not and cannot be protected adequately by law. Institutions which claim the right to confer such degrees have increased so rapidly and their standards vary so widely that the value of a degree is greatly lessened. Some small and new institutions and some unauthorized agencies not only bestow the degrees that are properly honorary, for insufficient or no reason, but confer other degrees that should be won only after the completion of a definite course of study. There is a tendency for the non-formity of standards, however, and in 1908 a report was made by a committee of the National Association of State Universities upon standards for the recognition of American universities and upon standards for the recognition of the A.B. degree and higher degrees. The Carnegie Foundation (q.v.) is also using its influence to standardize degrees by giving the benefits of its pension fund only to those universities and colleges which adopt and enforce certain requirements for admission and study.

In general the lowest degrees, Bachelor of Arts (B.A. or A.B.) and Bachelor of Science (B.S. or S.B.), are given to students who have completed the non-professional four-year college course. There is considerable divergence in the significance of degrees even among the older colleges and universities, since the A.B. no longer indicates, as formerly, that the recipient has completed a definite amount of Greek, Latin and mathematics. The elective system and the tendency to replace the classics by modern languages have obliged the institutions either to change the requirements for the degree or else to substitute a new degree. The second or master's degree — Master of Arts (M.A. or A.M.) and Master of Science (M.S.) — are granted to holders of bachelor's degrees who have completed an additional year of study, although these degrees are often honorary. The degree of Doctor of Philosophy (Ph.D.) is usually bestowed upon those who have completed at least three years of graduate work and have prepared a thesis upon some subject approved by the faculty that will show ability to do original work. This degree is no longer given as an honorary degree by any institution of rank.

Among the more usual degrees, besides those above mentioned, conferred by professional schools are Bachelor of Laws (L.L.B.), Doctor of Medicine (M.D.), Bachelor of Divinity (B.D.), Bachelor of Civil Law (B.C.L.), Bachelor of Letters (B.L. or Litt.B.), Bachelor of Philosophy (B.P.), Bachelor of Business Administration (B.B.A.), Bachelor of Science of Medical Dentistry (D.M.D.), Doctor of Veterinary Medicine (D.V.M.), Doctor of Law (J.D., Juris Doctor), Doctor of Civil and Canon Law (J.U.D., Juris Utriusque Doctor), Doctor of Letters or Humanities (L.H.D.), Bachelor of Music (Mus.B.), Master of Letters (L.L.M. or Mus., Magister), Master of Civil Engineering (M.C.E.), Master of Mining Engineering (M.M.E.), Doctor of Music (Mus.D.), Graduate in Pharmacy (Ph.G.), Veterinary Surgeon (V.S.), and others which can be found under the title ABBREVIATIONS. The United States Commissioner of Education reports yearly on the degrees granted by institutions, and the catalogues of the institutions will give the conditions attaching to the bestowal of degrees. Consult Paul Monroe (ed.), "Cyclopedia of Education" (article "Degrees", 1911).

ACADEMIC LEGION, an insurrectionary corps of armed students who made themselves conspicuous at Vienna in 1848.

ACADEMICS, a name given to a series of philosophers who taught in the Athenian Academy, the scene of Plato's discourses. They are commonly divided into three sects: (1) The Old Academy, of which Plato was the immediate founder, was represented successively by Speusippus, Xenocrates and Polemon. (2) To them succeeded Arcesilas, the founder of the Middle Academy. Under his hands the Platonic method assumed an almost exclusively polemical character. His main object was to refute the Stoics, who maintained a doctrine of perception identical with that promulgated by Dr. Reid in the 18th century. Socrates is said to have professed that all he knew was that he knew nothing. Arcesilas denied that he knew even this. Wisdom he made to consist in absolute suspension of assent; virtue, in the probable estimate of consequences. He was succeeded by his disciples Academicus of Charmides, the third and last of the new academicians, appears to have been little more than a teacher of rhetoric.

ACADÉMIE DES BEAUX ARTS, ak-ad-ã-mé dà bô zar. See Academy of Fine Arts.

ACADEMIES IN AMERICA. In the United States the term academy is not generally applied, as in Europe, to learned societies. The oldest association of the academic type in the United States originated with Benjamin Franklin, who published "A Proposal for Promoting Useful Knowledge Among the British Plantations in America" in 1743. This resulted in the organization the same year of the American Philosophical Society. Held at Philadelphia for Promoting Useful Knowledge. Franklin was its first secretary, and from 1760 until his death in 1790 was its president. Its Transactions were first published in 1771, and its Proceedings in 1838. It numbers over 500 members and holds an annual general meeting. The American Academy of Arts and
Sciences was founded at Boston in 1780, and dealing largely with the antiquities and natural history of America, has published several volumes of Transactions dating from 1785. The Connecticut Academy of Arts and Sciences was founded in 1799. The Academy of Natural Sciences of Philadelphia was founded in 1818 and is a flourishing institution with a fine museum and library. The New York Academy of Science, originally known as the Lyceum of Natural History, was founded in 1818 and received its present title in 1875. The American Association for the Advancement of Science, first organized in 1840 as the American Association of Geologists, now has a membership of over 8,000. The National Academy of Sciences was chartered by Congress in 1863 to investigate and report on scientific questions. Originally limited to 50 members, the number was extended to 150 in 1907. The most important of the national organizations of academic character is the Smithsonian Institution (q.v.) at Washington. The Washington Academy of Sciences, amalgamating several scientific societies of the National capital, was incorporated in 1898. The American Academy of Political and Social Science of Philadelphia, and the Academy of Political Science of New York (Columbia University), are important institutions. Academies of medicine flourish in New York, Philadelphia (established 1799), Cincinnati and Cleveland, an academy of science in St. Louis, and in 1898 the American Academy of Arts and Letters was founded in New York. The Pennsylvania Academy of Fine Arts, famous for its annual exhibitions, was founded in 1807, and the National Academy of Design, in New York, in 1828.

Of scholastic institutions, the earliest was The Academy and College of Philadelphia, founded in 1749 by Benjamin Franklin, chartered in 1753, and in 1779 incorporated as the University of Pennsylvania. Other early schools of this type were the John Phillips academies, established at Andover, Mass., and at Exeter, N. H., and the term is also used in the well-known title of The United States Military Academy at West Point, for the promotion of learning from Cordoba to Samarkand. At the instigation of David of Alcuin, Charlemagne established an academy in his palace in 782, where men of learning were encouraged to assemble. Cesar Bardas founded, at Constantinople in the 9th century, a school for the promotion of science. Near the end of the 13th and the beginning of the 14th centuries, institutions of this kind, chiefly devoted to the cultivation of poetry, were established at Florence, Palermo and Toulouse, and were associated with the universities as seats of learning, culture and intellectual development. Academies of fine arts were established in Florence by Brunetto Latini in 1270, and by Frederick II, at Palermo, in 1300. In 1380 an academy of architecture was established in Milan. One of the most celebrated academies of mediaeval times, still surviving after a diversified history, is the Academie des Jeux Floraux (Academy of Floral Games), inaugurated May 1323 by a guild of troubadours; it was founded in 1500 through the munificence of Clemence Isaure, a wealthy lady of Toulouse; was incorporated by letters patent of Louis XIV in 1694, and reorganized in 1773; the
original name was 'College du gai savoir et de la gai science' (College of Gay Knowledge and of Gay Science). After the downfall of the Byzantine empire in the 15th century, and the revival of classical culture in Western Europe, academies of a more comprehensive kind were established in Italy. Antonio Bacadella founded, at Palermo, in 1433 the Accademia Pontaniana, so named after Pontania, its principal benefactor. Alfonso V founded an academy at Naples in 1440. From 1474 to 1526 the Accademia dei Lincei was in existence. The Academia de' Medici, founded by Lorenzo de' Medici, flourished in Florence. Devoted to the study of Plato and Dante, and to the improvement of the Italian language and letters, it numbered Machiavelli, Mirandola and other famous men among its members and became the model for many other similar institutions. Assuming peculiar names, and endowed by wealthy patrons of learning, or by the state, these academies were centres of literary activity for those members of the Italian nobility devoted to partisan reasons from political life. The Lincei flourished at Rome; the Arendti at Naples; the Insensati at Parma; the Addornamenti at Genoa. The academies of the Vagabonds, the Thunderers, the Smokers, of the New Men, the Unstable, the Confused, were to be found in other towns. The Accademia de' Lincei (the lynx-eyed), founded at Rome in 1609 by Prince Federico Cesi, and dissolved at his death in 1632, numbered Galileo among its members. It succeeded the Accademia Secretorum Naturae, established at Naples in 1560 for the study of physical science, which was soon suppressed by the Church. In 1725 Jakobis published at Leipzig an account of over 600 Italian academies. The most influential and enduring of all was the Accademia della Crusca, i.e., chaff, so called in allusion to its principal aim, that of winnowing and purifying the national language. It was founded by the poet Grazzini at Florence in 1582. The dictionary of the Accademia della Crusca, first published in 1612, and subsequently, in augmented form, is considered the standard authority for the Italian language. This academy, incorporated with two older societies, survives as the Royal Italian Academy of Turin, and is regarded as the mother country of modern academies, probably the most celebrated and important of all is the French Academy, founded in 1635 (see INSTITUTE OF FRANCE, THE). An Academia Secretorum Naturae was founded in Madrid in 1652, and the Spanish Royal Academy in 1714. An academy of Portuguese history was established at Lisbon in 1720 by King John V, and a flourishing academy of science, agriculture, arts, commerce and general economy, by Queen Maria in 1779. In Germany the Royal Academy of Sciences and Belles-lettres was established by the Elector Frederick at Berlin in 1700. In Sweden the Royal Academy of Sciences was founded at Stockholm by six scientists, including Linnaeus, in 1739. In Holland the Academia Lugduno-Batava was established at Leyden in 1766. In Belgium the Academie Royale des sciences, des lettres et des beaux-arts was founded at Brussels by Maria Theresa in 1772. In Bordeaux an academy of medicine was founded at Geneva in 1715. In Russia The Imperial Academy of Sciences was founded at St. Peters burg in 1725. In England an academy, first suggested as "King James, His Academe, or College of Honor," then as "The British Academy," was finally chartered as the Royal Society (q.v.) in 1662. The term academy in Great Britain is now reserved for institutions devoted to the cultivation of the fine arts and for schools of higher instruction. In Ireland the Royal Irish Academy was founded at Dublin in 1782. See also ACADEMIES IN AMERICA, and for a record of modern academies consult Kulkula, R., Platoanica. founded by K. Minerva: Jahrbuch der Gelehrten Welt" (Strassburg 1914); Steeves, H. R., 'Learned Societies and English Literary Scholarship in Great Britain and the United States' (New York 1913).

ACADEMY OF ARTS, The Royal. See ROYAL ACADEMY OF ARTS, THE.

ACADEMY OF ARTS AND LETTERS, an American institution founded in 1888 by the American Social Science Association. At its annual meeting that year the Association elected a select group of American authors and artists, who should constitute a National Institute of Arts and Letters. Membership was to be based on distinguished achievement in art, literature or music. At first the body was limited to a membership of 150, then increased to 250. This body then proceeded to organize an Academy of Arts and Letters, the members of which were, to be recruited from the general membership of the Institute. The first seven members were elected in 1904: William Dean Howells, Augustus Saint Gaudens, Edmund Clarence Stedman, John La Farge, Samuel Langhorne Clemens (Mark Twain), John Hay and Edward A. MacDowell. These were empowered to elect additional members, each new member being given a vote, until the whole body of 50 had been organized. The living members of the Academy in 1915 were: William Dean Howells, Theodore Roosevelt, John Singer Sargent, Daniel Chester French, John Burroughs, James Ford Rhodes, Horatio William Parker, William Milligan Sloane, Robert Underwood Johnson, George Washington Cable, Andrew Dickson White, Henry Van Dyke, William Crary Brownell, Basil Lanneau Gildersleeve, Woodrow Wilson, Arthur Twining Hadley, Henry Cabot Lodge, Edwin Howland Blissfield, Thomas Hastings, Brander Matthews, Thomas Nelson Page, Elihu Vedder, George Edward Woodberry, Kenyon Cox, George Whitefield Chadwick, Abbott Henderson Thayer, Henry Mills Alden, George deForest Brush, William Rutherford Mead, Bliss Perry, Abbott Lawrence Lowell, Nicholas Murray Butler, Paul Wayland Bartlett, Owen Wister, Herbert Adams, Augustus Thomas, Timothy Cole, Cass Gilbert, William Roscoe Thayer, Robert Grant, Frederick MacMonnies, Julian Alden Weir, William Gillette and Paul Elmer More.

ACADEMY OF DESIGN, National. See NATIONAL ACADEMY OF DESIGN.
ACADEMY OF FINE ARTS, The, a French institution, originally founded in 1648 at Paris under the name of the Academy of Painting and Sculpture. In 1795 it was joined to the Academy of Architecture and has borne its present name since 1819. It publishes memoirs, proceedings and a dictionary of fine arts. It has 1,41 members, besides corresponding members, etc.

ACADEMY OF FINE ARTS, Imperial Russian, was first established in a primitive form by the great Emperor Peter I, who, realizing the civilizing power of such institutions, invited to St. Petersburg notable artists in all branches for the purpose of training young Russian aspirants in the arts, or sent abroad those who desired to perfect themselves in painting and sculpture. In 1667 it was only Empress Catherine II, who, in establishing the Imperial Russian Academy of Science (q.v.), introduced into that institution the teaching of painting and sculpture from other and more progressive countries. While it was unable to produce at once great masters, it certainly succeeded in propagating the history of fine arts and in securing a few remarkable reproductions from French, Italian, Spanish and German masters, thus acquainting the Russian public with the aesthetic necessities. Emperor Elisabeth Petrovna went a step further by separating the School of Fine Arts from the Academy of Science, which act was amplified by Shuvalov, who submitted to the Empress plans for the establishment at the Moscow University of a Faculty of Fine Arts. However, as the court and the Russian aristocracy lived at St. Petersburg, it was definitely decided by the Senate (1757) to establish the Academy of Fine Arts (Akademia Hudozhestv) in that capital, and a sum of 6,000 roubles was appropriated to that effect. Professors of painting and sculpture were mostly French, but it was Russian Shevankin, to whom the chair of architecture was first entrusted and who secured permission from the Empress to move from her palace to the Academy from the finest paintings, which constituted the first picture gallery in that institution. But the small appropriation of 6,000 roubles was soon exceeded and the deficit was repaired by Shuvalov from his private purse. Shuvalov directed the Academy most successfully for six years and, after the death of Empress Elisabeth, he retired and for the following 30 years the Academy was entrusted to the care of Betzki, who secured a constitution and a charter of rights and privileges. Under the direction of Kokorinov the first public exposition of the Academy took place in 1765 to the marvel of the visitors. In 1812 the Academy was placed under the Ministry of Public Education whereby the financial state of the institution was greatly improved. The president of the Academy, A. L. Olenin, in order to check the rising criticism of the administration, published a short history of the Academy embracing the period from 1764 to 1829, which showed a crying inadequacy of the administration and caused the Academy to be transferred to the Ministry of the Imperial Court. Under this new protectorate the Academy prospered considerably; the budget was increased, a greater number of students were sent abroad (especially to Rome) and a new constitution was granted (30 Aug. 1859) where by the program of education was radically changed. The yearly budget was increased to 72,626 roubles and, besides the duty of preparing and training the students of art, the Academy now began to organize, at regular intervals, public expositions, and an art museum was also established. The complete course of study in either of the two divisions of the Academy (painting-sculpture and architecture) lasts five years and the number of students in the last decade varied from 500 to 1,000, of which number about 10 per cent were women.

W. M. Petrovitch, Chief of the Slavonic Division, New York Public Library.

ACADEMY OF FRANCE AT ROME, an institution for the advanced study of the fine arts in Rome, Italy; founded by Colbert in 1666, during the reign of Louis XIV. It was at first established in the Palais Mancini on the Corso, and in 1803 at the villa Medici. The young artists, painters, sculptors, architects, engravers and musicians who secure the annual prizes of the Academy of Fine Arts in Rome spend four years, and are provided with an annual pension of 3,500 francs and traveling expenses.

ACADEMY OF INSCRIPTIONS AND BELLES-LETTRES, an institution founded at Paris by Colbert in 1663, under the name of Petite Académie. It was composed originally of four members, chosen by the ministry to belong to the Académie Française. The first members, Chaplain, Charpentier, the Abbé de Bourziers and the Abbé Cassagne, met in a salon of the Louvre or in Colbert's library and devoted themselves to composing the inscriptions for the monuments erected by Louis XIV and the medals struck in his honor; hence their popular name. They undertook a medallic history of the reign of the King. In 1701 the Academy assumed its definitive form; 40 academicians were named. In 1803 the Academy was reconstituted and became the third class of the Institute. Comparative philology, Oriental, Greek and Roman antiquities and epigraphy have received the attention of the Academy, which has published a series of invaluable records and works.

ACADEMY OF MEDICINE, a French institution founded in Paris in 1820 for the purpose of keeping the government informed on all subjects appertaining to the public health. It has sections of medicine, surgery and pharmacy and its publications are highly prized by sanitarists.

ACADEMY OF MORAL AND POLITICAL SCIENCE, founded at Paris in 1795, became the second class of the Institute. It was suppressed by Napoleon in 1803 but was re-established by Louis Philippe in 1832 and forms the fifth class of the Institute. It is composed of 30 members, divided into five sections with five free academicians, five foreign associates and 30 corresponding members.

ACADEMY OF NATURAL SCIENCES OF PHILADELPHIA, an institution founded in 1812. It has one of the best natural-history collections in this country—especially rich in stuffed birds—and a valuable scientific library. It has published 'Journals' since 1817, and 'Proceedings' since 1841.
ACADEMY OF POLITICAL AND SOCIAL SCIENCE — ACADEMY OF SCIENCE

ACADEMY OF POLITICAL AND SOCIAL SCIENCE, American. See AMERICAN ACADEMY OF POLITICAL AND SOCIAL SCIENCE.

ACADEMY OF SCIENCES, an institution founded at Paris in 1666 by Colbert and approved by Louis XIV in 1669. It published about 130 volumes of memoirs from 1666 to 1793, when it was suppressed. It was re-established in 1816. It has now 66 ordinary and 10 honorary members in 11 sections, with three perpetual secretaries, eight foreign associates and 106 corresponding members. Its prizes include an annual sum of 3,000 francs, given alternately for the best essay on a subject in mathematics and physics; the Montyon prizes, six in number and valued at 45,000 francs annually, the Laland prize for astronomy, awarded annually, and several others. The Academy meets annually in December and publishes Mémoires.

ACADEMY OF SCIENCE, Imperial Russian. Animated by a desire to develop Russian science to the degree of complete individuality and independence, the great reformer Emperor Peter I united all the most learned men and scientific researchers into one group which he called Akademiya Nauk (i.e., Academy of Sciences), the technical realization of which was entrusted to his imperial physician, Professor Blumentrost. It was in 1724 that Peter the Great definitely approved the plan of Professor Blumentrost whereby the Academy was constituted in three principal parts: mathematics, natural sciences, and history with jurisprudence. Blumentrost was commissioned to invite to St. Petersburg not only Russian scientists but also a great number of foreigners which order he executed with the aid of Professor Wolf who had previously maintained an active correspondence with the Emperor. For the maintenance of the Academy Peter appropriated an annual sum of about 25,000 roubles and also presented that institution with his own library and art gallery. But Peter did not live to see the solemn inauguration of the Academy; that honor fell to the portion of Empress Catharine, which took place on 1 Aug. 1728, notwithstanding the fact that the constitution of the Academy was prepared previously and the first assembly of the members met in December 1725. The first president of the Academy was Blumentrost. When Peter II came to the throne certain members of the Academy were appointed to direct his education, but when the Emperor went to Moscow together with Blumentrost the directorship of the Academy was entrusted to the librarian, Schulmacher, who was a selfish and half-learned man with great power and who soon became most unpopular with the members of the Academy. Many of the most learned members resigned their posts, not being able to endure the interference with their scientific research of a director like Schulmacher. Among the learned members who left St. Petersburg were Professor Eiler and the astronomer de la Crus, who had spent 22 years in making astronomical researches in Siberia and whom Schulmacher charged with the theft of Russian state documents; the celebrated author of the history of Siberia, Gerard Friedrick Miller, and others. During the reign of Anna Ioanovna, Schulmacher's power increased all the more as he enjoyed the protectorate of Blumentrost, after whom the presidency was given over to Keiserling, who tried to curtail Schulmacher's power, but presided only a year and was succeeded by Korf who was friendly with Schulmacher. However he improved the finances of the Academy and established in it a department of geography, publishing also in 1739 the first scientific atlas of Russia. In 1740 the presidency was transferred to Bre vern who added to the Academy the library and the numismatic collection of Volynski. Finally the academicians lost their patience with Schulmacher and presented to the Senate a collective complaint against him. As Elisabeth Petrovna was not fond of the Germans and the investigations proved beyond doubt Schulmacher's misdeeds, he was arrested and the directorship passed over to Nartov, a favorite of Peter I, who immediately discovered some wholesome transactions of Schulmacher that were threatening the Academy with complete financial ruin. He asked and obtained from the Senate a new appropriation to repair the situation. Nevertheless Schulmacher, though not honorable, device proved his innocence, the complaint against him was set aside and he reoccupied his old position. When Lomonosov returned from abroad and the presidency passed over to Count K. G. Razumovski, the controversy started afresh and Lomonosov's plan to add a University to the Academy was ignored. In 1745 regulations were adopted in accordance with which there were 10 members to be appointed by the state and as many honorary ones. Soon afterward a fire broke out in the archives of the Academy and Schulmacher was suspected of being the incendiary. The administrative authority Catharine II granted to the new director of the Academy, Count G. Orlov (1766–74), who in turn was succeeded by Domoshnev (1774–82), who in turn was dismissed on account of disorders caused by him. In his stead was appointed Princess E. R. Dashkova (1782–94), a talented writer and follower of Lomonosov. She delivered a number of lectures in the Academy in Russian and translated into the native idiom the principal masterpieces of foreign literature. It was during her administration that the Academy started publishing Akademicheskiya Izvyestia (Academic Reports), 'Noviya yeshcheyeyo osobennosti sochineniya' (New monthly compositions), etc. But she was unable to agree with President Nikolay, who was succeeded by Novosiltzev (1803–10). This president issued new regulations increasing the number of the staff to 18 members and 20 assistants and organizing separate sections for history, statistics, political economy and Oriental languages. After Novosiltzev the office of the presidency was held for 37 years by S. S. Uvarov, who further increased the number of members to 21 and reduced that of assistants to 10. He also furnished research work in the fields of ethnography, history and statistics. After the death of Uvarov the presidency was given to Bludov (1847–64) who made many important investigations in the field of Russian philology. He was succeeded by the celebrated explorer, Admiral Likh. The Academy of Science consists of three parts: (1) physics and mathematics; (2) Russian language;
(3) history, political science and philology. Its annual budget amounts to over 500,000 roubles.

ACADIA (Micmac, "plenty"), the original name of Nova Scotia (q.v.).

ACADIA UNIVERSITY, Canada, at Wolfville, Nova Scotia, was founded in 1838 as Acadia College, its act of incorporation conferring the powers of a university, which were confirmed by an Act of 1891, creating a new corporation under the name of the *Governors of Acadia University.* They were invested with complete control over Acadia College and also over Horton Academy for boys and the Acadia Seminary for girls. The University grants degrees in theology, and the degrees of bachelor, master and doctor in the several arts, sciences and faculties. The governors are appointed by the Baptist Convention of Nova Scotia, but no religious tests are required of the faculty or students. The institution is coeducational.

ACADIALITE, a name given to chabazite (q.v.) from Nova Scotia (Acadia). Its color is usually salmon to flesh-red.

ACAJUTLA, a-k-a-hoot’la, Salvador, Central America; its second port in importance, exporting coffee and sugar, and the seat of a United States consular agent, 65 miles by rail from San Salvador, the capital.

ACANTHOPTERYGII, a sub-order of teleost fishes, the most comprehensive in the whole class. Its most prominent distinguishing feature is "the presence of non-articulated, more or less pungent, rays in the dorsal and anal fins." It embraces about 75 families of typical bony fishes, including almost all those taken for sport or food from the sea, except of the cod and herring tribes and a few freshwater forms.

ACANTHUS, the typical genus of the family Acanthaceae, or acanthads, a family of monopetalous exogens, consisting of herbaceous plants or shrubs, found chiefly in the tropics, where they often form a large part of the weedy herbage. Acanthus is a native of many parts of southern Europe. The family is represented in America by a few wild-growing species; but they are best known as tender garden plants. The best-known species of the genuine acanthus (or branches, as they were formerly called by a euphemism for the still older "bear's-breech"), are A. mollis and A. spinosus. The former has a stem about two feet high, surrounded in its lower half with large, soft, shining, hairily and deeply indented leaves, and covered from the middle to the top with large white flowers tinged with yellow. See Acanthus in Art.

ACANTHUS IN ART. There are several varieties of the acanthus plant. The two which find expression in art are the acanthus spinosus and acanthus mollis, the former having leaves of sharply pointed indentation, the latter having wider, blunter points. Of all the art motifs taken from plant life the acanthus has for many centuries been the most prolifically utilized. Its graceful foliage adapts itself, when

[Diagrams of Acanthus leaves]
ACCAD — ACCELEROGRAPHS

smith, the ironworker, the brass trade artisan; in woodwork the acanthus ornamentation is found universally in furniture and mural decorations. The ancient Greeks greatly favored this motif and the Romans quickly adopted the device in their art. In the East, also, the use of its decorative value was soon appreciated—in Byzantine it predominates. As in the above plastic arts, so in the graphic, where it is still in very great favor. Most art motifs take on a life of their own as well as the fauna dominate, owe some of their appreciation to the fact that they carry with them some reference to symbolism, but the acanthus has no symbolic value whatever.

The actual acanthus leaf is a perpendicular growth, but in the arts it is subjected to curves and convolutions not conforming to nature. The acanthus motif of the Greeks is the spinesus variety, while that adopted by the Romans was the mollis. Throughout the evolution of the various decorative arts the acanthus continues favored by the period styles. We find it taken up, of course, in the Renaissance when it revived the classic forms; the Romanesque utilized it, as did the Gothic. Its delicate scroll decorative approach art of Louis XIV, XV and XVI, though with specialized conventional formations which, to some extent, render these periods separately recognizable.

ACCAD or AKKAD, Babylonia, a royal city of Shinar which gave its name to northern Babylonia, as distinguished from Sumer or southern Babylonia. It is the Akkad mentioned in Genesis x, 10, identified with Agade the capital of Sargon and of Naram Sin, still flourishing in the days of Nebuchadnezzar, about 1100 years B.C. The Kings of Accad were dethroned in Sinaï and in Cyprus, 3800 B.C. The exact site of the city is unknown, although it was near Sippa, about 30 miles north of Babylon. It is surmised that it was the oldest quarter of Sippa, on the opposite bank of the Euphrates, identified by monuments excavated in 1881 with the modern Abu Habba. Consult King, H., 'A History of Sumer and Akkad' (London 1910).

ACAROID RESIN, or GUM, a resin which exudes so abundantly from the grass trees (Xanthorrhoea) of Australia as to cover the base of the leaves and the underground portions of the plants, and is also obtained by crushing and sifting or washing, as much as 50 or 60 pounds being obtained from one plant. Two kinds, red and yellow, are generally distinguished, and are used in varnishes as well as for several other purposes.

ACARUS, a genus of insects of the tribe Acaridae order, Arachnida. They are oviparous, have eight legs, two eyes and two jointed tentacula, and are very prolific. All the species are extremely minute, or even microscopic, as the cheese-mite (Acarus domesticus), and many of them parasitic; of the latter, the itch-insect (Sarcoptes scabiei) is a remarkable example. It is a microscopic animal found under the human skin in the pustules of a well-known cutaneous disease. Many others infect the skin of different animals, such as dogs, hogs and cattle and sometimes in considerable numbers. In some instances they damage cow-hides. (See MITES). Acarus folliculorum is a microscopic parasite of the hair follicles of the skin. It is the lowest form of mite, and is known also as Demodec folliculorum. See BLACKHEAD.

ACCELERATION, the rate of change of the velocity of a body. If the velocity of the body is constant, its acceleration is said to be zero. If the velocity increases uniformly, then that at the end of every second it is greater than it was at the end of a preceding second by a constant amount, the acceleration is said to be uniform, and the motion is said to be uniformly accelerated. If the velocity is decreasing, the acceleration is said to be negative. A body falling freely under the influence of gravity affords the most familiar example of uniform (or constant) acceleration. When the body falls in air or any other medium, the phenomena are complicated by the resistance of the medium; but when it falls in a vacuum its velocity increases every second by the same constant amount. Thus if the body starts from rest, it will have a velocity of 32.2 feet per second at the end of the first second, 64.4 feet per second at the end of the second second, 96.6 feet per second at the end of the third second and so on. The acceleration produced by gravity is therefore said to be 32.2 feet per second each second; but this varies somewhat with the latitude and the height above the sea. (See FORCE or GRAVITY.) The acceleration experienced under given circumstances is proportional to the force acting upon the body in the direction in which its motion is accelerated. Thus if the foregoing experiment with a falling body were tried upon some other planet, and we found that the velocity of the falling body was increased by 322.0 feet per second every second (instead of 32.2 feet), we should know that the force of gravitation at the surface of that planet is precisely 10 times as great as it is upon the surface of the earth. In physics and theoretical mechanics a force is always measured by the acceleration it produces when exerted upon a unit mass. For a further account of the relation between force, mass and acceleration, also see FORCE.

ACCELEROGRAPHS, devices or attachments for measuring the succession of pressure developed in a given point of a powder chamber by the combustion of a charge of powder either enclosed in a vessel or placed in the bore of a gun and acting on the projectile. The first accelerographs were experimented on in 1873 in Paris, for the study of combustion in a close vessel; afterward, in 1874, on the proving ground of the Nevers foundry for the study of combustion in guns. Since that time various improvements have been successively made in the mode of construction and in the manner of employment. The accelerographs thus modified were employed in numerous experiments, both at the laboratory of the central depot for powder and saltpetrs, and at the proving ground of the Sèvres-Livry powder works to the advantage of testing both the ingredients and the powder manufactured for the navy. In these trials they proved convenient for handling and also practical, and they furnished some valuable observations on the law of combustion of powder charges, and on that of the development of the pressure resulting therefrom both in close vessels and in guns of various calibres. Also by a slight modification of
ACCELEROMETER — ACCENT

the accelerograph, employed for measuring the pressures developed in the firing of guns, this apparatus can be utilized for determining simultaneously the law of the pressures developed in the bore and the law of the recoil of the gun. The accelerographs in question were of the types called slide accelerographs, in which the law of the movement of the piston, subjected to the action of the powder gases, is deduced from the known movement of a style-bearing slide displacing itself in a direction normal to that of the piston. More recently there has been a return to the employment of accelerographs, in which the movement of the piston is deduced from the tracing of the vibrating fork. Finally, from the commencement of the experiments on accelerographs, trial was made conjointly of apparatus called accelerometers, based on the same principle, but which indicated at each experiment only one isolated value of the pressure developed by the powder corresponding to an arbitrary subdivision of the duration of combustion of the charge. These, which require the repetition of identical experiments for determining perfectly the law of the development of the pressures produced by the combustion of a charge of powder placed in certain definite conditions, have been applied to the study of the combustion of powder in a closed vessel, as well as to the study of the pressure developed in the bore of the gun. But they have been more especially employed in this latter case by placing them in front of the initial site of the projectile for measuring the pressure existing against the "sabot" of this latter at the same moment when it attains a definite point of its passage in the bore, because one single experiment with this apparatus suffices to show the value sought. Accelerographs present different arrangements, according as they are intended to be mounted on fixed receptacles for the study of the combustion of powder in a closed vessel, or as it is proposed to mount them on guns; two principal types have been established, the one denominated weight accelerometers and the other spring accelerometers. Fork accelerometers have also been employed for increasing the precision obtained.

The Slide-accelerograph used for studying the combustion of powder in a closed vessel is arranged in such a manner as to indicate the law of the movement of a piston, of known section and weight, bedded in a groove cut normally in the sides of the powder chamber and subjected freely, on its base, to the action of the gases produced by the combustion of the charge. The apparatus registers the spaces passed by the piston each instant during the combustion and these passages can be exactly measured by very small and regularly divided intervals of time.

The Slide-accelerograph, employed for studying the combustion of powder in guns, has the piston lodged in a steel bushing like those that are designed for the apparatus called crushers employed also for estimating the pressures produced by the combustion of powder. The bushing is screwed into a hole pierced in the sides of the gun, normal to the bore, at a point chosen for the purpose, and is terminated on the outside in a threaded head on which is screwed the frame which serves as a guide for the cube designed to receive the table and as a support for the stylus-bearing slide. The only difference in signalling with the powder-mill apparatus is the arrangement placing the additional weight of the piston, without there being room, in order to increase, as occasion requires, the duration of the unobstructed stroke of the piston and to prolong it so as to continue the movement during an interval equal to that of the passage of the projectile in the bore. See BALLISTICS; CHRONOGRAPH.

ACCELEROMETER. An apparatus for measuring the velocity imparted by gunpowder. It shows, by direct registry, the law of the movement in the function of time of a piston subjected to the action of powder-gases. An additional weight placed on this piston in such a manner that it may be thrown vertically without obstacle, when this latter is suddenly stopped, can show, by a single observation, the velocity acquired by the piston up to the end of its stroke. In fact, this weight, thrown freely and preserving the velocity which it had in common with the piston, will be raised to a height, \( h \), given by the relation \( \frac{r^2}{2gh} \), so that the observation of the height of the vertical stroke \( h \) will show the velocity \( v \). If it is admitted that the phenomena of the combustion of the powder are reproduced identically in the like conditions, and if a series of determinations are effected with a constant charge, but varying the stroke each time, it is evident that the observation of the corresponding heights of throw of the additional weight supported by the piston would show the progressive velocities acquired by this piston according to the gradually diminishing paths. We could then determine, by this simple process, and without a special chronometric organ, but on condition of repeating the experiments, the law of movement imparted to the piston. See ACCELEROGRAHS.

ACCENT, the stress or emphasis given by the voice to a certain syllable or syllables of a word, or to certain notes in a bar of music; also, the peculiar intonation of one spoken language when compared with another; further, marks used in printing or writing to show the position of the stress. In a disyllable there is but one accent, as a back, but in a polysyllable there may be more than one. One of these, however, is always greater than the rest and is called the primary accent; the others are called secondary.

Two wholly distinct classes of accent are found in Aryan languages, the musical and the expiratory; the former, which is that of some Semitic tongues also, being that of Greek and Sanskrit, the latter that of Latin and Teutonic. Some languages, as French, have no accent, the stress on all syllables being the same, but even here the stopping of the voice gives the final syllable a slight tilt upwards, with the effect of an accent on that syllable. Accent may be free, as in Greek or old Teutonic,—that is, its position in a word may shift in accordance with the nature of the syllables or of the words which follow,—or fixed, as in later Teutonic and English: perhaps the only remnant of the free accent in English is the word the most which, though often spelled as two words, is really a compound word with an accent shifting according to emotion. By a change of stress we often indicate the change of an adjective or a noun.
into a verb, as fre'quent (adj.), frequen't (verb); pro'ect (noun), project' (verb).

In compound words the accent is commonly on the first; but when the first element is a prefix, separable or inseparable, it is accentuated only when the root-word is noun or adjective, the root receiving the accent if it is a verb;—this of course not applying to words borrowed from other languages, for which there is no settled rule, the chance of first usage commonly determining it. The inflections have almost always been left unaccented, and this has aided greatly to the writing (Acts 2:43; 15:10; Acts 20:20) of an inflectional system in modern languages: even where retained to the eye they are often not pronounced at all, as in French.

There is a certain analogy between accent and emphasis, emphasis doing for whole words or clauses of sentences what accent does for single syllables. One result of this has been to develop duplicate words with different meanings, as of and off, to and too, through and thorough (originally pronounced tho-roo). All mean root words depend on stress-accent (see MÁTRES); while that of classical Greek and Latin, as of some Semitic tongues still, rested on quantity or length of syllables,—a system not easy for those reared on stress to comprehend, much less imitate.

Marks of Accents.—In ancient Greek, accents marked the rise and fall in pitch of the voice, and were three in number, the acute (á), the grave (á) and the circumflex (ā or à). The same marks are now used in French, and the first two in Italian, though they are largely of historical or etymological interest only, and do not always indicate a difference in pronunciation. A mark similar to the acute accent is sometimes used to signify stress in English words, chiefly in poetry; and one like the grave is used to mark a separate syllable letters otherwise not pronounced so, for example, learned, abhorred. Marks sometimes called accents are used in mathematics; for example, \(a + b\) (read a prime plus b prime). In geometry, a circle at the right of a figure indicates degrees, one mark minutes, two marks seconds of a degree, as 13° 4′ 5″. In mensuration and engineering, the mark denotes feet, inches and lines, as 4′ 6″ 10″.

In Music.—The greater emphasis or intensity given to certain notes or passages, as distinguished from their length in time and their quality or timbre. It is divided into three classes,—grammatical, rhythmical and rhetorical or aesthetic. The grammatical accent is almost always on the first part of a bar; long measures have usually secondary ones, as have polysyllables in words. Rhythmic accent is the more pronounced character given to certain parts of larger compositions,—phrases, themes, motifs,—to mark off entrances, finales or climaxes. Rhetorical accent corresponds strictly to the same emphasis in oratory, in accordance with emotion or a desired effect, and is at the will of the performer.

ACCENTOR ("singer-together"), a literary name for the American water-thrushes (genus Stúrus) and the European warblers, of which the British hedge-sparrow (incorrectly named) is best known.

ACCEPTANCE, an act by which one agrees to be bound by the terms of a bill of exchange. To render a bill of exchange so valid that, if the drawee fails to liquidate it, the drawer may be charged with costs, the promise of the drawer should be in writing under or upon the back of the bill. An acceptance may be made before the bill is drawn, in which case it must be written (15 Johns. N. Y. 6). It may be made after it is drawn and before it becomes due, which is the usual course, or after it becomes due (1 H. Blackst. 313), or even after a previous refusal to accept. The proper form for the acceptance of a bill is to write the word "Accepted" across the face of the bill and sign the acceptor's name, but the drawee's name alone is sufficient or any words of equivalent force to "accepted." Bylles on Bills, 147; 21 Pick. (Mass.) 307. See BILL; BANKS AND BANKING—COMMERCIAL PAPER (Article 17).

ACCESS, (1) admission of a husband to intercourse or opportunity of intercourse with his wife. The mere fact that husband and wife live apart creates no presumption of non-access. The issue of the wife, in the absence of direct proof to the contrary, are presumed to be his issue. Except when modified by statute or custom, parties are not permitted to prove non-access in order to show illegitimacy of the wife's issue, either in civil or criminal actions. (2) Admission of an owner of adjoining land to a public road or a public navigable stream. See Access, RIGHT OR OF: (3) Admission of parents to children having a court as guardian.

ACCESS, Right of. The owner of land adjoining a road or public highway is entitled to access to such highway at any point where it comes up to his land. He may also have an action for the removal, by injunction, of any obstruction to such access, as well as an action for damages. It has been expressly held also that an abutting owner has a property right in the use of the street in front of his land as a means of egress and ingress, and for light and air. (47 N. J. Eq. 421; 106 N. Y. 157). If a man buys a lot of land from which there is no access to a public highway, upon application to the proper authorities he may obtain an order for the construction of a road or highway leading from his land to a public highway. See also RIGHT OF WAY.

ACCESSION is the right to all which a man's own property produces, and the right to that which is united to it by accession either naturally or artificially (2 Kent Comm. 360). If a man builds a house upon his own grounds with the materials of another, or, on the contrary, if a man shall have built a house with his own materials upon the ground of another, in either case the house becomes the property of him to whom the land belongs, for every building is an accession to the ground upon which it stands, and the owner of the land, if liable at all, is only liable to the owner of the materials for the value of them (2 Kent Comm. 362). The same rule holds where vines, trees, fruits and vegetation are planted or sown in the ground of another.

ACCESSORY, in law, one who is not the chief actor in an offense or present at its commission, but still is connected with it in some other way. Accessories may become so before the fact or after the fact. Sir Matthew Hale defines an accessory before the fact as one who, being absent at the time of the crime committed,
ACCHO—ACCIDENT INSURANCE

does yet procure, counsel or command another to commit a crime. If the procurer be present when the evil deed is being done, he is not an accessory, but a principal. An accessory after the fact is one who, knowing a felony to have been committed, receives, relieves, comforts or assists the felon. In high treason of a pronounced character there are no accessories at all are principals. In petit treason, murder and felonies, there may be accessories; except only in those offenses which, by judgment of law, are sudden and unpremeditated, as manslaughter and the like, which, therefore, cannot have any accessories before the fact. So, too, in petit larceny and in all crimes under the degree of felony, there are no accessories either before or after the fact; but all persons concerned therein, if guilty at all, are principals (Blackst. Comm., bk. iv, ch. iii). Presence and actual participation are necessary to constitute a person an accessory. The mere fact of presence or failure to interfere to prevent the commission of a crime is not, alone, an indictable offense. The person must act in concert with the principal party. He must be privy with him and be accessory to the felonious purpose. Presence need not be actual, it may be constructive. A man may commit a crime through the agency of an innocent person, but the agent cannot be convicted. Where an offense is committed within a State by means of an innocent agent, the employer is guilty as a principal, although he did no act in the State where the crime was committed, and at the time of the commission of the offense was in another State. (1 N. Y. 173 (s. c. 45 Am. Dec. 408); 123 Mass. 430).

AC'CHO. See ACRE.

ACCIAIOLE, aitch-yi-o'te, Renatus, a Florentine who conquered Athens, Corinth and part of Boeotia, lived in the beginning of the 15th century. He bequeathed Athens to the Venetians, Corinth to Theodosius Palaeologus, who married his eldest daughter; and Boeotia with Thebes to his son Anthony, who also got Athens, but this was retaken in 1455 by Mohammed II.

ACCIDENT, an unforeseen occurrence, particularly if it be of a calamitous character. This is the most common use of the word.

In logic: (a) Whatever does not really constitute an essential part of a person or thing; as the clothes one wears, the saddle on a horse, etc. (b) The qualities or attributes of a person or thing, as opposed to the substance. Thus bitterness, hardness, etc., are attributes, and not part of the substance in which they inherit. (c) That which may be absent from anything, leaving its essence still unimpaired. Thus a rose might be white without its ceasing to be a rose, because color in the flowers of that genus is not essential to their character.

Accidents, in logic, are of two kinds, separable and inseparable. If walking be the accident of a particular man, it is a separable one, for he would not cease to be that man though he stood still; while, on the contrary, if football is the accident connected with him, it is an inseparable one, since he never can cease to be, ethnologically considered, what he was born (Whately's 'Logic,' bk. ii, ch. v, sec. 4).

In grammar, a property attached to a word which nevertheless does not enter into its essential definition. Each species of word has its accidents: thus those of the noun substantive are gender, declension and number. Comparison in an adjective is also an accident.

In law, an event which under the circumstances is unusual and unexpected by the person to whom it happens. It is the happening of an event without the concurrence of the will of the person by whose agency it was caused, or the happening of an event without any human agency. If a house should be burned in consequence of a fire made for the purpose of cooking, or warming the house, this would be an accident of the first kind. If the house should be set on fire by lightning, this would be an accident of the second kind. (1 Fonblanque, Eq. 374, 375 n.). The best test of liability for the consequence of an accident turns upon the fact whether the person causing the accident was guilty of negligence or not. If he was guilty of negligence he would be liable unless the person injured was guilty of contributory negligence.

In heraldry, an additional note or mark on a coat of arms which may be omitted or retained without altering its essential character.

ACCIDENT INSURANCE. A policy of accident insurance is a contract providing indemnity for loss of life, limb, sight or time, because of bodily injuries, effected solely and independently of all other causes, through external, violent and accidental means. The full principal sum of the policy is payable in case of death, loss of both hands or both feet, of one hand and one foot, or the sight of both eyes. One-half of the full principal sum is payable in case of the loss of either hand or foot or the sight of one eye. A fixed sum is payable weekly for the term of temporary disability, whether total or partial, not exceeding a certain definite period, varying from six months to two years, and frequently for the life of the insured. The premium, which is generally estimated on the annual basis, is determined by the business, occupation or profession of the applicant, and is proportioned upon the amount of the principal sum and the weekly indemnity named in the policy. Double amounts, both of the principal sum and of the weekly indemnity, are payable in case of injuries received in or on a moving conveyance, provided for the use of passengers, and propelled by steam, electric or cable power; or for injuries received in or while entering or leaving passenger elevators; or in burning buildings, or for injuries caused by falling walls; or from automobile accidents on the highway; or caused by a stroke of lightning; or by the explosion or rupture of a steam boiler; or by a cyclone or tornado.

The policy also provides for hospital treatment; for the payment for medical and surgical fees and for operations; for the payment of optional indemnity, in cases of certain named injuries, in lieu of weekly indemnity; and for annual accumulations of the principal sum and the weekly indemnity until up to 50 per cent in addition to the original sums: also for emergency indemnity to place the insured in care of friends or relatives in case of injury away from home.

Accident insurance was first introduced in this country by James Goodwin Batterson of Hartford, Conn., after his return from a trip.
to England in 1859, where he learned of accident insurance, in the form of tickets, insuring the holder for a specified sum, in case of death or injuries resulting from railway accidents. The first American accident insurance company was organized in 1863 at Hartford, and it is said that the insurance contract made by the company was a verbal agreement between the president of the company and a citizen of Hartford, whereby, in consideration of a premium of two cents, the company agreed to indemnify the insured in the sum of $5,000, in case of accident to the insured while journeying from the post-office to his home in Buckingham street.

Growth.—The growth of the business has been phenomenal since that modest beginning, as the following figures will attest: Premiums received from 1873 to 1892, $42,027,207; losses paid $18,125,771; from 1893 to 1916 premiums received $426,600,679; losses paid $183,804,575.

The above figures cover the operations of the stock insurance companies, of which there were 41 in 1916 with premiums written in that year of $43,043,546, and losses paid of $19,159,528, including health insurance in the case of some companies that do not report their accident and health premiums and losses separately. There is in addition, however, a large number of mutual accident insurance associations operating in the United States upon the assessment plan and providing to their members accident and sickness insurance at a cost much less than could be obtained from stock companies. This business has increased since 1901 from premiums or assessments received of $1,111,232 and claims paid of $715,429 to premiums or assessments of $6,937,175 and claims paid $4,834,479 in 1916, covering the operations of 56 companies.

The number of certificates in force at the close of 1901 was 146,185, while at the end of 1916 this number had increased to 769,761. The total admitted assets increased during the same period from $930,471 to $4,360,666; total liabilities from $890,930 to $2,084,630, and net surplus from $845,841 to $2,296,747.

In a word, accident insurance has assumed a leading place in insurance underwriting of the United States, and the ever-increasing competition of new companies and the activities of those now in business has resulted in the continued broadening of the policy and the granting of additional benefits. At the present time, the modern, up-to-date policy is practically conditionless and pays indemnity for life, in case of total or partial permanent disability, thereby affording to the unfortunate an annuity that may be his only source of income. Partners in business and officers in corporations take out large policies, payable to the firm or to the corporation, protecting them against loss in case of the removal by death of a valued member of the organization. In many such ways, accident insurance proves to be not only a benefaction, but actually a conservator of credit.

Edwin W. DeLeon,
Member Insurance Society of New York.

ACCIDENTALISM. The theory that events may happen without any cause whatever. If accepted as a causal relation as fundamental and in need of no definition, the meaning of accidentalism is clear enough. If on the other hand, we take the Humian view that cause is mere constant concomitance, and that causal laws merely express one sort of occurrence as a function of another, accidentalism may be interpreted as meaning that this function is many-valued—that two qualitatively identical antecedents may be followed by different consequences—or that it is discontinuous—that a sufficient degree of similarity in the antecedents need not imply any similarity in the consequences. Accidentalism in ethical matters is indeterminism. However, many views which are considered as indeterministic merely hold that the physical antecedents of a deed are alone insufficient to determine the deed, while the physical antecedents together with the character, motives, conscience and understanding of the agent are adequate for this purpose. Accidentalism in metaphysics is known as tychism.

ACCIDENTS, Causes and Prevention of. Industrial Accidents.—For many years modern industry, especially in the United States, has been confronted with the serious problem of preventing injuries, whether avoidable or unavoidable. The avoidable injuries are due to the carelessness of the workman, the fellow employee, while unavoidable injuries or accidents constitute the occupational risk. The chief causes of preventable industrial injuries are: (1) Lack of provision of safety in construction; (2) excessive hours of labor; (3) unremitting pressure for large output, resulting in the maintenance of too great speed; (4) inadequate factory inspection; (5) failure to remedy known defects; (6) insufficient signal systems or methods of warning; (7) ignorance of workers and the failure of employers to instruct and direct them. The first annual report (1915) of the New York State Workmen's Compensation Commission states that there were not more than 100 cases in a total of 18,930 awards allowed in which the question of intoxication was raised either by the employer or insurance carrier; in not a single case did the commission decide that the injuries were due wholly to intoxication, nor was a single grant disallowed on the ground of intoxication. A Minnesota bulletin assigned an amount of industrial accidents to hazards of industry and 5.2 per cent to contributory negligence. The principal causes of accidents were ascribed to "youth, ignorance of the English language, incompetence, carelessness, ranging all the way from momentary inattention or forgetfulness to foolhardy recklessness, personal short-comings, like deafness, or excitability and absorption in the work at hand which make the workman oblivious of approaching danger, fatigue and nerve strain." A Massachusetts report states that "dusty trades, industrial poisons, and occupational diseases are responsible for an annual loss in the United States of $750,000,000, through needless disabilities and disabilities," and that poor conditions in many factories, mills and shops have a direct bearing upon the number of accidents. The Ohio report of 1915 ascribes the accidents that were passed upon by the commission to the following causes: Falling and shifting objects, 19,606; machinery, 14,018; hand tools and simple apparatus, 5,231; nature of similar working conditions, 4,900; falls, 4,774;
carrying, lifting or handling great weights, 1,196; transportation on tracks, 912; transportation on tracks, 69; transportation of foodstuffs and raw materials, 139; animals, 457; sunstroke and heat prostration, 107; intentional violence of fellow employee, 41; intentional violence of persons not employees, 34.

There are no statistics for the country as a whole relating to industries individually, but the mortality tables of the 1910 census give a fair idea of the accident rate, the statistics covering about 50 per cent of the country's population. Of the males 10 years of age and over, 22,652, grouped in 148 occupations, died through accident, while 881 females of the same ages, grouped in 140 occupations, met the same fate. Among the males one death out of every 10 was accidental, while the ratio among the females was one out of 30. Among steam railway employees there was one death by accident to 1.9 deaths by all causes; among manufacturing laborers one to 8.4; among miners and quarrymen one to 2.5; among persons engaged in agricultural pursuits, one to 15.5; among those engaged in public administration, one to 23; while teachers and clergymen appeared to be most free from fatal accidents, the ratios being one to 31 and one to 30 respectively. In the Bureau of Labor Statistics Bulletin 157 (1915) F. L. Hoffman estimates the number of fatal industrial accidents in 1913 at 35,000, while there were approximately 700,000 injuries which resulted in disability for more than four weeks. The ratio of fatal injuries per thousand employees ranged from 4.00 for metal mining, 3.50 for coal mining, 3.00 for fisheries, navigation, lumbering, building and street railway employees to 25 for general manufacturing. In coal mines the number of fatal accidents decreased from 2,785 in 1913 to 2,254 in 1914, the most prolific cause of death being the falling of roofs and coal. The death rate per thousand employees for the entire country was 3.22 in 1914 against 3.73 in 1913. Carl M. Hansen of the Workmen's Compensation State Bureau places the number of workmen killed annually at 40,000 to 45,000, while the Massachusetts Industrial Accident Board places those killed by accident at 75,000 and the number of those injured annually at 3,000,000.

Legislation and Safety Devices.— Undoubtedly a large proportion of industrial accidents are preventable, if the employer be compelled to make the protection of workmen rather than enormous production his first interest. If accidents constituted a heavy and unremunerative cost to the business, the employer would quickly realize that the prevention of accidents was to his economic interest. Safe but slower methods of production may result in reduced profits, but the welfare of the community demands that the human waste that is a direct result of the dangerous quicker ways be compensated for by a greater reduction in profits. In the Army and Navy Appropriation bill passed 4 March 1915, Congress inserted a provision permitting the employment of a "speeding up" system in government plants. The motive for prevention of accidents can never be compelling until a uniform and unescapable penalty be established for each injury or death. Many of the States have enacted laws for the prevention of work-accidents and diseases, and for the collection of reliable information concerning their nature and extent. Most of the territories have also passed laws compelling the payment of various sums of money by employers for personal injuries to employees causing death or disability for more than two weeks, arising out of and in the course of employment, not due to the employee's willful intention to injure himself or another or to his intoxication. The industries covered, the injuries and persons compensated, and the rates of compensation differ in the various States. Among the laws are the following, with the dates of enactment and amendment:

Alaska: 9 April 1915; in effect 28 July 1915.
Arizona: 8 June 1912; in effect 1 Jan. 1913; new act 13 May 1913; in effect 1 Jan. 1914; amended 1915.
Canal Zone: 24 Aug. 1912; executive order 26 Feb. 1913; in effect 1 March 1913 (suspended); new order 20 March 1914; in effect 1 April 1914.
California: 8 April 1911; in effect 1 Sept. 1911; new act 13 May 1913; in effect 1 Jan. 1914; amended 1915.
Hawaii: 28 April 1915; in effect 1 July 1915.
Illinois: 10 June 1913; in effect 1 Jan. 1914; new act 28 June 1915; in effect 1 July 1915; amended 28 June 1915.
Indiana: 8 March 1915; in effect 1 Sept. 1915.
Iowa: 8 April 1913; in effect 1 June 1913; (a) requiring industrial commission and providing for insurance of employees, 4 July 1913; (b) compensation for death 1 July 1914.
Kansas: 14 March 1911; in effect 1 Jan. 1912; amended 10 March 1913.
Kentucky: 23 March 1915; in effect 1 Aug. 1915.
Louisiana: 18 June 1914; in effect 1 Jan. 1915.
Maine: 1 April 1915; in effect 1 Jan. 1915.
Maryland: 16 April 1914; in effect 1 Nov. 1914.
Massachusetts: 28 July 1911; in effect 1 July 1912; amended 1913, 1914, 1915.
Michigan: 20 March 1912; in effect 1 Sept. 1912; amended 1913, 1915.
Minnesota: 24 April 1913; in effect 1 Oct. 1913; amended 1915.
Montana: 8 March 1915; in effect 1 July 1915.
Nebraska: 21 April 1913; in effect 17 July 1913.
Nevada: 15 March 1913; in effect 1 July 1913; amended 1915.
New Hampshire: 15 April 1911; in effect 1 Jan. 1912.
New Jersey: 4 April 1911; in effect 1 July 1911; amended 1912, 1913, 1914, 1915.
Oklahoma: 25 March 1915; in effect 1 Sept. 1915.
Pennsylvania: 2 June 1915; in effect 26 June 1915.
Porto Rico: 13 April 1915; in effect 1 July 1916.
Rhode Island: 20 April 1912; in effect 1 Oct. 1912; amended 1913, 1915.
Texas: 16 April 1913; in effect 1 Sept. 1913.
Vermont: 1 April 1915; in effect 1 July 1915.
West Virginia: 22 Feb. 1913; in effect 1 Oct. 1913; amended 1915.
Wisconsin: 3 May 1912; in effect same date; amended 1913, 1915.
United States: 30 May 1908; in effect 1 Aug. 1908; amended 24 Feb. 1909, 4 March 1911, 13 March, 27 July and 24 Aug. 1912. (Does not include private employment).
New act 7 Sept. 1910; in effect same date.

Most of the laws are enforced through factory inspection, but in many States this inspection is so lax and inadequate that the laws are practically ineffectual. In 1911 Wisconsin created an agency for administrative legislation as to details in safety provisions, resembling the systems in many foreign countries. The law requires the employer to take every reasonable precaution against risk and the industrial commission decides what safety devices the employer shall install in order that his factory may be as nearly free from accidents as possible. The commission is
expected to inform itself of the latest and most improved safety devices and so far as may be purchase and adopt, by employers. The success of this law induced Massachusetts and New York in 1913 to provide for similar tribunals. In 1915 Nevada created an industrial commission for the administration of the Workmen’s Compensation Act and provided that one of the commissioners should hold the office of labor commissioner for the enforcement of labor laws. In 1915 New York consolidated the workmen’s compensation commission and the labor department under an industrial commissioner, the act being in accord with laws in Wisconsin, Ohio and a few other States which have created industrial commissions with powers similar to those exercised by public utility commissions.

Almost all States have enacted laws requiring dangerous machinery to be fenced about, and that every possible means be adopted to protect employees. In 1915 Connecticut and Massachusetts passed laws requiring first aid rooms or emergency kits in all manufacturing establishments where machinery was used. Detailed provisions regulating heating, lighting and ventilating factories and guarding machinery therein were passed in Illinois in 1913, and Missouri in the same year provided for similar regulations in coal and zinc mines. Many cities too have enacted laws with the same object in view. New York city has passed ordinances to prevent unnecessary and reckless loss of life by compelling employers to furnish proper and safe scaffolding, to be more careful in employing men who work by caissons, to institute proper safeguards in the operation of elevators and to enforce the fire prevention law more strictly. The police forces of the various cities are compelling a more strict observance of the traffic regulations with the result that street accidents are being reduced to a minimum.

The various safety appliances could not be here described; suffice it to say that their effectiveness is conclusively proved by statistics published in 1913 by the Department of Labor in a report entitled ‘Accidents and Accident Prevention in the Iron and Steel Industry.’ The report covered 155 plants, employing 158,604 workers, the accident rate for all plants was 0.13 accidents per 100 workmen, 1.89 permanent disabilities and 240.6 temporary disabilities. In those plants where the best systems of accident prevention were installed, the accident rate was 0.1 per thousand, while the rate in the most poorly equipped plants was 507.9 per thousand. The United States Steel Corporation annually spends nearly a million dollars to maintain its safety system, but by so doing has reduced its fatal and disability accidents by about 45 per cent, and its less serious accidents by a still greater percentage. Safety engineering has now become an accepted branch of the science of engineering. One of the motives impelling employers to install or increase their safety appliances has been the difference in accident rates put into vogue by those who issue employers’ liability policies.

An International Association of Industrial Accident Boards and Commissions has been formed to bring into closer relation with one another the various boards and commissions administering compensation laws of the United States and to effect so far as possible unanimity in the administration of such laws and to cooperate to all measures tending toward the prevention of accidents and the safeguarding of plants and machinery. At a convention of the National Safety Council at Philadelphia in October 1915, much time was devoted to the discussion of means of safeguarding machinery; the connexion between the consumption of liquor and the number and seriousness of accidents; the necessity of more drastic legislation; the value of physical examination and of other methods of excluding the subnormal and the unfit; and the financial advantages accruing from the use of safety devices.

Railway Accidents and Legislation Regarding.—The result of the installation and application of safety devices appears nowhere more strikingly than in railway statistics. In 1914 there were a total of 192,662 persons injured on steam railways and 10,302 killed, while in 1915 the total was 8,621 persons killed and 162,040 injured. This showed a remarkable reduction over any year since 1900. The fact that the number of persons carried one mile in 1915 was 106 per cent greater than in 1900 and the number of tons of freight hauled one mile was about 92 per cent greater. On 31 Dec. 1915 the Railway Age took the statement that 97,809 miles of railway in the United States were operated under the block signal system, which may account for the increased safety of passengers. Many casualties are due to carelessness of motorists at crossings, though in many cases these are inadequately guarded.

In order to promote safety in railway operation many States have railway commissions that investigate and report accidents themselves while other States require the railways to render their own reports. In general these commissions are empowered to inspect railway property and operation (roadway, bridges, tracks, equipment) periodically or at discretion, to recommend and require repairs and improvements and to report to the governor or the legislature their recommendations and any neglect of them. They are authorized also to require the proper guards at crossings; to regulate the heating and lighting and the carrying of tools in passenger cars; to regulate the speed of trains in cities and near grade crossings and the transportation of explosives and inflammables; to regulate the weight and quality of rails and the style of interlocking devices; to prescribe the number of brakemen and the qualifications and hours of labor of various employees; to impose penalties upon railway employees who become intoxicated while on duty or for neglect of duty which would endanger life or safety.

A number of Federal safety appliance, accident and compensation laws have been passed. The act of 3 March 1901 was superseded by another 6 May 1910 requiring monthly reports of all accidents injuring persons or railway property and authorizing the Interstate Commerce Commission to investigate serious accidents. On 11 June 1906 an act was passed which was later declared unconstitutional and was superseded by the acts of 22 April 1908 and 5 April 1910. These constitute the Federal Employers’ Liability Act and hold common
ACCIDENTS

carriers liable for injury or death resulting in whole or in part from the negligence of any of the officers, agents or employees of such carrier, or by reason of any defect or insufficiency due to its negligence, in its cars, engines, appliances, machinery, track, roadbed, works, boats, wharves or other equipment. Workmen’s compensation acts are not applicable to cases of employees injured while engaged in interstate commerce traffic and no recovery may be had under them. Other acts are designed to prevent casualties. The original safety appliance act was passed 2 March 1893 but was amended 1 April 1896, 28 June 1902 and 2 March 1903, with the result that now all freight cars must be equipped with automatic couplers and grab-irons, and in each train at least half the cars must be provided with brakes operated from the locomotive. On 6 June 1910 the Interstate Commerce Commission ordered that on all trains operated with power or train brakes at least 85 per cent of the cars should have their brakes operated from the locomotive. By the act of 14 April 1910, as amended 4 March 1911, the Commission is required to regulate hand-holds or grab-irons, hand-brakes, running-boards, step-steps and ladders on freight cars. Under the joint resolution of 23 June 1910 the Commission is required to investigate the block signal systems and appliances for automatic train control. The railways are required by the act of 30 May 1908 to equip locomotives with ash pans that can be cleaned without an employee going under the locomotive. The use of unsafe boilers and other appurtenances on locomotives and tenders is forbidden by the act of 17 Feb. 1911 (as amended 4 March 1915) and provision was made for the inspection of boilers and their appurtenances by the railways and by inspectors under the Commission’s supervision. The transportation of explosives for a time was regulated by the act of 4 March 1909 which superseded the act of 30 May 1908. On 1 Jan. 1910 the law was again amended and the provisions which have been the result of occasional amendment went into effect 1 Oct. 1914. There is a Bureau for the Safe Transportation of Explosives and Other Dangerous Articles which was first instituted in June 1904. The inspectors of this bureau are officers of the American Railway Association, but which now also works in conjunction with and under the authority of the Interstate Commerce Commission. On 4 March 1907 an act became law providing that, save in cases of great emergency, trainmen must have 10 hours off duty after 16 hours of continuous service, and eight hours off after 16 hours of service in any one day. The work of operators, dispatchers and others must be limited to nine hours per day in posts operated continuously, and to 13 hours in other posts.

Steamship Accidents.—The Federal government has full and complete jurisdiction over marine transportation and there is a bureau in the Department of Commerce denounced by the act of 23 June 1902, whose function it is to supervise steam vessels for the promotion of safety. The service must inspect structural materials for marine boilers and each year must thoroughly inspect the hulls, machinery, boilers and fire apparatus of vessels under its jurisdiction. It is empowered to determine the carrying capacity of vessels, and to promulgate laws for the provision of life-saving devices. Many laws have been passed by Congress regarding marine transportation, the most important of which have been on the statute books since the days of steam navigation. An important enactment is that of 23 July 1912 amending the law of 24 June 1910 requiring wireless equipment on all vessels, American or foreign, licensed to carry 50 or more persons, navigating the ocean or Great Lakes.

ACCPITRES: Lat. plural of Accipiter, the common hawk), or RAPTORES. An order of birds, comprising the birds of prey, — eagles, hawks, owls and vultures. See BIANS OF PREY.

ACCLAMATION ("calling to"): properly, expressing any judgment of an assembly or a large part of it by shouting; but in usage restricted entirely to a favorable one. The choice of rulers among most early Aryan tribes or the acclamation of the candidate was presented by a previous understanding - among the Vikings raised on a shield in the presence of the chiefs - and acclaimed by the voices of the assembled multitude. In some cases, as with the Foës even quite late in their history, the agreement was only made when the throng had gathered and there were more than one set of acclaimers, often ending in a pitched battle to decide which party preponderated. In the minor divisions of modern political life, voting by acclamation is usual; a ballot being called for only when the parties are so evenly balanced that the preponderance is dubious, or a small majority has great strength of lungs, or the minority wish to make the majority seem on record, or simply to have the satisfaction of a proved vote. In ecclesiastical councils the vote by acclamation comes first also, the question being put as "place" or "non placet." In private matters, acclamation has been used from early times as an expression of good feeling or enthusiasm, as in the custom "hurrahs," "huzzas" and "tigers," and the "hearp, hear* of political assemblies, and the responsive shouts and groans of religious revivals or prayer-meetings. The applause in theatres, etc., being non-vocal does not etymologically belong to the group, but is usually included as having the same intent. It began with genuine applause, an actor closing the play by some word asking for approval of the company - in the Roman theatre, "Plaudite" ("applaud ye"), or a poet or orator who recited in public expecting and receiving applause; but the claque, in modern French phrase, was very early organized by rich amateurs, who kept bands of paid applauders not only for their own, but for others. Nero hired 5,000 of these, many of them equites or knights, to chant his praises at the direction of a professional music-master; they were called Augustiniani. In the modern French theatre the claque is on a more modest footing and is paid by the management; the understood reason being (curiously) that it keeps up the spirits of the actors when the audience's coldness might depress them beyond the power to play well, and more rationally that it guides and stimulates the audience itself to genuine applause - when it might be simply sluggish and indifferent. In old times applause was shouted at marriages, as "Io Hymen," "Hymenææ," "Talasso"; in festive or religious processions; to victorious commanders in triumphs or ovations, as "Io triumphæ"; and even, contrary to modern feelings of decorum, in churches, the pupil orator being cheered at good passages.

ACCLIMATIZATION, the gradual alteration which fits a plant or animal to a climate differing from that in which the habits of its species or race have been formed. Acclimatization and naturalization are often mistakenly used as synonymous, but naturalization properly means establishment in a new country, and, if the climates of the two countries chance to be the same, acclimatization is implied. In the consideration of marine animals and plants acclimatization takes on a slightly different meaning, since aquatic life is more affected by the various conditions of the surrounding water than by climate.

In plants, many examples of acclimatization are furnished by cultivated plants, among which the most noteworthy are perhaps the cereals. The original species of most of these has not been discovered, but in most cases it is supposed to have lived in sub-tropical or warm temperate regions. Some of these cereals now thrive far better or are more productive in cold, northern climates than in warm regions. But in such cases an important influence may to a greater or less extent obviate or emphasize the apparent period of growth, the productiveness, etc. This is the daily duration of sunlight. During the growing period the sunlight lasts longer as the pole is approached, so that the shorter season is more compensated for by the increased hours of sunshine. It has been found by experiment that certain varieties of corn brought from the southern States to the northern attained their customary height, but generally failed to ripen seed. The progeny of such plants as did mature seed gradually assumed the characteristics of northern varieties; they reduced their height and shortened the time necessary to attain maturity. In a few years they resembled other northern varieties in these two respects. The reverse of this case has also been proved; northern varieties taken to the south at first reached the height and attained maturity in the time natural to them in the north, but gradually assumed the characteristics of southern varieties — increased height and greater number of days to reach maturity. But even considering the frequent preponderance of this influence and remembering that the production of seed is usually in opposition to marked development of vegetative parts, there is no doubt that plants, in becoming acclimatized, are compelled to adjust themselves to many other less prominent influences, such as humidity, temperature, light and wind. The peach is supposed to have come from China by way of Persia, and since early historical times has gradually been fitting itself to more and more northern conditions. It is now found to be a profitable crop in Michigan and New York, which are several degrees farther north than its supposed place of origin. The influence of climate upon cultivated plants is recognized by progressive agriculturists and horticulturists, and each prefers seed grown in a more northerly locality than his own. The effects of the new environment, however, soon become evident, and new importations must be made. Seeds grown at high altitudes exhibit the same characteristics as those produced in high latitudes; that is, they are harder and require a shorter period to reach maturity than those grown in low latitudes or low latitudes.

Among naturally acclimatized plants there are many remarkable phenomena. Deciduous plants taken from cool climates to tropical conditions hold their leaves for a much longer period than where they are indigenous, or may even become evergreen like their new associates. Plants im-
ported from warm regions to cooler may lose the power to ripen seeds, but this defect may be compensated by development of vegetative reproductive powers. The reverse case is also true. Southern plants may fail to ripen wood completely, and winter killing may result. In cultivated plants, however, this phenomenon, which is often observed in the peach, may be due to improper methods of cultivation resulting in abnormal wood-development.

**In Animals.—** The capacity for acclimatization is possessed in very different degrees by different animals, even by different individuals of the same species, and depends much upon general hardihood. Exactly what changes take place during acclimatization is not known; sometimes the very specific gravity of the animal is altered, as when fresh-water fishes become adapted to the denser water of the ocean; similarly, the normal temperature of the individual may gradually become altered, as in the case of fishes native to cool water, which chance to work up-stream into hot springs and live there at a temperature which would kill normal individuals of the same species. The animals which are most widespread over the earth are those which have the greatest adaptability to new climates and new conditions of environment, and the best examples of this adaptability are found among domestic animals (q.v.). About the middle of the 19th century there was much enthusiasm for transplanting animals from one country to another; but the results have so often been harmful rather than beneficial to the recipients of the new forms that the effort to improve on nature in this way has been abandoned. Conspicuous examples are afforded by the sending of the European rabbit to Australia and New Zealand, where it multiplied so excessively in a favorable climate, with abundant food, and through the almost complete lack of enemies, as to become a nuisance and a menace to the pastoral industry. (See RABBIT.) The introduction of the agouta toads, and afterward of the mongooses (q.v.) into Jamaica, to subdue the rats that were devouring the sugar-cane, had evil results. The spread of the European house-sparrow in the United States is another pertinent example. Many highly injurious insects have been accidentally introduced and acclimatized in America from abroad; and the same is true of other countries. On the other hand a few instances like the acclimatization of the silkworm in Europe, of bumblebees in New Zealand, or of ladybirds in California, have been highly beneficial; while much good has come from stock ing new streams with desirable fishes. Of the several societies founded to promote such transferences, that of Paris (Société d'Acclimatation) is most important, but latterly has been inactive.

**In Human Beings.—** See HYGIENE.

**Bibliography.—** "Variations of Animals and Plants Under Domestication," Darwin; "Island Life," Wallace; "Tropical Colonization."

**ACCO, ak′ō.** See ACRE.

**ACCOLADE, ak′ō-lād′.** (Fr. "embrace," literally, "on the neck"), in heraldry, the ceremony by which in medieval times one was dubbed a knight. On the question what this was originally are not agreed. It has been made an embrace around the neck, a kiss or a slight blow upon the cheek or shoulder. In some cases it was a literal box on the ear, for which later was substituted a gentle tap on the shoulder with the flat of a sword. In conferring knighthood the King strikes the kneeling subject lightly on the shoulder with a sword and uses the words "Thou didst rise, Sir Knight.

**ACCOLTI, Benedetto, ak′ō-lēt′ō, ben-a-det′ō, the Elder, Italian jurist: b. Arezzo, 1415; d. Florence, 1466.** Several other members of his family were noted for legal attainments. He became professor of jurisprudence in the University of Florence, and on the death of the illustrious Poggio was made one of the council of that republic. With his brother Leonardo he wrote in Latin a three-volume history of the first crusade, not of great value, but interesting as having furnished Tasso the material for "Jerusalem Delivered": pah. Venice 1452, Italian tr. 1543, French tr. 1620. He also wrote a volume of biographies of his distinguished contemporaries (Parma 1689).

**ACCOLTI, Bernardo, Italian poet and ecclesiastic: b. Florence, before 1460; d. after 1534.** He was greatly admired, especially as an improvisatore. Whenever the occasion occurred, the attention of reciting his verses the shops were closed and the people flocked in crowds to hear him. He was surrounded by prelates of the first eminence; a body of Swiss troops accompanied him, and the court was lighted by torches. Leo X esteemed him highly and made him apostolic secretary, cardinal, and papal legate at Ancona. He it was who drew up the papal bull against Luther (1520). Though styled in his own day "The Only (one) of Arezzo" (L. 'Unico Arentino'), the fame of his works perished with him. Their style is hard, his images forced and his taste marred by affectation. The best known is a comedy, 'La Virginia.' His other productions include some lyric poetry, epigrams, octaves and verses in terza rima.

**ACCOMMODATION, the process by which the mind is brought into adjustment with its surroundings; adaptation.**

**In physiology,** the accommodation of the eye is the function by which objects, near or distant, may be seen distinctly. It is accomplished by the relaxing or contracting of the ciliary muscle. See EYE.

**In biology,** the process by which an organism becomes adapted to its environment.

In theology, properly, the presentation of a truth not absolutely, but with some modification to suit it either to some other truth or to the person addressed. It is distinguished as formal and material, the former relating to the method of teaching, and the latter to what is taught. The former includes teaching by parables or symbols, by progressive stages graduated to the capacity of the learner, etc.; more usually, now, the forcing of texts from their obvious meaning to conform them to theories derived from other sources. The latter, as now commonly used, means the theory that Christ and the writers of Scripture modified or perverted the truth to accommodate it to the limited intelligence or the prejudices of their times,—the cosmogonies of Genesis, or Jesus' acceptance of demoniac possession as a truth, etc.

**In commerce** it usually denotes temporary
accompaniment — account

financial assistance rendered by one merchant or bank to another. Accommodation paper includes notes or bills of exchange made, accepted or indorsed, without any consideration. While in the hands of the party to whom it is made, or for whose benefit the accommodation is given, such paper is open to the defense of want of consideration, but when received by third parties in the usual course of business it is governed by the same rules as other paper (2 Duer, N. Y. 33; 2 Kent, Comm. 86).

ACCOMPANIMENT, in music, is that part which serves for the support of the principal melody (solo or obligato part). This can be done by a single instrument, or by a combination of instruments. The principles on which the effect of accompaniment rests are so little settled that its composition is more difficult than that of the melody itself. Frequently the harmony, or the effect of the accompaniment, is the most important part of the piece. The accompaniment is, however, a necessary part of the piece, and must be given due consideration.

ACCOMPANY, in law, to stifle a criminal prosecution for a criminal offense such as an assault and imprisonment is void (2 Wils. 241; 5 East, 294).

ACCORD AND SATISFACTION signifies a satisfaction agreed upon between the parties to a contract or agreement, without the intervention of the court.

ACCORDION, a musical instrument in the form of a small box, generally from 8 to 12 inches long by 4 wide, and containing a number of metallic reeds fixed at one extremity, but left to vibrate freely. A small bellows, formed by a folding apparatus which unites the top and bottom of the box, supplies the wind, which, admitted by keys acting on valves, sets the reeds in vibration. In the harmonium (q.v.) and the American cabinet-organ the same principle is employed. The accordion was introduced into America from Germany about 1829 but the principle had long been known in China, and employed for instruments played by the breath. The concertina, flautina and organ-accordion are improvements.

ACCOUNT, a register of pecuniary transactions, whether for personal use, to satisfy a contract, in obedience to law, or as a bill of items sent to a customer who buys on credit. A mutual account is one where debtor and creditor items are opposed between two parties. An open account, or account current, in commerce is one in which the balance has not been struck; in banking, one that may be added to or drawn upon at any time. An open account is subject to the direction of the party who has a right in the account, where notice is required for withdrawals. To keep an open account is to keep such a one running on, instead of closing it. A stated account is one which all parties have expressly agreed to have by implication (as by the debtor's retaining it beyond a reasonable time) and admitted to be correct. To open an account is to begin pecuniary transactions with a banker or merchant.

In law, an account is a detailed statement of the mutual demands in the nature of debt and credit between parties, arising out of contracts
or some fiduciary relations. An open account is one which some term of the contract is not settled by the parties, whether the account consists of one item or many.

In equity, jurisdiction concurrent with courts of law is taken over matters of account on three grounds: Mutual accounts; dealings so complicated that they cannot be adjusted in a court of law; and the existence of a fiduciary relation between the parties.

ACCOUNTANT, properly any one who keeps accounts, and till lately applied in the United States to all bookkeepers without distinction; more generally now restricted to the head bookkeepers of large houses or corporations, with difficult or complex accounts calling for expert ability. Especially an expert accountant or public accountant is understood as one not in the employ of any one house, but hiring his services out to such firms or companies, banks or public institutions, as either find their accounts in disorder or wish a legal verification or a guaranteed statement for the public; or report on bankrupt estates under legal process. Few large financial institutions neglect to support public confidence by having their books periodically investigated and reported upon by an accountant unconnected with the concern. This is gradually building up, through many scandals and frauds upon the public, a much higher standard of professional duty among these experts: it is recognized that it is their duty not merely to certify to the correct balancing of the figures submitted to them, but to use reasonable intelligence and honorable purpose on the manner in which those figures were made, and whether they represent facts or gross fictions to deceive outsiders and lure in money to be mishandled. The proper, and in the United States the only, business of an accountant is to examine accounts and make out balance-sheets and statements. In England they assume a still further duty, that of managing estates and legacies.

ACCOUNTING. It is difficult to distinguish between bookkeeping and accounting. In attempts to do so bookkeeping is called the art of recording business transactions and accounting the science. Bookkeeping gives the history of the business in a manner while accounting classifies, analyzes and then interprets the facts thus recorded and shows the results as losses and gains, leakages, economies, changes in value, etc., in such a way as to reveal the progress, or retrogression and the limitations and possibilities of the business. The primary object of bookkeeping is to show debts, both those due to the owner and those due by him to others; the purpose of accounting is to show profits and losses and valuations. Accounting is more than advanced bookkeeping and an accountant is more than an expert bookkeeper. A person might keep a set of books with perfect accuracy by mechanically observing the rules of debit and credit. The accountant must be able to design the set of books and the system of accounts which will give the desired information with the minimum of effort. He must have such a comprehensive view of business, both its economic and legal aspects, that he can not only see the effect of all kinds of transactions on the profit and loss statement and balance sheet, but also recognize and classify all other factors which enter into the determination of the true status of an enterprise. The development and rapid rise of accounting is due to the change from private to corporate form of business organization. The enormous growth of manufacturing, transportation and mining companies, and the investment of the funds involved in the hands of many shareholders demands a more accurate determination of profit and loss and valuation of assets than when such enterprises were owned by small private companies. A proper accounting system is laid to the creditors of a corporation in determining the value of its securities and shows the stockholders whether they are receiving a just share of its profits. Since the charges for service rendered by the public service companies are coming more generally under the regulation of legislative authority, it is essential to know the exact value of the capital upon which dividends must be paid and the true profit which has been earned in order to fix those charges on an equitable basis requires a careful classification of items and a regard for certain factors which bookkeeping, as formerly known, did not take into consideration.

Increasing interest in municipal affairs has resulted in the development of accounting systems for cities, counties and States with a view to unifying and classifying their revenues and expenditures so as to show true costs and the comparative efficiency of various departments and changing administrations.

Accounting has made prominent the problem of distinguishing between a revenue expenditure and a capital expenditure. If an item is regarded as a revenue expenditure, it is debited to some expense account and decreases profit; if it is considered a capital expenditure, some real account is debited and the assets increased. For many years the railroads, quite generally, regarded as an expense most improvements in their rolling stock and betterment of their tracks. They charged those expenditures instead of to construction account the cost of reduction of grades, the replacement of wooden bridges by those of steel, and even the cost of extensions and branches. They claimed that such expenditures were necessary to hold business against competition and were not simply factors to increase business.

The commonly accepted theory of accounting requires that in so far as any expenditure results in an addition of substantial and permanent character which increases the value of the plant, such expenditure shall be considered an increase in assets and debited to construction account. This is not always upheld by legal decisions but since 1906 the Interstate Commerce Commission has prescribed a uniform set of accounts for railroads engaged in interstate commerce which embodies this principle. It is often difficult to determine whether an expenditure should be considered a real expense or is capital, sometimes it partakes of the nature of both and has to be divided, as when an old machine is replaced by a new one of an improved and more expensive type.

Accounting recognizes depreciation as a business factor. All machinery used in pro-
duction and even the most fixed assets, as buildings, decrease in value with use, the lapse of time and because of new inventions and improvements. This decrease in value must be considered an expense or cost of production just as much as wages and materials, interest and rent. Consequently, true profits cannot be determined nor the real value of the assets stated until after an allowance has been made for depreciation. In Germany, Austria, France, Switzerland and Belgium, all corporations are required by law to set up a special account to cover depreciation. In England and the United States there is no general regulation but the Interstate Commerce Commission and the State legislatures compel the railroads and certain public service corporations to make such provision. Most large corporations voluntarily do so.

There are various ways of treating depreciation on the books. Sometimes the particular asset is credited with the amount of its decrease, the balance of the account showing its net value. This is called “writing down” the asset. Sometimes the asset is carried at its original cost and a valuation account credited with the amount of the depreciation. The two accounts, taken together, show the actual value of the asset. Since some assets are consumed slowly while others are short-lived, the determination of the proper allowance for depreciation is a difficult problem. Absolute accuracy cannot be attained and even approximate estimates are not entirely trustworthy. Tables applicable to various kinds of machinery and buildings have been worked out from experience.

Fluctuations in the value of fixed assets, as measured by the market price, may be considered as due to causes not under the control of the business. They may be favorable or unfavorable and are often not at all permanent. Usually no consideration is given to them on the books except as there results a depreciation in the value of goods for sale or in the process of manufacture.

Stocks, bonds and the securities of other concerns bought for investment are carried on the books at their original cost, if this is below the market quotations, otherwise the market quotations are substituted. In Austria, the law requires the use of the market value in case of either depreciation or appreciation. In this country it is considered conservative to disregard appreciation unless the increased value of the asset is actually realized upon by its sale.

Goodwill may be defined as the monetary value placed upon the reputation, connections or advantages possessed by a firm whereby it is able to make unusual profits. In forming consolidations it is often used to represent the difference between the price paid and the intrinsic value of the property required. Although a firm may possess or create advantages by which its profits are increased, it is generally agreed that it is bad practice to set up an account for goodwill unless it has been purchased. As to whether goodwill should be considered a depreciating asset and gradually written off the books is a question of dispute among accountants. On account of its intangibility it is regarded conservative to do so.

Cost Accounting is one of the latest developed and most difficult and technical branches of accounting. It is applicable to all manufacturing business rather than to a mercantile or trading concern. The manufacturer buys raw materials, semi-raw materials, parts already finished, etc., and by means of a properly equipped factory and the employment of skilled and unskilled labor converts these materials into a finished product which he sells. In order to meet competition intelligently and to prepare estimates on work to be performed with accuracy the manufacturer must be able to determine from his records the actual cost of each unit produced, the cost of labor and the cost of goods in process of manufacture at the end of the period. This necessitates the keeping of a class of expenses known as manufacturing expenses, different from those of a mercantile firm, and the use of many additional ledger accounts.

Three elements enter into the cost of a manufactured article: (1) Raw materials; (2) productive labor; (3) manufacturing expenses. Manufacturing expenses are also called indirect or overhead expenses and include all expenditures outside of those for raw materials and productive labor, such as power, heat, light, factory supplies, taxes, insurance, repairs, depreciation of machinery, etc. Sometimes a fourth element is included—the selling expenses. The first two elements may be called the Prime Cost; the third the Factory Cost; and all four the Total Cost. But these terms are used to express so many various meanings by the different writers on Cost Accounting as to render a complete discussion too long for this article.

Two of the several general methods of computing costs are: (1) The Production Order Method; and (2) the Process Method. In the Production Order Method an account is opened with each job in the cost ledger. Each job is given a number by which it is always known. Every productive laborer reports the amount of time he spends on it. All material required is requisitioned from the stock room by this number. Thus, the account of each job can be easily debited with the cost of direct labor and the cost of material and parts used. This gives the prime cost of the job and leaves the indirect expenses to be apportioned to it.

The apportionment of the indirect or overhead expenses must of necessity be arbitrary. Many schemes have been suggested but it is impossible to find one that is generally agreed to be logically correct or uniformly accurate. Among the various methods used are: (a) the "man-rate" method, which divides up the indirect expenses in proportion to the direct wages paid for the productive labor; (b) the "man-hour" method, in which the division is according to the total number of hours of productive labor; (c) the "mixed method," which uses the cost of raw materials plus the cost of productive labor as the basis of division; (d) the "machine-hour" method; and (e) the units of product method. Having decided upon the most practical method of apportioning the manufacturing expenses, the proper amount is debited to each job and the factory cost of that job determined.

The Process Method of determining costs is used when the lots of material in the process of production follow one another in such a way that one lot cannot be distinguished from
another. Each process is known by a name or number, as milling, rolling, annealing, dipping, etc., or, as operation No. 1, No. 2, No. 3, etc. The amount of time of productive labor spent on each process is reported and its cost debited to the account of that process. The cost of raw materials or finished parts used in each process is also debited to its account. The indirect expenses are apportioned by one of the methods described above to arrive at the total factory cost of the process.

Auditing.—Every auditor, as required by law, has become the custom for most large business firms to have an audit of their records made by outside accountants employed for the purpose of carefully examining their books and certifying to their correctness. It is the duty of the auditor to check up all the entries of the bookkeepers and to compare their amounts with all the original documents and papers, such as checks, notes, bills, receipts, etc., and to discover any errors of principle, of omission or commission. The auditor's report consists of a profit and loss statement and a balance sheet, with necessary comments and suggestions for increase in efficiency and accuracy of record. In preparing the profit and loss statement the auditor endeavors to make certain that it contains all of the expenses of the period, whether they have been paid or not; that charges properly made against income have not been made against capital; that all the profits earned are included; in short, that the statement is a true report of the income and expense of the period. The balance sheet is the statement of the business most often published and the auditor should be able to certify that the assets are not overstated; that proper allowance has been made for depreciation; that the liabilities are all included.

The auditor may be called in only at the end of a period to make a complete audit, or he may be employed to make a continuing audit, that is, to check the bookkeeper’s work during the period at frequent intervals, so that the statements may be prepared at the end without delay.

Historical.—The practice of accounting was recognized as a profession in Great Britain long before it had attained the highly specialized character it enjoys to-day. In 1834 the Society of Accountants in Edinburgh was incorporated by royal charter. Similar societies were established in Glasgow and Aberdeen in 1855 and 1867 and the Institute of Accountants in London in 1850. The New York State Society of Certified Public Accountants was the first to be organized in the United States. In 1896 the New York State legislature passed an act authorizing the State University to confer the degree of C.P.A. (Certified Public Accountant) only on those passing an examination. Many other States have followed this lead. The various State and National societies with their official journals and publications promote the discussion and solution of new problems and methods of practice. During the past few years many colleges and universities recognizing the importance of accounting and its direct relation to economics, have included its study in their curriculums and greatly developed its literature. Specialists have arisen in the field. Cost accountants and efficiency engineers devise ways and means for cheaper production. System builders organize the accounting of a firm so as to give most satisfactory results. The general expert accountant acts as auditor and business physician, whose advice is sought whenever unusual conditions arise. See Bookkeeping.

Department of Political Science, College of the City of New York.

ACCOUNTING, MUNICIPAL. See Municipal Accounting.

ACCOUNTMENTS, ak-kō′ter-mánts, military equipment carried on the person of the soldier or his horse, in particular such as is used to bear his arms and ammunition. In the United States Army the pattern of the infantry equipment was selected by a special board of officers in 1910; that of the cavalry in 1912. Both arms carry extra clothing, a shelter-tent half, a cartridge-belt (suspended from the shoulders), a mess outfit (including bacon-box, condiment-box, knife, fork, spoon, meat-can with cover and cup), a canteen with cover and a first-aid packet. The dismounted troops carry in addition a pack-carryer, slung down the middle of the back, an entrenching-tool and a poncho. In the case of the mounted troops these are replaced by a pair of saddle-bags, a saddle-blanket, a set of horse-equipment and a slicker. The infantry entrenching tools are issued as follows: To each squad of 8 men 1 wire cutter (carried by the corporal), 4 short-handled shovels 2 collapsible picks and either an axe or a bolt (a leaf-shaped heavy knife for cutting brush). The bayonet of the infantryman may be carried on his belt, but is now more usually strapped on to the left side of his pack. Those enlisted men and officers who carry pistols carry them in a leather or khaki-colored canvas holster at the right hip and strapped to the leg to prevent swinging. The material of which the pack, bayonet-scabbard, cartridge-belt, canteen-cover, etc., is made is khaki-colored canvas or webbing and the entrenching tools are painted khaki-color. The mess-tin, canteen and cup are aluminum. The accompanying diagram exhibits the respective details of the present issues of infantry and cavalry equipments. The cavalryman is provided with a small box or pouch for revolver-cartridges and a cap-pouch. The sabre-belt, to which all the preceding are attached, consists of a waist-belt, with two rings for the
ACCRA—ACCURACY OF FIRE

81

shoulder-strap and sabre-sling. The usual accom-
triments for horse-artillery consist generally of a pistol and cap-pouch and a sabre-belt, which differs from the cavalry-belt only in the omission of the shoulder-strap.

Field Equipment of Enlisted Men, United States Army, Navy, and Marine Corps.

Enlisted Men Dismounted.
1. Full Equipment.
   A. Meat can pouch
   B. Haversack
   C. Bayonet
   D. Entrenching tool
   E. Suspenders
   F. Cartridge pocket, open
   G. Cartridge belt
   H. Roll (contains blanket, shelter-tent, half, extra clothing)
   I. Canteen
   J. First-aid packet

Entrenching tools (carried by some men in place of tool marked D).
2. Pick-mattock
3. Axe
4. Wire cutter

Enlisted Men Mounted. (They wear a cartridge belt with canteen and first-aid packet attached)
5. Saddle and equipment
   A. Slicker
   B. Roll (contains blanket, shelter-tent, half, extra clothing)
   C. Saddle-bag (contains meat can pouch and extra articles)
6. Holster (carried by men equipped with automatic pistol
   A. Leg-strap. (To prevent swinging)
   B. Bacon box
   C. Condiment box
   9. Bottom of meat can
   10. Top of meat can

ACCRA, or AK'KRA, British West Africa, capital of the Gold Coast colony since 1876, a fortified seaport town, the starting point of a railway to the northeastern cocoa plantations and connected with South Africa and Europe by telegraphic cable. Since a destructive fire in 1894, Accra has been almost rebuilt, and in 1896 was raised to the rank of a municipality. The residential section is at Victoriaborg where there is a racecourse, and on the Aquapini hills, at Aburi, 26 miles northeast of Accra, are the government sanatorium and botanical gardens. Pop. including about 200 Europeans, 20,000.

ACCSTRING, England, a manufacturing town and municipal borough in Lancashire, on the Hyndburn, 20 miles north of Manchester and five miles east of Blackburn; on the Lancashire & Y. Railway; incorporated 1878. It is well laid out, and has various handsome buildings, including the town-hall, a splendid market hall, technical school and school of art, clubs, etc. The manufacture and printing of cottons, chemical works for their use, and the manufacture of spinning and other machinery, are the chief industries. Coal is wrought extensively. Pop. about 47,000. Accrington gives name to a parliamentary division of the county; pop. 84,878.

ACCUM, Friedrich, Fréd'rin, German chemist: b. Bückeburg, 1769; d. Berlin, 1838. Removing to London at 24, eight years later he was made professor of chemistry and mineralogy at the Surrey Institution. He published several textbooks on these sciences, but is remembered mainly for being (with an energetic print-seller, Ackermann) the introducer of gas-lighting into England. His 'Practical Treatise on Gaslight' appeared in 1815. Another valuable service to society was his 'Treatise on Adulterations of Food and Culinary Poisons' (1820). As the result of charges against his honesty he returned to Germany, and in 1822 was made professor in the Industrial Institute and Academy of Architecture in Berlin.

ACCUMULATION, in law, the increase of a trust fund by the interest or revenue thereon being added to the principal, for the future benefit of a person or persons. The period of time during which this may be done is limited generally by statute both in England and in the United States to the life of the settlor only or for 21 years or during the minority of the cestui que trust. The common-law rule makes void any disposition of any realty for a greater period than a life or lives in being and an additional period of 21 years.

ACCUMULATOR, a device for the storage of energy, more particularly when the energy is supplied from an intermittent source, or when it is to be withdrawn intermittently or irregularly. The fly-wheel on a steam-engine is a device of this sort, but it is not commonly referred to as an accumulator. The word is practically restricted to the following two senses: (1) A storage-battery; (2) a hydraulic apparatus, commonly consisting of a plunger which is fitted to a vertical cylinder and heavily loaded with weights. Water is forced into the cylinder by pumps, with the result that the plunger and its weights are raised, and a considerable quantity of water is thus stored in the cylinder under a high pressure. By the use of such an accumulator it is possible to deliver water for a short time in far greater volume than the pumps feeding the accumulator could deliver if it were at the maximum pressure that the pumps are capable of producing. Hydraulic accumulators are used in connection with riveting-machines, cranes and many other heavy tools.

ACCURACY OF FIRE.—The firing for accuracy, whether with artillery or small-arms, involves two entirely separate and distinct con-
ditions: (1) The determination of the personal skill of the individual using the weapon; (2) the determination of the qualities as regards accuracy of the weapon itself. The most common way of determining the relative accuracy of guns is to ascertain their mean errors in range and deflection for a given mean range, and compare them. It is not always possible to test the practice of guns under precisely similar circumstances.

It is easier to determine, from the practice of the gun itself, a rectangle with which there would be an equal chance of any shot from the gun striking or not striking; or, if a given number of shots were fired, the number which fall within the area. The accuracies of two guns would be in the inverse order of rectangles for the same range. The relative precision of small-arms is decided by various methods. To determine the centre of impact the piece should be fixed in a frame and be pointed at the centre of a target stationed at the required distance, and fired a certain number of times, and the positions of the shot-holes, measured in vertical and horizontal directions from the lower left-hand corner of the target, are ranged in tabular form. The sum of all the vertical distances divided by the number of shots gives the height of the centre of impact above the origin. Similarly the sum of all the horizontal distances divided by the number of shots gives the horizontal distance from the origin to the centre of impact. The co-ordinates of the centre of impact being known, the point itself is known, and its distance from the centre of the target is called the absolute mean deviation. This is equal to the square-root of the sum of the squares of its vertical and horizontal distances from the centre of the target. To obtain the mean deviation it is necessary to refer each shot-hole to the centre of impact as a new origin of co-ordinates, and this is done by taking the differences between each tabular distance and the distance of the centre of impact and adding them. The sum of all the distances thus obtained in one direction divided by the number of shots gives the mean deviation or figure of merit.

The mean horizontal error is found by adding the horizontal distance at which the balls have missed the centre of the target and dividing this sum by the number of balls; this quotient indicates how much the average of the balls have missed horizontally the point aimed at. To get the absolute mean error there are two methods. The first is short and simple, and consists in calculating the hypotenuse of a right angle triangle, in which the other two sides are the mean horizontal and mean vertical errors. The second, which should be called the calculation of the mean of the absolute errors, consists in measuring for each ball its absolute error, a distance from the point aimed at, and to take the mean of these absolute errors by dividing their sum by the number of balls fired. This method is very long, since to have the absolute error of each ball it is necessary to square two numbers and then extract the square-root of these sums as the distance of the points struck have been measured by the vertical lines passing through the point aimed at. The results are not exactly the same; the mean of

The actual mean initial velocity is that for which the sights of the gun are graduated; if the range is exactly known and the sights are set accordingly; if the density of the air is standard; and if there is no wind and no motion of gun or target, then the mean point of impact will coincide with the point at which the line of sight is directed. These conditions, however, are not always fulfilled, nor is it possible to compensate exactly for their non-fulfilment, and consequently the mean point of impact is never exactly at the centre of the target. To bring it as near as possible to that point is the object of the regulation of gun-fire. See Gun-fire.

ACCUSATION, in law, the charging of a person with a crime, or of a minor offense; the declaration containing the charge of an offense or crime. The term is a broad one, including indictment, presentment, information (q.v.), and any other form in which the charge of a crime can be made against an individual.

ACCUSATIVE CASE, in Latin,—and thence applied to the corresponding case in Greek and other declensions,—that case of the noun, pronoun, etc., which designates the object to which the action of a verb is immediately directed. It corresponds with what, although the English noun is nearly without declension, is called in English the objective case. See Declension.

ACELداما, a-kel'da-ma, a cemetery in Jerusalem used to bury strangers in. The traditional site is on a small plateau up the southern slope of the valley of Hinnom, near its junction with the valley of Jehoshaphat; and it was certainly used in the 5th century for the burial of Christian pilgrims, and continued in use till the 17th. According to Matt. xxvii, 7-8, it was bought by the chief priests and elders for a burial-ground with the 30 pieces of silver returned by Judas after the betrayal; according to Acts i, 19, it was bought by Judas himself with the money, which he did not return, and his bowels burst open in it; according to both, the name means "the field of blood," and it was a potter's field. But as the Greek text gives "Aceldamach," which would mean "field of sleep," a natural and beautiful term for a burying-ground, and as, according to Jer. xviii, 22, there was a potter's house in the valley of Hinnom, it appears that the use and name of the place were very old at the time of Christ, and that the meaning "field of blood" was a misunderstanding, or a play on the real meaning, and its connection with the horizontal line described by Schick, 1892, quarterly statement of the Palestine Exploration Fund, pp. 283-89).
ACEPHALI—ACETIC ACID

ACEPH'ALI (‘headless”), in civil history, certain levellers, in the reign of Henry I of England, who acknowledged no head or emperor; or, according to another explanation, who were too poor to own any head and so have any legal superior.

In Church history: (1) Bishops exempt from the jurisdiction and discipline of a patriarch. (2) Clergy belonging to no diocese. (3) Those who, on occasion of a dispute in the Council of Ephesus, a.d. 431, refused to follow either John of Antioch or Cyril of Alexandria. (4) Those who rejected the decision of the Council of Chalcidon, 451, on the nature of Christ. (5) In the 5th and 6th centuries, a large section of the followers of the Monophysite, Peter Mougus, who cast him off as their leader because of his accepting a peaceful formula called the Henothicon. They soon afterward split into three parties, the Anthropomorphites, the Barsanuphites and the Essiastians, who again gave origin to other sects. (6) The Flagellants (q.v.).

ACEPH'ALOCYST ('headless cyst”), a growth found in the liver, kidneys and other glandular organs of man and oftentimes of those of the lower animals.

ACER, genus of trees of the family Aceraceae, containing about 100 species and abundant in north America and eastern Asia. They are natives of the north temperate regions. The most widely known European species are A. campestre and A. pseudoplatanus. See MAPLE; WHISTLEWOOD.

ACERATHERIUM, a-së-ra-thè-ri-um, an extinct rhinoceros which inhabited Europe during the Miocene epoch. It had no distinct horn, whence the name (Gr. ἄ - without, κεφαλή horne, θηρίον animal), but a small boss on the top of the skull indicates a rudimentary horn or callosity. American fossil hornless rhinoceroses formerly referred to this genus are now distinguished as Canoceras.

ACERB! Giuseppe, a-chèr-bë, ju-sep'-a, Italian traveler and scientist: b. near Mantua, 3 May 1773; d. there August 1846. He studied at Mantua, devoting himself to natural science; in 1798 journeyed through Scandinavia, Finland and Lapland, and in 1799 visited the North Cape, the first Italian ever there. On his return he stayed some time in England and published his 'Travels' in English, later having them translated into French and German. He rendered great service to Italian literature by starting in 1816 the Biblioteca Italiana, which fought the Accademia della Crusca. Made Austrian consul-general to Egypt in 1826, he contributed valuable articles on Egypt to the Biblioteca, and obtained many Oriental objects of interest to European museums. From 1836 till his death he lived at his native place.

ACERRA, a-chèr-rä, Italy (the ancient Acreria), admitted to Roman citizenship 352 a.c. a bishop and a city located on the left bank of the river Bormida, near the river Bormida, 12 miles northeast of Turin, with which it is connected by railroad, and opposite Mount Somma. It has a cathedral.

The inundations of the neighboring Agno formerly made it uneasy, for at high tides the marshes are now drained. Pop. about 18,000.

ACESTES, or ΑΕΓΓΕΣΤΟΣ, in Greek legend, son of Crinus and Ασγέρετα, king of the country near Drepanum, in Sicily. He assisted Priam in the Trojan war, entertained Ανεα in his voyage and helped him to bury his father on Mount Eryx. In commemoration of this Ανεα built a city there and called it Acesta.

ACETAL, a-së-tål. (1) A colorless, pleasant-smelling liquid, formed as a by-product in the preparation of aldehyde from alcohol, and occurring naturally in crude alcohol. Its formula is CH₃CH(OH)₂. It boils at 219° F. under ordinary atmospheric pressure. Its specific gravity is about 0.831, and its critical temperature is 490° F. Acetal mixes in all proportions with alcohol and ether. It is soluble in 18 volumes of water at 80° F., and is more soluble at higher temperatures. (2) "Acetal" is also used to signify any one of a group of compounds formed by the combination of one molecule of an aldehyde with two molecules of alcohol and the elimination of one molecule of water. They are obtained as by-products in the preparation of aldehydes from alcohols, a certain portion of the aldehyde formed combining with the unmodified alcohol.

ACETANILIDE (known in the drug trade as aniline), a crystalline compound obtained by the action of glacial acetic acid upon aniline (q.v.). Its formula is C₆H₅NH COH. It melts at 237° F., and boils at 563° F. without decomposition. It is readily soluble in alcohol and ether and dissolves in hot water, but is only sparingly soluble in cold water. It is given in medicine as a sedative and febrifuge. Its physiological action is similar to that of antipyrin but its administration is considered to be safer. It is a common ingredient of "headache powders," and when taken habitually it is liable to cause cardiac symptoms, cyanosis of the membranes, anæmia, heart failure and death.

ACETATES, compounds of acetic acid with metals or organic radicals. See ACETIC Acid.

ACETIC ACID, an organic acid belonging in the fatty series, and resulting from the oxidation of alcohol. It is important on account both of its extensive use in the arts, and of its properties as viewed from the standpoint of the theoretical chemist. Its formula is CH₃COOH, or C₂H₅CO. It is a monobasic acid, the hydrogen in the radical CH₃ not being replaceable by a metal or another radical. In its dilute state it has been known for centuries as vinegar, and in strong vinegar the characteristic odor of the acid is quite marked. It is formed naturally in the fluids of many plants, especially trees; in some cases as a free acid and in others in combination, usually as acetate of lime or of potassium; also in many organic acetates, and in the oils of many seeds. It is a constituent also of certain animal fluids, as, for example, milk. It may be obtained by the oxidation, decomposition and distillation of many organic bodies. It is produced, as in the manufacture of cider vinegar, by the action of the microscopic plant Mycor- derma aceti, better known as *mother-of-vinegar," or "vinegar plant," upon weak alcohol. In the manufacture of vinegar the alcohol
required for the transformation is present in the cider as the result of a previous alcoholic fermentation. It has been shown that "mother-of-vinegar" has no effect upon pure alcohol; a certain amount of albuminous and mineral matter must be present to serve as food for the plant. A very pure form of acetic acid is prepared by subjecting alcohol to the powerful oxidizing action of spongy platinum hung above it in abundance of air. The platinum absorbs oxygen and alcohol vapor at the same time, and these combine to form acetic acid and water. Acetic acid has also been produced by oxidizing alcoholic liquors by blowing ozone into them. The greater part of the acetic acid of commerce is obtained by the destructive distillation of wood, acetate of lime being a by-product in the manufacture of wood-alcohol. (See Wood-Alcohol, under Alcohol.) The acetate of lime so obtained may be decomposed by the addition of sulphuric acid, when acetic acid is liberated, or it may be treated in any one of a number of other ways for the recovery of the acetic acid. One of the best methods consists in mixing the commercial acetate of lime with calcium chloride, and concentrating the solution until the compound known as calcium acetato chloride (CaCl_2H_2O ClH_2O) crystallizes out. The crystals so formed are then dissolved in water, the solution is filtered through animal charcoal, 10 per cent more calcium chloride is added, and the operation is repeated to obtain a new crop of purer crystals. These crystals are finally distilled with moderately strong sulphuric acid, when a very pure acetic acid is given off. This is concentrated to the required degree by distilling.

By heating dry acetate of sodium with an equivalent quantity of concentrated sulphuric acid it is possible to obtain acetic acid in a state free from water. The acid so obtained is a colorless liquid boiling at 244° F., and solidifying in prismatic or tabular crystals at about 63° F., into an ice-like mass; from this property the anhydrous acid has been called glacial acetic acid.

Acetic acid is unflammable in its liquid state, but its vapor burns with a fine blue flame, with the production of water and carbonic acid gas. It has a stinging sour taste, and when strong it blisters the skin. It mixes with alcohol and with ether in all proportions and is used as a solvent for resins, essential oils, gelatin, albumen, fibrin and other organic substances, being a useful substitute for alcohol in certain cases on account of its relative cheapness.

The commercial acid is generally very impure, containing more or less of sulphuric acid and sulphates; sulphuric acid; hydrochloric acid and chlorides; and the salts of copper, lead, zinc, tin and arsenic. Acetic acid is used in the production of the acetic lead, copper, aluminum and iron; in calico printing; in the manufacture of varnishes; and in domestic economy as vinegar. It has also some medicinal use as an outward application. Its extended solvent properties have already been noted.

Acetate (or sugar of lead) and copper acetate (or verdigris) are the most important compounds of acetic acid with the heavy metals. Aluminum acetate and the iron acetates are much used in dyeing. The acetates of lead, potassium and ammonia are also largely used in medicine.

Acetic acid may be formed synthetically by exposing a mixture of one volume of acetylene (q.v.) and two volumes of air to daylight, in the presence of a weak solution of caustic potash. The acetylene is slowly oxidized, combining simultaneously with the caustic potash to form acetate of potash, according to the formula:

\[ \text{C}_2\text{H}_2 + \text{O}_2 + \text{KOH} = \text{CH}_3\text{COOK} \]

Acetylene Caustic Acetate of potash potash

From the acetate of potash so formed the acetic acid can readily be obtained. This mode of formation is of no practical value, but it has a theoretical interest.

The relations of acetic acid with the organic radicals are too numerous and complicated to receive general treatment in the present article. The more important ones are noticed elsewhere. See ALDEHYDE; ACETONE; ETHER; VINEGAR, etc.

ACETIC ETHER, or ETHYL ACETATE, a colorless, inflammable liquid having the formula \( \text{CH}_3\text{COOC}_2\text{H}_5 \), or \( \text{C}_2\text{H}_5\text{OH} \), prepared by the action of sulphuric acid upon a mixture of alcohol and acetic acid. It has a specific gravity of about 0.91 and a specific heat of 0.48 and boils at 77° F. under ordinary atmospheric pressure. It mixes readily with alcohol and with ether and at ordinary temperatures is soluble in about 17 parts of water. See ESTERS; ETHER.

ACETIN, a substance resembling fat in its constitution, obtained by acting upon glycerin with glacial acetic acid. Acetins are known as monoacetin, diacetin and triacetin, according as the acetic acid has displaced one, two or three of the hydroxyl molecules in the glycerin. The formula of monoacetin is \( \text{C}_3\text{H}_5(\text{OH})\cdot(\text{OC}_2\text{H}_5) \); of diacetin, \( \text{C}_3\text{H}_5(\text{OH})(\text{OC}_2\text{H}_5) \); of triacetin, \( \text{C}_3\text{H}_5(\text{OC}_2\text{H}_5) \).

ACETO-ACETIC ACID, a thick acid liquid, having the formula \( \text{CH}_3\text{COCH}_2\text{COOH} \). At 212° F. it splits up into carbon dioxide and acetone. Aceto-acetic ether, or ethyl acetetoacetate, has the peculiar property of reacting either as \( \text{CH}_3\text{COCH}_2\text{COCH}_2\text{OH} \) or as \( \text{CH}_3\text{C}-(\text{OH}) \cdot \)CHCOCOH+.

ACETONE. (1) A limpid, mobile liquid with a taste suggestive of peppermint. Formula, \( \text{CH}_3\text{COCH}_2\text{H} \). It occurs in crude wood-alcohol, from which it can be separated by distilling over calcium chloride. It is also obtained by the destructive distillation of acetates, notably those of barium and lead. It occurs in the urine, blood and brain of calcium diabetic patients. Lieben's test for acetone in the urine is as follows: Distilled urine is made alkaline by caustic potash and a few drops of a solution of iodine and iodide of potassium are added. If acetone is present a yellow precipitate of iodoform is formed at once; if alcohol be present in the distillate, the same reaction takes place, but more slowly; but with acetone the reaction is immediate. Acetone is very inflammable and burns with a white smoky flame. It boils at 133° F. at ordinary atmospheric pressure; its specific gravity at ordinary temperatures is about 0.800. Acetone is a valuable solvent for scientific and technical pur-
poses. One of its most important uses is the solution of acetylene (q.v.) (2) Any one of a certain class of carbon compounds in which two or more double bonds are united by the group CO. These compounds are now called ketones to distinguish them from the particular member of the group defined in (1), above.

ACETONITRILE, a colorless liquid with a pleasant ethereal odor and burning with a red phosphorus-colored flame. The formula is CH$_3$CN, and is isomeric with methyl cyanide. It is best prepared by distilling a mixture of potassium cyanide and potassium-methyl-sulphate. It boils at 178°F. at ordinary atmospheric pressure and has a specific gravity of 0.79. It mixes with alcohol and water.

ACETYL, the radical of acetic acid, its formula being CH$_3$CO. Acetic acid may be regarded as the hydrate of this radical, its formula being CH$_3$COOH. Acetly chloride, CH$_3$COCl, is obtained by the action of phosphorus trichloride upon acetic acid. Acetyl chloride is almost hydrochloric acid when it is heated with any substance containing the radicals hydroxy, amidogen or imidogen, and hence it is of importance as a test for these substances.

ACETYLENE. See COMPRESSED GASES.

ACHÉA. See ACHAIA.

ACHÉI, ak-é, ACHAİANS, ak-a-ıı, or ACHÉANS, ak-ıı, the descendants of the mythical Acheus, son of Xuthus and grandson of Helen; a generic term employed by Homer to designate the whole Hellenic host before Troy, and in poetic use applied to all the Greeks indiscriminately. They appear to have been that branch of the Greeks which inhabited southeastern Thessaly and northern Peloponnesus, and by the Dorian invasion were driven altogether beyond the Corinthian Gulf and cooped into a strip of Peloponnesus along its southern shore, where they were the nucleus of the later Achaian League. See ACHAIA.

ACHÉMENIDÆ, ak-ıı-men-ıı-dê, the Greek name of the Persian dynasty (558-330 B.C.) founded by Cyrus the Great, including Cambyses, Darius I and II, Xerxes, Artaxerxes, etc., and ended by Alexander the Great. The name itself took its name from an ancestor of Cyrus, found in Persian inscriptions as Haxama-niya, which the Greeks softened to Achaemenes (a-ıı-ıı-men-ıı).

ACHAIA, ak-á, or ACHÉA, ak-á, according to Homer, southeastern Thessaly, where was Phthia, the home of Achilles. In later history, a strip of Peloponnesus along the southern shore of the Corinthian Gulf, rising from the coast to wooded hills abounding in beasts of the chase; the uplands were fertile with grapes and olive oil. The nome of 12 towns—Pellene, Ägeira, Bura, Helice, Äegium, Rhytsea, Patrae, Pharsa, Olenus, Dyne and Tritea—headed by Helice, and keeping much to itself in Greek affairs. Helice was destroyed by an earthquake and swallowed by the waves 373 B.C., and Äegium succeeded to the hegemony; and at some time unknown Olenus was deserted.

The League took no share in the Peloponnesian war, but the Macedonian supremacy and the dynastic struggles after Alexander's death broke it up altogether. Some of the remaining 10 towns were held by Macedonian garrisons, some by local tyrants, a state of disunion equally gratifying to Macedon and intolerable to Greek patriots. In 280, when several kings were dead, Macedonia in confusion, and the great Pyrrhus absent in Italy, Patrae and Dyne, the two westernmost towns, formed an alliance; Tritea and Pharsa joined them; and the new Achaian League, famous in history, which gave southern central Greece more than a century of order and good government, was begun. The cities probably drove out their garrisons or rulers, as later ones certainly did. Five years afterward Äegium expelled its garrison and joined the League; Bura was freed and its tyrant slain by its people and their exiled brethren, and joined also; and Iseas, tyrant of Ceryneia, seeing how events were trending, voluntarily surrendered his city with a guaranty of safety, and annexed the city to the League. Seven towns were now included; and the other three were recovered and annexed not long after. But all were small and poor; fortunately for the League, as it was thought too insignificant to molest, and grew up peacefully and solidly for some 30 years. The chief name in its early history is Markos of Ceryneia, who helped liberate Bura even before his own city was freed, and seems to have been the Washington of the League. But its first entrance into the role of a great Greek political force began with the expulsion in 249 of the tyrant of Sicyon by Aratus of that city, who induced it to join the League; it not only gained thereby the first city outside the old Achaian confederacy, and became more or less Pan-Greek, but gained Aratus, its second founder, and a statesman and administrator of high order, though his jealousy of other leaders and his military incompetency injured it deeply. A still greater accession came in 242, when Corinth expelled its Macedonian garrison and joined; and in 234 Lydiadas, tyrant of Megalopolis, the powerful city founded by Epaminondas, voluntarily resigned his place like Iseas and brought in his city, being made commander-in-chief of the League's army the next year. Before the century had begun its last quarter the League included all northern and central Peloponnesus, and many towns elsewhere.

The League was a federal union of absolutely independent states, each having equal power in the Council, which met twice a year—at first and for a long time in a grove near Äegium, but later, at Philoppomen's motion, in the League cities in rotation. The vote of each city was given as a unit, not by elected delegates, but by any of its citizens who were present, any one over 30 having a right to be so; attendance therefore naturally fell to the richer citizens with means and leisure, and the assembly was a rough representative body of the leading men. The union acted as a unit in foreign affairs, and there was a secretary to record the debates and resolutions. The head officer was the strategos, who was commander-in-chief and civil president at once; he had under him a hipparchos (cavalry commander)
and nauarchos (admiral), and a board of 10 demiotargoi as assistants in the Council.

The League of course had its internal feuds and discordances of policy; and the Eolian League, ecclesiastical, of the Gulf, (only half Greek, and wholly barbarian in instability and lack of proper Greek feeling), which alternately allied itself with it and ravaged its territory, was a mischievous rival and enemy. But the League would probably have fully held its own till the Romans came, but for Sparta. Cleomenes II had revolutionized that state, which had shrunk into the narrowest of oligarchies and could not maintain its position; he had turned it into a socialistic one, and wished to force the League to join him in a great Peloponnesian union, of which Sparta would be master, imposing both its foreign policy and perhaps its internal organization on the rest, and which would destroy the internal independence of the League and infringe upon the property-holders in it. The League was badly defeated by Cleomenes in the field, and was between hammer and anvil; for the only power which could save it was Macedonia, its natural foe and old master, and Antigonus Doson refused to give aid unless they bought him the key of Corinth, held by the League, were given up to him. Aratus felt, however, that the suzerainty of Macedonia, now that the League was strong enough to prevent active tyranny, was a less evil than the mastery of Cleomenes; and by cunning management he induced the League to pay the price asked for Antigonus' help. Cleomenes was crushed at Sellasia, and his Spartan constitution came to an end, and the League became a dependency of Macedonia. Yet Aratus' policy was justified by events so far as the League was concerned; it did not suffer from Macedonian tyranny, though the chance of forming a united Greece was at an end. But that was probably as little possible under Cleomenes as under Macedonia.

In point of fact the destroying enemy was not Macedonia but Rome. Under the noble and able Philopemen of Megalopolis, soldier and statesman of high rank, the League was prospering and giving the citizens an enviable government. But a pro-Roman policy prevailed, and Philopemen left the country. In 198 it allied itself with Rome against Macedonia, and this was always the beginning of the end with the other party to a Roman alliance. There were wars against Sparta, and a struggle between Roman and anti-Roman partisans in the assembly, with Roman envoys and intriguers to fan the flames. Finally, in 167, the Romans deported the flower of the Achaian citizens to Italy, many of them being imprisoned, others as the future historian Polybius (q.v.), then a youth of 18 — kept as hostages but given Roman advantages. The last struggle took place in 146, when Mummius defeated the League at Corinth, and the independence of Greece or any fraction of it was at an end. All southern and central Greece was made a Roman province called Achaea.

The first-hand authority for the League is Polybius, unfortunately extant only in fragments; in some parts he is pieced out by Livy, passages of whose work are often obvious translations from Polybius. In English the one great work is E. A. Freeman's 'History of Federal Government,' nearly all devoted to the Achaean League (London 1893).

ACHAIAN, or ACHÆAN, LEAGUE. See ACHAIA.

ACHAN, or ACHAR, ā'hān, a Biblical character whose story is found in the Book of Joshua, chapter VII. Israel had been forbidden to take captives or spoil at the capture of Jericho. Achan violated the taboo. Disaster came to Israel. Investigation followed. After he was discovered by lot, Achan confessed. He and his family were stoned and burned and their property was also burned. The family were destroyed as accessories after the fact. This incident has suggested a phrase often used in literature — "there is an Achan in the camp," meaning that some member of the group is not true to his obligations.

ACHAQUA, a-chá'kwá, a South American Indian tribe probably extinct, though a few hundreds, who lived in the upper Orinoco forests in northeastern Colombia, were still existent in 1850. They were utter savages, practising infanticide beyond the second child, polyandry, and tattooing.

ACHARD, Franz Karl, ā'hart, frants karl, German chemist and physicist; b. Berlin, 28 April 1753; d. 1821. He published in 1780 the results of many and careful experiments on the adhesion of bodies. But later he devoted himself to the development of the beet-sugar manufacture, and after six years of laborious endeavor discovered the true method of separating the sugar from the plant. His process was of enormous service to the countries whom the Napoleonic blockade shut off from the West India sugars. He was afterward director of the class of physics in the Academy of Science in Berlin.

ACHARD, Louis Amédée Eugène, āsh-ar, loo'a-am-ā-dē e-zhan, French novelist; b. April 1814; d. 25 March 1875. Originally a merchant, he became a contributor to several Paris journals in 1838. After the revolution of 1848 he was active as a royalist political writer; 1848–72 the Revue des Deux Mondes brought out almost annually a new story from his pen. He depicts pre-eminently conflicts in family life and society. 'Parisian Letters,' published in 1833 under the pseudonym of 'Grimm,' made his reputation. Other works of his are 'Belle Rose' (1847); 'The Royal Chase' (1849–50); 'Castles in Spain' (1854); 'The Shirt of Nessus' (1855); 'Chains of Iron' (1867); 'The Viper' (1874).

ACHARNAE, a-kār'nē, a large town of Attica, where the Thirty Tyrants (q.v.) encamped when they marched against Thrasybulus; and where the Lacedaemonians, their king Archidamus, pitched their tents when they made an irruption into Attica at the beginning of the Peloponnesian war. Aristophanes, in his comedy 'The Acharnians' — where a citizen of the place, sick of war, ravage and the stoppage of trade, makes a treaty of peace with the Lacedaemonians on his own account — represents the inhabitants as charcoal-makers; and other comic writers stigmatize them as rough and boorish.

ACHATES, a-kātēz, in the Aeneid, a friend of Aeneas, whose fidelity is depicted as
so exemplary that *fidus Achates* (the faithful Achates) has become a proverb.

**ACHEEN.** See ACHIN.

**ACHELOUS,** ak-e-lo'us (now ASPROPO-TAMO, "White River"), the largest river in Greece, 130 miles long, and not navigable. It rises in the Apennine range, flows south in a boisterous torrent, forming the boundary between Eötolia and Acarnania, and empties into the Ionian Sea opposite Ithaca. In its lower course it is an alluvial stream, winding in great loops through very fertile and marshy plains; it comes from the mountains heavily laden with fine white mud, which it deposits along its banks and in the sea at its mouth, where it has formed a number of small islands.

In Greek legend, the son of Oceanus and Terra, or Tethys, god of the river. As one of the numerous suitors of Dejanira, daughter of Géneas, Achelous entered the lists against Hercule, and, being inferior, changed himself into a serpent and afterward into an ox. Hercules broke off one of his horns, and Achelous, being defeated, retired into his bed of water. The broken horn was given to the goddess of plenty.

**ACHEMENIANS,** Joh'ann ("Hans") von, a'hen-yó'bähn fon, or ACHEN, a'ken, German painter: b. Cologne, 1512; d. 1615. He studied at home, and at Venice under Kaspar Rums, and took service with the Bavarian army. He went to Prague at the invitation of Emperor Rudolph II. The Protestant church at Cologne contains his "Crucifixion," the cathedral at Bonn his "Entombment," and among his other works are "Christ Raising the Widow's Son," and "Truth Victorious under Protection of Justice."

**ACHEMENID** or** ACHENBACH,** Andreas, a'hen-bähn, German landscape and marine painter: b. Cassel, 1815; d. 1910. He studied under the eminent Schadow at Düsseldorf, and became one of the leading artists of that school. He painted in Holland, along the Rhine, and in Norway, producing landscapes of rich coloring and intense realism. He was made R.A. in Berlin, and knight of the Legion of Honor in France; and took a first medal in Paris, 1855. Private galleries in the United States have many of his finest works.

His younger brother Oswald, b. Düsseldorf, 1827: d. 1 Feb. 1905, was also a landscape artist, of the same name. His pictures of Switzerland, Italy, etc., were largely bought in the United States. Consult Achenbach, C., 'Andreas Achenbach in Kunstadt und Leben' (1912).

**ACHENE, ACHENIUM, AKENE, a-kên'** etc. ("not gaping"), a dry, hard, one-seeded fruit in which the wrappings of the seed set closely to it, forming almost a coat. The entire family of Compositae are of this sort. The "seeds" of borage, the sunflower, thistle, dandelion, etc. Sometimes they are grouped on a common receptacle, called an etario; as in the strawberry, where it is fleshy, the achene being in the center of the buttercup, where they form the "fruit"; sometimes they are inclosed in the fleshy tube of the calyx, as in the rose.

**ACHESEE,** a'hen-zâ, a lake in northern Tyrol, Austria, 3½ miles long by ½ mile wide, 20 miles northeast of Innsbruck. Its shores are of great beauty, and it is a noted summer resort, having many hotels and private villas, while steamers carry passengers to points of interest.

**ACHEWALL, Gottfried, a'hen-val, got'froid,** German statistician: b. Elbing, 20 Oct. 1719; d. Göttingen, 1 May 1772. He studied at Jena, Halle and Leipzig, and became professor of philosophy, and later of law, at Göttingen. In economics he belongs to the school of "moderate mercantilists"; but it is in statistics that he holds a really high place. The work by which he is best known is his 'Constitution of the Present Leading European States' (1752). In this he gives a comprehensive view of the constitutions of the various countries, describes the condition of their agriculture, manufactures and commerce, and frequently supplies statistics in relation to these subjects. German economists claim for him the title of "Father of Statistics"; but English writers dispute this, asserting that it ignores the prior claims of Petty and his earlier writers on the subject. He gave currency to the term *Staatswissenschaft* (politics), which he proposed should mean all the knowledge necessary to statecraft or statesmanship.

**ACHERON,** ak'e-róhn, the ancient name of several rivers in Greece and Italy, all connected by legend with the lower world. The principal was a river of Thesprotia in Epirus, which passes through Lake Acherusia, receives the Cocytos (Vuvó), and flows into the Ionian Sea south of the promontory of Chimerium, at Glycys Limen or Elaea, now Port Fanari. At one part its course lies between mountains rising precipitously to the height of 3,000 feet. The name is also given to a river of Elis, a tributary of the Alpheus, and to a small river of Brutium, in Italy, near Pandosia (location uncertain), near which Alexander of Epirus fell in battle against the Lucanians and Bruttians (326 B.C.). Their legendary celebrity appears to have been originally due to the Acheron in Thesprotia. This country being regarded by the Greeks as the end of the world in the West, they supposed the entrance to the lower world here. As this district became better known, the legendary river was placed elsewhere, and finally transferred to the lower regions. In Homer, Acheron is represented as a river of Hades. According to later traditions a son of Helius and Gaea or Demeter, who bore this name, was changed into an infernal river as a punishment for giving drink to the Titans during their war with Zeus. The Etruscans are said to have worshipped Acheron. The name of Acheron was ultimately used in a poetic or figurative way to designate the whole of the lower world.

**ACHERONTIA ATROPOS.** See DEATH'S HEAD MOTH.

**ACHERSON, ak'chè-sôn,** Edward Goodrich, American inventor: b. Washington, Pa., 9 March 1856. At 18 he was engaged with a civil engineering corps, opening mines and laying railroads in the vicinity of Reynolds ville, Pa. Upon the termination of his military service he designed a small dynamo, and after meeting many discouragements he secured a position at Edison's establishment at Menlo Park, where his ability speedily attracted the attention of Thomas A. Edison. He was pro-
moted rapidly, given every opportunity for the exercise of his inventive faculty and was sent to Europe to develop the electric telegraph and to study Edison interests at the Paris International Electrical Exposition. Mr. Acheson declined an executive position offered him by Mr. Edison in order to pursue individual research and, after a series of unsuccessful inventions, he brought out an automatic electric telephone which he removed to Pittsburg, where he succeeded in interesting capital in his schemes. In the same year Mr. Acheson concerned himself with the synthetic production of rubber, as a substitute for the more important field of artificial abrasives which now engaged his attention. While passing natural gas into a highly heated furnace containing some clay articles, he found these, after cooling, to be impregnated with carbon and, he believed, rendered harder in consequence. Experiments with a mixture of clay and coke heated electrically failed to produce the result for which Mr. Acheson was striving, but on the end of the arc carbon carrying the electric current into the mixture he discovered a black rock. Testing this substance he discovered that it would not only cut glass as readily as a diamond, but would cut diamonds as well. On 21 Sept. 1891, the Carborundum Company was formed. At first carborundum was so expensive that it could compete only with diamond powder, used for polishing gems, but after extended work the price was reduced, and about 1899 he invented a graphite (Acheson-graphite), superior to the natural product. The emery wheel manufacturers declared their ability to turn carborundum into wheels, whereupon Mr. Acheson tried the experiment himself, and secured the contract for grinding the joints of the new Westinghouse electric lamp. The valve grinders next found a great timesaver in carborundum, while new vistas were opened up by the utilization of Niagara Falls for the generation of electric power. Mr. Acheson built a new plant there in 1895, contracting for 1,000 horse power, the largest amount ever used in bulk up to that time. As early as 1895 he had taken out a new patent for the purifying of carbon, the first of a series resulting in the artificial production of graphite.

What is often considered his greatest achievement is the discovery of graphite lubrication. Before he finally met with success here his experiments brought him upon other discoveries of inestimable importance. Making a test of various clays, Mr. Acheson became convinced that the greater plasticity and strength of the imported article over the Home product was the result of a natural addition of organic matter. Experiments along this line showed him that a treatment with a dilute solution of tannin would produce the same results. Although straw contains no tannin, a liquid extracted from it was found to produce a similar effect, and the clay so treated was called by Mr. Acheson "Egyptianized Clay," and under that name has taken its place on the market as a more important product.

An important discovery of Mr. Acheson's came as the result of an attempt in 1906 to increase the abrasive value of carborundum. Instead of a harder, a softer material was discovered, the ideal lubricating product. A patent of 20 Nov. 1906 secured the perfected process to the International Graphite Company, which is now marketing a mixture of the new graphite with steel to the great satisfaction of the company.

Gredag. This discovery of the process for making this unctuous graphite led to the greatest invention of all, as by applying to it the treatment which produced "Egyptianized Clay" the discoverer succeeded in rendering the graphite so fine that it would pass through the finest of filtered papers, while it freely diffuses of itself through oil or water. Graphite in this state of fineness is termed "Deflocculated." This graphite diffused in water is called "Aquadag." The advantages of this new lubricant over oil, besides cheapness, are the elimination of viscosity and consequent loss in power, and impossibility of explosion in air compressors. In order to mix deflocculated graphite with oil a process for separating it from the water at this point had to be devised, and this Mr. Acheson met, with the result that he produced the most efficient lubricant known to man, namely, "Oildag."

Besides receiving the Paris and St. Louis Exposition prizes, the University of Pittsburg conferred upon him the honorary degree of Sc.D. 12 Feb. 1909; the John Scott Medal was given him by the Franklin Institute of Philadelphia, first for the discovery of carborundum (1899) and again for the manufacture of graphite (1901). In 1907 the American Academy of Arts and Sciences awarded him the Rumford Medals for application of heat in the electric furnace for industrial purposes, and in 1909 the Society of Chemical Industry conferred upon him the Perkin Medal. See CARBORUNDUM; AQUADAG; GRAPHITE; GREDAG; OILDAG.

A CHEVAL POSITION. Military term signifying the position of an army astride a river or other obstacle preventing co-operation of the wings of the army.

ACHILL, å'kîl or EAGLE ISLE, Ir., largest island off the coast, included in the western county of Mayo. It is of triangular shape about 15 miles long from east to west and 12 miles from north to south; area, 57 square miles. The surface is mountainous, rising in peaks to heights of over 2,200 feet; and the coast line is bold and picturesque. There are several fishing villages, of which Dugort, the principal, has made effort to accommodate summer visitors. Pop. 5,000.

ACHILLES, a-kîl'e, one of the heroes of Greek mythology, and in particular the hero of Homer's Iliad. According to the latter he was the son of Peleus, king of the Myrmidons in Phthiotis, a district of Thessaly, and of the Nereid or sea-goddess Thetis, and the grandson of Æacus; hence often called Peleides and Æacides. He was educated from childhood by Phoenix, a friend of his father, who accompanied him to the Trojan war; and Cheiron the Centaur instructed him in the art of healing. Achilles went to this war with the knowledge that he was to perish in it; his mother having foretold him that he should either live a long and inglorious life, or die young after a glorious career. He led his troops, the Myrmidons, against Troy in 50 ships. In the last years of the war we have no minute detail of his actions; in the tenth a quarrel broke out between him and the general-in-chief, Agamemnon, which led him to withdraw entirely from the contest. In consequence the Trojans, who
before scarcely ventured without their walls, now waged battle in the plain with various issue, till they reduced the Greeks to extreme distress. The Greek council of war sent its most influential members to soothe Achilles' anger, among them Thetis, who went without effect. Rage and grief caused by the death of his friend Patroclus, slain by Hector, induced Achilles to return to battle. Thetis procured from Hephaestus (Vulcan) a fresh suit of armor for her son, who at the close of dawn, arrayed in his new armor and kirtled him at his chariot wheels to the camp, but afterward gave the body to Priam, who came in person for it. Achilles then performed the funeral rites of Patroclus, with which the Iliad closes. It contains, however, several anticipative allusions to the death of Achilles, which is also mentioned in the Odyssey. He was killed in a battle at the Okean Gate.

Here ends the history of Achilles so far as it is known to later authors. By later authors a variety of fable is mixed up with it; some perhaps old legend, much certainly outright invention. To make him immortal, his mother during his infancy concealed him by night in fire, to destroy the mortal parts inherited from his father, and annulled him and day with ambrosia (the story of Demeter and Demophoon). His father discovering him one night in the fire, Thetis fled; and his father entrust him to the care of Cheiron, who fed him with the heart of lions and the marrow of bears, and gave him the education proper to a hero. According to another story Thetis made him invulnerable by dipping him in the Styx, but the heel by which she held him was untouched by the water; accordingly he received his fatal wound in the heel. The story of Siegfried is patterned on this. To prevent his going to Troy, where it was predicted he should perish, Thetis sent him, disguised as a girl, to the court of Lycomedes of Scyros. He was educated with Lycomedes' daughters, one of whom, Deidameia, became the mother of Pyrrhus or Neoptolemus by him. Odysseus (Ulysses) went to the court of Lycomedes to discover him and induce him to join the war, in which Calchas had declared his aid indispensable. He succeeded by a stratagem. Presenting himself as a merchant, he offered the daughters of Lycomedes female ornaments and articles of attire for sale, among which he laid a shield and spear. He then raised an alarm of danger, on which Thetis fled; and Achilles seized the weapons. He is said to have been killed either by Apollo in the likeness of Paris, or by an arrow of Paris directed by Apollo. According to another account he made love to Polyxena, a daughter of Priam; and, induced by the promise of her hand on condition of his joining the Trojans, went unarmed to the temple of Apollo at Thymbra, and was there assassinated by Paris. Various stories are told of the relations of Achilles with Iphigenia (q.v.), who was brought to the camp at Aulis on pretext of being married to Achilles. In one account Achilles interferes to rescue her from being sacrificed, and sends her to Scythia; in another he marries her, and she becomes the mother of Pallas. In one story he says she is his wife and went to her brother to the lower world, where he became a judge; others again say he married Medea in Elysium. Annual sacrifices were offered to Achilles by the Thessalians at Troas by command of the oracle of Dodona; at Olympia and other places in Greece sacred honors were likewise paid to him. This has led to the unsafe inference that he was originally an Achaean god; but remembering the propitiousness of his arms, and the superlative genius among them, and such cases as that of Roland, it is much more likely that he was a chief before he was a god. It is probable that a real Thessalian warrior existed who has been thus idealized, though we do not know his name or real deeds. See Homer; Trojan War.

ACHILLES TATIUS, a-ki'lēz tā'shē-us, a Greek writer of romances: b. in Alexandria; flourished in the 5th century of our era. Suidas says he was a Christian bishop, but this is doubted. He wrote 'The Loves of Cithophon and Leucippe,' an erotic story in eight books, of pleasing but florid style, and without much regard to unity or consistency of plot; it was modeled on Heliodorus' Ethiopica." That the story was very popular in its day is proved by the number of copies of it that are still in MSS., and by the plentiful imitations of it in the Middle Ages. An English translation by Anthony Hodges was published in 1638.

ACHILLES TENDON, a tendon, so called because, as fable reports, Thetis, the mother of Achilles, held him by that part when she dipped him in the river Styx to make him invulnerable. It is the strong and powerful tendon of the heel, which is formed by the junction of divers muscles, and which extends from the calf to the heel. When this tendon is unfortunately cut or ruptured, as it may be in consequence of a violent exertion or spasm of the muscles of which it is a continuation, the use of the leg is immediately lost; and unless the part be afterward successfully united the patient will remain a cripple for life. The indications are to bring the ends of the divided parts together, and to keep them so until they have become firmly united. This tendon is frequently the seat of a synovitis, just above the heel, from excessive exercise.

ACHIMENES, a-ki'mē-nez (from the Greek name of an East Indian plant used in magic), a genus of tropical American plants of the family Gesneriaceae, greatly cultivated in greenhouses for the beauty of their red, white and blue flowers, which, if the rhizomes are potted by the first of April, bloom from the last of May till into October or even November. They may also be propagated by cuttings. The species are numerous.

ACHIN, ACHIEEN, or ATCHEEN, a-chen' (properly Ateh, Portuguese corruption Acheen, Dutch Ateh or Atchee), a district at the northwest extremity of Sumatra, till 1873 an independent sultanate, now a province of Dutch Indies: area, 20,471 square miles; pop. (1912) 789,664 (but a true census must be impossible). The surface is divided into an eastern and a western half by a mountain chain which traverses the whole island, rising in the peak of Abong-Abong to 11,000 feet. At the farthest north is the famous Gold Mountain, at the base of which lies the capital. On both sides are numerous stretches of coal, watered by small but deep streams and admirably adapted for tree-culture, gardening and rice. The flora and fauna agree with those
of Sumatra; pepper-trees and areca-nuts grow there. The natives employ themselves in agriculture, cattle-rearing, trade, fisheries, weaving cloth and working in gold, silver and iron. The chief agricultural industry is the production of rice, and pepper. The latter is sent from many small western ports. From Pedir and other northern ports large quantities of betel-nut are exported to India, Burmah and China. Achin pomo are also much reputed and exported. Major exports are sulphur, iron, sappanwood, gutta-percha, dammer, rattans, bambooos, benzoin and camphor, the latter highly valued in China and bringing an enormous price. Silk, once plentiful, has nearly disappeared. Nor is there now much export of the gold that once drew so much trade thither and made it so rich as to astonish foreigners. No place in the East save Japan was so abundantly supplied with it, and it was from far antiquity part of the Golden Chersonese. It exported probably 15,000 to 18,000 ounces yearly. The imp-amb, a state rice (the native supply being insufficient), opium, salt, dried fish, cotton goods, iron and copper wares, firearms, pottery, etc. The people are distinct from the rest of the Sumatrans, while the Malays; they are taller, handsomer and darker, more active and industrious, and good seamen; but they are treacherous, blood-thirsty and revengeful, immoral and inordinately addicted to opium. Their ethnological place is not settled; they are believed to be Malay at root, though probably with some admixture from India, and not impossible an Arab strain. Their speech is said by some to be Polynesian at root, though with much Malay loan element. Their literature is entirely Malay, and comprises poetry, theology and chronicles.

The capital of the province is Kota Radja or Achin, situated at the northwest extremity, on a stream navigable by boats, about 4 1/2 miles from its port Oleh-leh, with which, since 1876, it has been connected by a railway. Formerly a large and flourishing city, it was almost entirely destroyed by the war, but is now beginning to revive. It contains a Dutch garrison.

History.—Civilization was first introduced into Sumatra by Hindu missionaries in the 7th century, and a considerable amount of immigration from India followed. In the 13th century it was converted to Mohammedanism by Arabs—the sultans of Achin claim descent from the first Mohammedan missionaries—and the Arabic alphabet displaced the Japanese. Northern Sumatra was visited by several European travelers in the Middle Ages, as Marco Polo, Friar Odorico and Nicolo Conti; and some of these, as well as Asut and Malin Lambh, a state which must have corresponded nearly with Achin; but the first to name it as such is Alvaro Tellez, a captain of the Portuguese Tristan d'Acunha's fleet, in 1506. It was then a dependency of Pedir adjoining, but within 20 years it had not only gained independence, but swallowed up all the other states of northern Sumatra. It attained the climax of power under Sultan Iskandar Muda, 1607-36, when it extended from Aru, opposite Malacca, round by the coast to Padang, on the western side of Sumatra, a distance of 1,100 miles; and its supremacy was owned also by the large island of Nyas, and by the continental Malay states of Johor, Pahang, Quedah and Perak. It is in fact the only Sumatran state which has at any time been powerful since the Cape route to the East was discovered. Its wealth astonished the European visitors and traders; and its great commercial repute is shown by the fact that it is said that the first Dutch (1599) and English (1602) commercial ventures were directed. Lancaster, the English commodore, carried letters to Queen Elizabeth to the king of Acheen," and the other letters, signed letters with Iskandar Muda in 1613, and the Acheenese sent envoys to the Dutch republic, who were received by Prince Maurice in camp (1602). But native jealousy of foreigners and the latter's rivalry with and destruction of each other's ventures prevented the establishment of permanent factories there. Still, the trade, though spasmodically interrupted, was very important; foreign merchants of many nations were settled in Achin city port, while other Chinese merchants came as far as Malacca and used to hold fairs through June and July. For 58 years after Iskandar's death the Malay oligarchy of chiefs placed females on the throne; in 1699 the Arab party suppressed this system and set up an Arab ruler, and the state was divided into four internal factions. From 1666 on, the Dutch had held possessions around Padang on the western coast, and gradually gained much in old Achin; in 1811 the British seized this as well as the other Dutch East Indies. In 1816 Java was restored to the Dutch, but the English colonies insisted the more strenuously that English influence should be maintained in Achin; and in 1819 the Calcutta government made a treaty excluding all other foreigners from permanent settlements there. In 1824 an exchange was made with the Dutch, of the Sumatran settlements for others in Asia; the above article was not mentioned, but it was privately understood that it should not be insisted on if the Dutch would make no war on Achin. In the convention at The Hague, 2 Nov. 1871, the Dutch insisted on the latter stipulation being formally withdrawn, as the Acheenese were pirates and chastisement was often needed; and in 1873 Holland—with plenty of provocation, but grave doubts even at home of its ability to carry it on—began the war, which cost it 15,000 lives and about $100,000,000, and ended in 1880 in the real subjugation of the country. Achin city was captured and civil government has been instituted in the coast territory; but the natives are fierce and have a good country for guerrilla warfare, and outbreaks occurred in 1896, 1898 and 1901-04. Many evidences of these wars may be seen in Holland. The authoritative works are all in Dutch; the chief is Snouck Hurgronje 'De Achehers' (2 vols., The Hague 1893-95). There is also one of Veth, 'Achinn' (Leyden 1873). For the geography of Achehn consult Volz 'Die Gajoländer' (Berlin 1912).

ACHIKUNDA, an African tribe inhabiting the Lower Shire, Nyasaland, Central Africa. They are quiet and peaceful, with marked tribal characteristics and are engaged chiefly in agriculture, boating and fishing.

ACHISH, a king of Gath in Philistia, with whom David was on friendly terms when out of favor with Saul; represented as a dull, easy man whom David dupes into believing that he is making war only on the Judahites and their al-
ACHMET — ACID INDUSTRY

lies, when in fact he is raiding the native tribes, and enriching his stronghold Ziklag with their plunder. His lords are not so blind, however, and make him dismiss David before going to battle at Mount Gilboa. David lived with him four months according to one account, a year and four months according to another.

ACHMET, åk-mёт, VERIK PASHA, Turkish statesman, son of a Greek renegade and a Jewish mother: b. Constantinople, 1818; d. 12 Aug. 1891. In 1834 he accompanied his father to Paris, where he entered the College of Ste. Barbe. Having finished his education in France, he returned to Constantinople, where he was given a position in the official translation bureau, of which he soon became the director. He made accurate and detailed knowledge of the Ottoman Empire more easily accessible to Europeans through the publication of his yearbook, 'Salaame, ou Annaire de l'Empire Ottoman,' which first appeared in 1847. He was later appointed by the Sultan to fulfill many important diplomatic missions abroad and was president of the council and minister of the interior for the Russo-Turkish war in 1877-78. He translated many of the French and German classics into Turkish.

ACHOR, åh-ot'er, a valley which forms the northern boundary of Judah (Josh. xv, 7) near Jericho. Its identification is uncertain.

ACHRO'MATISM. Because the several components of a beam of ordinary light are of different refrangibilities, it follows that they are not brought to a common focus by a simple convex lens. The violet rays meet at a point nearer the lens than that at which the red rays unite, and the optical image is confused and fringed with prismatic colors.

The difficulty is greatest with lenses of short focus, whence the early practice of constructing telescopes of enormous length. Sir Isaac Newton, misled by a really remarkable series of petty accidents, concluded that this difficulty could not be obviated, and that large refracting telescopes were therefore impracticable. He therefore gave his attention to the development of the reflector. In 1757, however, John Dollond, a Spitalfields weaver, discovered that different substances separate the colors of light, for a given mean refraction, to a different degree. He therefore constructed double lenses of two different kinds of glass,—crown glass and flint glass. A concave lens of flint glass brings the colors together while not entirely destroying the refraction caused by a convex lens of crown glass. The correction is far from perfect, however, and even the best telescope lenses produce a blue halo surrounding the stellar images. This outstanding color may be reduced by combinations of three or more lenses; but such devices greatly increase the mechanical difficulties of the optician. The present practice is to bring together such portions of the light as most powerfully affect the photographic plate, leaving the other tints uncorrected. The introduction of new kinds of glass, especially the Jena glass, so called, has somewhat improved the chromatic correction of smaller objectives.

ACHSHARUMOV, Nikolei Dmitrievich, åch-sha-roo'mof, né-kol'ait dém-tré-yev'ich, Russian novelist and critic: b. Saint Petersburg, 15 Dec. 1819; d. Moscow, 30 Aug. 1893. For a time he held a post in the ministry of war, but came later to devote himself to painting, and particularly to literature. He first attracted attention by a dramatic sketch, 'The Masked Ball,' and became more widely known through his novels, 'The Double,' 'The Gambler,' 'The False Name,' 'An Unusual Case,' 'The Mandarin,' and 'At All Costs' ('Was es auch Kosten mag?'). His critical essays include studies of Tolstoi, Turgeniev, Dostoievski and Herbert Spencer.

A CHULA, å-shoo'la (Port.), a dance resembling the fandango (q.v.).

ACIC'ULITE, a mineral better known as needle-ore (q.v.).

ACID INDUSTRY, The. The manufacture of chemicals in the United States began with that of sulphuric acid. The indispensable part that this acid plays in all branches of manufacturing created an insistent demand that could not be met by imports. From the early days onward the manufacture of acids has steadily increased until, at the present, the tonnage of acids made annually in the United States exceeds the tonnage of any other one product, excepting only fertilizers, which in themselves contain enormous quantities of salts made with the aid of acids.

In gathering statistics of the acid industry it is customary to place the making of sulphuric and nitric acids and their mixture ('mixed acids') under a separate classification, as the production is so very much greater than of other acids, and their use in general manufactures is so widespread. The Census Bureau in its report on the acid industry for the calendar year 1914 gives the total value of the acids made for sale in the United States at $30,001,-364. The amount made and consumed is not valued, but was estimated as worth at least as much more.

Sulphuric Acid.—The number of establishments making sulphuric acid was 194—including those plants producing it for consumption in their regular business of making fertilizers and explosives, refining petroleum and the manufacture of general chemicals. The total production amounted to 4,076,572 tons, while 2,337,977 tons were made for sale, in value, $15,395,133 — and 1,709,698 tons for consumption in the factories where produced. In this total all the acid made was reduced to the basis of 50° Baumé. It included 1,677,649 tons of 50° acid; 795,489 tons of 60° acid; 828,466 tons of 66° acid; and 77,758 tons of oleum or fuming acid. Of the establishments reported, 34 were in Georgia, 18 in New Jersey and 16 in Pennsylvania—the location being governed obviously by proximity to deposits of the pyrites needed as raw material. Preliminary official figures of the Geological Survey place the 1916 output of sulphuric acid in the United States at about 4,500,000 tons of 50° acid and nearly 1,000,000 tons of acids stronger than 66° Baumé. The enormous increase over the production of 1914 has nearly all gone into the manufacture of explosives in this country. The exports of sulphuric acid for 1916 were only 30,000 tons.

Nitric Acid.—The manufacture of nitric acid engaged 32 establishments, of which 11
ACIDASPIS—ACIDOSES

were located in Pennsylvania and 10 in New
Jersey. The total output was 78,589 tons, of
which 14,685 tons were for sale and 63,904
tons for consumption in the making of other
products in the plants where produced. The
production sold was valued at $8,181,020.

Mixed Acids,—In 1914 there were 37 estab-
lishments making the mixture of sulphuric and
nitric acids known to the trade as "mixed
acids," and used so largely in the manufacture
of explosives. The total production was 112,124
tons of which 42,725 tons were for sale, and
valued at $2,204,480, and 69,399 tons for con-
sumption by the plants making it. The mixed
acid industry showed a notable increase since
the previous census of 1909, amounting to 49.4
per cent in quantity. The value, however, in-
creased only 18.5 per cent.

The quantities of the principal raw materials
consumed in the manufacture of sulphuric and
nitric acids and mixed acids in 1914 were as
follows: sulphur or brimstone, 62,340 tons, cost-
ing New York $727,242; pyrites, 918,255 tons,
costing $3,928,069; and nitrate of soda, 59,604 tons,
costing $2,772,495. In addition, the fertilizer
industry used in making acids: 2,041 tons of sul-
phur; 613,842 tons of pyrites; and 15,194
tons of soda; nine explosives industries used in
making acids: 15,832 tons of sulphur; 25,885 tons
of pyrites; and 190,960 tons of nitrate of soda.
The petroleum industry used in making acids: 2,035
tons of sulphur and 23,669 tons of pyrites.

The less important acids separate reports
for 1914 were made as follows:

Acetic Acid was made in 13 establishments,
the output amounting to 75,303,375 pounds, of
which 70,617,637 pounds was for sale and
valued at $1,272,294. The remaining 4,685,738
pounds were for factory consumption. The in-
crease in output since 1909 was 24.1 per cent,
but the value of the product was less than in
1909 by 4.8 per cent. The bulk of the produc-
tion was in Pennsylvania, with Massachusetts
and New Jersey second.

Boric Acid was made in 1914 by five establish-
ments whose combined production amounted to
8,590,311 pounds of which practically the whole
was for sale, and valued at $588,981. The figures
show a decrease of 54.5 per cent in quantity
over the production of 1909, and of
99.1 per cent in value.

Citric Acid was made in three establishments
in 1914, the combined output being 2,657,940
pounds, valued at $1,516,336. The production
was 26.4 per cent greater than in 1909, and its
value was greater by 95.1 per cent.

Hydrofluoric Acid was made in nine establish-
ments in 1914, and their combined output was
7,209,248 pounds, of which 5,373,657 pounds,
valued at $325,840, were for sale; 1,835,911
pounds were for consumption by the maker.

Muriatic or Hydrochloric Acid was made
in 1914 by 31 establishments, the total produc-
tion being 337,167,882 pounds. Of this, 170,
876,878 pounds were made for sale, and valued
at $1,348,190; the remainder of 166,291,004
pounds being consumed by the maker. The
figures show a decrease of production from
that of 1909 by 15.9 per cent, and a decrease of
value by 23.3 per cent.

Oleic Acid was made in 1914 by seven establish-
ments, with a total output of 23,187,570
pounds, of which nearly all was for sale, the
value being $1,301,353. The increase of produc-
tion over 1909 was 33.9 per cent, and the in-
crease in value 54 per cent.

Phosphoric Acid was made in seven establish-
ments in 1914, the total output being 12,420,191
pounds valued at $680,259 — only 1.9 per cent
greater than in 1909.

Stearic Acid was made in 10 establishments
in 1914, the combined production amounting to
14,351,404 pounds, valued at $1,242,492. In ad-
inement, 608,705 pounds were made and consumed
by the makers.

Tannic Acid was made in five establish-
ments, four of which were located in New York.
The total output was 853,830 pounds, valued at
$287,142.

In addition to these separate reports values
are given for the production of "fatty acids" at
$206,576, and miscellaneous acids at $1,980,
816. This latter classification includes — in the
order of the value of their respective outputs —
tartaric, carboxyl, picric, salicylic, lactic, oxalic,
hydroxyalkylalcohols, pyrogallic, gallic, sulphyros,
pyrrole, glycylnic, phosphoric, benzoin and
arsenic acids.

ACIDASPIS, ās'-dāsp's ("spine-shield"), a small trilobite widely distributed through Silu-
rian and Devonian rocks, whose striking char-
acteristic is the thick setting of the dorsal
shield with such numerous and formidable
spines that it must have been almost impossible
for even much larger enemies to prey on it.
The head-shield is entirely different from that
of other trilobites, the trilobation being ob-
scured by extra furrows and longitudinal false
furrows. The thorax has 9 or 10 segments,
each with long lateral spines and two shorter
median ones; the small tail-shield in nearly
all species also has them; in some a row of
slender ones on the sides of the head-shield,
and a long one projecting from each posterior
angle; and from the middle posterior edge two
long ones, straight or curved, often project up-
ward and backward. A few species have the
eyes placed, like some crabs and lobsters, on
the ends of long, slender stalks, commanding a
view in all directions.

ACIDIMETRY. See CHEMICAL ANALY-
SIS.

ACIDOSIS, a condition of the body due to
excess of acid formation or lack of oxidation
of the same. It is chiefly seen in the disorder
known as diabetes. Acid intoxication results
from the direct production of acid substances
within the body, or from the administration of
acids chiefly inorganic.

The chief acids concerned in acidosis are
collectively termed acetone bodies and are:
(1) Butyric acid, (2) diacetic acid and
(3) acetone. These bodies are formed from
cause substances and fats or proteins, practice-
ally from the fats and proteids however, the amino
acids of the latter being the chief sources. The
Butyric acid is the starting point of the
other two. By oxidation it is converted into
acetone-acetic (diacetic) acid and this by losing
a molecle of water from its carboxyl group
produces acetone. These substances were first
found in the urine and later isolated from the
blood of patients with acidosis.

The acetone bodies appear normally under
conditions of starvation; even abstinence from
carbohydrates will cause their presence in the
urine. Under pathological conditions acidosi
is found in a number of conditions, such as
cyclic vomiting of children, pregnancy with
vomiting, eclampsia, marked grades of temper-
ature, tuberculosis, asthma, atrophy, morphine,
carbon monoxide poisoning, and chiefly in the
disorder known as diabetes (q.v.).

ACIDS. In popular language, acids are
substances of a corrosive nature, with a sour
taste when diluted sufficiently to lose their cor-
rosive action on the tongue, capable of turning
certain blue vegetable coloring matters, such as
limus, to a red, dissolving metals and forming
neutral compounds with alkalies. They are
classified generally into two groups: the inor-
ganic and the organic, referring to their origin
in the mineral kingdom, or in the vegetable
and animal kingdoms. Inorganic acids are
rarely found as such in nature, but usually in
combinations. A small quantity of nitric and
nitrous acids is often present in the atmosphere
after thunderstorms, carbolic acid is found in
liqueurs and other liquid for culinary uses and hy-
drochloric and sulphurous acids are detected in
the fumes from some volcanic fissures. On the
other hand, organic acids are freely distributed
throughout the vegetable world—as in all fruit.
Also less degree in the animal kingdom. In modern chemistry an acid is re-
garded as a salt of hydrogen in which one or
more of the hydrogen atoms are replaceable by
metallic atoms or by organic radicals. For ex-
ample, hydrochloric acid (HCl) brought into
contact with sodium hydroxide (NaOH) seizes
upon the sodium, and releases the hydrogen
atom—forming sodium chloride (NaCl) and
water (H2O). An acid containing one such
atom of replaceable hydrogen is called mono-
basic; if it has two such atoms of hydrogen it
is called dibasic or dibasic; if three, tribasic;
and so on. Hydrochloric acid, HCl, is a familiar
example of a monobasic acid; it has only one
atom of hydrogen that can be replaced by potas-
sium (for example), with the formation of the
single compound KCl. Sulphuric acid, H2SO4,
is a familiar dibasic acid; with potassium it
forms the two compounds KHSO4 (hydrogen
potassium sulphate), and K2SO4 (normal or
basic potassium sulphate). Phosphoric acid,
H3PO4, is a tribasic acid in which one, two or
three of the hydrogen atoms may be re-
placed by metals or radicals. In a polybasic
acid the hydrogen atoms need not necessarily
all be displaced by the same element or radic-
als; thus microcosmic salt is the phosphate of
hydrogen, sodium and ammonium, with the
formula HNa(NH4)PO4+4H2O. Acids may be
formed synthetically by uniting hydrogen with
non-metallic substances—as with chlorine, to
form hydrochloric acid.

When an acid contains oxygen it is com-
monly named for the substance that is present
with the oxygen and hydrogen in the acid. For
example, nitric acid is named for nitrogen, and
phosphoric acid for phosphorus. It often hap-
pens that the same element forms more than
one acid with oxygen and hydrogen. In these
cases it is usual to give the termination -ic to the
one in which the oxygen is present in its high-
est valency, or combining proportion; and the
termination -ous to its next lower valency.
For example, H2SO4 is called sulphuric acid,
while H2SO3 is called sulphurous acid. Hydro—
is used as a prefix where the oxygen is in still
lower proportion—as hyposulphurous acid. If
the acid contains no oxygen it has the prefix
hydro— as hydrochloric acid (HCl). When
an acid has an unusually large oxygen com-
ponent it has the prefix per— as perchloric
acid. When an acid has been deprived of all
its water component it becomes an acid an-
hydride. The salts formed by acids ending in
-ic have the ending -ate, such as the acid sul-
phate of potassium, produced by substituting
the metal potassium for one of the hydrogen
atoms of sulphuric acid, while those formed by
acids ending in -ous have the ending -ite, as the
sulphite of sodium, and the hypophosphite of
calcium. Salts are considered by some chem-
ists to be acids in which the hydrogen atom has
been replaced by the metals. Organic acids are
oxides in the second degree of alcohols and
aldehydes, combined with a hydrocarbon. They
are distinguished by the presence of the car-
boxyl group —COOH, in which the hydrogen
atom is replaceable by metals, resulting in salts.
When the hydrogen is replaced by alkyl radicles
esters are formed. The relative strength of
various acids is determined by saturating them
with a metallic hydroxide. The proportion
taken up by each acid is the measure of its
relative strength.

ACIPENSERIDEÆ, a family of fishes in the
suborder Chondrostei (by some called
Acipenseroidæ), comprising the sturgeons
(q.v.).

ACIREALE, āˈkēr-e-ˈalē, Italy, an episco-
cal city of Sicily, nine miles northeast of Ca-
tania, at the mouth of the river Acis which
flows from Mount Etna. An important trade
is carried on in grain and flax; there are manu-
factures of silk, linen and cotton goods, and the
thermal springs dating from Roman days, and
the surrounding scenery filled with classic tra-
dition, attract numerous visitors. The grotto of
Acis and Galatea, the cave of Polyphemus and
the seven Scogliade' Cyclopi or Faraggioni which
the blinded Polyphemus hurled at Ulysses, are
shown in the neighborhood. Pop. 35,600.

ACIS, a character of Greek mythology, a
handsome shepherd of Sicily, son of Pan and
the nymph Synaethis. Beloved of Galatea the
Nereid, they were surpased by the two Cyclops Polyphemus who crushed Acis to death
with a rock. Galatea transformed his gushing
blood into the river Acis, which has been famous for its cold waters since the time of Ovid. See ACIREALE.

ACKER, Charles Ernest, American in-
vventor: b. Bourbon, Ind., 12 March 1868. He
was graduated from Cornell University in 1888,
began a private practice as electrical engineer in
Chicago, which he continued until 1893. He is
the inventor of the Acker process of manufact-
uring caustic soda by the electrolysis of molten
salt and he was the first in America to manu-
facture carbon tetrachloride. He has invented
many processes pertaining to chemical and
electro-chemical manufacturing. He was
awarded the Cresson gold medal by the Frank-
il Institute, and is a member of many scien-
tific societies.

ACKERMANN, ākˈər-mən, Louise Vic-
1813; d. Nice, 2 Aug. 1890. Her principal

98
work, 'Pousses, premières poésies, poésies philosophiques' (Paris 1874), analyzing and revolting against human suffering in powerful but sombre verse, attracted wide attention. Her last work 'Pensées d'une solitaire' (Paris 1883) contained a short autobiography.

ACKERMANN, Rudolph, German-English publisher and inventor: b. Schneeburg, Saxony, 20 April 1764; d. London, 30 March 1834. In 1775 he opened a print-shop and art-school in the Strand, London, and developed a lucrative business as publisher of Ackermann's Repository of Arts, Literature, Fashions, etc., a monthly periodical of which 40 volumes, illustrated by Rowlandson and other leading artists, appeared up to 1828. In 1825 he published 'Forget-me-not,' the originator of the English annuals: 'The Microcosm of London' (3 vols., 1808-11); 'Westminster Abbey' (2 vols., 1812); 'The Rhine' (1820); 'The World in Miniature' (43 vols., 1821-26); etc. He invented and manufactured waterproof cloth and paper; was one of the first to apply the lithographic process to illustration; and was a pioneer in the use of illuminating gas. In philanthropic work he raised nearly $1,000,000 for German relief after the battle of Leipzig.

ACKNOWLEDGMENT, the act of one who has executed a deed, in going before some competent officer or court and declaring it to be his act and deed. The function of an acknowledgment is twofold: To authorize the deed to be given in evidence without further proof of its execution, and to entitle it to be recorded. The same end may be attained by a subscribing witness going before the officer or court, and making oath to the fact of execution, which is certified in the same manner, but in some States this is permitted only in case of the death, absence or refusal of the grantor. The certificate should be in substantially the following form:

I, 19...

I, hereby certify that 19...

whose name is signed to the foregoing conveyance, and who is known to me, acknowledged before me on this day that being informed of the contents of the conveyance, he executed the same voluntarily on the day the same bears date.

Given under my hand this 19...

In many of the States it is necessary that a married woman be examined separately and apart from her husband touching her voluntary execution of the deed, and the fact of such examination must be included in the certificate.

ACLAND, Lady Christian Henrietta Caroline Fox, commonly called "Lady Harriet"; daughter of the first Earl of Ilchester; b. 3 Jan. 1750; d. 21 July 1815. She married Maj. John Dyce Acland, September 1770, accompanied him to America, and shared his campaigns. In 1777 with him. He being wounded and carried prisoner into the American lines in the second battle of Saratoga, 7 October, she left the British camp by night in a small rowboat and in a driving storm to rejoin him, with her chaplain and two servants; was cordially received by Gates and nursed her husband back to health. Acland reciprocated the kindness when on parole in New York, by helping to relieve the sufferings of American prisoners. He died of paralytic stroke 2 Dec. 1778; the gratifying story that he was killed in a duel for defending American courage against aspersion being pure invention. Equally untrue is it that she went insane and afterward murdered Captain Nelson; she died Acland's widow. She was a graceful and elegant woman and is remembered for her charities.

ACLAND, Sir Henry Wentworth Dyke, English sanitarian: b. 1815; d. 16 Oct. 1900. He was long an expert on cholera and the various forms of plague. He was professor of midwifery at Oxford (1857-94), besides serving on various sanitary bodies. He was one of the founders of the Oxford University Museum, and with Ruskin published an account of its objects (1859). He accompanied the Prince of Wales to America in 1860. He was author of numerous works on medicine and medical education, among them 'Memoir of the Cholera at Oxford,' in 1854. He was created a baronet in 1890.

ACLINIC LINE, an imaginary line on the surface of the earth, at every point of which the magnetic dip is zero. It is irregular in shape, and its shape and position vary somewhat from year to year; but, roughly speaking, it lies close to the equator. See MAGNETISM, TERRESTRIAL.

ACMITE, a mineral, in Dana's pyroxene group, crystallizing in the monoclinic system, and having essentially the composition NaO. FeO. 4SiO. Hardness 6 to 6.5; sp. gr. 3.5; lustre vitreous, inclining to resinous; usual dark green to greenish black, with a vitreous to pearly, bronzy. Occurs in slender lustrous prisms in the ezolite-syenites of Norway, Greenland and Arkansas.

ACNE, ak'ne. Among the diseases of the skin there is none which is more annoying than this, particularly because of its frequent location upon and disfigurement of the face and because of its common occurrence in young people of both sexes with whom disfigurements of this character are keenly distressing. It also appears upon the scalp, back, chest and shoulders, and in people of all ages. It may be a serious matter in the aged for it sometimes terminates in cancer.

Specifically it is a disease of the sebaceous glands of the skin, due sometimes to retention of their oily, greasy secretion, to the action of certain drugs like the bromides, or to the influence of various kinds of germs which find a lodgment upon the skin. It appears in various forms, as black specks or comedones, as reddened spots, as hardened shot-like points, as elevated conical lumps from a pinhead to a pea in size, as suppuring sores resembling boils, etc. In many instances it terminates in disfiguring scars which gradually become inconspicuous, in striae, or in increase or atrophy of the scalp. When the scalp is involved there is dandruff and loss of hair, on the nose and cheeks it gives rise to crusts and scales, and on the face of the aged it may take the form of horn-like masses. Wens and similar tumors of the face and scalp are other forms of this disease.

It may result from indigestion, constipation, bad nutrition, bad habits connected with the sexual apparatus and disturbance of the peripheral nerves. The sebaceous glands which
may be involved in this disease are destroyed, and if they perish in very large numbers the nutrition of the skin to which they have been distributed is of course impaired.

Some symptoms are sometimes active and acute and the eruption painful, and at other times the eruption will disappear only to return when provoked by the use of sweets, pastries, fats or other substances which are not easily digested or after the use of irritating drugs. It is very apt to recur periodically in young women in connection with the function which is peculiar to their sex, especially when there are anatomical defects which prevent its normal performance. Therefore all persons who have a tendency to this disease, for some are immune and some are sensitive just as they are to other diseases, must avoid all things which have an irritative action upon the skin, whether drugs or food, or bad habits; as a rule they must also avoid tea, coffee, alcohol, pork, veal, game, shell-fish, cheese and fats of all kinds, also sweets, nuts, fried and greasy food and hot and imperfectly baked biscuits. The diet must be very simple and include more eggs, cereals, fresh vegetables, stale bread or toast, prunes, figs and a minimum of meat and fish. Those foods which have a constipating tendency must be rigidly avoided, and if constipation exists it must be combated by the systematic and regular use of efficient laxatives, including castor oil, fluid extract of cascara, the salines—Epsom and Rochelle salts, and phosphate of soda, or the saline mineral waters. The old-fashioned sulphur and molasses which was a standard, though disagreeable, household remedy a generation ago need not be despised in the treatment of acne. Exercise is very important and it will tend to equalize the blood circulation and direct to the face its proper share of this vital fluid. The sebaceous glands are far more likely to do their work properly when the face and scalp have an adequate supply of freely circulating blood. Bathing is very important, both for preventing and curing this disease, hot baths being preferable. A good way to keep the face and scalp will frequently be found both agreeable and serviceable. Solutions of alcohol, boracic acid, mercury and formaldehyde are often used in the treatment of acne and the X-ray has been found beneficial when used skillfully and cautiously. The most recent mode of treatment, which however is not uniformly successful, consists in the use of autogenous vaccines composed of dead cultures of acne bacilli and staphylococci in a saline solution. A stock vaccine from four to ten million with staphylococci at intervals of one or two weeks is sometimes used successfully. When the eruption takes the pusular form, a polyvalent vaccine of cultures of staphylococcus albus, citreus and aureus may be used. In all cases it is important that the general health be kept in the best possible condition and that the habits of life be simple and normal. The disease is not a dangerous one and is seldom painful except when the glands become inflamed, but when once acquired it is seldom gotten rid of easily.

ACOMETE, āk'emēte (the "sleepless"), a monastic order of the Greek Catholic Church, who in harmony with the universe and the ceaseless music of the spheres celebrated the divine service of perpetual adoration to God, day and night, through the whole range of the canonical hours and the calendar year. For this purpose they were divided into choirs which relieved each other in their labors. The order was founded on the Euphrates in 400 by Alexander, a courtier exile from Constantinople. A mother house, the *Irenon* or great monastery was later founded near Constantinople, followed by the *Studium* in the city which from the 5th to the 7th centuries became "through true piety toward God, to zeal ever on the watch, and to a special gift of the Holy Spirit," a centre of learning as well as devotion, which brought to a culmination the glory of the order. Their influence was considerable on Christianity, and the splendor of their religious services contributed largely to shape the liturgy of the Church. The order declined after excommunication by Pope John II, owing to Nestorian tendencies.

ACOLYTE, āk'ó-lit (a "follower"). An attendant of the fourth clerical order in the Catholic Church, whose chief duties are to assist the sacred ministers at the Mass and other public services of the Church, to light the candles on the altar, to carry them in procession and during the singing of the Gospel, and to prepare the wine and the water for the sacrifice of the Mass. It is the highest minor order of the Church ranking next to a subdeacon. The office originated about the 3d century. At ordination acolytes receive from the bishop an unlighted candle and an empty cup as symbols of the office. Altar boys are frequently designated as acolytes and perform the duties.

ACOMA, ā-kō'ma, N. Mex. (the old Spanish Acuña or Acuco), in Valencia County, 60 miles southwest of Albuquerque and 15 miles southwest of Laguna. It is an Indian pueblo of 830 people, famed especially for its original site, the *Enchanted Mesa,* a rock table 430 feet high, accessible now only by scaling, and of old (traditionally) by spiral stairs cut in the stone, in a deep cleft of the upper portion and along a huge detached fragment leaning against it. From the bottom, itself reached by a tall tree or a ladder, furnishing a secure place of rest for enemies. The Indian tradition is that a long storm washed the loose earth away from the foot of the lower rock while all the tribe except two women were away in the fields, and it fell over into the plain, leaving the upper portion inaccessible; the women perished, but the remainder of the tribe built a new place on the present site, which is the same as when the Spaniards found it. The essence of the tradition is verified by the finding of an old well, and of shards, etc., in the talus high around the base. Acoma was visited in 1540 by Alvarado, of Coronado's command, and in 1582 by Espejo, who estimated the population at about 5,000. The Indians under Zuataca stubbornly resisted the Spaniards, and in 1599 defeated a band of them from Onate's force; later in the same year Zaldivar captured Acoma and slew five-sixths of the inhabitants. A Spanish mission was afterward set up for the small remnant. Consult H. H. Bancroft's "Arizona and New Mexico" (San Francisco, 1889); F. W. Hodge, "The Enchanted Mesa," (in National Geographic Magazine, Vol. 8, Washington 1897).
ACONCAGUA, a-kon-ka’gwà (Sp-Am. pron. ka’wà), Chile. (1) An extinct volcano in the south Andes, on Chilean territory and dividing it from Argentina; one of the highest summits in the western hemisphere, estimated at about 23,000 or sometimes nearly 24,000 feet. (2) A river about 200 miles long rising on the southern slope of the above mountain and emptying into the Pacific 12 miles north of Valparaiso. (3) A rich central province of Chile, bounded north by Coquimbo, south by Santiago, east by Argentina, southwest by Valparaiso. For route of Trans-Andine Railway, via Uspallata Pass in this province, see SOUTH AMERICA. The valleys are very fertile, vineyards and orchards are plentiful and in summer numerous flocks are pastured on the mountain slopes; figs, nectarines, peaches, etc., are sent to Santiago and Valparaiso. Copper and some silver and gold are found. Area, 5,000 square miles. Pop. about 130,000. Capital, San Felipe.

ACONITE (Aconitum), a genus of hardy herbaceous plants of the natural order Ranunculaceae, long known for their poisonous properties. Many of them are of great beauty and several are cultivated, especially the common wolf’s-bane or monk’s-hood (A. napellus), so called from the form of its flowers, characteristic of the genus, which are shaped like a helmet or hood. The United States has also several species growing wild. The wild monk’s-hood (A. uncinatum) is common in rich, shady soils along the margins of streams as far west as Wisconsin, its blue flowers being one of the marked features of the summer’s bloom. Trailing wolf’s-bane (A. reclinatum), a white-flowered variety, grows in the southern Alleghanies. The winter aconite (Eranthis), with yellow flowers, is common throughout the Rocky Mountain regions extending to the Pacific coast. It is perhaps more closely related to the hellebores. These flowers hang clustered round an upright stalk and make the aconite a very imposing plant. Some powerful medicines are prepared from the leaves and roots of monk’s-hood. Applied externally they produce numbness of sensory nerves and are used to relieve pain in certain forms of neuralgia and in acute and chronic rheumatism. Given internally they diminish the force and frequency of the heart’s action, render breathing slower and are employed in acute fevers and inflammations. A poisonous dose causes cessation of breathing and of the heart’s action. Many of the plants of this genus are poisonous; common monk’s-hood is very virulent; but the most deadly seems to be the A. ferox, the bish, or bikh, of Nepal. The different species contain different but related alkaloids. See ACONITINE.

ACONITIC ACID (also called equisetic or citric acid), a tribasic acid having the formula C\textsubscript{6}H\textsubscript{8}(COO)\textsubscript{3}, the calcium salt of which occurs in several plants of the genus Aconitum and the common Equisetum or horsetail. The acid itself is most easily prepared by the dry distillation of citric acid. It crystallizes in small four-sided plates which melt and are decomposed at about 406° F.

ACONITINE, a powerful vegetable alkaloid found in the tuberous root of Aconitum napellus and other species of Aconitum. In its chemical structure it is an acetyl-benzoyl-aconine, C\textsubscript{6}H\textsubscript{4}(OCH\textsubscript{3})\textsubscript{2}NO\textsubscript{2}\cdot\text{COCl}\textsubscript{2} or expressed in simple form, C\textsubscript{6}H\textsubscript{4}H\textsubscript{2}NO\textsubscript{2} (Freund and Beck). However, different formulæ are assigned to it by other authorities. It is one of the most deadly poisons and has been known for hundreds of years. Its action as a medicine was first carefully studied by Stoerck in 1762. When locally applied it produces the constitutional symptoms. Its local use in the form of an ointment is of service in neuralgias. Its primary effect is first to stimulate and then to powerfully depress the central nervous system. It thereby slows the heart and dilates the blood-vessels, causing a marked decrease of blood pressure. It is because of this action that it is so widely used in the acute stages of many affections that are accompanied by a rapid heart and high tension, bounding pulse. Aconite has been called the "vegetable lancet" since it dilates the blood-vessels so, bleeding one into one’s own veins, as it were. In poisonous doses it causes nausea, vomiting, cold, clammy skin, very slow weak beating and finally paralysis of the heart and respiration and death. Death has taken place in from one to five hours from the root. Doses above three milligrams (1-20 gr.) a day are dangerous; 1-400 gr. is an average dose. Treatment is symptomatic, special attention being paid to the respiration by artificial means, and heart stimuliants,—strychnine, etc.

ACONIUS, in a Greek legend retold by Ovid in his 'Heroides,' a youth of the island of Cea, who went to Delos to see the sacred rites performed by a crowd of virgins in the temple of Diana, and fell in love with Cydippe, a beautiful virgin. Not daring to ask her in marriage on account of the meanness of his birth, he presented her with an apple on which were inscribed these words: "I swear by Diana, Aconitus shall be my husband." Cydippe read the words and, feeling herself compelled by the oath she had inadvertently taken, married Aconitus. William Morris has used the story in the 'Earthly Paradise.'

ACORDAD, a court established at Queretaro, New Spain (Mexico), for the summary trial of brigands and others. It was suppressed in 1813.

ACORN, a’korn (from the Gothic akran—"fruit of the field"—), the saucer-cupped nut or fruit of oak trees. On the Pacific Coast from Mexico to northern California, Indians dry and pound acorns into meal and use it in making bread, and as mush food. In northern Italy and other parts of Europe, acorn meal mixed with grain is also made into black bread which, however, is heavy and indigestible. Acorns dried and ground are also used as a substitute for coffee. Children in many places are fond of eating fresh and sweet acorns. The hogs of the Southern States which feed on acorns with a varied diet of occasional corn are distinguished for the agreeably flavored pork, ham and bacon they yield. Beech acorns made into food for pigs is commonly called mast. The word acorn is also used as a nautical term for the cup-like piece of wood which keeps the vane on the mast-head.
ACORN-SHELL, a barnacle of the family Balanidae. See BARNACLE.

ACORUS. See FLAG, SWEET.

ACOSTA, Gabriel, á-kös'ta. Portuguese philosopher, b. Oporto, 1591; d. April 1640. Of a converted Jewish family, educated a Roman Catholic, his studies led him back to Judaism, and he fled with his mother and brothers to Amsterdam. He again developed heretical opinions to task by the synagogues and excommunicated; his writings were confiscated and himself fined; and years of persecution by the Jewish authorities and his family drove him to suicide. Gutzkow made him the hero of his novel "Sadducee der Amsterdam" (1834), and of his tragedy "Urieil Acosta" (1846). The work which caused Acosta's excommunication was "Examen Traditionum Pharisearum Collatarum cum Lege Scripta" (1623, in Latin).

ACOSTA, Joaquín, á-kös'ta, hoo-ś'k, South American soldier and geographer, b. Guachias, Colombia, 29 Dec. 1799; d. there 1852. He was an officer of engineers in the Colombian army, member of the New Granada Convention 1831, later representative in its Congress. In 1834 he explored the Socorro valley to Magdalena with the botanist Cespedes, and in 1841 traveled from Antioquia to Aserma to study the various Indian tribes. For a time he was minister from New Granada to Ecuador; was chargé d'affaires at Washington 20 July to 8 November; and later secretary of state in New Granada. He published at Paris in 1848 a history of the discovery and settlement of New Granada, with a valuable map of his own drawing, the first made since the independence of Colombia; and in 1849, at Paris, a "Miscellany of New-Granadan Sciences, Literature, Arts, and Industries," with portraits and map.

ACOSTA, José, á-kös'ta, hoo-śá', Jesuit and historian, b. Spain, c. 1540; d. rector of Salamanca in 1600. In 1571 he went to Peru, where he spent 15 years, becoming provincial of his order. In two years in Mexico and the West Indies he returned to Spain laden with manuscripts and information, and became a royal favorite. His theological works evinced great learning, but it is by his "Natural and Moral History of the Indies" that he is best known. The complete work was published at Seville in 1590 and proved the most popular and most satisfactory account of the New World up to that time. An English translation appeared at London in 1604, a reprint of which was issued by the Hakluyt Society in 1889.

ACOUCHI, or ACOUCHY. See AGOUTI.

ACOUMETER, á-koo'me-tér,"(hearing-measurer), an instrument to determine the acuteness of hearing. It is a small steel bar of uniform pitch, to be struck with a hammer or falling weight with gradations of force.

ACOUSTICS, á-koo'stiks, (from akous, to hear, et.), is the science of the production, propagation and audition of sound. The term sound is sometimes by definition restricted to the sensation involved in hearing, but is never consistently so used. Both by derivation and by common and best usage it should be applied to those aerial or other vibrations which, were they to reach the ear, would produce audition. The term being thus used, sound consists of waves of longitudinal vibration, that is to say of waves of to and fro motion perpendicular to the wave-front. Such motion, propagated through an elastic medium with a finite velocity, results in alternate rarefaction and condensation.

A moment's consideration of any source of sound will show it to be of such a nature as to give either a single impulse, or a repeated blows, usually systematically repeated, to the surrounding medium. In the great majority of cases, and those the more interesting both theoretically and practically, the source of sound consists of an elastic body distorted from its normal shape, and, released, vibrating more or less symmetrically about this normal shape or position. It results from this vibratory motion that a series of impulses is given to the surrounding medium which are periodic, nearly similar in character, and nearly equally timed. These impulses, propagated through the surrounding medium all with the same velocity, follow each other in the form of a train of waves. The distance from a point in one impulse to the corresponding point in the next impulse is called the wave length of the sound. The frequency of these waves as they strike the ear determines the pitch of the sound; the character of the wave in respect to form determines the quality of the sound; the combination of these together with the amplitude of vibration and the density of the medium determine the loudness or strength of the sensation.

In respect to pitch sounds audible to the human ear range in frequency from about 24 vibrations per second to 40,000 vibrations. Sounds very much higher in pitch are audible to some animals, the cat for example, while for some animals it is probable that the upper limit is not so high, although in regard to the latter point no reliable data have been secured, the interest of the biologists apparently being to extend the range. In regard to the lower limit in other auditors than man no reliable experiments have been made, and if attempted it would be extremely difficult because of the difficulty of distinguishing the reactions due to the mechanical disturbance from the reaction due to true audition,--a difficulty which indeed affects all such experiments, but which is enhanced in the case of the lower limit.

The quality of a sound is determined by the wave form. A pure musical tone is due to simple harmonic motion, a type of periodic motion best described as the projection on a diameter of uniform circular motion, and most familiarly illustrated by the motion of the pendulum of a clock. Perfectly pure tones are rare, the nearest approach being that of a tuning fork reinforced by a resonator. Most musical sounds are far from being pure tones. They may, however, be regarded as a complex of a number of pure tones, each pure tone being then called a partial tone. Of these partial tones the lowest, which is generally though not always predominant, is called the first partial, and the other partial tones in order of their pitch are called the second, third, etc., partials. In many of the more interesting cases such as the tones of the organ pipe, or of a bowed, struck or plucked string, the upper partials are harmonics of the fundamental. The pitch and the relative intensities of the partials determine what is called the quality of the sound, the pitch of the whole being usually rated as that of the lowest
partial. When a sound is incapable of analysis into pure tones it is called a noise. In many, indeed it is safe to say that in most, sounds that are classed as noise there is some trace of a predominant note, and of a definite musical pitch, being associated with each of these.

The loudness of a sound is capable of being variously defined. If by the loudness of a sound is meant physical energy and if the sound is a pure tone then its loudness depends on the amplitude of vibration and the pitch, being proportional to the square of each, and on the density of the medium, to which it is directly proportional. The loudness of a sound is ordinarily defined, however, by the intensity of the sensation which it is capable of producing. Thus defined loudness is a function not merely of the amplitude of vibration and the density of the medium, but of the pitch and the quality as well, and moreover it is a complicated function of each. It is an interesting fact that in many cases of a defined note of loudness which it renders it possible to compare, in respect to the intensity of the sensations which they produce, sounds differing in pitch by the whole of the musical scale. Moreover, this sense of loudness is apparently physiological and not dependent on familiarity with the "balance" of any musical instrument, and is to a high degree of accuracy the same for different persons, independent of age, sex or musical training.

Production of Sound.—The best example of the single impulse as a source of sound is an explosion in unconfined and therefore non-resonant space. The result is an approximately single wave. When, however, the explosion occurs in a resonant cavity the result is a note of definite pitch determined by the cavity. Or a single explosion and impulsive wave may result in a train of waves and therefore a sound of definite pitch, by being reflected from uniformly spaced surfaces, such for example as the pickets of a fence. The next simplest source of sound is a siren, long a laboratory instrument, more recently made familiar by use in fog signals and steam whistles. The siren consists of two circular discs, the one fixed, the other pivoted to revolve nearly in contact with it. As the latter revolves the air escapes through holes in the two discs, hence the high frequency vibrations of the air escapes to the holes in the two discs come opposite each other.

A straight bar of metal or wood may vibrate either transversely or longitudinally. If distorted transversely it vibrates to and fro through its normal straight form. The simplest form of this transverse vibration is that in which the bar at points one-quarter the total length from either end remains at rest. These points are called nodes and the intermediate part of free vibration is called an antinode. When vibrating in this manner the bar emits a note having twice the frequency of the fundamental and in pitch an octave above it. Continuing in this manner a series of simple notes may be determined. The notes thus produced have twice, three times, four times, etc., the vibration frequency of the fundamental. Any transverse free vibration of the bar is a combination of these forms, and the sound which it emits is a combination of these notes. In this manner the quality of the sound is determined. If the bar is clamped at one end the lowest note which it emits is an octave lower than the lowest when entirely free; and the higher tones, instead of being two, three, etc., multiples of the fundamental, skip every other one, being three, five, seven, etc., multiples of the fundamental.

Touching the bar at any point tends to produce a node at that point and to strengthen the corresponding partial tone, and to diminish the partial tones having antinodes at that point. The exact converse is true in regard to striking the rod. Finally, the frequency of the several notes is proportional inversely to the length, and to the square root of the density, and directly to the square root of the rigidity, other dimensions being the same in each case.

When the rod is rubbed or stroked so as to vibrate longitudinally, either free or clamped at one end, its fundamental and overtones form the same systems as before, but all are of a different pitch, determined now by the length, density and modulus of elasticity. Thus the longitudinal vibrations of the rod have the rod's vibration frequencies of its overtones all integral multiples of the fundamental. If the same rod is rigidly clamped at one end, its fundamental is an octave lower than the fundamental of the free rod, and the even integral overtones are absent.

A stretched string or wire, so small in diameter in comparison with its length that its rigidity is insignificant in comparison with its tension, vibrates for its fundamental over its whole length with nodes at each end. The first overtone is an octave above this in pitch, the wire vibrating with a node at the centre. The second overtone (third partial) is three times the fundamental in pitch frequency, the wire vibrating with nodes a third of the whole length of the wire from either end. The third overtone (fourth partial) is four times the fundamental in pitch frequency, with nodes at the quarter and middle points. A string set in vibration by any ordinary method vibrates in a number of waves, a single string of a gauge containing the fundamental and overtones. The overtones present and their relative intensities are determined by whether the string is plucked, struck or bowed, and also by the point of application. The fundamental note emitted by a string is of a vibration frequency equal to the square root of the tension divided by the mass per centimetre of length, divided by twice the length.

If the vibrating elastic solid is in the form of a plate the system of overtones bears a complicated relationship to the fundamental, no longer being integer multiples in vibration frequency. The manner in which the plate vibrates may be shown by sprinkling sand on the plate, the latter being horizontal. When the plate vibrates the sand dances away from the parts of the plate in motion and settles in ridges along the nodes. When the plate is square and emitting its lowest tone the nodal lines traced by the sand form a cross reaching from the centres of the motion. By striking the plate at different points the plate may be made to vibrate in very complicated forms, the sand figures thus traced often making attractive de-
signs. The production of these various patterns is much guided by touching the plate at various points, each of which determines the ends of nodal lines. This experiment was first performed by Chladni, and the sand figures are called after their inventor Chladni's figures. Similar experiments can be carried out on stretched membranes, and one may investigate in this way the various vibrations of drum heads. The result of such an experiment shows that the quality of sound from a drum depends on the point at which it is struck, and that the upper partials are inharmonics of the fundamental.

Next to the stretched string the most interesting case of a vibrating body is that of a column of air. To a first approximation the problem of the vibration of an air column is as simple as that of a stretched string, but in its practical forms and more accurate solution it is by no means so simple. The vibration of a column of air, according to the theory advanced by Bernoulli, is identical with the longitudinal vibration of a straight bar of metal. If the pipe is open at both ends, the simplest form of vibration and that in which it emits the lowest possible note is such that the air moves to and fro at both ends having a node at the middle. The first overtone, having a vibration frequency twice that of the fundamental, is produced by the column of air vibrating freely at both ends, vibrating freely at the middle, and having nodes at points one-quarter of the total length of the pipe from either end. The second overtone has three times, the third overtone four times, etc., the vibration frequency of the fundamental. If the column of air is closed at one end the lowest tone which it can emit is an octave below the lowest tone emitted by the same pipe open at both ends. The overtones in this case are three, five, seven, etc., times the fundamental in frequency. The analogy of this with the bar of metal is obvious. It might be added that according to Bernoulli’s theory the note emitted by the column of air is such that the sound could travel from the open end to the first node during one-quarter of a vibration. This, only approximately true in the case of the column of air, is very strictly true in the case of metal rod. It follows from it that the pitch of the note emitted by a column of air can be varied either by varying the length of the column, the pitch being inversely proportional to the length, or by so exciting the air that it vibrates according to the higher forms with nodes nearer the ends. The application of this to musical instruments is very simple. Take, for example, organ pipes of what are called flue stops as distinguished from reed stops. All such organ pipes are obviously open at the end at which they are attached. According as they are open or closed at the other end they are called open or closed pipes. Open pipes have nodes at their middle when sounding the fundamental note, while the closed pipes have their nodes at the closed end. A closed pipe is therefore an octave lower in pitch than an open pipe of the same length, accurately according to the theory of Bernoulli, but as a matter of fact only approximately so.

In a pipe organ the variation in pitch is accomplished not merely by using open and closed pipes, but principally by using pipes of different lengths. The pipes not uncommonly vary in length from 32 feet to half an inch. In the military trumpet we have an exceedingly simple instrument whose whole available scale consists in the overtones, the particular note being determined by lip tension and wind pressure. In the slide trombone the scale is produced not merely as in the trumpet, but by varying the length by means of the slide. In the cornet the variation in length is accomplished by means of keys turning valves which throw into the length of the pipe or cut out from it short auxiliary convolutions. In the French horn the scale is played not merely by the means adopted in the cornet, but by means of the hand thrust into the bell or flared end, thus partially closing it and so lowering the pitch. In the flute, clarinet and woodwind instruments generally the variation in pitch is accomplished by opening and closing ports on the side of the tube.

A little more might be said in regard to stringed instruments. The strings are, in general, so narrow that when vibrating they cut through the air, communicating practically no motion to the air and therefore emitting, practically, no sound directly. The sound which we hear therefore comes not from the string, but from the sounding boards with which they are always placed in contact. It is thus because the sound which we hear comes from the body of the violin and scarcely at all from the strings directly that its quality depends so much more on the instrument than on the strings with which it is strung.

Propagation of Sound.—When a sound is produced in free air at a distance from all obstacles it spreads in spherical waves, diminishing as it spreads over greater and greater surfaces, the intensity of the sound diminishing as the wave increases. The area of a sphere being proportional to the square of the radius we have the so-called law of the inverse square of the distance. The velocity of propagation of a sound through a medium is independent of the pitch of the sound or of its loudness and depends only on the nature of the medium, its elasticity and its density. In any medium the velocity of the sound is proportional directly to the square root of the elasticity and inversely to the square root of the density of the medium. Since the wave travels with so great rapidity that the air does not have time to cool during compression, the elasticity here referred to is that of adiabatic compression. A table is here given of the velocity of sound in various media:

In this table the velocities given are in feet per second and at 0°C. A variation in temperature produces a variation in the velocity, particularly in the case of gases. A rise in temperature results in an increase of velocity, the increase being about .18 per cent for every degree Centigrade for all gases. This amounts to a little less than two feet per second in the case of air.

When the source of sound is coming toward the observer, the observer being sta-
tionary, the sound as heard is of a higher pitch than when the source were stationary, for the number of waves reaching the observer per second is increased in the ratio of the velocity of sound plus the velocity of the source to the velocity of sound. Similarly when the source is receding from the observer the sound received is of lower pitch. The change is strikingly observed as a bicycle bell or a clanging street car gong passes close by an observer. In this case the fall in pitch is abrupt and marked. Similar phenomena are produced as the observer approaches or recedes from a stationary source. This is called Doppler's principle.

When the sound instead of being produced in uniform and stationary air is produced in air moving with various velocities the phenomena are much more complicated. These phenomena were first studied with care in connection with fog signals by Henry, Tyndall, and Stokes. It was an old observation that fog signals plainly audible at a very great distance could often not be heard at a little less distance, still nearer were audible again. Further, the regions of silence and audibility varied, not merely on different days, but rapidly in the most mysterious and disconcerting manner, so much so as to receive the name of "sounding ghosts." The explanation, for a long time sought in vain, was ultimately given in a suggestion by Stokes that they were due to a variability in the velocity of the wind in different strata of the atmosphere. The result of such an irregularity would be that the spreading sound waves instead of remaining spherical would be distorted very considerably. For example, the waves would be tipped back if the wind were greater at the higher altitude and against the sound. In such case the sound would rise from the water and there would be a region close to the surface over which the fog signal would be inaudible. If, on the other hand, the wind retarded the sound less above than below, or if the wind above favored the sound the wave would be tipped forward and the sound would descend upon the sea. There would then be a resulting area of audibility. As the wind at different altitudes varies greatly and changes abruptly we have an entirely adequate explanation of the phenomena.

The explanation that why the sound is being propagated is not homogeneous another very interesting series of phenomena will occur. Whether the variation in homogeneity results from the variation in composition or a variation in temperature, the effect is the same. A change in either temperature or composition results in a general in a change in the velocity of the sound. Whenever sound passes from one medium to another or from one region to another in which the velocity is different the direction of the sound is changed. It is said to be refracted. The law of refraction is a very simple one,—that the ratio of the sines of the angles made by the direction of propagation of the sound in the two media with a normal to the surface separating the media is equal to the ratio of the velocities in the two media. The sound is thus always bent toward the normal in passing from a medium in which the velocity is greater to a medium in which it is less. According to this principle the so-called acoustical lenses have been made. This may be done by filing a large but thin walled spheric

ical balloon with some heavy gas. Such a lens properly placed will focus the sound of the ticking of a watch so that it can be heard at a distance considerably greater than that at which it can ordinarily be heard. When the lens is thus made with heavy gas it is a converging lens; whereas with light gas it is a diverging lens. A curious but unintentional example of the latter occurred in the House of Parliament when a shaft of warm air, rising through the large ventilator in the middle of the floor, so diverted the sound that a speaker on one side could not be heard clearly by a member immediately opposite him.

Whenever a sound traveling through one medium comes to another medium in which its velocity is different a certain portion is reflected, the amount reflected depending upon the change in velocity of the sound and upon the angle at which it strikes the surface of separation. This furnishes the explanation of the so-called aerial echoes observed by Tyndall, and a partial explanation of the rolling of thunder.

When the reflecting surface is a solid wall a very large per cent of the sound is reflected, how much, depends, of course, on the nature of the wall. Under these circumstances there are produced a large number of important phenomena which are in connection with architectural acoustics. Under special but usually accidental conditions very peculiar phenomena arise as is illustrated in the case of whispering galleries. Whispering galleries are of one or the other of two general types usually illustrated, following the lead of Herschel, by the dome in Saint Paul's Cathedral, London, and by a much less familiar building, the cathedral in Girgenti. In Saint Paul's Cathedral if a person takes a position at one side of the dome and very close to the wall he can whisper with great ease and distinctness to a person at the opposite side of the dome. This is not the case of focusing sound in the ordinary sense. The sound starting from one point is carried by the curved surface along great circles on the interior of the almost spherical dome. The sounds traveling by all these paths meet again at the opposite end of the diameter. As distinguished from this the whispering gallery of Girgenti is produced by a single, isolated, but focused reflection. A better and more familiar illustration of this was until recently to be found in the Hall of Statues in the Capitol at Washington. It is a necessary condition for both types of whispering galleries that the wall surfaces should be smooth and free from great projections. The whispering gallery in the Capitol at Washington has recently been destroyed by replacing the formerly smooth spherical ceiling by a rather deeply coffered ceiling in plaster. The ideal whispering gallery should one be planned, would be secured by constructing a room a considerable portion of whose wall surface would be part of an ellipsoid of revolution with foci at the points between which the whispering is to occur. Another interesting and somewhat related phenomenon is that of multiple reflections. An interesting example of this recently occurred in a private athletic court at Rhinebeck-on-the-Hudson. In this case the ceiling was a smooth dome so nearly flat that its centre of curvature was at a distance below the
floor equal to the height of the room. Here the echo was repeated very many times and the sound was reflected three times between each repetition of the echo. Such special forms of walls not infrequently occur in auditoriums, often in a subtly concealed manner, and are thus loudness and even the loudest sound can not appreciably be increased in loudness and even the loudest sound can not appreciably be increased in loudness. The reverberation results in an increased loudness, particularly of sustained sound. On the other hand, the prolongation of each sound it results in, or less confusion. When the room is to be used for musical purposes, the effect of this reverberation, unless it is to be carried too great an extent, is to blend the tones and give to the performer a sense of space, and the audience is then in a position which is, in some measure, a balance which favors the musical effects must be accurately calculated in order to fully satisfy expert musical taste. The reverberation in the room as well as the general loudness of the sound at the several points can be calculated when the dimensions of the room and the absorbing power of its various surfaces are known.

Another feature of architectural acoustics is the phenomenon of interference. Taking first the simplest possible case when a sound from a distant source strikes normally on a plane wall, the reflected waves meeting the following on-coming waves produce by their superposition a system of stationary waves parallel to the reflecting surface. The result would be great nodal and antinodal surfaces parallel to the reflecting wall. An observer moving about in such a medium would hear the sound as very loud at the nodal surfaces. When the sound is produced in a confined space, such as a room, it is reflected from wall to wall many times and in many directions before it is ultimately absorbed. The result is an exceedingly complicated system of stationary waves. Under certain conditions the sound may be so intense as to cause parts of itself to be undulatory, while at other points but a few feet distant it is so faint as to be scarcely audible. The distribution of such a system of stationary waves depends on the shape of the room, the material of the walls and the position of the source of sound. It also depends on the pitch of the sound.

When the conditions of the room are such that a system of stationary waves are so formed that a region of great intensity coincides with the source, the phenomenon of resonance occurs. That is to say the emission of that particular note will be increased in comparison with other notes of such pitch that their greatest nodal intensity in their own interference systems does not coincide with the source. This phenomenon is called resonance. Both interference and resonance result in the destruction of chordal balance.

Audition.—The ear is ordinarily divided, in anatomical work, into three parts, the outer, the middle and the inner ear. The drum of the outer ear separates the outer from the middle ear, the middle ear being an air cavity connected by the eustachian tube with the nasal cavity. The sound is conducted across the middle ear by a system of three bones which connect the drum with another membrane separating the middle ear from the inner ear. The inner ear is a somewhat complicated cavity in the solid bone of the skull. It consists essentially of three semi-circular canals, and a much longer and larger snailshell-like cavity called the cochlea. This inner ear is separated from the middle ear not merely by the membrane already referred to pressed against and vibrated by the bones, but also by another small membrane. Starting from between these two membranes a diaphragm runs along the length of the cochlea. This diaphragm, somewhat intricate in its complete structure, has as an essential part, a system of numerous stretched fibres, varying in length and probably also in tension. When the sound is conducted from the outer ear to the inner ear by the three bones in the middle ear, the vibration is communicated to a liquid which fills the inner ear. This liquid in which the various fibres of the diaphragm, called the fibres of the Corti, to vibrate. As the fibres of Corti are of different lengths and of a different tension, different regions of the diaphragm respond to different notes. On this diaphragm terminate the auditory nerves which are stimulated by the vibration of the fibres, and communicate the corresponding sensation to the brain. The variation in pitch sensation is due to variation in the stimulated region of the diaphragm. When the sound is not a pure tone the various partial tones excite the corresponding parts of the diaphragm. When two notes are sounded, each with its system of overtones, there are regions of the diaphragm more or less excited simultaneously by the two systems. When the two partials which excite overlapping regions of the diaphragm are not of exactly the same pitch beats occur between them. These beats when slow are not wholly disagreeable, and having a tremolo effect in moderate use are not without musical value. When, however, the beats are more rapid, and this occurs when the overlapping partial tones differ more in pitch, the beats lose their distinct character as such and produce the effect known as discord. If the two partials when the notes are such that they excite overlap less and less and the discord diminishes. Following out this line of argument Helmholtz was able to show that when the fundamentals having harmonic upper partials bear to each other simple ratios in their vibration frequencies their discord is a minimum, deriving in this way a complete explanation of the musical scale as used in harmonic composition. The scale thus obtained is the true or natural scale. The intervals between the successive notes are not equal, but fall into two groups of so-called whole and half tone intervals. The whole tone intervals are not equal among themselves and are not twice the half tone intervals. Therefore, even after inserting sharps and flats to subdivide the whole tone intervals the resulting musical scale is not one of equal interval. While this is the scale which would be employed by instruments without fixed key-boards, and by the human voice accurately trained, it cannot be employed in instruments with fixed key-boards, since such instruments are to be used on different keys.
For this purpose Bach invented a scale called the equally tempered scale in which all the half tone intervals are made equal. On this scale no key is accurate, but no key is so inaccurate as to result in serious discord. The following table gives the vibration frequency of the eight notes of the middle octave on the natural and on the tempered scale:

As the invention of the musical scale long preceded its use in harmonic composition, and during the period preceding the 11th century was used only in melodic composition—that is for notes sounded in sequence—the simultaneity necessary for harmonic effect was obtained by the prolongation of one note into the other. WALLACE CLEMENT SABINE,
Professor of Physics, Harvard University.

ACQUAVIVA, Andrea Matteo, an'drâ'-a mà́frá'-ò a'kwa-ve'va, Duke of Atri and Prince of the Kingdom of Naples: b. 1450; d. 1528. He seems to have been the first who conceived the idea of an *Encyclopedia,* or *Universal Dictionary of Arts and Sciences.* He published a useful work under that title in two folio volumes.

ACQUI, a'kwi, northern Italy. (1) A district in the province of Alessandria, on the north side of the Ligurian Apennines. Area, 445 square miles. Productions, corn and fruit. Chestnut-trees furnish the peasant with an article of common food, and silkworms are reared. (2) Its capital and episcopal city, the Bormida, 18 miles south southwest of Alessandria, 37 miles northwest of Genoa. It has commodious hot sulphur baths, and is celebrated for its great antiquity and for the remains of a Roman aqueduct. The hot sulphur baths were known to the Romans, who called the place *Aqua Statilia.* There is an extensive trade in wine, silk lace and rope. Acqui has a cathedral, a royal college, and is a bishop’s see. It was taken by the Spaniards in 1745; retaken by the Piedmontese; and afterward dismantled by the French. Pop. about 16,000.

ACQUISITION is the act by which a person procures property in a thing; also the thing the property in which is secured. Original acquisition is that by which a man secures a property in a thing which is not at the time he acquires it and in its then existing condition, the property of any other individual. It may result from occupancy, accession or intellectual labor.

ACQUITTAL, in law, the judicial setting free or releasing a person from a contract, debt or other obligation; but the term is more commonly used in criminal law to signify the deliverance from a charge of an offense, either by a verdict of not guilty by a jury, or by simple operation of law, as in the case of an accessory where the principal is acquitted. In the United States acquittal may be the result of some technical defect in the proceedings or by the verdict in favor of the accused on the merits of the case. In the first case a second trial of the case may be instituted, but the second case is a bar to any further prosecution of the accused for the same offense. This is guaranteed by a constitutional provision that "no person shall be twice put in jeopardy for the same offense."

ACRE, a sub-family of butterflies of the family *Nymphalidae,* deriving its name from the leading genus *Acraea.* There are about 85 species, mostly African. They are of small or moderate size, and have semi-transparent wings, reddish-brown marked with black.

ACRA'NIA, a primary division of *Vertebradae,* represented by *Amphioxus* (q.v.) in which, as the name indicates, there is no skull, while the notochord extends to the anterior end of the snout, in advance of the central nervous system. There is no true brain, the region corresponding to the brain of the genuine vertebrates being very imperfectly differentiated. There are only two pairs of cerebral nerves, and the dorsal and ventral spinal nerves do not unite. There is also no trace of limbs. The pharynx is of comparatively immense size, perforated by numerous gill-slits, and surrounded by an atrium. The liver is a hollow pouch of the intestine. There is no heart, and the blood is colorless. The numerous nephridia remain distinct and open in to the atrium. There are no paired eyes, only a single median pigment-spot in the wall of the brain; there are no ears, though an olfactory pit is present. The reproduction glands are segmentally arranged, but have no ducts.

ACRA'SIA (Gr. ἀκρασία, intemperance), a beautiful woman, the personification of all that is intemperate and immoderate, portrayed in Spenser's *Faerie Queene,* and *Bower of Bliss,* on a floating island, in which there is everything to delight the senses. Her character was suggested by Circe, but probably more directly by the Alcina of Ariosto.

ACRE, a'kér, Syria (Biblical *Accho,* Greek *Ptolemais,* other forms *Acco, Akka, Acon, Accaron,* modern French St. Jean d'Acre), a port some miles north of Mt. Carmel, on the Bay of Acre, opposite Haifa on the opposite horn. The harbor is one of the best on the coast; even so, it is much choked with sand. Its interest is chiefly in its varied and picturesque past, as the chief landing place for invasion of Syria; it has perhaps suffered more from political revolutions and war ravages than any other place in history. Its name first occurs in a letter of King Buramutriash of Babylon to Amenhotep IV of Egypt, c. 1400 B.C. Semachri of Assyria captured it 701 B.C., and his son Esarhaddon about 675 b.c. gave it to the King of Tyre. After the break-up of Alexander's empire, Ptolemy Soter of Egypt took possession of it and renamed it Ptolemais; it afterward became part of the Seleucid empire of Syria; and later the Romans acquired it and made it a colony of it. Under the early empire it was a city of great importance, and remnants of its grandeur in the shape of fine granite and marble
pilars still exist. In 635 A.D. the Saracens under Khaled and Obeida captured it and Damascus. They were expelled from it in 1110 by the Crusaders, who made it their principal port and retained it till 1187, when it was recovered by Saladin. Four years later it was retaken by Richard Coeur de Lion and Philip II of France, at the cost of 100,000 lives. They made it a bishopric and gave it to the order of St. John (Fr. St. Jean, from which it took its French title). These held it for just a century, despite continual assaults from the Saracens; and it was a large, rich and powerful city, filled with churches, convents and hospitals. In 1291, when it had become the last Christian stronghold left in Syria, the Saracens retook it after a bloody siege which injured it greatly. From that time it sank rapidly. In 1517 it fell into the hands of the Turks under Selim I; and at the beginning of the 18th century it was a vast scene of ruin, relieved only by a few cottages, a mosque and the houses of French factors. Toward the end of that century the Turks, emboldened by the strengthening of their maritime power, improved it, and it rose to some importance again. It is now best known in modern times for its brave and successful defense in 1799, by means of a body of English soldiers and marines under command of Sir Sydney Smith, against Napoleon, who, after spending 61 days before it, was obliged to retreat. It continued to prosper and be the seat of a considerable trade till 1832, with consuls from all the great states, though crippled by the insurrections of the Turks, which the Turks lightly every year, and a protection that endures them. On the revolt of Mehmet Ali, the great Viceroys of Egypt, his son Ibrahim besieged it for five months and 21 days in the winter of 1831–32, and before he captured it its public and private buildings were mostly destroyed. The Egyptians repaired and improved its fortifications; but on 3 Nov. 1840 a three-hours bombardment by a combined English, Austrian and Turkish fleet reduced it to a ruin. The Turks were again put in possession of it in 1841.

ACRE, á'kär, originally "field," "pasture," "hunting-ground"; but later a rough measure of size, somewhat similar in different countries, and supposed to represent what one man could plow in a day. The Italian term giornata (day's work) is significant on this point. In England reckoned as the amount a yoke of oxen could plow in a day, till the laws of the 13th century and later settled a definite measure. There and in the United States this is termed the statute acre, old customary acres being still used in Scotland, Ireland and Wales, as well as in several English counties, all different and some of them less than half the statute, while others are more than double. The statute acre is 43,560 square feet, or 4,840 square yards, or 160 square rods or perches (from the yard and the perch, the pole with which it is divided) 4 rods, though this and perch are mere book-words in the United States at least, as is the square "chain" of 22 yards or 484 square yards, from the surveyor's chain used in much of the West. Commonly measured in feet in the Eastern States the acre is a square measuring 208 feet 8½ inches on the side. The following table gives various measures in relation to the English and American acre as the unit.

The German empire having adopted the French metrical system, the German morgen are becoming of historical significance merely.

ACRE RIVER, á'kra, South America (also called ACQUITY, á'kri-en), a tributary of the Purus River. Its sources are on the eastern
ACRE TERRITORY. See Brazil.

ACRES, a'kérz, Bob, an awkward young country booby of the gentleman class of England, who figures in Sheridan's comedy of 'The Rivals.'

ACRIDINE DYESTUFFS. See Coal Tar Colors.

ACRISIUS, a-krí'shú-ús, in Greek mythology, King of Argos. He expelled his twin brother Proetus (q.v.) from his inheritance and for a time ruled alone in Tiryns and Argos, but was later forced to surrender to his brother the former kingdom. He was the reputed founder of the Delphic amphictyony. For the legend concerning the prediction of the oracle that he would die at the hands of his grandson, see PERSEUS.

ACROBAT. See Gymnastics.

ACROCEAUMN, ak'ró-se-rā'nē-um, the northwestern promontory of Epirus, with mountains called Acroceumna ("thunder-peaks"), which separated the Ionian and Adriatic Seas from an affranchising storms, and hence dreaded by mariners. Its modern name is Chimara or Cape Glossa, or Cape Linguetta.

ACROCORINTHUS, in ancient times the acropolis or citadel of Corinth: a steep rock nearly 1,900 feet high, overhanging the city, and crowned with the remains of Venetian and Turkish fortifications, ruins of mosques and dwelling-houses, and also a barracks with a few soldiers. On its top stood of old a temple of Aphrodite.

ACROLEIN, a colorless liquid which has a very irritating odor. Its chemical formula is CH₂CHO. Acrolein is produced in the incomplete combustion of fats and when glucose is distilled with sulphuric acid. When the wick of a candle is left smoldering after the flame has been blown out some acrolein is produced. It is classed with the aldehydes.

ACROLITHS (Gr. signifying "extremities of stone"), statues of which head, hands and feet were of marble, attached to a trunk of wood, covered with drapery, or gilt. The Athenian Ares of the Plateaus mentioned by Pausanias is one of the best known acroliths.

ACROMEG'ALY (Gr., signifying "extremes enlarged"), a disease first described by Marie in 1886, as a permanent enlargement or overgrowth of the extremities—head, hands and feet—caused by certain types of tumor, chiefly adenomatous, of the hypophysis or pituitary gland. Both sexes, but a larger percentage of the female, are subject to the disease which has a gradual beginning, usually in the thirties. Giants are mostly cases of acromegaly which are arrested early and which have sprung from disorder of the pituitary before adolescence. Consult Osler, 'Modern Medicine' (Vol. VI, New York 1910); Jelliffe and White, 'Diseases of the Nervous System' (1917); Cushing, 'The Pituitary Body' (1913).

ACROPOLIS, the high part of any ancient Greek city; usually an eminence overlooking the city and frequently its citadel. Notable among such citadels were the Acropolis of Argos, of Messene, of Thebes and of Corinth; but pre-eminent among the Acropolis of Athens, to which the name is now chiefly applied. This was the original city (as indeed most of the acropolises date from the times of barbaric insecurity), later the upper city as distinguished from the lower, and was built upon a separate spur or butte of Hymettus. The hill rises out of the plain, a mass of rock about 250 feet high, with precipitous sides save for a narrow access at the western end where there was a zigzag road for chariots. The summit of this rock forms an uneven plain 500 by 1,150 feet at the maximum breadth and length. Within this area were reared, chiefly in the days of Pericles, remarkable specimens of architectural art. The buildings were grouped around two principal temples, the Parthenon and the Erechtheum. Between these temples stood the statue of Athena Promachos ("fighter in front"), by Phidias, the helmet and spear of which were the first objects visible from the sea. About these centre-pieces, covering the rocky height and extending down the steep sides, were lesser temples, statues, theatres, fanes and odea (music halls). Among the famous buildings on the sides of the Acropolis were the Dionysiac theatre, the Odeum of Pericles and the Odeum, built by Herodes Atticus in honor of his wife Regilla. The ravages of accident and war and Athenian marble-merchants, and in case of the Parthenon (q.v.) its deliberate dismantling by Lord Elgin early in the 19th century, have largely destroyed and despoiled these classic works. Archaeologists have secured many important portions of the Acropolis, which are preserved in the collections of various European capitals and in the new archaeological museum at Athens.

ACROPOLITA, Georgius, Byzantine historian and statesman: b. Constantinople 1217; d. 1282. Appointed "great logothete" or chancellor in 1244, he was instrumental in effecting a reconciliation between the Latin and Greek churches in 1274. His 'Annales,' covering the period from the capture of Constantinople by the Latins in 1204, to its recovery in 1261 by Michael Paleologus, is a valuable contemporary work which, with his other writings, was published in a complete edition in 1903. Consult Heisenberg, A., 'Teubner Series' (Vol. II, which contains a full life, with bibliography Leipzig 1903).

ACROSTIC, a poetical composition, disposed in such a manner that the initial letters of each line, taken in order, form a person's name or other complete word or words. This kind of poetical trifling was very popular in the French poets from the time of Francis I until Louis XIV. Among other English writers, Sir John Davies, who lived in the 16th century, amused himself in this way. He produced 26 pieces called 'Hymns to Astrea,' each of them
forming an acrostic upon the words Elisabetha Regina. The following is an example:

B teet, a troy's balance, a treasure
L et me presume to sing to you.
S ove, e'en great Jove, hath leisure
H ear the vulgar crew, and heed them oft with pleasure.
B lessed Astraea! I in part,
E ye not the blessings great impart.
T he peace, the milk and honey,
H umanity and civil art,
A wealth don't, and have not -
R ight glad am I that now I live,
R 'm in these days where to you give
G reat happiness and glory.
I f after you I should be born,
O doubt I should my birthday scorn,
A duming your sweet story.

In the Old Testament there are 12 psalms written according to this principle. Of these the 119th Psalm is the most remarkable; it consists of 22 stanzas, each of which commences with a Hebrew letter and is called by its name. Acrostic verse is no longer cultivated by serious poets, and has in fact been relegated mainly to country newspapers, except as a jest or social pastime. Edgar Allen Poe, however, wrote some striking acrostics, varying the form with great ingenuity, one example, beginning with the first letter of the first line, the second of the second, and so on, forms a lady's name.

AC'ROTERION (*extremity*), in architecture, an ornament — statue, palmette, or leaf-decoration — placed on the apex of a pediment or one of its lower angles.

ACT. In the drama, one of the parts into which a play is divided, to mark change of time or place, to give a respite to the actors and audience from the strain and physical fatigue of sitting intent on a long play, and to enable actors to change costumes and managers to change scenery. In Greek plays, where there was no scenery and no change of costume, there were no separate acts — the episodes separated by the lyrical portions being not such either in design or effect, — and the action was continuous from the beginning to the end and the units strictly observed. If the principal actors left the stage the chorus took up the argument and contributed an integral part of the play; chiefly in the form of comment on the action, but often by supplying necessary information impossible to give in proper stage language. For a great drama there is a real reason, though in light comedy it is almost universally dropped at present. The natural division is into three — introduction, climax and conclusion; and the central act still fulfils the true function. But for a great action this is apt to hurry matters too fast for a proper development either of character or interest; hence the first and the last act are doubled, the approach to the main point and the preparation for the catastrophe being both rendered more gradual. Some critics have laid down exact rules as to the part each act is to sustain in a play; but these cannot be justified and have never been regarded. It is obvious, however, that each act should form a certain unity, ending with a point of deep but suspended interest, yet should be an integral part of the whole. Molière began the three-act comedy; but even to an impatient generation this is too short for a play of power, and four is most preferred. See DRAMA.

In law. — (1) Anything officially done by the court, as the phrases "Acts of Court," "Acts of Sederunt," etc. (2) In bankruptcy, an act the commission of which by a debtor renders him liable to be adjudged a bankrupt. (3) In civil law, a writing which states in a legal form that a thing has been said, done or agreed. (4) In evidence, the act of one conspirator performed in pursuance of the common design may be given in evidence against his co-conspirators. (5) Acts done, distinguished into acts of God (q. v.), of the law and of men.

In mental philosophy, an operation of the mind supposed to require the putting forth of energy, as distinguished from a state of mind in which the faculties remain passive. In this sense such expressions as the following are used: The act of thinking, the act of judging, the act of resolving, the act of reasoning or of reason; each of these being viewed as a single operation of the human mind.

In parliamentary language, an ellipsis for a law enacted by a congress, legislature, parliament, etc. A statute, law or edict, consisting of a bill which has been successfully carried through both Houses of Congress or legislature, and received the approval of the executive. See specific title infra, Act of God; Act of Settlement; Act of Supremacy; Act of Toleration; Act of Uniformity; Acts of Congress; Acts of Parliament; Acts of Trade; Bills, Course of; Bills, Private.

In theology, the carrying out of an operation in a moment, as contradistinguished from the performance of a work requiring a considerable time for its accomplishment.

In universities, of old, the commencement or taking of degrees; now disused save as a form at Cambridge, England. The student *keeps the act* by reading a Latin thesis which he must defend against three opponents named by the proctors.

ACT OF GOD, an accident which arises from a cause which operates without interference or aid from man. The term is sometimes used as equivalent to inevitable accident, but incorrectly according to some authorities, although Sir William Jones proposed the use of "inevitable accident" instead of "act of God."

ACT OF INDEMNITY, or ACT OF OBLIVION, an English statute of 1660, entitled "An Act of Free and Generall Pardon, Indemnity and Oblivion," by which all political offences committed during the time of the Commonwealth were pardoned, certain offenders mentioned by name in the act being excepted, particularly those engaged in the trial and execution of Charles I.
ACT OF SETTLEMENT, an act of the Parliament of England in 1601, vesting the hereditary right to the English throne in Sophia, Electress of Hanover, and her Protestant descendants, constituting the source of the sovereignty of the House of Hanover or Brunswick, the present ruling line. The act prohibited the king (or queen) from going to war in defense of non-English powers without the assent of Parliament.

ACT OF SUPREMACY. (1) An act of the Parliament of England, in 1534, by which the king was made the sole and supreme head of the Church of England. (2) A re-enactment of the above, with changes, in 1559.

ACT OF TOLERATION, usually known as the Toleration Act, an act of the reign of William and Mary, granting freedom of religious worship, under certain comparatively moderate conditions, to all dissenters from the established Church of England except Roman Catholics and persons denying the Trinity. This act, as confirmed in the reign of Anne, was the basis of various subsequent measures of religious toleration, culminating in the Catholic Relief Act of George IV, and became at length so great that the last volume, for 1776, was published in 1782, exactly a century from the time when the journal was commenced. The whole consists of 117 quarto volumes, including the supplementary volumes and indices. In this journal Leibnitz first gave to the world his notions respecting the differential calculus.

ACTAEON, ak-te-on, in Greek mythology, the son of Aristeus and Autonoë (a daughter of Cadmus), a great hunter. He was turned into a stag by Artemis (Diana) for looking at her when she was bathing (or, as some say, for boasting that he was superior to her in hunting), and was torn to pieces by his own dogs. This incident is exhibited in various ancient works of art.

ACTA SANC'TO' RUM, or MARTYR- RUM, the collective title given to several old writings respecting saints and martyrs in the Greek and Roman Catholic Churches, but now applied especially to one extensive collection begun by the Jesuit Roswey, and continued by J. Bolland. The work was carried on (1661) by a society of learned Jesuits, who were styled Bollandists, until 1794, when its further progress was prevented through the invasion of Holland by the French. In recent times the undertaking has been resumed.

ACTINA. See SEA-ANEMONE.

ACTINIA'RIA (Gr. aktis, ray), the sea- anemones. See ANTHOZOA; SEA-ANEMONE.

ACTINIUM. A radio-active substance discovered by Debierne in 1906 which was later used for purifying uranium residues of the Curie laboratory. It has the chemical properties of an element between calcium and lanthanum. All efforts to isolate it from the rare earths, with which it is found in mixture, have failed, and its place in the periodic table is only provisionally determined. The substance is radioactive, giving off alpha-rays and ionizing rays. It has been discovered. Actinium gives off the same kinds of rays as radium but the emanation diminishes to half its initial vigor in a few seconds. Like radium and polonium, actinium is prepared from pitchblende and belongs to the iron group. Actinium preparations which are some months old emit α, β and γ rays.
ACTINOGRAPH — ACTINOZOA

The last, however, have a lower penetrating quality than those of radium or thorium. By fractional crystalization of the double nitrate of the rare earths and magnesium nitrate preparations of actinium have been obtained which show 100,000 times the radio-activity of uranium. The spontaneous decomposition of actinium affords a series of six successive products. Actinium preparations are highly radio-active and induce radio-activity in surrounding objects. As with other radio-active substances the ultimate product of actinium is helium. Actinium salts evolve an inert gas having the molecular weight of (about) 70. (See Radioactivity). Consult Rutherford, E., 'Radio-Active Substances and Their Radiations.' (Cambridge, Eng. 1913).

ACTINOGRAPH, a name sometimes given to the actinometer (q.v.), especially when it is arranged so as to give an automatic record of the intensity of the light. The simplest form of this instrument is one in which standard photographic plates or films are exposed to the sun's action for short, definite periods.

ACTINOMETER, an instrument for measuring the intensity of the chemical action of the sun's rays. For use in photography and the judging of times of exposure, the essential part of the instrument is a strip of sensitive silver paper which is blackened by the sun's rays, the time required to darken the paper to a definite shade being taken as the index to the intensity of the light. Any other chemical action that light rays are capable of performing may be made the basis of an actinometer; but the indications of instruments in which the fundamental chemical changes are different will not necessarily agree with one another, because any given actinometer shows nothing but the intensity of the particular part of the spectrum which performs the chemical change upon which that instrument is based. Sir John Herschel's actinometer was a thermometer with a bulb containing a blue solution of sulphate of copper and ammonia. The expansion of this solution, by absorbing the sun's rays, measured the quantity of chemical rays in the sunshine. Bunsen, Draper and Roscoe selected indicators to certain selected reactions, such as cause chemical or other changes. In this case the sun's rays perform molecular work and are measured by the effects. For example, when a chlorine and hydrogen mixture is converted into hydrochloric acid, the quantity of acid produced in a given period is a measure of the intensity of the rays which produced it. Ferric-oxalate and chlorides of iron dissolved in water and exposed to the sun's rays give out carbonic acid gas and the quantity of the latter given off may be used as a basis of measuring the intensity of the rays. A photographic plate exposed for a short period of time receives an impression the intensity of which is determined by a scale of tints or shades, and this intensity of the impressed image is made the basis for determining the intensity of the sunshine. When the sensitive element, used as a measuring medium, absorbs all the radiation of all wave-lengths the instrument is more properly called a pyrheliometer. (q.v.)

ACTINOMETRY, in general, the measurement of either the relative or absolute effect of solar or other radiation. In particular, it refers to the measurements of only actinic effects, i.e., chemical, photographic and similar reactions.

ACTINOMYCOSIS, a disease due to a vegetable parasite known as the ray fungus, Actinomycetes bovis, of the fungus class. This fungus lives its life in grasses and plants and thus infects cattle, in which animals it is comparatively frequent, causing the disease by eating as "big jaw," or "lumpy jaw." These in turn affect man. It is also found in horses, pigs, sheep, deer and llama. The disease has been recognized since 1825 and is often mistaken for cancerous, tuberculous or syphilitic tumors. Böllinger first accurately described the disease in cattle in 1877. It is found throughout Europe and the Americas. The fungus is found in all tumors and abscesses of the disease and is readily detected by the microscope. Cattle are usually affected in the salivary glands, the inferior maxillary bones, the tongue, esophagus and pharynx. Hogs are generally affected in the udder. Great difference of opinion exists regarding the position of the fungus, but it is generally held that part of it is spent on a plant host. Grasses with sharp awns appear to be a chief agency for the transfer of the ray fungus to cattle. The general treatment consists in opening, draining and sterilizing the abscesses, wherever accessible, and by administering internally potassium iodide. The disease pursues a slow, chronic course. Infection in man and cattle most frequently takes place through diseased teeth or abrasions of the mucous membrane of the mouth. See Parasites.

In man the symptoms are often very obscure. Some infections of the lungs have appeared to be cases of pulmonary tuberculosis. Pathologically the disease is one of new connective tissue formation with abscess production. It is a chronic disease, and often is a slow, suppurrative affair affecting the tissues about the pharynx and neck. The bones, lungs and intestinal tract may be affected. The diagnosis may be readily made by the microscope. Consult Salmon, D. E., 'The Treatment of Lumpy-Jaw, or Actinomycosis in Cattle, Bulletin No. 2 (1893); Salmon, D. E., et al., 'Special Report on Diseases of Cattle and Feeding,' Report of United States Department of Agriculture for 1904, Bureau of Animal Industry (Washington 1904). For the disease in man consult Osler, 'Modern Medicine' (New York and Philadelphia 1910).

ACTINOPHONE, better known as the radiophone (q.v.).

ACTINOZOA, or ANTHOZOA, a class of coelenterates which exist only in the polyp state, not giving rise to a medusa form. They are represented by the sea-anemone (q.v.) and coral polyps. Their bodies are vase-shaped, usually fixed at one end, though most of them are capable of slowly moving about. They are provided with a digestive sac partially free from the body-cavity opening into it below and held in place by six or eight mesenteries radiating from the digestive cavity and dividing the perivisceral space into chambers. The mouth is surrounded with a circle of tentacles which are hollow, communicating directly
with the perivisceral chambers. There is a slightly marked bi-lateral symmetric. To the edges of the mesenteries (usually the free ones) are attached the reproductive glands, both male and female, or of one sex alone; also the *craspeda,* or mesenterial filaments, which contain a large number of thread-cells (cf. The body is either entirely fleshy or secretes a calcareous or horny coral-stock, and when the species is social it is connected by a coenenchyme. In some forms, as sea-pens (q.v.) the entire colony is capable of limited locomotion. There is no well-marked nervous system, but a plexus of fusiform ganglionic cells connected by nerve-fibres in the base of actinians. Reproduction takes places by self-division, gemmation, or by eggs, the sexes being separate or united in the same individual; the young undergoing a blastula and gastrula condition and then becoming fixed.

The Actinooza are divided into two sub-classes, the Zoantharia and the Alcyonaria (q.v.).

ACTION. In law, the formal demand of one's right from another person, made and insisted in a court of justice which has jurisdiction of the person and the subject-matter of litigation. In a quite common sense, action includes all the formal proceedings in a court of justice attendant upon the demand of a right made by one person, or party, of another in such court, including an adjudication upon the right, and its enforcement or denial by the court.

The parties to an action are called plaintiff and defendant, and the former is said to sue or prosecute the latter, hence the word suit instead of action. In some few instances the redress sought by a civil action consists in the recovery of some specific article of property wrongfully and unlawfully taken by the defendant from the plaintiff, but most frequently the object of an action is to obtain compensation in money for an injury complained of, which compensation is technically called damages.

The action is said to terminate properly at judgment.

Civil actions are those actions which have for their object the recovery of private rights, or of damages for their infractor.

Criminal actions are those actions prosecuted in a court of justice, in the name of the government, against one or more persons accused of a crime.

Transitory actions are those civil actions the cause of which might have arisen in one place or county as well as another.

Local actions are those civil actions the cause of which could have arisen in some particular place or county only.

Personal actions are those civil actions which are brought for the recovery of personal property, for the enforcement of some contract or to recover damages for the commission of an injury to the person or property.

Real actions are those brought for the recovery of lands, tenements and hereditaments. Mixed actions are those which partake of the nature of both real and personal actions.

In higher theoretical mechanics the word "action" is used to signify the value of a certain integral, whose form may vary according to the character of the problem in hand. In the case of a single particle the action is the space integral of the momentum of the particle, or it is double the time integral of its kinetic energy. In a system of such particles the total action is the sum of the actions of the constituent particles. It is probable that the physical principle corresponding to the mathematical expression called "action" will some day be exhibited to us in a simple form, but up to the present time no mathematician or physicist has succeeded in doing this. The importance of "action" as a mathematical conception may be seen from the following theorem, which has long been known: "The energies of a system is the same in all its configurations, then, of all the sets of paths by which the parts of the system can be guided by frictionless constraint to pass from one given configuration to another, that one for which the action is least is the natural one, and requires no restraint." The theorem just stated is known as Maupertuis' principle of least action. There is also a principle of stationary action, and one of varying action; but it is impossible to elucidate these without a preface of mathematics. The last two principles were formulated by Sir William Rowan Hamilton.

In theoretical mechanics the word "action" is also used to signify a force acting upon a body, as in the expressions the action and reaction. See FORCE; MOTION, LAW OF.

In applied mechanics the mechanism by which some operation is effected in a machine is often called the action of the machine; thus were the speak of the action of a gun, meaning the mechanism governing the loading and firing of the gun; or of the action of a piano, meaning the combination of keys, hammers and other parts, by which the player causes the strings of the instrument to vibrate.

ACTIUM, ak'shium, Greece, now Akri, a promontory on the west coast jutting out from the northwest extremity of Acrania, on the Ionian Sea at the entrance of the Gulf of Atria (old Ambricia), opposite Prevesa and just north of Santa Maura (old Leucadia). Forts Punta and Aktium defend it. It represents one of the greatest of historical landmarks: the naval battle of 2 Sept. 31 B.C., between Octavianus (later the Emperor Augustus) and Antony, which decided the mastership of the then civilized world. For the reasons of the engagement, see ANTONIUS; it was fought by him, not for victory but for escape, which partly explains its half-heartedness and result on his side. Both armies were drawn up on the shore watching it. After waiting four days for a calm they engaged about noon on the fifth. Antony had some 500 large ships, Octavianus fewer and lighter ones. Antony on his right was opposed by Agrippus, Octavianus by his to Callius; Cleopatra's 60 were in the rear supporting Antony's forces. Antony's vessels were huge hulls, too clumsy for maneuvring; but on the other hand so impenetrable with iron-bolted timbers and brass plates and Octavianus' galleries dared not ram them for fear of shattering themselves, and skirmished rapidly around, hurling missiles and trying to board. It was more like the hesiaging of forts than a naval battle; one of Antony's tall structures being often surrounded with three or four of its
nimble foes pouring darts and fire-balls into it, to which it replied from catapults loaded with heavy missiles. At length Agrrippa used his superior numbers to attempt a flanking movement; Antony's flag-captain drew his wing away from its position, and Cleopatra took alarm, and to make sure of escape her squadron broke through the front rank, throwing it into disorder, and sailed away for Egypt. Antony jumped into a small galley and followed her. In the meantime the enemy fought on till about 4 p.m., when 300 ships had been taken and many burned, and 5,000 men killed; it then yielded. The land army surrendered a week later. In commemoration of the triumph Octavianus enlarged the temple of Apollo at Actium, dedicated his trophies there, instituted quinquennial games and built Nicopolis ("city of victory") on the site of his army's camp, near the modern Prevesa. (Plutarch's 'Life of Antony' is the only first-hand account in an English translation; and Dion Cassius, in Greek, is much later and less judicious). See Antonius, Marcus; Augustus; Cleopatra.

ACTON, John Emerich Edward Dalberg, Baron, historian: b. Naples, 10 Jan. 1834; d. Bavaria, 19 June 1902. He was educated under Dr. (afterward Cardinal) Wiseman at Oscott College, England, and at Munich under Ignatius von Döllinger, whose friend and adherent he remained throughout life. He was returned to Parliament for Carlow (1859) and for Bridgnorth (1865), but was unseated on a scrutiny of the vote; created a peer (Baron Acton of Aldenham) in 1869 by Gladstone, whose trusted friend and adviser he was. A strong Liberal in politics and religion, he founded the 'Home and Foreign Review' (1862-64) in the interest of the liberal Catholic party, and adopted the Home Rule idea before Gladstone himself. At the Ecumenical Council in Rome (1870) he vigorously opposed the dogma of papal infallibility. From 1895 to 1902 he held the office of regius professor of modern history at Cambridge University. A scholar of wide and vast erudition for whom the very knowledge seemed to act as a check upon his productive powers. No modern man of such first-rate abilities has left so few literary productions by which posterity may judge of those abilities. Between 1868-90 he gave to the press a few historical essays and anonymous letters; and in 1895 he published a 'Lecture on the Study of History.' In 1882 he planned a comprehensive history of liberty, but never carried out the design. His university lectures were models of narrative, fullness of thought and flawless exactitude of statement. 'The Cambridge Modern History' (Vol. I, 1902) was planned and outlined by him.

ACTON, Sir John Francis Edward, English adventurer, son of an English physician and a French lady: b. Besançon, France, bapt. 3 June 1737; d. Sicily, 12 Aug. 1811. Entering the Tuscan navy under his uncle's auspices, he commanded a frigate in the Algerian expedition of 1775, performed daring exploits in covering its retreat and attracted the notice of Caramanico, favorite of Queen Caroline of Naples; and the Queen, ambitious of playing a larger part in politics, proposed extending the Grand Duke of Tuscany, to lend Acton to her to reorganize her navy. He soon became her prime favorite, commander-in-chief by both land and sea, and ultimately prime minister, shelving Caramanico on foreign missions. He improved the roads and ports, but excited great discontent by the consequent taxation and the positions given to foreigners. In 1793 he formed the league between Naples, Austria and England against France; in 1798 the French victories forced him to fly with the royal family to Sicily, and the Parthenopean Republic was formed. Five months later they were driven back, and he, with a 'Junta of State,' instituted a reign of terror, sending many to the prison or the block. In 1804 he was removed at French demand, and in 1806, when the French entered Naples, he was obliged to take refuge in Sicily again, where he died with the ill will of all parties.

ACTON, Thomas Coxon, American financier and public official: b. New York, 23 Feb. 1823; d. there, 1898. He was a leading banker, and in early years was assistant to the county clerk and deputy register of the State, and a police commissioner, 1862-69 president of the board. During the draft riots of July 1863 he commanded the entire police force in person for a week, rendering highly valuable service. He was superintendent of the United States Assay Office 1870-82, and assistant treasurer of the United States at New York 1882-86. He was always an active agent in administrative and social reforms in the city; carried through against bitter opposition the creation of a paid fire department; and assisted in founding the Society for the Prevention of Cruelty to Animals and the Society for the Prevention of Cruelty to Children. He declined a nomination for mayor.

ACTORS' CHURCH ALLIANCE OF AMERICA, an organization whose purpose is to establish a closer relation between the church and the theatre, founded in 1899 by Walter E. Bentley, a clergyman who had once been an actor. It uses its influence against theatrical performances on Sundays and provides chaplains of all denominations for the spiritual needs of all connected with the dramatic profession. It is affiliated with a similar organization in Great Britain. The total membership is about 5,000 and it has at its call about 1,500 chaplains in 400 American cities.

ACTS, Apocryphal. See Apocrypha.

ACTS OF THE APOSTLES. One of the books of the New Testament. The title, Acts of the Apostles (simply Acts in the old Codex Sinaiticus), was not bestowed by the author, and does not correspond to the contents of the work. The book seeks to describe a great historical fact, namely, the growth and expansion of the Christian Church, under the guidance of the spirit of Jesus, from its beginning in the small group of personal friends and disciples of Jesus (who were all Jews living in or near Jerusalem), until, having penetrated the Gentile world, it finally reached and gained a foothold in the capital of the empire, Rome itself. That this, and not to record the acts or deeds of the apostles, was the purpose of the work is indicated in i, 8, which forecasts the general plan and contents. The narrative begins with Jesus' last appearance with His disciples before His ascension, and then exhibits the origin and development of the Christian
community or church, externally, in virtue of the gift of the Spirit at Pentecost and of the preaching and missionary activity of the spirit-filled apostles, especially Peter and John; implicitly in reference to certain details of organization and modes of conduct and worship. In its first stages the movement was confined to Jerusalem or its immediate vicinity, was limited to Jews exclusively, and in due time attracted the attention of the Jewish authorities, who tried in vain to check its progress (i, 1—vi, 7). A crisis came when Stephen, a Hellenistic Jewish convert, who had defined this as different from and superior to the existing Jewish system, suffered martyrdom, and a violent persecution of the Christians of Jerusalem followed. The resultant scattering of active Christian workers throughout Palestine only fostered the growth of the new movement, and soon Christian disciples and converts were to be found in all parts of the land (vi, 8—vii, 39).

As yet, however, the Gospel had been preached to none but Jews. But soon, under the guidance of the Spirit, the movement took on a new aspect and spread to the Gentile world. The blessings of the new faith were made known. The historian notes three significant facts that were influential in bringing about this great result: (1) The conversion of Saul, the ardent Jewish persecutor, destined to become the great apostle to the Gentiles (ix, 1—30); (2) The revelation to Peter in the case of the Roman centurion Cornelius of Caesarea (ix, 31—xi, 18); (3) the spontaneous preaching of the Gospel to Gentiles at Antioch and its consequences (xi, 19—30). After noting the vain attempt of Herod Agrippa I to check the growth of the Church (Ch. xii), the interest of the narrative centres on the great Gentile-missionary propaganda, of which the chief exponent and champion was the Apostle Paul. The first section of this (xiii, 1—xv, 35) tells how Paul and Barnabas, by direction of the Holy Spirit, were the first to conduct a mission to the Gentiles on a large scale, and how the seal was set on this work by the apostle's arrest at Jerusalem. The remainder of the work is devoted to Paul's subsequent missionary activity, first in the East (Asia Minor, Macedonia, Achaia) and then, after his arrest and imprisonment, in Rome itself, though as a prisoner (xv, 36—xxviii). The book ends somewhat abruptly.

As 'Acts' is the only early account in existence of the apostolic period, and is also our one and only source for the historical background of Paul's Epistles, and thus enables us to construct an intelligible outline of the great apostle's career, its value is inestimable.

Because of its great importance 'Acts' has been subjected to a criticism more severe than has been meted out to any other New Testament book with the possible exception of the four gospels.

The traditional view that 'Acts' was written by Luke the physician, one of Paul's companions and fellow-workers, the author of the third Gospel, may be said still to hold its place. No other view has succeeded in gaining any general acceptance. The uniformity of style and vocabulary shows quite conclusively that the book is the work of one hand, and until a more plausible view is set forth the early church's tradition that it was Luke's hand is to be accepted as true.

The problem of the sources used by the author of 'Acts' is of some weight. The narrative, as far as xv, 35, as has been shown above, relates facts that transpired or were well known in the Aramaic-speaking circles of the early Jewish-Christian church. This is especially true of Chs. i—xii. The remainder of the narrative is not so ancient, but the story of the mission to the Gentiles. Recent investigations (such as those by Dr. C. C. Torrey, noted below) have only made quite probable what had been suggested earlier, namely, that for the material given in i, 1—xv, 35, Luke depended mainly on written Aramaic sources, which he himself translated quite literally, adding only a comparatively small amount of his own free composition. It must be said, however, that this view needs a thorough testing and sitting before it can be accepted as true.

For the remainder of his narrative (xv, 36 to the end), Luke must have depended partly on the results of his own inquiries of those cognizant with the facts, including the Apostle Paul himself, and partly on the story concerning those events with which he was personally acquainted. This personal responsibility is probably indicated by the author in the use of the first person plural in the so-called "we" sections (xvi, 10—17, and xv, 39 to the end of the book), sometimes called the "travel-document." Closely related to the problem of the sources is that of the credibility and accuracy of 'Acts.' Of the credibility of the narrative in its general outline there can be no reasonable question. But its accuracy in detail, in many instances, is open to doubt. Such errors as exist may be due in some cases to the source Luke was using; in others, to imperfect or incorrect information which he took to be reliable; in others, to simple omissions of facts which Luke may have known but chose not to mention, and in still others to a failure on Luke's part to grasp the significance of events, or to carelessness in the way he set them down. The latter is also indicated by the fact that in the later passages he set down Paul's own account as he remembered hearing it given. The discrepancies between Ch. xv and Paul's own account in Gal. ii, i—10, of his experiences at the council, may be due to Luke's faithful transcription of an Aramaic source written from a point of view entirely different from that of Paul himself. If the "we" sections alone cover the events and period of Paul's career with which Luke was personally acquainted or connected, it is not surprising that Luke may not have been minutely acquainted with the small details of Paul's relations to the churches of Corinth and Ephesus as these are revealed in Paul's letters. But such discrepancies, which are doubtless to be found in considerable numbers between 'Acts' and some parts of Paul's Epistles, are more than offset by the number of and often reciprocally explanatory agreements between the two. This is the more significant when we consider that there is no probability that Luke had read
these Epistles when he wrote Acts. That Luke always caught Paul's viewpoint and accurately comprehended the motives and principles that actuated the apostle cannot be assumed. Paul was admired and loved by many, but thoroughly understood by very few in the early church. Luke's aim was not, however, to give a biography of Paul, but, as has been stated, to write a history of the spread of the Gospel, under the guidance of the Spirit, until it reached its fulfillment. Unfortunately, the author's work must be pronounced a remarkable achievement, one of the greatest books ever written. It is the worthy companion and sequel to the author's Gospel, in which he so forth the things Jesus began both to do and teach (Acts i, 1).

Bibliography.—Besides the standard commentaries, e.g., by H. H. Wendt in the Meyer-Weiss series (in German), by R. J. Knowling in the Expositor's Greek Testament, by J. R. Luthy in the Cambridge Bible, by J. D. Smith in the New Century Bible, the most up-to-date discussions will be found in The Acts of the Apostles, by A. Harnack (London 1909); Introduction to the Literature of the New Testament, by James Moffatt (Philadelphia 1919); and The Composition and Date of the Acts of the Apostles, by C. C. Torrey (Cambridge 1916).

Edward E. Nourse
Professor Biblical Theology, Hartford Theological Seminary.

Acts of Congress. The two branches of Congress are co-ordinate in legislative power, the bills passed by either being subject to the absolute veto of the other. The only exclusive power possessed by either House was the provision that all bills for raising revenue should originate in the House of Representatives, but this power has practically been nullified by the unrestrained freedom of amending such bills which the Constitution gives to the Senate. In one case this freedom was exercised to the extent of placing 872 amendments in a House bill and of eliminating everything but the enacting clause and substituting a new bill. Annually many thousands of bills and resolutions are introduced by the Senators and Representatives (during the 61st Congress nearly 46,000), are then referred to the proper committees for consideration, and if worthy of presentation and action by Congress are introduced for debate. While the congressional committees are guided by many legislative principles, the House is left to decide, and the author's work must be pronounced a remarkable achievement, one of the greatest books ever written. It is the worthy companion and sequel to the author's Gospel, in which he so forth the things Jesus began both to do and teach (Acts i, 1).
your Majesty in this session of Parliament, have resolved to grant unto your Majesty the sums hereinafter mentioned; and do therefore most humbly beseech your Majesty that it may be enacted, etc. Thus the collective body of such declarations is the written law or statutes of the realm of the British nation and is the highest legal authority recognized, which cannot be amended or repealed without the same authority of Parliament. It binds every subject and every alien (with few exceptions) and, if named therein, the sovereign himself. Unless a specific date be set by the act itself, an act of Parliament takes effect immediately on receiving the sovereign’s signature. Acts of Parliament are either public or private. A public act is one relating to the whole Empire or a main subdivision (in which case it is called general) or a subordinate part (in which case it is called local). Private acts are those which relate to particular persons or concerns. (See Bills, Private). Originally the whole number of acts passed during each session constituted a single statute having a general title and for this reason acts of Parliament are divided by the year of the reign and the chapter of the statutes of that year, e.g., 2 and 3 Richard III, c. 45. Since the passage of the Short Titles Act of 1892 important acts up to that time may be cited by their short title, either individually or collectively. Most of the recent acts have borne short titles. See Great Britain—Parliament.

ACTS OF TRADE, a series of acts to regulate trade passed by the British Parliament between 1660 and 1674. These acts levied heavy duties in England on agricultural products and manufactured goods imported from the colonies. The intent was to protect the British landowner, but the actual result was to force the colonists to seek other markets where they could exchange their produce for manufactured materials and eventually to erect their own manufactories. On non-colonial importations heavy or prohibitory duties were imposed to give protection to colonial products which were admitted into England under nominal duties. Enumerated goods (such as sugar, tobacco, colo- nial credits, in, go, ginger, fuscid, molasses, South Carolina rice, etc.) were required to be shipped to England and heavy duties were levied upon intercolonial trade so as to force the shipment of such articles to England. In order to prevent trade with other countries or their colonies and to encourage the colonial production of articles obtained therein, heavy prohibitory duties were laid on all non-English goods imported into the colonies. The colonists were either greatly restricted in their production of or prohibited altogether to manufacture woolens, linens, hats, iron and many of its products, since the manufacturers of the mother country greatly feared the competition of the colonists in these articles. Indeed the imposition of a duty on English manufacturers by Massachusetts and a slight discrimination in favor of her shipbuilding industry led the British ship-builders to exclaim that the colonists would soon be able to live without Great Britain. Candidates who stood to their inclination, [would] be of very ill consequence. But the colonies were benefited to a degree by the two bounties granted by the government: First, that paid directly to the colonists to encourage the production of indigo in South Carolina and of naval stores, such as masts, hemp, flax, lumber, pitch and tars, by the British manufacturers which reduced the prices to colonial consumers. Irish linen was allowed to be shipped to the colonists duty free, salt needed for curing fish might be imported from any European port, and drawbacks were allowed on goods warehoused in England and then shipped to the colonies. The colonists were allowed later to ship grain, lumber, salt provisions, fish, sugar and rum to any port in the world, provided these goods were carried in English or colonial ships, of which the owners and three-fourths of the crews were British subjects.

At first the acts of trade were so unproductive of revenue that the funds raised thereby in the colonies did not pay the costs of administration, but in 1764 a statute known as the Sugar Act was passed containing the provisions of the previous Molasses Act, and an attempt was made to collect the duties which had been placed purely on a revenue basis. This indication bore fruit and tended to convert the acts of trade into revenue acts, which later was demonstrated by the passage of the Stamp Act (q.v.) and the Townshend Acts. These were among the contributing causes of the Revolutionary War. See United States—Causes of the Revolution; Great Britain—Navigation Acts; Virginia Conventions of the Revolution; Stamp Act; Declaration of Independence; Consult Beer, G. L., Commercial Policy of England toward the American Colonies (in Columbia University 'Studies in History, Economics and Public Law,' Vol. III, No. 2, 1893), 'British Colonial Policy, 1754-1765' (1907), and 'The Old Colonial System, 1660-1764' (1912); Osborn, H. L., 'The American Colonies in the 17th Century' (1907); Doyle, J. A., 'English Colonies in America' (1882-1907); Andrews, C. M., 'Colonial Self-Government' (1904); Howard, G. E., 'Preliminaries of the Revolution' (1905); MacDonald, William, ('Select Charters') (containing text of some of the acts); Lord, E. L., 'Industrial Experiments in the British Colonies of North America' (in Johns Hopkins University 'Studies in History and Political Science,' Extra Vol. XVII, 1889); Bruce, P. A., 'The Economic History of Virginia in the 17th Century' (1896); Weeden, W. B., 'Economic and Social History of New England' (1890).

ACTUALITY, LAW OF, in philosophy, the state of being actual; reality. The actuality of these spiritual qualities is thus imprisoned, though their potentiality be not quite destroyed.—Cheyne.

ACTUARIAL SOCIETY OF AMERICA, a scientific organization established in April 1889, having for its object the promotion of actuarial science by such methods as may be found desirable. The membership is composed of those connected with actuarial pursuits. The enrolment is divided into fellows and associates. Candidates must be nominated to the council by at least two fellows of the society, and after their nomination has been approved are required to pass such preliminary examination as may be pre-
scribed; a second examination is demanded of candidates for fellowship. An annual meeting is held on the first Thursday after 14 May in each year. The meetings may be called by the council from time to time and by the president at any time on the written request of 10 fellows. The officers of the society are a president, a first and second vice-president, a secretary, a treasurer and an editor of the Transactions. The president and vice-presidents are not eligible for the same office for more than two consecutive years. The council is composed of the officers, ex-presidents and nine other fellows, three elected to serve for three years, three for two years and three for one year. The society publishes 'Transactions,' containing the proceedings of the meetings, including original papers presented by fellows or associates, discussions on said papers and other matter expressly authorized by the council. In 1911 the total number of fellows was 144; that of associates, 113. Enrolment is not restricted to the United States. International congresses are held from time to time under the auspices of the society. Office of the secretary, 346 Broadway, New York.

ACTUARY, in ancient Rome, a clerk of public bodies who recorded their acts; also one of the public reporters who prepared the daily news of the city as a written newspaper. (See ACTA DIURN A.) In modern times, the mathematician of an insurance company, who makes the calculations on which its policy plans and prices are based, and applies the doctrine of probabilities to fire, life or accident insurance. Although the material on which he works is theoretically furnished by the experience of his and other cognate companies, and the records of public and private bodies, with the common rules of interest, in fact it needs not only great mathematical capacity but great practical sagacity to apply them to actual business; and no actuary of the highest class is a mere mathematician. In the early days, when experience was still mostly to make, the actuaries were usually the presidents of their companies; in recent times a safe body of experience has accumulated which enables business men to head them, and the actuary's calculations and advice is used whether or not they understand the plans. In accident companies the actuary needs to be and usually is a man of large practical acquaintance with different employments, their hazards, the meaning of given employment names, and those under which the more hazardous employments are disguised as less so; in fire insurance equally he must know the character of different risks. See INSURANCE.

ACÚNA, Christoval de, a-koon'yā, Chris-tō-vāl, Spanish missionary and South American explorer: b. Burgos 1597; d. 1676. After mission work in Chile and in Peru, he became rector of the College of Cuenca. In 1639, as scientist, he accompanied the second expedition of Teixeira to explore the Amazon, and wrote his 'Nuevo Descubrimiento del Gran Río de las Amazonas.' The work was published at Madrid in 1641, a French translation in 1682 and an English translation from the French edition in 1698.

ACUNA, Manuel, a-koon'yā, mān-oo-el', Mexican poet: b. 1849; committed suicide 1873 from disappointed love, which was the principal theme of his poems.

ACUÑA DE FIGUEROA, Francisco, a-koon'yā dá fe-ga-roā, frán-the'-sō-kō, Uruguayan poet: b. Montevideo 1791; d. there, 6 Oct. 1862. His works are a Spanish-American classic from their metrical perfection, though deficient in warmth. The collection 'Poetic Mosaic' comprises every variety of secular and religious poetry, from heroic poems to psalms.

ACUPUNCTURE, an old remedy for the relief of pain, swelling or dropsy. Steel needles about three inches long are used. One or more are inserted by the surgeon to the required depth and are left there from a few minutes to an hour. The result is a great relief from pain and, provided the needles are aseptic, the wounds are entirely harmless. Electric currents are sometimes sent into the needles to remove birthmarks, moles, etc., and some needles are made hollow so that a sedative may be administered and pain relieved at once.

ADA, Okla. county-seat of Pontotoc County, about 75 miles southeast of Oklahoma City, on the St. Louis & San Francisco, the Missouri, Kansas & Texas and the Oklahoma Central railways. Its industries include the manufacture of cement and asphalt. Cotton is raised extensively in the vicinity. Here is situated the State Normal School. The citizens have adopted the commission form of government, and the municipality owns its own waterworks. Pop. 5,000.

ADABAZAR, a-da-bā'zār, Turkey in Asia, town in the Kohja III sanjak, an active commercial centre on a branch of the Anatolian Railway, and on the military road from Constantinople. It has silk and linen industries, and trades with Constantinople in tobacco, cocoons, walnut wood and vegetables. Its annual imports are valued at $400,000; its exports at $2,400,000. Pop. 18,000 (Christians, 8,000; Mohammedans, 10,000).

ADAGIO, a-da'jō, a musical term denoting a slow movement or measure of time, between largo, grave and andante. In more extended compositions of instrumental music the second or third movement is sometimes marked adagio, and serves as a contrast to the rapid and energetic movement of the preceding and following parts of the sonata or symphony. It must be written in a measure of time which will afford scope for a flowing and expressive slow melody with a gracefully varied accompaniment. A clear and expressive execution of an adagio is an infallible test of a performer's art, as it demands a pure and beautiful tone and calls for great variety of tonal color. The diminutive adagietto is no longer used as denoting a tempo slightly more animated than adagio, but as a generic title for a short adagio movement.

ADAIR, James, American 18th-century Indian trader and author. He lived 1735-75 among the Indians, mainly the Cherokees and Chickasaws, and in the latter year published a 'History of the Indians.' Presumably the southeastern ones, containing an admirable first-hand account of their manners and customs, and a still more valuable, though unsatisfactory, set of Indian vocabularies. But the
chief object of writing the book was to trace the origin of the Indians to the Lost Tribes of Israel; a curious phantasm (especially as the tribe is nowhere known to have been lost, and the differentiation of stocks must far antedate the Christian era) which has bewitched many enthusiasts since, and was revived and expounded by Dr. Elias Boudinot in his 'Star of the East' (1816). Adair's views are summarized in H. H. Bancroft's 'Native Races' (Vol. V, p. 91).

ADAIR, John, American general and public officer: b. Chester County, S. C., 1759; d. Harrisburg, Ky., 18 May 1840. He served in the Revolution; removed to Kentucky 1787; in 1791 was major under St. Clair and Wilkinson in the northwestern Indian expeditions, and was defeated by the Miami chief "Little Turtle," near Fort St. Clair. He was a member of the constitutional convention which made Kentucky a State, 1 June 1792; was State Representative and Speaker, register of the United States Land Office, and 1805-06 United States Senator. He was volunteer aide to General Shelby at the battle of the Thames, 5 Oct. 1813; made brigadier-general of State militia November 1813, as such commanded the State troops at New Orleans under Jackson, 8 Jan. 1815. He was governor of Kentucky 1820-24, and United States Representative 1831-33, on the committee on military affairs.

ADAIR, Robin. See Robin Adair.

ADALBERT, or ALDEBERT, a native of France, who proselytized the banks of the Main. He is remarkable as the first opponent to the introduction of the rites and ordinances of the Western Church into Germany. He rejected the culture of the Saints and Confession, but distributed his own hair as sacred relics to his followers; was accused of heresy by Boniface the apostle of Germany, and condemned by two councils, at Soissons in 744 and at Rome in 745. Finally escaping from prison, he is said to have been murdered by some peasants on the banks of the Fulda.

ADALBERT, SAINT, OF PRAGUE, the apostle of Prussia proper: b. 939; d. 23 April 997. He was the son of a Bohemian nobleman, and his real name was Voitick ("host — comfort"); was educated in the cathedral of Magdeburg, and appointed the second bishop of Prague in 983. He labored in vain to convert the Bohemians from paganism, and to introduce among them ordinances of the Church of Rome. Discouraged by the fruitlessness of his pious zeal, he left Prague (988) and lived in convents at Monte Casino and Rome until the Bohemians in 993 recalled him; but after two years he again left them, disgusted with their barbarous manners. He returned to Rome, and soon followed the III to Germany; which journey he baptized, at Gran, St. Stephen, afterward king of Hungary. He proceeded to Gnesen to meet Boleslas, Duke of Poland. Being informed that the Bohemians did not wish to see him again, he returned to the provinces of Prussia, but was murdered by a peasant near what is now Fischhausen. His body was bought by Boleslas for its weight in gold, and became famous for its miraculous power. Its influence was greater than that of the saint himself; the Bohemians, who had refused to receive the ordinances of the Church, now suffered them to be introduced into Prague, on the sole condition that these protests should be transferred to their city. They were rediscovered in a vault in 1880 and deposited in the cathedral. Consult 'Life' by Heger, (Königsberg 1897); Voigt (Berlin 1898).

ADALBERT, "THE GREAT," archbishop of Bremen and Hamburg: b. about 1000; d. 17 March 1072; descendant of a Saxonic princely house; lived in his office in 1043 from the Emperor Henry III whose relation, friend and follower he was. He accompanied Henry to Rome in 1046 and was a distinguished candidate for the papal chair. Pope Leo IX made him his legate in the north of Europe (1050) He superintended the churches of Denmark, Norway and Sweden, converted the Wends, and aspired to a great northern patriarchate to vie with the Roman Curia. During the minority of Henry IV he usurped, in concert with Hanno, archbishop of Cologne, the guardianship of the young prince and the administration of the empire, and gained an ascendancy over his rival by indulging the passions of his pupil. After Semp, had become of age Adalbert exercised the government without control in his name. His pride and arbitrary administration induced the German princes in 1066 to remove him by force from the court; but after a short contest with the Saxon nobles, who laid waste his territory, he received the gospel in 1070, and held it till his death in Goslar in 1072. His injustice and tyranny were instrumental in producing the confusion and calamities in which the reign of Henry IV was involved.

ADALIA, a-dā'ı-la', Turkey in Asia, a seaport on the south coast, in the vilayet of Konieh, finely situated on the Gulf of Adalia, from which the houses rise in terraces like an amphitheatre, on a rocky hill and surrounded by fig, orange and mulberry gardens. It lies in a fertile, but hot and unhealthy locality, producing grain, figs, oranges, wine, etc. It has a small but good port, and carries on a considerable trade, exporting grain, timber, cattle, volania, etc. It was anciently called Attalia, later Satalia. Pop. about 30,000, 7,000 Greeks.

ADAM ("one made") and EVE ("living being," feminine). As the Old Testament almost invariably uses the article before "adam" ("the adam" = "the made one" or "the man"), its use as a personal name is a mere misapprehension, and the implications drawn from it are no part of the text; nor is there any reason to suppose it was so intended by the writers who used it, or so understood by the Jews. This, however, is a minor point, as the narratives of the creation and fall, etc., have the same bearing whether the first created beings had names or not; they remain themselves no less. But those narratives were certainly not understood by their compilers themselves, who merely took them from Babylonian sources (See Genesis 2), as implying literal history — which their discords should render obvious — and the difficulties involved in it result from being more Biblical than the Bible, as the Yahvistic portions of the later chapters disregard them, and the Yahvish adds to them at will. The accounts
in Genesis are three: (1) The Elohist (q.v.), in which "male and female" are created at the same time; that is, the whole race; just as the whole animal race, created in a single stroke. And interpretation as "one couple" is thrown back from the second account. (2) The Yahvistic, in which "the adam" is made from the dust, and "the eve" from the adam; and which contains the theological part of the story—the location in the garden of Eden, the prohibition of the tree, and its disregard, the expulsion, the birth of Cain and Abel, and the first murder. (3) The genealogical list in chapter 5, where the race is derived through Seth, and Cain and Abel are unknown; and where the first generations of men are demi-gods with enormous spans of life. The last is not only later than the other two, and corresponding to Greek, Assyrian, etc., pedigrees carrying the race or its first families back to the gods, but it is entirely unconnected with the actions, etc., which have a certain relation to the efforts of early man to account for the origin and propagation of life on the earth, which every race has undertaken as soon as it attained self-consciousness. The first, however, is that pure and genuine, and therefore, the superior purpose. The second and third are quite other, combining the creation story of a single couple, the progenitors of the human race—as with the Greek Deucalion and Pyrrha, etc.—with a deeply moralized account of the origin of moral evil, and the rapine and violence, pain and disease and hardships, which it brought into a world previously free from it. They is this, reflecting the predominant religious tone of the Jewish mind, that has formed the basis first of the Jewish and then of its successor the Christian theology: Adam as the reason for and spring of human sin. This resulted in Paul's conception of two Adams: the falsely one, whence come sin and death; and the spiritual one, whence springs salvation.

Most of the later Jews regarded the story as an allegory. Philo, the foremost writer of the Alexandrian school, explains Eve as the sensuous part, Adam as the rational part, of human nature. The serpent attacks the sensuous element, which yields to the temptation of pleasure for the reason. Clement and Origen adapted this interpretation somewhat awkwardly to Christian theology. Augustine explained the story as history, but admitted a spiritual meaning superinduced upon the literal; and his explanation was adopted by the re-formers, and indeed generally by the orthodox within the Catholic and the various Protestant Churches alike. More modern critics, loath to abandon it wholly as legend, have sought to separate a kernel of history from the poetical accretions, and to attribute the real value of the story not to its form, but to the underlying thoughts. Martensen describes it as a combination of history and sacred symbolism, "a figurative presentation of an actual event." The second narrative may be regarded as embodying the theosophy of the Hebrew mind applied to the everlasting problem of the origin of sin and suffering, a question the solution of which is scarcely nearer us now than it was to the primitive Hebrews. Hesiod describes man in his primitive state as free from sickness and evil before Prometheus (q.v.) stole fire from heaven and Pandora (who corresponds to Eve) brought miseries to the earth. Prometheus gives man the capability of knowledge; his daring theft is for man the beginning of a fuller and higher life. Aeschylus regards Prometheus as the representative of humanity led into misery by his self-will until he submits to the higher will of God. This corresponds with the story of Genesis, save that in the latter the spiritual features are clearer and more distinct. Consult Jere-mias, 'Das Alte Testament im Lichte des alten Orients' (1906); Schrader, 'Die Keilschrifttexte und das Alte Testament' (1903); and Reisig, 'Der Mid-rasch Rabba zu Genesis' (1882).

ADAM, Alexander, Scottish classical scholar and author: b. Forres, 24 June 1741; d. Edinburgh, 18 Dec. 1809. In 1768 he became rector of the High School, Edinburgh, and among his pupils were Sir Walter Scott, Lord Brougham and Jeffery. Edinburgh University conferred upon him an honorary L.D. in 1780. His chief work, 'Roman Antiquities,' (1791) passed through several editions and was translated into German. He also wrote 'Principles of Latin and English Grammar' (1772); 'A Summary of Geography and Her story' (1790); and a 'Compendious Dictionary of the Latin Tongue' (1805).

ADAM, Graeme Mercer, Canadian author and editor: b. Scotland 1839; d. 1912. He was trained in Blackwood's publishing house in Edinburgh, and, emigrating, became a publisher in Toronto and New York. He later edited several Canadian periodicals, assisted Goldwin Smith on the Bystander, and founded with him the Canadian Monthly (1872). In 1879 he founded the Canadian Educational Monthly. In 1896 he became editor of Self-Culture. He wrote 'An Outline History of Canadian Literature' (1886); 'The Canadian Northwest' (1895); and with Ethelyn Wetherald, the historical novel 'An Algonquin Maiden'; etc.

ADAM, Julie-ette, ad-ane, zhah-le-et (MM: ADAM, née LAMBER), Parisian journalist and author: b. Verberie, Oise, 4 Oct. 1836. She founded in 1879 the Nouvelle Revue, the organ of the Extreme Republicans, and edited it till her retirement in 1897; it has had a noted influence in Paris. Her second husband, Edmond Adam (later life senator, d. 1877), was prefect of police in Paris during the Prussian siege, and her first book was 'Le siège de Paris, journal d'une Parisienne' (1873). She has written largely (often under the pseudonyms Julie-ette Lamber and Comte Paul Vasili) on women's rights and various literary and social subjects; novels assailing Christianity for its confuxion of natural instincts;'The Hungarian Fatherland' (1884); 'General Skobelev' (1886); 'Après l'abandon de la revanche' (1910); 'Impressions françaises en Russie' (1912).

ADAM, ad'am, Lambert Sigisbert, "Adam l'aîné — the elder," French sculptor: b. Nancy 1700; d. Paris 1759. The son of a provincial sculptor, he went to the Louvre in 1723. His masterpiece, 'The Triumph of Neptune Stillin the Waves,' is at Versailles. His brother ADAM NICOLAS SÉRUSTEN, "Adam le jeune — the younger": b. 1705; d. 1778; also achieved fame as a sculptor. His chief work is the mausoleum of the Duchess of Stainislaus, Catherine Opalinska, wife of King Stanislaus, at Nancy. Another brother, ADAM, FRANÇOIS GASPARD BALTHASAR: b. 1710; d. 1761; was
Book of:

Schürer, 'Geschichte des jüdischen Volkes' (1901, p. 396).

ADAM BEDE, the first long novel of George Eliot (MARY ANN EVANS), was published in 1859. The action takes place in the English village of Hayslope, where the hero, Adam, a simple workman of sterling worth, pursues his trade of carpentry. Very different from Adam is his brother, Seth, a gentle and loving spirit, whose religious emotions have been strongly engaged by Methodist revival of the time. Seth is devotedly in love with the leading exponent of the sect in the Hayslope community, Dinah Morris, but she, consecrated to her work of evangelical preaching, refuses to think of him except with sisterly and religious affection. Adam loves Hetty Sorrel, a beautiful but vain and shallow country girl, who encourages him but secretly hopes to make a much loftier marriage. When young Arthur Donnithorne, son of the village squire, falls in love with her, both her ambition and ambition are stirred. Arthur, who is kind-hearted but weak-willed, tries to resist his infatuation, but finally yields to it. When Adam discovers them together there is a stormy scene between the two men, and Arthur agrees to tell Hetty that he can never marry her. Hetty, in her loneliness after Arthur's departure, becomes engaged to Adam, not knowing that she is to be a mother. When at last she realizes her condition she goes to Windsor in search of Arthur. Finding, after a painful journey, that he has gone to Ireland, she wanders miserably to seek Dinah. The scene now changes to Hayslope, where the girl's long absence has aroused anxiety, and the reader learns, with Adam, that she is in prison, charged with the murder of her child. She is condemned to death, but at the last moment, when, supported by Dinah, she is going to the gallows, her sentence is commuted to transportation, the release from death being brought by Arthur Donnithorne. The subject of Hetty's sin is handled with peculiar delicacy, and her wretched journey is one of the most poignant incidents of fiction. The story ends with the marriage of Adam and Dinah, who have been unconsciously drawn together from the first.

The characters in the story, simple country people as they are, working on the farm or in the shop, are portrayed with unusual distinctness, and their appeal is direct and powerful. The analysis of Hetty's character is particularly keen. In the midst of pity for her fate the reader is never allowed to forget the girls' shallowness and selfishness. Finely contrasted with Hetty is Dinah Morris, in her purity and selflessness. But the dominant figure is Adam Bede himself, level-headed and iron-willed, morally uncompromising, finding his best religion in work well done. The theme of the inevitable consequences of wrong-doing, which is ever present in George Eliot's novels, is strongly emphasized, and the story as a whole is not to be forgotten.

JAMES H. HANFORD,
Associate-Professor of English, University of North Carolina.
ADAM FAMILY—ADAMAWA

ADAM FAMILY, British architects, a celebrated 18th-century family consisting of William and his four sons, William, Robert, James, and John: of whom Robert ranks first and James next. The father was born in Fifeshire, Scotland, and his work was done in his native country; the town hall at Dundee, the library and university at Glasgow, and many other public and private buildings there and in Edinburgh, etc. Robert was born in Edinburgh, studied in Italy, and examined the noble remains of Dalmatia before settling in London; his work on Dioleitans' palace at Spalato was a valuable advertisement to his talents and taste, and all the brothers increased their repute by publishing engravings of their plans. Under Robert's direction they constructed a great number of buildings in London,—the Adelphi Terrace and the streets around commemorates them specifically. He also did much to remodel the appearance of the city. Robert also built Lansdowne House, Kedleston Hall near Derby and Register House near Edinburgh. The works of the brothers' work was their careful attention to harmonious interior arrangement and decoration.

ADAM DE LA HALE, or HALLE, ad-an duh là ál, French poet and composer: b. Arras about 1235; d. Naples about 1287; nicknamed of Arras, although he was not deformed. His satirical extravaganza, 'The Play of Adam, or the Play in the Arbor' (1262), constitutes the earliest comedy in the vulgar tongue; while the pastoral drama, 'The Play of Robin and of Marion,' may be looked upon as the earliest specimen of comic opera.

ADAM HOMO, a poem by Frederik Paludan-Müller, and his most important work, appeared during the years 1841-48. It is of particular significance in Danish literature, as it marks the end of Romanticism in Denmark. In Oehlenschläger's 'Aladdin' which introduces the period of Romanticism, imagination is given full play; in 'Adam Homo' cool reason prevails. Oehlenschläger points to Aladdin, the favorite of fortune; Paludan-Müller shows us Adam Homo, man as he really is. (The name of Homo also means a hero who represents the average man, as we find him in every-day life. Human life as it is, contrasted with the ideal, is the theme of the book). For 'Adam Homo' is realistic, and presents modern life with all its ugliness and wickedness. With shocking truthfulness the author shows how one may lose sight of ideals and squander a spiritual heritage. Adam is the son of a minister in Jutland, who over-emphasizes the material things of this world. His mother, a spiritual woman, tries to interest her boy in the higher life. While Adam studies at Copenhagen, his nobler impulses are kept alive by the loving letters of his mother and by his association with a pure-minded young woman. Unfortunately Adam succumbs to the temptations of new conditions, and almost without being aware of the fact he gradually loses sight of his ideals, and makes material gain and social recognition the goal of his efforts. Though he becomes a distinguished society man, he leads a sordid life, for his enthusiasm for truth, beauty and goodness is gone. Consult V. Andersen, 'Paludan-Müller'; Georg Brandes, 'Aesthetiske Studier' (pp. 191-222); Georg Brandes, 'Danske Digtere' (pp. 251-313); P. Hansen, 'Illustreret Dansk Litteratur Historie' (pp. 295-303); Karl Møller, 'Litteratur Historie' (pp. 248-261); Torvald Strom, 'Dansk Litteraturhistorie' (pp. 286-291).

JSEPH ALEXIS

Professor of Germanic Languages and Literatures, University of Nebraska.

ADAM OF BREMEN, German historian: b. probably in Meissen, Saxony; d. 12 October of an unknown year, probably 1076. He lived at Magdeburg, removed to Bremen in 1067, was made canon of its cathedral and next year principal of the cathedral school. His fame rests on his 'History of the Church of Hamburg' (1072-76), an inestimable mediaeval classic, for which he gathered material far and wide; making a special trip to Denmark to interview King Svend Estridson, whose communications he gives. As an appendix to his last book he gives an account of the Danish, Swedish and Norwegian possessions, containing a passage of the first interest to Americans, as verifying the Saga stories of Vinland: 'He [Svend] told of still another island found by many in that [Atlantic] ocean. It is called Wineland, because grapes grow there spontaneously. I have learned through definite information from Danes that unsown crops also grow there in abundance.'

ADAM OF ST. VICTOR, famous medieva

vocal theologian: d. in Paris c. 1192; nothing is known of him save his great hymns, the most numerous of any mediaeval writer, and among the foremost in rank. A few have been finely translated by J. M. Neale; a complete (so far as known) edition from the French of Léon Gautier was published in London (3 vols., 1881). Consult Dufield, Latin Hymns' (1888); French, 'Sacred Latin Poetry' (1874); Julian, 'Dictionary of Hymnology' (1888).

ADAMANT, a word loosely used to signify a substance of extreme hardness. It is probably derived from the Greek adamas, "unconquerable." Very possibly the name adamant was at one time applied to a definite substance; but it has been used to signify anything hard, or gems, a hard metal (probably steel) that was used in making armor, the lodestone and various other substances. It is now chiefly used in a poetical or rhetorical sense.

ADAMANTINE SPAR, a name sometimes applied to corundum (fr.) on account of its hardness; especially to the dark colored, non-transparent varieties which are used in pulverized form for polishing gems.

ADAMANTOID, a crystalline form belonging to the isometric system, and bounded by 48 similar scalene triangles. It has 6 octahedral solid angles, at the extremities of the principal axes; 8 hexahedral solid angles at the extremities of the trigonal axes; and 12 tetrahedral solid angles, at the extremities of the digonal axes. Its name is due to the fact that the diamond usually occurs in this crystalline form. (Also, and more commonly, called hex-octahedron).

ADAMAWA, ádá-má'wá (formerly Fum

bina), an internally autonomous sultanate of central Africa, between lat. 6° and 11° N., and long. 11° and 17° E.: part of the Sokoto empire in northern Nigeria; area some 50,000 square
miles. Much of the surface is mountainous, the mountains rising to about 8,000 feet. The principal rivers are the Benue and its tributary the Faro. The eastern part belongs to the German Kamerun; the western to British North Nigeria. A great part of the country is covered with thick forests, though there are also extensive and splendid pasture lands and cultivated fields. The native inhabitants are industrious and intelligent, but they have been in a great measure subdued by the Mohammedan Fulahs, who possess innumerable slaves. Slaves and ivory are the chief articles of trade. Pop. about 3,000,000. Chief towns, Yolo the capital, est. 12,000 to 20,000; Banjo, chief ivory mart; and Ngnudere.

ADAMI, Friedrich Wilhelm, ä-dä-mé, fréd-rikh, German author: b. Suhl, 18 Oct. 1816; d. Berlin, 5 Aug. 1893. He wrote stories, plays, etc., a very popular biography of Queen Louise, 'The Book of Emperor William' (1887-90); 'Ein erlicher Mann' (1850); 'Der Doppel gäuer' (1870), and contributed regularly to the Kreiszeitung. His literary style was much admired.

ADAMI, John George, American pathologist: b. Manchester, England, 1862; educated at Owens College there and Christ's College, Cambridge. He studied at Breslau and Paris; became demonstrator of pathology at Cambridge in 1887, and fellow of Jesus College in 1891. In 1892 he came to Montreal as professor of pathology at McGill University; from 1894 has been head of the pathological department at the Royal Victoria Hospital there; from 1896 lecturer to the New York Pathological Society. He has published papers on pathological topics, and is the author of 'The Principles of Pathology' (1908); 'Inflammation: Introduction to the Study of Pathology' (1910).

ADAMITE (named for M. Adam, a French mineralogist), a mineral, isomorphous with olivine, and occurring in small orthorhombic crystals that are often grouped in fine granular aggregations. It is an arsenate of zinc, having the formula ZnAsO₄Zn(OH)₂, although copper and cobalt may also be present. Its hardness is 3.5, and its sp. gr. 4.35. Its color varies from violet at Cap Garonne, near Hyères, France; and also at Laurium, Greece, and in certain parts of Chile.

ADAMITES. (1) A Christian sect said to have existed in the 2d century: so called because both men and women appeared naked in their assemblies, either to imitate Adam in the state of innocence or to prove the control which they possessed over their passions. The tradition is probably baseless, originating in a name of derision given to the Carpocratians. (See Gnostics). (2) Also called Picards, from the founder of their sect, Picard (perhaps also Bechhards). He called himself Adam the Son of God, and advocated community of women. They appeared about the year 1421 on an island in the River Lusinicz, where Zisca subsequently encountered them, and were able to destroy the whole sect. In the following year they were widely spread over Bohemia and Moravia, and especially hated by the Hussites (whom they resembled in hatred toward the hierarchy) because they rejected transubstantiation, the priesthood and the Supper. They subsequently formed one sect with the remaining Taborites, who have accordingly been confounded with them. In 1849 a similar sect sprung up in Austria.

ADAMNAN, Saint (der. of Adam), Irish ecclesiastic and author: b. in Donegal, c. 625; d. 703 or 704. He was descended from a cousin of St. Columba and from powerful Irish chieftains. Entering the monastery of Iona, he became abbot in 697; but was involved in quarrels with his monks over Easter and the tonsure (enforcing the orthodox Roman view against the Irish Church view), which hastened his death. He wrote a most valuable life of St. Columba (q.v.), the founder of Iona, full of historical information about the early Irish-Scottish Church (best edition Reeves', 1857; English translation in the 'Historians of Scotland', 1874, reissued Oxford 1895); and a hearsay but valuable report of matters in Palestine in his time, the first we have of that land in the early Middle Ages.

ADAMS, Abigail Smith, wife of President John Adams: b. Weymouth, Mass., 23 Nov. 1744; d. 28 Oct. 1818. She was daughter of a Weymouth clergyman, who opposed the match and took for a text My daughter is grievously tormented with a doubt. Though lacking strength and regular school education, she became a self-made force of high order in public affairs and one of the best of early American writers; her letters to her husband, collected and published, are not only of great historical and social value, but full of delightful personal humor and acute comment and judgment. Her husband's position kept them apart for years; but she joined him in France in 1784, went with him to his life of torment in London, and lived in Washington 1789-1801; thence till death at Braintree, now Quincy.

ADAMS, Alvin, founder of Adams Express Co.: b. Andover, Vt., 16 June 1804; d. 2 Sept. 1877. On 4 May 1840 he started an express business between Boston and New York which developed into the great company above named, formed in 1854 by the consolidation of several rival firms,—including Hanover's—of the express business,—with Mr. Adams as president. In 1850 he helped to organize the pioneer express service through the California mining camps, which on the consolidation above he sold out. In the Civil War the Adams Express Company was of immense help to the government; in 1870 it extended its business to the far West.

ADAMS, Arthur H., Australian journalist, novelist and poet: b. Lawrence, New Zealand, 6 June 1872. He was graduated from Otago University, New Zealand, studied law and became private secretary to C. J. Williams, the noted Australian theatrical manager. Later he went to China as war correspondent for Australian newspapers during the Boxer trouble; and he was in England from 1902 to 1905. Among his published works are: 'The Thrashing Boy' (1899); 'The Nazarene' (London 1902); 'London Streets' (poems, 1907); 'Tussock Land' (a novel); and stories, poems and articles in numerous periodicals, magazines and newspapers. In 1906 he became an editor on the 'Sydney Bulletin.'
ADAMS, Benjamin Matthias, American clergyman: b. Stamford, Conn., 1824; d. Bethel, Conn., 27 Dec. 1902. He was the son of General Adams and his mother was a daughter of the noted Rev. John J. Matthias. He was educated in a private school in which William Miner, afterward governor of Connecticut, taught. After considerable mental struggle he entered the ministry of the Methodist Episcopal Church and joined the New York Conference in 1848, in which he labored for 17 years. He was then transferred to the New York East Conference. He was a close observer of the habits of birds and nature and lectured on "Fun in Animals." He was a member of the general conference of 1884. He was a personal friend of the Warner sisters. A letter which he wrote to Anna Warner contained a passage which led her to compose the widely known hymn, "One more day's work for Jesus." His ministry, spent in and around New York and Brooklyn, was noteworthy.

ADAMS, Brooks, American writer on sociological themes: b. Quincy, Mass., 21 June 1848. He is a son of Charles Francis Adams (1st), was graduated from Harvard University in 1870 and followed the law for the succeeding year. He is a member of the Massachusetts Historical Society, the Institute of Arts and Letters, etc. In 1890 he published 'The Law of Civilization and Decay,' which has been issued also in French and German, and among his other works are included 'The New Empire' (translated into German and Russian); 'Centralization and the Law' (1896); 'The Theory of Social Revolutions' (1913); 'Charles Francis Adams, an American Statesman,' the last named work being a contribution to the proceedings of the Massachusetts Historical Society for December 1911. His literary works are 'Laws and Lamps,' chiefly upon the Emancipation of Massachusetts' (1887), a work intended as a philosophic exposition of a theory of social development.

ADAMS, Charles Francis, American statesman, son of President John Quincy Adams: b. Boston, 7 May 1807; d. there 21 Nov. 1866. At the age of two he was taken by his father to St. Petersburg; in 1815 went with his mother thence to Paris; the same year his father was made minister to England, and he was placed in an English boarding-school. In 1817 both returned to America; he was placed in the Boston Latin School, and in 1825 he was graduated at Harvard. His father had just been inaugurated President, and he spent two years in Washington; then returned to Boston, studied law with Daniel Webster and was called to the bar in 1828, but never practised — engaging in literature and political writing in magazines and pamphlets, and editing John and Abigail Adams' letters (1840–41). He was Representative in the legislature 1841–44, State Senator 1844–46, as a Whig; heading the "Conscience Whig" wing, he edited the Boston Whig, 1846–48, was chairman of the Free-Soil Convention at Buffalo in 1848, and was nominated for Vice-President on the ticket with Martin Van Buren. In 1856 he united with United States Adams' 'Works' in 10 volumes. He joined the Republican party on its organization in 1855, and in 1858 was sent to Congress, and re-elected in 1860. In 1861 Lincoln sent him to England as minister, as his father and grandfather had been before him. But even their problems were trivial beside his, when the very existence of the Union perhaps depended on how far the English upper classes could drag the government in evasion of international obligations and covert help to the South. The seizure of Mason and Slidell on the Trent nearly precipitated war; the fitting out of cruisers to destroy United States commerce was put a stop to only after the escape of the Alabama (q.v.) in the face of Mr. Adams' representations, and his declaration to Earl Russell, then foreign secretary, that permitting the Laird rams also to leave Birkenhead was "war." Napoleon III's persistent efforts to seduce the English government into a joint intervention in favor of the Confederacy had to be checkmated, and the rancorous hostility of one section and the coldness of the remainder of the best society made it a lonely and trying place, which for seven years he filled with a dignified resolution of immeasurable importance to his country. Returning to America in 1868, he was elected president of Harvard the same year but declined; for several years, however, he was president of its board of overseers. In 1871 he was the United States representative on the board of arbitrators at Geneva to settle the Alabama Claims (q.v.) ; in 1872 he nearly obtained the nomination as Democratic-Independent candidate for the presidency, which Horace Greeley secured. In 1874–77 he edited the 'Memoirs of John Quincy Adams' in 12 volumes.

ADAMS, Charles Francis (2d), American publicist, son of above: b. Boston, 27 May 1835; d. Washington, D. C., 20 March 1915. He was graduated at Harvard in 1856, and served as a cavalry officer through the Civil War, rising from first lieutenant to colonel, and being brevetted brigadier-general at its close. Shortly becoming noted for ability in discussion of economic, political and social questions, he was appointed railroad commissioner of Massachusetts in 1869; wrote 'Chapters of Erie' (1871) in collaboration with his brother Henry, a series of papers on railroad accident based on 'The State and the Railroads' (1875–76) for the Atlantic Monthly; 'Railroads, the Origin and Problems' (1878); 'Notes on Railway Accidents' (1879), etc.; and 1884–90 was president of the Union Pacific Railroad Company. In 1892 he published 'Three Episodes of Massachusetts History,' on the settlement of Boston Bay, the Antomanian controversy and early town and church government, and in 1893 'Massachusetts; Its Historians and Its History.' In 1895 he was chosen president of the Massachusetts Historical Society, and in 1901 president of the American Historical Association. He has also written lives of Richard Henry Dana (1891) and of his father (1900, American Statesmen Series). 'Lee at Appomattox,' etc. (1902), and much miscellaneous work. As chairman of the State Park Commission, 1893–95, he contributed materially toward planning out and establishing the great Metropolitan Park System of Massachusetts.

ADAMS, Charles Kendall, American historian and educator: b. Derby, Vt., 14 Dec. 1835; d. 26 July 1902. He removed to Iowa in 1855; was graduated at the University of Michigan in 1861; became assistant professor there 1863–67, and professor of history 1867–85. He studied
abroad 1867-68; in 1869-70 introduced the German seminary method in the United States by establishing the Historical Seminary in the University of Michigan; and was made dean of its School of Political Science when established. In 1885 he succeeded Andrew D. White as president of Cornell; resigned 1892, and till 1902 was professor of law and history at the University of Wisconsin. He was chief editor of "Johnson's Universal Cyclopedia," 1892-95. His most valued work is a "Manual of Historical Literature" (1882); he wrote also "Democracy and Monarchy in France" (1872), "Christopher Columbus" (1892); compiled "British Orations" (1884); and wrote much magazine and review matter.

ADAMS, Ephraim Douglass, American educator: b. Decorah, Iowa, 18 Dec. 1865. After graduating from the University of Michigan he took a post-graduate course in the same institution, receiving his degree of Ph.D. in 1890. He was immediately appointed special agent in charge of street railways for the 11th census. In 1891 he became assistant professor of history at the University of Kansas, and in 1899 he was promoted to the chair of European history. In 1902 he was appointed associate professor of history in Leland Stanford University, becoming full professor four years later. His books are: "The Control of the Pursuit of the United States Government" (1894); "The Influence of Grenville on Pitt's Foreign Policy" (1904); "British Interests and Activities in Texas" (Albert Shaw Lectures, Johns Hopkins University 1910); "Power of Ideals in American History" (Dodge Lectures on Citizenship, Yale University, 1913).

ADAMS, Frank Dawson, geologist: b. Montreal, Canada, 17 Sept. 1859; he was graduated at McGill University in 1878; took advanced courses at Sheffield Scientific School (Yale), and at Heidelberg, applying himself particularly to lithology and physical geology. In 1889 became lecturer on geology at McGill, in 1893 succeeded Sir William Dawson as Logan professor of geology there; and in 1908 was appointed dean of the faculty of applied science.

ADAMS, Franklin Pierce, American lawyer: b. Chicago, 15 Nov. 1881. He was educated at the Armour Institute and the University of Michigan. On graduating, in 1903, he entered newspaper work, which he followed for two years, on the Chicago Journal, after which he went to New York and became a member of the staff of the Evening Mail. For this paper he wrote a daily column under the caption "Always in Good Humor." His "Diary of our own Samuel Pepys" was another daily contribution which attracted popular attention. Besides his prose he has written much humorous verse. His works in book form are "Tobogganing on Parnassus" (1911); "In Other Words" (1912). Collaborated with O. Henry in writing "Lo!" (musical comedy, 1909).

ADAMS, Frederick Upham, American author and inventor: b. Boston, Mass., 10 Dec. 1859. While still a child his parents removed to Elgin, III., where he attended the public schools. From 1882 until 1890 he was engaged in the profession of mechanical engineering, and it was during this period that he invented an electric lamppost, which has since been unversally adopted, and an electric light tower. In 1894 he was appointed chief signalographer for Chicago, which position he held for three years. In 1900 he constructed an experimental passenger train for the Baltimore & Ohio Railroad which broke all previous speed records. He was the founder of a periodical entitled "The New Time," dealing with social problems, and which he edited from 1896 until 1898. Besides his works on technical subjects, he has also written several novels. The most important of these publications are: "Atmospheric Resistance and Its Relation to the Speed of Railway Trains" (1893); "President John Smith" (1896); "The Kidnapped Millionaires" (1901); "John Burt" (1903); "How Cities are Governed in Great Britain" (1904); "John Henry Smith" (1905); "The Bottom of the Well" (1905); "The Revolt" (1907); "The Vegetarians" (a comedy, 1911); "Ramley" (a drama, 1911).

ADAMS, Henry, American historian, son of Charles Francis: b. Boston, 16 Feb. 1838. He was private secretary to his father during the latter's English ministry, and assistant professor of history at Harvard 1870-77, being reputed one of the most stimulating and original instructors as well as brilliant expositors in the country. With several pupils he published in 1876 "Essays on Anglo-Saxon Law," of which he wrote on "Anglo-Saxon Courts of Law." In 1871 he collaborated with his brother, Charles Francis, in "Chapters of Erie." He edited the "North American Review," 1875-76. In 1879 he published Albert Gallatin's "Writings" (3 vols.); in 1882 a life of Jefferson Randolph (American Statesmen Series). But his life-work, and with one exception the foremost historical work of America in matter and style, is his "History of the United States from 1801 to 1817," covering the wars of Jefferson and Madison (9 vols, 1889-91), in motive it is a defense of his grandfather, John Quincy Adams, for deserting the Federalist party; in essence, a history of the causes and conduct of the War of 1812. For this task he took up his residence in Washington and spent years ransacking its archives. He also lived for long periods abroad, examining various European records, and trained himself thoroughly in military and naval science and construction, besides studying historical and economic problems. Besides the works named he is author of "Mont Saint Michel and Chartres" (1904); "Letter to American Teachers of History" (1910); "Life of George Cabot Lodge" (1911).
sion in the standardization of accounting records for the government railways in China. He went to China for that purpose in 1913 and while there assisted in organizing the ministry of commerce and statistics and accounts. He returned in March 1916.

ADAMS, Henry Cullen, United States Congressman from Wisconsin: b. Verona, N. Y., 28 Nov. 1850; d. 1906. His parents removed to Wisconsin while he was still a child. He began, as a farmer, then went into politics and filled various public offices, notably that of dairy and food commissioner, from 1895 to 1902. He was elected to Congress in 1903, where he remained until his death. He was the author of the Adams Act of 1906, under which the state experiment stations receive $720,000 annually for original research in agriculture. He took a prominent part in the Drug and Food Act of 1906 and in the organization of the meat inspection that followed.

ADAMS, Herbert, American sculptor: b. West Concord, Vt., 26 Jan. 1828. After early studies at the University of Vermont, he studied at the National Academy of Design and in 1856 vice-president. Among his distinctive works are tinted marbles and polychromed busts, notably that of "St. Agniss, of "Primaera, and of A. "V. Pond, the artist, in the Metropolitan Museum, New York. His portrait busts of women are remarkably beautiful, among the best examples being that of Miss A. V. Pond (who afterward became his wife), completed in Paris in 1887, and one of Miss Julia Hale, the actress, in the Congrional Library, Washington, are a statue of Professor Channing and two bronze doors, by Olin Warner. A "Madonna with Angels in marble, and the Vanderbilt bronze doors in St. Bartholomew's Church, New York. His other works of importance are the bronze Jonathan Edwards Memorial at Northampton, Mass., bronze statues of Richard Smith, in Philadelphia, and William Ellery Channing, in Boston, and William Cullen Bryant, in New York. Adams' works were exhibited at the Chicago Fair of 1893 and at the Louisiana Purchase Exposition, St. Louis, in 1904, in both of which he received high awards. While modern and original, Adams, of all Americans, approaches closest to the Early Renaissance in his refined realism and in his great technical skill in marble cutting. Consult Taft, Lorado, "History of American Sculpture" (New York 1904).

ADAMS, Herbert Baxter, American historical student and educator: b. Shutesbury, Mass., 16 April 1840; d. 1901. He was graduated at Amherst in 1862; took Ph.D. at Heidelberg; and on the opening of Johns Hopkins in 1876 was made fellow in history, 1878 associate in history, 1883 associate professor in history, and in 1891, full professor. In 1901 he resigned on account of ill health, and died shortly afterward. In 1884 he was a leader in organizing the American Historical Association, and was secretary till 1900, then becoming first vice-president. He edited the "John Hopkins Studies in History and Political Science" from the start, also the "Contributions to American Educational History" published by the United States Bureau of Education. His chief work, "The Life and Writings of Jared Sparks," (2 vols., 1893). Among his historical monographs are the "College of William and Mary," "Thomas Jefferson and the University of Virginia," "The Germanic Origin of New England Towns," and "Maryland's lost inheritance: the Making of a National Commonwealth." But his best work was not in writing history, but in training others to write it, and he was a powerful influence in creating the new school of historical research.

ADAMS, John, American statesman, 2d President of the United States: b. Braintree, Mass., of a line of farmers, 19 Oct. 1735; d. 4 July 1828, the year after his son was inaugurated President. Graduated at Harvard, he taught school, and read theology for a church career; but seeing his unfitness for it studied law and began practice in 1758, soon becoming a leader at the bar and in public life. In 1764 he married his famous wife, Abigail Smith. All through the germinall years of the Revolution he was one of the foremost patriots, steadily opposing any abandonment or compromise of essential rights; and in 1766 published essays in the Boston "Gazette," reprinted in London 1767, entitled "A Dissertation on Canon and Feudal Law," really on colonial rights. In 1765 also he was counsel for Boston, with Otis and Gridley, to support the town's memorial against the Stamp Act. In 1766 he was a selectman, or in other words, one of the three official rulers of the head of the New England colonies. In 1768 the royal government offered him the post of advocate-general in the Court of Admiralty,—in fact a lucrative bribe to desert the opposition, but he refused it. Yet in 1770, as a matter of high professional duty, he took his future in his hands to become counsel (successfully) for the British soldiers on trial for the "Boston Massacre." Though there was a present uproar of abuse, Mr. Adams was shortly after elected Representative to the General Court by more than three to one. In March 1774 he was contemplating writing the "History of the Contest between Britain and America." June 17 he presided over the meeting at Faneuil Hall to consider the Boston Port Bill, and at the same hour was elected delegate to the first Congress at Philadelphia (1 September), by the Provincial Assembly held in defiance of the government. Returning home, he was made a member of the Provincial Congress, already organizing resistance to England. Just after Lexington he again journeyed to Philadelphia to the Congress of May 1775; where he did on his own motion, to the disgust of his associates and the reluctance even of the Southerners, one of the most important and decisive acts of the Revolution,—induced Congress to adopt the forces already gathered in New England as a national army and put George Washington at its head, thereby engaging the Southern colonies irrevocably in the war and securing the one man who could make it a success. In 1776 he was a leader in carrying the Declaration of Independence. He remained in Congress till November 1777, serving on the Committee on Foreign Relations and as chairman of the Board of War and Ordnance, very useful and laborious, but making
one dreadful mistake; he was largely responsible for the policy of ignoring the just rights and decent dignity of the military commanders, which lost the country some of its best officers and led ultimately to Arnold's treason. His reasons, exactly contrary to his wont, were sound abstract logic, but thorough practical ineptitude.

In December 1777 he was appointed commissioner to treat to sue Edmondland. David Franklin and Arthur Lee were there before him; and though he reformed a very bad state of affairs, he thought it absurd to keep three envoys at one court and induced Congress to abolish his office, returning in 1779. Chosen a delegate to the Massachusetts Constitutional Convention, he was called away from it to be sent again to France. There he remained as Franklin's colleague, detesting and distrusting him and the foreign minister Vergennes, embittering himself with both, and earning a diaeresis of his worst dislike from both, till July 1780. He then went to Holland as volunteer minister, and in 1782 was formally recognized as from an independent nation. Meantime Vergennes intrigued energetically to have him recalled and in April 1784 the Senate consented so that but for his contumacious stubbornness half the advantages of independence would have been lost, as Vergennes was employed to gain points for France and not for the United States. In the final negotiations for peace he persisted (against his instructions) in making the New England fisheries an ultimatum, and saved them. The wretched state of American affairs under the Confederation made it impossible to do his country any good abroad, and the vindictive feeling of the English made his life a purgatory, so that he was glad to come home in 1788.

In the first presidential election of that year, he was elected Vice-President on the ticket with Washington; and began a feud with Alexander Hamilton, the leading man of the Federalist party and a chief organizer of our executive machine, which is accredited with the premature overthrow of that party, and had momentous personal and literary results as well. As official he was thought himself entitled to its real leadership as well; Hamilton would not and indeed could not surrender his position, for the lesser men looked to him for counsel and policy, and the rivalry never ended till Hamilton's death. In 1796 he was elected President against Jefferson by three electoral votes, one "scratch" vote each in Pennsylvania, Virginia and North Carolina, a virtual defeat as not likely to recur. His term is recognized as one of the ablest and most useful of our administrations; but its personal memoirs are most painful and scandalous. The members of the Cabinet — nearly all Hamiltonians — said official secrets before Hamilton and took advice from him to thwart the President. They disliked Mr. Adams' overbearing ways and obtrusive vanity — for modesty or a low sense of personal dignity were not parts of his character, — considered his policy destructive to the party and injurious to the country, and felt that loyalty to them involved and justified a disloyalty to him. Finally his best act brought on an explosion. The French Directory had provoked a war with this country, which the Hamiltonian section of the Federalist leaders and much of the rank and file hailed with delight, thinking it a service to the world to cripple France as then ruled; but when it showed signs of a better spirit, Mr. Adams, without consulting his Cabinet he would oppose it nearly or quite unanimously), nominated a commission to frame a treaty with France. He had the constitutional right to do so; but a storm of fury broke on him from the Hamiltonian leaders as the most unpatriotic action that was renominated for President in 1800, but beaten by Jefferson, owing to the loss of New York despite heavy gain in Pennsylvania. The causes were natural and local, and while machine unity might have gained the upper-class party one more election it was bound soon to be swamped by popular growth; but as it never won another, each faction laid its death to the other, and American History is hot with the fires of this battle even yet.

His later years were spent at home, where he was always interested in public affairs and sometimes much too free in his comments on them; where he read immensely and wrote somewhat. He heartily approved his son's break with the Federalists (see Adams, John Quincy) of 1814; trusted in him on the same day as Jefferson, both on the 50th anniversary of the Declaration of Independence.

Mr. Adams' greatest usefulness and popularity sprang from the same cause that produced some of his worst blunders and misfortunes: a generous impulsiveness which made it impossible for him to hold his tongue at the wrong time and place for talking, his vehemence, self-confidence and impatience of obstruction. He was fervid, combative, opinionated and masterful; but he had trust, admiration and respect from the majority of his party at the worst of times, and history justifies it. Consult 'Works' by his grandson Charles Francis Adams; Parker, T., 'Historic Americans' (1910).}

Forrest Morgan, Connecticut Historical Society.

ADAMS, John, American educator; b. Connecticut 1772; d. 1863. He was graduated at Yale in 1795, was a school teacher till 1810, and thence till 1833 principal of Phillips Academy, Andover, Mass., which he developed into a reputation throughout the country. He was teacher of Oliver Wendell Holmes, who, in the lines beginning "Grave is the Master's look," commemorates him in his poem 'The School-Boy,' read at the Phillips Academy centennial in 1878.

ADAMS, John, Confederate soldier; b. Tennessee 1825; d. 30 Nov. 1864. He was graduated at West Point in 1846; was brevetted first lieutenant for bravery at Santa Cruz de Rosales, 1848; promoted captain of dragoons, 1856; and resigned 1861 to join the Confederate army, in which he rose to the rank of brigadier-general. He was killed at the battle of Franklin, Tenn.

ADAMS, John, the name assumed by Alexander Smith, one of the mutineers of the Bounty. After intoxication and massacre had killed off all the mutineers but himself, he was shocked into a complete change of heart, and became something of a pious and of upright life; he was the patriarch of the little native and half-caste group on Pitcairn's Island, taught a school and held worship there. It was nearly
JOHN ADAMS
Second President of the United States
20 years after the mutiny before his existence was known; and though technically liable to execution for the mutiny the English officials felt that his hardships, exile and repre- sentation had atoned for the crime, and that it would be wrong to remove the head from the little settlement. He was left unmolested and died in 1829. See Bligh, William; Pit- cairn's Island.

ADAMS, John Coleman, American clergyman: b. Malden, Mass., 25 Oct., 1819. He was graduated from Tufts College in 1870 and the Divinity School in 1872, and entered the minis- try of the Universalist Church and has since served several churches of his denomination. He is author of The Fatherhood of God (1888); Christian Types of Heroes (1891); The Leisure of God (1895); Nature Studies in the Berkshires (1899); Life of William Hamilton Gibson (1901); Hosea Ballou and the Gospel Renaissance (1903); Honorable Yogi (1906); Short Studies in the Larger Faith (1907).

ADAMS, John Couch, English astronomer: b. in Cornwall, 5 June 1819; d. 21 Jan. 1892. A precocious mathematician, he became senior wrangler at St. John's College, Cambridge, and mathematical tutor there. He discovered in 1845, by calculation of the perturbations of Uranus, that another planet must exist beyond it, and fixed its position within two degrees; but search for it not being made, Leverrier of Paris independently made the same discovery next year, and Galle of Berlin at once found the planet (see CERES). This mathematical discovery of Neptune is justly regarded as one of the greatest triumphs of science. To com- memorate it the University of Cambridge founded in 1848 the Adams prize to be awarded biennially for the best essay in astronomy, mathematics or other branch of natural philosophy. In 1851 he became president of the Royal Astronomical Society; 1858-59 pro- fessor of mathematics at Aberdeen University; 1859-92 Lowndean professor of astronomy and geometry at Cambridge, and in 1861 di- rector of Cambridge Observatory. He was a delegate to the International Prime Meridian Conference at Washington 1884. He received the Copley medal of the Royal Society in 1848. His papers were edited by his brother, William G. Adams, and R. A. Sampson (2 vols., 1, 1896; II, 1901).

ADAMS, John Quincy, American statesman, 6th President of the United States, son of John Adams: b. in Braintree, Mass., 11 July 1767; d. Washington, D. C., 23 Feb. 1848. At 10 he accompanied his father on his first embassy to France, and was placed at school near Paris. He returned with his father in about 18 months; but soon went back with him to Europe, and attended school in Holland and at the University of Leyden. In 1815 Francis Dana, his father's secretary of legation, who had been appointed minister to Russia, took him with him as his private secre- tary. After 14 months' stay in Russia, where Catherine refused to recognize Mr. Dana, he tried back home through Sweden and Den- mark to The Hague. Soon after his father's appointment as ambassador at London in 1785, he returned home to complete his studies, as he believed an American education to be the best for an American career, a coolly judicious choice for a lad of 18. He was graduated at Harvard in 1788, entered the office of Theophilus Parsons (q.v.), and in 1791 was admitted to the bar. He afterwards began to take an active interest in politics. He wrote a series of letters to the Boston Sentinel under the signature of "Publicola," in reply to Paine's Rights of Man, and in 1793 defended Washington's policy of neutrality under the signature of "Marcellus." These letters attracted great atten- tion, and in 1794 Washington appointed him minister to The Hague. In 1798 he received a commission to negotiate a treaty of commerce with Sweden; and traveling through Silesia wrote an account of it which was published in London, and later translated into German and French. On Jefferson's accession to the presi- dency he was recalled and resumed law practice.

In 1802 he was sent to the State Senate; the next year to the United States Senate in place of Timothy Pickering, leading Hamiltonian. But the Hamilton-Adams feud (see ADAMS, John) had split the party into rancorously hostile halves, and Mr. Adams was practically "boycotted" by the dominant faction of his own party, as being an Adams, with an in- genuity of indecent insult curious to read of; still worse was it when Pickering was made his colleague by the other faction at the next vacancy. It was good training for the great career of his later life; he was not the man to conciliate his foes, and soon made the breach irreparable by breaking away from the party policy. Through life any action which strength- ened the United States, or increased its duc- nity in the eyes of the world, or simply "showed fight" for any purpose, met with his heartiest approval and warmest support, even though fathered by his worst enemies; and he first supported (with some reservations) Jefferson's Louisiana purchase,—precisely in the line of the former Federalist policy and the nature of the party, but now fought by them as Jeff- erson's,— and in 1807 took a far more radical step. The action of France and Great Britain in plundering American commerce through their mutual blockade laws, and of the latter in impressing American citizens under pre- tence of their being English runaways, had enraged the country, but it was helpless against both and felt not strong enough at the time to fight either; finally the outrage of the Leopard on the Chesapeake (see the latter name) roused the Republicans to fury, and even many of the Federalists. But the leaders of the lat- ter sympathized with England's difficulties in the war with Napoleon, would do nothing to embarrass her and even defended the Leop- ard's action. Mr. Adams was as hot as any Republican; he tried to have the Boston Federalists hold a meeting and pledge the government their support in any measures to disturb British insolence, and on their refusal attended a Republican meeting and was put on a committee to draft such resolutions. The Federalists were soon compelled by popular feeling to do likewise, and Mr. Adams also drafted resolutions the passage of which by the House of Congress in October the Embargo on all American shipping was passed, to see if England could not be starved into better be- havior; half ruining New England, most of
whose capital was invested in commerce, and injuring Americans much more than the enemy. Mr. Adams, as a member of the committee which reported the bill, and earnestly advocated it,—not because it went as far as he liked, but as preferable to showing no resentment whatever, and all the Federalists would permit. The executions leveled at his father for the French mission, and the censure of sectional and party treachery, were repeated on the son; political literature for half a century was glowing with the acrid polemics on the subject, and the prime object of his grandson Henry Adams’s ‘History’ is to exculcate him. His term in the Senate was to expire 3 March 1809; in the preceding June the Massachusetts legislature elected James Lloyd to succeed him, as an insult, which he accepted and at once resigned. Meantime he had been made professor of rhetoric at Harvard and delivered lectures there. The next month he declined a Republican nomination to the House.

On Madison’s accession in 1809 he at once appointed Mr. Adams minister to Russia; the Senate for some months refused to confirm the nomination, but at length yielded, and he passed four and one-half years there. In the peace negotiations with England over the War of 1812, he was a commission with Gallatin and Bayard, and again defeated assaults on the American fishing rights like his father. The treaty is usually considered a humiliating fiasco for America; but it is significant that the British press considered it a surrender on their side, and especially revised Mr. Adams for his share in it. Visiting Paris, he was made commissioner to negotiate the American-English commercial treaty signed 13 July 1815. Meantime he had arrived in England, 26 May, and received the news of his appointment as minister to that country. The synchronism of wars, treaties and ministerships between father and son is so curious that in ancient history it would be treated as indubitable confusion of persons.

Eight years later, after leaving America, Mr. Adams was recalled to it as secretary of state under Monroe, inaugurated March 1817. His greatest achievement was the treaty with Spain ceding Florida to the United States for $5,000,000, to be used in paying American claims against Spain; and rectifying the boundaries of Louisiana and Mexico. His utter independence of personal against national considerations is singularly shown in his support of Jackson for invading Spanish Florida and hanging Arbuthnot and Ambrister; he hated and despised Jackson, who surely had violated all international law, but had roughly vindicated United States rights and put down dangerous intrigues with savages, and Mr. Adams vigorously defended him. Adams was the author of the ‘Monroe Doctrine,’ and though he never dreamed of its later interpretations would not improbably have sympathized with them. He also drew up a report on weights and measures which is still a classic, and showed an almost incredible amount of investigation. An ultimately far more important question came up over the admission of Missouri as a slave State. The Missouri Compromise (q.v.) had been passed and put before Monroe for signature, but he submitted to his Cabinet the questions whether Congress had a constitutional right to prohibit slavery in a Territory, or whether the prohibition of slavery “forever” in the North of Mason and Dixon’s Line meant while it remained a Territory or thereafter. The Cabinet was unanimous in the affirmative on the first question; Mr. Adams was alone in declaring that “forever” included statehood also.

In the presidential election of 1824 there was no electoral majority: Andrew Jackson had 99, Mr. Adams 84 (a remarkable vote considering his ungracious manner, gift for making enemies and refusal to do anything to promote his election), William H. Crawford 41 and Henry Clay 34. Crawford was put out of the field by a paralytic stroke. As Clay could not be elected, his supporters cast their votes for Adams as preferable to Jackson: the former represented the same public policy as theirs, he was the ablest public official in the country and not personally hostile to Clay, while Jackson was regarded as an ignorant and violent demagogue. Mr. Adams was not re-elected, and made Clay’s successor to the state a place to which Clay’s talents and position gave him almost a prescriptive claim. The Jacksonians denounced this as a corrupt bargain to defeat the people’s will, and absurdly gave it the name of the unsavory English “Coalition,” a catchword which was an efficient party weapon for many years. Mr. Adams’ administration had no dramatic events. Its policy was based on a new division of parties. The Federalists were dead, consequently their opposition was dead also, and the new division was into National Republicans, afterward Whigs, and Democratic-Republicans, or Democrats; the former favoring internal improvements, a national bank and high tariffs, the latter opposing them. In reality, the division was between the preferences of the capitalist class and the masses; and the vast overlap of the latter in the South, now concentrated on Jackson instead of a threefold split (they had given almost none to Adams), carried him in four years later by 178 to 83. Much is always made of the hostility of the northern commercial classes whose trade the tariff was intended to cut down, of the southern planters who would lose as consumers while having nothing to protect as producers, and the Jacksonian bribe and threat of “spoils”; but by the figures they cost Adams nothing.

Mr. Adams retired, as he supposed, from public life. But in 1831 the constituency of his district around Braintree elected him a member of Congress on the Anti-Masonic ticket (see ANTI-MASONRY; MORGAN, WILLIAM); and though that party soon died, his immensability and unique power in Congress kept him there till his death. By a singular fortune, he owes by far his greatest fame to this relatively small position after his crowning office was laid down. Belonging to no party, a political Ishmaelite, of the loftiest patriotism and the highest integrity, but scornful of nature and irritable in temper, rousing every demon of his nature and the envy of the world, he envenomed battle with them and more than a match for them all, the “old man eloquent” was for many years a storm centre of wonderful picturesque ness. But his repute is not a mere political curio: he had the fortune to
JOHN QUINCY ADAMS
Sixth President of the United States
take his place at the very outset of the struggle of the slave oligarchy to suppress free speech and writing on the slavery question, and crush political liberty to uphold slavery. He fought the attempt unflinchingly year after year by purely legal methods, upholding the right of petition as indefeasible under any government or for any purpose,—he did not hesitate to submit a petition from Virginians praying for his own expulsion as a nuisance,—and consequently a right of slaves or of others in their interest; and with little sympathy for the anti-slavery cause as such, became by force of circumstances its mightiest champion. He died of a stroke of apoplexy on the floor of the House. Consult ‘Writings of John Quincy Adams,’ edited by W. C. Ford (New York 1897).

FORREST MORGAN, Secretary Connecticut Historical Society.

ADAMS, John Quincy (2d). American politician, son of Charles Francis: b. in Boston, 22 Sept. 1833; d. 14 Aug. 1894. He was graduated at Harvard in 1853, and became a lawyer. A Democrat after the war, he took hopeless candidacies for the governorship to keep the organization together, in 1867 and 1871, and for the vice-presidency in 1872. He also served in the legislature in 1866, 1869 and 1870. In 1877 he was made a member of the corporation of Harvard.

ADAMS, Maria Kiskadden. American actress: b. Salt Lake City, 11 Nov. 1872. She is the daughter of an actress, who, under the stage name of Adams, was leading woman of a stock company in that city. Her first appearance was made while a child on a stage in the West; she then continued to take children's parts till she reached the age of 16 when she left Daniel Frohman's company to take an important rôle in Hoyt's 'A Midnight Bell.' She later became a member of Charles Frohman's stock company; in 1892 supported John Drew in 'The Masked Ball'; and in 1898 scored a marked success as Lady Babbie in J. M. Barrie's 'Little Minister.' In 1899 she played Juliet in 'Romeo and Juliet'; in the season of 1900-01, won further approval as the Due de Reichstadt in Rostand's 'La Jiglone'; in 1901-02 took the character of Miss Phoebe in Barrie's 'Quality Street'; in 1903-04 played 'The Pretty Sister of Jose'; and in 1905-07 Barrie's 'Peter Pan.' She has appeared in such Shakespearean roles as Viola and Rosalind and assumed the title rôle in Rostand's 'Chantecler' in 1911. In 1913-14 she starred in Barrie's 'Legend of Leonora.' Consult Clapp and Edgett, 'Players of the Present,' in the Dramat Society Publications (New York 1899).

ADAMS, Nehemiah. American Congregational clergyman: b. Salem, Mass., 19 Feb. 1806; d. 6 Oct. 1878. He was graduated at Harvard in 1826, and at Andover Theological Seminary in 1829. The same year he settled at Cambridge, but 1834-70 was pastor of the Essex Street Church in Boston, and was widely known as a religious leader. He published several polemic works; a great sensation and much hostile criticism were created by 'A South Side View of Slavery,' published in 1854 after a winter in Georgia, in which he lauded slavery as beneficial to the negroes' religious character. He published also a 'Life of John Eliot.'

ADAMS, Samuel. American patriot: b. Boston, 27 Sept. 1722; d. 2 Oct. 1803. He was son of a rich merchant, ship-owner and magistrate, a leader in provincial contests with royal governors, and inventor of the caucus in fact and perhaps unintentionally in name. Educated at the Boston Latin School, he was graduated at Harvard in 1740. In 1743 he wrote for his master's degree a thesis upholding the lawfulness of resisting supreme magistrates. He became a lawyer; but the profession was under ban with the upper classes, and at his family's wish he entered a leading merchant's counting-house. Shortly afterward his father set him up in business, in which he lost half his capital, losing the other half by a loan never repaid. Then he became partner with his father in a rather unsuccessful brewery. Soon the father lost nearly all his property in a land-bank scheme crushed by an act of Parliament, which extended an English banking enactment to the colonies. The hundreds of ruined shareholders denounced this act as an invasion of chartered colonial rights; and turned the cream of the business leaders of Massachusetts, and their sons and daughters, into potential rebels at a blow. On his father's death in 1748 he carried on the brewery alone, and was nicknamed by his opponents 'Sammy the malter,' changed to 'Sammy the publi-can' when he was made tax-collector of Boston 1763-65. Meanwhile he had become a great power in town meetings, having strong and sincere democratic feeling and a manly generous genius for political management and caucusing. As collector he was a bad business manager and was sharply assailed; but his political headship is shown by his being selected in 1764 to draft the town's instructions to its representatives relative to the Stamp Act,—the first public American protest against the parliamentary right of taxation,—and the like instructions the next year. He was himself in the legislature 1765-74, being clerk of the House and on the leading committee that turned up the most important state papers of that stormy time, and spokesman as well as prompter of the incessant wrangles with Governors Bernard and Hutchinson. When the Townshend Acts were passed in 1767, he drafted the legislature's petition to the King, the instructions to the Massachusetts agent in England, and the circular letter of February 1768 to the other colonies asking their aid. The latter led directly to the Revolution. George III ordering Bernard to command the legislature to rescind it or be instantly disolved. The latter refusing by 92 to 17, the King thereon resolved to send troops to overawe the colony. The same year Adams wrote 'The True Sentiments of America,' and in 1769 a famous 'Appeal to the World.' The morning after the 'Boston Massacre' he was made chairman of a committee to communicate to Governor Hutchinson and his council the town-meeting vote that the two regiments of British soldiers should be removed to the castle in the harbor. When the governor wished to compromise on one, Adams had the people insist on 'both or none,' and both were removed, thereafter being known in Parliament as the 'Sam Adams regiments.'
In 1772 the order was issued that the judges should thereafter be paid by the Crown, not by the colony, and be removable at the King's pleasure; the Boston town-meeting requested Governor Hutchinson to convene the legislature on the question, and on his refusal Mr. Adams reviled a proposal of Jonathan Mayhew's in 1785, to have the towns of Massachusetts appoint committees of correspondence to consult about the common weal. Eighty towns soon adopted the suggestion, forming an omnipotent revolutionary legislature beyond the reach of government veto or dissolution, yet quite within the law. The next spring intercolonial committees of the same sort were formed,—an unorganized government of the united colonies. Meanwhile Mr. Adams had kept the public spirit inflamed and alive to the nature of the crisis by articles under various pseudonyms in the Boston Gazette, arguing the colonists' legal rights and the practical impossibility of any compromise; thus not only preparing the public for the crisis and bringing over the wavering, but making the crisis itself more inevitable. The management of the sea ship matter was in the hands of the committees of correspondence of Boston and five adjoining towns, of which Mr. Adams was the active head; and the throwing of the tea into the harbor, 17 Dec. 1773, was unquestionably supervised or arranged by him. When as a punishment the port of Boston was closed and the charter of Massachusetts annulled in April 1774, and the legislature met at Salem under parliamentary order to abase itself and undo its bad work, Mr. Adams locked the door, pocketed the key and carried through the measures for calling a congress at Philadelphia in September; the legislature adjourned sine die while the governor's clerk was hammering at the door with the writ of dissolution, and British authority was at an end. Mr. Adams' lifework,—of assuring the breakdown of a system difficult to work at best, the government of a country by scornful aliens plus the aristocratic native families—was now useless and an upright public servant, he was of secondary importance in presence of large problems of constructive statesmanship; his abilities were parochial, and he does not figure on a national scale. He could manage caucuses and organize jealousies, but hardly frame constitutions. At the Philadelphia Congress he was of course a delegate, and greatly smoothed over sectional distrusts by his shrewdness, tact and geniality. In 1775 he and Hancock were the only patriots excepted from amnesty; and it was Gage's attempt to seize them,—under government orders, and with London forecasts that their heads would soon adorn Temple Bar,—that brought on the battle of Lexington and opened the Revolutionary war. They escaped by Paul Revere's warning. He led in pushing forward the Declaration of Independence, of which he was one of the signers; and was active in Congressional work till the close of the Revolution. With much creditable service, he had always been always with division of authority; he believed in committees instead of executive heads, and national policy was often affected disastrously by the delays and irresponsibility involved. He was largely instrumental in framing the State Constitution of 1780. Nationally, he was of course an Anti-Federalist, opposing a strong national government in fear of tyranny; after long hesitancy over supporting the Constitution of 1787, he did so only on the understanding that amendments constituting a bill of rights should be submitted; but his conviction by Massachusetts secured it by 187 to 168, and saved it to the nation. He was long on the Executive Council of Massachusetts, lieutenant-governor 1789-94, and governor 1794-97 (three terms).

ADAMS, Samuel Hopkins, b. Dunkirk, N.Y., 26 Jan. 1871. He was graduated from Hamilton College in 1891 and spent the next nine years as reporter and special writer on the New York Sun. He was managing editor of McClure's Syndicate 1900-01; advertising manager of McClure, Phillips & Co., 1901-02; and a member of the staff of McClure's Magazine 1903-05. He contributed a noteworthy article on quack medicines in a series of articles to Collier's Weekly in 1906, which resulted in the correction of many of the abuses described and the closing down of several patent medicine factories. He has written: The Great American Fraud (1906); 'The Mystery' (with Stewart Edward White, 1905); 'The Flying Death' (1906); 'Average Jones' (1911); 'The Secret of Lonesome Cove' (1913); 'The Stormy Petrel' (1914); 'Little Miss Grouch' (1915); 'Our Square and the People in It' (1917).

ADAMS, Suzanne, American soprano singer: b. Cambridge, Mass, 28 Nov. 1873. After studying with Marchesi in Paris she made her debut at the Paris Opera in 1894 as Juliette in Gounod's 'Romeo et Juliette.' After three years in Parisian opera she went to Nice. In 1898 she appeared at Covent Garden, London, and during the season of 1898-99 she appeared at the Metropolitan Opera House in New York. In 1898 she married Leo Stern, the violincellist, who died in 1904. Her roles include Juliette, Marguerite, Gounod's Mireille in 'Les Huguenots,' Queen of the Night in 'The Magic Flute,' Mimi and Micaela.

ADAMS, Thomas, English clergyman and author: d. 1655. From 1612 to 1614, he preached at Willington Bedforshire, where he published 'Heaven and Earth Reconciled,' and 'The Devil's Banquet.' These were followed by a great number of other works, admired for their diversified brilliance, and by occasional sermons which place him in the front rank of contemporary English preachers. His works are said to have influenced John Bunyan; while he is compared to Jeremy Taylor in brilily expounding of fancies, to Thomas Fuller in wit, and Southey styles him "the prose Shakespeare of Puritan theologians." In 1618 he was attached to St. Paul's Cathedral and became "observant chaplain" to Sir Henry Montague, lord chief justice of England. His writings edited by J. Angus and T. Smith were published in J. P. Nichol's 'Puritan Divines' (3 vols., London 1862).

ADAMS, Thomas Sewall, American economist and educator: b. Baltimore, Md., 29 Dec. 1873. Having graduated from the Baltimore City College in 1893, he entered Johns Hopkins University and there obtained his degree of Ph.D. For a year he filled an
appointment as a clerk in the Census Bureau in Washington; he became assistant treasurer of Porto Rico. In 1901 he was appointed associate professor of political economy at the University of Wisconsin, being promoted to a full professor in 1905. In 1910 he became professor of political economy in Washington University, where he remained a year, then resumed his former position at the University of Wisconsin. In 1911 he became tax commissioner of Wisconsin. His works include: 'The Problems of Wealth and Taxation' (1905), 'Mortgage Taxation in Wisconsin and Neighboring States' (1907), 'Outlines of Economics' (with R. T. Ely 1908). ADAMS, Walter Sydney, American astronomer: b. Antioch, Turkey, 20 Dec. 1876. He was graduated from Dartmouth College in 1899, and took post-graduate courses in the University of Chicago and at Munich. In 1901 he was appointed assistant in the Yerkes Observatory. Three years later he was made assistant astronomer at the Mt. Wilson Solar Observatory, and in 1911 he was acting director of this observatory. Beside numerous articles on astronomical subjects he has published 'Investigation of the Rotation Period of the Sun by Spectroscopic Methods' (111). ADAMS, William, the first Englishman in Japan: b. Kent, c. 1575; d. 10 May 1620. In 1596 he sailed as pilot of five Dutch vessels from the Texel to the East; landing at Kausiu. The great Shogun Iyéyasu, who shortly before crushed his rivals and ended Japan's feudal anarchy, first imprisoned and then took him into service, employing him in shipbuilding, as informant, etc. Iyéyasu dying in 1616, a reaction against foreigners set in, and Adams wished to return to England, where he had left a wife and children; but was forbidden, and married a Japanese wife, their descendants still living in Japan. ADAMS, William Taylor, American author and editor, best known by the pseudonym 'Starry Flag', b. Medway, Mass., 30 July 1827; d. 27 May 1897. He taught for many years in the Boston schools. He was a voluminous and highly popular writer of fiction for young readers, his works including over 100 volumes, mainly travel and adventure: 'Young America Abroad', 'Starry Flag Series', and others. ADAMS FAMILY, of Massachusetts. In the varied abilities and conspicuous public importance of its members, this family confessedly outranks every other in the United States. It has furnished in a single line two Presidents, both of great weight and permanent importance, and even more interesting as virile and individual characters, provoking admiration or hate, but never indifference; a statesman and a diplomat of high order; the author of one of the two first-rate histories yet written in America, matter and style both considered; a noted financier and business magnate, and prominent author as well; another keen and vigorous writer; and an able lawyer and local politician who might have attained larger importance but for belonging to a party in a hopeless minority in his State. The founder in America was Henry Adams, an Englishman with eight sons, who removed to Braintree, Mass., in 1636; but the fortunes of the family began when to this tough stock—in the person of John Adams, who died in 1760, a selectman of Braintree and a deacon, and a farmer almost a rich man for the times—was added the energetic, passionate Boylston, commemorated in Boylston Street, Boston, and the town of Boylston, Mass. The son of John Adams and Susanna Boylston was President John Adams (q.v.), the real founder of the family greatness and its striking individuality. All its members since have been distinguished by the same general qualities in varying mixture. They have mostly been vehement, proud, pugnacious and independent, with hot tempers and strong wills; but with high ideals, dramatic devotion to duty and the intense democratic sentiment so often found united with personal aristocracy of feeling. They have been men of affairs first, with large practical ability, but with a deep strain of the man of letters which in this generation has outshone the other faculties; strong-headed and hard-working, as well as able, with powerful memories and fluent gifts of expression. But no curio of heredity in all time is stranger than the contrast between the President father and his President son, John Quincy Adams (q.v.), when it is remembered that the fiery, combative, bristling Adams-Boylston blood was added an equal strain from the gay, genial, affectionate Abigail Smith (see ADAMS, ABBAG). The son, though of deep inner affections, and even hungering for good will if it would come without his aid, was on the surface incomparably colder, harsher and thornier than his father, with all the socially repellent traits of the race and none of the softer ones. The father could never control his tongue or his temper, and not always his head; the son never lost the bridle of either, and much of his terrible power in debate came from his ability to make others lose theirs while perfectly keeping his own. The father had plenty of warm friends and allies—at the worst he worked with half a party; the son, in the most superb part of his career had no friends, no allies, no party except the group of constituents who kept him in Congress. The father's self-confidence deepened in the son to a solitary and almost contemptuous gladiatorship against the entire country through long years of hate and peril. The father's irritable though generous vanity changed in the son to an icy contempt or white-hot scorn of nearly all about him. The father's spasms of acrimonious judgment steadied in the son to a constant rancor always finding new objects. The country has reason to be thankful for his unamiable traits, for each one strengthened his fibre to do the work awaiting him, and only John Quincy Adams could have accomplished the work of John Quincy Adams. His son, Charles Francis Adams, Sr., had the useful and forcible qualities of both without their besetting defects. He was in youth as hotly pugnacious as his grandfather; he was always as self-centred as his father, and as willing to stand alone amid hate and blood as his father, but he had far more self-control than the former, and far less bristling repellation and contempt of co-operation than the latter. His diplomacy was cast in a spot where he was too much "boycot ted" to make the softer side of much avail; but he roused no useless and costly
ADAMS — ADAMSON

hatreds, and ranked the peer in effectiveness of any European diplomat. Of his three sons (see CHARLES FRANCIS, 2d; HENRY; BROOKS) it would be invidious to analyze the personal traits. The former, soldier, railroad commissioner, president of the Union Pacific Railroad, and eminent historical scholar and publicist, has shown the family traits of courage, independence of thought and action, and intellectual energy, to the full, and is still an active public force. The historian was distinguished during his life as a public professor as the most original, independent and stimulating of instructors; and his history displays not only massive research, enormous power of acquisition in the most widely separated fields, and entire freedom from beaten roads and traditional views, but tempered self-control, the moderation of judgment bred by thorough knowledge and a pervasive atmosphere of gentlemanly irony. The essayist assailant of the Massachusetts theocracy, and student of economic history, as sagacious, was as eager to be as his great-grandfather, and in striking contrast with his brothers in literary style, but none the less a man to reckon with. The late John Quincy 2d would perhaps have filed a larger public field in a less straggling Republican community. It is not likely that this virile stock has lost its energy with the present generation.

This by no means, however, ends the contributions of the Adams stock to our public life. The patriot, Samuel Adams, the father of American liberty, was own cousin to John Adams the President; a more dexterous and political man, and much abler political manager, but not otherwise cast in as large mold. From different sons or grandsons of the pioneer have descended William Taylor Adams ("Oliver Optic"), the well-known juvenile writer; Charles Baker Adams, the naturalist, and Edwin Adams, the actor, the grandfather of the first being the great-grandfather of the second; Herbert Baxter Adams, the eminent American historical scholar and educator; Alvin Adams, the founder of the Adams Express Company; William Claflin, the Massachusetts merchant and governor, whose mother was an Adams; and many other strong figures in public life. Consult Adams, A. H. "Geological History of Henry Adams, of Braintree, and His Descendants", (1910).

ADAMS, Mass., town in Berkshire County, containing villages of Adams (formerly South Adams), Maple Grove, Zylonite and Renfrew; the first and chief 16 miles north of Pittsfield, 6 miles south of North Adams, which was set off in 1878; on Pittsfield & N. A. branch of the Boston & A. division of the New York & Central Railroad. It is on Hoosac River, and contains Greylock Mountain, the highest point in Massachusetts. Founded in 1749 as East Hoosuck, it was renamed for Samuel Adams 1778. Its manufacturing industries, including paper, fabrics, foundry work, etc. (U. S. Census 1914), are carried on in 35 establishments and employ 4,047 persons of whom 3,930 are wage earners, receiving annually $1,793,000 in wages. The aggregate capital employed was $7,119,000. The annual value of the products amounts to $6,530,000. It has a public library and a town board of three selectmen, the government being administered by town meeting. Pop. (1910) 13,026; (1917) 14,000.

ADAM'S APPLE, in botany, (1) the name given by Gerard and other old authors to the plantain tree (Musa paradisiaca, from the notion that its fruit was that sinfully eaten by Adam in Eden. (2) The name given, for the same reasons, to the females of many animals.

In anatomy, a protuberance on the forehead of the throat, due to the thyroid cartilages. The name is supposed to have arisen from the absurd popular notion that a portion of the forbidden fruit, assumed to have been an apple, stuck in Adam's throat when he attempted to swallow it.

ADAM'S BRIDGE or RA-MA'S BRIDGE, a chain of shoals across the Gulf of Manaar, between Hindustan and the island of Ceylon, in the Rāmāna fabled to have been constructed by monkeys.

ADAM'S PEAK, one of the highest mountains in the island of Ceylon, about 45 miles east of Colombo. It is of a conical shape, 7,420 feet high, and is seen, when the weather is clear, from sea 150 miles away. From its solitary position and immense height above the surrounding country the peak forms a striking and awe-inspiring object and has been for centuries venerated by the inhabitants. On the top, under a sort of open pagoda, is the sacred footprint, a natural hollow in the rock, artificially enlarged, and bearing a rude resemblance to a human foot. Mohammedan tradition makes this the scene of Adam's penitence after his expulsion from Paradise; he stood 1,000 years on one foot weeping for his sin, hence the mark. To the Buddhists, the impression is the Sīri-pada, or sacred footprint, left by Buddha on his departure from Ceylon; and the Hindus recognize Buddha as an avatar of Vishnú or Siva. Devotees of all creeds here meet and present their offerings (consisting chiefly of rhododendron flowers) to the sacred footprint, finishing their devotions by a draught from the sacred well. The ascent of the mountain is very steep, and toward the summit is assisted by steps cut and iron chains riveted in the rock, the last 40 feet being accomplished by an iron ladder. The top is an area of 64 feet by 45.

ADAMSON, Patrick, Scottish prelate (real name was spelled Constyne, Constean, Conston, Constant, and Constans; later changed to Constantine, then to Adamson): b. Perth, 15 March 1536; d. 19 Feb. 1592. He took his degree at St. Andrews, and in 1566 went to Paris as tutor. Here he wrote a Latin ode on the birth in June of James VI, and called him "king of France and England," for which the French court gave him six months' imprisonment. Released, he went to Padua, Geneva and Paris, and finally to Bourges, where he lay in hiding for seven months in fear of the rage against Protestants let loose by the massacre of St. Bartholomew (1572), and which cost his host's life. Recalled to Scotland (in 1573), he became a prominent minister, one of the commissioners to settle Church matters, and chaplain to the regent Morton, who in October 1576 made him archbishop of St. Andrews. The tragedy of his life lay in his attempting to be an old-fashioned prelate in the new Scotland which hated prelacy, and to air High-Church preferences before men who considered them
ADAMSON ACT—ADAPTATION

popery. He began the warfare himself by declaring that he would oppose all attempts to deprive the archbishopric of any of its former power; the presbytery took up the glove, and never ceased till they had pulled him down. He was assailed first for not having been consecrated to his post; making his peace somehow for this, they again attacked him for insolence to the presbytery, for opposing its interference with a patronage for popery and heresy. The conflict grew to the height of being extended to the castle of St. Andrew's, where he was cured by a wise woman of a disease the doctors could not handle, and the presbytery afterward seized and burnt her for it. In 1583 he went to England as James's ambassador, exciting attention by his eloquence, and being savagely libeled by the Presbyterians for alleged looseness of behavior. Returning next May, he was high in favor with James, and his chief agent or prompter in severe measures against the Catholics. In December 1583 he published a paper on the "King's Majesty's Intent in the Late Acts of Parliament," which was a chief article in his delegates then, but in 1646, in the heart of the Civil war, was reprinted by the Puritans as on their own side. The 1585 Act drew Melville and other Presbyterian leaders after the Raid of Ruthven (q.v.), and that party was gaining the upper hand: Morton had been executed in 1581. In April 1586 Adamson was impeached and excommunicated; the next year the excommunication was removed, but in 1588 he was freshly accused,—among other things, of mutilating and abstracting registries,—and the King, tired of the quarrel or convinced that it was Adamson's fault, transferred the revenues of his see to another party and left him in actual want for himself and family. A small pension was afterward granted him, but he died poor and wretched.

ADAMSON ACT. See Arbitration, Industrial; Labor Legislation.

ADANA, a-ða-nä, an ancient town in the southeast of Asia Minor, capital of Adana vilayet, on the Sihun, about 25 miles from its embouchure in the Mediterranean, and about 30 miles from its port Mersina, with which, and with Tarsus about half way between, it is connected by railway. Pop. about 45,000. Of vilayet, 422,400.

ADANSON, a-dan-sön, Michel, French naturalist and traveler (of Scotch extraction): b. 7 April 1727; d. 3 Aug. 1800. Although he gave much time and attention to the study of the sciences, particularly electricity, his chief work was in the realm of botany. From 1784 he spent five years in Senegal and collected a large number of plants and animals which he classified and described. His more important works are: "Histoire Naturelle du Sénégal" and "Familles des Plantes," in which he opposed the system of Linnaeus.

ADANSONIA. See Baobab.

ADAPTATION, the power and process of gradual change in an organism to fit it to its environment. See Biology; Evolution. Life came to be, it is inferred, when the gradual accumulation of energy resulting in physical and chemical forces forced a better medium for its interchange, which science, to-day, symbolizes under the term vitalism. This is then a sort of superchemistry which arose out of the need of handling the cosmical energy constantly being delivered to the earth's surface. One of the methods of interplay between the living and the environment is adaptation. This adaptation is never perfect save in those forms which become fixed and these are on the decline in structural differentiation. They cease to evolve to higher types; for evolution implies new conquests over the environment. By the terms environment, surroundings, conditions of life, medium or milieu, or monde ambiant, is meant everything outside of the individual plant or animal, between which and the living matter there is an energy interchange. The nature of the earth's surface, of the soil, of well-watered regions, of deserts, plains or barrens, the physics of the air and sea, are taught in our textbooks of physical geography. Each such area is inhabited by assemblages of living beings adapted well or ill to such or such conditions. We speak of alpine or arctic life, of the flora and fauna of deserts, of mountains, of lowlands, of the great plains, of forests, of the coasts and abysses of the sea. The term "fauna" means the assemblage of animals inhabiting any area, as the word "flora" is used for the plants. Now each of these areas, with its peculiar surface features, climate, soil, etc., is characterized by a set of plants and animals which flourish better there than in adjoining regions, and hence are spoken of as being better adapted.

The most unique cases of adaptation to extreme conditions of life are seen in animals living in the darkness of caves, or in the dark abysses of the sea, or parasitic animals, as the fluke and tapeworm, the root-barnacles (Sacculina), the fish-louse (Lernaea) and many insects. In all these forms the body has, as the result of a parasitic life, undergone profound modification, becoming so atrophied in certain respects as to present the utmost contrast to their free-living allies. Adaptation is continually correlated with certain given conditions. If the conditions be changed, in time the organisms, unless they are modified and changed to what are called new species, become unadapted, unfit for the new environment and unsuccessful in the struggle for existence. Extinct species are such unfit, unadapted forms. However well adapted they were at the period in which they lived, when the conditions of existence changed; when the climate changed from warm to cold, or the reverse; when the soil changed its elevation above the sea, or degree of dryness or humidity; when one area subside; and another became elevated,—certain species or groups of species, unless they migrated, or were plastic enough to undergo modification and become what are called "new" species or "new" genera, unable to resist the change, died out,—became extinct. The harder parts of these extinct species are found in the rocks and are called "fossils." They are the relics of former worlds, witnesses of the profound changes in physical geography through which the earth has passed. Extinction has not yet taken place for certain forms. A few ancient primitive forms have persisted and are still flourishing. Such
ADAR—ADICKS

are many of the Protozoa (Saccamina and others), the Lingulida and Lingula, the king-crabs, Homarids, Heterocotyle, and Scolodrella, which are probably the ancestral forms of insects; among the fishes the Australian lung-fish (Ceratodus), and among lizards the Hatteria of New Zealand. These forms, for various reasons, have withstood the most widespread and the profoundest geological changes, but they are exceptional. On the other hand a vast number of species which were plastic enough to yield to the changes in their surroundings and became modified into new species became adapted to new conditions of existence. It is undoubtedly the case, then, that certain forms become maladapted and suffer extinction, though all through the ages the plant and animal census by no means became at any time lessened, but rather gradually increased in extent. Another fact clearly established is that the earlier forms were generalized and the later were specialized, and the former, the ancestors of the present species, had to make way for their more specialized descendants. Thus the trilobites were succeeded by the king-crabs, the creeping dinosaurs were succeeded by the flying reptiles or pterodactyls, and the highly generalized tailed Amphibia yielded the right of way to the tailless, frogs and toads of the present day. Adaptation then, is the process of modification of organisms caused by changes in the conditions of life. The most fascinating of all adaptive forms is man, who retains all of the characters which have been found most valuable for the utilization of more and more of the energy of the environment and who through structural specialization has fashioned organs of increasing efficiency to utilize these energy resources. The chief tool of adaptation of man is his use of symbols by means of his brain structures, which have given him increasing power to manage the vast amounts of energy which have been and are being subject to constant interchange.

ADAR, Jewish month, 12th of the ecclesiastical and 6th of the civil year; represents parts of February and March of ours. The 7th was a fast for the death of Moses, the 9th for the falling-out of Hillel and Shammi. But the important days were the 13th, a fast in commemoration of that of the Jews for their threatened destruction by Haman (see ESTHER), followed by a feast on the next two days for their escape.

ADARCE, a-dar-sé, a salty deposit found on the grasses and sedges growing in wet places in ancient Galatia. It is used somewhat for cleansing the skin in cases of leprosy.

ADDA, a-dá (ancient Addua), a river of north Italy, descending from the Rhaetian Alps, falls into Lake Como, and leaving this joins the Po after a course of about 170 miles.

ADDAI, a-dá, is said to have introduced Christianity into the principality of Edessa. The tradition is that he was one of the 70 disciples and was sent there by the Apostle Junius, and the Syrian saint, the Doctrine of Addai, the Apostle (now first edited in a complete form in the original Syriac with an English translation and notes by Phillips, London 1876), contains practically all that is known of him. The critics place the above-mentioned work at about the year 300. Bickell even placed its date in the 1st century, some authors try to identify him with Thaddeus.

ADDAMS, Jane, American philanthropist: b. Cedarville, Ill., 6 Sept. 1860. Was graduated at Rockford College in 1881, and after post-graduate studies in Europe and the United States became an active social-reformer. She inaugurated in 1889 at Chicago the establishment known as Hull House, an adaptation of the *social settlement* plan to Chicago conditions; acted as street-cleaning inspector in Chicago, and has lectured on the improvement of the condition of the poor in great cities; and on social and political reform. She has written *Democracy and Social Ethics* (1902); *Newer Ideals of Peace* (1907); *The Spirit of Youth and the City Streets* (1901); *Twenty Years at Hull House* (1901); *A New Conscience and an Ancient Evil* (1911). See SOCIAL SETTLEMENTS.

ADDA, or ADDAS (Lat., of African origin), a North African antelope (Addas nasomaculatus), related to the oryx and similar to it in habits. Its large broad hoofs fit it for traveling over loose sand. It has a long tail, long ears, and spirally-twisted horns three to four feet high. The animal measures about three feet in height at the shoulder; in color it is nearly white, with shading of reddish brown on the head and front of the body. The hoofs are black and there is a black, shaggy marking on the forehead above a white blaze on the nose. It is now becoming very rare in all parts of the Sahara. The Arabs hunt the addax with greyhounds.

ADDER (Anglo-Saxon nadder, Goth. nadro, Ger. natter, a snake), a colloquial name for several poisonous snakes, mostly belonging to the family Viperidae, such as the copperhead, moccasin, asp, etc.; and also for certain harmless snakes of the family Colubridae, particularly the spreading adder (Heterodon platyrhinos), which when angry resembles the poisonous snakes. (See HOGNOSE). In England the name denotes the only venomous snake of Great Britain,—the European viper (Pelias berus). See ADDERTAIL; PUFF-ADDER; VIPER; etc.

ADICKS, John Edward, American capitalist: b. Philadelphia, 21 Nov. 1841. He acquired a large fortune as a gas manufacturer, organizing and becoming president of the Bay State Gas Company of Boston in 1884, and buying control of the Brooklyn (N. Y.) Gas Company in 1892. For 11 years he was of national prominence as candidate for the United States senatorship for Delaware, which he did not succeed in obtaining, but till 1906 was able to prevent the election of any rival, leaving both of Delaware's seats vacant. In 1885 his rival was H. A. Du Pont, and among the members of the legislature voting was the former speaker of the Senate, later governor through the death of Governor Marshall. On this Du Pont charged that the vote illegal, and refused to seat Du Pont. In 1896 the Republican State Convention to elect delegates to the St. Louis National Convention split and elected two sets, Du Pont and Addicks; the former was recognized as *regu-
lar by the St. Louis Committee on Credentials, while the other section called themselves Union Republicans. In 1899 a successor to Senator Gray was elected, but the Senate had no election following. In 1900 as in 1896 two sets of delegates went to Philadelphia, and this time the committee seated the Addicks party; though he was thus recognized as State party chief, the 1901 election for Senator was again a sham election. The next year to the State was left entirely unrepresented in the Senate. In the session of 1903 Addicks nominally withdrew, and the legislature elected two Senators, a Regular for the short term and a Union for the long term. On 12 June 1906 Du Pont was elected. Addicks's fortune was greatly impaired by his political course and was still further diminished by a court order in 1907 which obliged him to pay $890,000 of profits unlawfully drawn from the Bay State company.

**ADDING-MACHINE.** See Calculating-Machine.

**ADDINGTON, Henry, Viscount Sidmouth, English statesman:** b. 30 May 1757; d. 15 Feb. 1844; educated at Winchester and Brasenose College, Oxford; he then studied law and, through the influence of Pitt, entered Parliament (1784); was speaker of the House of Commons (1789–1801); chancellor of the exchequer and first lord of the treasury; he put through a bill disqualifying clergymen from sitting in the House of Commons, and later, with Pitt's advice, negotiated (1802) the Peace of Amiens, a cessation of war much needed by England. In 1805 he was raised to the peerage. As home secretary (1812–22), he was strict in his administration of justice and in conservative oversight of the press and public meetings. Partly due to his too great zeal was the "Manchester massacre." He resigned in 1824, owing to his disapproving of the recognition of the independence of Buenos Ayres.

**ADDIS ABEBA.** See Adis Ababa.

**ADDISON, Daniel Dulaney, American clergyman and author:** b. Wheeling, W. Va., 11 March 1863. After graduating from Union College in 1883, he studied at the Episcopal Theological School at Cambridge, Mass. He became assistant rector of Christ Church, Springfield, Mass. In 1889 he was appointed rector of St. Peter's Church, Beverly, Mass., where he remained until 1895. He then became rector of All Saints Church, Brookline, Mass. He was especially interested in conditions in Liberia and was a trustee of the College of Monrovia. In 1904 he was knighted by the government of Liberia for his services. He is the author of: "Lucy Corcoran, Life, Letters and Diary" (1894); "Phillips Brooks" (1894); "Life and Times of Edward Bass" (1897); "All Saints Church, Brookline" (1896); "The Clergy in American Life and Letters" (1900); "The Episcopallans" (1904).

**ADDISON, Joseph, English essayist:** b. Milston, near Amesbury, in Wiltsire, 1 May 1662; d. Holland House, London, 17 June 1719. Addison was the eldest son of Rev. Launcelot Addison, a Royalist clergyman, who, after the Restoration, had been chaplain of the garrisons at Dunkirk and Tangier, and at the time of the birth of Joseph was rector of Milston. Later (1683) he was made dean of Lichfield. He was a man of character, attainment and considerable literary gift, which found its most interesting expression in the "Resolution of the Kingdoms of Per and Morocco," a historical sketch of lively character. Addison's mother was Jane Gulston, daughter of Dr. Nathaniel Gulston and sister of William Gulston, bishop of Bristol. Addison was brought up in a pleasant country and in a family of admirable manners; his home life is described by Steele as delightful. He went to schools in the neighborhood and to the Charter House School, where he acquired some knowledge of Greek and a considerable familiarity with Latin literature.

In 1687 he entered Queen's College, Oxford, whence, after two years, he transferred to Magdalen. The change was the result of some excellent Latin verses, "Inauguratio Regis Gulielmi," in honor of King Charles II, which so much attracted the admiration of Addison's preceptor and obtained for him a demisyhip. At Magdalen he lived a quiet, studious life, and his scholarly reputation is said to have extended itself to London. His acquaintance was chiefly connected with Magdalen; his M.A. came from that college in 1693; he was made probationary Fellow in 1697 and actual Fellow the following year; and a pleasant walk along the Cherwell to-day bears his name.

Addison's first published work was an "Account of the Greatest English Poets" (1693), chiefly interesting, to-day because of the low plane which, following the taste of the times, he accorded to the great Elizabethans. Complimentary verses to Dryden (q.v.) the same year won for him the favor of the dictator. He next experimented with translation, rendering the fourth book of the "Georgics," two books of Herodotus, and the second book of Ovid's "Metamorphoses." This last task, though a distasteful one, had, according to Mr. Courthope, a marked effect on his taste in that it taught him to avoid extravagance of style. By this time he had made a fair name as a writer and had attracted the notice of the ministers. Charles Montague, first earl of Halifax, and Somers, who may have induced him to write a perfunctory "Address to King William" (1695), and who probably persuaded him to enter civil rather than ecclesiastical life. At all events, Halifax and Somers obtained for him, in 1699, a pension of £300 a year for foreign travel. One of Addison's recommendations for this honor had been his "Peace of Ryswick," a Latin poem (1697), and various trifling contributions to the "Muse Anglicanae" (1699). It was a critical period in Addison, in that his career was then determined.

Addison set out, in the summer of 1699, for France, where he remained a year and a half, chiefly at Blais, studying the language. From December 1700 to December 1701 he was touring in Italy, whence he went to Switzerland and, in the autumn of 1702, to Vienna. Thence he visited the Protestant cities of Germany, remaining in Holland in the spring of 1703, and, in the fall, on receipt of news of the death of his father, returning to England. Some time previous to his return he had been deprived of his pension, for the death of King William, in 1702, led to the dismissal of Addison's patron, Halifax, and Addison was accord-
ingly out of employment. The literary result of his travels was a ‘Letter from Italy’ in verse, and his prose ‘Remarks on Italy.’ The latter is an interesting and in the history of English taste. Italy is interesting to Addison chiefly as the source of classical poetry, and his pleasure in it is almost wholly literary. His judgments, too, on the taste of the mediæval church builders are made from a narrow classical point of view. During the journey, Addison wrote his ‘Dialogue on Medals’ (1702) and the first four acts of ‘Cato.’

In 1704, Addison, on the recommendation of Halifax, was asked by Godolphin to write a poem on Marlborough’s victory at Blenheim, and accordingly, in that year, produced ‘The Campaign,’ a panegyric narrative in heroic couplets. The poem was of such aid to the Whig party that Addison at once gained preferment and was, in 1706, made under-secretary of state. His political duties did not keep him wholly from literature; in 1705 he helped Steele with ‘The Tender Husband,’ a drama, and on 2 April 1706 himself signally failed with the presentation of his opera ‘Rosamond,’ though it was not wholly without success. On the loss of his political office in 1708, he was almost immediately made secretary to the Lord-Lieutenant of Ireland, Lord Wharton, and the same year sat in Parliament for Malmsbury, a position that he held till his death. From the Irish appointment dated his friendship with Swift (q.v.). The friendship of the two suffered some strain when, in 1710, at the fall of the Whig ministry, they found themselves arrayed on opposite sides in a bitter struggle for ascendency. Addison wrote five numbers of the ‘Whig Examiner’ (up to 8 October) in opposition to the ‘ Examiner of the Tories,’ of which Swift took charge in November. Most of his offices Addison lost with the change of the ministry, and was free to pursue the course on which his fame rests.

Steele had issued the first number of the ‘ Tatler ’ on 12 April 1709. It appeared three times a week and was first issued as a newspaper, with different classes of news—political, literary, etc.—arranged under different heads to correspond with different quarters of London. The paper, however, was not long in losing these distinctions and soon became chiefly moral. For this change Addison, who entered at the 18th number and wrote 42 out of the total 271 numbers, may have been largely responsible. Coming to an end on 2 Jan. 1711, the ‘ Tatler ’ was followed, on 1 March of the same year, by the ‘ Spectator,’ which, while modelled on the ‘ Tatler,’ was an improvement on it in all ways. It appeared daily; it was more essay-like in form, it was more varied in subject, more satirical in tone, and it addressed a wider range of readers, particularly women, in the belief that improvement in manners must begin with them. Since its place, as a form of literature, had been called into existence by the rise of the daily press, and, as an organ of education, by the growing reaction against the dissoluteness of Restoration manners and literature, it had marked success. Its circulation is estimated to have been 10,000 copies at the close of its career, 6 Dec. 1712 (a continuation, issued thrice a week, came to an end in 1714), and the sale of completed volumes was equally great. Addison contributed 274 papers to 236 by Steele; Addison’s are nearly all signed by one of the letters C. L. I. O.

On 13 April 1713, ‘Cato’ was acted. Though written in part for the prevailing and the traditional English play in that it was built on severely classical and unromantic principles, and though succeeding generations have pronounced it to be a poem of noble sentiments rather than a dramatic play, it had great success and ran for 35 nights, an unprecedented period. This was largely due to the political situation—the eve of the fall of Tory power and of Whig success—and was in man of such political eminence that his play was naturally to be regarded as of uncommon importance. Abroad, the play was well received. It was twice translated into Italian, twice into French and once into Latin, besides being often adapted. Voltaire praised it highly as a ‘regular tragedy,’ and regarded it as much superior to preceeding English ones. ‘Spectator,’ on which Addison wrote ‘The Drummer,’ which was coldly received at Drury Lane.

In 1714, on the ascendency of the Whig party, Addison was made chief secretary to the Lord-Lieutenant of Shrewsbury, an office which he held till August 1715. From 23 December of that year till 9 June 1716, he wrote the ‘ Freeholder,’ a semi-weekly of 55 numbers altogether, designed to prove to the people of England the justice of the Whig cause and the need of the Protestant succession. In 1716, he was made a commissioner for trade and the colonies. This same year he married Charlotte, Countess Dowager of Warwick, to whom he is said to have been long attached. The marriage has been called unhappy and there is a fairly established tradition to that effect; in Pope’s innuendo he ‘married discord with a noble wife.’ For the tradition there is, however, no good evidence. By her he had one daughter, Charlotte, who died unmarried, in 1797. His marriage was coincident with the height of his political career; in 1717 he was made secretary of state, an office which he resigned in March of the following year. His health was failing and he had never been robust. The last half decade of his life was somewhat embittered by two famous literary quarrels. The first, with Pope, in 1715, was due, generally, to the fact that the two were essentially incompatible, and, in particular, to the fact that Pope felt aggrieved because Addison had praised warmly a rival translation of the ‘Iliad’ by Tickell, and even went so far as to suspect Addison of being the real author. Addison’s acquaintance with Pope began with a favorable comment in the ‘Spectator’ on the ‘Essay on Criticism,’ but thereafter he never spoke of Pope so highly as of the members of his little senate. Addison may have advised Pope against adding to ‘The Rape of the Lock’ the brilliant and charming machinery of the ‘fairies,’ and, according to some, he tried to dissuade Addison from presenting ‘Cato’ on the stage, neither pieces of counsel likely to increase the mutual respect of the two authors. The result was that long after Addison’s death Pope published ‘Ode on the Death of his famous satire on Addison, already written during the latter’s life, and then defended his course by the publication of a somewhat doctored correspondence.
ADDISON'S DISEASE — ADDRESS

In 1719, Addison and Steele found themselves on opposite sides of a bill for definitively limiting the number of peers. Steele, though a Whig in party measure in a pamphlet called the Plebeian (14 March), and was answered by Addison five days later in the Old Whig. The contest ended in some personalities on Steele's part. Before a reconciliation could take place between the two life-long friends, Addison died of dropsy. He lies buried in Westminster Abbey.

By Addison's contemporaries and biographers he is almost always spoken of as a man of fine intellect, lofty character, considerate and distinguished manners and great personal charm. He has been called the chief architect of public opinion in the 18th century. His posthumous fame, of course, rests almost exclusively on his contributions to the Tatler and the Spectator, which contain nearly all that he had to say of permanent value. Their influence was directed, socially, to the bettering of contemporary life and manners and the incultation of virtue, and, intellectually, to the improvement of the taste of his generation; of his mild satires in the affectations of his time are perhaps the best example, and, of the latter, there may be taken his somewhat formal but enlightening examination and criticism of Paradise Lost. In literary history he is commonly said to have contributed to the art of novel-writing an unprecedented skill in drawing individual character or personality and of thus preparing the way for Richardson (q.v.) and Fielding (q.v.); and the proof of this remark lies in his lively sketches of the members of the Spectator Club, particularly Sir Roger de Coverley. As a stylist he has, in his own field of inoffensive social satire and gentle humor, no superior, and the famous phrase of Dr. Johnson that 'Whoever writes to attain an English style, familiar but not coarse, and elegant but not ostentatious, must give his days and nights to the volumes of Addison,' remains largely true. Addison brought English prose to a degree of finish and accessibility that had been wanting before. Edward Young, Dryden (q.v.), or of the most flexible and easy of prose-writers, has not quite that sense of the audience which Addison possessed to so great a degree, and which is the basis of his secret of writing easy, readable prose. Technically, this is Addison's contribution to the art of expression.

Bibliography.—Editions of Addison's works are numerous. Bohn's 'British Classics' contains his complete works. 'The Spectator' was edited by Morley (1868) and by Gr. Smith (8 vols., 1898). The famous essays on Addison are Johnson's, in the 'Lives of the Poets.' Macaulay's 'The Life and Writings of Addison,' and Thackeray's in 'The English Men of Letters Series' (1849) is excellent, and is more convenient than the older and longer life by Lucy Aiken (1846). For Addison's place in literature consult Perry, T. S., English Literature in the 18th Century (1883), and Belloc's, A., 'Le public et les hommes de lettres en Angleterre au XVIIIe siecle' (1881; 2d ed., Paris 1897); they are more satisfactory than the criticism in Taine's 'History of English Literature' (1863), or

Professor Gosse's 'A History of 18th Century Literature, 1660-1780' (1889).

WILLIAM T. BREWSTER,
Professor of English, Columbia University.

ADDISON'S DISEASE, a disease associated with diminution of the functions of the suprarenal glands, a hypoadrenalemic. It is characterized by general depression of the mobility, as evidenced by pronounced muscular weakness (asthenia), by anemia, lowered tone of the circulatory apparatus, irritability of the stomach and pigmentation of the skin. This last symptom is the most pronounced and was fully described by Addison in 1855. The disease is more common in men and between the twentieth and fortieth years. The heart muscle also suffers very markedly, there being frequent attacks of rapid and feeble pulse with vertigo, and fainting, sometimes fatal. Headache is frequent. In the pronounced types there is usually a severe disease of the suprarenal structures, most often a tuberculosis, less frequently a malignant disease (cortical). In mild inflammatory states of the adrenals, recoverable hypoadrenalemias may occur. Sudden death is not infrequent result in acute hemorrhagic disease of the adrenals. A number of irregular forms of suprarenal disease are known, Addison's disease being one of the more pronounced and terminal states.

The treatment is symptomatic with the prolonged use of the suprarenal gland. See Adrenals.

ADDED PARLIAMENT, The, a nickname given to James I's second Parliament, of 1614, because it passed no statute and finished no business. It did, however, settle a far more important question than any point of administration, namely, that the Commons were to have the power of the purse thereafter—that is, the rule of the kingdom—unless the Crown crushed them by force. In a word, it proclaimed the revolution, though not consciously. The previous Parliament had been dissolved for not granting supplies until the King had abolished the illegal imposts and regulated the Court of High Commission—statute—that is, given church as well as state into their hands. The elections for 1614 were contested with a passion unknown for generations; the court candidates were overwhelmingly defeated, and 300 of the victorious ones were new men sent up for the first time, among them John Pym, Thomas Wentworth (afterward Earl of Strafford) and John Eliot. After a two months' session they became involved in a quarrel of privilege with the Lords, and the King dissolved the House on that pretext—rely on the point of their refusal of supplies,—and imprisoned four of them.

ADDRESS, The, in British parliamentary procedure, is the answer to the King's Speech (q.v.) moved in both Houses. In former times it was connected to the answer to each paragraph in the speech, but it now forms a single resolution expressing the thanks of the House to the Sovereign for the speech. The debate on the address occupies the first days of the session, but both Houses show their independence by formally disapproving other business before considering the answer to the King's Speech. The mover and seconder of the address are chosen from the younger supp-
ADE — ADELAARD

porters of the Ministerial party. If any amendments condemning the policy of the government are moved to the address and carried, the ministry usually resigns.

ADE, George, American journalist and author: b. Kentland, Ind., 9 Feb. 1866. He made his mark as a writer of 'Stories of the Streets and the Town' in the Chicago News, which showed remarkable variety of motive and local reporters' knowledge. He published 'Artie,' a sequel from these, a rep 1897 the dialect story 'Pink Marsh'; in 1901-02 two sets of 'Fables in Slang,' full of pungent wit and intimate knowledge of the less agreeable phases of human character; in 1903 the satirical comic opera 'The Sultan of Sulu,' a musical comedy, 'The County Chairman'; a comedy of college life, 'The College Widow'; a play for William H. Crane called 'Father and the Boys. Still other plays produced have been: 'The Life of a College,' 'The Fair Co. Ed.,' 'The Sho-Gun,' 'The Old Town,' 'Marse Covington,' 'U. S. Minister Bedloe' and 'Nethe.' His published books, in addition to those mentioned above, include 'In Bahel,' 'The Girl Proposition,' 'People You Know,' 'The Kids of the Neighborhood,' 'True Billows,' 'Pastures New,' 'The Slim Princess' and 'Ade's Fables.' Delegate to the Republican National Convention 1908, trustee Purdue University 1909, and member of the National Institute of Arts and Letters.

ADE, Alvey Augustus, American diplomat: b. Astoria, N. Y., 27 Nov. 1842, son of a fleet surgeon; was secretary of legation at Madrid 1870-77, chargé d'affaires at different times; in 1878 became chief of the United States diplomatic bureau. 1882 third assistant secretary of state, in 1886 second assistant, which he still remains. He was secretary of state ad interim 17-29 Sept. 1898; and acting secretary during some of the most acute Chinese troubles of 1900.

ADELAER, a'dē-lær (Norwegian, signifying 'The Eagle'), the honor title conferred on Knorr, Sver-ng, Danish admiral: b. Breig, Norway, 1622; d. Copenhagen, Denmark, 1675. After early service in the Dutch navy, he joined the Venetian navy and rising to the rank of squadron commander, achieved his most brilliant victory at the Dardanelles, 13 May 1654, when he compelled the Turks to surrender. He afterward became commander of the Danish fleet, but died suddenly when about to start on an expedition against Sweden.

ADELAIDE, capital of South Australia on the river Torrens, seven miles by rail southeast of Port Adelaide, on St. Vincent Gulf, and 506 miles northwest of Melbourne. It stands on a large plain, and is walled in on the eastern and southern sides by the Mount Lofty range; the town proper is enclosed by a wide belt of park lands, laid out in terraces, making it one of the most beautiful cities of Australia. It was first surveyed and staked off by Col. William Light in 1837, and named after the queen of William IV. The Torrens divides the town into North and South Adelaide, the former being occupied chiefly with residences and the latter forming the business portion of the town. Four substantial iron bridges span the Torrens, which has been formed by a dam into a lake one and one-half miles long. The streets are broad and regularly laid out, especially in Adelaide proper, to the south of the river, where they cross each other at right angles, and are planted with trees. Among the public buildings are the new Parliament Houses, erected at a cost of about $300,000; the government offices, post-office and town hall; South Australian Institute, with museum, library and art galleries; and hospital. There are a number of fine churches, including the Anglican Cathedral of St. Peter. The botanical garden covers more than 40 acres of ground, and many other beautiful parks and squares embellish the city. The chief manufactures are woolen, leather, iron and earthenware goods, and there are flour mills, mines and metallurgical works; but the chief importance of Adelaide depends on its being the great emporium for South Australia. The city controls the trade of the large back country and rich mining districts, which have a population of 200,000 within a radius of 10 miles from the town hall. Wool, wine, wheat, flour, copper, gold and concentrates, skins, butter, tallow and leather are the staple articles of export. The value of total exports in 1913 was $49,048,815; of imports, $36,741,700. Among the educational institutions the most important is the Adelaide University, with a working capital of $894,850, including a conservatory of music, schools of engineering, science and commerce. It was opened in 1876 and has about 1,000 pupils, and 25,000 volumes in its library. Other institutions include a school of mines and industries, the largest in Australia; St. Peter's Episcopal College; St. Barnabas Theological College, opened in 1881, and Prince Alfred (Wesleyan) College. It is the seat of an Anglican and of a Roman Catholic bishop. Adelaide, incorporated in 1840, is the oldest and third largest municipality in Australasia. The government is vested in a mayor elected annually, six aldermen elected for three years, two auditors and two councillors. Adelaide has been very successful in carrying on municipal enterprises. It is required that all the meat supplied to the population of over 200,000 must be slaughtered in the municipal abattoirs. The Municipal Tramway Trust operates the city and suburban electric lines, and the Municipal Harbor Trust conducts the business of the port. The city also carries on the usual public utilities — water supply, lighting, etc. Area, including parks, 3,700 acres. Pop. (1917), city proper, 43,438; metropolitan area, 205,443.

PORT ADELAIDE, its haven, dates from 1840. It is the principal port of call for vessels arriving from Europe; has a fine harbor, extensive quays and railway communication with Melbourne, Sydney and Brisbane. Pop., local gov. area, 24,015.

ADELARD, or ÆTHELHARD, of BATH, English philosopher and mathematician of the 12th century. Little is known of the facts of his life, except that he traveled widely, visiting Greece, Asia Minor and Africa. He wrote 'Perdiffilis Questiones Naturales' and 'De Eodem et contrario,' a philosophical allegory in which he sought to reconcile the theories of Plato and Aristotle. He also made a Latin translation of Euclid and of several Arabian
mathematical treatises. See ARITHMETIC, HISTORY OF.

ADELBERT COLLEGE. See Western Reserve University.

ADELELAND', an Antarctic continent discovered 20 Jan. 1840 by Du Mont d'Urville. It consists of a chain of mountains without prominent peaks, dotted with a few shallow bays filled with icebergs, and a number of islands with rounded summits.

ADELOCHOR'DA, a group standing at the base of the branch of the phylum Chordata, and including certain animals, formerly supposed to be worms, but now placed in the same group as the vertebrates. The class Adelochorda is represented by Balanoglossus, while with it are provisionally associated two forms of doubtful position, the worm-like Rhabdopleura and Cephalodiscus. The Adeloccephala are worm-like, but from the fact that the body is in part supported by a structure supposed to be homologous with the notochord of true vertebrates, and that the animal breathes through gill-slits, like those of the lowest vertebrates, it is supposed to be related to some extinct form which gave rise to the vertebrates. They are also placed within an ancestral persistent form. If we throw out the doubtful forms Rhabdopleura and Cephalodiscus, leaving only Balanoglossus, we have the old group Enteropneusta. A typical example of the Adelochorda is Balanoglossus (q.v.).

ADELPHI, "The Brothers," the last and in the truthful portrayal of human nature, perhaps, the best of the six comedies of Terence, had its first performance in 160 B.C. The action turns upon an old yet ever new problem, whether a policy of good-natured indulgence which seeks, though it does not always win, mutual confidence between father and son, will lead to better results in the upbringing of young people than one of sternness and insistent preaching of duty. In the sequel neither plan is successful. Both of the young brothers (one of whom has been adopted by his uncle) compromise themselves by love-affairs. Terence, as his admirers might conjecture in advance, favors the principle of the "golden mean" in education as in all other things. But while his answer to the problem of this play is no clearer than life itself commonly affords, the advantage on the whole appears to lie with the theory that parental authority, to be effective, must rest upon a friendly understanding and a tactful allowance for the difference in the point of view of youth and age. The general idea is worked out with great skill and abundant humor. The last act, in particular, is conceived in a spirit of drollery that is rare in Terence. The "Adelphi," like all of Terence's work, has had a great influence upon modern literature. Among the plays that are indebted to it may be mentioned Molière's "École des maris," Baron's "L'École des pères," Fagan's "La pucelle," Garrick's "Guardian," Cumberland's "Choleric Man," and Shadwell's "Squire of Alsatia." Sargeant's translation has been reprinted in the "Loeb Classical Library" (New York 1912).

NELSON G. MCCREA

Professor of Latin Language and Literature, Columbia University.

ADELPHI, a district in London, England, south of the Strand, close to Charing Cross. It was so named from the architects, four Scottish brothers Adams (G flamboyant, four brothers). There is also a theatre of that name in the Strand.

ADELPHI COLLEGE, Brooklyn, N. Y., a college for women, non-sectarian, was incorporated by the regents of the University of the State of New York, 24 June 1856. It is intended to be a college of liberal culture. The requirements for admission and graduation are the same as those of the leading Eastern colleges. It is the only institution in Brooklyn in which a woman may obtain the usual baccalaureate degrees. The curriculum is arranged semestrially, and eight semesters are required for graduation. The courses in pedagogy are arranged so that the studies preparatory to the profession of teaching may all be taken as a part of the work offered for the degrees of bachelor of arts and bachelor of science. From the beginning the college has always offered special facilities to students who wish to enter the profession of teaching. It also makes provision in afternoon, evening and Saturday morning classes for teachers in public schools who desire to study for a degree without giving up their positions. Connected with the college are the Normal School for Kindergartners, with a two years' course, organized in 1893. The college reported in 1916: Professors and instructors, 30; students, 588; volumes in the library, 14,000. Adelphi College maintains a coeducational preparatory department, known as Adelphi Academy, which has 50 instructors and 760 students. The total value of the property and endowments of the college is $600,000. The total annual income is $118,000.

ADELSBERG, 'a-delz-berk, Austria, a market town of Carniola, 22 miles by rail northeast of Triest. Pop. 4,000. It is a favorite summer resort for tourists attracted there by the celebrated stalactite cavern which, with its four chambers and lateral recesses, was known as early as 1213, but was not rediscovered in modern days until 1816. The length of its underground passages, through part of which flows the river Polk, is over five miles; in 1890 a connection was discovered with the neighboring Ottokar grotto. About four miles to the north is the Magdalene grotto, noted for its extraordinary specimens of subterranean life.

ADELUNG, 'a-del-ung, Johann Christoph, German philologist, grammarian, lexicographer and librarian: b. Spanketow, Pomernia, 8 Aug. 1732; d. Dresden, 10 Sept. 1805. His services to the standardizing of the German language were of incalculable value. His chief works are: "Grammatisch-Kritisches Wörterbuch der hochdeutschen Mundart" (1774-86); "Ueber den Ursprung der Sprache und den Bau der Wörter" (1785); "Deutsche Sprachlehre für Schulen" (1781); a periodical "Magasin für die deutsche Sprache" (1782-84); "Ueber den deutschen Stil" (1785); "Directorium Diplomaticum" (1802); and "Müthridates, oder Allgemeine Sprachenkunde" (1806). Adelung was chief librarian of the Electoral Library at Dresden from 1787 until his death.
ADEN, a'dên, or a'dên, Arabia, peninsula and town belonging to Great Britain, on the southern coast, 105 miles east of the mouth of Bab-el-Mandeb, the entrance to the Red Sea. The peninsula is a mass of volcanic rocks, five miles long from east to west, and rising to 1,776 feet. It is joined to the mainland by a narrow, level and sandy isthmus. The town is on the eastern shore of the peninsula, stands in the crater of an extinct volcano and is surrounded by barren, cinder-like rocks. The main crater is known as the Devil's Punch-bowl. The climate of Aden is normally hot and dry with hot, sandy winds at certain seasons. The rainfall during 1916 was four inches, the average is three inches. The maximum temperature in 1916 was 101°, in July, and the minimum was 68.2°, in December. Nevertheless the climate is unusually healthy for the tropics. The Romans occupied it in the 1st century a.d. Till the discovery of the Cape route to India (1498) it was the chief mart of Asiatic produce for the Western nations; in 1839 it was sunk to be a village of 600 inhabitants. The increasing importance of the Red Sea route gave Aden great value as a station for the British to hold; and in 1839 after a few hours' contest it fell into their hands. It is of high importance both in a mercantile and naval point of view, especially as a coaling station; it has a garrison and strong fortifications. The population and resources of the place increased rapidly after 1838, and the opening of the Suez Canal in 1869 gave it a great impetus. The affairs of the port are administered by a board known as the Aden Port Trust. The annual gross revenue of the settlement is about $2,279,417. For purposes of government Aden is included in Bombay Presidency of India and the currency and postage stamps are the same as those used in that country. The rupee ($0.3244) is the currency unit. Whereas Aden of itself produces and consumes but little, conditions at the port are important, as it is the market through which a large commercial district is best reached. Aden's only industries worthy of mention are the manufacture of salt and of cigarettes. The total sea-borne merchandise trade for the year 1916 was valued at $31,904,607 against $27,875,101 in 1914-15. According to the Aden Port Trust returns, imports of merchandise in 1915-16 were valued at $17,010,190, as compared with $15,200,389 in 1914-15, and of treasure $1,305,702, against $1,906,230, respectively. Exports of merchandise increased in value from $12,674,712 in 1914-15 to $14,794,477 in 1915-16, but those of treasure declined from $2,601,368 to $1,890,934. Exports to the United States reached a value of $2,427,764, an increase of approximately 50 per cent over the exports for the preceding year and formed approximately 15 per cent of the total exports. Imports of American goods reached $2,595,600, practically double that for the preceding year. Cotton manufactures, grain and pulse, coffee, hides and skins, tobacco and coal are the chief articles imported. Exports include principally cotton manufactures, skins, coffee, grain, tobacco, spices, sugar, gums and salt. It is a telegraphic station on the cable between Suez and Bombay, and on the line to Zanzibar and the Cape. To provide for its growing population, a considerable territory on the mainland was acquired and added to the peninsula, the total area (including the island of Perim), being about 80 square miles. Population, about 46,000.

ADENZE or ADANS LE ROI, a'dná or a'dän-lé-rwá, a French troubadour and poet of the 13th century, attached to the courts of Henry III, Duke of Brabant, and of Guy de Dampierre, Count of Flanders. In 1243 he accompanied the crusade which ended disastrously at Tunis with the death of Louis IX, and returned by way of Sicily and Italy. His chief claim to remembrance is 'Cléomades, a long roman d'advenires based on Moorish and Spanish traditions, an edition of which in two volumes was published in Brussels (1863-66). His other poems are, 'Les enfances Ogier,' 'Berte aus granspies,' and 'Beuves de Co-marchis.' His writings are distinguished by the purity of their French and the simplicity of their stanzas, and also by the occasional occurrence of words which he traveled. His romances were edited by A. Scheler and A. van Hasselt for the Académie Impériale et Royale of Brussels (1874).

ADENEY, Walter Frederic, English clergyman, educator and author; b. Ealing, Middlesex, England, 14 March 1849. He was educated at New College and University College, Oxford, and at the University of London. For 17 years he was pastor of the Congregational Church, Acton. For two years he was lecturer in biblical and systematic theology at New College, London; 1889-1903 professor of New Testament exegesis and church history. Since 1903 he has been principal of the Lancashire Independent College, Manchester. He has been a voluminous author, contributing nine volumes to the 'Pulpit Commentary,' an edition of which to the 'Expositor's Bible,' editing the 'New Century Bible,' besides several volumes and many articles.

ADENitis, a'd-ni'tis, or LYMPH-ADENITIS, lim'fäd-, inflammation of the lymphatic glands or of the vessels which lead into and bind them together. In either case the inflammation may become acute or chronic. The acute form is usually caused by a wound or a sore on the skin or mucous membrane. The inflammation then extends from the first lesion along the series of lymphatic vessels, causing intense pain in the glands with which these vessels connect. If the original wound or abrasion has been infected, the inflammation is accompanied by the gathering of pus around the glands. Where the inflamed condition is severe, fever, headache, sickness of the stomach and general prostration may follow. The chronic form of adenitis is usually caused by tuberculosis or syphilis. In such cases the treatment consists in putting the affected part at rest and applying moist, antiseptic dressings and regulating the bowels by means of diet and laxatives. If suppuration follows, the pus must be freed by lancing. When tonic and constitutional treatment fail, surgical removal of the enlarged glands is resorted to.

ADENOIDS, a term applied to an excessive growth of spongy tissue lying back of and above the soft palate. The growth may begin in early infancy, and if not removed
ADHERNO—ADHESION

may continue until the age of puberty. In the first stages the tissue is soft and apt to bleed easily, but as the nose becomes older it grows fibrous and harder, sometimes causing an enlargement of the glands. Adenoid tissue is present in all normal children, the disease being merely abnormal growth of this tissue, due to various causes. Adenoids are prominent, improper diet, poor ventilation, and often, in large part, it is due to heredity. By filling the air passages adenoid growths render breathing difficult and cause a permanent expression of the features not unlike that of the feeble-minded. Sometimes the growth of the facial bones may be affected, the teeth being irregular, the upper jaw may become narrowed and the hard palate unduly arched. The mentality of the sufferer is also affected, the mind being sluggish and incapable of concentration. This condition is termed aprosia. All the evils due to habitual mouth-breathing are also likely to result, such as bronchitis, weak lungs and asthma. Digestive disturbances of the stomach or of the intestines may also result from the constant swallowing of mucus.

Treatment is usually by means of surgical operation, which should be resorted to as soon as any of the above symptoms appear. The operation is without danger, except to those prone to excessive bleeding, on whom no operation should be attempted. Timely removal invariably causes a marked improvement in the child's mentality and physical condition. If the development has set in, absolute cure may be impossible, mouth-breathing having become a confirmed habit.

ADHERNO, ädér-nô, Italy, town of Sicily, 22 miles northwest of Catania, near Mount Etna. It is famous as the historic Adranon, the site of the ancient Roman temple of Vulcann, guarded by a thousand gods, ruins of which are shown, and also of the city walls, founded by Dionysius I, 400 B.C. Here Timoleon defeated Hicetas of Syracuse, 344 B.C., and Adronon was the first city captured by the Romans, 263 B.C., in the first Punic War. The Neapolitan convention of St. Lucia dating from 1157, with its church columns of black lava and its frescoes representing Adelasia (granddaughter of Roger I, the founder) taking the veil, rise in the centre of the town. Aderno is a busy market town with an important trade in agricultural products. Pop. 30,200.

ADHEMAR DE CHABANES, a'dē-mar de shâbân', French chronicler: b. Chabannes about 988; d. Jerusalem about 1030. He adopted a monastic life and wrote several works of which the most important is 'Chronicon Aquitanicum et Francicurn,' or 'Historiae Francorum' (3 vols.). The third volume covering the period from 814 to 1028, as a valuable historical source, is published in 'Monumenta Germaniae Historica' Band IV (Hanover and Berlin 1856-92). Other works are published in Migne, P. 'Patrologia Latina' (Tom. CXLI, Paris 1844-55). Adhemar died while on a pilgrimage to Jerusalem. Consult Molinier, F. 'Les Sources de l'Histoire de France' (Vol. II, Paris 1902).

ADHESION, in physics, the force which holds together two surfaces brought in contact; distinguished from friction. Mutual attraction exerted by particles of the same body, and from affinity, since the particles adhering remain unchanged. It is a force exerted on each other by the molecules of the adhering bodies, and not to be confounded with mere mechanical contact due to pressure. The wetting of solid bodies is an instance.

It usually happens that when a solid and a liquid come in contact, a film of the liquid adheres to the solid too firmly to be detached, showing its adhesion to the solid to be stronger than the cohesion of its particles or the force of gravitation, as it can be removed only by forcible rubbing or evaporation. On the other hand, solutions are supposably cases where the adhesive force of solid and liquid overbalances the cohesive force of the solid, so that it loses its form and adheres particle by particle; but see Solutions, the true theory of which is keenly debated. The force of adhesion is measured by poising a metal plate on a balance, and then finding the amount of friction required to detach it from the surface of a liquid which does not wet it (otherwise it would be measuring the cohesive force of the liquid) nor act on it chemically. The phenomena of capillary attraction depend on adhesion. Solid bodies also adhere to solids; most smooth surfaces will adhere; the smoother the tighter; and two plates of polished glass laid together can hardly be parted without breaking them. If the solids are pressed together, it usually increases the adhesive force; but it depends but little on atmospheric pressure. Friction is a looser kind of adhesion, which prevents surfaces moving freely on each other, and may result from gravitation or mechanical appliances. Plating, gilding, etc., also depend on adhesion. Soldering, the use of mortar, cementing, gluing, etc., are familiar applications of the principle, intermediary substances being employed, whose particles have at once great cohesion among themselves and great adhesion to each of the bodies to be joined. A familiar example is the splitting of a sheet of paper by pasting it between two sheets of cloth and pulling them apart after it has dried; the adhesion of paste to paper and cloth is so great that the paper fibres yield to it. Furthermore, air and other gases adhere to solids; a favorite children's experiment is to float a dry needle in a basin of water, it resting on a cushion of air; and when thermometers are filled with mercury it has to be boiled in them to expel the air that adheres to the glass. Every material body, and every particle of such body in however fine division, is surrounded by its own atmosphere of condensed gases, which are an efficient factor in many physical and chemical phenomena; this property in concreted bodies is called adsorption, and in metallic substances is sometimes so avid that they grow red-hot.

In pathology, adhesion is sometimes applied to the closing of a wound. It occurs when two granulating surfaces are kept in contact that they may fuse and the wound unite by adhesion. The pleura, pericardium and peritoneum often adhere when inflamed, and in inflammations of the vermiciformis appendix, pelvic organs, etc., more or less extensive adhesions
sometimes occur, and special operations may be necessary to allow the free functioning of the organs.

**ADRAPATIC TRANSFORMATION.**

See THERMOODYNAMICS.

**ADIA*BE*NE, a'dé-à-bé'nê, an ancient kingdom, lying between the Tigris and its two tributaries, the Upper and the Lower Zab. At one time it included all of Assyria proper and the Mesopotamian province of Nisibis and the district of Ecbatana. In 116 A.D. the country was conquered by Trajan, who made it a Roman province under the name of Assyria. Hadrian, however, allowed it to resume its autonomy under Parthian suzerainty. The capital of the kingdom was Arbela.

**AD'IA*PH*OR*IST*S, a-di-af'o-rist*s, or AD'IA*PH*OR*ITES, a party or wing of the Lutheran reformers of Germany, who held that certain things practised by the Roman Catholic Church were indifferent and might be received. In 1548 an ecclesiastical controversy broke out among the reformers. The Emperor Charles V, having issued a paper popularly called the "Interim," in which he prescribed what faith and practice the Protestants were to adopt till the Council of Trent should dictate a permanent form of belief and worship, Maurice, Elector of Saxony, urged MelANCHTHON and his friends to decide what portions of the document they would accept and follow. Melanchthon considered that to a very large extent the "Interim" might be accepted and obeyed. A controversy in consequence arose between the followers of Luther and those of Melanchthon. It was called the adiaphoristic controversy, and embraced two questions: (1) What things were indifferent; and (2) whether, with regard to things indifferent, the Emperor could or could not in conscience be obeyed.

**ADIBUDDHA, a-de-bud'hâ, from the Sanskrit, the Primord Buddha, a conception of Buddha due probably to the influence of Christianity. It came into vogue among the Northern Buddhists about the middle of the 10th century. In this conception he is represented as self-existent and omniscient.

**ADIGE, a'de-jê, a considerable river of North Italy, which has its source in the Alps of Tyrol, above Brixen; it enters Italy by Bolzano and the valley of Trento, flows in a southern direction by Roveredo, parallel to and for the most part about six miles from the lake of Garda, then, turning abruptly toward the east, passes through Verona and Legnano; it afterward enters the great delta between the Brenta and the Po, and, forming several branches, empties its waters into the Adriatic Sea. It is a deep and rapid stream, dividing by its course the old Venetian territories from Lombardy proper. The valley of the Adige has been rendered forever memorable by the wars of Bonaparte.

**ADIGR*ANTH, a'de-grant'h, the Bible of the Sikhs (q.v.), mainly compiled by the gur'M (spiritual guide) Arjun (1584-1606), fifth successor of the founder Nanak (q.v.). He gathered up the poetical pieces of his four predecessors and fragments from other great teachers like Ramananda, Kabir, Nanak, etc., and added compositions of his own. The tenth and last Sikh guru, Govind (1675-1708), made additions to it and composed an entirely new Granth, the "Granth of the Tenth Reign." The language of these is an archaic Punjabi called Gurmukhi ("from the guru's mouth"). These Granths, with the biographies of gurus and saints, and instructions for rituals and discipline, comprise the Sikh sacred books.

**ADINOLE, a variety of the mineral albite.**

**ADIPATE, any salt of adipic acid (q.v.).** Thus the compound of adipic acid with sodium is called sodium adipate.

**ADIPIC ACID, an organic acid having the formula C_4H_6O_4 and crystallizing in monoclinic lattices which are sparingly soluble in cold water, but freely so in alcohol and ether. It melts at 300° F. and is formed by the action of nitric acid on natural fats.

**ADIPITE, a gelatinous mineral substance of the same composition as chabazite (q.v.).**

**ADIPOCERE, a-dipô-sér (Lat. adipis, fat + cera, wax), a fatty substance consisting largely of palmitic, stearic and maragarcic acids, combined to some extent with ammonia. It is sometimes formed by the decomposition of animal matter which has been in a cold mass for a long time.

It was first observed by Fourcroy. The most notable example of its occurrence was in the Cimetière des Innocens at Paris. A large number of coffins had been piled together in this cemetery for many years, and in 1786-97, when the coffins were removed, it was found that in many cases the corpses had been changed into shapeless masses of a dingy white color and waxy consistency, only the bones remaining unaltered. Adipocere is not a result of the decomposition of albuminous tissue, but is formed from the fats that are present in the body at the time of death, the fatty matter collecting together, undergoing further decomposition and finally losing its glycerine and oleic acid. A similar substance, called bog-butter, is occasionally found in peat bogs in Ireland and Wales. Sometimes spelled adipiscere.

**ADIPOC*ER*ITE, a mineral better known as hatchettite (q.v.).**

**ADIPOSE TISSUE, animal tissue consisting of vesicles filled with fat or oil and supported by a network of capillary blood-vessels. Each drop of fat is confined within a protoplasmic envelope thickened at one part where a flat nucleus is found. Adipose tissue is found in a considerable layer under all skin surfaces, around the nerves and large vessels, and around the kidneys, joints, etc. The vesicles are round or oval, the tissue is organic and vital; fat is secreted from the blood-vessels. The fat is unorganized and devoid of vitality. Adipose tissue differs from cellular tissue in that the vesicles are closed so that even when fluid the fat does not escape.

**ADIPOSIS DOLOROSA, a special form of endocrinopathy first described by Dercum in 1892, and characterized by enormous collections of fat in different parts of the body, not in the hands or feet, and associated with marked tenderness to pressure over the fatty deposits, neuralgic pains and other signs of interrelated endocrinopathic disturbances. It is but one of a group of related syndromes which are related to faulty metabolism of the fatty structures, chiefly of the skin.
Various types of lipomatosis belong in the group. The precise mechanisms which bring it about are not yet worked out, but pluriglandular defects are probably the chief endocrine glands at fault being a combination of the glands (generative glands). Osteopathy has occasionally been of service. Consult Jelliffe and White, ‘Disease of the Nervous System’ (1917).

**ADIRONDACK MOUNTAINS**, a group in the northeastern part of New York State, lying between the depressions occupied by Lake Champlain on the east, the St. Lawrence on the northwest and the Mohawk River on the south. The group is sometimes included in the Appalachian system, but physically and geologically the two uplifts are quite independent. The Adirondacks cover an area of more than 12,000 square miles and include within their limits most of the counties of Clinton, Franklin, Essex and Hamilton, and portions of St. Lawrence, Lewis, Herkimer and Warren. They are separated by several forested areas and parallel or echelon, with a northeast-southwest trend, sloping on either side toward the narrow longitudinal valleys that separate the individual ridges. Most of the peaks have a rounded outline due to long-continued erosion, although in the northern part, where the highest elevations are found, the peaks are bold and picturesque and have bare rock walls rising several hundred feet in vertical escarpments. Avalanche Pass, Indian Pass and Wilmington Notch are the most noteworthy of several passes formed by these escarpments. The summit of the group is Mt. Marcy, 5,344 feet above the sea, and there are many prominences exceeding 4,500 feet, including Mt. McIntyre, 5,112; Sky Light, 4,920; Whiteface, 4,872; Santanoni, 4,044; and Nipple Top, 4,684 feet. Toward the south and west the elevations become less pronounced and rise but a few hundred feet above the level of the plateau, which stands 1,500 feet or more above the sea. The parallel ridges are interrupted frequently by gaps or passes; some of them, like the Avalanche Pass and Indian Pass, possess beautiful scenic features. Gorges and waterfalls occur along many of the stream valleys, the Ausable Chasm being especially noteworthy.

**Rivers and Lakes.**—The Adirondacks form the water parting between the Hudson and St. Lawrence, both of which streams receive many important tributaries from this region. Most of the western region drains directly into the St. Lawrence through the Oswegatchie, Grass, Raquette and St. Regis rivers, but a small portion is drained by the Black River, which flows into Lake Ontario. On the eastern side there is the Saranac and Ausable rivers and many short streams flowing into Lake Champlain. The Hudson River receives the waters of the Sacandaga, Indian and Boreas, and has its source in the interior of the mountains in the northeastern part of Hamilton County.

The most attractive feature of the Adirondacks; they are distributed over the entire area to the number of many hundreds. The greater proportion lie in the larger valleys, to which they conform more or less in outline, being elongated along a northeast-southwest axis. Many, however, are nestled on the higher slopes at an elevation of 2,500 feet or more above the sea. Lake Tear of the Clouds on the crest of Mt. Marcy has an altitude of 4,320 feet. Lakes Champlain and George, the largest of the Adirondack lakes, are among the most attractive sheets of water in the United States. Among the smaller lakes much frequented by tourists are Long, Raquette and Blue Mountain in Hamilton County, the Fulton Chain in Hamilton and Herkimer counties, St. Regis and the Saranac in Franklin County and Lake Placid in Essex County. Most of the lakes are of glacial formation, the outlets of the old rivers having been obstructed by deposits of glacial material.

**Geology and Mineral Resources.**—The strata of which the mountains are formed belong to the most ancient geological period, the Pre-Cambrian, consisting for the most part of crystalline formations which were uplifted long before the Appalachian ranges had been defined. Gneisses, granites and basic igneous rocks predominate, although there are small areas underlaid by limestones and shales. One of the most prominent types is a basic feldspar rock called anorthosite, composed almost entirely of the mineral labradorite. It constitutes the highest peaks in Essex County. On the borders these ancient formations are overlaid by early Paleozoic strata of Cambrian, Ordovician and Silurian age, which have been little disturbed from their original horizontal position. The whole region was invaded by the great northern ice-sheet, which eroded and polished the rock surfaces and upon its retreat left a heavy mantle of drift covering all but the highest elevations. Valuable ores and minerals occur at numerous localities. The deposits of iron ores have been of great economic importance, although in recent years the industry has suffered from competition with the Lake Superior and Pennsylvania ores, which can be extracted at much less expense. The ores of magnetite ore near Port Henry yield a large annual output, which is shipped to distant points for smelting. There are also deposits at Lyon Mountain, Lake Sanford and Benson Mines and other localities, which are not exploited at present. One of the richest graphite mines in the United States is located at Hague on Lake George. Pre-cambrian fissure veins of beryl and tourmaline are mined in large quantities at North River, while extensive deposits of foliated talc occur near Gouverneur. Marble, granite and other stones suitable for building and other purposes are the basis of a large quarry industry.

**Forests.**—Pine, spruce and hard woods are found over extensive areas. Chestnuts are found in the lower and open valleys of the south and spruce is to be had only at an elevation of 1,000 feet or more above sea level. The mountains have been denuded of much of the larger timber and the principal lumbering industry is based upon the cutting of pulp-wood for paper manufacture. Spruce and poplar are most valuable for this purpose. The wholesale destruction of the forests has led to government to purchase extensive tracts with a view to forest-cultivation and to preserve the sources of the principal rivers. See Adirondack Park.

**Game.**—The Adirondacks are one of the favorite hunting-grounds of America. Owing to the stringent legal restrictions limiting the
season for killing game, there is an abundance of deer, rabbits, partridge (grouse) and water-fowl. Deer are hunted chiefly by stalking, the use of dogs being prohibited. Black bears and wildcats may be found in many parts of the mountains, but moose and caribou, which formerly were plentiful, have entirely disappeared. Several moose were introduced from other States in 1902 with the hope that they might again become common in numbers. Brook and lake trout and black bass are found in most of the streams and lakes and furnish excellent sport for the angler.

Resorts.—The climate of the mountains is bracing and healthful; in the summer season the heat is tempered by cool mountain breezes and by the elevation, and the severe cold of winter is made more endurable by the dry atmosphere. There are many sanitariums for invalids, especially for those afflicted with pulmonary diseases. The pleasure-seekers, who visit the mountains in great numbers, find ample accommodations in the many hotels and camps. The railway lines afford easy access to most parts of the Adirondacks, while by taking advantage of the network of rivers and lakes the most remote regions can be reached without much difficulty. During the summer months steamboats make regular trips for the convenience of travelers on many of the larger lakes. Pure geology and mineral resources constitute Bulletins of the New York State Museum and Reports of the New York State Geologist; for forestry, the Reports of the State Forestry Commission; for botany, Reports of the State Botanist; all published at Albany. See New York (State).

ADIRONDACK PARK, a large district in the heart of the Adirondack region, principally forest land, set apart by the State of New York in 1892 for the conservation of the forest, protection of the watershed of the Hudson and other rivers of the State, for public recreation and for the practical study of forestry. (See Cornell University). It covers Hamilton County and parts of Essex, Franklin, Herkimer, St. Lawrence and Warren counties, and contains many mountains and lakes. It is over 3,000,000 acres in area, about 159 of these acres being State lands (which also form part of the Adirondack Preserve) and the rest being owned by lumber companies, associations, clubs and individuals. From time to time additions are made to the reservations, as the appropriations are available, and it is hoped that in time the whole region not under cultivation for crops will be under State control, and, while saved for the use of the people, will become a source of revenue to the State from the forestry industries.

ADIS ABABA, ad'dês a-bâ'ba', Abyssinia, capital of the kingdom and of the province of Shoa, is situated 9,000 feet above sea-level on the southern slope of the Entotto hills. It consists of groups of villages and suburbs scattered around the Gebi or royal palace and enclosure placed on a small hill, commanding the whole neighborhood. There is telegraphic communication with Massowah, Harrar, Dire Dawa, and the seaport of Jibuti in French Somaliland, whence a railway line to Dire Dawa 187 miles, on the southeast border of Abyssinia, is projected, via Harrar and the Hawash River, 300 miles to Adis Ababa. Telephone communication has been established with Harrar and intervening points. At the military camp a mile northeast of the palace were the seventeen British and Italian railway troops from the camp of Adowa, 1 March 1896. Adis Ababa, signifying “the new flower,” was founded in 1892 by Menelek II after abandoning Entoto, 10 miles to the north. Here on 29 December 1896 the treaty of peace between Italy and Abyssinia was signed. The population ranges from 50,000 to 70,000, about a third being of a floating character.

ADIT ("approach"), an underground passage with but one opening; distinguished from the tunnel proper, which has two. In military use, the burrow by which a place they wish to sap. In industrial mining, a gently sloping drift, used to drain a mine of the water coming into the workings from the top or from below; usually but improperly called a tunnel. When there are two adits at different levels, the lower one is termed the “deep adit.” The greatest in the United States is the Sutro Tunnel, 2,000 feet deep and 20,000 feet long, made in the palynic days of the Comstock Lode near Virginia City, Nev., to drain the mines along it.

ADITI, adî'tî, in the mythology of the Hindu Rig-Vedas, Infinity, endowed with life and form, from which are born the Adityas—the source and substratum of the universe; in later Vedic literature, the mother of the gods of storms (which are represented as life-producing), and of the sun. Aditi is the daughter of Daksha and wife of Kasyapa, and besides being the mother of the 33 gods and of the sun, was also the mother of the Tushitas, or the 12 Adityas. The latter in the Vedic literature numbered seven and are the gods of the heavenly light, with Varuna at their head. In the Brahmanas and later they numbered 12 with supposed reference to the months of the year.

ADIVE, a local Asiatic name of the corsac (q.v.).

ADJECTIVE. See Grammar.

ADJOINING LANDOWNERS. The mutual rights, duties and liabilities of adjoining landowners are dependent on the general principle which requires one to enjoy his property in such a manner as not to injure that of another; but the application of this principle is to be limited so as not to restrain an owner of property from reasonable and prudent use and enjoyment of it. It is therefore a general rule of law that every owner of land has absolute dominion over it and may make any reasonable use of it he sees fit, and if injuries result to adjoining land by such use it is damnum absque injuria. The test as to whether a particular use of the premises is a reasonable one is whether or not it is such a use as, under the circumstances, an ordinary man would make of his premises, taking into consideration the importance of the use to the owner as well as the extent of the damage to be inflicted upon his neighbor, and if he uses ordinary care therein to prevent unnecessary injury to adjoining owners the fact that the use is one which will inevitably produce injury to such adjoining owners does not necessarily make it negligence.
ADJOURNMENT, technical law term, signifying the termination of a session of court, as distinguished from the suspension of a pending case, which is technically known as a continuance. Adjournment may be for a designated time, as from day to day, or it may be indefinite, in which case it is said to be "without day." When the period covers less than a day, it is called a recess. The suspension at the end of the day, when the session is to be resumed next morning, does not call for an order of adjournment, the session being deemed continuous.

ADJUDICATION, the term used in English and American law to denote the final decision in a proceeding in bankruptcy. The Federal Bankruptcy Act of 1898 defines it as "a decree that the defendant, in a bankruptcy proceeding, is a bankrupt." Former adjudication is a phrase often used, the rule being that persons shall not re-litigate a case which has once been adjudicated between them.

ADJUSTABLE TRIANGLE, a triangle with a 45°-degree angle in which the latter can be set to any degree very quickly by shifting the hypotenuse, and held in position firmly by clamping the thumb screw. It is divided into one-half degrees from 0 to 45 on the base of the angle. In drawing roof pitches, arch keys, towers, bay windows, etc., it is very convenient, as the lines can be drawn with absolute correctness; it is only necessary to measure one pitch, set the angle to it, move the hypotenuse along every similar line, then turn the angle over, drawing the corresponding lines on the other side. It is also a great help in hydraulic and railroad engineering and drainage work. There is no better or quicker method of transferring angles from one drawing board to another than by means of this adjustable triangle. Parallel and vertical lines can be drawn with the utmost correctness. When lettering on drawings or tracings, etc., it is also very useful, as the letters A, B, M, V, W, X, Y and Z are marked on the base of the angle, each giving the desired slope for these letters. The following 11 slopes are indicated on the bases of the triangles: 1:1, 1:1½, 1:2, 1:2½, 1:3, 1:4, 1:5, 1:6, 1:8, 1:12 and 3:4.

ADJUSTMENT, in insurance, is the determining the amount of a loss. No specific form is necessary to an adjustment. It must be intended and understood by the parties to a policy to be absolute and final, in order to render it binding. It may be made by endorsement on the policy, by payment of the loss or by the acceptance of an abandonment (4 Burr. 1905; 1 Camp. 134; 22 Pick. (Mass.) 191). If an adjustment is brought about by the fraudulent conduct of one of the parties, it will not bind the other person (2 Johns. Cas. 233; 3 Camp. 319). If one party is led into a material mistake of fact by fault of the other, the adjustment will not bind him. (2 Johns. (N. Y.) 157; 2 Johns. Cas. 233).

ADJUTANT ("assistant"), in the armies of most civilized powers, a staff officer, the chief assistant of a regiment, battalion or squadron, in the drill and discipline of the troops, and their general management off the battlefield, and in such other duties as fall to the commander's charge. In the United States army he is appointed by the colonel for four years, has the rank of captain, and is not eligible to reappointment; he is the colonel's private secretary, and the adjutant generally supposes that in time of war ambitious men often dreaded the appointment as death to further promotion. The squadron and battalion adjutants rank as lieutenants, are similarly appointed for two years, and have the same relation to their colonels; they, too, if posted, garrison and brigade adjutants. For further details consult the 'U. S. Army Register.'

ADJUTANT, a large stork (Leptoptilus argala) found in India and southeastern Asia, and so called by the English on account of its erect, officer-like appearance. Its Hindu name is "argala." Its height is about five feet, its spread of wings about 14 feet. The back and wings are slate-colored, the bare, flesh-colored head and neck are marked with black, and elsewhere it is white. The beautiful "maribou" plumes of commerce are taken from the under side of the wings. A pouch, which probably serves some purpose in connection with the organs of breathing, hangs from the under part of the neck and is capable of great distension. The bill is of great size, and the appetite of the bird is correspondingly large. It is a scavenger, its food being carrion, offal and small live animals, and it runs freely about Indian villages, protected for its useful works. The maribou of Africa is a closely related species.

ADJUTANT-GENERAL, an officer on the staff of the commander-in-chief, his secretary and principal assistant in issuing orders and supervising their execution, making reports and keeping registers, etc.; and having general charge of the drill and discipline of an army. In the United States army there is a department known as the Adjutant-General's Department, all the officers of which are above the grade of captain, and who have, in addition to the title of adjutant-general, the specific title of brigade or division adjutant when serving as such with a brigade or division in the field. The chief of the department has the rank of brigadier-general and the title of "the adjutant-general." He is charged under the direction of the secretary of war, and subject to the supervision of the chief of staff in all matters pertaining to the command, discipline, or administration of the existing military establishment, with the duty of recording, authenticating and communicating to troops and individuals in the military service all orders, instructions and regulations issued by the secretary of war through the chief of staff; of preparing and distributing commissions; of compiling and issuing the Army Register and the Army List and Directory; of preparing the annual returns of the militia to be submitted to Congress in managing the recruiting service; of collecting military information, and with the custody of all official and historical records, including all pension, pay, bounty, etc., pertaining to or based on the military service of former officers or enlisted men. Individual States also have their own adjutant-general, with cognate duties regarding the State militia. In many countries, such as Germany and
Russia, the term has retained its original meaning of an officer on the personal staff, and is the designation of personal aides-de-camp to the sovereign.

ADLER, Cursus, American librarian and archaeologist: b. Van Buren, Ark., 13 Sept. 1863. He was graduated at the University of Pennsylvania in 1883, and took the degree of Ph.D. in 1887 at Johns Hopkins University, where for several years he was instructor in Semitic languages. Since 1892 he has been librarian of the Smithsonian Institution; special commissioner of World's Fair to Turkey, Egypt, Tunis, Algiers and Morocco; president of the American Jewish Historical Society; president of United Synagogue of America, and member of numerous learned societies, such as the American Oriental Society, and the American Philosophical Society. He is the author of numerous articles on Oriental archaeology, Assyriology, Semitic philology, Academical and Popular literature and bibliography: and one of the editors of the 'Jewish Encyclopedia.' He also edited the 'Jefferson Year-Book' (1899-1905), with Allen Ramsay; 'Told in the Coffee House' (1898); 'Jews in the Diplomatic Correspondence of the United States.'

ADLER, Felix, American lecturer and scholar: b. Alzey, Germany, 13 Aug. 1851, son of an eminent Jewish rabbi. In 1887 he emigrated to the United States, in which country and at Berlin and Heidelberg he was educated. After being for some time professor of Hebrew and Oriental literature at Cornell University he founded in New York (1876) the Society for Ethical Culture, of which he is lecturer. Similar societies have been established elsewhere in the United States and in other countries. He is an effective writer and speaker. He has published 'Cred and Deed' (1878); 'The Moral Instruction of Children' (1892); 'The Essentials of Spiritualism' (1905); 'The Religion of Duty' (1912); 'Marriage and Divorce' (1915); 'The World Crisis at Its Millennium' (1915). In June, 1902 he was called to the newly-created professorship of social and political ethics in the department of philosophy in Columbia University. From 1908 to 1909 he was American exchange professor at the University of Berlin. He has served for 10 years as chairman of the National Child Labor Committee.

ADLER, Friedrich, German architect: b. Berlin, 15 Oct. 1827; d. Berlin, 15 Sept. 1908. After finishing his studies at the Berlin Architectural Academy he traveled extensively. In 1863 he was appointed professor at the Berlin Academy and remained there until he retired in 1893. He was consulting architect to the Prussian minister of public works. Among his greater architectural works are the designing of Christ Church and St. Thomas' at Berlin, St. Paul's at Bromberg and the Church of the Redeemer at Jerusalem. He specialized in the architecture of ancient times and the Middle Ages and took a prominent part in the excavations at Olympia. Among his published works are: 'Mittelalterliche Backsteinbauwerke des preussischen Staats' (1858); 'Die Baugeschichte von Berlin' (1861); 'Bau geschichtliche Forschungen in Deutschland' (1870); 'Das Mausoleum zu Halikarnass' (1900); 'Zur Kunstgeschichte' (1906).

ADLER, Georg, German economist: b. Posen, Germany, 28 May 1863; d. 1908. He began his career as extraordinary professor of sociology at the University of Basel, Switzerland, and then became professor of political economy at the University of Freiburg, Germany. In 1900 he was appointed professor of political science at Kiel University. His sociological writings tend strongly against the revolutionary programs of the socialist schools. His works are: 'Karl Marxsehe Kritik' (1886); 'Internationaler Arbeiterschutz' (1888); 'Soziale Reform und Theater' (1891); 'Staat und Arbeitslosigkeit' (1894); 'Die Social- Reform im Altertum' (1898); 'Geschichte des Sozialismus und Communismus' (1900); 'Ueber die Epochen der deutschen Handwerkerpolitik' (1903); 'Die Bedeutung der Illusionen fur Politik und soziales Leben' (1904); 'Sinners Anarchist' (1907); 'Hauptwerke des Sozialismus und der Sozialpolitik' (1908).

ADLER, George J., German-American philosopher: b. Germany 1821; d. 1868. He came to New York 1833; was graduated at the University of the City of New York 1844, and from 1846-54 was professor of German there. He published a valuable 'German-English Dictionary' (1848, many editions since), still very useful for its careful discrimination of synonyms; 'German Grammar' (New York 1868); 'Wilhelm von Humboldt's Linguistic Studies' (New York 1868), and translated Fauriel's 'History of Provençal Poetry.'

ADLER, Guido, Austrian writer on music: b. Ebenschoitz, Moravia, 11 Jan. 1855. After studying in the gymnasium and university in Vienna, he continued his musical studies at the conservatory under Bruckner and Dessimoff. In 1881 he was appointed lecturer on the science of music at the University of Vienna and in 1885 he became professor of music at the German University of Prague. In 1898 he returned to the University of Vienna as professor of the history and theory of music. Together with Chrysander and Spitta, he founded in 1884, the Viertel jahreschrift der Musikwissenschaft, to which he was one of the most important contributors, writing on the history and theory of music. At the same time he began the publication 'Denkmaler der Tonkunst in Oesterreich,' published by Artaria in Vienna and by Breitkopf and Hartel in Leipzig and which is subsidized by the Austrian government. Up to 1913, 19 double volumes had appeared, containing works of the old Austrian composers or of such of the great masters who had lived in Austria. Many of the historical introductions are written by Adler himself. During the International Exhibition in Vienna in 1892 Adler acted as chairman of the historical section. The most important of his independently published works is 'Der Stil in der Musik' (1911).

ADLER, Hermann, Anglo-Jewish leader: b. in Hanover, 29 May 1839; d. London, 18 July 1911. He lived most of his life in England, where he held many positions of high trust connected with his race, having been since 1891 chief rabbi of the British Empire, and active in general benevolence. He was
principal of the Jews' College, London, 1863–91, and as chief rabbi became its president. Besides sermons, lectures, etc., he wrote 'The Jews in England,' 'The Chief Rabbis of England,' 'Ibn Gabirol, the Poet Philosopher,' etc.

**ADLER, Nathan Marcus**, German-Jewish leader: b. Hanover 1803; d. 1890. Educated at Göttingen, Erlangen and Würzburg, he became chief rabbi of Oldenburg 1830, of Hanover and now resides 1831, of Bremen, 1837. He was a chief organizer of schools for Jews in England, assisted Sir Moses Montefiore in raising the £20,000 fund for Palestine, was co-founder of the United Synagogue (association of the leading synagogues), and founded and first president of the Jews' College. He published several volumes of sermons and a commentary on the Targum.

**ADLER, Samuel**, German-Jewish rabbi and author: b. Worms, Germany, 3 Dec. 1809; d. New York city, 9 June 1891. After studying at the universities of Bonn and Giessen, he was appointed, in 1842, rabbi of the congregation in Alzey. In 1857 he came to the United States, being appointed rabbi of the congregation of Emanu-El of New York city. He was considered a profound scholar of the Talmud. His works include: 'Jewish Conference Papers' (1880); 'Benedictions' (1882); 'Kobez al Yad' (collections 1886).

**ADLER, Victor**, Austrian socialist editor: b. Prague, 24 June 1852. After studying in the Viennese he played accompaniment on whose system of factory inspection he wrote his first book. On his return to Vienna he founded a Social-Democratic weekly publication, which the Austrian government suppressed. He then founded and edited the *Arbeiter Zeitung*. He was for a time a member of the Lower Diet and, in 1907, became a member of the Imperial Council. His most important publication is 'Die Arbeiter Kammern un die Arbeiter' (1886).

**AD LIBITUM**, musical term, which implies that the part so marked may be played according to the taste of the performer and not necessarily in strict time. When there is an accompaniment to the music so marked, it must strictly follow the ad libitum time of the principal performer. Ad libitum also frequently means that a part for a particular instrument, or instruments, in instrumental scores or pianoforte arrangements may be either played or entirely left out. Thus, a song written with cello accompaniment "ad libitum" may be sung to the piano accompaniment alone or with the 'cello added.

**ADMINISTRATION**, in general, the management of any business; especially executive government. In public affairs it refers to the actions of the government in exercising its authority agreeable to the constitution of the nation. The word is applied more commonly to the collective body of governmental officers exercising authority as an executive power. In a narrow sense it is used in America, in national politics, to designate the President and his executive officers and in municipal politics the mayor and heads of departments. In England the administration consists of the Premier and his cabinet, who hold office while their party has a legislative majority in the House of Commons.

In law the management of the personal estate of anyone dying intestate or without an executor. If the deceased leaves real estate, the estate devolves upon heirs related by blood; if personal property is left and no executors named, administrators are appointed. In the United States a surrogate is the judge of probate appointed in general, to administer and grants letters of administration. The administrator is a trustee within the jurisdiction of a court of equity as well as of a court of probate. His duties are to inventory the estate, collect accounts due, pay all debts, and distribute the remainder among those entitled to it. In England the power of such appointment was vested in the ecclesiastical courts until 1857, when it was transferred to a court of probate. The personal property of a deceased is appropriated to the payment of his debts so far as required, and until exhausted must first be resorted to by creditors; but by certain statutes, courts may grant an administrator power to sell, lease or mortgage real estate when the personal estate is not sufficient to pay his debts. At common law the real estate of an intestate goes to his heirs; the personal to his administrator. The fundamental rule is that all just debts shall be paid before any further disposition of the property.

**Ancillary Administration.**—That which is subordinate to the principal administration, for collecting the assets of foreigners. It is taken out in the country where the assets are locally situate.

**Of Estates.**—The term is applied broadly to denote the management of an estate by an executor, and also the management of the estates of minors, lunatics, etc., in those cases where trustees have been appointed by authority of law to take charge of such estates in place of the legal owners.

**Foreign Administration.**—That which is exercised by virtue of authority properly conferred by a foreign power. In England and in the United States the general rule is that letters granted abroad give no authority to sue or to be sued in another jurisdiction, though they may be ground for new probate authority. Consequently, when persons are domiciled and die in one country, as A, and have personal property in another, as B, the authority must be had in B, but exercised according to the laws of A. (Story, Conf. Laws, 23, 447). There is no legal priority between administrators in different States. The principal administrator is to act in the intestate's domicile, and the ancillary is to collect claims and pay debts in the foreign jurisdiction and pay over the surplus to his principal. (2 Metc. (Mass.) 114; 3 Day, 74). But some courts hold that the probate of a will in a foreign state, if duly authenticated, dispenses with the necessity of taking out new letters in their State. So it has been held that possession of property may be taken in a foreign state, but a suit cannot be brought without taking out letters in that State.

**Public Administration.**—That which the public administrator performs. This happens in many of the States by statute in those cases
where persons die intestate, without leaving anyone who is entitled to apply for letters of administration.

Jurisdiction over administrations is in England lodged in the ecclesiastical courts, and these courts delegate the power of administering by letters of administration. In the United States administration is a subject charged upon courts of civil jurisdiction. A perplexing multiplicity of statutes defines the powers of such courts in the various States of the Union. The public officer authorized to delegate the trust is called surrogate, judge of probate, registrar of wills, etc. As to surrogate courts and proceedings therein in the State of New York, consult the Code of Civil Procedure (Chase's ed. 1902, ch. 18). The death of the intestate must have taken place or the court will have no jurisdiction. A decree of the court is prima facie evidence of his death and puts the burden of disproving upon the party pleading in abatement. (26 Barb. 383.) The formalities and requisites in regard to valid appointments, and rules as to notice, defective proceedings, etc., are different in the various States.

ADMINISTRATIVE DEPARTMENTS.

See United States — The Beginnings of Executive Departments of the; Executive Cabinet and Cabinet Government; Appointments; Budget System; Commission Government; and the departments by name.

ADMIRABLE CRICHTON, crét'on. See Crichton, JAMES.

ADMIRAL (Arabic amir-al or emir-al, commander of the—whatever follows it) the highest rank of naval officer; the title of the general officer who commands a fleet or a subdivision of a fleet. As a naval term the word appears to have been used first by the Sicilians and then by the Genoese, from whom it was taken by the French during the crusades of the 13th century. By the end of that century the word had come into use in England to designate the officer in command of the Cinque Port ships. The French preserved the word without change, as amiral, and in France it was borne as the title of an officer by the military, judicial and administrative officer known as grand amiral, in England as lord high admiral and in Spain as almirante mayor. In Spanish and Portuguese the word has developed into almirante, supposedly being derived from the Latin admirari, since the admiral is to be admired for surmounting all dangers and difficulties; both in Spanish and in Elizabethan English the word has been applied to the flagship of the commander of a fleet, the Spanish almiranta being the ship of the second in command and the capitanía the ship of the ranking officer. In England the early forms were amyreli, and admyreli, the present form arising from a confusion with the Latin admirabilis. The first English admiral was William de Leybourne (1286) but he did not command the sea forces, his duties corresponding to those afterward vested in the lord high admiral, viz., the administrative powers now delegated to the lords commissioners of the admiralty and the judicial and military duties now belonging to the high court of admiralty. From 1632-50, from 1685-1702 and from 1708-1827 the duties of the office were performed by a board of commissioners, while under the Commonwealth a committee of Parliament administered the office. The last lord high admiral was the Duke of Clarence, afterward William IV. When he resigned in 1828 the office was put in commission, in accordance with a previous practice. In Spain the title of admiral is an hereditary honor still borne by the descendants of Columbus, the Dukes of Veraqua.

In the modern navy the admirals correspond to the general officers of the army. In the British navy there are four classes. There is an admiral of the fleet, corresponding to the field marshal and conferred at the sovereign's will, but it is little more than an honorary distinction. The three active ranks are those of admiral, vice-admiral and rear-admiral, ranking respectively with generals, lieutenant-general and major-general. In former times there were also three subdivisions of each grade known as admirals (or vice- or rear-admirals) of the red, the white and the blue respectively; the color of the flag flown by the admiral (hence called flag-officer) corresponded with his section and all the ensigns and pennants of all ships under his command were of the same hue. This distinction is now abolished. The sea pay of an admiral of the fleet is £6 per day of the admirals £5, of a vice-admiral £4 and of a rear-admiral £3; and an admiral commanding-in-chief is allowed £3 per day additional at home and £4 10s. abroad, as table money. In the British navy the vice- and rear-admiral are also honorary but without the active functions conferred in compliment on senior naval officers. The former extensive functions of the admiral have been absorbed by the Crown and have been divided among other officials. In Russia the highest rank is that of lieutenant admiral-general. In other foreign navies there are admirals, vice-admirals and rear-admirals, whose duties correspond, save in minor details, to those of the above officers.

In the United States navy the three ranks of admirals were adopted during the Civil War period, the rank of rear-admiral being established by Congress in 1862 (as was also that of commodore, though this title had previously existed as one of courtesy, but without legal sanction); the rank of vice-admiral in 1864, when Lincoln was authorized to promote one of the rear-admirals to that position; and the rank of admiral in 1866, when Congress enacted a law providing an active list of one admiral, one vice-admiral and five rear-admirals. Originally these three grades were established for the express purpose of conferring exceptional honors and distinction upon David Glas-
gown Farragut (q.v.) and in order he became the first rear-admiral, first vice-admiral and first admiral. In 1855, when the rank of admiral was established and Farragut had assumed the rank, Rear-Admiral David D. Porter (q.v.) was promoted to vice-admiral, and in 1870, on Farragut’s death, he became admiral. Rear-Admiral Stephen C. Rowan then became vice-admiral. Porter died in 1859 and Rowan in 1891, whereupon both grades were abolished. In 1899 the grade of admiral of the navy was established by Congress and conferred upon George Dewey (q.v.) as a reward for services at Manila Bay. This rank is a grade above admiral and resembles the rank of admiral of the fleet in the British navy. In 1882 Congress reduced the number of rear-admirals to six and the number of commodores to 10, but in 1899 increased the number of rear-admirals to 18, comprising two classes of nine each, and abolished the grade of commodore on the active list. The rank of rear-admiral is also borne by the chiefs of the Navy Department bureaus during their term of office. Originally the admiral, vice-admiral, and rear-admiral of the navy corresponded to the general, lieutenant-general and major-general of the army, and various acts after 1862 confirmed these provisions, but the act of 1899, which abolished the rank of commodore, provided that the three nine rear-admirals should rank with major-generals and the junior nine rear-admirals with brigadier-generals. The admiral of the navy and admiral receive $13,500 annually; senior nine rear-admirals, $8,000 each; and junior nine rear-admirals, $6,000; while an additional 10 per cent above these amounts is allowed for sea duty or shore duty beyond the continental limits of the United States. A retired officer receives 75 per cent of his active pay at time of retirement. The flag of the American admiral, which flies at the main, is rectangular and blue, with four white stars; that of the vice-admiral, flown at the fore, is similar but has only three stars; that of a rear-admiral, flown at the mizzen, is similar in shape but has only two stars and usually is blue, but if two or more rear-admirals be together, the senior flies a blue flag and the others red. See United States, Navy or the, and similar articles under the titles of the various nations.

ADMIRAL. (1) In entomology, a nymphalid butterfly, any one of several species, the red admiral (Pyraeuctis atopala), and the white admiral of the genus Basilaria. (2) In conchology, one of the cones (Conus Admiralis). See Cone-shell.

ADMIRALTY, The. In Great Britain, the governmental department which manages all matters pertaining to the British navy and the royal marine. The admiralcy derives its character from the fact that it represents the lord high admiral, whose administrative functions have been transferred to and vested in a board of commissioners. Among the duties of these commissioners are the maintenance and upkeep of the fleet according to governmental policy, keeping its roster filled with trained officers and men, and preserving it in the highest possible degree of preparedness and efficiency as regards personnel and material. The board consists of five lords commissioners, who decide collectively all important matters and who, in theory, are jointly responsible; they are the first lord, the first and second naval lords, the additional naval lord and the junior naval lord and the civil lord who execute the office of lord high admiral, and with them are the parliamentary and financial secretary and the permanent secretary. The first lord, who is always a cabinet minister and who is responsible to the Crown and to Parliament for all admiralty business, besides having general direction and supervision, manages the political affairs of the navy; as its representative in Parliament, controls the naval estimates and finances and has charge of appointments, promotions and removals. The first naval lord is responsible for the commissioning of ships, the personnel of the fleet, its fighting efficiency and employment, its discipline and the appointment of inferior officers; he directs the operations of the admiral superintendent of naval reserves in regard to ships, the hydrographer, the director of naval ordinance and the naval intelligence department; and makes the necessary preparations to protect trade and the fisheries. The second naval lord has charge of the personnel of the fleet, the manning of the navy, and mobilization, supervises the training establishments and colleges, attends to naval education, training and the affairs of the royal marine force, appoints navigating officers and inferior officers and supervises the management of the reserve. The additional naval lord and controller has charge of everything pertaining to the material of the fleet, design, construction, machinery, equipment, dockyards and building establishments, gunnery and armament, maintenance repairs and repairs and naval stores. The junior naval lord has control over the transport, medical and victualling services, the regulation of hospitals, the coaling arrangements of the fleet, of uniforms, prize money, naval savings banks, pensions and the appointment of chaplains, naval instructors, medical officers and officers of the accountant branch. Among the duties of the civil lord are the supervision of admiralty buildings and works, construction and labor contracts and purchases of building stores and land, and the direction of the civil staff of the naval establishments; Greenwich Hospital is under his authority and the charitable funds, compassionate allowances, etc., are in his charge. The parliamentary and financial secretary has charge of the finances of the department, the navy estimates and general expenditures. The permanent secretary supervises and directs the general office work of the admiralty, of the military, naval and legal branches, the civil branch and the record office. When the prime minister resigns, all the lords of the admiralty do likewise and those who have seats in Parliament are succeeded by others.

ADMIRALTY AND MARITIME JURISDICTION. The system of law and procedure under which maritime transactions are regulated. It derives its name from the fact that it was originally administered in England by the lord high admiral. The modern laws have been adopted from the civil law and from such sea codes as those of Rhodes and Oléron (q.v.). Article III, § 2 of the Constitution provides that the judicial power of the United
States "shall extend to all cases of admiralty and maritime jurisdiction" and as is the custom in many. The United States Supreme Court has declared that by virtue of these words our admiralty courts shall entertain jurisdiction not only over the high seas but also over all public navigable waters, including interior lakes, rivers and canals, and that this jurisdiction is not confined to the public waters. The admiralty jurisdiction of the Federal courts is fixed by statute and in general covers cases that arise under contracts calling for the performance of certain duties or obligations upon navigable waters, such as contracts involving the transportation of passengers or merchandise between different States or foreign ports, cases of salvage, bonds of bottomry or hypothecation of ship and cargo, contracts (express or implied) for seamen's wages, seizures under the laws of impost, navigation or trade, cases of prize or ransom, charter-parties, contracts with materialmen, jettisons, maritime contributions and averages, policies of marine insurance, contracts for the furnishing of materials for or the making or repairs on foreign-born vessels, and generally all assaults and batteries, damages and trespasses taking place on the high seas. Under war conditions the admiralty jurisdiction is extended so as to include the power to determine questions of jurisdiction. Cases committed upon the high seas or beyond the jurisdiction of any country come under the jurisdiction of the admiralty courts, but as no crimes save those specified by statute are punishable in the Federal courts, the jurisdiction in this respect does not differ from that regarding other statutory offenses. A suit is commenced in admiralty by filing a libel, upon which a warrant is issued for the arrest of the person, or attachment of his property if he cannot be found, or a simple motion to appear; such proceedings are called actions in personam, that is, actions between individuals for tort or breach of contract. There may be a proceeding in rem, under which a warrant is issued for the arrest of the thing in question; in other words the proceedings are to determine the rights to or claims against a vessel or other particular subject-matter. In cases of actions in personam, the admiralty courts do not possess exclusive jurisdiction, since under the statutes the parties to such actions may obtain their rights of action at common law; but in cases in rem, admiralty courts exercise exclusive jurisdiction and no other remedy can be sought in any other court. In the latter class of cases the vessel or other subject-matter involved must be brought by seizure or otherwise within the jurisdiction of the court. Since, in the United States, there are no courts whose duties and jurisdiction are confined to admiralty cases the district courts, by statute, have original jurisdiction in general admiralty and maritime cases and appeals may be made to the circuit court of appeals but in a few specified cases and in prize cases the appeal is to the Supreme Court. The court usually tries admiralty cases without a jury, but in a few special cases trial by jury is provided by statute or provision. There is no admiralty jurisdiction. Among the more prominent cases in the Supreme Court are: Waring v. Clark (1846), 5 How. 441; The Propeller Genesee Chief v. Fitzhugh (1851), 12 How. 443; The Moses Taylor (1866), 4 Wall. 411; Insurance Co. v. Dunham (1870), 11 Wall. 1; Leon v. Galceran (1870), 11 Wall. 185; Ex parte Mayer (1884), 100 U. S. 629; Manchester v. Massachusetts (1891), 139 U. S. 240. See COMMERCIAL LAW; LAW, MARITIME; INSURANCE, MARINE. Consult Benedict, E. C., 'The American Admiralty, Its Jurisdiction and Practice' (4th ed., Albany, N. Y., 1910). The early continental and English authorities are collected in Judge Story's opinion in the case of De Lovie v. Boit (1815), 2 Gallison 398, 7 Fed. Cases, No. 3,776. The Laws of Oléron and other early maritime codes and ordinances may be found in Peter's 'Admiralty Decisions,' 1792-1807, Vol. I, App., and in the appendix to 'Federal Cases,' Vol. XXX.

ADMARILTY INLET, a narrow body of water connecting Puget Sound with the Strait of Juan de Fuca.

ADMARILTY ISLAND, a mountainous island, 90 miles long, off the west coast of Alaska, to the northeast of Sitka; belongs to the United States.

ADMARILTY ISLANDS, a group of 40 islands, to the northeast of New Guinea; Basco, the largest of them, being 60 miles in length, mountainous but fruitful. The total area of the islands is 878 square miles. They were discovered by Schouten in 1616. Carteret named them in 1677. Some are volcanic; others are coral islands. They abound in coconuts and are inhabited by a race of tawny, frizzle-headed savages of the Papuan stock, about 800 in number. Together with New Britain and some adjoining groups they were annexed by Germany in 1885, and now form part of the Bismarck Archipelago.

ADMARILTY LAW. See Admiralty and Maritime Jurisdiction; Law, Maritime.

ADMISSION. In practice, the act by which attorneys and counsellors become recognized as officers of the court and are allowed to practise.

In corporations or companies, the act of a corporation or company by which an individual acquires the right of a member of such corporation or company. In trading and joint-stock companies no vote is requisite, for any person who owns stock therein, either by original subscription or conveyance, is in general entitled to, and cannot be refused, the rights and privileges of a member. Nothing more can be required of a person demanding a transfer on the books than that he prove to the corporation his right to the stock.

In evidence, a concession or voluntary acknowledgment made by a party of the existence of certain things or conditions, or of the truth of certain statements. The admissions or declarations of a party in respect to the subject-matter of an action at law or suit in equity may always be given in evidence against him. As distinguished from confessions, the term is applied to civil transactions, and to matters of fact in criminal cases where there is no criminal intent. Express or direct admissions are those which are made in direct terms. Incidental admissions are those made in some other connection or involved in the admission of some other fact. Implied admissions are those
ADOBE. á-dō'ba (Sp., from adobar, to daub or plaster), colloquially *dobie*: sun-dried bricks, from any native clays; especially those made in the arid western and southwestern sections of the United States, as in the Great Basin, Arizona, New Mexico, etc., by molding the bricks and then turning the sides alternately to the sun day by day for a week or two, stacking up for use when sufficiently baked. These, however, are the resource only of people in an inferior state of civilization, as the rain soon dissolves them into streams of mud; hence also they are impossible at all save where rain is very infrequent. The sizes are usually two, 18 x 9 x 4 and 16 x 12 x 4, the larger ones in the best building used as headers (the greatest length crosswise to the wall) and the others as stretchers (lengthwise). The earliest building material in Assyria and Egypt was adobe, usually strengthened with straw, and it is still made in Japan and China. Adobe soils are clay soils very plastic when wet, but too hard for cultivation when dry; they are lightened by plowing in sand or sandy loam and are often very fertile.

ADOLESCENCE (Latin, adolescere, to grow up) is the period of life between the advent of puberty and maturity. Puberty, or the period when an individual first becomes capable of begetting or of bearing children, occurs approximately in the 12th or 13th year for girls and the 14th year for boys, though in individual cases its advent may be as early as the 10th or as late as the 21st year. These alterations of structure and function in the body which fit it for the processes of reproduction are the primary aspect of the period of adolescence on its physical side and the remaining phenomena, both physical and mental, which make the period so significant for psychology and education, can be shown to be related more or less directly to this fundamental process of preparing the body for its rôle in the perpetuation of the race.

Physical Changes.—Thus, on the physical side, measurements of the body and its capacities show during adolescence, and particularly in the four or five years from puberty onward, distinct acceleration in the rate of growth, and this acceleration begins earlier and ends earlier in boys than in girls, just as the onset of puberty itself is earlier in girls. The consequence of this sex difference in the appearance of adolescence is that for a time, approximately from the age of 12 to the age of 14½, girls are actually fatter than boys of the same age, while in other respects, as for example in strength and in breathing capacity, the girls come near to, though they do not exceed, the capacity of boys during these years. These bodily changes at adolescence are prominent in every aspect of physical development; the bones not only lengthen and thicken but alter their shapes and their structure. The facial expression changes during this period and the shift in the shape of chest and pelvis, particularly in girls, is marked. There is quite exceptional growth of muscles. There are decided changes in the volume and capacity of the heart. The alteration in the dimensions of the larynx and its vocal cords is responsible for the characteristic mutation of the voice in boys. The brain, while not increasing appreciably in weight, certainly undergoes rather marked alterations in its connective systems, if we may judge from the corresponding alterations in instinctive tendencies, impulses, feelings and emotions and the obviously greater maturity of thought.

While all these physical changes are to be noted in adolescent boys and girls, it remains true that there is considerable unevenness in their appearance when we consider the individual rather than the group. It is agreed that one of the characteristics of the period is this increase in variability; there is more difference between individual and individual during adolescence than during the first 12 years of life, and this is true of all the aspects of development, both physical and mental.

Mental Characteristics.—On the mental side adolescence is characterized by analogous and equally striking alterations. The phenomenon is the correlate of the physical changes of puberty, namely, the emergence and rapid development of sex feelings and impulses, in the widest sense of these terms. Thus, concomitant with the ripening of the sex instinct, appear such psychological manifestations as *showing off,* jealously, heightened consciousness of social relations, deeper and richer appreciation of beauty in all its forms, a wider range of ambitions and ideals, an enlarged mental horizon, new and more vital appreciation of moral and religious relations, a lessening of home ties with a corresponding augmentation of interest in the world’s life outside the familiar circles of the earlier years. Mere maturity would account for a portion of these manifestations, yet psychologists detect the undercurrent of sex in all of them, so that they are to be regarded as primarily due to the irradiation or *sublimation* of the sex impulse.

The more direct expressions of the developing sex impulses are significant sex fearlessness, *showing off,* sudden and strong attractions or repulsions for individuals of the opposite sex, new interest in dress and adornment and numerous vague, though emotional, responses to sex stimuli of all sorts.

For the best physical and mental development it is of the highest importance that these attitudes toward sex should be *normal* and wholesome. No one conversant with the facts doubts that boys and girls who are entering the period of adolescence ought to be sufficiently warned and protected as to keep them from vicious sex practices; it is perhaps less generally understood that there is danger of unwholesome mental attitudes toward sex and that there is corresponding need of guidance here. The forces liberated by the sexual desire can be diverted or *sublimated* in such a way as to provide a tremendous incentive toward sound mental development. The cardinal issue of moral training in adolescence is to divert the energies of youth into the best channels of effort, to replace crude and selfish by refined and unselfish interests; in short, to compass the shift from the natural egoism of childhood to the desired altruism of maturity.
Sex Hygiene.—In this connection much debate has arisen concerning the instruction of adolescents in sex hygiene. The problem is intricate and difficult. Perhaps the best opinion of experts would be that information concerning the elementary facts of sex ought by all means be given to children before the advent of puberty and preferably by their parents; instruction in childhood is easy because self-consciousness has not developed so far; children are naturally curious about these matters; their parents are the natural sources from whose knowledge they can pick information; if unconcerned by their parents they will almost inevitably pick up from their associates misinformation of an appalling character. In addition, adolescent boys and girls ought to know the main facts concerning the physical changes going on in them at puberty, and they ought probably a little later to be given the main facts concerning venereal diseases, though without overstressing the pathological aspects in a lurid way. Instruction in adolescence, in any event, should not be confined to the physiology and pathology of sex, but should include talks on the family, on divorce, on the larger social relations of the individual, all so couched as to appeal to the better emotions and stimulate the adolescent to a broad and wholesome attitude toward the participation which is about to be his in the life of his fellows.

Special Impulses.—Statistics show that adolescence tends to arouse the so-called migratory instinct. Running away from home, yearning for adventure, the Wanderlust appears to be stronger about the years 17 to 19 than at any other period. In boys, especially, this instinct is often seen clearly at work; no other explanation is adequate for the apparently motiveless way in which young boys suddenly strike out for themselves and leave perfectly comfortable homes. Closely akin to this is the desire for activity that figures so prominently in causes of withdrawal from schools. It is written that the secondary attempt should be made in secondary education to supply in connection with the work of the school opportunities for satisfying this impulse to explore, to visit new places, to try new and exciting things; to be something; the history of ideas form incentives to conduct of the most powerful sort, it is clear that parents and teachers must take definite measures to supply material for their formation, to check the wholesome or unworthy, to encourage the wholesome and worthy.

Social Tendencies.—In adolescence all the tendencies that we term social are decidedly intensified. Wanting to be where others are, wanting to be liked by others, wanting to help others, entering seriously into the joys and sorrows of others; these are all manifested in adolescence much more clearly and consistently than in childhood. It is obvious that these tendencies, all of which are instinctive attitudes more or less closely correlated with the sex impulse, have in themselves possibilities both of good or of evil. Parents and teachers must seek to direct these social tendencies so that good associates are preferred, so that the youth seeks the approbation of the best, so that the relations formed between the youth and his fellows are harmonious and not his moral undoing. Naturally, at this age the appeal to social approval is a powerful incentive; the adolescent boy and the adolescent girl will do what will secure the good opinion of their social group when they will be moved by no other motive. Similarly, the tendency during adolescence to form numerous social organizations—boy gangs, secret societies, literary societies, musical societies, sketch clubs, athletic association and the like—demands a reasonable amount of judicious supervision on the part of parents and teachers. Without such supervision there is always danger of moral deterioration. Witness the very serious problem of the high school fraternity and sorority, which has grown to such dimensions and assumed such an aspect that secondary school teachers will at all events be almost entirely in effect in the dark; it is alarming and have persuaded the legislatures of several States to forbid fraternity membership to high-school students under penalty of suspension or expulsion.

Mental Changes.—Religious conversion is essentially an adolescent phenomenon; the great majority of conversions occur during the ages of 15, 16 and 17. Even when the young man or young girl fails to experience the typical conversion of the evangelical sort, he may undergo a form of mental transformation termed a "secular conversion," to turn from selfishness to unselfishness, to reconstruct his thinking so as to give due heed to the rights of others, to be concerned with his own duties. In the later years of adolescence, many young men and women also pass through a period of doubt, of skepticism, often of a serious sort. It is, of course, to be expected that the broadening intellectual horizon shall disclose inconsistencies between the newer views of life and the earlier notions of God, heaven, immortality, the nature of evil, the efficacy of prayer, the possibility of miracles, etc. Whether a different form of instruction in childhood might obviate the necessity of this reconstruction may be debated; in any event, adolescents need and deserve the utmost sympathy from those who are watching over their religious and moral development.

Akin to the growth of religious interests and the widening of social interests is the striking increase during adolescence in the range and variety of ideals; these differ in the two sexes, differ in the poor and the rich, differ with race but in all cases are prone to shift rapidly to change something; the history of ideas form incentives to conduct of the most powerful sort, it is clear that parents and teachers must take definite measures to supply material for their formation, to check the wholesome or unworthy, to encourage the wholesome and worthy.

In the opinions of some psychologist, adolescence is accompanied by impulses which if unchecked, would carry their possessor: "with almost resistless fury toward a life of crime." It is true that there is a sudden increase at this period in the commission of certain types of criminal offense, of which lying stealing and vagabondage are most typical, and that we are prone to believe that all boys must sow their "wild oats." Apparently, the mental tug of adolescence brings it about that certain young men and young women, before they have become "converted," before the have made the adjustment of self to society and taken on the responsible attitude of the adult, do exhibit for a time "streaks" of lawlessness, or rebellion against authority, but it
ADONAI, a-dó'naí, a Hebrew name for the Supreme Being; a plural form of Adon, "lord," connected with a word meaning "lord of the first person. In reading the Scriptures aloud, the Jews pronounce "Adonai" wherever the old name "Jwh" is found in the text; and the name Jehovah has arisen out of the connotations of "Jwh" with the vowel points of Adonai.
ADONIJAH—ADOPTION

ADONIJAH, the fourth son of King David, by Haggith. His claim to the throne was best after Absalom's death, and the chief commander Joab and the high-priest Abiathar supported him; but the captain of the bodyguard, Adi民族, and the high-priest Zadok, the prophet Nathan and Solomon's mother Bathsheba, induced the old King David to make Solomon associate at once. Adonijah fled to the tabernacle for protection; but after the death of David he was slain by order of Solomon on the pretext that his request for a concubine of David's was a claim to the throne.

ADONIS, a-dō-nís, in Greek legend, son of Myrrha, daughter of Cinyras King of Cyprus: born in Arabia. Before the birth of her son she was transformed into the tree which produces the fragrant gum called by her name; this gum did not hinder his being brought into the world in due season. He grew up a model of manly beauty and was passionately beloved by Aphrodite (Venus), who quitted Olympus to dwell with him. Hunting was his favorite pursuit, until, having gone to the chase again, the entreaties of his mistress, he was mortally wounded in the thigh by a wild boar. Venus, coming too late to his rescue, changed his blood into flowers. After death he was said to stand as high in the favor of Persephone (Proserpine) as before in that of Aphrodite; but, the latter being insensible, her rival generously consented that Adonis should spend half the year with his celestial, half with his infernal mistress. This is a highly decorated form; the simpler and older myth seems to have been that Aphrodite and Persephone occupied the beautiful child's possession, and Zeus ordered that he should spend four months with each and four as he chose. The fable has been variously interpreted. The alternate abode of Adonis above and under the earth is typical of the burial of seed, which in due season rises above ground for the propagation of its species. How much of the myth was cause and how much result of the famous Greek woman's festival, the Adonia, cannot be said. This represented the union of Adonis and Aphrodite on one day and the sorrow over his death the other, and the women performed the funeral rites over small images of him; also planting quick-growing herbs like fennel and lettuce in shards filled with earth, and throwing them into springs after the burial. It was a worship of the reproductive principle of plants, which after a short life die and are buried and again spring up; naturally, it was involved with the grossness of phallic worship. The worship of growth—cults tended to be an excuse. The name is Semitic, adon, "lord;"—though of course all the local gods were "adons" of the place,—and the cult was widespread in the east; in Phoenicia the Adon was termed Thammuz, "the hidden." The Greek celebration was probably a結合 of the priests of Aphrodite's courtesans; hence Theocritus' charming Idyl XV shows that in his time at least it was perfectly respectable for decent women to attend.

ADONIS, a genus of plants of the family Ranunculaceae, or crowfoot family. The plants are natives of Europe, and only a single species, A. autumnalis, the "peasant's eye" of the flower-garden, is grown commonly in the United States. It is a low leafy annual with scarlet or crimson flowers, darker in the centre. It is said to have been stained with the blood of Adonis.

ADONI-ZEDEK, a-dō-ní zé-dék, King of Jerusalem at the time of the invasion of Canaan by the Israelites under Joshua. He was the head of an alliance of five kings designing to stop the progress of Joshua's invasion. The kings were defeated and took refuge in a cave. By Joshua's order the mouth of the cave was closed and a guard set until the pursuit was over. The kings were then brought out and made to prostrate themselves, when Joshua and his generals placed their feet upon the necks of the kings in token of triumph. The kings were then executed and their bodies hung on trees until evening when the bodies were taken down and put in the cave which was blocked with stone.

ADOPTIAN CONTROVERSY. The, one which arose in Spain toward the end of the 8th century. Its leaders were Felix, bishop of Urgel, and Elipand, archbishop of Toledo; they modified the doctrine of Nestorius (see Nestorianism) to the opinion that Christ was the Son of God only in his divine nature, and in his human nature only so by adoption. It was hoped that this doctrine would be more acceptable to the Mohammedans than the orthodox view, and a means toward their conversion; and Elipand was a zealous missionary among them. Felix introduced it into Frankish Spain, and Charlemagne called a synod at Regensburg (Ratisbon) in 792 to have him explain and justify it. Instead he renounced it, confirming the renunciation by a solemn oath to Adrian I, to whom the synod sent him; yet on returning to his diocese he taught it as before. Another synod was held at Frankfurt in 794, and the doctrine was formally condemned, nor any of his followers attending. After some controversy a commission of clergy was sent to Spain to put down the heresy. Leidrad, archbishop of Lyons, one of the commission, persuaded Felix to go before a synod at Aix-la-Chapelle in 799 and recant; which after a week's dispute with the great Alcuin he did, and was prevented from further relapse by being kept under surveillance at Lyons for the rest of his life, to 816. Elipand, at Toledo, maintained his Adoptian views despite their ban by the Church; but after his death they were abandoned by practically all. Occasional advocates afterward arose during the Middle Ages, however, and the question has been discussed even in modern times.

ADOPTION, the act of taking a stranger into one's family, as a son or daughter; or the taking of a person, a society, etc., into more intimate relations than formerly with another person or society; or the taking as one's own, with or without acknowledgment, an opinion, plan, etc., originating with another; also the selecting one from several courses open to a person's choice.
In law, both ancient and modern, the act of taking a stranger into one's family constituted the person so adopted one's heir to all intents and purposes. The practice was common among the Greeks and Romans, and is still in use among some modern nations. A practice which so materially affects the succession of property and the rights of natural heirs is a very important one. It is not recognized by the common law of England, and exists only in the United States by special statute. Consequently, few of the States have engrafted it upon their systems of jurisprudence. But among many of the Continental nations it has been practised from the remotest antiquity. The effect of adoption was to cast the succession on the adopted in case the adopting father died intestate.

The statute in force in the State of Michigan is substantially similar to other statutes in the various States upon the subject. The Michigan statute provides, among other things, that the person so adopting such child shall thereupon stand in the place of a parent or parents to such “child-in-law,” and be liable to all the duties, and entitled to all of the rights, of parents; and such child shall thereupon become an heir of such persons, the same as if he or she were in fact the child of such person or persons.

Adoption by marriage is the placing the children of a former marriage on the same footing, with regard to inheritance, etc., as those of the present marriage.

Adoption by testament is the appointing of a person one's heir on condition of his assuming the name, arms, etc., of his benefactor.

Adoption by hair was performed by cutting off the hair of the person adopted and giving it to the adoptive father.

Adoption by arms was the presentation of arms by a prince to a brave man. These the recipient was expected to use for the protection of his benefactor.

In heraldry, arms of adoption are the heraldic arms received when the last representative of an expiring aristocratic family adopts a stranger to assume his armorial bearings and inherit his estates. The recipient may obtain permission from Parliament to take the name of his benefactor, either appended to, or substituted for, his own.

In Scripture and theology, the act of admitting one into the family of God, or the state of being so admitted. The previous position of the person adopted in this manner was that of a “servant,” now he is a “son,” an “heir of God,” and a “joint heir with Christ.”

In ecclesiastical language, adoption by baptism is the act of becoming godfather or godmother to a child about to be baptized. Unlike real adoption, however, this does not constitute the child heir to its spiritual father or mother.

ADORATION, in unsealed modern usage, a spiritual homage to God; but originally an act to express obedience and reverence performed before the images of the gods. Among the Romans it was performed by raising the hand to the mouth, kissing it, and then waving it in the face of the image; the devotee had his head covered except before Saturn and Hercules, and after the act turned himself around from left to right. Sometimes he kissed the feet or knees of the images. This homage was afterward transferred to the emperors, by bowing or kneeling, laying hold of the imperial robe, and then pressing the hand to the lips. The Oriental methods were of course still more abject,—bending the knee, falling on the face, striking the earth with the forehead and kissing the ground or floor. Alexander borrowed this from the Persians and made it a feature of his court; the rough Macedonian Cassander burst into a roar of laughter when he saw the Persian grandees performing this kotour (the Chinese term for the same act) before Alexander, who was so enraged that he seized him by his long hair and dashed his head against the wall. But the Greeks considered it impious and degrading, and the best of them would not bend it; Conon refused it to Artaxerxes, and Callisthenes to Alexander. The abject degradation which the mediaeval far-Easter rulers exacted from foreign traders, by submitting to which the English would not—crawling on the face from the door to the monarch's seat, licking up the dust as they went, till the victim was often unable to speak when he reached it, and could only gasp with his mouth full of dirt,—are well known. Milder forms in modern times, hardly thought degrading even by the sternest democrat, are kneeling and kissing the monarch's hand; and the similar homages of lovers have never been considered so. The ceremony of kissing the cross embroidered on the Pope's slipper is a like form, said to have been borrowed from a similar ceremony introduced by the Emperor Diocletian, who greatly extended court ceremonial. The original signification of the word as an act and not an emotion is preserved in the marriage service of the English and Protestant Episcopal Churches, “with my body I thee worship.” In the Roman Catholic Church, also, a distinction is made between latrina, the worship due to God alone, and dulce the veneration paid to the Saints, and hyperdulce, that accorded to the Virgin.

ADOR, a river of southern France, having its source in the mountains of the Tournel, in the department of Hautes-Pyrénées. Its course is first north, then west, southwest and south southwest, passing St. Séver and Dax, to the former of which it is navigable, and falling into the sea a little below Bayonne, flowing through many exceedingly fertile valleys. Its whole length is estimated at about 200 miles. The current is rapid, and sometimes serious inundations are caused by the melting of the snows on the slopes of the Pyrenees. At the mouth of the river there is a shifting bar.

ADOWA, Adou, ad'ó-a, Abyssinia, capital of Tigré province; on the left bank of the Hassan, a tributary of the Tamar, 2,400 feet above the sea, about 10 miles east of Axum. It is the chief commercial depot on the great caravan route from Massowah to Gondar, about 110 miles from the former. Though it still carries on some trade and has manufactures of cotton cloths, iron and brass, on the Abyssinian civil wars it has greatly declined from its former prosperity and presents a rather miserable appearance. The inhabitants, numbering about 5,000, are considered the most civilized of the Abyssinians. It was here that
ADRA — ADRENALS

the Italian General Baratieri was defeated by the Negus Menelik, 1 March 1896, when 7,000 men, 250 officers and the whole artillery were lost.

ADRA, å'drâ, (the ancient AĐERA), seaport of southern Spain, in the province of Almeria, 29 miles west southwest from the town of that name, near the mouth of the Adra, on an eminence facing the Mediterranean. The inhabitants are employed in agriculture, fishing, distilling brandy and manufacturing lead from the ore produced from the extensive mines in the neighborhood. Pop. about 12,000.

ADRAR', å'drâr', Sahara, a district peopled by Berbers, possessing camels, sheep and oxen and cultivating dates, wheat, barley and melons. Chief towns, Wadan, pop. 4,000, and Shungit, which has inexhaustible beds of rock-salt. The region embraces about 30,000 square miles and since 1892 is a part of the French possessions.

ADRASTUS, in Greek legend, King of Argos, son of Talaus and Lysimache. Poly- nices, being banished from Thebes by his brother Eteocles, fled to Argos, where he married Argia, daughter of Adrastus. The King assisted his son-in-law, and marched against Thebes with an army led by seven of his most famous generals. All perished in the war except Adrastus, who, with a few men saved from slaughter, fled to Athens and implored the aid of Theseus against the Thebans, who opposed the burying of the Argives fallen in battle. Theseus went to his assistance and was victorious. In a later story Adrastus after a long reign died from grief occasioned by the death of his son Ægialeus. He was worshiped at Sicyon, Megara and Athens, perhaps also at Argos and the Troad. See ARGOS; THEBES.

ADRENALS, also known as suprarenal glands. Paired structures, which in the human animal are located in the kidney fat just above the kidney. They have no physiological relation with that organ. They are a vital necessity to life and removal of the glands by accident, experiment or disease causes almost instant death. Disorders of the glands are numerous and of enormous importance to the well being of the body since by their internal secretion, the hormone, known as adrenalin, the blood pressure of the body is regulated. They belong to a group of structures, known as the glands of internal secretion, which are a part of the vegetative nervous system of the body, and the action of the hormone is chiefly made effective through the sympathetic fibres of this vegetative nervous system.

The suprarenal glands are made up largely of chromaffine tissue, which like the cells of the sympathetic ganglia is derived from neuroblasts of the central nervous system. The cortex of the suprarenals is made up of entirely different types of cells. Chromaffine cells are found also in the sympathetic para-ganglia of the solar plexus, Zuckerkandl's aortic ganglia, the cardiac paraganglia, the coccycgeal and cardiac ganglia of Luschka, and the mesoblastic paraganglia. The tissues themselves are richly supplied with sympathetic nerve fibres.

The chromaffine tissues produce a true internal secretion adrenalin, whose chemical composition is known: ortho-dioxy-phenyl-ethanol-methylamine.

\[

\text{HO-} & \quad \text{C-} \\
\text{C-H} & \quad \text{H}
\end{align*}
\]

Its nearest relative is tyrosin, a well-known product of protein decomposition. The chief action of adrenalin is through the sympathetic nervous fibres increasing their reactive capacity, or sensitizing them as it were. The routine function of the chromaffine tissue is to react to metabolic stimuli largely in response to desire and fear. Their emergency function, as Cannon has termed it, is to provide the necessary over-response to emotional hyperactivity, i.e., to increased or diminished desire and fear — which, as their correlate, love and hate, are the ultimate expressions in the symbolic sphere of what are instinctively known as useful or harmful agencies to the organism and to the race. This over- or under-response brings about, through widespread vegetative nervous system activities, including those upon other endocric glands, the approximately necessary metabolic adjustment. This takes place chiefly through the regulation of the blood volume and of the organic and inorganic constituents of its plasma. Adrenalin itself is present in the plasma in proportions of 1 to 20,000,000. Notwithstanding this extreme dilution it acts upon unstripped muscle fibre and on sympathetic receptors. Adrenalin then is a typical product which demonstrates the metabolic regulation mechanisms of the vegetative nervous system. In addition to this broad function of keeping the sympathetic nerve fibres in adjustment it has certain specific functions, over- or under-activity of which give rise to a typical hyperadrenalemia and to hypoadrenalemia. The latter syndrome, when well developed, is known as Addison's disease.

Furthermore, very minute amounts produce results antagonistic to those from large doses. This bears upon the facts known concerning the antagonisms of sympathetic and autonomic impulses. This idea should prove of service in the entire range of opotherapy in calling attention to the results obtained by large and by small doses.

Hyopoadrenalemia. — The most acute form which is present in complete or great loss to the suprarenals is rare. Pende, in 'Patologia del apparato surrenale' (Milan 1909), has described six types to which he gives the names impromptu death of suprarenal origin, pseudo-peritonitc type, choral-like or gastro-intestinal adrenalemia, apoplecticiform type, meningoencephalitic type and myocardial type. In the first form individuals suddenly die without warning, without symptoms save perhaps an epileptic form or acute dyspneic anginas. Caseous degeneration of the suprarenals has been observed. The pseudoperitonitc forms resemble an inexplicable attack of acute peritonitis with death. The gastro-intestinal form behaves
like an acute poisoning. The apoplectic form resembles a cerebral hemorrhage, but autopsia has shown to more cerebral total involvement. As early as 1855 this disorder was first described by Thomas Addison whose outline practically covered the essential symptomatology. It is a disorder of adult life, 30 to 40 years. Its chief features are a gradually developing asthenia, with arterial hypotension. There is morning nausea or vomiting, lumbar pains, an advancing yellowish pigmentation of the skin and mucous membranes, amyatrophy, depression, unwillingness to do anything, with episodic occurrence of myoclonic, tetanic or epileptiform convulsions with periodic palsy, fusional states, delirium, chronic paranoid ideas, coma, death. The chief lesion found is tuberculosis of the medulla of the suprarenal gland. The more complete symptom picture may be consulted in works on general medicine.

Partial Hypoadrenaleanias.—These have been termed the abortive or latent types of Addison's disease. The melanodermia is absent, but the other symptoms noted are observed. Constitutional hypoadrenalemic states no doubt are very numerous and show themselves as rare and obscure forms of lowered vascular tonus, cardiac instability, muscular asthenia, viscera and ligamentous ptoses. These are often correlated with a chronic sclerosing adrenal.

Hyperadrenalea.—Several types are known, the most striking of which are: (a) Genito-adrenal syndrome of pseudohemaphroditism, (b) virilism, (c) precocious macrogenitosomia. The fact that these syndromes occur only in women, as well as the pathological data, point to a simultaneously invoked ovarian disturbance. These are feminine hemaphroditic forms externally with virile secondary male sexual characters. The earliest report was by Creech in 1895. Gibney described a woman of 52, taken to be a man. She had a large penis-like clitoris with hypospadias, no scrotum nor testicles, a uterus with two tubes, two ovaries without trace of corpora lutea, an enlarged and voluminous suprarenal. She had been markedly asthenic, dying in a syncopal attack with vomiting and persistent diarrhoea. Other cases show other combinations such as amenorrhoea, gynecomastia, adipoxy, hypertrophied clitoris, hypertrichosis, masculine voice, muscular activity, nervous and agitated, even overactive. Others only show continued hypertension and secondary arteriosclerosis possibly with glycosuria. Some patients pass through a nervous agitated crisis with all signs of marked hypertension, approaching a manic episode.

The virile type are made up of those intensely masculine females with traces of beards and often with marked homosexual traits.

The third type consists of the "infant hercules" anomalies, who at the age of from four to ten years develop genital hair, beards, general hypertrichosis and markedly older skeletons. Sometimes the intelligence is precocious, again they are imbeciles.

Therapy.—Polyglanular opherty with careful analysis of each type may give relief in certain cases. The indications are slowly crystallizing but cannot be ever be made to Consult Jelliffe and White, 'Diseases of the Nervous System' (1917); Sergent, 'Les Glandes Surrénales' (1917); Pende, 'Pato- logia dell apparato surrenale' (1902); Faita, 'The Dullness Glands' (1915); Gley, 'The Internal Secretions' (1917).

SMITHELY JELLIFFE.

ADRETS, Baron de, d'a'z'dr'a, Francis de Beaumont: b. Dauphiné 1513; d. 1587; a violent French Huguenot, who distinguished himself by many daring exploits as well as cruelties. From 1562 on he made himself noted for a ferocity matching his opponents, but seemingly from no religious motive. He subsequently became a Catholic, but died as he had lived, in general detestation. At some places he obliged his prisoners to throw themselves from the battlements upon the pikes of his soldiers. Reproaching one for retreating twice from the fatal leap, "Sir," replied the man, "I defy you, with all your bravery, to take it in three." This keen rejoinder saved his life.

ADRIA, a'dr-ä, Italy, in the province of Rovigo, between the Po and Adige, is one of the oldest cities in Europe, having been founded by the Etruscans. So late as the 12th century A.D. it was a flourishing harbor on the Adriatic Sea, to which it gave name; but by the continual deposition of alluvium on the east coast of Italy it has been gradually separated from the sea, from which it is now 15 miles distant. It still retains several interesting remains of Etruscan and Roman antiquity, with a fine cathedral. It has a considerable trade in cattle, grain and wine, silk, linen, leather and pottery. Pop. about 18,000.

ADRIA, an abbreviated name of the Adriatic Sea. It is used by Milton in 'Paradise Lost.'

ADRIAN, Emperor. See HADRIAN.

ADRIAN I, Pope, b. Rome; succeeded Stephen III in 772; d. 795. Like his predecessor, he had to struggle against the power of the Longobards, who had invaded the Exarchate and other provinces bestowed by Pepin, King of the Franks, on the Roman see. Adrian applied to Charlemagne for assistance against Desiderius, King of the Longobards, Charlemagne crossed the Alps, defeated Desiderius and overthrew the Longobard kingdom in 774; he then went to Rome, where Adrian acknowledged him as King of Italy, and the latter renewed Pepin's grant. Charle- magne paid another visit to Adrian at Rome in 787, when his son Pepin was christened by the Pope. In 787 the 7th General Council of the Church was held at Nicaea. Adrian died after a pontificate of nearly 24 years. He was a man of talent and dexterity; he succeeded in gaining and preserving the friendship of the greatest sovereign of his time and saved Rome from the last barbarian invaders of the Western Empire. He was the first Pope to change his name on election.

ADRIAN II: b. Rome; succeeded Nicholas I 867; d. 872. He had been married and had a daughter by his wife Stephania, from whom he afterward separated in order to live in
celibacy. During his pontificate Photius, Patriarch of Constantinople, withdrew from the Church of Rome; from which time dates the schism between the Greek and Latin Churches. He was succeeded by John VIII.

ADRIAN III: b. Rome; succeeded Marinus 884 and died the following year.

ADRIAN IV, the only Englishman ever raised to the papacy; succeeded Anastasius IV, 1 May 1159. He was Nicholas Breakspear, and for some time filled a mean situation in the monastery of St. Albans. Being refused the habit in that house, he went to France and became a clerk in the monastery of St. Rufus, of which he was afterward chosen abbot. Eugenius III created him cardinal in 1146, and in 1148 made him legate to Denmark and Norway, which he converted to Christianity. As Pope he granted to Henry II a bull for the conquest of Ireland. In 1155 he excommunicated the King of Sicily; and about the same time the Emperor Frederick II, meeting him on a journey, held his stirrup while he mounted his horse. Adrian took the Emperor with him and consecrated him King of the Romans in the Church. The next year the King of Sicily submitted and was absolved. His term was stormy; the Romans, influenced by Arnold of Brescia (whom he put to death), opposed him; his high claims for the papacy opened the long struggle with the Hohenstaufen house; and he was about to excommunicate Frederick II when he died. He was succeeded by Alexander III.

ADRIAN V, a Genoese, succeeded Innocent in 1276, and died five weeks after his election. He was succeeded by John XX.

ADRIAN VI, succeeded Leo X 1522; d. 1523. He was born at Utrecht, of an obscure family, advanced himself by his talents to the post of vice-chancellor of the University of Louvain. Ferdinand of Spain gave him the bishopric of Tortosa. After Ferdinand's death he was protector of Spain with Cardinal Wolmernes. He was elected Pope chiefly through the influence of Charles V, whose authority was then spread over Italy. He was succeeded by Clement VII.

ADRIAN, Mich., city and county-seat of Lenawee County; on the Kaisin River, and on the N. Y. C., the Wabash and the Detroit, T. and I. railroads, 33 miles west of Toledo, Ohio, and 60 miles southwest of Detroit. It is situated in the midst of a prosperous agricultural section and is fast becoming an important manufacturing centre owing to its favorable location and railway advantages. Among the chief industries are wire-fence plants, condensed milk plant, steel and iron casting foundry; and manufactories of cotton knitted underwear, screens for doors and windows, electrical goods, organs, washtubs, wash-rockers, razor strops, concrete products, steel posts and rural mail boxes, baskets, gloves, mittens and toothpicks. Tomato preserving and tomato seed growing are also important industries, with headquarters at Adrian. The United States Bureau of Census lists manufacturing establishments on a factory basis employing 1,506 persons of whom 1,256 were wage earners, and a combined capital of $5,032,000. The annual value of the products amounts to $5,442,000. There are five banks with a combined capital and earnings of $737,298 and deposits of $4,805,834. The city has a fine system of public schools with 2,500 pupils and is the seat of Adrian College (q.v.); St. Joseph's Academy for Girls (Catholic) with 500 pupils; a good business college, and the State Industrial Home for Girls. There are many fine churches, a Y. M. C. A. building, a new post office, a public library with 23,264 volumes. Streets shaded with maple trees and lighted with electricity and handsome private residences make Adrian an attractive home city. It was founded in 1829 by Addison J. Comstock, incorporated as a village in 1828 and chartered as a city in 1853. The government is the commission form with a mayor and two commissioners. The city has a good sewerage system, water works, public steam heating and an electric street car line, and is connected by an interurban line with Toledo. Pop. (1910) 10,763; (1917) 12,000.

ADRIAN, Bull of (1156), issued by Pope Adrian IV (q.v.), granting the sovereignty of Ireland to Henry II in return for his undertaking to support the papal authority and to pay Peter's Pence.

AD VALOREM DUTY, a tax or duty the amount of which is not fixed, but is calculated at a rate of so much per cent on the value of the article imported.

ADRIAN COLLEGE, Michigan, located at Adrian, county-seat of Lenawee County, a Methodist Protestant coeducational institution, one of the oldest in the United States, organized at Leoni, Mich., in 1852, and in 1859 transferred under a new charter to Adrian. The college grounds cover 22 acres with five large collegiate buildings on the campus. The departments of instruction comprise: College of literature, science and arts; school of theology; commercial school; school of domestic science; school of fine arts; conservatory of music. The college library contains over 10,000 valuable reference works. The conservatory of music is equipped with a superior modern $20,000 four-manual pipe organ. From the time of its organization the college has maintained a reputation for thorough work as one of the best educational institutions in the state, and its facilities continually improved and kept abreast of the times, presents advantages for securing thorough scholarship, superior to those of any previous period. Special advantages are offered to the children of Methodist Protestant ministers and to candidates for the Methodist Protestant ministry. The average annual enrollment of students is over 200.

ADRIANO DE CASTELLO (ADRIANO DI CASTELLO, a'dré-ănô dê kás-tel’ô), Italian cardinal and scholar; b. Corneto, Tuscany, c. 1460; d. 1523. He was educated at the University of Padua by Innocent VIII to England, and to Scotland and reconciled James III to his subjects; after that monarch's death at Sauchieburn he remained in England, and obtained a prebend and rectory from Henry VII. In 1492 he returned to Rome and became prothonotary or secretary to Alexander VI (Borgia), and finally cardinal just before Alexander's death in 1503. The story that Alexander fell a victim to his own attempt to poison Adrian in order to inherit his great fortune is
scouted by recent historians. In 1502, in his absence, Henry VII made him bishop of Hereford, and in 1505 bishop of Bath and Wells. In 1517 he was involved in the plot of Cardinal Petrucci, De Sauli and Riario to poison Leo X, and was absolved on condition of paying 25,000 ducats, though deprived of his cardinalate and English dignities. He fled from Rome, however, lived in retirement till late in 1521, when he died in Venice, and was suddenly on his way back to Rome, there being a suspicion that he was murdered by a servant. He is honorably remembered as one of the first who sought to rescue Latin from its mediæval corruptions and restore it to purity. He wrote a religious treatise 'De Vera Philosophia' (The True Philosophy, 1507, printed Cologne 1548); 'De Sermone Latino et Modo Latine Loquendi' (The Latin Speech and Mode of Speaking Latin, a scholarly work published at Rome in 1515, and repeatedly since).

ADRIANOPLE ('Hadrian's city'), Turkey: its third city in size, next after Constantinople and Salonica; 137 miles west northwest of Constantinople, connected by rail; near the western end of the great Thracian coast-plain, with the Rhodope mountains; the confluence of the large Martza (ancient Hebrus) which drains the centre of South Bulgaria, the Tuna from the north, and the Arda from the west, all navigable. This position and the conglomeration of several trade routes have made it from very old times a place of great importance. It was an antique Thracian city, rebuilt by the Emperor Hadrian, seized by the Turks under Amurath (Murad) I in 1361, and the residence of the Sultan thence till the capture of Constantinople in 1453. Since the Russo-Turkish war of 1877-78 and the separation of Bulgaria, it has lost nearly half its population and a large part of its trade. The old wall that once surrounded it, now existing only in a few fragments, has been replaced by a circle of modern forts. It has a palace and two fine bazaars, besides schools and mosques. Pop. about 83,000, half Turks and the remainder Bulgarians, Greeks, Armenians and Jews.

ADRIATIC SEA, a'dri-ak'tik, or GULF OF VENICE (ancient Mare Adriaticum), an arm of the Mediterranean, stretching in a northwestern direction from the Straits of Otranto, between the east coast of the Italian Peninsula, and the west coasts of Turkey, Dalmatia and Illyria; length, about 480 miles; average breadth, about 100 miles; area, estimated at about 50,000 square miles. Its depth in the north, between Istria and Venice, is only from 12 to 20 fathoms, but increases in proceeding south to 100 fathoms near its centre, and to 500 fathoms between its centre and its entrance. At the straits between Otranto and Valona its depth does not exceed 350 fathoms, but increases very rapidly toward the Ionian Sea. Its opposite shores present a striking contrast, the east being generally bold and rocky, lined with islands and furnished with good harbors, but thinly peopled and comparatively sterile; while the west are low, shallow, marshy and ill provided with harbors, though generally populous and fertile. The Adriatic is evidently a continuation of the longitudinal valley of the Po, forming a long and narrow trough between the parallel ranges of the Apennines and the mountains of Illyria. The rivers which it receives, particularly the Po, its principal feeder, have produced, and are still producing, great changes in its basin by their alluvial deposits. Hence Adria, between the Po and the Adige, which gives the sea its name, though once a flourishing seaport, is now 15 miles inland. The principal trading ports on the Italian side are Brindisi, Bari, Ancona and Venice; on the opposite side, Ragusa, Fiume, Pirano, Pola
and Trieste. From July 1915, the Adriatic Sea was a scene of great naval activity between Italy and Austria. See War, European.

ADSORPTION (a variation of the word "absorption"). The condensation of a gas or vapor upon the surface of a solid. The fact that solid bodies are capable of condensing upon their surfaces air films or gas films of considerable density was probably first forced upon the attention of the physicist by the difficulty of obtaining a permanently good vacuum. Thus it was found that a glass globe (for example) might be highly exhausted, and yet after a time the vacuum would be found to be materially reduced, even when it was apparently impossible that any air should have leaked in from without. It is now known that unless special pains are taken to prevent it, a film of air remains condensed against the surface of the glass, even when the vacuum through the general bulk of the globe is very high; and air molecules from this film are gradually given off until the vacuum becomes much less perfect than it was at first. To prevent this action it is customary to heat the vessel that is being exhausted, as the air film is largely driven off from the walls of the vessel when they are heated. See Vacuum.

The condensation of gaseous films upon the surfaces of solids is undoubtedly due to the molecular attraction exerted by the solid upon the gas. This molecular attraction is insensible at distances that are easily measurable, but it may be very great at points sufficiently near to the surface of the solid. The expression "sensible molecular attraction," which is in use among physicists, is indefinite, and no very precise statement can be made with regard to the limiting distance beyond which the attraction is not sensible; but from the investigations of Quincke, Plateau, Maxwell, Kelvin and others, we may infer, in a general way, that molecular attraction is not sensible at a greater distance than about 1-200,000th of an inch. Hence it is safe to say that this is the maximum thickness that the gas film condensed on the solid surface can have.

Concerning the condition of the gas in the film we can only say that where it is in immediate contact with the solid it probably has a very great density, this density rapidly falling off as we pass away from the solid. Under ordinary conditions of temperature the air film condensed against a solid cannot actually be in the liquid state, because it is not possible for air to exist in this state at any temperature higher than 220° below zero F. See Critical Point.

It is well known that a solid body appears to weigh less when it has been recently heated, or is still hot, than it does when it has been allowed to stand for some time in contact with the air at ordinary temperatures. This phenomenon is apparently due to a considerable extent, to variations in the thickness of the film of air and moisture that the body condenses upon its surface. In accurate thermometry (see Thermometer), where the gas thermometer is used at a standard, great pains are taken, in filling the thermometer bulb with gas, to avoid the contamination of the thermometric gas by moisture condensed upon the surface of the bulb; the bulb being repeatedly exhausted, heated and refilled, until there is no longer the smallest chance of an appreciable part of the original surface film remaining. The phenomena of adsorption have not yet been fully studied.

ADULLAM, Palestine, a town in the Shephelah or southwestern Judean coast-land; the centre of a Canaanitish clan later fused with Judahite Hebrews, but not till after David's time, when it was still "outside Judah," for which reason he and his 400 freebooters took refuge in its stronghold (not "cave," a misreading which has led to many fruitless identifications of site and a familiar English nickname—see below) when outlawed by Saul (1 Sam. xxii). He also dwelt there when at war with the Philistines. Rehoobam fortified it. In Judas Maccabaeus' time it was in "Idumæa," as he stopped there when he raided that territory.

ADULLAMITES, in English history, the Liberals who left their party in 1856 and joined the Conservatives, to oppose extension of the franchise by Mr. Gladstone and Earl Russell. John Bright in a speech compared them to the outlaws in the Cave of Adullam; to which Lord Elcho retorted that the band was hourly increasing, and would develop from the tyranny of Saul (Gladstone) and his armorbearer (Bright). The group was also known as "The Cave."

ADULT EDUCATION. See Education, Adult.

ADULTERATION ("making otherwise"), in its legal sense the deceiving of buyers of goods as to their quality by secretly adding or taking away basic constituents. The element of deception must be present; only selling any mixture, however poor, is not adulteration legally or morally. In current usage the term is restricted to food products, drugs and dyestuffs. The adulteration of coinage is termed "counterfeiting" (q.v.) that of unsound meat, fish, etc., "doctoring," a term which, with "sophistication," is also used for wines and liquors. Adulterated woolen fabrics are colloquially but not always properly known as "shoddy." The object of gain more profit: with costly wares, either by diluting them with cheaper ones, or by removing some valuable element for separate sale; with cheap ones, to make them look like or have the exterior of costlier ones; with spoiled or damaged ones, to make them appear sound. Most adulterations are not directly injurious to health, the public being cheated rather than poisoned, and it is to some extent a copartner in the deception, as the cost of wholly pure articles would greatly curtail buying. On the other hand, it is often forced into such copartner by inability to find or know the good when willing to pay for it, and wastes money by paying for a pure article and receiving an adulterated one. And as the reduction of the nutritive value of food is itself a great evil; as the extent or harmfulness of adulterations cannot be known offhand and tends always to grow worse as the maker grows greedier and his character deteriorates from losing his self-respect (first stage of social evil); as honest dealers are not only prejudiced by unfair competition, and suspected of fraud when qualities are poor, but often driven into the
same course in self-defense; and as hasty additions of cheap materials are always hable to come from diseased sources and menace public safety—modern legislation constantly broadens its scope in dealing with this offense alike from a pecuniary, a sanitary and a moral standpoint. Ignorance is not considered a valid excuse to a dealer who sells adulterated wares under the ordinary trade name; the offense is a fraud at common law, and he may be compelled to take back the goods or pay damages.

The history of adulteration would probably be coexistent with that of trade. We know that it was practised by the Greeks and Romans, and the comic dramatists have diverging references to the "doctoring" of stale fish. English statutes exist from 1260 with penalties for debasing beer or wine and selling inferior bread or meat, while tea (see below) had later a special statute; and the law-makers have never ceased struggling with the problem. But the first great general agitation was in 1851, when the London Lancet aroused the public by a special investigation, publishing analyses and names of dealers; and the first commission was appointed. The first general adulteration act was passed in 1860.

The chief articles subject to adulteration have been, first of course, the great staples of life: flour and bread, milk, butter and cheese, with beer, wines, liquors and tobacco, staple in use if not needed; relishes and seasonings, as sugar, honey, preserves, vinegar, pickles, condiments and spices; oil and lard; tea, coffee, cocoa and chocolate; confectionery; drugs and dyestuffs. The selection and extent of adulterations vary indefinitely with place and time; as cost or popular wealth differs in different countries and epochs, adulterations common in one place or generation are almost unknown in another.

Beer.—The objects of its adulteration are three: To give artificial strength to weak beer, to disguise the badness of poor or spoiled beer and to keep it from spoiling. The most common adulteration is the substitution of quassia, gentian, aloes or other bitter extract for the bitter principle of hops. Capsicum is added to give pungency and flaxseed and glucose to give the body which should be derived from malt. Carbonic acid gas is forced into imitation beer to give it "life." Alum, potash, cream of tartar and salt, used to make beer keep, are not regarded as deleterious adulterants. Salicylic acid is the preservative most commonly used, and benzoic acid and sulphates perhaps as frequently. Formaldehyde is also a frequent addition. A common practice is to fumigate beer casks with sulphuric acid gas and the beer afterward put into the casks taken up enough of the acid to preserve it. Wild cherries, various herbs and foliage, etc., are employed to improve a poor flavor. They are cheap but not injurious.

Butter.—A formidable list may be made of butter adulterants at different times and places,—tallow, lard, wort, spirit, glycerin, alum and borax, burnt sugar, salicylic acid, etc., but for practical purposes they may be reduced to water, buttermilk, cheese, salt and oleomargarine (q.v.) as increasers of bulk, with arsenic, aniline yellow, etc., to improve the color. The latter is hardly adulteration either in bad intent or bad effect; the public universally connects a yellow tint with richness in cream,—quite irrationally, as the milk of many cows gives butter as white as if made from perfect quality and taste,—and the harmless pigments merely remove incorrect prejudices. The first four others are equally innocuous (save that buttermilk makes it grow rancid more quickly; it is usually careless or incompetent rather than fraud) and are mere dilutions. In normal butter, water should not exceed 12 per cent and salt 5 per cent. By adding certain chemicals to butter and churning them together the butter may be made to take up from 25 to 35 per cent of water and 10 per cent of salt. Oleomargarine is not even an inferior product in any respect; its nutritive value equals that of butter and it keeps better; and the severity of the laws regulating its manufacture and inspection guarantee its quality better than that of any other manufactured article. Its use as an adulterant is to be condemned chiefly on the ground of fraud in selling oleomargarine at butter prices. Glucose is sometimes found as an adulteration in butter to the amount of 10 per cent. The chemical composition was passed in 1860. Adulterants in butter are borax and boric acid chiefly and rarely formaldehyde and salicylic and sulphurous acids.

Cheese.—English cheeses are practically not adulterated. Fancy foreign cheeses, as the Swiss, etc., often contain coloring matter and potato meal. American cheese is by law permitted to contain coloring matter and is required to contain in its water-free substance not less than 50 per cent of milk fat. However, it is not forbidden to sell cheese with less than this proportion of milk fat provided it is sold as "skimmed cheese," a provision too commonly ignored. A frequent deception practiced is the substitution of some cheap fat in cheese for the natural butter fat of the milk skimmed before being made into cheese.

Cocoa and Chocolate.—The chief adulterants are starch and sugar; but they have also contained wheat and potato flour, sawdust, oils and fats and other things, with iron rust as coloring matter. Ground cocoa-shell and arrowroot are common adulterants. The tests are for theobromine (the characteristic principle of the cacao bean), fat, starch, inorganic matter, etc.

Coffee.—Its usual adulterations are seeds (roasted peas, beans, etc.) or roots (chicory, dandelion, carrots, turnips, parsnips, etc.) with caramel to color their gray tint. All these are mere diluents; though there are some who actually prefer an admixture of chicory for its flavor though it gives black, bitter and muddy grounds. It and the roots may be easily detected by putting a little of the sample into a glass of water; each bit of chicory or other root will soon the centre of a yellowish-brown cloud which will rapidly spread till the water is all colored. A more serious adulteration is made by adding coffee pellets,—imitation coffee beans made of roasted wheat, peas, and molasses—to bean coffee. These are not discovered by examination; the purchaser is only aware when ground disappear in the dust and chaff. Coloring matters are frequently used to make an inferior grade of raw coffee resemble a high-priced grade. There are also chemical tests for both tea and coffee, by determining
ADULTERATION

the amount of theine or caffeine, the percentage of matter soluble in water, treatment with hot mineral acids which increase the sugar in coffee, and adhesives in cacao, etc. The microscope, however, is the most effective detector of adulterations in coffee.

Confectionery.—The extreme cheapness of sugar has practically put an end to the adulteration of all but the very poorest grades of candiders and closely confined to the harmless terra alba, or pipe-clay, and paraffin wax. The term "sugar," however, in this use of it includes glucose or corn syrup, permitted by law to be used in food products. A wide range of coal-tar colors are used but in such minute quantities as to be considered harmless.

Distilled Liquors.—Whisky, brandy and rum are often purely factitious, being made from caramel and dilute alcohol and given the characteristic flavors by ethers of various sorts and fusel oil (often left in genuine whisky, etc., from carelessness or grudging the cost of purification, and recognizable by its nauseous smell when a little of it is evaporated in the hand). The more common adulterants are raspberry syrup, prune juice, ceylon sugar, caramel, cayenne pepper and "cognac oil" (made from cocoanuts) for flavoring.

Drugs.—The adulteration in each case is special, with some article looking like the genuine but inert. This, of course, potential manslaughter wholesale, as each prescription made from such materials might cost a life. Unfortunately, a large part of the drugs are imported and the fraud is probably committed before they come to this country at all. Many of the adulterations of drugs, however, must be considered accidental; they consist of dirt upon roots insufficiently cleaned and twigs and stems included with valuable leaves and berries. There are also the more serious deteriorations from age or careless handling, which amount practically to adulteration. Among this latter class are especially articles in which the valued ingredients are essential oils, as in cinnamon, cloves, peppermint leaves, lavender flowers, etc. When not intelligently cared for these articles lose their active principle by evaporation.

In the line of chemicals many of these accidental adulterations exist and the labelling of such substances "C.P." (chemically pure) should never be taken at its face value but proved by rigid tests. At the same time it must be borne in mind that a failure to meet all the requirements of an arbitrary standard is not evidence of adulteration or deterioration. Standards are generally established with but one or two objects primarily in view and a conditioned chemical may be entirely suited to another use.

Among intentional adulterations in this class may be mentioned as examples: Alcohol with wood alcohol; beeswax, with starch and cerasin artificially colored; geranium oil, with gingergrass oil; glycerine, with glucose and cane sugar; linseed oil, with mineral oils; linseed meal, deprived of its natural oil which is "restored" with cheaper oils; phencatine, with the color artificial; Seltzer water; Epsom and Glauber's salts; soaps, with starch, flour, mineral oils and excess of water; tea sweetenings (for the manufacture of caffeine), with many sorts of leaves and dirt; turpentine, with kerosene, etc., etc. Many drugs in leaf and root form have had their active principles removed by distillation or solution and some powdered drugs show an admixture with flaxseed meal and bread, etc. The microscopic, however, is the most effective detector of adulterations in coffee.

Dyestuffs.—These are very variously adulterated with cheaper dyes, determinable, if at all, by expert chemical examination.

Flour and Bread.—Flour is not much adulterated in the United States, though it is in Europe, while the chief admixture is ground gypsum or other minerals, which can be detected with the microscope; diluents but harmless. Wheat flour is too often adulterated with corn, rye flour with both corn and low grade wheat and buckwheat flour with all three. The chief illegitimate additions to bread are alum and sulphate of copper, to whiten it or correct savoriness. Alum in baking-powder is not thought objectionable, the heat of baking converting the mixture into insoluble aluminium phosphate; and by itself its chief harm is in disguising any savoriness of the bread. Copper sulphate is always dangerous. Both are tested by dissolving gelatine, laid for some hours on a spot of bread, in water, and after heating the wood with ammonium carbonate, which turns blue for alum and green for the copper salt.

Honey.—Strained honey, a costly article when pure, is often heavily adulterated with glucose syrup, invert-sugar, cane sugar, gelatine, etc. An educated taste is a better guide to these than any analysis, as that of native flower-fed honey is beyond counterfeiting; but chemical analysis can detect most of them. Formerly comb honey was regarded as necessarily pure but modern beekeepers have been able to feed their bees with glucose and cane-sugar syrup which the bees innocently store in the combs as readily as they do pure honey. The charge has been made by English chemists that American combs are often made of paraffine; this is most improbable as the profit would be extremely small; and a very simple test will decide it. The microscope will show pollen grains in the real wax and warm sulphuric acid will blacken beeswax but not paraffine.

Lard.—Hogs' lard is frequently adulterated with tallow, tallow and cottonseed oil; other vegetable oils such as peanut oil, corn oil and cocoaanut oil are more rarely used. The worst adulteration is water, which is sometimes incorporated with the lard under pressure and, of course, sold at the price of lard. A common commercial fraud is the selling of low-grade hog fat for "leaf lard," the choice layers of fat from certain tissues of the animal.

Milk.—The adulterations of milk are reducible to five: Diluting, skimming, replacing the skimmed cream with cheaper animal fats, coloring to give it the look of cream and adding preservatives or correctives to keep it from souring or to sweeten its taste when beginning to turn. Its use as the staff of life for children and invalids makes its purity one of the most exigent demands and its poor quality or injuriousness a direct or promoting source of widespread disease. The adulteration of the cities pure milk is not attainable for the masses at any price within the means of ordinary workmen; the dairy districts within reach of the city by train, during any time it will keep sweet and not churn, cannot supply enough for
ADULTERATION

all and it is inevitably diluted with water and more or less of it treated with chemicals. This adulteration may be still further incrased by the addition of milk, while real milk and cream are sold to the consumer. It is usually diluted with starch,—wheat, corn or rice,—millet, rape-seed, flaxseed, old turnip- or radish-seed, charlock (wild mustard) seed, cayenne pepper, corn-meal, gypsum and wheat-bran. The adulteration is so large in some samples of mustard-paste that salicylic acid is added to keep it from spoiling. For starch, easy tests are iodine, which turns it blue, and its thickening in boiling water; for mineral matter the chemist determines the amount of ash. For the others, though the microscope is useful, the best remedy is to pay for a known brand,—which indeed is best of all.

Olive Oil.—A large part of the so-called olive oil of the market is cottonseed, peanut or mustard oil or greatly mixed with it; probably the equal in quality and taste of the genuine (as it is indistinguishable), but a fraud in price through deception. The very finest qualities of olive oil is rarely employed. One part of formaldehyde in 10,000 parts of milk will keep the milk sweet for five days. In this proportion it has not been proved injurious to infants. It is usually added in only half this proportion, preserving the milk for three days. It is urged against is use that it destroys beneficent bacteria in the milk. Borax, salt and carbonate of soda are also used; neither they nor the amotto used to give the milk a cream color are harmful in themselves, but only as disguising the real quality of the milk sold. Benzoeic acid and salicylic acid are also found by milk inspectors in some samples. Cane sugar, glucose, starch, gelatine and even chalk are used to bring up diluted milk to a density which will stand the lactometer test. In some instances this has been done by adding condensed skimmed milk and some oil.

The method of testing for dilution is by the lactometer to determine specific gravity, which is lowered by admixture of water; in exact mixture, it detects skimming (which increases specific gravity by removing the lighter cream) by showing normal specific gravity when looks and taste are inferior. Skimming is also inferred from increase in transparency, as indicated by the lactoscope; opaque normal milk needs thinning with a certain percentage of water before a dark object or black line drawn on a white surface will show through; the less water a given sample needs for this visibility, the less cream it contains. For more precise determination the chemist finds the amount of solids in a sample by evaporating a mixture of milk and newly-heated asbestos and weighing the residue; the amount of fats, by dissolving them out with ether from a measured strong colorless spirit, and the water in the mixture of the fat in the ether and water may be determined by analysis. Watering may often be detected by testing for nitrates, which milk does not contain and most water does, and contaminated water practically always. The detection of animal fats used to replace cream is not easy, though the butyrates have some individual qualities.

Mustard.—This is perhaps the most heavily and universally adulterated article in the market; only a small percentage of it is pure. For one harmless adulteration the public is responsible, as for butter-color and picklegeen; that of turmeric or coal-tar color to give it the bright yellow demanded by customers, while real mustard is so strong as to be disfigured, sometimes merely from cooling leasly cans in the tainted water; from decaying animal or vegetable matter, or from the germs with which street dirt is laden. (The contamination from sores on cows kept in unsanitary conditions belongs to another subject). As to the effect of the adulterations Skim-milk is a cheap and valuable food for blood-making protein, as evinced by the cheese made from it; but it should be sold as such, otherwise infants and invalids who need the milk fat may be injured. Other fats do not replace the characteristic and valuable qualities of the cream. Of the chemicals used to preserve milk for short periods, formaldehyde (also used in making rubber) is the most commonly employed. One part of formaldehyde in 10,000 parts of milk will keep the milk sweet for five days. In this proportion it has not been proved injurious to infants. It is usually added in only half this proportion, preserving the milk for three days. It is urged against its use that it destroys beneficent bacteria in the milk. Borax, salt and carbonate of soda are also used; neither they nor the arnotto used to give the milk a cream color are harmful in themselves, but only as disguising the real quality of the milk sold. Benzoeic acid and salicylic acid are also found by milk inspectors in some samples. Cane sugar, glucose, starch, gelatine and even chalk are used to bring up diluted milk to a density which will stand the lactometer test. In some instances this has been done by adding condensed skimmed milk and some oil.

The method of testing for dilution is by the lactometer to determine specific gravity, which is lowered by admixture of water; in exact mixture, it detects skimming (which increases specific gravity by removing the lighter cream) by showing normal specific gravity when looks and taste are inferior. Skimming is also inferred from increase in transparency, as indicated by the lactoscope; opaque normal milk needs thinning with a certain percentage of water before a dark object or black line drawn on a white surface will show through; the less water a given sample needs for this visibility, the less cream it contains. For more precise determination the chemist finds the amount of solids in a sample by evaporating a mixture of milk and newly-heated asbestos and weighing the residue; the amount of fats, by dissolving them out with ether from a measured strong colorless spirit, and the water in the mixture of the fat in the ether and water may be determined by analysis. Watering may often be detected by testing for nitrates, which milk does not contain and most water does, and contaminated water practically always. The detection of animal fats used to replace cream is not easy, though the butyrates have some individual qualities.

Preserves, Jams, Jellies.—Gelatine and glue are often used to help the fruit to jelly (not always an easy thing to assure even by experts) and are often not restricted to the amount needed; the goods are also artificially colored and flavored with so-called "fruit oils," chemical analysis being needed to determine the constituents. The demand for cheap jams and jellies brings into the market concoctions of glucose and apple juice artificially flavored and colored to conform to the name on the label on the jar. In some instances a little real fruit is scattered through the material. The
deception is self-evident, as every housewife knows the impossibility of making such goods at the price. Zinc oxide has been found in preserves, from its use as cement to make covers of jars airtight. Most of the cheap products contain the allowable percentage of benzoate of soda to prevent their decay. To make up for the lack of sweetness in the glucose saccharine is a frequent addition. The apple-pulp from cider-mills is a common basis of cheap jams and this is sometimes given body by the addition of boiled starch, agar-agar or dextrin. Additions of this sort are injurious to health. The fraud is in the name under which they are sold.

Spices: Nutmeg, Pepper, Cinnamon, Mace, Cloves, Allspice, etc.—Whole spices are generally thought safe from adulteration; but they are not, as inferior members of the same species may be substituted for them with immense loss of quality, exactly as if crab-apples were sold for dessert apples. Thus, wild nutmegs are often sold for the cultivated ones and even most of the mace for cinnamon. The method of detection is to know the genuine. For instance, the best nutmegs are about an inch long and shaped like a damson plum, weigh one-seventh to one-fifth of an ounce and exude oil liberally when pricked with a pin; the wild ones are small and pointed and have less oil and fragrance. The genuine Ceylon cinnamon is a thin small roll, of delicate flavor which lasts long in the mouth, and tears rather than breaks; the cassia cinnamon is much coarser and thicker; the tea, but does not tear, is rather mucilaginous when chewed and has a strong woody flavor. Cloves are adulterated by making them absorb water, of which they will take up a great deal to increase their weight. Another form of adulteration is the removal of a part of the essential oil and the subsequent sale of this exhausted spice at regular prices.

The immense adulteration of ground spices makes their convenience a costly purchase. At the outset, sawdust and starch are added even to the best, to absorb the oil which makes them difficult to grind; and it rarely stops there. Of 12 specimens called "ground cinnamon" examined by the New York Board of Health, only three contained any cinnamon whatever and even those were largely mixed with cassia and sawdust; the others were almost entirely composed of those ingredients, two were sawdust with a very little cassia and one was pure sawdust. Seventy per cent of the allspice, 70 per cent of the pepper, 82 per cent of the cinnamon, 57 per cent of the cassia, 76 per cent of the cloves, and 66 per cent of the ginger, was adulterated. The most universal adulterations are starch for bulk, mustard for pungency and turmeric for color. Other substances used are cocoa-nut shells, rice, charcoal, sand, ground date and olive stones, buckwheat hulls and the ground shells of walnuts, brazil nuts and almonds and corn meal. Ginger, like cloves, is often exhausted by removing its essential oil with alcohol or even by soaking in water. The most easily detected is used in making ginger ale. Black pepper demands a special note, as it is the exception rather than the rule to find it pure. A large percentage of the samples examined in the past have contained no pepper at all. "Pepper dust" (the sweepings of warehouses, in trade a regular article of sale as "P. D."), mustard husks, ground wheat, corn or rice, capsicum, and even gypsium and sand, have been found in it. Red or cayenne pepper is much purer than black pepper and is mainly adulterated with flour, Three.—White cane sugar has become so cheap that it does not pay to adulterate it and the old-time adulterants like marble-dust, terra cotta, etc. have vanished. In the process of making cheap confectionery. Sand was never much used except in brown sugar (4 per cent has been said to be unavoidable in raw Manila sugars, but any percentage is indictable if the direct addition can be proved) and glucose has taken its place; equally healthful with cane sugar but, of course, a fraud, as lacking in sweetening power, and a deception.

Tea.—Owing to its cost and the difficulty of judging its quality by the eye or taste, tea has always been a favorite for counterfeiting. The method of detection is to know the genuine. Tea is the most curious reason imaginable: the Act of 17 Geo. III alleges that the admixture of the leaves of sloe, ash, elder and other trees and shrubs with it was working great injury to the local timber and undergrowth. Being a luxury whose cost presses heavily on the very poor, its substitutes within the means of that class have usually none of the characteristic properties, good or bad, of the genuine and are mere flavored warm drinks; curiously, the poisonous adulteration alleged against it (groundlessly), that of obtaining its green color from copper pans, was against the very costliest brand of all. It has been found, however, that tea is faced with Prussian blue and indigo, soapstone, plumbago and gypsium. But the stuff sold to the poor, besides spent tea-leaves and those of various plants, as above, has been found to contain sheetrock, sweepings, brickdust, iron fillings and iron salts, sand, etc., unwholesome and liable to contain disease germs. Matechu is sometimes added to give increased astringency. Owing to careful inspection very little tea in the American market is adulterated otherwise than by mixing a lower grade tea with a more expensive one and selling the mixture at the top price. Tea.

Tobacco.—Color and flavor are often given to inferior grades by artificial means. No leaf is known which will counterfeit the tobacco leaf outright. Snuff, however, lends itself readily to debasement by colored powder, and lime and chromate of lead have been found in it.

Vinegar.—The most usual form of adulteration is thinning down with water, then restoring the lost acidity with sulphuric, muriatic, nitric or other cheap mineral acids. The first is easily detected; used in making ginger ale. Black pepper demands a special note, as it is the exception rather than the rule to find it pure. A large percentage of the samples examined in the past have contained no pepper at all. "Pepper dust" (the sweepings of warehouses, in trade a regular article of sale as "P. D.")
are made by the acetic fermentation of malt sugar, cane sugar and alcohol, all diluted with water. The real thing is more costly and their agreeable effects are more lasting. These vinegars, of course, derive their acidity from acetic acid. They lack the flavor of apple-juice. However, this is sometimes added, together with a proportion of pulp from the cider-orchards, to counterfeit the body and taste of pure cider-vinegar.

**Wines.** — Naturally their chief adulterants are water and alcohol, to increase bulk or strength; colors and flavors, astringents, etc.—caramel, logwood, glycerine, syrups, etc.—to give artificial qualities resembling wines of repute; salicylic acid to prevent souring; gypsum to precipitate organic matters that muddy the wine (the latter injurious as likely to turn into acid potassium sulphate); sugar in the must, to increase the alcohol, etc. Natural colors like fruit juices and cochineal are harmless; aniline colors not always. The chemical tests are too special to be detailed in a popular work. It should be said, however, that by far the leading adulteration consists in the wine not being real fermented grape-juice at all; this applies only to foreign wines, the American being generally pure and practically the only pure wines at moderate price on the market. Real wine from foreign vineyards is a costly article and the better grades are pledged years ahead to the great foreign courts, noble houses and private European buyers. Cheap foreign wines should be understood from the outset to be made either from exhausted grape-skins or raisins treated with alcohol and water (it is not for dessert use that the great majority of the California raisin crop is exported to France) or from pear-juice (much the greater part of the so-called French "champagne" in America beingerry).  

**Bibliography.** — Leach, 'Food Inspection and Analysis' (1913); Olsen, 'Pure Foods: Their Adulteration, Nutritive Value and Cost' (1911); Vacher, 'Food Inspector's Handbook' (1913); Wiley, 'Eating and Their Adulterations' (1912); Wiley, '1001 Tests of Foods, Beverages, and their Adulterations' (1914); also the United States Chemistry Bureau's Bulletins 41, 80, 100 and 147, and Circulars 25, 63, 113 and 180; and the Animal Industry Bureau's Circular 203.

**ADULTERY,** unlawful intercourse between two married persons not standing to each other in the relation of husband and wife, or between a married person and another unmarried. In the former case it has been called double and in the latter single adultery. Unlawful voluntary sexual intercourse between two persons, one of whom at least is married, is the essence of the crime in all cases. In general it is sufficient if either party is married and the crime of the married party will be adultery while that of the unmarried party will be fornication. In the United States there is a wide diversity in the laws relating to this offense. In some States it has been made a crime while in others civil proceedings are allowed substantially similar to those of the English law. Varied punishments, mostly of a very severe character, have in nearly all countries and ages been inflicted on those who have committed this offense. In some cases it has been deemed lawful for a husband or the woman's father to kill the guilty person if taken in the act. By the law of England the slaughter of the offender in such an instance is deemed manslaughter of a very aggravated sort. In English law the act is punishable only by the censure of the ecclesiastical courts, but when committed by a wife it is regarded as a civil injury and for criminal conversation may be brought by the husband against the paramour. Adultery is now considered in England a ground for total divorce.

**ADVAYTA,** ā-dvāita, a philosophical school of India, founded by Sankarājya or Cankaracārya, who flourished about the middle of the 8th century A.D. or earlier. Its principal doctrines are that the human soul is not essentially different from God, but that it is imprisoned in the body from which at death it is released to return to the impersonal God and that the material world is not different from God. Its adherents are called Advavādins, or Confessors of Monism.

**AD VALOREM** ("according to value"), a term denoting the method by which customs taxes are determined at a percentage of the value of the imported article at its place of export on the seller's oath and appraiser's estimate. Theoretically, this is much fairer than a specific duty (on a unit of measure, yard, bushel, bale, etc.), since the costlier pay their equal percentage with the cheaper; but in practice it has serious drawbacks, annoys both sellers and government much, defrauds the latter somewhat and its people a great deal. Values are unstable, the exporter is interested to understate them and the officials are eager to scent fraud, whence much friction and many lawsuits. As to the last item, general tariffs are apt to produce an appearance of moderate average by equating a low duty on grades of slight consumption with a high one on those chiefly used; a deception impossible on specific duties, which at least must declare themselves. The customs officers much prefer these also. The United States tariffs are of both kinds, some articles having a combination of the two. See **DUTY**.

**ADVANCE GUARDS.** The principal detachment insuring security for the command in the field, which covers the head and flanks of a column or army advancing in the direction of the enemy. For a large force the advance guard is necessarily composed of troops of all arms; its strength being proportioned to that of the main force; the more or less resistance of an independent character it may be required to make; and the greater or less extent it may be found necessary to embrace by its advanced posts on the front and flanks to watch and anticipate every movement of the enemy. The proportion of the advance guard to the main body may vary from a third to a fifth of the total force. In armies of some strength, or large corps d'armée, particularly where the nature of the country requires a wide development of advanced posts, the larger proportion is demanded; as at least one-third or even one-half of its strength will be required for the advanced post service. In a small force of two or three thousand men one-fifth will usually be all that can be well spared for the same
purposes. The purpose in all cases should be to keep the enemy in a state of uncertainty and prevent him from obtaining a clear view of the ground. If the enemy offers to attack, keep him in doubt as to the actual character and numbers of troops before him. In all definitive positions the advance guard and its advanced posts should be held in reserve. The main body may have time to take all defensive measures. In the offensive, the attack of the advance guard should be decided and vigorous; pressing upon the enemy at every point; and leaving nothing undone to demoralize him by the confusion which so often follows from an impetuous onset. In all affairs of advance guards great circumspection is to be shown both by the officer in command of the advance guard in throwing forward fresh troops to strengthen a point assailed, as well as on the part of the general-in-chief in sustaining the advance guard by weakening his main body. These are points that can only be decided on the spot. The safer rule in all cases is not to weaken the main defense, or main attack, by sending it away from the main body to assist a weak point. If the force engaged under such circumstances does not suffice for its own defense, it is best for it to fall back in time and, taking position with the main body, endeavor, by their combined efforts, to turn the scales of victory in their favor.

Strength.—The strength of an advance guard depends upon: (1) The force it is covering. (2) The object for which it is organized. If its commander is instructed to engage the enemy whenever he finds, its strength should be one-third of the command. If the enemy is only to delay the enemy's advance, the main body to deploy, it should be as small as is consistent with this duty—a large force, from one-eighth to one-twentieth of the command will suffice. (3) On the nature of the country. (4) The character of the enemy. (5) The distance it is required to precede the main body. Its strength should never exceed one-third of the command and rarely be diminished below one-sixth. The strength of an advance guard usually be as follows:

- One battalion of infantry (four companies), one-half to one company.
- One regiment of infantry (12 companies), two to three companies.
- One brigade of infantry (36 companies), six to 10 companies.

In an infantry division, approximately the following number of troops would be detailed on advance guard duty:
- From the three brigades of infantry, two regiments;
- From the two regiments of artillery, one battalion;
- From the regiment of cavalry, two battalions;
- From the one company of engineers, one-half company of engineers.

One of the important duties of the army commander is to determine the strength and composition of his advance guard and he must be prepared by detailed instructions to those already mentioned. (1) If the enemy is near the duty will be arduous. (2) Thatdetachments from the main body may impair its strength at a critical moment. (3) That an ambitious officer, finding himself in command of a strong force, may unwisely be involved with a stronger one and thus force his advance guard to bear the brunt of the battle. He must also remember that the defensive powers of small bodies have been increased by improvements in fire-arms. Duties.—The duties of the vanguard are:

1. To examine the ground and remove all obstructions from the route.
2. To gain information of the enemy, especially when the cavalry division is not in advance.
3. To drive back or capture any detachments of the enemy they may find or hold the ground until they can receive reinforcements. As the principal duty of the vanguard is reconnaissance, it should be largely composed of cavalry. The duty of the reserve is to fight and it would naturally be composed of infantry and artillery.

The remainder of the unit from which the advance guard is taken ought, when convenient, to march at the head of the main body. The place for the commander of the advance guard is with the reserve. In open country the scouts and flanks should be opened and sent forward to obtain information on the ground. The proper place for the cavalry is to be in the middle, as it may meet with obstacles to its progress, such as detachments of the enemy's cavalry or villages, defiles and roads. The cavalry patrol should be sent on the roads beyond the lookout for the enemy. Defiles, ravines, and rough country generally must be examined by the infantry. As all kinds of country are apt to be found in a day's march, the advance party and flankers must be cavalry alone. It is impossible to give a general rule as to the proportions of the various arms.

Artillery.—The mobility and the offensive and defensive powers of modern field artillery have become so great that it is now assigned an important place in the advance guard in country favorable to its movements. As it must come into action early, some pieces are frequently attached to the support and the remainder of the battery or batteries march with the reserve. A division would have one battery with the advance guard, two pieces to march at the rear of the support and the other pieces behind the first battalion of the reserve. The limber-chests should be filled with ammunition and the caissons be left in the rear out of the way. It can assist in dislodging the enemy from villages, buildings, woods and bridgeheads.

The battles of the future will generally be preceded by a concentration similar to that of
the German armies, at least for the corps of the first line. There is nothing to prevent placing the corps artillery in the advance guard if the situation is strong and well known. No intervals and an avenue of retreat. For when the artillery is called to participate in the combat it will take the trot and leave the interval between the advance guard and the main body for the zone of manœuvre. In immediate contact with the enemy the advance guard must form a curtain of fire, for with its skirmishers and advanced parties while the main line of resistance must be formed from the reserve. The masses will march in the rear of the advance guard. The disposition will depend upon the ground and the intentions of the chief — the important thing is that the artillery find the ground free in its front. The artillery has also a reconnaissance rôle in connection with the cavalry for, with its long range, it can assist in searching by its fire places unapproachable to the cavalry.

Infantry.—The rôle of resistance belongs to the infantry, as it is essentially the fighting arm in the combination. Its mobility imposes upon it also the duty of assisting the cavalry in reconnaissance work and of covering the artillery. The more artillery in the advance guard the more infantry it must have. In rough country the service of exploration and the advance guard duty will fall almost entirely upon the infantry. In the combat with the enemy's advance guard the infantry must advance quickly to protect it from the enemy's infantry fire. We may say that all of the duties, which from the nature of their organization the cavalry and artillery cannot perform, fall to the lot of the infantry. Its rôle is "to conquer and to preserve."

A light bridge train and some engineer troops should also be assigned to the advance guard to bridge streams, destroy obstacles and repair roads for the progress of the main body.

The Commander.—When the enemy is near the selection of a commander for the advance guard is very important. He must combine boldness, activity and knowledge with good judgment, and be well disciplined as to subordinate his actions to carrying out the orders and instructions of the commander-in-chief, and avoid bringing on engagements through his own desire for distinction. He is responsible for the proper arrangement of the various parts, and that each faithfully performs its particular function. He must see that information obtained as to the strength, position or movements of the enemy is promptly and accurately transmitted to the commander-in-chief. Before assuming command of the advance guard, he reports to his chief for instructions. If they are verbal, he should write them in his notebook and have them verified. He should quickly inspect his command, divide it into the proper parties and give his subordinate chiefs their general instructions before the march is begun. If attacked, he must do the following: (1) Move forward and drive the enemy from his position. (2) Assume a defensive position and hold it until he can be reinforced from the main body. (3) Or, if outnumbered, retire slowly on the main body, using every device to check the progress of the enemy until the main body can be formed. See Flank Guards, Rear Guards and Vanguard.

ADVANCED POSTS. Positions taken up by a force in advance of the main body of an army, and in such a situation that they shall be within easy communication of it and of one another. The duties of the advanced posts are the same whether the troops are stationary or in movement. They are: (1) To keep a lookout for the enemy and when in his presence to take all means accurately to be informed of his strength, position and movements. (2) Should the enemy advance, to hold him in check long enough to give the main body ample time to be prepared for his attack. By a faithful discharge of these duties the whole army can, at all times and under all circumstances, be kept in a state of readiness for action without subjecting the soldiers to any fatigue beyond the ordinary physical endurance of a well-developed manhood; as but a small portion, comparatively, of the force present is required to watch over the safety of the rest, and can therefore be frequently relieved, so that every one may have time sufficient for the repose demanded after extraordinary exertions. The object being to protect the front and flanks of the position occupied by the main body from any attempt either to reconnoitre or attack it, the detachments which form the advanced posts must be so distributed as to embrace all the avenues by which the enemy can approach the position. The system adopted, in most services, to effect this object consists of two or three concentric lines of posts, disposed in a fan-shaped order. The exterior line, which forms the outposts, embraces a wide circumference, and by means of a chain of sentinels, posted in advance, prevents any one from penetrating to the rear between the posts without being seen. The second line, which is one of grand guards, embraces a narrower circumference than the line of outposts, occupying the avenues from the outposts to the interior, so as to be in a position to support the outposts in case of necessity, and to receive them if driven in. The interior line consists of several strong detachments, termed pickets, posted upon the main avenues to the position. They serve as supports to the two exterior lines, upon which they rally if forced to retire before the enemy. Besides these dispositions for security, patrols are kept up between the line of posts, to keep the one informed of the state of the other; and also between the outposts and chain of sentinels, to see that the duties of the latter are well performed and to search any ground not brought well under the eyes of the sentinels. The whole, in this way, forms a connected system for observing the enemy and for mutual support in case of attack. The ground taken up by the advanced posts will depend on the capabilities which its natural features offer for defense; on the number and character of the approaches it presents to the enemy for attacking the front or flanks of the position occupied by the main body; and upon the facilities it may afford for communication between the posts.

ADVANCEMENT, in law, is a gift by anticipation from a parent to a child of the whole or a part of what it is supposed such
ADVANCEMENT OF LEARNING — ADVENTISTS

child would inherit on the death of the parent. An advancement can only be made by a parent to a child (2 Jones 137), or in some States by statute to a grandchild (4 Kent Comm. 419). The effect of an advancement is to reduce the distributive share of the child by the amount so received, estimating its value at the time of receipt. In some States, however, the child has his option to retain the advancement and abandon his distributive share.

ADVANCEMENT OF LEARNING, The, by Francis Bacon, 1605, the original title being 'Of the Proficience and Advancement of Learning.' Since Dr. Humany. 3 This book was received with great favor by the court and by scholars, was afterward enlarged and published in Latin with the title 'De Augmentis Scientiarum,' as the first part of a monumental labor, 'The Instauratio of the Sciences,' of which the second part was the still famous 'Novum Organum,' on which Bacon's fame as a philosopher rests.

ADVENT, the period of some weeks before the Nativity, observed in all the apostolic churches as a season of solemnity of emotion and reflection, marriages and public amusements being interdicted or reproued; in the Roman Catholic Church also a season of fasting and penance. In the Western Churches — Roman, Lutheran, English and Protestant Episcopal — it is a four weeks, beginning the Sunday next after 26 November, or that nearest St. Andrew's Day (30 November); in the Greek Church it is six weeks, beginning 11 November, St. Martin's Day. Our first notice of it is in the 6th century, at the Synod of Lerida (524); and two sermons on it in 524 show that it was then in general observance. In that century also the Eastern and Western Churches, following the Nestorians, made it the beginning of the ecclesiastical year instead of Easter. Its four Sundays were believed to have been introduced into the calendar by Gregory the Great; and to have reference to Christ's fourfold coming early spoken of — in the flesh, at the hour of death to his faithful followers, at the fall of Jerusalem and at the day of judgment. On these grounds the gospels were read on the four Sundays. Its ordering was settled in the Western Church by Charlemagne's 'Homiliarium.'

ADVENT, Second. See Millennium.

ADVENTISTS. Bodies of believers who take their name from their belief as to the second coming of Christ. They came out of the movement begun by William Miller, a Baptist of New England, who, after a long study of the Scriptures, especially of the prophecies, reached the conclusion that the second coming of Christ would take place in 1843, at which time Christ would personally descend to earth and reign with the saints a thousand years. He based this prediction on the prophecies of the book of Daniel, holding that the periods spoken of as 2,300 days, the seven years of Gentile supremacy, and the 1,335 days, were prophetic periods and, applied chronologically, led the Lord to rule the world in 1843. He also interpreted the Gospels and the Apocalypse as showing that the only millennium to be expected is the thousand years which are to intervene between the first resurrection and that of the rest of the dead. He confessed his disappointment at the failure of his prediction and admitted his error; but insisted that the day of the Lord was at hand. Miller drew many followers from the Baptist, Christian, Methodist and other churches, and the discussion was attended with considerable excitement. He fixed upon a second date, 22 Oct. 1844, after which many left the movement. Those who remained he gathered to a place in Albany, in April 1845, and set forth their belief in the personal proximate coming of Christ, without naming any dates, and in the resurrection of the saints at his appearance, the millennium to follow. Small companies of Adventists have since fixed upon various dates, but the body of believers have not supported these predictions.

Societies, or churches, were formed during the progress of the movement, but no very definite organization was at first attempted to bind these societies together. Organization came into use when differences of view began to divide Adventists. The Evangelical Adventists may be regarded as the oldest organized branch. Adventists have also been called Millerites. The six bodies reported in 1916 a total of 112,054 church members, 2,794 churches and 1,501 ministers.

1. Evangelical Adventists. These refused to accept the belief that the soul of the wicked is immortal. They announced the doctrine that the soul is immortal; that all the dead will be raised, the saints first and the wicked last; that the saints will participate in the millennial reign of Christ and after judgment enter upon their eternal reward; that the wicked who will rise at the end of the millennium will be sentenced to everlasting punishment. They also held that the dead are in a conscious state. They had in 1890 two annual conferences and about 1,147 church members. According to the census of 1906 they had decreased to 481 members, with eight ministers and 18 churches. As an organization they are now nearly extinct.

2. Advent Christians. — This branch, which has shown a tendency in recent years to closer organization and to increased activity, opposed the doctrines enunciated by the Evangelical branch in 1855 as to the conscious state of the dead and the resurrection of the wicked, holding that immortality is conditional and does not belong to the wicked who will be raised at the end of the millennium to receive sentence of banishment and annihilation, while those who accept Christ shall rise and receive the reward of eternal life, at his second coming, which they believe is near at hand and is to be personal and visible. They avoid any attempt at fixing a particular day for his coming.

The Advent Christians are congregational in polity; they have district conferences to the number of 50 or more (including six in Canada, England and China) which hold annual sessions; also a general conference, meeting biennially, composed of delegates elected by the district conferences. Its function is to serve as a means of co-operation in carrying on the missionary, educational, publishing and other work of the denomination. In 1916 there were 602 ordained ministers, 30,316 church members and 640 churches. The body is strongest in New England where it originated; but it also has churches in the West and South. Their headquarters are at 160 Warren Street, Boston, Mass.
ADVENTURES OF BARON MUNCHAUSEN

3. Seventh-Day Adventists.—As early as 1845 a congregation in New Hampshire connected with the Advent movement began to observe the seventh day as the Sabbath, holding that the fourth commandment was still in force. Those Adventists who adopted this view gave a different interpretation of the prophecy of Daniel that 1,290 days and 1,230 days the sanctuary should be cleansed. They held that it did not refer to the renewal of the earth, as Miller had contended, but to the Sabbath, as ordered by the fourth principle of the code which was placed in the ark of the covenant, a type of the heavenly sanctuary. As the company of Seventh-day observers grew they established a paper to advocate their views (1849) in Middletown, Conn. In 1885 the headquarters of the denomination were removed to Battle Creek, Mich., and in 1903 to Washington, D. C. The Seventh-day people believe, with most of the other branches, that the second advent of Christ is to be personal, that it is near at hand, that it is to precede the millennium during which Christ and his followers will reign on the earth and Satan and all who do his work will be destroyed. Mrs. Ellen White, one of the founders of the denomination, was credited with divine revelations as a prophetess. The body is thoroughly organized with local, State and union conferences and a general conference. The latter meets quadrennially, the union conferences, which embrace five or six States, meet biennially and the State and local conferences meet annually. The local churches have the congregational form of government, but the conferences are presbyterian in character. There are departments of missions, publication, medicine, education, Sabbath school and young people’s work which are conducted systematically. The foreign mission work is quite extensive, embracing the countries of Europe, also including Iceland, China, Japan, Korea, India and Burma, five centres in Africa, Australia, Canada, Mexico and South America. The educational work includes 23 academies, with numerous church and intermediate schools. A sanitarium was established at Battle Creek in 1866; now there are upward of three score institutions of this kind for the rational treatment of diseases and inculcation of temperance and healthful living.

The denomination grows from year to year, reporting, in 1916, 77,724 members in the United States alone, with 2,036 churches and 558 ministers. It embraces all the States, but is strongest in the North Central group and in the Eastern.

4. Church of God.—This is a small body akin to the Seventh-Day branch, from which it sprang, but differs from it chiefly as to the prophecies of Mrs. Ellen White, which it refused to accept. On most other points they agree with the original denomination. The Church of God publishes a paper at Stanberry, Mo., called the Bible Advocate. There are in this branch 800 members, 22 churches and 34 ministers.

5. The Life and Advent Union, organized in 1864, holds that there will be no resurrection of the wicked dead. Eternal life will be given at the second coming to those who are to receive it and the millennium is not in the future, but in the past, and was a period of persecution and suffering for Christians. The Herald of Life, which represents this body, was published at Springfield, Mass. No statistics have been reported since the census of 1900 when there were 509 members, 12 churches and 12 ministers.

6. Churches of God in Christ Jesus, a small body of *Age-to-Come Adventists*, organized in 1888 in Philadelphia, Pa. They hold that the capital city of the kingdom of God, which Christ will establish at his second coming, will be in Jerusalem, and the Israelitish nation will then be restored to the favor of God. Hence they are often called *restorationists,* *restorationalists.* Their organ is The Restitution, published at Plymouth, Ind. They have 2,224 members, 65 churches and 61 ministers.

HENRY K. CARROLL

ADVENTURES OF BARON MUNCHAUSEN, The. Munchausen’s Adventures are a by-word among travelers’ tales for extravagant, methodical lying. They owe their name and first inspiration to Hieronymus Karl Friedrich, Baron Münchhausen (1720–97), of Bodenwerder, near Hanover, Germany, who had served in the Russian cavalry against the Turks (1737–39) and had had an adventurous middle life. He had been living on his German estate since 1760 and was renowned locally as a raconteur. Among his auditors was a German scholar and writer, Rudolph Erich Raspe, who, being in straits in London in 1785, published anonymously some of these stories in a little book of 49 pages, ‘Baron Munchausen’s Narrative of His Marvellous Travels and Campaigns in Russia.’ This with additions not by Raspe reappeared in 1786 as ‘Gulliver Revived, the Singular Travels, Campaigns, Voyages and Sporting Adventures of Baron Munchikhouzen.’ A free German translation by the poet G. A. Bürger (1786) gave the book international popularity. Raspe had drawn his materials not only from the Baron’s talk but from older sources, especially Bebel’s ‘Facetiae’ (1508) and Lange’s ‘Deliciae’ (1765). The English edition of 1793, with a sub-title, “or the Vice of Lying Properly Exposed,” had further additions and such continued to be made by publishers’ hacks for many years. The Baron, innocent source of all this, was far from relishing the reputation he had gained for unveracity by such practice of alchemy as cold so bitter as to freeze a music into a posthorn or thaws that would leave the rider after a night’s rest to find his horse hanging by the bridle from a steeple. Adolph Ellisen, in a German edition of 1849, says his father found the Baron exceedingly uncommunicative.
when he visited him in 1795. The most satisfactory modern English edition of the 'Adventures' is by Lawrence and Bullen, with an introduction by T. Seccombe. There are many others, some illustrated by talented artists. For the place of the 'Adventures' in the history of literary lying consult 'Diedeutschen Lügendichtungen bis auf Münchhausen' by Karl Müller-Fraureuth (1881) and Lienhard, E., 'Münchhausen's Lustspiel' (Leipzig 1900).

Benjamin W. Wells, Author of 'Modern German Literature.'

ADVERB, a word joined to a verb, an adjective or another adverb, to qualify or modify the sense, as adjectives are joined to substantives. An adverb cannot be the subject, copula or the predicate of a proposition. They are divided into adverbs of place and direction, of time, of degree, of manner, of doubt, etc., according to their signification. Adverbs admit of comparison to the same degree as adjectives. In English a large class of adverbs is formed from adjectives by the addition of the syllable ly, which is derived from the word lie. Phrases that can be represented by a single adverb or that fill the function of an adverb when there is no single equivalent to them are termed adverbial phrases.

ADVERSE POSSESSION, a possession against any other claimant. It is the enjoyment of land, or such estate as lies in grant, under such circumstances as indicate that such enjoyment has commenced and continued under an assertion or color of right on the part of the possessor. In a majority of the States of the Union, when such possession has been actual and has been adverse for 20 years, of which the just estimation of the circumstances, the law raises a presumption of a grant. This presumption, however, arises only when the use or occupation would otherwise have been unlawful. Such possession, however, must be open, notorious, visible, exclusive and continuous. But possession is not adverse when both parties claim under the same title, as if a man seized of certain land in fee have issue two sons and die seized, and one of the sons enter by abatement into the land, the statute of limitations is not operative against the other son; for when the abator entered into the land of his father, before entry made by his brother, the law intends that he entered claiming as heir to his father, by which title the other son also claims.

ADVERSITY HUME. See Hume, Joseph.

ADVERTISEMENTS OF ELIZABETH, orders issued by Parker, archbishop of Canterbury, in 1566, to enforce dignity and uniformity in the conduct of common prayer and the administration of the sacraments; prescribing the wearing of the surplice and college cap by the clergy, and of the cope in cathedrals and collegiate churches. They were so entirely in accord with Elizabeth's known views that the archbishop had no doubt of her sanction; but after a year's waiting and copious correspondence with her minister Cecil (Burghey), he could not extract an official guaranty and was obliged to assume personal responsibility. Their modern importance springs from the quarrel in the English Church over ritual and their varying interpretation by the High and Low parties. In the Ridsdale case of 1877, the latter, headed by Lord Selborne, held that they prescribed absolutely the vestments to be worn and were infringed by additions; the former, through Jardine, or, held them merely a minimum for decency.

ADVERTISING (from French Avertir, to notify). Originally, advertising implied mere publication, a notice for an individual or class, such as legal advertisements. The word, however, is now generally applied to the advertisement of merchandise to the public at large, through periodicals, circulars, posters, painted signs, electrical display, etc. In its present sense advertising is a powerful and legitimate force in the commercial world and in the distribution of commodities, and it has been designated as the literature of persuasion. Its volume in the United States figured in dollars is so great as to place it among the most important of the nation's activities.

History of Advertising. The rudiments of advertising as it is practised to-day for the promotion of commerce can be traced back as far as commerce itself. With the invention of the rudest forms of writing came advertisement, such as the rewards for runaway slaves. These were written on paper or vellum, and preserved copies have been exhumed at Thebes. Before writing was developed advertising by means of criers and sign-boards existed. The latter have been used in all ages for the information of the illiterate. Shops in ancient Pompeii had terra-cotta signs, showing a goat to denote a milk-seller's stall, or two men at sword-play to indicate a fencing school. Old tavern signs like the Star and Garter are a mediæval form of the same species of advertisement. All shops in London and Paris had such picture-advertisements in the Middle Ages, so that servants unable to read might find them. Until the invention of printing advertising was necessarily of this primitive character. But since the 16th century it has steadily kept pace with the increase in periodicals and books. The oldest newspaper advertisement preserved appears in a German newbook of 1591, and is a book notice. The first newspaper traceable in France (1641) did not operate as an advertising medium. The first English newspaper appeared in 1622 and the first advertisement 30 years later. But before that the pulling of books, plays, cure-alls and quacks by posters, processions, etc., was very common. The introduction of tea, coffee and chocolate into England is recorded in old newspaper advertisements (1652-58). Addison's 'Tatler' No. 224 (1710) is devoted entirely to descriptions of advertisements of that day in the public press and tells of methods of exploiting pills, plasters, cures, cosmetics, books, houses for rent and advertising for lost animals and runaway wives. Fifty years later (1759) Dr. Johnson thought that the trade of advertising is now so near to perfection that it is not easy to propose any improvement. The first newspaper advertisement in America appears in the Boston News-Letter, of 1704. Notices of shipping and rewards for slaves were numerous in the New England Weekly Journal (Boston, 1748), and shortly after this American newspapers began to carry miscellaneous trade advertisements.
In Great Britain advertisements were heavily taxed until 1833, an impost of 3s. 6d. being levied on each one appearing in a newspaper, though it might be for the benefit of a business. Upon the abolition of this tax advertising immediately began to grow. To-day Great Britain probably stands next to the United States in the extent of its advertising expenditure. The London and provincial newspapers are heavily patronized, while outdoor advertising is more extensive and less sighty than in this country. English magazines, though numerous, have never been developed as advertising mediums to the extent that the American have. In advertising practice British tradesmen and manufacturers respect and study American advertising methods, adapting many of our devices to their own needs. In Continental Europe advertising finds its chief outlet in the newspapers, which often have tremendous circulations, and by means of outdoor posters and bulletins. The latter forms of advertising are generally controlled by governments on the Continent, and not only yield a revenue, but are used as instruments of propaganda, size, location and display. While France, Germany, Italy and other countries have numerous weekly and monthly reviews, none of them have ever attained the importance of leading American magazines as advertising mediums. Great Britain and the continental countries have excellent facilities for the transportation of merchandise parcels through the posts, and it might be thought that on this account some system corresponding to our mail order advertising would have been developed. But mail order advertising is limited abroad, probably because most of the population is in close touch with distributing centres, and also because the mass of the people, not so evenly prosperous as American farmers, have a smaller purchasing power.

The real development of advertising as a factor in the distribution of commodities may be said to have begun only with the appearance of the steamboat and railroad, the modern postal system and the telegraph. Its rapid growth since then, especially in the United States, where the great distances between producer and consumer lessen direct dealing, would seem to indicate that it is a legitimate wheel in distributive machinery rather than a form of aggrandized publicity. In this sense, advertising is a modern development. In earlier times it had chiefly a curious interest. A full and entertaining description of early advertising will be found in Sampson's History of Advertising from the Earliest Times (London 1874).

Development of Advertising.—Advertising in the modern sense was first sparingly employed by retail merchants in large cities. About 1840 improved postal facilities in the United States gave opportunity for broadened circulation of periodicals and brought into being the earliest trade, denominational, agricultural and general publications of national circulation. These made it profitable to advertise over wide territory. Soon there were firms, comprising a current list of merchants, which expenditure was for advertising, and the value of the new force was appreciated by charlatans, quacks and swindlers to such an extent that the public soon learned to distrust advertising. For more than a generation it was not considered reputable by the great majority of legitimate business houses. The power of advertising as a force in merchandising, however, eventually brought reputable interests into the field. The swindler began to feel. Among the first classes of manufacturers to advertise widely were makers of commodities, such as sewing machines, typewriters, baking powders, infant foods, etc., then quite new for the most part. In recent years the chemical manufacturers have practically forced out of American advertising mediums as legitimate business increased in them, and during recent years, with public confidence gained, the growth of both advertising and publications in the United States has been so great that publishing and printing now rank seventh in the country's industries, being exceeded only by iron and steel, slaughtering, foundries and machinery, lumbering, milling and clothing. Where formerly the novelties of commerce were advertised, it is now the staples that predominate, such as automobiles and accessories, shoes, flour, cereal foods, clothing, sanitary appliances, etc. The advertising revenue of leading publications is to-day so important that the more progressive publishers often advocate and investigate a doubtful advertiser before his announcement is inserted. The practice of the publisher making good to readers any loss they may incur through a swindling advertisement is becoming common in this country, and few losses occur. Moreover, the Government has thrown safeguards around advertising, and through the Federal Post-Office Department effectually prevents swindling operations by denying the use of the mails to an advertiser whose methods will not bear investigation.

Advertising has had an immense influence upon the lives of the people, for it not only increases the standard of living and health by introduction of modern conveniences such as baths and sanitary appliances, heating and lighting apparatus, the spread of means of culture, the encouragement of travel, etc., but also tends to improve the quality of commodities without a corresponding increase in cost. Competition in advertising takes the form of price rivalry much more rarely than might be presumed. Advertisers seeking to create national demand for commodities sold under their trade-brands compete rather in offering excellent staples, assuring purity and marketing in sanitary packages. Advertising has resulted in the invention and use of dust, germ and air-proof cartons, boxes and containers. Formerly it was a kind of puffery, but at present the widest advertising is characterized by the completeness with which it presents information and the logical reasoning by which it seeks to persuade readers. One of the most notable phases of modern advertising has been the liberal use of space in newspapers and magazines by large corporations, such as the railroads, manufacturing concerns, political parties and associations, for the purpose of influencing public opinion, it having been proved that this method of reaching and affecting current thought on questions of the day was quick and dependable. In recent years advertising in newspapers has grown that of every other nation in volume, and has also been conspicuous for its division into special channels, following the lines of the various periodicals and conditions of demand for commodities.

Retail Advertising embraces the announce-
ments of merchants, large and small, in their own communities, from the full page in each day’s newspapers employed by great department stores to the small announcements once or twice a week of the minor shopkeeper. This form of advertising is really a species of news, prepared daily, and is of such interest to the public that many readers take newspapers for their store advertisements, and the journals which carry most of these have the largest circulations. Merchants also publish store news by means of circulars through the mails, minor local journals, house organ, store posters, etc.

General Advertising is the general term describing exploitation intended to reach the public nationally or in a group of States. It is found chiefly in magazines and reviews, and in daily newspapers. Street cars, billboards and bulletins are employed as accessories. General advertisers include large manufacturers of food articles, soaps, musical instruments, clothing, beverages, tobacco, household and office supplies, furniture, plate, jewelry, sanitary appliances, etc., as well as the greatest insurance companies, cities and villages seeking population, banks and trust companies and so forth. This is easily the largest branch of advertising, and the one most influential in distribution. It acts as a stimulus to the local merchant’s efforts, and is so wide in scope as to touch every class and interest of the nation, however remote.

Mail Order Advertising is the term applied to a form of exploitation peculiarly American. When the new communities of the West were insufficiently supplied by their local merchants, several intelligent merchants in Chicago, a city advantageously situated for this form of trade, began to advertise commodities to be forwarded direct to consumers by freight and express, receiving orders and remittances through the mails. This was the beginning of mail order advertising. Several of these merchants have built up businesses with a gross annual income of $50,000,000 or more, selling practically everything in the way of supplies, machinery, food, clothing, etc., direct to the consumer. Thousands of small advertisers operate with a few commodities through the mails, and many local merchants conduct mail order departments. Mail order advertising is found in the magazines, the farm and religious press, the newspapers and in a class of cheaply printed periodicals known as mail order journals, having enormous circulations among people on farms and in villages who are not reached by more costly magazines or daily papers. A large volume of mail order advertising is also done through catalogues and printed matter sent through the mails. This branch of trade has had a very large increase in volume since the introduction of the parcel post system.

Agricultural Advertising is a form of publicity similar to mail order advertising, but which appears chiefly in farm periodicals and exploits machinery, fertilizers, farm animals, stock food, building materials and farm supplies. Agricultural Advertising is found in numerous special publications devoted to manufacturing, retail and wholesale, commerce, finance, medicine and the professions, mining, transportation, etc. Its object is to acquaint local merchants with commodities manufacturers wish to distribute, to inform engineers and superintendents of manufacturing about new machinery, and, generally, to maintain that great organization which produces and handles commodities up to the point where they pass into the consumer’s hands.

Advertising Mediums.—In the United States advertising may be divided roughly into four groups, represented by the mediums used: Periodical advertising, outdoor advertising, street-car advertising and mail order advertising.

Periodical Advertising includes newspapers, magazines, reviews, trade, denominational and farm publications, periodicals printed in foreign languages, theatre and concert programs and other publications, of which there are not less than 23,000 of all kinds. In 1914 the output of printing and publishing in this country was valued at $810,000,000, of which it is estimated, fully $255,000,000 represented revenue from advertisements in periodicals. Advertising in periodicals exceeds receipts from subscriptions by $90,000,000. The advertising revenue of some of our largest newspapers runs into millions a dollars a year. Magazines, also, have shown the greatest growth in numbers, circulation and advertising patronage the past 20 years. It is held to be a safe rule to spend 5 per cent of the selling price of a commodity in advertising, so that the advertising for a person in the 30 leading publications would have to return a gross amount exceeding $25,000,000 to be profitable, or nearly $300,000,000 yearly. While the largest newspaper circulations seldom exceed 300,000 copies daily, the circulation of several monthly magazines is more than 1,000,000 copies per issue, and of one weekly more than 2,000,000 copies per issue.

Outdoor Advertising includes posters and placards pasted on billboards and barns, painted signs on barns, fences and walls, as well as specially constructed bulletin boards in large cities, many of which are electrically illuminated at night, the erection of advertisements about buildings in process of construction, the use of advertising along railroad lines and at populous seaside resorts, etc. As much as $20 per square foot has been paid for the privilege of advertising on a wall in New York city. Electric signs, with advertisements outlined in incandescent lamps, are an important form of expenditure for outdoor advertising. The greatest advertisement of this sort in the world is a single word on a New York building, with letters 60 feet high, visible to 50,000,000 passengers on ferries each year. Advertising of this character adds to the attractiveness of a city by its diffusion of light through the main streets at no cost to the public. Billboards and other outdoor advertising are more often charged with abuses and unsightliness than any other form, and in some cities are prohibited in the vicinity of parks by municipal regulation. They have never come under control to the extent common on the Continent, and in comparison with the outdoor advertisements of London are perhaps pleasing. Outdoor advertising is thought to appear in the city more often than habitual readers of newspapers, as well as to lay emphasis upon newspaper and magazine advertising by repeating the names of commodities more fully described in the press. It necessarily affords no opportunities for description of articles not confined to repetition of brands and trademarks.
Street Car Advertising is a medium that has become prominent in the United States since the introduction of electric traction and the spread of trolley lines through cities and suburbs. An enormous population is carried in these vehicles—more than 5,000,000,000 cash fares are paid on trolleys yearly, and perhaps twice as much as this represent an extra ride of the shape of a transfer. It is possible to maintain an advertising card in the 32,000 cars throughout the United States, covering about 400 towns and cities, for $150,000 a year, and in point of the number of persons who can be reached for a given sum the trolley, elevated and subway lines are said to offer the cheapest form of advertising. Car advertising in New York city, it is claimed, has a national circulation owing to the fact that 250,000 persons from all over the country are constantly in the metropolis. More matters may be printed on a car card than on an outdoor poster, and while there are few instances where large advertisers have attained success through the use of billboards alone, quite a number have confined their operations to street cars with profit. All outdoor advertising aims toward a balanced effect in magazines, newspapers, cars, billboards and printed matter.

Mail Advertising.—In 1679 a London haberdasher gave to each customer who purchased goods to the value of a guinea a printed list of his stock, and this was regarded as a dangerous innovation because, if followed generally, it would result in the investment of too much tradesmen's capital in printed bills. From this humble beginning the use of circulars and catalogues has grown to a point where, at present in the United States, every second letter carried through the mails is an advertising letter, and for every periodical posted there is mailed a catalogue or brochure. Postage on advertising matter aggregates between $25,000,000 and $30,000,000 annually and this perhaps represented only one-tenth the cost of compiling and printing such advertising. Mail advertising takes many forms, from the leather-bound catalogue of 500 or more pages to the plain postal card. Every form of advertising has descriptive matter in booklet form which is mailed freely to those who express interest in his magazine or newspaper advertising, and in many instances the periodicals are used only to excite such interest, printed matter being relied upon to tell the whole story of such complicated apparatus as an agricultural implement, heating furnace or piano player. Many advertising letters are sent out to lists of persons who may be interested in certain commodities, either printed in imitation of typewriting or actually written on a typing machine. Mail advertising also embraces the distribution at regular postal rates of small periodicals devoted to the interests of a manufacturing or merchandising house. There are hundreds of these personal business organs, some of which have been of sufficient interest to enlarge into standard magazines. Mail advertising also includes the distribution of what are known as “advertising novelties,” ingenious or useful devices, in imitation of booklets and comic cards to desk calendars, all bearing the name of an advertiser. Blotters, calendars, almanacs, reproductions of paintings and many other forms of printed advertising, upon tin, cardboard, paper, wood, leather, cloth, bark, porcelain, glass and other substances travel through the mails. This is the most costly form of advertising known, in proportion to the number of persons that can be reached for a given expenditure, but as most of this matter is sent to persons thought to be directly interested, it often pays a larger return than advertising distributed promiscuously through periodicals, etc.

Advertising Agencies.—Soon after advertising began to be used nationally instead of locally, it was found convenient to put details of correspondence with newspapers, arranging rates, writing the advertisements, seeing that they were properly inserted, etc., into the hands of a new functionary who then sprang up—the Advertising Agent. The first advertising agent to open an office for the reception of advertisements in this country was Volney B. Palmer. He began business in Philadelphia in 1840, and subsequently established offices in Boston and Baltimore as well. Before this, however, the advertising agent was known abroad, for Balzac mentions (“Le Depute d’Arcis”) as among the tenants of a Paris rookery in the thirties, “...women of the town, stealing in companies, newspapers fated to die young, impossible railway companies, discount brokers and advertisement agents who lack the publicity they profess to sell—in short, all description of shy or doubtful enterprise.” When national advertising was new there existed no newspaper directories. To advertise in a given territory it was necessary to go to an advertising agent who had lists of the newspapers and knew their rates. Agents often purchased several columns of space in a number of newspapers by the year, reselling allotments to advertisers for a price less than the newspaper would charge direct. The advertising agent was thus a broker, and to encourage him in developing advertising the newspapers paid him a commission on what he sent in. Then, as demand grew, he became also an adviser to new advertisers, giving counsel as to the ways in which a given appropriation should be spent, preparing the text and illustrations and supplementary matter to be used, checking its insertion in the bills, etc. This detail work is complex, and the advertising agent usually performs it more reasonably than an advertiser could do himself. From a broker in space, the advertising agent of the present day has become a specialist whose services are valued because he has a wide experience in directing the operations of many advertisers, as well as an equipment for writing and illustrating advertising matter. While the advertising agent is still paid by commissions of 10 to 15 per cent allowed him by publishers of newspapers and magazines, he is in no sense the agent of the publishers, but receives rather a wholesale rate upon advertising space, which he sells to the advertiser at a retail or gross price. An advertising agent’s interests are so wholly bound up with his advertising client’s that in some instances he receives for his services a salary besides. Advertising agents have been of the utmost importance in the development of advertising; for by their work, conserving conservative business houses to utilize this modern distributive force, they have built up the revenues of publishers, improved publications and driven advertising charlatans from...
the field. A few of the largest advertisers maintain departments in their business to prepare and supervise their own advertising, while publishers of magazines and newspapers also carry on independently the work of converting business houses to advertising. Despite this, the agent’s function has remained an indispensable one, and with the development of advertising he has entrenched it by specializing. One of the leading New York advertising agencies, for example, has been instrumental in building up the large showing of steamship, railroad and travel advertising now carried in leading magazines, with supplementary advertising of hotels and resorts. Two other agencies are known for their work among advertisers of agricultural implements, another has found its field in the development of textile advertising through magazine and trade journal advertising, etc.

With the past decade the advertising agent has ceased to be what the name would imply and has really become a professional man whose advice special agencies are found by the largest commercial and financial concerns. The leaders in this new profession have become experts on trade conditions and in the introduction of new goods or the development of trade in well-established lines. The modern well-equipped advertiser has attuned himself to not only compet- ent writers of advertisements, artists and photographers, but experts in salesmanship who study economic questions and conditions with the greatest thoroughness. This branch of the work has been carried by some of the leading agencies to the point of becoming advisers and lecturers to the regularly employed traveling men of the concerns represented.

Special Advertising Agencies differ from the foregoing general advertising agencies in that they actually represent the publishers of certain newspapers or miscellaneous journals in a given territory, promoting advertising only for those journals and receiving commissions on all business that comes from such territory. These special agencies are found in New York and Chicago, where a large percentage of advertising originates, and are simply branch offices of publishers outside such cities, who take such means for being represented. In some States associations have been formed among the smaller daily papers who unite in employing a representative who acts as their agent in procuring business.

As advertising has developed in this country it seeks ever new, varied channels, so that while it is possible by a proper selection of mediums to reach practically the whole public, it is also possible, on the other hand, to appeal to a small group of persons interested in some special commodity. No adequate outline of the many forms of advertising could be given in an article of this scope, and readers interested in a fuller presentation of methods, cost, the stories of famous advertisers, etc., are referred to ‘History of Advertising’ (London 1874); ‘Modern Advertising’ (New York 1905); ‘The Theory of Advertising’ (Boston 1904); ‘Twenty Years an Advertising Agent’ (New York 1906); ‘Principles of the Mail Order Business’ (Chicago 1903); ‘The Business of Advertising’ (London 1905); Balmer, ‘The Science of Advertising’, ‘The Art of Publishing’, ‘Advertising and Progress’ (London 1914); ‘Advertising: Its Principles and Practi-

cise’ (New York 1915); ‘Analytical Advertising’ (Detroit 1912).

American advertising has a large periodical literature of its own, comprising fully 25 weekly and monthly journals. Many of these are illustrated and assume the dignity in matter and typography of the standard magazine. Among the most notable of these are ‘Printers’ Ink’ (weekly, New York); ‘Advertising and Selling’ (monthly, New York); ‘Mail Order Journal’ (monthly, Chicago).

ADVERTISING, The Psychology of. It seems quite natural that the first notably successful attempts to apply psychology to the needs of the commercial world should have been made in the field of advertising. The fundamental purpose of the advertiser is to influence human minds. Inasmuch as psychology is simply a systematic study of those same minds, the advertiser, seeking a scientific basis for his work, must find that basis in the science of psychology. But for other reasons than those pertaining to subject matter problems of advertising are peculiarly open to psychological treatment. The customer is not a machine. To the salesman, the labor leader and many others are primarily concerned with influencing human minds, but the conditions of mind with which these men have to deal are all remarkably complex and, in the present stage of science, it is extremely difficult to isolate them for purposes of exact observation. The problems of advertising, on the other hand, are more simple and consequently more open to exact observation.

Perhaps we can gain an idea of what applied psychology really is in no better way than by surveying a few of the psychological principles to which the successful advertiser pays heed. It stands without saying that an advertisement, in order to be effective, must gain the attention of the person who may purchase the product the merits of which that advertisement sets forth. So the question becomes: “To what kinds of things are people most apt to give attention?” The psychologist says that on the whole people pay most attention to those things which are novel, either in themselves or because of their unusual setting or presentation. And the psychologist adds further that the comparatively prolonged attention which people give to the best examples of advertising would not be thus prolonged were it not for the fact that those advertisements are interesting and easily comprehended. These few underlying principles of securing and holding the attention of possible customers are much easier to cite than to put into practice. As a result a distinct profession of advertising artists and copy-men is growing up in this country. In experimental psychology these men can find many facts to guide them in making the most of the space at their disposal. The laws of color contrast, the pleasantness and displeasingness of certain color combinations and of figures of certain proportions; all these had been worked out and more or less organized in the psychological literature of that time, but the use of these facts for advertising was still appearing in its earlier crude forms.

To gain and hold the attention of the pub-
lic is not, however, the final purpose of an advertisement. The advertiser aims so to influence the minds of purchasers that when they are in the market for a cake of soap or an automobile they immediately think of his particular brand of soap or his particular make of automobile. In other words, he must get the idea of the article which he is offering associated with the idea of the class of articles to which it belongs. Here again in this need he can find psychological fact to guide him in conducting his campaign. For example, the psychologist has established that the strength of the association between two ideas depends among other things upon the frequency, vividness and recency of the past association of those same ideas. If, upon thinking of automobiles in general, that idea is followed by the idea of some particular make of automobile, that sequence of ideas may be due to the fact that all automobiles this one has been brought to his attention most often by advertisements, by the talk of his friends or by seeing the actual article. The sequence may be due equally well to the vividness of a particular experience with this machine or to the recency of such an experience. These few principles of association readily explain why experienced advertising men asssent to the superiority of the long, persistent campaign. When the advertising man conducts a continuous campaign he is paying heed to the two laws of frequency and recency. When he enrolls the services of a convincing and clever writer or artist he is paying heed to the law of vividness.

Still it is one thing to get the public to think of a particular brand of goods and quite another to get that public to complete the act of buying. Having done his best to influence men’s thoughts, the advertiser must know how to turn those thoughts into action. Now, according to one of the most fundamental laws of psychology, any thought of an act tends to result in that act unless it be interfered with by a stronger or a contrary idea. Few laws are more important for the advertiser to keep in mind than this one. Unless he has salesmen to follow up mere educational advertisement he has put into the public mind only an idea of his goods but also the idea of purchasing those goods. If his advertisement is to do his selling it must give the public a specific idea of just how and where the purchase can be made. Moreover, if the goods which the advertiser is offering are expensive or in a line where the public still feels no need, then there are contrary ideas already in the public mind which the advertiser must overcome. Often he will have to make use of argument. To do so effectively he must be familiar with the motives which make one course of action seem more favorable than others. He must take into account the instincts and emotions of men and the customs, prejudices and sentiments of particular groups. And again he will find the scientific basis for his procedure in psychology.

It should be kept in mind that the above account is but a sketch of some of the outstanding applications of psychology to advertising. Many of the scientific principles outlined were recognized by the advertiser before any serious attempts were made to apply psychology to his work. But the later knowledge of psychological methods has systematized what in most cases was formerly unorganized tradition. And there is still much to be done. The relative merits of the daily press, the weekly journal, the fiction magazine, the billboard, the street-car display, for particular kinds of advertising; the various motives to which the advertiser of this or that product can appeal with the greatest success; these and many other problems can and will be solved by this youth among the applied sciences—the psychology of advertising.

ADVOCATE, (1) Originally one whose aid was called in or invoked; one who helped in any business matter; (2) in law, at first, one who gave his legal aid in a case, without, however, pleading, this being the function of the patronus; (3) the advocatus fictus, who attended to the interests of the fiscus, or the emperor’s privy purse.

In the old German empire, a person appointed by the emperor to do justice. In Germany and elsewhere juridical advocates were made judges in consequence of their attending when causes were pleaded in the court’s court.

In the mediæval church, one appointed to defend the rights and revenues of a church or monastery. The word advocate, in the sense of a defender of the Church, was ultimately superseded by that of patron but it still lingers in the term advowson (q.v.).

Constitutional advocates, in Rome, pleaded before the consistory in cases relating to the disposal of benefices which they opposed. Elective advocates were chosen by a bishop, an abbot or a chapter. Feudal advocates were persons assigned lands on condition of their fighting for the Church, leading out their vassals for the purpose. Matricular advocates defended the cathedral churches. Military advocates were appointed for the Church. The Devil’s advocate is a Roman ecclesiastic whose office it is to urge whatever objections may exist to the canonization of any proposed saint.

In English law, originally one who pleaded a cause in a civil, but not in a criminal, court; alone entitled to plead as counsel in ecclesiastical and admiral courts which are now thrown open to the ordinary bar. Now, in English and American law, one who pleads a cause in any court. It is not, properly speaking, a technical word but is used only in a popular sense, while the attorney and barrister (q.v.) have defined special attributes.

ADVOCATUS DIABOLI, dɪ-ˌab-ə-lɪ, or "devil's advocate," popularly applied to persons who accuse maliciously or slander. The term and its significance is derived from the procedure in the Roman Catholic Church, in which, when a sanctified person is to be canonized, someone is appointed to scrutinize his past life and bring forth all facts mitigating against the proposed honors. This official is termed the "advocatus diaboli," while the official appointed to defend the candidate for honors is termed "advocatus Dei," God’s advocate.
ADVOWSON, signifying in England the right of presentation to a church or ecclesiastical benefice. Advowsons are either "appendant" or "in gross." Lords of manors were originally the founders, consequently the only patrons of churches, and so long as a right of patronage exists annexed or appended to the manor it is called an advowson appendant. Such rights are conveyed with the manor. But where the property of the advowson has once been sequestered from the property of the manor by legal conveyance it is called an advowson in gross, or at large, and is annexed to the person of its owner and not to his estate. Advowsons are further divided into "presentative," "collative," and "donative." The first is where the patron has the right of presentation to the bishop and may demand of him to institute his clerk if he find him qualified. The second is where the patron and the bishop are identical persons. The third is when the sovereign, or a subject by his license, founds a church and ordains that it shall be at the sole disposal of the patron, subject to his visitation only. Blackstone classed advowsons as the first of the incorporeal hereditaments and they still constitute in England an important class of property interests.

ADYE, a'dlé, Sir John Miller, British soldier, administrator and author: b. 1 Nov. 1819; d. 26 Aug. 1900. He served in India and in Egypt, rising to be general and colonel commandant of the Royal Artillery, and was governor of Gibraltar from 1883 to 1889. He wrote "The Defense of Cawnpore" (1858); "A Review of the Crimean War" (1860); "Sitana: A Mountain Campaign on the Borders of Afghanistan in 1853" (1867); "Recollections of a Military Life" (1895); and "Indian Frontier Policy" (1897).

A. E. See Russell, George W.

ÆDILES, ë'dilz, public functionaries or commissioners of ancient Rome, who, according to Cicero, undertook the care of the city, the repair and preservation of temples, aqueducts and sewers, street-cleaning, paving and traffic regulations, precautions against fire, dilapidated buildings and dangerous animals, superintendence of baths and taverns, punishment of gamblers and usurers, inspection of weights and measures and the care of public morals generally. From 494 B.C. there were two "plebeian ædiles" until 471 B.C., when two "ædiles curules" were added from the patricians, chiefly to manage the Roman games. In 44 A.D. Caesar added the two "ædiles cœrales" to have charge of the public granaries. Consult Abbott, F. F., "Roman Political Institutions" (New York 1901).

ÆETES. See ARGONAUTS.

ÆGADIAN ISLANDS, a group lying off the western extremity of Sicily and consisting of Maratimo, Favignana, Levanzo and Le Formiche. Favignana, the largest, is about 14 miles in circuit and has productive tuna and anchovy fisheries. The group has a population of 6,300. Near these islands the Romans won the naval battle with the Carthaginians, 741 B.C., which ended the first Punic war.

ÆGEAN SEA, ë-jé'an or ë-gá-an, the old name of the gulf between Asia Minor and Greece, now usually called the Grecian Archi-

pelago (q.v.). During the European War from 1914 it was the scene of much naval activity. See WAR, EUROPEAN.

ÆGEUS, æ'jús. See THESEUS.

ÆGINA, a Greek island about 15 miles southwest of Athens, in the Gulf of Ægina (old Sinus Saronicus); area, 32 square miles; pop. about 7,000. It is the stronghold of a partly submerged rocky hill, with deep gorges and ravines, and the eastern half rocky and unproductive; but the western is a well-cultivated plain which, under the warm air and sea, produce the best Greek almonds, with olives and other fruits, wine and some grain. The non-agricultural inhabitants do a considerable commerce and navigation from the one port, the capital, Ægina (pop. about 5,000), at the northwest, on the site of the old Greek town, of which considerable remains are left, the ruins of solidly-built walls and harbor mole still attesting its ancient size and importance. According to the legend, the island was named after the nymph Ægina, brought thither by Zeus. Historical settlers were Achaeans and were expelled by a Dorian colony from Epidaurus, under whom it was one of the foremost commercial cities of Greece, full of hardy, energetic people, born sailors, who covered themselves with glory at Salamis. They were later forced to become a tributary part of the Athenian empire, and in 431 B.C. were expelled altogether. Lysander afterward restored them, but the city's old importance was gone. On a hill in the northeast are the remains of a splendid temple of Zeus Panhellenius (or, as others maintain, of Athena), many of the columns of which are still standing. Here are found early in the 19th century a number of marble statues which once adorned the east and west fronts of the temple; they were purchased by the King of Bavaria in 1812, the deficient parts restored by Thorwaldsen, and are now among the chief ornaments of the Glyptothek at Munich.

ÆGINETA, æ'jin'e'ta, Paulus, a Greek physician of the 7th century b. in the island of Ægina. He was a fellow of the school of Hippocrates, and his work, Ægineta, a synopsis of medicine in seven books, the sixth of which, dealing with operative surgery, is of special historical value. An English translation by Adams was published in London (1834) and a French edition by Brian d'Aniz in Paris (1855).

ÆGINHARD. See EGINHARD.

ÆGIR, æ'jir, a Norse god of the sea-storms, who treats the other gods to foaming beer and has a wife Ran caring for those lost at sea. Their nine daughters are sea-waves, with names representing the aspects of the ocean.

ÆGIRITE, a mineral essentially identical with acmite (q.v.). Like it, aegirite is monoclinic and is a silicate of sodium and both ferric and ferrous iron, the former largely predominating. It is a member of the pyroxene group and is regarded by Miers as an alkali diopside. It is distinguished from acmite by its simple, prismatic crystals, which are usually bluntly terminated, its dark green color and its characteristic grass green, pale green and brown pleochroism. Its hardness is 6 to 6.5 and specific gravity about 3.53. It occurs in long prismatic crystals chiefly in the elaeolite-syenites of Norway and Arkansas.
EGIS, *ējīs* (*storm*), the shield of Zeus, fashioned by Hephaestus (Vulcan). From a probably mistaken etymology it was often said to have been the skin of the goat Amalthea, who suckled Zeus and to have had the Gorgon's head in the centre. When Zeus was angered and shook the ægis, making a sound like a tempest, by which the nations were overawed. It was the symbol of divine protection and became in course of time the exclusive attribute of Zeus and Athena.

ÆGISITHUS, *ējīs-thūs*, son of Thystes and cousin of Agamemnon; adopted son of Atreus. He did not accompany the Greeks to Troy, and during Agamemnon's absence lived in adultery with his wife Clytemnestra. He assisted her in murdering her husband on his return, but was himself put to death seven years later by Orestes, son of Agamemnon. This is the account given by Hомер; the tragic poets make Clytemnestra alone murder Agamemnon, her motive in *Æschylus being her jealousy and wrath at the death of *Agamemnon*. In *Sophocles* and *Euripides* the latter alone. Later writers also describe Ægisthus as the son of Thystes by unwitting incest with his daughter Pelopia. See Agamemnon, Atreus.

ÆGIUM, *ē-jūm*, Greece, modern Vasi-tzea, though officially restored to its ancient name. See Achaea.

ÆGLE, *ēgīl*, a genus of plants of the natural order *Aurantiaciae*. The *Ægle marmelos* is the tree which produces the bael fruit. This fruit is most delicious to the taste, being exquisitely fragrant and nutritious, but laxative. It has been long used in India with great effect as an astringent in cases of diarrhoea and dysentery, when a little unripe.

ÆGOSPOTAMOS, or ÆGOSPOTAMOI ("goat-river"), the Thracian Chersonesus (now peninsula of Gallipoli): a river and town memorable for the battle, or rather surprise, in which the Spartan general Lysander annihilated the Athenian fleet, 13 Dec. B.C. 405, and ended the Peloponnesian war by the temporary ruin of Athens. The latter had 180 vessels, with a number of coequal commanders, one of whom (Coron) had common military sense, and perhaps treachery was at work; while Lysander was an eminent military genius had no one to consult but himself. Having put them off their guard by ostentatious carelessness and absence for several days, he swooped down upon them one day at dinner-time while their ships were totally unprepared (despite the warnings of Alcibiades, whose castle was close by and who was fully a match for Lysander and destroyed or captured except Coron's small squadron. Athens fell under the rule of Sparta, which set up an aristocratic government, the outcome of which is infamous in history as the Thirty Tyrants.

ÆGYPTUS, in Greek legend, son of Belus, King of Arabia; conquered the land called Egypt and founded Egypt. He married to the 50 daughters of his brother Danaus, who had established himself in Argos and was jealous of his brother, and who obliged all his daughters to murder their husbands on the night of their marriage; Æyphnestra alone spared her husband, Lyceus. Even Ægyptus was killed by his niece Polyxena. See Danaus; Egypt.

AHERNTHAL, ʿaḥ-rēn-tāl, Baron (afterward Count), Alois Lexa von, Austrian statesman: b. Grosskal, Bohemia, 27 Nov. 1854; d. Vienna, 18 Feb. 1912. Studied law at Prague and Bonn; entered diplomatic service 1877; attaché, Saint Petersburg 1878; chief of cabinet under Count Kalnoky (foreign minister) 1883–88; councilor of embassy, Saint Petersburg, till 1894; minister to Rumania 1895–99; ambassador to Russia 1899–1906. In October 1906 he succeeded Count Goluchowsky as foreign minister, the latter being forced to retire on account of Hungarian hostility. Aherenthal was believed to be a strong Russophile with Conservative leanings and to have worked for the restoration of the Drei Kaiserbund, or League of Three Emperors, which had dominated Europe between 1870 and 1878. He soon made a new departure in the foreign policy of his country. Whereas Goluchowsky had earned the title of a "brilliant second" to Germany, the new minister maintained, under which no foreign subject could be arrested or tried without the presence of a consular officer of his own nationality. Nearly all the powers interested had signified their readiness to abolish the capitulations if every other one would consent. Austria, however, had always opposed the change, and it was left for Aherenthal to render Bulgaria this graceful service, which cost his country nothing and laid the principality under a great obligation. He reversed the 10 years' old policy of playing off the Slav against the non-Slav Balkan states and settled an old quarrel with Serbia by resuming negotiations with that country. In January 1908 he sprang a surprise upon Europe by his plans for a Novi-Bazar railway, which he said would lay the foundations for further developments of Austria in the Balkans. This proposal was regarded as peculiarly unfortunate in view of the changes taking place in Turkey, which, it was hoped, gave promise of true progress in the Ottoman Empire. Aherenthal had exerted himself to prevent the Russian rapprochement of 1907, and the railway project was his answer to it, as a blow aimed at Russian predominance in the Balkans. The meeting of King Edward and the Tsar of Revel (July 1908), and the Turkish revolution, gave him his opportunity. A meeting between him and the Russian foreign minister (M. Izvolsky) in September relieved the strain between the two powers for a time, but events followed one another with startling rapidity. Eight days later Prince Ferdinand proclaimed his brother-in-law a king of independent Bulgaria, and in another two days the Emperor Francis Joseph issued a proclamation that Austro-Hungarian sovereignty was extended to Bosnia and Herzegovina, in other words, the two annunciations were reversed. This was a step undoubtedly premeditated ever
since the Berlin Treaty of 1878, by which these provinces were handed over to Austria to administer until such time as the Turks should be more competent to govern them. The move was a flagrant violation of that treaty, and Achrenthal refused to entertain the idea of a conference on the ground that it would seem like "a tribunal in which Austria-Hungary would be the defendant." Serbia and Montenegro threatened war, and the situation at last became so dangerous that the acquiescence of Turkey had to be bought by concessions and a sum of $11,000,000. Early in 1909 everything was ready for war on the southeastern frontier, but Serbia was forced to yield when it became evident that Germany had compelled Russia to give a hope of practical support. Achrenthal had won a victory; but he had planted the seeds of the European war and placed his country more firmly than ever under German tutelage.

ÆLFRIC, a'lfrik, the Grammarian, Anglo-Saxon author and translator; fl. 1006. In his youth he was taught by a secular priest who could scarcely understand Latin. "There was no one," he says, "who could write or understand Latin letters until Dunstan and Æthelwoald revived learning." This may account for his warm interest in education and his industry in translation and compilation. "A Treatise on the Old and New Testaments" (printed 1623); the "Heptateuchus," an abridgment and translation of the first seven books of the Old Testament, with the Book of Job (printed 1659); a "Pastoral Letter," written for Wulfstan, archbishop of York (1003-23), in which he makes the archbishop declare that he will not forcibly compel his clergy to chastity, but admonishes them to observe it; a "Latin Grammar and Glossary" (published by Sommer 1659).

ÆLIA, a Roman gens, whose members included Sejanus, Hadrian and the Antonines, as also the families of Pætus (q.v.), Gallus, etc.

ÆLIA CAPITOLINA, the new name given to Jerusalem by Hadrian when he colonized it with Romans after the insurrection of 132-35 A.D.; he built a temple to Jupiter Capitolinus and prefixed the name of his own gens, the Ælian. The Christian emperors after Constantine restored the old name.

ÆLIANUS, Claudius, ë-li'anus, a noted Roman sophist who flourished in the first half of the 2d century: b. Praeneste, Italy. Of his many works written in Greek, two are extant: 'Various Histories,' or narratives, in 14 books, and 'Of the Nature of Animals,' anecdotes of animals,—most entertaining and uncritical compilations. The 'Peasants' Letters' accredited to him are spurious. Best ed., Heather, 1858 and 1864.

ÆLIANUS TACTICUS, a Greek tactician and author of the 2d century. His 'Tactiké Theòria' (written about 106 A.D.) is a valuable historical and bibliographical treatise on Graeco-Macedonian military tactics, based on the authorities, the chief of which is the lost work of Polybius. The treatise exerted great influence on the Byzantines and Arabs, and was the groundwork of the Spanish, Dutch and other European army organizations of the 16th and 17th centuries. Theodore Gaza translated it into Latin, and from this a German translation appeared (Cologne 1524); it was translated into French by Machault in 'Milles des Grecs et Romains' (Paris 1615); into English by Bingham (London 1616), and by Viscount Dillon (London 1814); it reappeared in German with translation, notes and reproductions of the original illustrations, edited by Ristow and published in 'Griechische Kriegsschriften' (Leipzig 1855).

ÆLRODON, ël-ur-ô'don, a primitive carnivore fossil in the rocks of the Wasatch and Uinta (American) stages of the Pliocene Age; a hyena-dog. It was as large as the modern wolf, but had a short, heavy, mastiff-like head, and was distinguished from any living canids by the cat-like construction of the carnassial teeth. (Osborne, 'Age of Mammals,' 1910).

ÆMILIANUS, C. Julius, Emperor of Rome: a Moor who rose from the lowest stations; governor of Pannonia and Mesia, whose troops killed the Emperor Gallus and gave him the crown. He reigned only four months, when he was killed in his 46th year by his own soldiers, who then offered the crown to Valerian, August 253 A.D.

ÆMILIAN WAY, a Roman state road about 185 miles long, built by the consul Marcus Æmulius Lepidus, 187 B.C., primarily as a military road to make easy communication between Rome and her new possessions in Cisalpine Gaul (Lombardy). Beginning at Ariminum (Rimini) on the Adriatic, where the Flaminian way from Rome ended, it traversed Bononia (Bologna), Mutina (Modena) and Parma, crossed the Pádus (Po) at Placentia (Placenza) and ended at Mediolanum (Milan).

ÆMILIUS PAULUS, surnamed Macédonicus, a noble Roman of the ancient family of Æmilli; b. 230 B.C.; d. 160. He conquered Perseus, King of Macedon, and on this occasion obtained a triumph, 168 B.C. During the triumph two of his sons died. He bore the loss like a hero and thanked the gods that they had chosen them for victims to avert bad fortune from the Roman people. He was father of the renowned Scipio Africanus the Younger.

ÆNEAS, in the Iliad, a Trojan prince, son of Anchises and the goddess Venus; second only to his kinsman Hector among the Trojan chiefs. Other stories tell that the care of his infancy was entrusted to him at the age of five he was recalled to Troy and placed under the inspection of Alcathoüs, his father's friend and companion. He afterward improved himself in Thessaly under Chiron the Centaur, whose house was frequented by all the young princes and heroes of the age. Soon after his return home he married Creusa, Priam's daughter, by whom he had a son called Ascanius. Virgil, whose object is to connect him (according to Latin tradition of an unreliable source) with the origin of Rome, tells his further story as follows in the Æneid: In the night of the capture of Troy by the Greeks, Hector warned him in a dream to fly. Æneas not-withstanding, rushed to the fight; but after Priam was slain returned to his home, where he married off his father, his child and his household gods, losing, however, his wife, Creusa, in the confusion. With 20 vessels he sailed for Thrace, where he began to build Ænos, but terrified by a mirage abandoned the attempt. Thence he went to Delos to consult the oracle.
ANEAS SILVIUS — ÆNEID

Misunderstanding its reply he went to Crete, from which he was driven by a pestilence; thence to the promontory of Actium, and in Epirus found Helenus and Andromache; thence past Italy and through the Straits of Messina, and circumnavigated Sicily to Cape Drepanum on the western coast, where Anchises died. A tempest drove him on the shore of Africa, where Dido received him kindly in Carthage and wished to detain and marry him. Jupiter, however, mindful of the Fates, sent Mercury to Æneas and commanded him to sail for Asia. While the deserted Dido ended her life on the funeral pile, Æneas set sail with his companions and was cast by a storm on the shores of Sicily, in the dominions of his Trojan friend Acestes, where the wives of his companions, wearied of a seafaring and homeless life, set fire to the ships. Nevertheless, after building the city Acesta, he sailed for Italy, leaving the women and the sick behind. He found near Cumae his father's ghost had ordered him to seek, who foretold his eventual aid to his descent into the lower world; here he saw his father and had a prophetic vision of the glorious destinies of his race. On his return he embarked again and reached the eastern shore of the river Tiber, in the city of Rome, the King of the Aborigines (q.v.). His daughter Lavinia was destined by an oracle to a stranger, but promised by her mother Amata to Turnus, King of the Rutuli. This occasioned a war, after the termination of which, Turnus having fallen by his hand, Æneas married Lavinia. His son by Lavinia, Æneas Sylvius, was the ancestor of the kings of Alba Longa, and of Romulus and Remus, the founders of the city of Rome. From Ascanius' son Iulus the Romans derive the Julian family. For the real origin of Rome, see that title.

ANEAS SILVIUS. See Pius II.

ÆNEAS TACTICUS, a Greek writer on war tactics of the 4th century a.c., by some authorities identified with Æneas of Symphalaeus, Arcadia, a general who fought at Mantinea 362 a.c., as recorded by Xenophon. His several treatises on the art of war, of which the only one in existence deals with the best methods of seated city, were epitomized by Cineas, minister of Pyrrhus, King of Epirus, and are mentioned by Polybius and Ælianus. Containing anecdotes and illustrations from Thucydides and Xenophon the work, as edited and published by Hoerzer (Berlin 1870), and with introduction and notes by Hug (Leipzig 1874), has much value and interest. For a challenge as to the identification with the Symphilian general and for a bibliography consult Wilmer Thal, in American Journal of Philology (Vol. XXV, 1904).

ÆNEID. The. The Æneid of Vergil is the epic of imperial Rome, as the Homeric poems are the epic of early Greece, the Divine Comedy of mediæval Italy, and Paradise Lost of Puritan England. For two hundred years before Vergil (70-19 a.c.) there had been current the legend of the founding of Rome by Æneas, a minor Trojan hero of the Iliad, son of Venus and Anchises and father of Ascanius or Iulus, ancestor of Julius Caesar and Ascanius or Iulus. The Æneid gave it final form and sanction, and made it canonical. The first six books of the poem, after introducing Æneas and his companions shipwrecked near Sicily and driven to the Carthaginian coast, where they are received at the court of Queen Dido, narrate the hero's escape from burning Troy, his wanderings on sea and shore in search of the divinely appointed but unknown goal, his tarrying at Carthage, the passion of the Queen and her fatal despair when divine intervention forces him on, the funeral games in Sicily in honor of Anchises, the visit to the underworld, where the destiny of Rome is made known to him, and his departure from sacred Cumae, near Naples, for the Tiber's mouth, where his landing takes place at the opening of the seventh book. The last six books, the narrative of his troubled alliance with King Latinus of Latium, and of his wars, assisted by the Arcadian King Evander of primitive Rome, with Latian and Etruscan enemies under Turnus and Mezentius, close with the slaying in single combat by Æneas of Turnus, his most persistent and singular foe, and the clearing of the stage for the beginnings of Roman greatness.

It is immediately apparent — to the shallow reader offensively so — that the Æneid is an imitation or adaptation of the Homeric poems. The six books after the first six books an Odyssey, with the divinely guided and divinely hindered hero Æneas reaching Italy after seven years of blind wanderings, as Odysseus reached his Ithaca home in similar wise 10 years after the fall of Troy, and the last six an Iliad of battling, with the Trojan cause victorious in Latium as the Greek cause had been at Troy. This manner of blending, or rather building, a unit out of two Greek originals was so well known in Roman literature that as early as Terence (157-169), who practiced it in the field of the drama, continuing a tradition at least as old as Nævius (circa 270-199), it had received the technical designation of "contaminatio." To deny the Æneid originality, however, or even genius, argues in the critic only a superficial acquaintance with it. It was immediately received with enthusiasm by the cultivated in a generation which was well acquainted with good literature and highly critical, it enjoyed no less favor with the multitude, was used in the Roman schools, made deep impressions on the hearts, and often on the style and content, of such men as Horace, Propertius, Seneca, Lucan, Statius and Juvenal, captivated Augustine, took possession of the Christian imagination, cast over its author in the Dark Age the glamour of prophetic and magical power, inspired in Dante lo bello stile and gave him the maestro who directed his feet in the other world, was made Christian in Tasso's Jerusalem Delivered, entered into the ideals and execution of Spenser, Milton and many others of the long line of modern poets in all European languages, was to Tennyson "Light among the vanished ages, that star that glidest yet this phantom shore," and has held its place through the centuries as a necessary part in the culture of the Caucasian peoples. Admiration so widely spread and so long continued, and influence bearing such abundant fruit, are possible only with works of power. With its faults freely conceded, the Æneid remains one of the world's three or four epic masterpieces.

For reasons both of content and form, comparison of the Æneid with the Iliad and
the 'Odyssey' is inevitable; it is also not quite just. There are two kinds of epic. There is the natural or folk epic, a more or less spontaneous and naive growth by oral and popular tradition, such as the 'Nibelungenlied,' 'Beowulf,' the 'Song of Roland' or the 'Cid'; and there is the artificial or literary epic, the deliberate, though also inspired, creation of a single mind in an age of cultivation and reflection, such as the 'Divine Comedy,' 'Jerusalem Delivered,' 'Orlando Furioso,' 'The Iliad,' and 'Paradise Lost.' To the former belong the Homeric poems, though their art is by no means unconscious as is sometimes supposed; to the latter class belongs the 'Aeneid.' Vergil's poem is not merely a more or less dull reflection of the 'Iliad' and the 'Odyssey.'

In the first place, the 'Aeneid' is a poem with a purpose. It is not the spontaneous 'singing' of primitive inspiration; it is not, and was not intended to be, the mere telling of an entertaining tale. The bard and epic has usually a conscientious purpose — to justify the ways of God to men ('Paradise Lost'), to fashion 'XII Moral Virtues' ('The Faire Queene') — as well as the less artificial purpose of artistic self-expression. The 'Aeneid' is the poem with a national, patriotic purpose. The writer of the 'Eclogues' and the 'Georgics,' who had helped to reawaken the love for field and orchard in a time when the Roman world was fattigued with the disorders and violence of a century and longing for peace and quietude, was prompted by the court, as well as by his own inspiration, to celebrate the greatness, under divine warrant, of Roman achievement and Roman purpose. The great figure in the 'Aeneid' is not Aeneas, or Dido, or the Julian ruler, but Rome. Throughout the 12 books — in the councils of the gods, in the Carthage episode, in the hero's converse with the underworld, in the endless conflicts and cruelties on the plains of Latium — there is ever felt in the background the idea of the oncoming, divinely ordered, irresistible greatness of Rome. It was the century in which the phrase wērt eterna was coming into use and the faith in Roman destiny was ripening.

The source of the 'Aeneid' is not the 'Iliad,' but the 'Odyssey,' but the Cyclic poems and the Homeric Hymns, Apollonius Rhodius 'Tale of the Argonauts,' and the whole range of Roman historical and poetic literature — Ennius, Livy, Varro, Lucretius. In other words, Vergil was a widely and deeply cultured student and lover of poetry and history, and the 'Aeneid' is the product of poetic inspiration working upon an exceedingly rich intellectual and spiritual equipment in an age of culminating greatness. In the respect of intellectual preparation Vergil is to be compared with poets like Dante, Tasso, Milton and Spenser, whose works are so permeated by the classical spirit and so filled with classical material as to remind the reader of a rich mosaic. He is no more the plagiarist that Macробius, three centuries later, charged him with being, than Milton, using from the full store of the classics and Hebrew literature, was a plagiarist. The 'Aeneid' is a poem of many and varied interests. The reader must not look to it for the simplicity and spontaneity and speed of primitive story-telling genius, the qualities that make the natural epic great. As compared with the Homeric poems, it is not easy and fluent reading. It is a complex of the primitive and the sophisticated, of the heroic and the actual, of the legendary and the real, of the historic and the prophetic, of the Hellenic and the Roman, of age-old religion and the new philosophy, of the archaeological and the modern, of the political and the poetic, of the classic and the romantic. It is filled with the humility of faith, and with gentle personal emotion, but also with national pride, and with the dignified and austere feeling of might consciously engaged in working the will of heaven.

'To write an enduring epic,' says Cruttwell ('History of Roman Literature,' p. 285), "a poet must not merely recount heroic deeds, but must weave into the recital all the tangled threads which bind together the grave and varied interests of civilized man." It is not to be wondered at that criticism has found in the 'Aeneid' not a Greek but a Roman poem; just as the triumphal arch, in spite of its Greek column and architrave, is a Roman, not a Greek, structure.

Posterity has rejoiced that Vergil's order for the destruction of the 'Aeneid' was not obeyed. The poem has its own pronounced excellences, some of them unsurpassed, and to call a thing Vergilian is to give it high praise. If any single word will in a measure express the sum of its qualities, it is the word 'richness.' The natural epic is of a texture firm, warm and yielding, with simple pattern in glowing, joyous colors; the literary epic is a brocade of gorgeous, mingled hues, with strands of gold and silver inwoven in complicated pattern, so stiff it will stand alone. The 'Aeneid' is especially rich. It is kept from the defects of undiluted Renaissance art only by Hellenic restraint. It is rich in allusive content — mythological, historical, religious, archaeological, literary. It is rich in story. The fortunes of its hero as a whole are no uninteresting narrative, and no tales could be more fascinating than the episodes of the fall of Troy, the loves of Aeneas and Dido, the descent to Avernus, the adventures of Nisus and Euryalus. It is rich in memorable characters. It may be that not even allome far the contemporary, under which Aeneas labored and for the ancient lack of chivalrous sentiment toward woman, to say nothing of the woman who was Queen of the Carthage one day to threaten Roman existence, can move the modern reader to more than a purely intellectual acceptance of the principal character; but even Aeneas is a thoroughly consistent figure in his steadfast, sad-hearted obedience to the commands of heaven. And as for the Dido he was compelled to leave, in her Vergil has set pictures of a dignified and truthful portrayals of a dignified, beautiful and passionate woman wrought upon by the extremities of love and despair. This one intense
figure goes far to compensate for the lack of vividness and reality in so many of the dramatic personae of the 'Æneid.' It is rich in the mystical and the romantic. For Dante to make the sixth book into the stage of the Inferno was natural; the sixth book is already mediaeval. It is rich in love of nature and sensiveness to beauty of every kind. No reader forgets the familiarly modern feeling for natural scenes—for the sea tempestuous under the light of the moon, the winds whirling to the sea between leafy banks, with wild fowl in the air all about; or misses the charm of numberless allusions in simile and metaphor to the beauty of Italy, the garden, and her sister Mediterranean lands. It is rich in pathos. Vergil's tenderness, the haunting melancholy of Vergil, the archaism of the dactylic hexameter, have become literary phrases. It is rich in religious feeling, in its fond looking back toward the old-fashioned gods of field and grove, farmhouse and fold, and in the yearning note always pathetically sounding when death is envisaged and the life beyond is glimpsed.

Vergil's poems, writes F. W. H. Myers, lie at the watershed of religions. Filled as they are with Roman rites and Roman tradition, they contain another element, gentler, holier, till then almost unknown; a change has passed over them like the change which passes over a Norwegian midnight when the rose of evening becomes silently the rose of dawn. It is rich in the personality of the poet. The emotional qualities of the 'Æneid' are felt to belong to Vergil himself. It is as if we were in the presence of the tall, dark, delicate, serious, retiring friend of Horace, the 'soul than whom the earth has brought forth none more fair,' and heard his earnest, melancholy tones, and felt his enthusiasm for poetry and responsiveness to the noble and the beautiful. It is rich above all in the dignity, variety, sonorosity, adaptability and spiritual suggestiveness of the statement, measure ever moulded by the lips of man. In other respects the 'Æneid' may be uneven; in this it is of unfailing excellence. We shall not find, says Mackail, that the splendour of the poem depends on detached passages, but far more on the great manner and movement which, interfered with the unique Vergilian tenderness, sustains the whole structure through and through.

The 'Æneid' may be read in the verse translations of Conington, Bowen, Morris and Dryden, or in the prose of Conington, with essays by Francis G. and Anne C. E. Allinson, or of Fairclough in the Loeb Classical Library, or of Mackail. For appreciation, Seller's 'Vergil': Boissier, 'The Country of Horace and Vergil'; Glover, 'Vergil'; Comparetti, 'Vergil in the Middle Ages.'

GRANT SHOWERMAN,
Professor of Latin Literature, University of Wisconsin.

ÆNESIDEMUS, ënës-i-dëmëus, Greek philosopher, fl. 80-60 b.c.: h. Cnosus in Crete, removed to Alexandria. He was leader of the Stagirite school and is famous for the 'Ten Tropes' attributed to him. His arguments prove the impossibility of absolute knowledge, and reducible in essence to two, that no two things are alike and everything is relative. They are: (1) That each sentient being must have a different perception and conception of the universe from every other because differently constituted; (2) that human beings differ; (3) that sense organs differ; (4) that the circumstances of perceptions differ; (5) that objects perceived differ in location and distance; (6) that different objects arecompound; (7) that different combinations make the same sensation seem different; (8) that all knowledge is relative; (9) that degrees of familiarity cause differences in perception; (10) that the intellectual speculations, mental theories, laws, manners and customs, civilizations, etc., of all races differ (Locke's argument against intuitive ideas).

ÆNIANES, ë-ni-a-nës, in classic Greek, an Achenian people living on the southern border of Thessaly, in the mountains west of Thermopylae; members of the Ætolian League and the Delphic Amphictyony.

ÆNON, ãnón, a place near Salim where John the Baptist baptized (John iii, 21). Its location is now difficult to determine. Eusebius and Jerome place it eight miles south of Seythopolis, now called Assa, and a mile south are seven springs. A place which is now called Ainun, five miles northeast of Jerusalem in Wady Farah, is thought by Barclay and Conder to be the right location. Here are a great number of rock-hewn cisterns, and a short distance south are many springs, which may seem to connect it with Ænon, a place where was "much water," or many waters.

ÆOLIAN, a musical instrument. See MUSICAL INSTRUMENTS, MECHANICAL.

ÆOLIAN DEPOSITS. See ÆOLIAN DEPOSITS.

ÆOLIAN HARP, or ÆOLUS' HARP, is generally a simple box of thin fibrous wood to which are attached a number of fine strings, sometimes as many as 15, stretched on low bridges at each end and carefully tuned so as to be in harmony. Its length is made to correspond to the size of the window or other aperture in which it is intended to be placed. It is about five or six inches, its depth two or three. It must be placed in the strings uppermost, under which is a circular opening in the centre, as in the belly of the guitar. When the wind blows athwart the strings it produces the effect of a choir of music in the air, sweetly mingling all the harmonic notes and swelling or diminishing the sounds according to the strength or weakness of the blast. A simpler kind of Æolian harp has no sounding-board but consists merely of a number of strings extended between two boards.

ÆOLIANS ("variegated," mixed race), an ancient Greek people, perhaps the very earliest Greek stock—a mixture of Hellene and Pelasgi—before the special races like Ionians and Dorians had differentiated from it; as their language was not a distinct dialect like those, but is a mixture of elements from all and presents the closest link of any between Greek and Latin. The Hesperian language is Æolic. The race extended from northeast to southwest through Greece, from the Pagasaic Gulf through Thessaly or at least Pthisiotis, Boeotia, Phocis, Locris and Ætolia, north of
the Corinthian Gulf, to Elis and Messenia, south of it. The sons of Æsculapius (q.v.), Philectetes, Odysseus, Nestor and the Ollean Ajax, were Æolians; and legend accredits to them the descent of Melampus the herdsman who understood the song of birds, Sisyphus, the founder of Corinth, and Athamas, the great King of the Minye, son-in-law of Cadmus and father of Phrixus and Helle. The Æchæans, if not originally part of the same stock, became by time with them and are claimed by the ancients as part of them; and there is no separate Æchæan dialect or art. Probably they were one, and the Peloponnesian Æchæans were certainly part of them; and the great emigration commonly called the Æolian was an emigration of Æchæan people. It seems probable that the emigration from the Peloponnesus began before the Dorian invasion, or return of the Heraclidæ, as it is often called, which caused so great a revolution in the peninsula. Strabo says the Æolian settlements in Asia were four generations prior to the Ionian. Their colonies on the Asiatic mainland were widely spread, extending at least from Cyicus, along the shores of the Hellespont and the Ægean, to the river Calcium and even the Heræus. Many positions in the interior were also occupied by them as well as the fine island of Lesbos, with Tenedos and others of smaller importance. Homer mentions all these parts as occupied by a different people, which would be proof, if any were wanted, that the race of new settlers came after his time. There were 12 cities or states included in the older settlements in that tract of Asia Minor on the Ægean which was known in Greek geography by the name of Æolis and formed a part of the subsequent larger division of Mysia. Smyrna, one of them, which early fell into the hands of the Ionians, the neighbors of the Æolians, still exists nearly on the old spot, with exactly the same name; thus adding one to the many instances of the durable impression made by Greek colonies wherever they settled.

ÆOLIPILE, an invention of Hero of Alexandria, often called the first steam engine. It consists of a hollow metal sphere supported by castings, through one of which steam at admitted to the interior of the sphere. At opposite points on the sphere short tubes are inserted with their ends bent. The steam escapes through these ends and causes the sphere to revolve. Consult Gerland and Traumüller, 'Geschichte der physikalischen Experimentierkunst' (Leipzig 1899); Schmidt, 'Herön von Alexandria' (ib, 1899); Thurston, R. H., 'Growth of the Steam Engine' (New York 1878).

ÆOLIS. See ÆOLIANS.

ÆOLUS, in Greek legend: (1) Ruler of the winds; a sort of sub-deity, having his residence on a floating island, said to be one of the Æolian Islands, or by the Latin and later Greek poets one of the Lipari Islands. Here he kept the winds in bags (Vergil says in caves), restraining or letting them loose at the orders of the gods. In the Odyssey he gives them to Odysseus to take care of for a time. (2) The eponymous ancestor of the Æolians, located in Thessaly; Hellen was his father and Dorus his brother (eponyms of the Hellenes and Dorians), and Sisyphus his son, the significance of which is not ascertainable. (1) and (2) may have been originally the same, but if so they arose as independent metaphors or epithets.

ÆONS (from the Greek, signifying "an age," "everlasting"), a designation applied to celestial powers and spirits which, according to Gnostic philosophy, proceed from God the all-perfect Æon, the fountain-head of divinity, which existed before heaven and distinctly ruled the successive eras of the universe, throughout eternity. See GNOSTICISM. Consult Mead, 'Fragments of a Faith Forgotten' (London 1900).

ÆPINUS, Æ-pi'nús, Franz Maria Ulrich Theodor, German physicist and Prussian educator: b. Rostock, Saxony, 13 Dec. 1724; d. Dorpat, 10 Aug. 1802. From 1757 until his retirement in 1798 to Dorpat, he was professor of physics and member of the imperial academy of sciences in Saint Petersburg (Petrograd). He was a prolific author of various works on the physical sciences, chief of which are: 'Tentamen Theoriae Electricitatis et Magnetismi' (Saint Petersburg 1759); 'De distributione caloris per tellurem' (Saint Petersburg 1761); and a treatise on the effects of parallax in the transit of a planet over the sun's disc (1764), which created great interest. He was tutor to Prince Paul, son of the Empress Catherine II, and inspector-general of the imperial normal schools which the Empress unsuccessfully tried to establish throughout the empire.

ÆQUI, Æ'kwî, an ancient people of Italy, conspicuous in the early wars of Rome. They inhabited the mountain district between the upper valley of the Anio (Teverone) and Lake Fucinus. Their origin is unknown; but they were probably akin to the Volscians, with whom they were in constant alliance. This league after the fall of the monarchy made great headway and captured many towns, their power culminating in the 5th century B.C. At length they were severely defeated by Cincinnatus in 458, and again by the dictator Publius Horatius in 457. They were finally subdued about 304, and soon after were admitted to Roman citizenship, being included in the new tribes Aniensis and Terentina. Henceforth their name disappears from history; but the inhabitants of the upper valleys began to be called Æquiculi, by which name they are mentioned by Vergil as predatory mountaineers. The name Æquiculani occurs in Pliny.

ÆRARUM, e-ra't-ri-um ("money-place"), the public treasury of ancient Rome; containing not only the state moneys and accounts, but the legionary standards, the public laws (on brass plates), Senate decrees, and other important papers and registers. It was located in the temple of Saturn, on the summit of the Capitoline hill. Besides the general treasury, filled from general taxes and drawn on for regular expenses, there was in the same building, a "sacred treasury," or reserve fund, replenished chiefly by a 5 per cent tax on the value of manumitted slaves, which was never drawn upon except on occasions of extreme necessity. The Senate controlled the æarium nominally even under the early emperors, who had their separate imperial treasury
called the *fasces*; but as the Senate became a mere name, the figit of two treasuries was gradually abolished. Augustus established also a military treasury devoted solely to army accounts. The later emperors had likewise a private treasury aside from the general one which they administered for the empire.

**AERATED BREAD.** See Bread.

**AERATED WATERS.** See Mineral Waters.

**AERATOR,** an apparatus used in dairying for aerating milk to remove the animal and barn odors. The usual process is to run the milk in a thin layer over an exposed surface immediately after milking. In most appliances of this kind the animal heat is removed at the same time by having the exposed surface cooled with ice, ice water or cool spring water. Care must be taken that aeration be carried on in a place free from dust in order to lessen the conditions favorable to the growth of microorganisms. The aèrator itself, like all dairy appliances, must be so constructed that it may be easily and thoroughly cleaned.

**AERENCHYMA,** a loose, spongy tissue in plants, especially in water plants. It is supposed to facilitate aeration. Typically it is composed of radially arranged systems of thin-walled cells inclosing large air spaces.

**AERIAL CONVEYER.** See Conveyer.

**AERIAL NAVIGATION, Legal Aspect of.** The rapid development of aerial navigation seems as yet to have produced no actual decisions upon the novel questions of private right and public regulation which sooner or later will be presented for solution. In the absence of express statute or international regulation by treaty, the principles and analogies of the common and maritime law must furnish the rule of decision. The right of an aviator to fly over another's land depends upon the true meaning and present application of the ancient maxim, "Whoever owns the soil owns also to sky as high as the dew." Literally construed and applied, any passage over another's land, at whatever height, is a trespass and therefore unlawful. On the other hand, the view is taken that this maxim is not to be applied literally, that the owner's rights in the air space above his land are appurtenant to the soil and extend only so far as is necessary to the enjoyment of the use of the soil without interference and that therefore a mere passage across his land at a sufficient height and without other interference is not an actionable wrong. It is everywhere agreed, however, that if navigation over another's premises is conducted so as to constitute a nuisance, or to result in actual damage, an action will lie. The conflict of opinion is as to whether the right of action is limited to cases of actual damage and of nuisance. An opinion fast gaining ground is that the landowner cannot be heard to complain of any use of the air spaces above his land by which no damage to his premises was done; the right of passage that the height necessary to the full enjoyment of his land free from any interference are too unsubstantial to be protected by the law (4 Am. J. Int. L. 126, 127).

**AERIAL TELEGRAPHY.** See Semaphore; Wireless Telegraphy.

**AERIAL TORPEDOES,** the designation given to explosive missiles which are capable of propelling themselves through the air by self-contained forces. See Torpedoes.

**AERIANS,** a-e-ri-ans, a religious sect who arose in the 4th century in the Church and present many features of modern religious liberalism in the way they combatted ecclesiastical tradition and the institutionalism professedly derived from the apostolic age. They derive their name from their originator and leader, Aërius, a presbyter of Selaste, a city of Pontus. Aërius flourished about 355 A.D. He was fired with a spirit of revolt against the condition of the Church as he found it. Although an ascetic of a very stern and rigid character, he was shocked at the extravagant lengths to which some of his fellow Christians carried the practice of fasting, and the claims which they made to merit because of this rigorous self-maceration. Although he found fasting a settled institution of the Church he opposed the practice because of the delusions it seemed to lead to. He was also an opponent of those special festivals of intercession which were held in behalf of the faithful departed. "Pray for the living, whose needs and sufferings some of which you may have caused," he seems to say. To this vigorous and uncompromising onslaught on the common and ordinary practices of the Church he recalls such earnest and outspoken fathers of the Reformation as Martin Luther and John Knox. There were a great many people who sympathized and agreed with him, and his sect at one time was very flourishing. The ascendancy of the episcopal order in the Church was a natural aristocratic movement, although Bishop Lightfoot in commentary on the Philippian does not seem to think that it was sanctioned either by divine command or apostolic precedent. Aërius maintained that the bishop was not superior to the presbyter, that they were of the same order, and that a bishop was merely a chairman elected for convenience sake to preside among equals. He seems also to have been opposed to holding of any such set festivals in the Church as Easter. This sect seems to have sown the earliest seed of modern Presbyterianism.

**AERIDES,** a-e-rides, the wind flower, one of the Orchidaceae, of which there are 15 species. The finest species, *Aerides adoratum,* grows wild in parts of Asia, but in cold and temperate climates is cultivated under glass, though flowering at rare intervals. This genus of plants derives its name from the fact that the species appear to take their principal nourishment from the air, as they can exist and thrive in their native clime, sending forth blossom after blossom while suspended and far away from any vegetable soil. They bear distichous leaves and their flowers are big and brilliant, while at the same time possessing a rare fragrance.

**AERINITE,** a bright blue earthy substance found in the Pyrenees. It has no definite composition, and its blue color is perhaps of artificial origin.

**AERO CLUB OF AMERICA.** Club organized on 16 Feb. 1910, having for its objects,
as stated in the certificate of incorporation, the promotion of a social organization or club composed in whole or in part of persons owning aeronautical inventions for personal or private use. To advance the development of the science of aeronautics and kindred sciences. To encourage aerial navigation, conferences, exhibitions, congresses and contests. To maintain a club house or club houses, aerial garages, and accessories, aeronautic or otherwise incidental to the purposes or the furtherance of any of the powers hereinbefore set forth, and to do every other act or acts incidental or appurtenant to or connected with the aforesaid purposes, sports or powers, or any part or parts thereof; provided the same be not inconsistent with the laws under which this corporation is organized. The Aero Club is the sole representative in the United States of America of the Federation Aeronautique Internationale, and as such, it may grant aeronautical and aviation pilots' certificates to persons who are over 18 years of age, citizens of the United States, or citizens of a country not represented in the Federation Aeronautique Internationale.

AERODYNAMICS. That branch of physics which treats of forces, equilibrium and motion in a gas. It is a branch of hydrodynamics (q.v.), but differs from this latter science as applied to liquids in that it concerns itself with a compressible medium. See AIRPLANE; AEROSTATIC GAS; SOUND; WAVE; WIND.

AEROKLINOSCOPE, an instrument to indicate differences of barometric pressure at remote stations. It consists of a vertical axis 30 feet high, turning on a pivot, carrying at the top a horizontal arm, of which the inclination can be varied according to the difference of barometric pressure at different sides of the station, the amount of dip being indicated by a sliding rod held in position by grated notches at the lower part of the axis, each notch corresponding with one millimetre in pressure. It is used in the weather service and at military stations.

AERONAUTICAL NOMENCLATURE. The following are the principal terms which have come into use in the development of aeronautics and are new and peculiar to the subject.

Aeroplane, a thin wing-like structure, flat or curved, designed to obtain reaction upon its surfaces from the air through which it moves.

Aeroplane, a form of aircraft heavier than air which has wing surfaces for sustenance, with stabilizing surfaces, rudders for steering, and power plant for propulsion in the air. The landing gear may be suited for either land or water use.

Aileron.—A type of airplane with the propeller or propellers in rear of the wings.

Air-Screw.—A type of airplane with the propeller or propellers in front of the wings.

Altimeter.—A movable auxiliary surface used for the control of rolling motion—i.e., rotation about the fore and aft axes.

Air-SPEED METER, an instrument designed to measure the velocity of an aircraft with reference to the air through which it is moving.

Altimeter, an instrument mounted on an aircraft to continuously indicate its height above the surface of the earth. A small balloon is equipped with a hand ring and for maintaining pressure on the outer envelope to prevent deformation. The balloon is kept inflated with air at the required pressure, under the control of a blower and valves.

Balloon, a form of aircraft comprising a gas bag and a car, whose sustenance depends upon the buoyancy of the contained gas, which is lighter than air.

Capote.—A balloon restrained from free flight by means of a cable attaching it to the earth.

Kite.—An elongated form of captive balloon, fitted with tail appendages to keep it headed into the wind, and deriving increased lift due to its axis being inclined to the wind.

Bank, to incline an airplane laterally—i.e., to rotate it about the fore and aft axis. The right bank is to incline the airplane with the right wing down.

Barograph, an instrument used to record variations in barometric pressure. In aeronautics the charts on which the records are made are prepared to indicate altitudes directly instead of barometric pressure.

Biplane, a form of airplane in which the main supporting surface is divided into two parts, one above the other.

Body of an Airplane, a structure, usually inclosed, which contains in a stream line housing the power plant, fuel, passengers, etc.

Cambre, the convexity or rise of a curve of an aerofoil from its chord, usually expressed as the ratio of the maximum departure of the curve from the chord as a fraction thereof. "Top Cambre" refers to the top surface of an aerofoil, and "Bottom Cambre" to the bottom surface; "Mean Cambre" is the mean of these two.

Capacity.—Lifting.—The maximum flying load of an aircraft.

Carrying.—Excess of the lifting capacity over the dead load of an aircraft, which latter includes structure, power plant, and essential accessories.

Centre, the point in which a set of effects is assumed to be accumulated, producing the same effect as if all were concentrated at this point.

Cylinder.—The centre of gravity of the fluid displaced by the floating body.

Cylindrical.—Of pressure of an aerofoil.—The point on the chord of an element of an aerofoil, prolonged if necessary, through which at any instant the line of action of the resultant air force passes.

Cylindrical.—Of pressure of a body.—The point on the axis of a body prolonged if necessary, through which at any instant the line of action of the resultant air force passes.

Chord, of an aerofoil section.—A right line tangent to the under curve of the aerofoil section at the front and rear.

Length.—The length of the chord is the length of the aerofoil section projected on the chord, extended if necessary.

Controls, a general term applying to the means provided for operating the devices used to control speed, direction of flight and altitude of an aircraft.

Dirigible, a form of balloon, the outer envelope of which is of elongated form, provided with a propelling system, car, rudders and stabilizing surfaces.

Non-rigid.—A dirigible whose form is maintained by the pressure of the contained gas assisted by the car suspension system.

Rigid.—A dirigible whose form is maintained by a rigid structure contained within the envelope.

Semi-rigid.—A dirigible whose form is maintained by means of its attachment to an exterior girder construction containing the car.

Drag, the total resistance to motion through the air of an aircraft—i.e., the sum of the frictional and head resistance.

Drift, the component of the resultant wind pressure on an aeroplane or wing surface parallel to the air stream attacking the surface.

Elevator, a hinged surface for controlling the longitudinal attitude of an aircraft—i.e., its rotation about the athwartship axis.

Engine, Right or Left Hand, the distinction between a right-hand and a left-hand engine depends on the rotation of the output shaft, whether that shaft rotates in the same direction as the crank or not. A right-hand engine is one in which, when viewed from the output shaft end, the shaft is seen to rotate anti-clockwise.

Fin, small planes on aircraft to promote stability; for example, vertical tail fins, horizontal tail fins, skid fins, etc.

Flight Path, the path of the centre of gravity of an aircraft with reference to the air.

Gap, the distance between the projections on the vertical axis of the entering edges of an upper and lower wing of a biplane.

Helicopter, a form of aircraft whose support in the air is derived from the vertical thrust of large propellers.

Inclinometer, an instrument for measuring the angle made by any axis of an aircraft with the horizontal.

Lift, the component of the force due to the air pressure of an aerofoil, resolved perpendicular to the flight path in a vertical plane.

Monoplane, a form of airplane whose main supporting surface is disposed as a single wing on each side of the body.

Nose Dive, a descent of the nose of an aircraft.

Ornithopter, a form of aircraft deriving its support and propelling force from flapping wings.
Pilot Tube, a tube with an end open square to the fluid stream; used as a detector of an impact pressure. More usually a concentric tube surrounded by a gauze having perforations normal to the axis for indicating static pressure. The velocity of the fluid can be determined from the difference between the impact pressure and the static pressure. This instrument is often used to determine the velocity of an aircraft through the air.

Race of a Propeller, the air stream delivered by the propeller. Aft of the Rudder, a hinged or pivoted surface, usually more or less flat or streamline led, used for the purpose of controlling the attitude of an aircraft about its vertical axis when in motion.

Skidding, sliding sideways in flight away from the centre of the turn. It is usually caused by insufficient banking in a turn, and is the opposite of side slipping.

Skids, long wooden or metal runners designed to prevent nosing a land machine when landing or to prevent dropping into holes or ditches in rough ground. Generally designed to function should the wheels collapse or fail to act.

Slip, this term applies to propeller action and is the difference between the actual velocity of advance of an aircraft and the speed calculated from the known pitch of the propeller and its number of revolutions.

Spread, the maximum distance laterally from tip to tip of an aircraft. Stability, the quality of an aircraft in flight which causes it to return to a condition of equilibrium when meeting a disturbance. (This is sometimes called "Dynamical stability").

Directional Stability with reference to the vertical axis.

Inherent.—Stability of an aircraft due to the disposition and arrangement of its fixed parts.

Lateral.—Stability with reference to the longitudinal (or fore and aft) axis.

Longitudinal.—Stability with reference to the lateral (or athwartship) axis.

Statical, an instrument to detect the existence of a small rate of ascent or descent, principally used in ballooning.

Stay, a wire, rope or the like, used as a tie piece to hold parts together, or to contribute stiffness; for example, the stays of the wing and body bracing.

Strip, a compression member of a truss frame; for instance, the vertical members of the wing truss of a biplane.

Tail, the rear portion of an aircraft, to which are usually attached rudders, elevators and fins.

Tail Fins, the vertical and horizontal surfaces attached to the tail, used for stabilizing.

Thrust Deduction, due to the influence of the propellers, there is a reduction of pressure under the stern of the vessel which appreciably reduces the total propulsive effect of the propeller. This is termed "Thrust deduction."

Triplane, a form of airplane whose main supporting surfaces are divided into three parts, superposed.

Truss, the framing by which the wing loads are transmitted to the body; comprises struts, stays and spars.

Warp, to change the form of the wing by twisting it, usually by changing the inclination of the rear spar relative to the front spar.

Wings, the main supporting surfaces of an airplane.

Wing Loading, the weight carried per unit area of supporting surface.

Wing Rib, a fore and aft member of the wing structure used to support the covering and to give the wing section its form.

Wing Spar, an athwartship member of the wing structure resisting tension and compression.

X-ray, the cross section about the vertical axis, owing to gusts or lack of directional stability.

Angle of Attack, the temporary angular deviation of the fore and aft axis from the course.

AERONAUTIC CHARTS. The rapid progress of aeronautics demands the development of a system of signals and charts which will enable pilots to find their way in the air and indicate convenient landings, atmospheric conditions, etc. One proposed method involves the construction of special aeronautical charts; another requires merely the establishment of easily visible signals by which a pilot can find his position on the very accurate ordnance maps which are commonly used as standard maps in France and other European countries. In the French system, the country is divided into 256 districts, each of which extends about 38 miles east and west and 32 miles north and south, and is represented by a numbered section of the map.

According to one proposed system of signals, a large rectangle having the proportions of the corresponding map section and in the correct relative position to the points of the compass will be marked out on the roof of a balloon shed or other building, or on the ground. The rectangle is marked with the number of the section, and the exact position of the locality in the section is indicated by a conspicuous mark. For example, the towns of Beauvais, in section 32, and Nantes, in section 11, would be indicated as is shown in the drawing. A glance at any one of these signals near which he passes will show the pilot the exact place on the map so that he need not be long lost or go very far astray if the signals are sufficiently numerous. A predetermined course can be followed without carrying a set of maps. It is necessary only to draw on a small card a rough outline of the sections crossed by the course and adjacent thereto to mark each section with its proper number, to mark the positions of the starting and destination points and to connect these by a straight line. A diagram for a flight from Orleans to Mourmelon is shown in the drawing. It will be observed that the straight course crosses the northwestern part of section 81. Hence, if the aviator comes to the signal shown in the lowermost portion of the drawing, which indicates a point in the southwestern part of section 81, he knows that he has deviated toward the right hand. The map is required only for the purpose of selecting a good landing place, if the goal is a large town.

If the signals are composed of white lines on a black ground, or conversely, they need not be very large in order to be visible at a considerable distance. A rectangle 12 feet broad and 20 feet long, with lines 20 inches wide and figures 6 feet in height (in actual use at Mourmelon), is easily seen from a distance of one mile and an elevation of 600 feet.
For the guidance of aviators and aeronauts at night a German inventor has devised a translucent red balloon about 8 feet in diameter, containing an electric light of 100 candles or more, and moored by means of an electric cable. These balloons are easily distinguished from other lights, and from stars, and can be seen from a great distance.

AERONAUTICS, History of. There has always been interest by philosophers and scientists in aerial navigation, and the problem was given serious thought by the first physicists of ancient history. Archimedes, a Grecian mathematician who lived several centuries before the Christian era, are now followed and are successfully applied in the most modern types. Students of ancient history are familiar with the mythological legend of Daedalus, Grecian sculptor, and Icarus, his companion, who made a flight with wings fashioned by the former, and which, like so many actual flights, ended in disaster. Icarus, feeling over-confident in his own ability, flew too near the sun, the heat of which melted the wax attaching the wings to his body, and plunged him into the sea, which sea was named the Icarien Sea to commemorate the event.

The first human being whom history records as having actually risked his life in demonstrating his theories was Fausto Veranzio, who in 1587 made a descent from a high tower in Venice supported by a primitive parachute consisting of a square framework covered with canvas. There were no imitators of his methods for many years though there were many suggestions made, most of them fanciful and impracticable. Among these might be mentioned the creation of Francesco De Lana, which was to be sustained by four large hollow metal spheres, from the interior of which all the air was to be exhausted, the theory being that as the spheres were lighter than air they would float in space as does a cork upon water. It seems that even at this early period there was knowledge that air had a definite weight just as any liquid or solid, and that bodies lighter than air would rise as would a chip of wood when released under the surface of the water. These metal spheres of De Lana's were held in fixed relation by a framework of wood and a boat or body was provided with oars and sails by which it was to be propelled. While his ideas and theories on the problem were very much the same as those which determine the aerostats, or balloons of the present day, there existed obvious practical difficulties and the proposed airship remained as a rather fancifully designed drawing.

It is interesting to note at this point a form of glider constructed by Karl Friedrich Meervin, a German architect who lived early in the 18th century, which proves that even at that date considerable was known of the law of resistance. These balloons are easily distinguished from other lights, and from stars, and can be seen from a great distance.

Aerostats. The discovery in 1776 by Cavendish of hydrogen gas and his proof that it was lighter than air represents the beginning of actual aerial navigation. It was natural for philosophers to conclude that if containers of sufficient dimension but little weight were filled with this gas they would rise in the air. Experiments were made by filling and heating bubbles with this gas, which, however, escaped so rapidly little was learned. Then attempts were made to fill bladders and paper bags, but again the gas escaped through the pores almost as fast as it was let into them.

The credit of inventing the aerostatic airship or balloon is given to the Montgolfier brothers, Stephen and Joseph, who were the sons of a wealthy manufacturer of paper bags. These experimenters, after many trials, made a paper balloon of 700 cubic feet which was filled with smoke and heated air from a fire fed with wet straw and wool under the open mouth, and which surprised the multitude when it rose to the height of 1,000 feet. This was on 5 June 1783. Next experiment was of a balloon of 30,000 cubic feet filled with smoke and heated air from a fire fed with wet straw and wool under the open mouth, which rose to the height of 1,000 feet, and was supported by using a gas lighter than air, his success would be greater.

But the problem which he had to face was that up to that time no fabric had been made which was thoroughly airtight. Happily, just when he was experimenting with hydrogen, two brothers named Roberts discovered that it was possible to absorb such air into a fabric which to silk fabric and thereby secure an airtight covering. This fabric was fashioned into a balloon, and on 20 Aug. 1783, the balloon, made possible by the co-operation of the genius of S. Pond and the Roberts brothers, was filled with hydrogen and inflated. It rose to a very great height, but because of too strong inflation it ruptured and the envelope fell to the ground.

The tests thus commenced were continued by De Rozier, and Count Zambeserii, until in January 1785, Blanchard, a professional balloonist, accompanied by Dr. Jeffries, an American, drifted across the English Channel from Dover to Calais. To-day a marble column marks the spot on the coast at Calais where this historic landing was made.

The next important advance in practical ballooning was made by the substitution of coal gas for hydrogen. This was England's contribution to an art which previously had not greatly flourished west of the channel. It was a consequence of the natural growth of science, for in 1814 coal gas began generally to be used for lighting in London and several years later for inflating balloons. This valuable advance was made by the famous aeronaut Charles Green. It gave a powerful stimulus to aeronautics by rendering inflation
cheap and convenient. The first aerostat constructed on anything like our present proportions was the great balloon of Nassau which, on the occasion of the coronation, was navigated from London to Weilburg, a distance of nearly 500 miles. This was in 1836. In 1863 a still more elaborate and colossal airship was the Géant. It was made of a double layer of white silk, had a volume of 215,000 cubic feet and a buoyancy of 4½ tons. The Géant was in turn eclipsed in size by the great balloon of Henri Giffard. This measured 450,000 cubic feet and even to-day ranks as the largest captive balloon ever constructed. It was a familiar object at the Paris Exposition in 1878.

On 31 July 1901 Professor Bergson of Germany, accompanied by Dr. Suring, ascended in the balloon Preussen to an altitude of 10,800 metres (6,7 miles), which at present constitutes the world's altitude record. No serious attempt has been made to surpass this altitude record, but though it is easily possible to carry humans being to a greater height than seven miles, the results seem hardly to justify the cost. To ascend very much higher would require an enormous and costly balloon and to ensure the comfort of the passengers might require a cotton car, or armor, supplied continuously with fresh air or oxygen.

In recent years some of the most notable balloon flights include that of M. Goddard, who sailed from Leipzig to Wilna, a distance of 1,032 miles in 24½ hours. This was in 1897. In 1900 M. Balsan voyaged from Vincennes, France, to Rodom, Russia, a distance of 843 miles in 27 hours and 25 minutes, and De la Vaulx, starting from the same point, landed at Kostochiff, Russia, having traversed 1,193 miles in 35¾ hours. Until 1912 this remained the longest balloon flight on record. A close second to this record was made by Alan R. Hawley in his spherical balloon America, aided by Augustus Post, in the Gordon Bennett International Balloon Race in 1910. Sailing from Saint Louis they drifted 1,172 miles from their starting point and landed in a great forest at Peribonka River, North Lake Chigogoma, Quebec, Canada. In 1912 M. Dubonnet and Dupont started from La Motte-Breuil, France, in the Condor III and landed at Sokolowo, Russia, having traversed a distance of 1,211 miles. This record was supplanted in the same year by that of M. Bienaimé and Rumpelmayer in the Picardie. They started from Stuttgart, Germany, and in 48 hours landed near Moscow, Russia, after a trip of 1,361½ miles. Rumpelmayer made a new record on 24 March 1913 by a trip of 1,492 miles from Paris to a point near Kharkoff, Russia.

The recent advances in aerostation, though not radically changing the balloon itself, contributed greatly to the convenience and improvements have occurred in the means of inflation and deflation, in devices for making topographical and meteorological observations, as also for transmitting and receiving signals. Hydrogen shipped in steel tubes is now available for easy and rapid process of obtaining it on a large scale making it practically as cheap as illuminating gas.

During an ascension the rise and fall of the vessel may now be instantly noted on the dial of the statoscope, the temperature, pressure and moisture of the atmosphere may be read on the recording instruments, messages may be sent by telegraph and telephone, either by wire or without, and sky and landscape may be photographed.

Kite Balloon.—The kite balloon is a development of the captive spherical balloon, especially constructed and designed for military purposes and deriving its name from the fact that it performs the service hitherto performed by man-carrying kites. The kite balloon is sausage-shaped, with a series of ballonets at the lower end which are so adjusted that they act as stabilizers, permitting the observer's basket to remain in the air without the disastrous yawing motion which affects the basket suspended from a spherical balloon.

Power Balloons.—It is natural that after the first launching of human passengers in a crude aerostat, many schemes designed to control the course of a balloon should be evolved. The investigators of the early days fully knew that if a propelling mechanism could be made to act in conjunction with favorable aerial currents something might be achieved. They knew that the wind frequently has different directions at different levels. They believed that by causing the craft to rise and fall to a suitable stratum, by use of various then known devices, it could be made to travel in any direction at the will of the pilot.

Several devices for changing the altitude of the balloon were proposed or tried. For instance, with the Montgolfier, the mere increase or lessening of the fire would cause it to rise or fall. If a gas bag were used it would be let up or down by dropping out ballast or opening up the valve. Not realizing the enormous power required to propel swift balloons of the very best shape, and in the light of present achievement, the first efforts at a balloon propulsion as viewed to-day could not be seriously regarded by trained engineers, even at the inception of aeronautics. Historically they call for brief mention. It was in 1784 that Blanchard made the first real effort to steer a balloon, using a spherical gas balloon, two aerial oars and a rudder. An even simpler device was that of the two physicists Miolan and Janinet. The balloon was a Montgolfier with a large hole in one side, through which the hot air could escape with such strong reaction as to drive the bag forward.

In 1784 the Roberts brothers made a melon-shaped balloon of silk and inflated with pure hydrogen, suspended from which was a longish car of white wood. This ship was to be rowed through the air by a crew of six by means of silken oars. A seven hours' cruise was made in the vessel, and before coming down the crew managed to have the envelope navigate a curve nearly one kilometer in radius.

While these experimentations were being carried out, even more important experiments were being made by other inventors. In 1784, in a letter written to Benjamin Franklin, Francis Hoppinson of Philadelphia proposed to build a balloon of spindle shape and to drive it by means of a wheel-like propeller. This proposed craft, the forerunner of the modern screw-driven motor balloon, antedated the screw-driven boat, the submarine and the aero-plane. In 1820 Rulius Porter, an American inventor, and later the original founder of the
Scientific American, patented an airship which was decidedly in advance of that day. Its hull was a long, finely tapering symmetrical spindle, suspending a car of similar shape by means of cords, which were vertical at its middle, but more and more slanting toward its ends. Midway between the hull and the car was a large screw propeller, actuated by a steam engine in the car. The inventor, being too poor to develop his airship alone, did little with the patent during his life.

The Dirigible.—Henri Giffard was the inventor of the first dirigible which was successful both in design and operation. It was a spindle-shaped bag covered with a net whose cords were drawn down and attached to a horizontal pole, from which the car and motor were suspended, and at the end of which was a triangular sail serving as a rudder. To guard against fire, the furnace of the coke-burning boiler was shielded by wire gauze, and the draft, taken from its top through a downward pointing smokepipe, was ejected below the car by force of exhaust steam from the engine, thus obliterating, as Giffard asserted, all danger from the use of fire near to inflammable gas. The car hung 20 feet below the suspension pole, and carried a three horse-power engine driving a three-blade propeller 11 feet in diameter, and making 110 turns per minute. The motor complete, including the engine and boiler without supplies, weighed 110 pounds per horse power. The bag measured 143 feet long, 39 feet in diameter and 75,000 cubic feet in volume. Giffard reports of his first voyage that although he could not sail directly against the strong wind then blowing, he could attain a speed of 6 to 10 feet per second relatively to the air, and he could easily guide the vessel by changing the rudder. Captain Charles Renard of the French War Department continued the good work of Giffard. He manifested uncommonly good judgment and excellent scientific method in combining the researches and contrivances of others with those of his own. As a consequence he produced the first man-carrying dirigible that ever returned against the wind to its starting point, and the first aerial vessel whose shape and dynamic adjustment even approximated the requirements of steady and swift navigation in a surrounding medium presenting various conditions of turbulence and calm.

In 1884 Renard, with Captain Krebs, constructed the La France, the success of which stimulated anew the hope of conquering the air. Its hull was 165 feet long, 27.5 feet in greatest diameter and cubed 66,000 feet. It was kept rigid under varying conditions by means of a balloonet filled with air. The car suspended from the balloon was 108 feet long and 6 to 7 feet across. It carried at its forward end the propeller, and at its rear a rectangular rudder and a tail. The car contained the car, the batteries and electric motor. The motor weighed 220 pounds and developed nine horse power. The battery, composed of chromatic cells, was the result of researches of Renard. While Renard was experimenting with electric power, a few German inventors were applying gas and benzine engines with better promise of practical success. The first of those was Hanlein, who in 1872 advanced the project of driving a well-shaped balloon by means of a gas engine taking its fuel from inside the balloon, and making good the loss by pumping air into the balloon. In 1879 Bannigarten and Wolfelt in Germany built a dirigible equipped with a Daimler benzine motor. The year 1888 witnessed the completion of two famous systems of navigation by the lighter than air, one in France, the other in Germany, destined quickly to revolutionize the art and to establish it on a substantial basis. The leading exponents of these two systems were Alberto Santos-Dumont, a rich young Brazilian living in Paris, and Ferdinand von Zeppelin. Both achieved success by applying the gasoline engine to the propulsion of elongated balloons, but by very different methods. Santos-Dumont’s first dirigible was designed to carry his weight of 110 pounds and a 3½ horse-power petroleum engine taken from his tricycle and reduced in weight to 66 pounds. The hull was a cylinder of varnished Japanese silk, 82 feet long including its pointed ends, 11½ feet in diameter and having a capacity of 104 cubic feet of gas. A balloonet, or air pocket, occupied the lower middle of the envelope. The basket for the pilot, engine and two-blade propeller was suspended below the hull. The noise of the engine was controlled by shifting weights, the balloon was partially filled up like a pocket knife. Santos-Dumont continued his pioneer work until he encountered the rivalry of great wealth employing highly trained engineering and constructive talent. But he continued to do excellent work for the popularizing of the science. Santos-Dumont’s experiments were continued by Le Baudy, the most notable of whose ships were the Le Baudy, La Patrie, Morning Post and the Ville de Paris. The Locomotive Company, under the compelling energy of Count de la Ferté, furthered the work by the production of the Zodiac I, II, III and IV.

During all of these developments English and American authorities pursued a policy of interested waiting, watching the progress and hoping to benefit by the costly experimenting of the others. In 1909, the British government appropriated nearly $400,000 for aeronautics, and the United States House of Representatives voted $500,000, but promptly reversed its action. Considerable progress was made in England subsequent thereto through the monetary stimulus offered by various London newspapers.

The United States War Department, in 1908, started an aerial squadron by purchasing from Thomas S. Baldwin for $10,000 a tiny airship of the Zeppelin model, the Aerosaut. It was a 6-foot long, 5-ft. silver gray silk cylindrical hull slightly tapering toward the rear and terminating in ogival ends, its length being 96 feet, its major diameter 19½ feet.

Coincidentally much work was done in Germany. The work done there by Von Zeppelin really commenced in 1898, when he formed a limited liability company for the purpose of developing a new type of dirigible which he had long contemplated. In the summer of 1900 he
brought forth from his floating laboratory on Lake Constance the first of his airships.

Through disaster after disaster and grievous hardships, Count Zeppelin pushed his work from 1900 to 1910, when he had his first passenger machine ready. The maiden voyage of this great airship was a modification to the fortunate few traveling in such celestial style. Great progress was made between 1910 and 1914 and at the outbreak of the European War the Zeppelin was one of the most potential elements of Germany's air fleet.

Aeroplane, The.* The art of aeroplane flight presents two main groups of fliers. The first comprises the various man-kites, parachutes, gliding machines, soaring machines. These may be called passive fliers, because they carry no motive power, but ride passively on the air by the force of gravity or a towline. The second group comprises the bird-like flapping machines called "orthopters;" the screw- lift fliers called "helicopters;" the aeroplanes, also called monoplanes, biplanes, triplanes, according to the number of superposed main lifting surfaces; and lastly the gyroplanes, whose sustaining surfaces may turn over and over, like a falling leaf, or whirl round and round, like a snow-capped windmill. These may all be called dynamic, or power, fliers.

Disregarding the crude essays at human flight, recorded in the early histories and literature of many peoples, we may notice first the well-authenticated sketches of Leonardo da Vinci. His fertile mind conceived three distinct devices for carrying a man in the air. But he and his successors for nearly four centuries could do little more than invent. For lack of motive power they could not navigate dynamic fliers, however ingeniously constructed. Da Vinci's first design provided the operator with two wings to be actuated by the power of both arms and legs. His second design was a helicopter; an aerial screw 96 feet in diameter was to be turned by a strong and nimble artist who might, by prodigious effort, lift himself for a short time. His third scheme of flight was a framed sail on which a man could ride downward, if not upward.

Mr. Henry Woodhouse, one of the foremost aeronautical writers, author of the "Textbook of Naval Aeronautics," the "Textbook of Military Aeronautics," has summarized the work of pioneer experiments in aeronautics as follows: History has a list of some two-score of experimenters who tried to develop power flight, among whom were: Sir George Cayley, an English inventor, whose writings (1809-10) show that he was first to plan dynamic flight on a scientific basis. He planned an aeroplane built with slightly oblique planes, resting on a wheeled chassis, fitted with propellers, motors and steering devices. Samuel Henson, another English inventor, in 1843, patented what was designated as an "aerial steam carriage," an aeroplane of immense size, which was to be used for passenger carrying. This he never built. Another English scientist, F. H. Wenham, improved on Henson's idea, and in 1867 developed a multiplane. This model was taken up by another inventor, M. Strongfellow, who reduced the number of planes to three, making a triplane, which he fitted with a tail and two propellers. This model was shown at the exhibition of the Aeronautical Society of Great Britain in 1868. As in the case of previous inventors, nothing in this model indicated that he had any comprehension of the principles of stability or knowledge of the lift of the wing or the power required for dynamic flight. Strongfellow deserves, however, much credit for building a very light motor, one of sufficient lightness to support a well-designed aeroplane. In 1872, a French inventor, named Alphonse Penaud, constructed a small monoplane. It was only a toy—two flimsy wings, actuated by a twisting rubber, but had fore-and-aft stability, something that most of the creations of the time lacked. Subsequently, in 1875, Penaud took out a patent on a monoplane fitted with two propellers, and having controlling devices. But this was not built, principally because it would have required a light motor, and the lightest available at the time weighed over 60 pounds per horse power, or 20 times the weight of the motors of to-day. Louis Pilet, a Frenchman, having observed that large birds in flight, while seeming at rest, could go forward against the wind without a stroke of the wings, constructed a number of gliders, built on the principle of bird wings, and experimented with gliding. In 1890, he published a valuable work entitled "L'Empire de l'Air," which inspired many of the latter experimenters. Subsequently he invented a soaring machine, which he patented in 1892.

Pioneers of Modern Aviation.—These early experimenters laid the foundations of modern aviation. They showed the supporting power of their rigid surfaces, defined the general shape and structure of the aeroplane, and prepared the work for the next generation, which was to perfect these, and find ways and means to make the aeroplane rise from the ground and maintain equilibrium in the air. This new generation came toward the close of the 19th century. These new men, the pioneers of modern aviation, were divided into two schools. The first sought to achieve soaring flight by means of kitelike apparatus, which enabled them to soar in the air against winds, their machines being lifted up and supported by the inertia of the air as kites are. The second sought to develop power flight, that is, to send their kitelike machines through the air at high speed, being tracted or propelled by revolving screws actuated by motor power. The most eminent experimenters in the first schools were Otto Lilienthal, who was the chief expounder of gliding flight; P. L. Pilcher, an English follower of Lilienthal; Octave Chanute, an American follower of Lilienthal, and J. J. Montgomery, an American experimenter. Lilienthal, a German, was the first to make gliding flight a science, and he first defined the value of arched wings, and the pressure to be obtained at various angles of incidence. He met with untimely death while experimenting in 1896. Chanute's experiments were in the line of Lilienthal, but his great contribution was his early encouragement of the Wilbur Wrights, although the Wrights did not succeed by adopting Chanute's theories.

The leaders of the second school, who actually built and tried power-driven aeroplanes,
were Clement Ader (1890-97) and Sir Hiram Stevens Maxim (1890-94) and Samuel Pierpont Langley (1895-1903). Clement Ader was the first to construct an aeroplane large and powerful enough to carry a man, and the French government considered the craft of immense value and expended much to build the tryout, but as each of the two experiments toppled over at the trial and wrecked, the government refused to further finance the enterprise. While Ader was making his experiments in France, Sir Hiram Maxim was at work constructing a machine for the English government, which he fitted with two steam engines of 175 horse-power. But like Ader’s experiment, it toppled over at the first trial and was badly damaged, and the British government refused further backing. The experience of Samuel Pierpont Langley in America is not unlike the experience of Ader in France and Maxim in England. He was employed by the Board of Ordnance and Fortification of the United States army to construct the “Aerodrome” of his invention. Congress appropriated $50,000 for the purpose. Langley’s machine was a tandem monoplane, 48 feet from tip to tip and 52 feet from bowsprit to the end of its tail. It was fitted with a 50 horse-power engine and weighed 350 pounds. The trials of his aerodrome, two attempts to launch it, were made on 7 Oct. and 8 Dec. 1903. On both occasions the aerodrome became entangled in the defective launching apparatus, and was thrown headlong in the Potomac River—on which the launching trials were made. Following the failure of the machine, was wrecked, the press ridiculed the whole enterprise, and Congress refused to appropriate money for further experiments. The Langley aerodrome, partly reconstructed and fitted with a Curtiss motor and Curtiss controls, flew in 1913-14.

As with the experimenters of the first school, they did not attain practical results. Their machines were usually wrecked at the first trial without giving any clue to the nature or whereabouts of the trouble. Just how much each of these contributed toward the final success it is hard to say. The matter has not yet been defined, and, possibly, only one man—Orville Wright—is qualified to say. Most of these men made valuable additions to the knowledge of the science, but all of them mixed the practical with the impracticable in such a way as to make it risky to adopt their conceptions as the basis of actual flight, a fraction of error being enough to spoil the unity of truth that must be present, and so to end an experiment in a catastrophe. Wilbur Wright, having made exhaustive tests and dissected the theories and notions of all these pioneers, knew the exact worth of each. He could have made the valuation, but died before he had done so. In a paper on Lilienthal, which he wrote for Flying a few days before his death, he made, in view of the previous failures, and made a general rule by which all could be judged and their works valued. The realization of power flight was thus left to the 20th century—and to the Wright brothers. In view of the complex problems to be solved, this achievement was stupendous.

Wilbur Wright and his brother, Orville Wright, two men of remarkable characteristics, sons of the Rev. Milton Wright, were presented in their boyhood, 30 odd years ago, with a toy helicopter, a butterfly-shaped contrivance, consisting of paper wings fitted with a tin propeller which, when made to revolve by twisted rubber, caused them to fly and then to fall to the air. That toy fired their imaginations, and they saw it, in magnified form, capable of carrying a man.

Their attempt to fly large helicopters constructed on the idea of the toy did not bring practical results, and until 1903 they did not give the matter of artificial flights more than passing attention. In the summer of that year, however, the news of the accident and death of Otto Lilienthal, the German champion of gliding flight, stirred them to action, and they set themselves to study aerodynamics and the works of Lilienthal, Mouillard, Chanute, Maxim and Langley, the most prominent experimenters at that time. Their experiments with a glider began in the fall of 1900 at Kitty Hawk, N. C. There, on the barrier bar, in North Carolina, these two intrepid investigators took all the theories of flight and tried them one by one—only to find, after two years of hard, discouraging work, that they were based more or less on guesswork. Thereupon they cast aside old theories and patiently put the apparatus through innumerable gliding tests, ever changing, adding, modifying—changing again and again, advancing inch by inch, until they had, at last, developed a glider wonderfully exact, which, when fitted with a light motor, also built by them, made its first flight Dec. 1903, of from 12 to 59 seconds’ duration. This, then, was the birth of the aeroplane, the flimsy, iconoclastic thing which seems to evade Newton’s laws, eliminates frontiers and promises to expand civilization as much as have the steamship, the railway and electricity.

The Wright’s Success Created New Interest.—The Wrights did not make their achievements public at the time; in fact, until 1908, they flew only in private. But the report of their wonderful achievement, nevertheless, went far and wide, and stimulated those who had given up experimenting and inspired others to take up experiments. Octave Chanute, in 1902, went to France and related the early successes of the Wrights with their glider, and described the general shape of the Wright machine. The result of this trip was that half a dozen enthusiastic, including Louis Bleriot, Capt. Louis Ferber, Ernest Archdeacon, and later the Voisin brothers and Albert Santos-Dumont took up the work, thus founding the mighty French school which has increased so greatly and done so much since. The first of this school to succeed was Santos-Dumont, the Brazilian aeronaut sportsman. He constructed a machine of original design, and in 1906 made short sustained flights of from 50 to 700 feet in straight line flight the wondrous sensation at the time. Meantime others of the French school graduated and won honors. The Voisin brothers turned constructors and teachers, and with their cooperation Leon Delagrange, Henry Farman, Louis Bleriot and other prosecuted practical experiments and succeeded in getting their creations to leave the ground for modest flights. At this juncture,
1 Caproni Italian Triplane. Flies 90 miles an hour; carries 9 machine guns and 25 passengers
2 Curtiss Biplane, for use by the United States on the French front
1 Sikorsky Aerobus
2 The Geest-German Monoplane
3 Curtiss Triplane
4 Burgess Military Pusher
5 High Speed Scout Machine

6 Morane Monoplane
7 Wiegandt's 3-seater Monoplane
8 The German Fritz Biplane
in the summer of 1908, the Wrights started out to give public demonstrations, and their methods supplied and suggested to the French experimenters the means to modify and improve their aeroplanes, particularly the means of balancing them, which had, until then, been a perplexing problem. Some months before this some American enthusiasts had combined, under the auspices of Mr. Alexander Graham Bell, the inventor of the telephone, and Mrs. Bell, and organized the Aerial Experiment Association. Glenn H. Curtiss, one of the experimenters, developed a suitable type of aeroplane, and in 1908-09 became proficient in piloting it, and founded a school which did much in the following years to popularize and develop aviation in America. Consult Zahm, A. F., 'Aerial Navigation.'

The progress in aerial locomotion from 1909-14 was very rapid in Europe—especially in France and Germany—but slow in America on account of lack of the governmental stimulus which prevailed in Europe. But even in America the progress from 1911 and 1914 was important, especially in the field of marine flying, in which field America is likely to retain its supremacy. The great stimulus to aviation throughout the world came with the outbreak of the European War. The work of aircraft in the war has been of supreme importance. The co-operation of aeroplanes with artillery has proved extraordinarily effective. Of purely fighting aeroplanes, when the war began there were none—after two years there are machines weighing 10 tons, carrying a ton of ammunition, rapid-fire machine-guns and heavy guns—literally aerial cannon.

Large airships in the war have proved disappointing when compared with the aeroplane, because they are in a cruder state of development. They have almost the size of a battleship, offering a large target, without the battleship's armor or guns. The seaplane has had many achievements to its credit in the naval operations and the types which will be equipped with aerial torpedoes will constitute a real dynamite force in the future. The development of aerial locomotion during 1914-16 has exceeded the expectations of the most sanguine enthusiast—no man can prophesy what the next decade will produce. See AEROPANE DISTANCE AND SPEED RECORDS; AEROPANE ALTITUDE RECORDS; AERONAUTICAL NOMENCLATURE.

AERONAUTICS, Military. See MILITARY AERONAUTICS.

AEROPLANE (from the Greek aer, air; planos, wandering), a term now commonly used to define a "heavier than air" flying machine equipped with fixed aerofoils or main supporting surfaces and driven by suitable motive power.

Principle.—Everyone nowadays is familiar with the appearance of an aeroplane, but many there are, nevertheless, who do not know what, scientifically speaking, an aeroplane is. They see the machine on the ground; they observe someone giving frantical kicks at everything that moves in jerks: they hear a roar, which they know must come from an engine; they perceive that, in starting, the machine runs for a while along the ground before rising gently into the air; but still they do not know why the aeroplane flies.

It has something to do with the wings, of course, but how? That is the question at which the average lay mind stops short, not for ability to understand the problem, but generally for lack of some appropriate explanation that will bring what is fundamentally a very simple phenomenon out of its proper sphere of aeronautical science into the realm of everyday things that are comprehended by common sense.

There is an elusive aspect of the general view, and only one, that is apt to hide itself from the uninitiated unless brought prominent into the full light of the mind in the very first instance and that is the significance of a simple scientific expression much used in aviation, namely, "relative motion." If the man in the street saw an aeroplane apparently standing still in the air it would not occur to him to think that the man in the street must be moving through the wind at its full speed and that its relative motion in the air is quite unaffected by its motion relatively to the ground on which he is standing. Yet the same man knows very well that if he starts running on a calm day he will feel a slight breeze in his face, which is solely the result of his own relative motion through the air. He is also aware that if he puts his head out of an express railway car he will encounter half a gale of wind notwithstanding that the leaves of the trees may show not so much as a tremor. If, instead of putting his head out of the window, he were to take a sheet of stiff cardboard and put that outside he would have a still more practical demonstration of the force of the relative wind which supports the aeroplane in its flight. If the train is moving fast the cardboard will exhibit a violent tendency to flap upwards and downwards with the least vibration from its truly edge-on horizontal position. It is at this point that the embryo scientist begins to think really hard. His mind perceives an unsuspected fact that he senses to be of great importance. He has observed that by slightly raising one free edge of the piece of cardboard so that it is at a slight angle to its line of motion, instead of being truly edge-on, an extremely strong lifting force acts on the cardboard, although its resistance to the air is but little more than it was when the cardboard was edge-on. So pronounced is the preponderating value of the lifting effort over the resistance at very small angles that anyone making this experiment would at once conclude that if he wished the wind to support a weight he would certainly arrange some sort of a surface beneath it, like a table, but tilted so as to have only a slight angle of inclination to the line of its flight through the air.

An aeroplane has its table-like supporting surfaces so arranged as to get the best lifting effect for the least effort, having regard, of course, for the conditions under which the machine is designed to fly. It is clear, merely from a glance at a number of aeroplanes, that they are not all exactly alike, but it will be noticed that they all have one point in common which is that the surface
instead of being flat is cambered or slightly bellied like the sail of a yacht. This is an important analogy because a yacht is one of those commonplace objects that are so familiar that the man on the shore never stops to ask himself whether or not he understands how it sails. It will be the same with the aeroplane in a few years' time, which is why it is worth while troubling to appreciate an explanation now in order that one really may be informed as to the essential facts by the time aviation, in common with so many other interesting things, becomes veiled under the ever-spreading pall of public indifference. The sail of a yacht is an aeroplane in principle but its use differs materially from the purpose of the wing of an aeroplane. When the wind blows obliquely on the sail of a yacht the pressure that it exerts is mostly directly toward capsizeing the boat, but owing to the set and camber of the sail the force is also directed slightly forward toward the bows and the amount of this component is sufficient to propel the boat. If a real wind were to blow obliquely from beneath on the wing surface of an aeroplane the same propelling effect would be produced and the main force that tends to capsize the yacht would be turned to the useful purpose of supporting the weight of the machine, which would continue to fly without using its engine so long as the conditions remained appropriate.

At this point let us become familiar with the idea of power in connection with flying. When the wind blows it often possesses enormous power and when it blows suitably against a windmill or the sail of a yacht or the wing of a bird, it may transfer some of its energy into mechanical movement as grinding, sailing, and flying, respectively, in the three instances cited.

When the air itself does not move, or does not move in a suitable way to enable the transformation of its energy into soaring flight, the power necessary to the continuance of flying must be supplied by the object which flies. The bird flaps its wings, the aeroplane starts its engine. There may be little resemblance between the action of a bird's wing and that of the propeller which is driven by the aeroplane. Scientifically, there is a close analogy between them. One of nature's masterpieces is the perfect articulation of the joints of an anatomy that permits such smooth-acting to-and-fro movement as is manifested by the legs of an animal when walking and of a bird's wing when in flapping flight. Reciprocating motion is anathema to engineering, but the engineer finds a great compensation in the principle of rotation, and when opportunity is possible to do so, the mechanism of mechanical power is confined to the continuously revolving shaft. Thus, on an aeroplane, you find an engine which generates the power, a revolving shaft, which transmits the power, and a propeller on the shaft, which transmits the power to the air and so pushes or pulls the engine as a whole through the air.

Power is essential to flight, but when the engine stops in mid-air the aeroplane does not fall to the ground, nor does the pilot in any nest of a balloon. The aeroplane itself, when properly designed and flown, possesses an inherent quality that is better than any artifice, and without which flying by aeroplane would be quite out of the question.

The principles of aeroplane propulsion and sustentation are shown graphically in Fig. 1. The case considered is that of a biplane. A single large propeller serves to pull the machine in the direction of flight and the air immediately ahead of the machine, being displaced by the action of the propeller, flows backward horizontally at high velocity and presses against the under surface of the aerofoil.

The following tables, giving the air resistance and corresponding horse-power and the air pressure at different velocities, will be found of value in calculations pertaining to the design of any class of aircraft.

The effect of varying areas and forms of planes is marked, and with planes of different form but of the same area results are obtained which are so different as to be the cause of comment. There is no question that the form of the wing of the bird gives proportions which can be followed in the aeroplane with good results. This means that the best results will be obtained with a plane which is wide when viewed from the front and short when seen from the side. The exact proportions have never been definitely determined and vary in all of the successful creations, but it was determined by Professor Langley that a plane with a wide advancing edge was the most efficient, not only by calculation, but by actual experiments. His tests were made with various forms and areas of planes, and for illustration it will be said that a plane with an advancing edge or width of six inches and a length of 18 inches, when moving at a horizontal velocity of 65.6 feet per second, or at the rate of 45 miles per hour, as in Fig. 5, would have vertically four feet in seven-tenths of a second. On the other hand a plane with an advancing

edge of 18 inches and a length of six inches, obviously having the same supporting area as the other, and moving at the same velocity, fell four feet vertically in two seconds, demonstrating that the sustaining power of the form shown in B was about three times as great as that of the form with the narrow advancing edge.

Aeroplane with narrow advancing edge.

Aeroplane with wide advancing edge.

**Constructional Features.**—Like birds, aeroplanes possess bodies, wings and tails; they also have undercarriages that serve the purpose of legs when alighting. The class of machine that most closely approximates to the bird type is the typical monoplane; biplanes often have no resemblance whatever, in appearance, to nature’s best flyers. The technical difference between a monoplane and a biplane, however, is merely that a monoplane, in common with the bird, possesses only one pair of wings, while the biplane is provided with two main supporting surfaces, one situated above the other.

There is apt to be considerable confusion about the use of the term *length* when applied to aeroplanes, owing to the fact that wings fly through the air broadside-on. It is natural, when speaking of the wings alone, to refer to their longest dimension as their length, as one would do when speaking of any other object; but, when the machine is in flight, one might equally remark how short is the length of the wings compared with that of the machine as a whole, meaning thereby the measurement of the wing from its leading edge to its trailing edge. For this reason it has become customary to apply the terms *span* and *chord* in this connection, and having an obvious derivation they justify their existence as technical words and are deserving of general use. One speaks of the span of a bridge and chord of the arc of a circle; both expressions have an analogous significance in reference to the aeroplane.

Thus, the wings, which are the supporting members of the machine, form a kind of bridge that spans the air in order to hold aloft the weight; the wings themselves, as has already been mentioned, are cambered so that a string stretched between the leading edge and the trailing edge would occupy the position of the chord to the arc that is formed by the wing surfaces. This arc, by way, is not circular, but is of such contour as is found best by experiment on models that are tested in an experimental wind tunnel. The highest point of the curvature of any wing section is always nearer the front edge than it is to the trailing edge. Two of the most important accessory features of the supporting planes are the elevator and the rudder. Since the aeroplane sails in, instead of on, the aerial sea, it must be equipped with two sorts of rudder, one for steering to the right and left in the ordinary way, and another for steering up and down. The latter we now call an elevator in order to avoid confusion of terms; actually it is merely a pivoted plane just like a rudder, but arranged horizontally instead of vertically. In a monoplane, the rudder and the elevator form part of the tail of the machine. The term “tail” applies to a group of organs of which the two just mentioned are hinged and movable to perform the directional functions under the pilot’s control. A third plane horizontally arranged like the elevator, but rigidly fixed, is commonly added in order to confer some degree of natural “longitudinal stability” in flight. In those aeroplanes that have long boat-like bodies extending the full length of the machine, this fixed tail plane is often a mere fin-like excrescence. On other types, however, the rigid portion of the tail is a much larger affair; in either case, it commonly carries the elevator as an extension in the form of a hinged flap. Instead of flapping its wings, to do which would involve constructional difficulties, the machine carries a propeller. This is usually a two-bladed unit built of timber, and it usually measures about eight feet or more in diameter. Owing to its high speed of rotation, which commonly is between 1,000 and 1,300 revolutions per minute, the propeller is invisible in some of the machines that are photographed in flight. It is common practice to put the propeller in front and to mount it upon the engine crankshaft. A general study of the designs of the machines makes it very clear that the forward position—or “tractor” screw as the propeller in front is often called—is structurally convenient. Monoplanes were from the first designed with long girder-like bodies, which necessitated a single air screw being placed either in front of the wings or behind the tail. When this form of body became more common on biplanes the tractor screw accompanied it. There exists a wide difference of expert opinion regarding the most effective plane area. Some of the most efficient aerofoils (consult Loening, “Military Aeroplanes”) have been developed by the Frenchman Eiffel. Experiments at the Royal Aircraft Factory in England have also been productive of some interesting wing surfaces and more recently tests made for the Signal Corps of the United States
army at the Massachusetts Institute of Technology have developed some interesting facts concerning aerfoils. It is well recognized, however, that the power of plane area is largely governed by the factor of velocity, and that slow speed machines require larger aerfoils than those operating at higher velocities. Since slow speed is not a desirable qualification of aircraft in general, and tends to influence the angle of incidence, thus increasing the air resistance and requiring the employment of excessively high driving power, the general constructive effort is being directed to the production of high speed machines having small aerfoils and powerful engines, the velocities commonly attained ranging from 65 to 150 miles an hour, with a speed of 180 miles an hour an easy probability in the near future.

The solution of the problem of control naturally follows the successful accomplishment of aeroplane sustentation, and in the successful execution of the acts of balancing, banking, and steering, depends the success of the machine as a practical commercial craft. In the design and construction of air craft there are 10 essentials to be borne in mind. (1) An aeroplane must have sufficient combined speed and plane area to raise its intended load, together with its own weight. (2) The greater the speed the less the plane area, and the less the necessary angle of that plane for the same effect. (3) To counteract the resistance set up by means of gaining momentum while on the ground, which is additional to the resistance the machine will have when once clear: a. extra power is required, or b. extra plane surface to meet the power we have, c. a better effect for the power we have, d. an outside agency that will assist. Extra power means more weight, extra plane means more resistance, better effect for the power we have means improvement in the engine or means of propulsion, an outside agency means a fixed starting point. (4) The planes must always be sufficient to permit of a safe landing. (5) Their exact shape depends upon the type of machine considered, the means employed for obtaining lateral and longitudinal balance and stability, and varies so greatly that no particular rule can be laid down. (6) The planes should be constructed of materials as strong as the end in view permits, and should in themselves create as little useless resistance as possible. (7) The general arrangement should be as simple as the design allows. (8) The control should be simple and easy of manipulation. (9) The Balance should be automatic. (10) Although it is difficult to obtain, a means of keeping afloat until a safe landing is made without engine power perfects the aeroplane.

Before starting to build any machine, either full size or model, the following points require to be known by the constructor: First, the weight of the complete machine; second, the area of supporting surfaces necessary; third, the amount of power required; fourth, dimensions; fifth, size and speed of propeller, and lastly, methods of control. Weight forms the basis of designing. It is difficult to assume the weight of an object, before knowing its dimensions, but it is not difficult to build an object of such dimensions that it will not exceed a certain weight.

Equilibrium.—In flight, the weight of the aeroplane is supported by the reaction between the wings and the relative wind created by their motion through the air. So long as the proper relative magnitude of these forces is maintained their function of maintaining an upward pressure, but it depends on a variety of circumstances whether that pressure continues to be applied exactly in the correct way. At this point it will be necessary to explain two technical terms: the centre of gravity (C.G.), and the centre of pressure (C.P.). The centre of gravity is the point where the weight of the machine seems to be concentrated, and the centre of pressure is the point at which the lift of the wings seems to be focused. Any object that is supported exactly at its centre of gravity is always balanced in any position in which it may be set. When it is not supported, it tends to fall into such a position as will bring the point of support vertically in line with the centre of gravity. Like ships, aeroplanes are potentially liable to pitching, rolling and yawing, and it is essential from the beginning to recognize that some of these acts may at times be essential to the guidance of the machine and to be borne in mind.

If, for example, an aeroplane were incapable of being made to swerve at will, it could not be steered; on the other hand, a tendency to make erratic changes of direction of its own accord would be described as directional instability. It is important to bear in mind that the air does not provide a fixed platform. When an aeroplane is canted, so that one wing is lower than the other, the C.G. of the machine has not necessarily been disturbed. There is a very ingenious side-show, often to be found at large exhibitions, that may assist the imagination in grasping the breadth of the subject. It consists of a flexible track that ceaselessly undulates in supposed presentation of the waves of the sea. The raft-like trolley serves as a very good object-lesson in two forms of stability. The machines in question are stable in the ordinary sense to the degree of absolute security, for they cannot conceivably capsize. On the other hand, the instability of their direction makes it almost impossible to guide them three or four yards without running into either side of the barrier. When an aeroplane is canted, the forces brought into play correspond with those that make the trolley run into the barrier, and their effect is equally to tend to make the aeroplane slip down sideways through the air. In the broader use of the term, what ordinarily is called longitudinal stability has to do with the prevention and cure of pitching; lateral stability—similarly related to rolling, and directional stability to yawing from the course.

Lateral Balance.—When an aeroplane is seen advancing from directly in front, the upward pressure or lift of its wings may always be assumed to be acting in a direction perpendicular to the spars. The downward force of the weight acts always vertically toward the earth. If, therefore, the wings are canted, their pressure is no longer precisely in line with the weight, and the necessary sideways component tending to make the machine swerve off its former course. On the assumption that the machine ascends into the air with its wings level, it is necessary to account for the disturbance of the balance by

the introduction of some extraneous force. This, however, is readily supplied by supposing that the machine is struck by a gust. A gust, for practical purposes, is assumed to be a sudden veering or backing of the relative wind.

It is not necessary that the machine should be possessed of vertical fin surfaces, against which the oblique wind may strike, in order to account for the tendency of a gust to carry an aeroplane. The characteristics of wing-forms as ordinarily employed suffice in themselves to explain the occurrence, for if a gust is a sudden veering of the wind, it is equivalent to a sudden spinning of the wings about their vertical axis, as a propeller might spin on a vertical shaft. Under such conditions there is an obvious tendency for one wing to lift more than the other, and so to upset the balance. Lateral balance in the modern machines is secured by various methods. First, warping, which means that the relation of the wing surfaces to the relative wind are changed by the pulling of wires for a temporary period to aid in the control of balance. Secondly, machines of the biplane type are constructed with their upper wing in a position that will enable, while spinning, which enables the pilot to manoeuvre the machine very effectively in gusty weather. (Consult Berrie, 'Aviation'). Thirdly, dihedral formation of wings has been introduced with much success. That is, wings which rise from a point at which they meet (exactly above the body of the machine) to their outward surface.

Steering.—There is perhaps no object of a technical nature so universally familiar by name, appearance and purpose as the rudder. Everyone knows that the rudder is to steer the craft to which it is attached. The direct effect of a rudder relates to the control of movements about the vertical axis of the craft. Such movements may conveniently and appropriately be referred to under the general term "yaw." It is the tendency of the craft to yaw on its own vertical pivot that the rudder is used either to check or to initiate. When steering a straight course, the rudder is used to counteract disturbances that otherwise might give rise to a yaw. A positive position of the rudder has no appreciable extent of vertical surface in the vicinity of the C.G., a slight yaw will of itself present equivalent to the side of a ship against which the air can react. But when an aeroplane with positive wing tips is caused to yaw, one tip is thereby accelerated while the other is retarded, and so a bank is established which in turn tilts the direction of the air pressure on the wing. It is this tilting of the air pressure by canting the wings that provides the steering force in the case of an aeroplane.

Types of Aeroplanes.—The different types of aeroplanes are distinguished according to their number of supporting plane surfaces. The "monoplane" with one plane surface; the "biplane" with two superposed plane surfaces; the "triplane" with three superposed plane surfaces; and the "multiplane" with any number of supporting surfaces in advance of three.

Monoplane.—For a considerable period in the history of practical aeronautics the monoplane held the pre-eminent position, in that period when France was in the forefront, and when she developed a corps of sportsmen who were eminent throughout the world. This was due to the excessive speed which could be acquired with this type of machine. The assets of the monoplane are, briefly, lightness, speed, both in climbing and racing. Its disadvantages, inability to carry a load, the proficiency which it demands of the pilot, the extensive smooth landing grounds necessary.

Biplane.—The most common of modern machines, because of its adaptability to all conditions of aerial navigation. The type greatly (consult Fage, 'Aeroplane') from the machine with narrow advancing plane edge for speed, to the machine with a wing spread of 157 feet, equipped with multiple motors, for load carrying and long distance reconnaissance.

Triplane.—This type has been developed to extend further the load carrying capacity of the biplane. It will undoubtedly represent in the period immediately succeeding the war the vehicle that will be entered first upon the aerial carrying commercial ventures.

Hydroaeroplane.—A hydroaeroplane has been described as an air-borne craft capable of floating on water. Such a machine must be made sufficiently strong to resist the severe buffeting of a rough sea, although its flying capacity is affected by any water resistance and load resistance. Single and double floats are used. The floats should not be too far apart, otherwise the lifting of one float out of the water due to excessive rolling causes the machine to suddenly swing round; and, moreover, the unbalanced forces called into action by the reduction of the resistance of the rising float, and the increase of resistance of the falling float, are greatly assisted by the leverage between the two floats. On the other hand when the two floats are close together, the behavior approximates that of a single float machine. The water resistance of the floats appears to be practically independent of their distance apart. To prevent the float driving into the water when the machine alights, and also to keep the nose of the float well out of the water when the machine is at rest on the water, it is desirable that the centre of buoyancy of the float, when the longitudinal axis of the machine is horizontal, should be well forward of the position of the centre of gravity of the machine. The total buoyancy of the floats should be almost equal to twice the weight of the fully loaded machine. While the float is rising from the water the free access of air to the bottom of the step should not be hindered. The tendency to hop—a characteristic of most floats when running along the surface of the water at high speeds and small buoyancy—is due to the inherent instability of a machine partly supported on a small area. Any tendency to dip the nose of the float under water may be minimized by a low position of the line of propeller thrust.

Flying Boat.—The flying boat had its inception in America, where Glenn H. Curtiss was the first to design this type of craft. It is an ordinary aeroplane in wing structure, either biplane or triplane, but with a boat-shaped hull for landing on, and subsequently, if necessary, navigating the water. See Aeroplane Distance and Speed Records; Aeroplane Altitude Records; Aeronautical Nomenclature. Consult Woodhouse, 'Naval Aeronautics.'

G. DOUGLAS WARDROP, Managing Editor Aerial Age.
AEROPLANE ALTITUDE RECORDS. As speed and duration of flight progressed according to the advances in engine and body design, so, too, the altitudes attained kept pace with the growth of engine power and of superior design in the planes. It was early realized that the greater the height attained the greater must be the power of the engine, when the plane is in the atmosphere which becomes ever rarer as the plane ascends. In 1909 the record altitude for the aeroplane stood at 1,473 feet; this was raised to 10,499 feet in the following year. In 1912 Garros ascended 19,032 feet at Tunis, Africa, but this record height was surpassed by Perreyon, who, on 14 March 1913, reached a height of 19,650 feet in a Blériot monoplane. In the closing days of the same year G. Legagneux made the record ascent of the year by attaining a height of 20,090 feet. On 27 June 1914 the Austrian, H. Bier, with one passenger, ascended 20,260 feet. In the same year Garais took four passengers up to a height of 10,000 feet; six passengers, 5,730 feet; and nine passengers to a height of 5,220 feet. On 25 April 1914 the Russian pilot Sykorsky, took 15 passengers to a height of 980 feet in a Sykorsky biplane fitted with a 400 horse-power Argus motor. In 1916 H. G. Hawker ascended at Brooklands, England, to a height of 24,408 feet.

AEROPLANE DISTANCE AND SPEED RECORDS. The aeroplane developed increased speed in successive years as a result of improved construction and design and especially of improvements in engine-building. A speed of 61 miles per hour was the greatest reached up to 1910, when this speed was attained in a Blériot monoplane. A speed of 100 miles per hour, the goal of years of designers and engineers, was reached and passed in 1912, when Vedrines, in a Duperdussin machine, made the record speed of 107.4 miles per hour over a distance of 124 miles. This record was not to remain long unsurpassed for in 1913 Maurice Prevost made new records for all distances from 10 to 200 kilometers (6.2 to 124 miles), when, at the Bennett cup competition at Reims, he traversed the 200-kilometer course (124 miles) in 59 minutes 45 3/5 seconds, making an average speed of 126.5 miles per hour. This speed was made in a Duperdussin monoplane with a 160 horse-power Gnome motor.

In 1914 M. Garais, in a Schmitt biplane, piloted four passengers a distance of 26.58 miles at the rate of 67.28 miles per hour; five passengers 12.5 miles at the rate of 67.26 miles, and six passengers a distance of 31 miles at the rate of 66.85 miles per hour. In 1913 Deroye, in a Blériot monoplane, made a non-stop flight of 486.87 miles, and in April 1914 Garais, with six passengers, covered a distance of 68.3 miles without alighting.

The European War completely paralyzed competitive aviation, aeroplanes being commandeered for military purposes and aviators pressed into army service, and there were no records accepted by the International Aviation Federation during 1915, 1916 or 1917. Several important flights were made, however, of which the following are the most noteworthy: On 20 June 1916 Lieut. A. Marechal of the French army made a non-stop flight of 812 miles, starting from Nancy, France, and alighting at Chlom, Poland. On 3 November of the same year Victor Carlstrom flew from Erie, Pa., to New York city (515 miles) in 4 hours 11 minutes, and on the 19th of the same month Miss Ruth Law set out from Chicago on a flight to New York, reaching Hornell, N. Y., 590 miles from Chicago, in 5 hours 45 minutes; on the following day she completed the remaining 294 miles of the journey in 3 hours 10 minutes and 35 seconds. On 11 Dec. 1917 Miss Katharine Stinson established a new record by flying from San Diego to San Francisco, a distance of 610 miles, in 9 hours and 10 minutes, the longest non-stop flight hitherto made in America.

AEROPLANE ENGINES. There are three prime requisites for a good aeroplane engine — reliability, small weight per horse-power and low fuel and oil consumption. Since these requirements are more or less conflicting, a compromise is necessary and the designer is confronted by the delicate question: Which of these is the most important? German designers, with their customary thoroughness, have produced more reliable, but generally speaking, heavier engines than those of England and France. For military work this has proved a weak point, because the lighter, and hence faster, aeroplanes can easily secure positions of advantage over their enemies, which usually makes it possible to bring them down. For non-military service, however, except racing, reliability is unquestionably the fundamental requirement. The balance between weight and fuel economy will be fixed by the particular service required, for the matter of importance is not the engine weight only, but the total weight of the engine and fuel. This is easily appreciated when one realizes that the fuel required for a flight of six or seven hours weighs as much as the engine itself. For short flights during which but little fuel is used, an exceptionally light engine is desirable, for the poor economy usually characteristic of such an engine is not very important. However as the length of flight increases, economy becomes more and more important. Other requisites which must not be overlooked, though they are by no means as important as those just mentioned, are compactness, accessibility, freedom from vibration, flexibility,
silence and reasonable cost. Little need be said in regard to these as they are almost self-evident to any engineer.

The reliability of an engine is the final proof of the skill of its designer in mastering every little detail. This is particularly true of an aeroplane engine because its service is so much more severe than that of an automobile engine that any weakness will show itself much sooner. Since weight is of such great importance, every member of an engine will probably be designed so as to be stressed to the maximum safe limit. For this reason any cast metal should be avoided as far as possible because of its uncertain strength. In nine engines a certain cast member will be strong enough, yet in the tenth some imperfection in the casting may cause a failure at a critical moment. Forged or rolled steel is one of the most dependable materials known today and as it is also the lightest for a given strength, it is ideal for aeroplane engines. Consequently lubrication. An aeroplane engine must, of course, be as economical as possible of both fuel and oil. Fuel economy implies a high compression, since efficiency rises with the compression ratio; and careful workmanship is an essential, so as to eliminate any unnecessary friction.

For any particular type of engine there are three places to look for a possibility of improved efficiency—the carburetor, gas passages and ignition system. These are facts well known to automobile engineers and have been the cause of much research. For very high engine speeds it has been proved that the number and location of the spark plugs has an appreciable effect upon efficiency. When two-point ignition is used, failure of one of the plugs must be guarded against because it will not cause missing and therefore may not be detected. Since two-point ignition requires a smaller angle of advance than the single point, the failure of one plug will cause late ignition in its cylinder with its resultant heating and lowered efficiency.

At present the magneto reigns supreme for the ignition of aeroplane engines, but it may be replaced by some battery systems because of the increasing necessity for an electric generator for wireless outfits, searchlights, stabilizers, etc.

It almost goes without saying that any unnecessary weight on an aeroplane engine must be eliminated and the greater use of aluminum and the higher grades of steel will play an important part in having decreased weight go hand in hand with all round efficiency.

G. DOUGLAS WARDROP,
Managing Editor Aerial Age.

AEROSTATICS, a branch of science treating of the equilibrium and pressure of air and other gases, and of the methods of measuring it by the barometer and other instruments. The expansive force or pressure of atmospheric air varies with time and place. In a medium condition of the atmosphere, and near the sea-level, barometrical observations give the pressure or weight equal to that of a column of mercury 30 inches high, or of a column of water about 34 feet high. This makes the mean pressure of the atmosphere nearly 15 pounds on every square inch. Aerostatics also investigate the phenomenon of the high compression of gases; in other words, the relations between the elasticity and the density or volume of a gas. According to the law of Mariotte, the expansive force of one and the same body of gas is proportional to its density; or, which is the same thing, the expansive force of a body of gas under different degrees of compression varies inversely as the space which it occupies. See Gas; Pneumatics; Thermodynamics.

AEROTHERAPEUTICS. This literally means the treatment of disease by air and is usually limited to the supposed value of air in certain chest diseases, notably of tuberculosis, and the use of compressed air for special chest conditions.

This is a difficult subject to treat since there is so much popular tradition and medical superstition regarding the value of air in the treatment of chest conditions. The general attitude that regards open-air treatment...
of tuberculosis as of prime importance stands in marked contrast to the position taken by the few that the air per se has little or nothing to do with the matter. In fact the open-air treatment of tuberculosis is a vastly more organized program than its name would imply. Under the general idea of open-air is included exercise, freedom from work, extra feeding, psychotherapy, humidity, skin stimulation, etc., etc. The air itself in reality plays an insignificant part in the therapy. The reason for this is plain. It is well known that the sole stimulus in air is the oxygen contained within it. It is also an axiom of physics that the composition of the air so far as its gases are concerned is constant for the world over at the sea-level and under average conditions. There is no more oxygen in one air than another and no less unless in a hermetically sealed space specially treated by physical procedures. Hence oxygen transfer in the lung is constant under the same barometric pressures and temperatures. Rarified air in high places contains differing proportions of oxygen but here the problem is not so much one of the oxygen as of the barometric pressure and the relationships of the tension of oxygen in the tissues and the external atmosphere and carbon dioxide tensions in the tissues. Special problems arise here which are in need of special forms of consideration, which cannot be discussed here. Here oxygen want develops a special type of illness—mountain sickness.

Water and air (oxygen) are among the most constant things in the environment. They rarely ever change in their gross composition, hence they have built up invariable interactions between the body and the environment. The real work of supplying the proper amount of oxygen takes place within the lung tissues and is not dependent upon the external oxygen supply which is always ample and constant under the ordinary conditions of life.

Hence it can be seen that although the physiology of respiration is extremely complex, there is, properly speaking, no real problem of air treatment in the ordinary sense, and the open-air treatment of tuberculosis is a misnomer. The largest factor is an elaborate psychotherapy. The oxygen itself plays the least rôle in the therapy. Popular misconceptions regarding air in buildings, in theatres, in subways, etc., etc., are abundant. When the laity speaks of "bad air," it really means foul-smelling, humidity, heat and other things. The air, so far as its oxygen and the respiratory needs are concerned, is not "bad." It is constant all over the world — in the garret or in the cellar, rooms with windows open or with pure oxygen — the air never varies. The aesthetic wishes of individuals vary and make them prefer sleeping porches or inside rooms and thus the psyche is affected. The actual respiratory needs are equal everywhere under similar atmospheric pressures and similar températes. Consult Bayliss, 'General Physiology'; Henderson, 'Fitness of the Environment.'

SMITH ELY JELIFFE.

AEROTROPISM, the sensitiveness of certain plant organs which enables them to orient themselves from certain gases dissolved in the medium in which they are grown. Various roots also possess this property. See CHEMOTROPISM.

AERSCHOT, a town of Belgium, 26 miles southeast of Antwerp and 20 miles northeast of Brussels. Situated on the river Demer, it is a junction of railroad and steam-tramway lines running to Louvain (q.v.), Herentals, Tirlemont and Haecht. Its modern importance was derived from its cloth manufacture and railway works. The town contains an old Gothic church with fine choir-stalls of the 15th century and an altar piece by the Flemish painter, Gaspar de Craeyen (1582-1669). At the beginning of August 1914 Aerschot boasted a prosperous population of about 8,000 souls; these were doomed to a tragic fate in the early stage of the European War. With the possible exception of Termonde, Aerschot seems to have suffered more than any other place in the Flemish-speaking part of the country. A fierce action was fought round Aerschot on 19 Aug. 1914. German infantry, supported by machine-guns and artillery, opened the attack, and the Belgians, although outnumbered, made a desperate resistance. The troops on both sides fought like demons and the fight soon developed into a terrible butchery. The Belgians in the front held their ground tenaciously for two hours and retreated on Louvain, the main army retiring upon Antwerp. The Germans entered Aerschot early in the morning of 19 August. Throughout the day the soldiers looted the town, broke store windows and ransacked them. A shot was fired about 7 o'clock in the evening, by which time many of the soldiers were drunk. The Germans were not of one mind as to the direction from which the shot proceeded. . . . No one was hit by the shot, but thereafter German soldiers began to fire in various directions at the people (Bryce committee). It was also said that a German officer had been killed at the burgomaster's house. The German version stated that the 15-year-old son of the burgomaster had killed the officer—a Colonel Stenger. On the following day a large number of civilians were brought together with the burgomaster, his brother and the boy. In the report presented by the Belgian Royal Commission to President Wilson at Washington it was stated that the Germans took every man who was inside of Aerschot; they led them, 50 at a time, some distance from the town, grouped them in lines of four men, and, making them run ahead of them, shot them and killed them afterward with their bayonets. More than 40 men were found thus massacred. About 150 inhabitants of Aerschot were supposed to have been killed. For three days the invaders pillaged the houses and set fire to them. Much of the portable property was sent into Germany (13th Belgian report). I know there were 91 shot at Aerschot and that there, under pain of death, their fellow citizens were compelled to dig their graves (Cardinal Mercier). Immediately after the battle of Malines (q.v.), which resulted in the evacuation by the Germans of the district of Mariemont, Saint-Hosfiet and Epeghem (25 Aug. 1914), a long series of excesses were committed either.
just before or during the retreat. At Aerschot and the other villages from which the Germans had not been driven, the effect of the battle was to cause a recrudescence of outrage and pillage. Large numbers of civilians, men, women and children, were herded into the church. The priest of Gelrode, a village near Aerschot, was brought here, made to stand for some hours with his hands above his head, and finally shot by five soldiers. Some of the prisoners were actually kept in the church until the arrival of the Belgian army on 11 September. They were released. Others were marched to Louvain, and with others from the surrounding districts were taken to Germany.

In May 1915 the German government published a White Book under the title of "Offenses against International Law in the Conduct of the War by the Belgians." It contained the results of an official inquiry into the Belgian allegations, and gave the evidence of numerous witnesses—German officers. In the case of Aerschot Captain Karge relates that he observed regular volleys from 8 or 10 rifles from a particular house; that he broke into it and set fire to it. No civilians are suggested to have been found by any of the soldiers who went upstairs to assist in the destruction; the house appears to have been empty. The captain stated: "Thereupon, I pushed into the house with the others, and using a fairly large quantity of turpentine... succeeded in a very short time in setting the house on fire." When I left the burning house, several civilians, including a young priest had been arrested from the adjoining houses. I then put the columns on the march out of the town, took command of all prisoners, among whom I set free the women, boys and girls. I was commanded by a staff officer to shoot the prisoners. Then I made some of my gendarmes arrange the columns and keep them in motion out of the town, while others escorted the prisoners and took them out of the town. Here, at the exit, a house was burning, and by the light of it I had the culprits—88 in number, after I had separated out three cripples—shot. No mention is made of any investigation or trial. See ANDINE, LOUVAIN.

ÆSCHINUS, Εσχίνης, the greatest of Greek orators except his rival Demosthenes: b. Attica, 389 B.C.; d. Samos, 314 B.C. That he rose to immense influence and high station by his unaided genius, despite family poverty, would be considered his best credential in democratized modern states; it was charged against him as a foul disgrace in Athens. The further "campaign" accusations of Demosthenes—that his father was a schoolmaster's freedman and his mother a public dancer and common shrew, and that he became the family's apprentice to a more genteel form—are valuable only as examples of what passed then for fatal obstacles to public trust and private honor, and the last-named reads curiously in a modern atomistic atmosphere. That his father was a schoolmaster, and that he worked in the school to help, is probable; more than probable also are his boasts of good blood despite it, as several of the brothers became leading citizens, one of them being on the board of 10 strategoi which conducted military and foreign affairs. He may have been, as alleged, a professional gymnast; unpaid athletics were too reverently worshipped there to make paid ones seem unnatural. He certainly served a long term of military duty (probably not all at once), and with distinction; for he was in the battles of Mantinea (362) and Tamynae (349), and for bravery in the latter was deputed to bring the news and accorded a crown. Meantime he had become a magistrate's clerk; a petty actor; finally secretary to the important political leaders Aristophon and Eubulus, who helped him twice to an election as government secretary. He was now 40 and had not "found himself", but with the chance of addressing the public his true talent soon became manifest. He quickly acquired an eminent mastery of legal and political knowledge, and became a singularly graceful and effective speaker, with remarkable finish, harmony and variety of oratorical effect. In 348 he was sent to the Peloponnesus to organize a union of the Greeks against Philip of Macedon, but failed entirely, and doubtless became convinced at that time that any such scheme was permanently impracticable. The next year he went as one of the embassy to negotiate peace with Philip, and on their report (which Grote pronounces "a tissue of impudent and monstrous falsehoods," not necessarily of their own invention, but acceptance of Philip's word), the Peace of Philocrates (another envoy) was concluded in 346. Philip grew more and more powerful, and Demosthenes more and more urgent for opposition to his plans, which, however plausible to a Greco-Macedonian union against the barbarians and the East—could in practice only be carried out, as they at last were, by absorbing Greece in Macedonia. Æschines as steadily supported the Macedonian alliance, and doubtless as honestly, from conviction that for disunited Greece the only choice was between league and conquest—which also was true. In 345 Demosthenes charged him with treason and bribery. He was acquitted without difficulty. Three years later the charge was revived in Demosthenes' great speech "On the False Embassy"; Æschines rebutted it with success in his speech of the same title. He helped on the Macedonian cause all through the reign of Philip and the early part of Alexander's, accused by the opposing party of being a hireling emissary of Macedonia, and returning as much and presumably as just abuse as he received. That the public made the necessary discount is proved by the fact that he lost no credit with them. At last he assumed the aggressive with disastrous results. One Ctesiphon having proposed a golden crown for Demosthenes in recognition of his services to the commonwealth, Æschines impeached him for proposing an illegal act, and made his greatest speech, "Against Ctesiphon," an indictment of Demosthenes' entire public life. Demosthenes replied with his greatest, "On the Crown"; so crushing that though the pro-Macedonian party was in the ascendant Æschines could not obtain the one-fifth minority with which he might have saved him from atimia, or infamy, and a fine of 1,000 drachmas. He left Athens at once without paying it, and thereafter taught rhetoric or schools of oratory in foreign parts; some say Ionia and Caria, and finally Rhodes after Alexander's death. He died at Samos,
aged 75. Three of his orations are extant—against Timarchus' charge of bribery after his second embassy to Philip, one on that embassy and the one against Ctesiphon. There is a story that he read the latter to his pupils at Rhodes, and on their protesting to be astonished that despite its brilliance he should have been defeated, replied, "You would not be if you had heard Demosthenes." A variant is that he read Demosthenes' speech as a model of rhetoric, and on their expressing admiration, replied, "If you wish me to tell it, I will; but if you aim to make it your own, then do it yourself."

The originals are in countless editions. Consult for text and best comment Jebb's "Attic Orators" (London 1876-80). Translations are also plentiful.

ÆSCHINES, Greek philosopher of the 5th century B.C., and a friend of Socrates. Of humble parentage and at first unfortunate in business, he achieved success as a teacher of philosophy in Athens, and as an orator and stylist of high rank. He was the author of several "Orations," "Epistles," and of three Socratic dialogues: "Virtue, whether it can or cannot be taught," "Riches, whether they are good?" "Death, whether it is to be feared." Consult Gomperz, T., "Greek Thinkers" (translated by G. C. Berry, Vol. III, p. 342, London 1903).

ÆSCHYLUS, the founder of tragedy: b. Eleusis, Attica, 525 B.C.; d. 456 B.C. His father, Euphorion, was a nobleman. One of his brothers distinguished himself in the Persian war. At 23 the poet brought out his first play. Fifteen years later he won his first prize. But Æschylus was not only a poet; he was also a soldier, for he fought at Marathon (490 B.C.) and at Salamis (480). No patriot felt more keenly than he the impulse of that mighty national movement of Greece against Persia. In a contest with Simonides he failed to win the prize for an elegy to be inscribed over the fallen heroes. About 476 he went to Syracuse, where Hiero had gathered about him the most famous poets. Shortly before the death of Hiero he contended with Sophocles for the tragic prize and lost. It is likely that he thought his failure was due to politics or to partisanship. Later he was successful; but there was still the rivalry between him and a large part of the Athenian public. His last and greatest work, the "Oresteia," received the first prize. Though acquitted of the charge of having revealed the Eleusinian mysteries, he withdrew from Athens. He died at Gela, Sicily, in 456. The Athenians erected a statue in his honor. In the epistle, written by himself, he speaks only of his valor in the Persian war.

Theoretically Sophocles was the greatest Greek dramatist, but Æschylus was a genius of a higher type; the magnificence of his imagery and the sublimity of his conceptions are unsurpassed, if equalled, by any poet. He was also a genius of great resource and an artist of consummate conscience. Theologian, as well as artist, Æschylus sought to interpret the higher truths of human destiny. He was the first poet to identify tragic action with a moral and religious question. There had been much skepticism in Greece; but the Persian war had brought a reaction reviving the national religion. The poet's Zeus is the supreme ruler of the universe. But Fate is above Zeus. Necessity governs all. Every violation of the law of righteousness is followed by punishment. The sinner thrives for a season, but the penalty is at last exacted. Even Zeus cannot avert what the Fates have ordained. The Ruler governs by and through Justice. This idea dominates all the tragedies of Æschylus. To his choral songs (Furies) is entrusted the moral government of the world; they execute the eternal immutable law, punishing every atrocious crime. Æschylus says nothing about the joys of the just in the next world, but he has a clear idea of retribution. Æschylus was thoroughly familiar with the stage; he superintended the performance himself; and he was excessively busy in improving the appliances of the theatre. But in his plays there are no carefully laid plots, no intricate weaving of incidents, no fine meshes of intrigue. His dramas, like his characters, are drawn only in large outline, with simplicity and manly straightforwardness. Lyric movement, epic interest and gnomic wisdom are first combined in Æschylus. To his choral songs rise to the loftiest height. But in Æschylus there are no surprises, no complications, no sudden reversals of situation. There is one idea and a uniform development. Whole personages are presented to the view of the audience. There is no unfolding of plot. The poet sometimes touches upon the tenderness and delicacy of the gentler sex, but he does not dwell on these traits and study them in detail. His heroes move in an ideal sphere; they are ethical types, majestic, terrible. The tragedies of Æschylus were written in trilogies—groups of three plays with a single main theme. A grotesque satyr drama followed each trilogy. The number of characters never transcends seven. Two actors played the roles for his earlier tragedies. Sophocles introduced a third actor. The Æschylean characters leave a lasting impression on the mind; they are not effeminate creatures, but "sturdy men that breathe of the spear and the lance and white-crested helmets, of casques and greaves and courage, doughty as the tough-hided seven-fold shield of Ajax" (Aristophanes, "Progs" 1014). The style of Æschylus is lofty, weighty in matter and original in expression. He has not the flashing eloquence of the Sophocles, nor the poise of Sophocles, but he possesses a grandeur and broad simplicity surpassed by no other writer. In a wonderful manner he combines energy and intensity with lucidity, elevation and rapidity. His vocabulary is bold and full of hard words; his enclitics strange and sonorous; his figures superb; in their Dionysiac elevation they approach the lyric flight of the Oriental. Both in diction and in sentiment the Greek poet bears a striking resemblance to Isaiah, "for his name shall be Immanuel:" 177, "Job xxxii, 15). In the splendor of his figures and in his powerful metaphors we see "visions vast as those of Ezekiel, yet conveyed withal in rich and radiant Greek. The mighty line of Æschylus gave unrivaled dignity to the dramatic art. To interpret them as a doctrine of human destiny. He was the first poet to identify tragic action with a moral and religious question. There had been much skepticism in Greece; but the Persian war had brought a reaction reviving the national religion. The poet's Zeus is the supreme ruler of the universe. But Fate is above Zeus. Necessity governs all. Every violation of the law of righteousness is followed by punishment. The sinner thrives for a season, but the penalty is at last exacted. Even Zeus cannot avert what the Fates have ordained. The Ruler governs by and through Justice. This idea dominates all the tragedies of Æschylus. To his choral songs (Furies) is entrusted the moral government of the world; they execute the eternal immutable law, punishing every atrocious crime. Æschylus says nothing about the joys of the just in the next world, but he has a clear idea of retribution. Æschylus was thoroughly familiar with the stage; he superintended the performance himself; and he was excessively busy in improving the appliances of the theatre. brisk dialogue and facile narrative of Euripides. Small wonder that Ben Jonson exclaimed:

"Call forth thundering Eschylus,"

or that Browning speaks of

"The thunder phrase of the Athenian, grown
Up out of the memories of Marathon."

Æschylus was an exemplar of the austere style. Dionysius of Halicarnassus classifies him with Pindar and Thucydides. Dio Chrysostomus praises him for his high-toned spirit, for his archaic coloring and for his boldness of thought and expression. There is no base cunning, no garrulity, no littleness in Æschylus. Though redundant at times, he surpasses all Greek poets in a certain Shakespearean concentration of phrase. The great number of reminiscences from Homer and the plasticity of his descriptions show how much he was influenced by the epic style. "The scraps from Homer's banquet," as he characterized his tragedies, included form as well as substance. Of all the tragic poets he is the one most steeped in Homer. His rhythms are finished and full of power and expression. Of the 79 tragedies attributed to him by his biographer only seven have come down to us. The 'Persians' was produced seven years after the battle of Salamis (472), the 'Prometheus Bound' in 470, the 'Seven Against Thebes' in 468, and the 'Oresteia' ('Agamemnon', 'Choéphoroi', and 'Eumenides') in 458. The date of the 'Suppliant' is uncertain. Many scholars consider it one of his latest works. I am inclined to place it about 459. See ORFNEIA, THE; PROMETHEUS BOUND.

J. E. HARRY.

ÆSCHYNTE, es'ki-nit, the mineral for which Dana's Æschynite group was named. It is essentially a niobate, titanate and thorite of the cerium metals, containing also iron and calcium in small amounts. It occurs in black, prismatic, vertically striated crystals belonging to the orthorhombic system. Its density is about 5.5, and its specific gravity about 5. It is rare, and occurs in the Ural Mountains, in Norway and in Silesia. It was named by Berzelius from a Greek word meaning "shame," in allusion to the intractability of chemistry, at the time of its discovery, to separate titanite acid and zirconia (two of its constituents).

ÆSCULAPIUS (Greek Asclepios), the god of medicine among the ancient Greeks and Romans. In Homer he is merely a man, the god of medicine being Pæon; the deification was probably founded on the Homeric story, and at any rate was subsequent. The notion that he was originally a god of light or the underworld, "reduced to the tradition of a human being, inverts all historic processes and the nature of early thought. In Homer he has two sons, Machaon and Podalirius, famous as heroes and physicians; they are called Asclepiads, a name retained by their descendants or at least a priestly physician-caste. His daughters, Hygieia (all-healer), Panacea (all-healer), etc., are later inventions and abstractions of relevant ideas. The later myths vary; some call him son of Apollo and Arsinoe, some of Apollo and Coronis, daughter of Phlegyas. In Hesiod the nymph was faithless, and with her bridgroom Iscys (one of the Lapithæ) was slain by the gods (the raven who brought the news being changed from black to white as a punishment); but Apollo rescued his unborn son from the mother's body on the funeral pile, where he grew to excel his master, able not only to prevent death but to raise the dead. At Plato's complaint Zeus slew him with a thunderbolt, and after his death he received divine honors. The supposition that his worship originated in the Peneus Valley in Thessaly is perhaps due to the Homeric tradition being our earliest record; but if he was originally a healer wonderful to rude barbarians, it is likely enough that the tradition was Thessalian. Anyway, Tricca there was an old focus of his cult; but it flourished also to the south, perhaps carried there by the Thessalians forced southward by invaders. It had noted seats in Phocis, Boeotia, and especially in the Peloponnesus, where Theopompos in Arcadia was one familiar seat; but by far the greatest was Epidaurus, south of Corinth. Here was a temple in a grotto, where the sick had to spend nights, and the proper remedies were revealed to the priests in a dream, and the cured made sacrifice to Æsculapius, commonly a cock. The sleep was of course a mere part of the priests' mystification; but from their accumulated experience and their register of cases they must have become really expert physicians for the times. From thence the worship spread all over Greece and the islands and to Rome—nearly 200 temples in all; there were celebrated ones at Cos, Epidaurus, and Pergamus; there was one into Athens as late as 420 B.C., and to Rome 293 B.C., in consequence of a plague. Consult Walton, 'The Cult of Asclepios' (New York 1894); Wilamowitz-Möllendorff, 'Isylius von Epidauros' (Berlin 1886).

ÆSCLULIN, es'ku-lin, a bitter principle found in the bark of the horse-chestnut tree (Æsculus hippocastanum), especially in the sprouting, before the buds open. It crystallizes in small prisms having the formula CaH₄O₂·2H₂O. Æsculin melts at 400° F. It dissolves sparingly in cold water, but easily in boiling water, the solution coagulating upon cooling. It is soluble in glacial acetic acid and in 3 parts of alcohol. Æsculin is of special interest to the physicist on account of the notable bluish fluorescence (q.v.) exhibited by its solution in water. The word is also spelled asculein, esculin and esculine.

ÆSOP, the fabulist. As early as the mid-5th century B.C. at least, fables were circulating in Athens attributed to a certain Æsopus, and held in such esteem that the city erected to him a statue by the great sculptor Lysippus; Aristophanes makes one of his characters learn the fables, Socrates versified such as he could remember and Plato speaks of them with approval; Herodotus, born c. 484 B.C., specifically tells us, as referring to a story too familiar to repeat, that when the Delphians offered compensation for his murder to the rightful claimant, it was claimed and received by one Iadmon, grandson of another Iadmon. Seir was the owner of Rhodopis the courtesan, who lived under Amasis, King of Egypt (c. 570–526 B.C.), and was redeemed by Charaxus, the brother of Sappho. That all this mass of detail concerning persons living less than a century before his
time, with easily verifiable dates, and about one whose fate was notorious, was in fact told of a myth and abstraction, and that there never was an Αesop, is exaggerating skepticism into absurdity; and the later accretion of fables and confusion of persons is irrelevant. Plutarch (late 1st century A.D.) fills out the story from lost authors, possibly with authentic traditions, perhaps mixed with real myth-making: that he was captured young and brought a slave to Athens, and after several changes of ownership, was franchised by Lysimachus (which is inconsistent with Herodotus); that during Pisistratus' usurpation he visited Athens and composed the fable of "King Log and King Stork" for the edification of the citizens; that, going to the Lydian court, he became Croesus' favorite; and, sent by him as envoy to Delphi to distribute money to the people (about 584 B.C.), and refusing to do so on account of a quarrel among them, was thrown from a cliff by them. This at least coheres with Herodotus. The stories of his being an ugly blackamoor, and others beyond the above, are derived from a worthless life of him published (but not written) by Maximus Planudes (q.v.), a 14th-century monk, in which he is apparently confounded with the mythical sage Lokman. As to the fables, it is probable that Αesop did not write them down, but merely told them to audiences; and it is perfectly certain that the ones we have under his name are not his (though they may incorporate the same incidents), but substantially a collection made from oral memories by Demetrius Phalereus of Athens about 320 B.C.; turned into Latin by Phaedrus of the 1st century A.D., with additions of his own much inferior in every way; verified by Babrius, a Greek poet of perhaps the late 1st century; and variously translated and re-edited since. The usual popular "Αesop is Phaedrus. The origin of the fables is largely Oriental; but they are much superior to any Oriental prototypes in pith and conciseness. It is often said also that they are part of the stock of beast-apologues common to the entire Indo-European races; but this is true only in the sense that animals have been made to talk in all old folk-lore. The special qualities of "Αesop— the immense comprehensiveness of idea almost to "indelible exposure," in Sydney Smith's phrase, the sweep of generalization, the acute analysis of typical human characteristics— make it unique; and it quite probably inherits these traits from the genius of the real Αesop, a Greek of the mighty age of Greece. See FABLES OF Αesop, and consult Jacobs' "Introduction to the Fables of Αesop" (New York 1896); Keidel, "The Ecliptic Princes of the Greek Αesop" (in American Journal of Philology, XXIV, 304-317, 1903).

ΑE SOPUS, Clodius, Roman actor of the 1st century B.C., a contemporary of Roscius. When acting he entered into his part to such a degree as sometimes to be seized with a perfect ecstasy. Plutarch mentions a report concerning him, while representing Atreus, that, deliberating how he should revenge himself on Thyestes, he was so transported beyond himself that he smote one of the servants who was crossing the stage and killed him on the spot. He was a dramatic tutor of Cicero, and befriended him in exile. His last appearance was at the dedication of Pompey's Theatre in 55 B.C.; his voice thereafter failed. His folly in spending money on expensive dishes made him as conspicuous as his dramatic talents. He is said, at one entertainment, to have had a dish filled with singing and speaking birds, which cost $4,000. His son Αesop inherited his father's worst traits; it was he who drank the $40,000 pearl dissolved in vinegar, to be noted as having drunk the most expensive known beverage.

ΑESTHETICS (from Greek αισθανόμενος, "to perceive"), is the science of beauty and art. It can be treated from the scientific standpoint, in which the actual qualities of the different varieties of beauty and art are investigated empirically, or from the historical standpoint, by the exhibition of the views which have been held as to the nature of art and beauty in their chronological sequence and under their authorship, or from the systematic standpoint, by the independent investigation of the philosophical question of the nature of art and beauty. The scientific standpoint is too technical and too intricate to be susceptible of treatment within the narrow confines of an encyclopedia article, so that we shall approach the question entirely from the other two avenues.

Αesthetics receives its first scientific treatment in the work of Plato (q.v., 428-348 B.C.). In accordance with the views of his master Socrates (q.v.), Plato identifies the good, the beautiful and the true. All these are regarded as being ultimately one ideal entity, the Idea of the Good. This is incarnated with increasing perfection in corporeal beauty, in the beauty of noble souls, in the virtues, and in the sciences, until at last we meet it unalloyed and pure. The beautiful as we find it in concrete beautiful objects is for Plato an imperfect exemplification, that is a copy, of the Idea of the Good. As it is the nature of art to copy and imitate, a work of art is still further removed from the Idea of the Good than the object of which it is a copy, and hence possesses less beauty. Accordingly the greatest care is necessary to prevent art from being a hindrance rather than a help in the search for beauty, and in the ideal state it will be under strict supervision in order that the deterioration consequent on its remoteness from the Idea of the Good may not turn it into a source of positive evil.

In so far as he exhibits a certain parallelism between the beautiful and the good, Plato, and indeed all the other Greek philosophers with him, is unquestionably right. Beauty and Virtue are both normative concepts—that is, they both establish a chain of values running from the lowest to the highest. Furthermore, both the beautiful and the good seem to have a claim on our action: we refrain from at least as many deeds because they are in bad taste as because they are evil. Still, there are so many cases where the two standards appear to conflict that their absolute identity is doubtful. It is a familiar experience to find an artist, a hopeless reprobate, or a thoroughly good man an utter Philistine. This would be quite impos-

* The word is also used by Kant in its etymological sense, as the science of sense-perception.
sible if goodness and beauty were completely identical.

In Aristotle (q.v., 384–322 a.c.) we find the first germ of a distinction between ethics and aesthetics, for he says that whereas beauty may be found in the unchanging, only actions are good. It will readily be seen that this is not a very sharp distinction, and Aristotle does not go on to develop its implications. In the spirit of his master Plato, he gives as the essential marks of beauty order, symmetry, and limitation. He makes the important statement, which has served as a basis of the theories of many later aestheticians, that the pleasure induced by beauty is disinterested.

Aristotle’s theory of beauty, in so far as we possess it, is extremely undeveloped, and accordingly we find no use made of it in his book on art, the ‘Poetics.’ Here he follows Plato in considering the essence of art to be imitation. The motive of this imitation is the universal desire for knowledge, so that the value of the knowledge imparted determines that of the imitation. Thereafter it performs its function properly when it gives us the most valuable knowledge of things—the knowledge of their inner essence. This requires idealization and generalization, so that the true art works on individuals—laws, not facts. Thus while for Plato art is essentially inferior to nature, for Aristotle it may and should be superior to nature.

Aristotle assigns to music—and implicitly also to the other arts—four functions. These are (1) that of serving as an amusement; (2) that of moral education; (3) that of constituting an enjoyable exercise; (4) that of “purification.” The first and the third of these four values are obviously only the passive and the active phases of a single one. As for the emphasis which Aristotle puts on the moral purpose in art, it is to be remembered that beauty and morality are for him essentially one and the same thing, so that this moral purpose undoubtedly stands not only for what we should ordinarily know by that name, but also for the intrinsic beauty of the work. The “purification” which art is supposed to produce is an emotional one. If we accept Zeller’s interpretation of this point, Aristotle means that music and the other arts free us from more violent emotions by turning them from the individual and particular to the general and universal, owing precisely to that typical reference which we have seen to be characteristic of art in the Aristotelian system.

The next great figure in aesthetics is the Neo-Platonist Plotinus (q.v., 204–269 A.D.). Like all the Greek philosophers, in fact, he too maintains that the beautiful is intimately related to the good, but this relationship receives less emphasis in his system than in those of Plato and Aristotle. Plotinus is a mystic, and he considers that all things are emanations from the One, which he also knows as the Good. In so far as these emanations are perceptible to our external senses, we experience them as beauty. As Boden puts it, in his view, it means that all that symbolizes in sensuous form laws eternally active ranks as beautiful. This symbolization need not involve any symmetry or order or proportion in the beauty. One itself has no parts, and can consequently share none of these qualities. Whereas on the Aristotelian view only that which possesses structure can be beautiful, Plotinus holds that nothing can partake of beauty whose parts are not beautiful in themselves.

Plotinus is the last of the ancient thinkers to have added anything really new to the theory of aesthetics. With the rise of Christianity and the barbarian incursions from the north and east, art and the theories of art to which it gives rise enter on a period of regression. Save as a tool of religion art is dormant until the Middle Ages, but foretokened the Renaissance. As a consequence, although we do find treatments of aesthetic problems from the time of St. Augustine to that of St. Thomas, these have been singularly arid and without fruit in modern aesthetic theory. It is remarkable, however, that the Renaissance itself, fertile in artistic interest and artistic production as perhaps no other time has been, should have left so small a contribution to the aesthetics of to-day, and that it is to the pedantic, dry Enlightenment that we must look for the rebirth of the theory of beauty and art.

As in all the philosophical theories of the Enlightenment, we find a sharp contrast between the empirical “tough-minded” tendency of the British speculators and the “tender-minded” rationalism of the Continent. The Continental tradition in aesthetics begins with Baumgarten (1714–62), a follower of Leibniz (q.v., 1643–1716). Leibniz believed that our experience of what is apparently matter is really the result of a confused perception of an aggregate of entities he calls monads, which are essentially spiritual or mental in nature. Accordingly Baumgarten considers that the property of these monads which is known to our intellect as the perfection of the ideas which they possess and the consequent correctness or truth of these is perceived after the confused method of our senses as beauty. It will be seen that this view of Baumgarten belongs to that utter pedantry which characterizes the decadence of the Leibnian tradition, yet it is the first sign of the resurgence of a philosophical aesthetics.

Not many years after Baumgarten we find the question of the norms and branches of art treated by Winckelmann and by Lessing (q.v., 1729–81). Winckelmann’s interest is primarily in those arts that appeal to the sense of vision, while Lessing, on the other hand, approaches aesthetics from the standpoint of the poet. Winckelmann has a formal view of the nature of beauty not unlike that maintained by the British artist Hogarth, but he does not make beauty the sole end of artistic endeavor, for he finds that beauty and expressiveness are not perfectly compatible. Lessing follows Winckelmann in applying the word “art” primarily to the plastic arts, so that poetry is for him something quite outside the scope of art. Consequently he is able to maintain that the ugly has its place in poetry, but not in art. Lessing follows Aristotle closely in his views on the drama and on the relative functions of the several arts.

In Britain at about this time Home (Lord Kames) (1696–1782) develops an aesthetical theory on the lines laid down by Shaftesbury and Hutcheson. This view is really hedonist.
istic, making the test of beauty a certain sense of immediate satisfaction, yet in essence it is not hedonistic at all, for this satisfaction is said to be not only quantitatively but qualitatively distinct from the satisfaction of the useful or the merely agreeable. This view in effect amounts to the postulation of a peculiar aesthetic feeling. Like the Greeks, the members of this school of British thought maintain that the norms of ethics and aesthetics are closely related, but it is the ethical norm which they subsume to the aesthetic one, for they base the basis of morality in the beauty of good deeds. Edmund Burke develops this empiricist vein in aesthetics further, and derives the feeling for the sublime from the instinct for self-preservation, that for the beautiful from the social impulse. The technical side of artistic theory is investigated by Hogarth (q.v.), who places great emphasis on the beauty of form or design.

As in metaphysics and in ethics, so also in aesthetics. The greatest genius of Kant (q.v., 1724-1804), which unites the twin streams of British and of Continental thought into a single mighty current. He combines the apriorism of Baumgarten with the empiricism of Home. In Home, the finds the criterion of the beautiful in some pleasure which it excites, but he does not consider this pleasure as a mere feeling. Beauty, he maintains, is that which universally and necessarily arouses disinterested satisfaction by its own form. Or again, he states that whatever please universally and without a concept is beautiful. Beauty then is determined by the pleasure it excites in us, but this pleasure must not apply to the sensory qualities of the object, but rather to their mere arrangement, and must be universally and necessarily determined by this arrangement. The nature of the arrangement in question is indicated by Kant when he says that a thing is beautiful when it corresponds to the nature of the cognitive faculty, or when it harmonizes human faculties. Kant denies that an absolute a priori treatment of the various types of beauty is possible, but he nevertheless attempts what practically amounts to this. One of his most important contributions to aesthetics is that of making a way for a true appreciation of the sublime. He finds that the sublime is that which by its quantitative or qualitative mightiness shocks us and fills us with pain at our own smallness, but then fills us with a feeling of the exaltation of the greatness of our moral nature, which is mightier and loftier than all the splendors of the outer world.

While Kant emphasizes the formal side of the beautiful to the exclusion of the material, the poet Schiller (q.v., 1759-1805) finds the nature of the artistic activity in a mediation between the matter-impulse and the form-impulse, between desire and reason. Art, then, consists of a sort of balancing or play of all the mental faculties. This suggestion was adopted by Spencer (q.v., 1820-1903), who attributes to this play the function of preventing the higher faculties from disuse and the atrophy consequent thereon. The fact that the higher we go in the scale of life the less completely do the lower necessities of life consume the energies of the individual furnishes both the need and the opportunity for a progressive increase in the attention given to play and to aesthetic appreciation.

In the great schools of idealistic philosophy which immediately follow Kant aesthetics plays a large part. According to Hegel (q.v., 1770-1831), art is a symbolic transcription of the universal, of practical action, or subject and object, of cognition and action, of conscious and unconscious activity, of freedom and necessity, of genius and deliberation. Beauty is the shining of the Absolute (cf. the One of Plato) through the veil of sense-experience. It is the result of the intervention of a sensuous medium that beauty differs from truth. The further developments of the Hegelian aesthetics are essentially Platonic.

That arch-pessimist Schopenhauer (q.v., 1788-1860) finds in beauty his respite from the toil and trouble of the world. Beauty is for him the expression of an Idea. Everything is in some measure beautiful. When we contemplate the beautiful we lose our individuality and will, and in so doing we enter into some experience on the World-Will. The appreciation of art gives us a partial attainment of the Buddhist Nirvana. The disappearance of will from consciousness takes place on the contemplation of the sublime by a productive effort of our will; while when we devote our attention to the beautiful, will merely vanishes of itself.

In Herbert (q.v., 1776-1841) we find a beautiful affinity both to British subjectivism and to Kant. He considers the beauty of the in involuntary and disinterested judgment of approval. We transfer this predicate of the judgment to the object and call it beauty. This capacity of judgment, or taste, differs from desire in that it can judge that which is present as well as that which is absent. The character of the beautiful is its form.

In Britain the early and middle part of the last century received relatively little influence from Kant. Dugald Stewart (1753-1828) and Bain (q.v., 1810-1903) develop a view which shares in all the hedonism of Home and Burke. Bain follows Alison and Jeffrey in attributing to association an important place in the genesis of the sense of beauty. Although in all these writers there is much that is relevant to the modern discussion, this is so bound up with false and unwieldy psychology that it is hard to isolate.

It is not worth while to arrange the writers of the middle and latter thirds of the last century historically. In England we have that great, paradoxical, sincere genius Ruskin (q.v., 1819-1900). *Art for art's sake* is a doctrine essentially repugnant to him. According to him, the three functions of art are to enforce the religious sentiments of mankind, to perfect their ethical state, and to do them material service. It will be seen that his opinion agrees closely with the practice of that period which furnished so much of his inspiration, the Middle Ages, for then art, like philosophy, was ancilla Theologiae.

In Taine (q.v., 1828-93) as in Spencer, the biological, anthropological consideration comes strongly to the front. Art is largely a matter of environment, and there can be, for example, no talk of the Flemish type of art as bad art, or of the Italian type as good art. It is the function of art to make predominant the essential character of the object it depicts. A Dutch
landscape is excellent in so far as it truly conveys to us the misty, foggy air, the rich, marshy fields, the careful husbandry of the Rhine delta. Landscape art not only is regarded as a means, not an end, and in this he agrees with Ruskin. Art is a human activity aiming at the transmission of emotion, and is not the pursuit of beauty. Art should not be the exclusive property of one class or one race, and should not be the province of sublimated subjects as sexual love, patriotism, or religious devotion. Its true function is ethical.

According to Bosanquet (q.v.), the beautiful is "that which has characteristic or individual expressiveness for sense-perception or imagination, subject to the conditions of general or abstract expressiveness in the same medium." Bosanquet finds beauty in chargedness with associated ideas. Here the voice is Hegel's but the topic is Bain's. Beauty is to be judged, not by individual human feeling, but by the tendency of human feeling. "Beauty" usually means such beauty as is recorded in art—i.e., by those who perceive best.

According to Bergson (q.v.), art exhibits the light of intuition, science, which presents its analysis. Art is the sphere of intuition, science that of reason. As Bergson considers the knowledge gained by intuition as deeper and truer than that gained by reason, he assigns a higher place to art in his philosophy than to science. He names sympathy as one of the cardinal marks of art.

Bergson's antithesis between art and science is foreign to the philosophy of Santayana (q.v.), who regards art as plastic instinct which is conscious of its aims. The instinct which constitutes art in Bergson's philosophy need not possess this consciousness. For Santayana art is reason propagating itself. This attitude is not unlike that of Benedetto Croce (q.v.). Croce holds that art is essentially lyrical, and consists in a representation of the feelings. He denies to art all ulterior metaphysical purpose. It should exhibit feelings and not deliberately construct them.

Let us now leave the historical for the systematic view of aesthetics. We find that the two cardinal problems of aesthetics are that of the nature of beauty and that of the nature of art. Although art does not always deal with what is prima facie beautiful, it would seem difficult to deny that any proper object of art, no matter how great its apparent ugliness, will be beautiful when approached from the standpoint of the artist or the appreciative observer. Although, then, it is easy to formulate paradoxes that appear to point in the opposite direction, we are justified in defining art as that human activity which has as its end the production of the beautiful. This definition does not tacitly introduce the "Art for art's sake" which Tolstoy combats, for it leaves entirely open the question of the independence of beauty from morality, and furthermore does not declare that the attainment of beauty is an end which justifies action. If we admit the validity of this definition, we have left of the two problems of aesthetics but one—that of the nature of beauty.

The most important question which, as we have seen, has historically presented itself as to the nature of beauty is that of its source. This question is completely analogous to that of realism or idealism in epistemology; is beauty something intrinsic in what is perceived, which is only disclosed through the act of perception and not at all inherent, or does beauty consist in a relation between the beautiful object and the subject who is aware of it or the act of perception by which it is brought to consciousness? Those who hold views of the first type, such as Plato, Aristotle, Plotinus, Hegel or Bosanquet are called idealists, while their opponents, including among others Home, Shaftesbury, Burke and in a limited sense Kant, are said to be subjective aestheticians.

The dispute between subjectivists and objectivists in aesthetics has been full of much confusion. The subjectivists have been accused of degrading their science by making the validity of the aesthetic judgment dependent on the mere passing whim of any self-appointed critic. Without in the least prejudicing the answer to the main question at issue, it may be pointed out that to say that a view is degraded or ignoble is not to say that it is false, and furthermore that a property of an object which is dependent on its relation to the perceiver is not necessarily mutable at the will of the perceiver. An aesthetic judgment which is dependent, let us say, on my feeling of admiration for a certain statue, is no more under my control for that reason than if it were solely dependent on the physical shape of the statue. As far as my will is concerned, my sentiment of admiration is as immutable a datum as the statue itself. The subjectivist, then, may have canons of taste quite as binding as those of the objectivist, but these canons involve a double reference—a reference not only to the object but to the subject.

Furthermore, a subjective aesthetics need not necessarily identify beauty with pleasantness. The old psychological hedonism, which made all the keys of human interest strike one of the twin strings of pleasure and pain is no longer upheld by any respectable authority. It is quite possible that the seat of the dispute between the claims of sensual pleasure and of beauty is within us, and that there is a clue to our nature. Therefore it is the answer to the subjectivist in aesthetics to say that the beauty of an object is introspectively other than the pleasure it may induce in us, and is often incompatible therewith.

It is through this method of introspection or self-examination, however, that the true nature of the beautiful is to be discovered, and the question of its internality or externality to be solved. Does recognition of the beautiful enter the mind after the manner of our perception of a quality in an external object—as we perceive that a tree is green and leafy or bare and brown—or after the manner of an awareness of our own emotions, such as anger, satisfaction, contrition, etc.? This is the attitude which should be kept in the mind of the reader throughout the following discussion.

Now, it is a familiar experience that one may be blind to beauty with much more readiness than to an ordinary sensory impression. Wordsworth's Peter Bell found that

"A primrose by a river's brim,
A yellow primrose was to him,
And it was nothing more."
It is obvious that the essential thing which Peter Bell lacked was not sensory acuity. He probably saw as much of the color, form, etc., of the primrose as the poet himself. What was wanting in him was a certain emotional response to the color and form. Furthermore, once this emotional response is present, machine shops or traveling crematories may be beautiful, as is shown by the work of Mr. Pennell, or city slums or barren deserts or in fact anything whatever. It is difficult to avoid the conclusion that in the emotion excited by any object and only is this beauty lie.

If we accept this view, we shall be subjectivists, and indeed the trend of the age is in this direction. There are still, however, many diverging types of subjectivism possible. One might say with Kant that though the seat of beauty is in the impression made by an object on the subject, this impression is bound by fixed a priori laws. Yet the very diversity of the beautiful and the fact that nothing appears ugly to him who considers it in the right light incline this view from being a real solution of the problem. But even if we admit that the connection between the beautiful object and the emotion it excites is a de facto one and not a priori, we have not yet pinned our aesthetics down to a single theory. Many maintain that beauty consists in the excitation of some peculiar aesthetic emotion. If we accept the James–Lange theory of the emotions—which has been seriously questioned of late—and maintain that an emotion is individuated only through the physiological response which characterizes it, it will be very difficult to attribute a separate existence to the aesthetic emotions. We react to different works of art in very different ways; one excites awe, another pity; we laugh at the comedy and weep at the tragedy; we exhibit the physical symptoms of admiration for this work and those of the enjoyment of that. It is impossible for a single physiological reaction to be found that is compatible at once with those of awe, pity, laughter, tears, pleasure, admiration, with is not also found in our reactions to things not beautiful. Even apart from the James–Lange theory, the multifariousness of the aesthetic emotions seems to contradict their possession of any common element. It seems, then, that the aesthetic sentiments are qualitatively identical with those of non-aesthetic character. Whatever distinction may subsist between them must be sought elsewhere than in their quality. Perhaps the distinction is to be found here: many of our emotions, such as desire, fear, hatred, satisfaction, etc., have a certain polarity about them—they are either emotions of approval or of disapproval. These emotions do not always agree in their direction at different times, or even at one and the same time, we may fear what we desire, or even hate it. Nevertheless, owing to the de facto uniformity of our nature, certain types of things will attract us in the long run and in general, and others repel us, even though these rules may be broken in a large number of particular instances. That is, we possess what may be known as a taste, which changes very slowly, if at all. Furthermore, we are able to recognize whether or not a thing will satisfy our taste, regardless of the conflicting promptings of our immediate emotions or of the presence or absence of the thing in question. Now, there are two ways in which we may apply our taste to an object or process; we may consider it in its environment in the causal chain, or by a more or less voluntary act we may blot out its actual associates, and look at it in complete isolation. The first is the method of the moral agent, while the second is that of the artist. Art and morality may differ in their promptings, and also why the artistic attitude has been called disinterested by Kant and so many other writers. If the whole world were summed up in one picture or the symphony, the artist would necessarily be a good man, but it is not, and the very disregard for the loose ends of causality which bind his activities to the rest of the world which makes the artist a genius is likely to interfere with his being completely good. Or to put it otherwise, the artist may have many masterpieces, but the good man only one—his life.

On this theory of art it is easy to account for both the mutability and the fixity of aesthetic taste. Taste is an aggregate of individual tastes by much the same process by which these take their origin from the single emotions of those to whom they belong. Taste is that part of personal tastes which is based on what is biologically and culturally common to mankind. Consequently it changes just as rapidly and just as slowly as mankind itself. Of course, in addition to this general human taste, every group of persons has its group taste. There are always certain individuals whose tastes have been more highly developed in the intricacy of their objects and the uniformity of their norms than those of the common run of humanity. These persons indicate the direction which the general human taste will assume with the increase of artistic and cultural education, and accordingly the group-taste of this community is Good Taste. With Bosanquet we may make this Good Taste the practical norm of aesthetics.

The norm of aesthetics, then, is to be found in the direction in which evolution and education are leading the judgments of mankind. It is because of the de facto permanency of the trends of education and evolution and of human nature itself that art is a social matter—that the works of one man can be appreciated by others—and not because of the absolute a priori character of the beautiful and of art.

ÆTHIOPICA, “Tales of Ethiopia,” a Greek romance in 10 books in which is told the story of the love, adventures and final union of Chariclea, an Ethiopian princess, and Theagenes, a Thessalian Greek. The author is a certain Heliodorus of Eumes in Syria, who lived in the latter part of the 3d century A.D., and not, as was until recently believed, Heliodorus, bishop of Trikka in Thessaly. The development of the tale, which is on the whole the best of the extant Greek romances, is extremely complicated, often, though Tasso thought otherwise, unreasonably so. For the author not only adopted the technique of the epic and disclosed subsequently through the speeches of his characters the events which had brought about the situation at the opening of Book 1, but he also allows these characters, as they successively appear, to relate their own previous adventures. The tale thus abounds in episodes, amid which the thread of the main story is lost. There are, besides, countless incidental discussions of matters connected with geography, natural science, war, literature, etc., etc. It may fairly be said that about one-quarter of the Æthiopica is either irrelevant to the story or impedes its progress. The interest naturally depends almost wholly upon the plot and the fantastic adventures in strange lands; there is but little character-drawing. The author displays, however, a remarkable power of pictorial description, especially in those scenes which mark some important turn in the action. Of these probably the most striking is the brilliant scene in Book VII in which the lovers met again under the walls of Memphis. The Æthiopica exerted no inconsiderable influence upon the fiction of the Renaissance. Tasso greatly admired the structure of the story and drew from it material for his Jerusalem Delivered.

In England, Sidney is heavily indebted to it in his Arcadia and Greene shows its influence in his Menaphon and Pandosto. Shakespeare in The Winter’s Tale took over from Pandosto some of Greene’s borrowings from Heliodorus. The Æthiopica was first translated into English in 1577 by Unudge from the Latin rendering of Warschewiczki and his version has been reprinted in Tudor Translations [Vol. V, London 1895]. A translation from the original Greek is that of Rev. R. Smith (London 1901). NORBERT WIENER, Editorial Staff Of The Americana.

ÆTHIOPI, a Greek epic poem in five books, written by Arctinus of Miletus, one of the earliest poets of Greece and a contributor to the epic cycle. He flourished about 744 B.C. The Æthiopis was so named from the Æthiopian Memnon, who, after the demise of Hector, became the ally of the Trojans. The poem takes up the narrative of the Trojan War from the close of the Iliad. It begins with the famous deeds and death of the Amazon Queen, Penthesilea. It describes the death of Achilles and the dispute over his arms between Ajax and Odysseus. Consult Allen, T. W., in Classical Quarterly, (pp. 82 et seq., April 1908); Lang, Homer and the Epic, (1893); Kinkel, Epicorum Graecorum Fragmenta, (1877).

ÆTHIOPS MARTIAL, an old pharmaceutical name for black oxide of iron.

ÆTHIOPS MINERAL, a name sometimes given to the artificial black sulphide of mercury.

ÆTHOGEN, a compound better known as nitride of boron. See NITRIDES.

ÆTHROSCOPE, eth’ri-ô-skôp, a form of differential thermometer devised by Sir John Leslie. Both bulbs of the thermometer are enclosed in a concave mirror, one of them being in its focus. The instrument is so sensitive that when directed toward the sky it is affected by a passing cloud. It is not much used at the present time.

ÆTIUS, ā-i’eshius, the last great Roman general and savior of western Europe from...
being Hun; b. Durostorum on the Danube (now Silistria), c. 390 A.D.; murdered toward the end of 454. He was son of a distinguished com-
mander Gaudentius (probably barbarian); in
military service while a boy, and given to Alaric
as a hostage after Pollentia in 403, remaining
three years; later a hostage to the Huns; and
gaining close intimacy with both races, of mixed
results. After Honorius' death he supported the
secretary Joannes against the Empress-regent
Placidia, and brought an army of 60,000 Huns
to his aid; but, Joannes having just been de-
feated and slain, the Huns were bribed to go
home, and Aëtius was made Count of Italy and
commander of the army, and became the chief
adviser and prop of Placidia and her children.
His main rival was Boniface, Count of Africa,
at Carthage; and the accepted story is that by
a base double intrigue he drove him into revolt
and calling the Vandals from Spain into Italy;
that on discovering the fraud Boniface fought an
Italy first a slight battle and then a duel with Aëtius, was mortally wounded,
and in dying counseled his wife to marry no
one but his rival. It is very suspicious; but
any way the Vandals overran North Africa;
Boniface was killed; Aëtius in 432 had to flee
to the Huns, came back the next year with an
army of them, was reinstated, and for the next
17 years was the ruling spirit in the Western
Empire, battling in Gaul with Visigoths, Burg-
duans and Franks, upholding by combined
soldiership and policy the declining state,
with a vigor and genius which made him the one
great man of the Roman world in foreign eyes.
In 450 the great Hunnish invasion under Attila
(q.v.) came rolling down into Gaul with a
volume it seemed impossible to stay, and the
success of which might have blighted western
Europe as their kinsmen the Turks have
blighted the eastern portion. Aëtius by his
diplomatic skill and knowledge of how to play on
the barbarians induced Theodoric the Visigoth
to league with him, followed Attila, into the
Seine valley, and on 20 Sept. 451 checked his
progress in the mighty battle of Châlons (q.v.);
the empire's last victory, and one of the world's
turning-points. Attila's death not long after
broke the Huns. Aëtius continued to rule the
empire from it; but it was also Aëtius' death
sentence, and with his the empire's. Valen-
tinian III, Placidia's son, hated Aëtius' power
and had only submitted to it from fear of Attila;
and, feeling now secure, seized the occasion of a visit of Aëtius to Rome, to
arrange the marriage of his son with Valen-
tinian's daughter, and stabbed him with his own
hand. The sack of Rome by the Vandals shortly
followed; and 22 years after Aëtius' murder the
last of the succession of puppet emperors was
pulled down by the barbarian Odoacer.
AETIUS, a Roman theologian of the 4th
century surnamed "the Atheist": d. Constantin-
nople 367. He was founder of the Anomo-
Arian sect, named after him the Aetians,
who held that the Homouian doctrine of the be-
gotten is self-contradictory, since the
nature of God is eternal and unbegotten.
He was banished from Alexandria by Constanti-
nius in 356, but was called to Constantinople
by Julian in 361 and made a bishop.
AETIUS, a-ë-shi-üs, a Greek physician of
the 6th century: b. Amida, Mesopotamia. He
became court physician at Byzantium and was
author of a voluminous work on medicine in
16 books, based on Orbiasi, Galenos and
other sources. A complete Latin translation
by Cornarius was published (Basel 1538). Con-
sult Zernos, 'Aetai sermo sextdecimus et ulti-
mus' (1901).
ÆTNA. See ETNA.
ÆTOLIA, a-töl'ia, ancient Greece, a dis-
trict lying along the north shore of the Gulf
of Corinth and having Epirus and Thessaly
north. Acarnania west, separated by the Ache-
loius and Locris and Doris east, separated by
the Daphnis. The only other river of any size
was the Evenus. Between it and the Acheleous
lies a marshy but fertile plain separated by the
Aracyntus range on the north from a similar
plain, of which two large communicating lakes
—Trichonis (Apokuro) and Hyria (Zygos)—
take up a great part. The rest of the country
is crossed in all directions by rugged mountains,
covered with forests and intersected by ravines.
The plains produced plenty of corn and fine
pasture and the Ætolian horses were famous,
while the mountain slopes gave some wine and
oil; but for some reason the tribes never till late in Greek history entered into the fel-
lowship of Greek civilization and then but
imperfectly. They were wild, backward, an-
archic and untamable; a race of robbers and
pirates and the best recruiting-ground in Greece
for mercenary soldiers. In the Heroic age,
when most other Greeks were like them, and
Odyssseus' grandfather won distinction as an
accomplished kheph, they were conspicuous;
and Ætolia was the scene of the Calydonian
boar hunt. (See MELEAGER). When they reap-
ppear in Thucydides' pages on the Peloponnesian
war, they are a congeries of unfederated inde-
dependent tribes, living by plunder and the chase,
with few and poor towns—Thermopolis, Caly-
don and Pleuron, the chief—and taking to the
mountains when hard pressed. They had a
sort of union like the Iroquois League, for
common action against a common enemy, but
no corporate accountability and nobody to make
a treaty with. After Alaric's death Attila, the
ruler and Craterus invaded the country; and
this, with the great new wealth their general
trade of soldiering was bringing in and conse-
quently increase of civilized interests, forced
them to strengthen the bond into the Ætolian
League, first mentioned in 314 B.C., but of im-
mense weight in later times and chief rival to
the Achaian League and Macedonia. Unlike
the former, it was a league of tribes, not towns.
But like that, it was a democracy nominally,
every freeman over 30 having a vote if he could
come to the capital and cast it, but an aristoc-
cracy or timocracy in practice, only the wealthier
being able. There was a Great Council, or
Panetolicon, which met yearly at Thermopolis,
elected all magistrates afresh and enacted gen-
eral laws and voted on foreign policy; a smaller
body of Apocleae, who were in fact a cabinet,
who prepared all questions to put before the
Great Council and seemed to have been perma-
nent; a chief magistrate, the strategos (gen-
eral), who was not only military commander
but president of the assembly, put such ques-
tions as he chose (Speaker), was elected annu-
ally and was not allowed a vote on the question
of peace or war; a hippocrachor or cavalry com-
mander; and a chief secretary. After the expulsion of the Gauls from Greece in 279, in which the League did good service, it expanded enormously; not like the Achaean League because of the advantages of its membership, but from a sense of its new superiority — for it never lost its piratical character wholly to its latest day. It took in Locris, Phocis and Bceotia, Acarnania, southern Thessaly and Epirus, many cities in the Peloponnesus, Thrace and Asia Minor and the island of Cephalonia; it controlled the oracle at Delphi and the Amphictyonic Council. But its wanton invasion of Messenia (southwest Peloponnesus) in 220 brought the Achaean League and Macedonia both against it; Philip V invaded Eetolia in 218, sacked Thermon with its vast accumulated national treasures and burnt the sacred buildings; and the next year they made peace. In 211 they again provoked a war with Macedonia and again Thermon was captured, peace being made in 205. In 200 they joined Rome against Macedonia and helped to win the battle of Cynoscephale, which crushed Philip; but they were so disgusted with Flaminius' settlement of the country without giving them the advantages they expected, that in 192 they made the fatal error of allying themselves with Antiochus of Syria against the Romans. Antiochus was crushed in 189 and the independence of the League came to an end. In 167 the pro-Roman party murdered 550 of the patriot leaders and the League was dissolved and Eetolia made a Roman province.

AFANASIEV, Aleksander Nikolaeveich, Russian folklorist and antiquarian: b. Boguchar, government of Voronezh, 11 July 1826; d. 23 Sept. 1871. He received his education in the gymnasium of Voronezh and at the University of Moscow, where he studied law. At his graduation in 1848 he entered the civil service and took a position in the record-office of the ministry of foreign affairs (1849) and in 1856 became head of the department. He was dismissed in 1862 on the charges of being involved in political affairs. His writings touch upon almost all branches of traditional Russian folklore. His love for antiquities and mythology shows the indirect influence of Buslavev, who was becoming prominent during Afanasiev's student days. He was more directly influenced by Kavellin and Solovyev whose literary direction he reproduced in his historical treatises, 'State Organization under Peter I,' 'Concerning Patrimonial and Country Estates' (both published in the Archives of Hist. and Juridical Studies). While yet a student he contributed to Sooremen'nik (1849-52), Otechestvenniki Zapiski (1850-60) and several other publications. His most important articles of those days are 'Ancestor-House Demon' (publ. in the Arch. of Hist.-Judicial Studies conc. Russia, ed. by Kalachev, 'Sorcerer and Witch' (publ. in the Arch. of Hist.-Judicial Studies conc. Russia, ed. by Kalachev), and a separate edition, Moscow 1851); 'Zoomorphic Gods of the Slavs' (in Otechestvenniki Zapiski Nos. 1-3, 1852). From 1858-59 he edited the Bibliographicheski Zapiski. His most important works besides those mentioned are: 'True and False Journalism' (in Otechestvenniki Zapiski 1855; separate edition, Moscow 1859. It is a valuable monograph of century literature dealing with journalism for the period of 1769-74); 'Russian Popular Legends' (1860); 'Russian Folk-Tales' (1860), which is the first scientifically treated collection of Russian fairy tales. In 1866 appeared his 'Poetical Conception of Nature of the Slavs,' which is the first attempt at a scientific study of Slavonic mythology. This work shows the influence of Grimm, Kuhn, Schwarz and Max Muller. The general criticism of his work is lack of originality.

AFANASIEV, Aleksander Stepanovich (Afanasev-Chuzhinin), Russian novelist and ethnographer: b. Poltava, 1817; d. St. Petersburg, 6 Sept. 1875. Graduating from a gymnasium in 1836, he entered military service but left it with disappointment and the rank of lieutenant (1843). In 1847 he took a civil service position in the office of the governor of Voronezh. Two years later he gave it up and devoted himself entirely to literary work. His first poem 'The Ring' appeared in 1848 under the pseudonym 'Chuzhinin.' In 1856 the government sent him, together with a few other writers, to study the life of the people in Russian sea-coasts. He chose the region of the Dnieper and expounded the result of his studies in his work 'Journey in Southern Russia' (Saint Petersburg 1861) which is a good description of Ukrainian life. He wrote a great deal and contributed almost to all Russian periodicals. Not counting his poems, newspaper articles and correspondence, his productions amount to 60 works. He founded in 1864 the newspaper Saint Petersburgski Listok. In the seventies he edited Magazin inostromnoi literatury (Journal of Foreign Literature) and the paper Novosti (1875). He had also been editing minor periodicals for a period of a few months each. During the last years of his life he was inspector of the museum of Saint Petersburg. His most valuable contributions are his ethnographical works. Besides the work named above, he started a 'Dictionary of the Ukrainian Dialect.' He wrote several very successful Ukrainian poems ('Tell me the truth, my good Cossack'). His Russian poetry is much inferior. Of his historical works which describe military and provincial life. They are written in an interesting style and contain good character sketches of Russian officers. Some of his works besides those mentioned are: 'Recollections about T. G. Shevchenko' (Saint Petersburg 1861); 'Fanya' (ib., 1872); 'Petrograd Gamblers' (ib. 1872).

AFFECTION, in psychology, is a mental element co-ordinate with "sensation." See FEELING.

AFFIDAVIT, a statement reduced to writing, and sworn or affirmed to before some officer who has authority to administer an oath. An affidavit should refer to the cause in which it is made. The common-law rule is that it must contain the title of the cause. The place where the affidavit is taken must be stated, to show that it is taken within the officer's jurisdiction. The affiant must sign the affidavit at the end. It is necessary that the officer signing the jurat should append his official title. An affidavit should also describe the affiant sufficiently to show that he is entitled to offer it, for instance that he is a party, or agent or attorney of a party to the proceeding. This
matter must be stated, not by way of recital or as a mere description, but as an allegation in the affidavit.

Affidavit of Defense.—A statement made in proper form that the defendant has a good ground of defense to the plaintiff's action upon the affidavit.

Affidavit to Hold to Bail.—An affidavit which is required in many cases before a person can be arrested.

Affiliation, is a species of adoption which exists in some portions of France and in other European states. The person affiliated succeeds equally with other heirs to the property acquired by the deceased to whom he had been affiliated, but not to that which he inherited. See Adoption. As to orders of affiliation in bastardy proceedings, see Bastard.

Affine Transformation, a-fin', in geometry, a transformation by means of which every point in a plane receives a displaced position parallel to a given fixed straight line called the axis of affinity, and whose magnitude is proportional to the distance of the given point from that axis. The affine transformation is projective; that is, it transforms every straight line into a straight line.

Affinity. In law, the connection existing in consequence of marriage between each of the married persons and the kindred of the other. By the marriage one party thereto holds by affinity the same relation to the kindred of the other that the latter holds by consanguinity; and no rule is known to us under which the relation by affinity is lost on a dissolution of the marriage more than that by blood is lost by the death of those through whom it is derived.

Affinity is distinguished from consanguinity, which denotes relationship by blood. The degrees of affinity are computed in the same way as those of consanguinity.

In Chemistry.—The tendency manifested by certain substances to unite with one another so as to produce new combinations, chemically different from the primitive ones. The word was originally applied in this sense in the belief that some obscure and undiscovered "affinity" or relationship existed between the combining substances; but it now appears probable that the contrary is more nearly true, and that the tendency toward combination is strongest, generally speaking, between bodies that are quite dissimilar; though it is impossible to lay down any fixed rule of this simple kind. The modern theory of chemical affinity is too elaborate to be treated adequately under a single heading. See Chemical Affinity; Dissociation; Electrolysis; Equilibrium, Chemical; Molecular Theory; Solution.

Affirmation, the act of affirming, in the sense of solemnly declaring in a court of law that certain testimony about to be given is true, or that a certain statement made. First the Quakers and Moravians, who objected on conscientious grounds to take oaths, were allowed to make solemn affirmations instead; now everyone objecting to take an oath has the same privilege; but, as is just, false affirmations, no less than false oaths, are liable to the penalties of perjury.

Affare, Denis Auguste, a-far, dé-né a-go, French ecclesiastic: b. 27 Sept. 1793; d. 27 June 1848. From his prudent and temperate character he was made archbishop of Paris by Louis Philippe's government in 1840. Though not yielding blind submission to all its measures, he abstained from offensive opposition; and when a republic was proclaimed in 1848 he kept aloof from political strife, but displayed earnest zeal for the public welfare. During the June insurrection he climbed on a barricade in the Place de la Bastille, carrying a green bough in his hand as messenger of peace; but he had scarcely uttered a few words when the firing recommenced, and he fell mortally wounded, to die next day. He wrote several theological works and one on Egyptian hieroglyphics.

Afghanistan, a-fgan'-ist-an, Asia, lit. the country of the Afghans is the term which, in the present day, designates the regions governed by the Amir of Kabul. The name "Afghan" is supposed to signify "noisy or tumultuous." It is very ancient in its origin and has gradually been assumed by the subjects of the Amir. During the Afghan conquest of India they were known as Pathans and Kohillas, terms which are still used in India to denote people of Afghan origin.

Topography.—Afghanistan, as it now exists, embraces the country between the River Oxus and the Indus, and consists of ranges of snow-covered mountains, deep ravines and valleys. Many of the valleys are well watered and very fertile. The surface on the northeast is covered with the lofty ranges of the Hindu Kush which reach 20,000 feet above the level of the sea. The total length of this range of mountains is estimated at 365 miles. The dominions of the Amir as now defined by various boundary commissions lie on the northwest frontier of India, and are bounded on the north by Russian Turkistan, on the west by Persia, on the south by Baluchistan and on the east by Cashmere and British India. It has an area of about 250,000 square miles and a mixed population estimated at 6,000,000. The rivers are very numerous. Among them are the Oxus, or Amu-darya, which separates Afghanistan from Russian territory; the Murgab, which flows from the Afghan hills and flows through the city of Merv; the Helmund or Sistan River, which flows from the city of Kabul and enters the Indus at Attock; the Kuram and the Gomal rivers, which enter the Indus in British territory; the Lora which flows through the Gomal valley and is 200 miles in length. The only lake of importance is the Ab-i-Basha or Tien Shan plateau about 65 miles from Ghazni. It stands at a height of 7,000 feet. It is about 44 miles in circuit and very shallow.

Provinces and Cities.—Afghanistan is divided into five provinces—Kabul, Herat, Kandahar, with chief cities Ghazni, and Afghan-Turkistan and Badakhshan; and two territories—Kafiristan and Wakh. The province of Kabul is bounded on the northwest by Koh-i-Baba, on the north by the Hindu Kush, on the northeast by the Panjshir River and on the east by Jagdalik. It is mountainous, but it also has large sections of rich
AFGHANISTAN

arable land. A very large portion of the population live in tents during the summer months. Herat extends from near the sources of the Hari Rud River on the east to the Persian frontiers on the west. The country is mostly fertile, and it has been estimated that it is capable of supplying an army of 150,000 men. Kandahar is the most important province of the country. It extends over a wide area from Ghazni to the Persian frontier, and includes the region of Afriz. The Ain, which lies to the south of the Amir, Afghan-Turkistan was formerly the ancient province of Balkh but has now assumed its present condition through the treaty arrangements with Russia and Great Britain. The province of Badakhshan lies to the extreme east of the kingdom and is bounded on the north-east by the River Oxus and on the south by the Hindu Kush. It consists of lofty mountain ranges and deep rugged valleys in which there is but little agricultural development. In the winter the climate is severe and the mountain passes are blocked by snow. Wakhan consists of two valleys watered by the Panja River. It is too elevated and sterile for tillage. Its lowest hamlet is 8,000 feet above the level of the sea.

Lines of Communication.—From India to Afghanistan there are four well-known lines of communication. The first is from the railway terminus at Peshawar through the Khaybar Pass. The second from Thul through Bannu over the Siawar and Shutturgar leads passes to Kabul. The third through the Jail Shahr, Surwandi and Sargo passes to Ghazni. The fourth from the railway terminus at Quetta to Kandahar via the Bolan Pass.

There are four distinct lines by which Russia can move on to Herat: First from the Caspian by the Mashat route second from Chi-kishia by the Bendessan Pass and across the desert to Merve; third from Tashkend via Gherjuit; fourth by Balkh direct to Herat. The distance from Peshawar to Kabul is 191 miles in 20 stages varying from 8 to 22 miles. From Kandahar to Herat is 365 miles. From Herat to Balkh 370 miles. From Kabul to the Oxus by Balkh 424 miles.

Climate.—As might be expected in a country having the physical conditions of Afghanistan there is the greatest variety of climate. In some parts, especially north of Kabul, the winter is rigorous. In the city of Kabul the snow lies for two or three months and the people seldom leave their houses. At Jalabad the climate is similar to that of the plains of India and the heat is intense in summer. Throughout Kandahar the summer heat rises to a very high temperature, but at Herat, although much lower than Kandahar, the climate in summer is more temperate and in winter much milder. The mutiny and chaos of some localities is much praised by the people, although they have by no means that immunity from disease which the dry climate of the country and the fine physical condition of the people might lead us to suppose. Fevers are common, stone is frequent, and eye diseases prevail.

Natural Productions.—Afghanistan is supposed to be rich in minerals. Small quantities of gold have been taken from the streams flowing from the Hindu Kush. There were at one time famous silver mines in Badakhshan. The ruby mines which lie some feet above the Oxus River have a world-wide reputation, but the deposits have not been worked regularly. There are also coal fields. Coal has been found near Ghazni. Silicate of zinc comes from the Kaki country. Sulphur abounds in Herat on the confines of Seistan. Sal-ammoniac is found in Seistan. Gypsum exists in large quantities in Kandahar. Nitre abounds in almost every part of the Amur.

Vegetable Productions.—On the Alpine ranges of the country there is a magnificent growth of forest trees—cedars, pines, hazels and walnuts; and growing under the shade of these trees are rich varieties of honeysuckle, currant, gooseberry, hawthorn and rhododen-dron. The wild rose is found in all parts of the land and is an important export. Lemons and wild vines are in abundance. In cultivated districts the chief trees are mulberry, willow, poplar and ash. An important product is gum resin which grows abundantly in Kandahar and Herat. In the highlands of Kabul edible rhubarb is a local luxury. Walnuts grow wild and are exported with the pistachio nut to both India and Russia.

Agriculture.—In most parts of Afghanistan there are, as in India, two harvests. One of them is called the "Bhahra" or spring crop, which is sown at the end of autumn and reaped in summer. It consists of wheat, barley and a variety of lentils. The other harvest is called "Paizah," and is sown at the end of the spring and reaped in autumn. It consists of millet, maize, beets, turnips, etc. The staple food of the country is wheat, but rice is largely imported from Peshawar. The growth of melons, especially of the "sarda melon," is an important cultivation as they are exported to Peshawar. Sugarcane is grown in the plains, and cotton in the warmer sections of the country. Tobacco is very widely cultivated and exported to Russia and India. The fruit crops are abundant. Every kind of European fruit—pears, apples, peaches, oranges and grapes are produced in many varieties and of excellent quality. Mulberries are reduced to flour, and when prepared in cakes form the staple food of many districts. Grapes are cultivated to a very high degree. They are placed in boxes protected with cotton wool and exported in large quantities to India. The vineyards and peach gardens at Kandahar and Herat are very productive.

Industrial Products and Trade.—Silk is produced in Kabul, Kandahar and Herat, and although it is largely consumed in domestic manufactures the best qualities are exported to Bombay. Excellent carpets, soft, brilliant and durable in color, are made in Herat and are very often sold in America as "Persian carpets." They are woven by the Nomads of the desert, and by the girls and women while the men are tending their flocks on the hills. Of recent years the Amir has given great attention to the manufacture of all kinds of articles, and English artisans have been brought into the country for promoting various industries. The chief exports of the country are wool, horses, silk, fruit, madder and asafetida. Under the fostering care of the Amir the exports of Afghanistan are very rapidly on the increase.
Animals.—Bears, jackals, hogs, monkeys, leopards, wolves, hyenas, wild dogs and cats are among the wild animals of Afghanistan. The wild ass is found in the southwest part of the country. During the breeding season Afghanistan appears to be the retreat of a variety of birds. Camels are frequently employed, although they cannot travel in rainy weather or through snow. The two-humped Bactrian camel of historic lineage is still seen. Horses are a staple export to India, especially the “Yabo,” a stout heavy-shouldered pony about 14 hands high. The breed has been much improved as they are used for the cavalry of the Afghan army. The cows are the humped variety of the east and the dairy produce is an important feature in Afghan diet, especially the pressed and dried curd called “krut.” There are two varieties of Afghan sheep both having the fat tail. One bear a white fleece and the other a russet or black one. The export of wool is very largely cultivated. Goats are also valuable on account of their hair which is used in the manufacture of shawls. Dog breeding is cultivated by the Afghan nobles as they are used in the sports of the field, especially fox hunting and participation for the hawk, hawking being a popular sport among both the nobles of Persia and Afghanistan.

The People.—The origin of the Afghans is involved in obscurity and has given rise to various opinions. Some have supposed that they are descended from the soldiers of Alexander the Great whom he left in these countries. Others affirm that the Copts of Egypt or the Chaldeans and even the Armenians were their ancestors. The Afghans themselves maintain that they are of Jewish origin descended from an Afghan who was in lineal descent from Abraham and Hagar by their son Ishmael. Some Afghan authors affirm that Afghanistan was the grandson of King Saul. Some writers state that they are descended from Jewish prisoners sent into the mountain by Nebuchadnezzar. It is related that when Nadir Shah marching to India arrived at Peshawar, the chief of the Yusufzai tribe presented him with a Hebrew Bible. There is no trace of Israelitish origin in the Afghan language (see Language and Literature), but there is not a single Afghan, from the Amir on the throne to the tiller of the soil, who does not believe that he is one of the “Beni Israel.” Of the Afghans proper there are numerous clans, somewhat similar to the clans of the highlands of Scotland. Of these the most important are the Durrani, originally called Abdalis, who received the name from their famous clansman the poet king, Ahmad Shah. The Barakzais are a powerful tribe represented by the present reigning dynasty. The Gilzais were supreme in power at the beginning of the 18th century and are still a powerful clan, occupying the high plateau of Kandahar. The Yusufzais inhabit a district called Yusufzai in Pashawar valley. The Kizilbash are Persianized Afghans who came into the country in the time of Nadir Shah. The Hazaras live in a district that north, came from the east with the army of Ghujn Khan. They have Mongolian features, and speak a Persian-dialect. The Hinkis are people of Hindu descent. They are the merchants and bankers of the country and being idolaters they pay a poll tax, according to Muhammadan law, and are denied many privileges. In religion the Afghans are of the Sunni sect of Islam, and in jurisprudence their belief of the Hanafi school of interpretation. The Kizilbash are of the Shia sect of Moslems. The people of Kafiristan are idolaters who are being rapidly converted to Islam.

As a race the Afghans are exceedingly attractive to the western traveler. They are handsome and athletic. They have fair complexions with aquiline features and long flowing beards. The women are exceedingly fair and handsome, and more intellectual than the average woman of the East. In cities they are rigidly secluded, but in outlying districts they are free to roam and are often employed in the field.

The Afghan, familiar with bloodshed from his boyhood, makes a valiant soldier, and there are many Afghans who have attained to high positions in the Anglo-Indian army. “The avenger of blood” is an institution among the Afghans and it is a point of honor for the next of kin to avenge a murder. With the Afghans honor is all-powerful and the ordinary salutations of the people bear this character. When passing along a road the mounted chieftain salutes the weary traveler with “may you never be tired,” to which the man on foot responds “may you ever be prosperous.” On approaching the village “Hugai” or guest house, the traveler is received by the host with the welcome of “may you ever come,” to which the guest replies “may you ever remain master of this house.” When the guest departs he is escorted to the village boundary and is sent on his way with the salutation “may God protect you.”

The Afghans of to-day believe that their nation has a great future in harmony with the noble traditions of the past and they believe that they will again become a great and powerful nation. They are shut in by Russia on the one side and by Great Britain on the other, and in consequence of the British conquest of Baluchistan and Sind they have been deprived of a seaport. But they hope against hope and consequently avoid committing themselves to either Russia or Great Britain, and pose as the enemies of Persia.

Language and Literature.—The national language of the Afghans is Pashto, or Pakhto, Pusho, or Pukhto, Pushtu, or Pukhto, the pronunciation varying in different tribes. It is an Aryan or Hindo-Persian language, written in the Arabic character, with three letters peculiar to Pushto. It is only of late years that the language has been expressed in writing with a system of phonetic spelling. Specimens of Afghan grammar are found in the “Kalid-i-Afghani,” a work compiled for the use of students in 1872. As the Afghans claim an Israelitish origin Oriental scholars have thought that there were traces of Hebrew in certain Afghan words, but these words, without exception, have been borrowed through the religious terminology of Islam. Pushto is the spoken language of the people in the Trans-Indus territories of British India, including Peshawar, also in the province of Kandahar, and among the hills between the
The earliest English grammar of Pushto was compiled by Prof. Bernard Dorn of the Imperial Russian University of Kharhov in 1829. There are Pushto grammars by Captain Vaughan, Maj. H. G. Raverty, Dr. Henry Walter Bellew and Dr. Trumpp; Pushto dictionaries by Dorn, Raverty and Bellew.

There must be a very large number of Pushto manuscripts in existence stored away in the mosques of the country, where native calligraphists employ their time in copying them. Peshawar has been the literary centre of the Afghan language. The earliest work discovered in Pushto is a history of the conquest of Swat by Shailk Mal Yusuufzai, A.D. 1413. There is also a history of Bunair by Khwajah Khan. In the reign of Akbar, 1600, Bayazid Ansari, known as Pir Roshan, the “enlightened saint,” wrote several works in Pushto. There are also several books, chiefly religious, by his contemporary Akhund Darweza. In Hughes’ textbook there is a selection from the Tarikh-i-Murassah, the “gem-studded history” by Afzal Khan Khattak, who was a voluminous writer. His grandfather, Khushhal Khan, chief of the Khattaks, translated about a hundred works from Persian into Pushto, and he is also the author of a “Diwan,” a poet of very high merit. He died in 1697 and is buried at Isur, near Attok. Ahmad Shah, the founder of the present Afghan monarchy, was a poet of some reputation. The popular poet of the Afghans, whose “Diwan” is read wherever the Afghan language is spoken, is Abdur Rahman, who resided near Peshawar at the beginning of the 18th century and whose grave is to be seen at Hazarkanha, two miles from Peshawar.

A STANZA FROM DIWAN-I-ABDUR RAHMAN.

The Christian scriptures have been translated into Pushto by William Carey, the Baptist missionary, 1823, Isidur Lowenthal, an American Presbyterian missionary 1862, and in 1886 by a committee of missionaries working under the supervision of the late Thomas Valpy, French bishop of Lahore 1886.

Government and Administration.—When Amir Abdur Rahman ascended the throne in 1878, the greatest confusion prevailed in every department of political, civil and military administration, while the supremacy of the Amir at Kabul was scarcely recognized by the chief-tains of the various tribes. But with statesmanlike ability, supported as he was by the British government, he succeeded in establishing a permanent government. It consists of a board of treasury, a board of trade, a bureau of justice, a department of police, a public works department, a postal system and a department of education. The government is conducted by a supreme council known as the “durbar.” This council has three sections. First the “Durbar-i-Shai,” or such members of the reigning family as are invited by the Amir. Second, the “Khawanin,” or assembly of Maliks and chief-tains. Third, the “Ulama” or representatives of the Mullahs or Moslem priesthood. The Amir is seldom absent from the council, and its assembling depends entirely on his pleasure. The Amir's cabinet consists of the lord of the seal, the commander-in-chief, the lord treasurer, the postmaster-general and the chief secretaries of departments. The laws are either established by the Moslem religion, the “Pukhtunsawali,” or peculiar customs of the Afghan people, and the supreme will of the Amir. Amir Abdur Rahman gave his closest attention to revenue and in order to establish the currency of the country he opened a mint in Kabul. The annual revenue is unknown but it probably amounts to a sum equal to $5,000,000 which includes the subsidy received from the government of India. According to the old system the Afghan army was composed entirely of tribesmen collected by their Maliks who were supposed to hold their land on condition of military service. At the present time the regular army is estimated at 150,000 men, consisting of a royal bodyguard of four regiments of infantry and three regiments of cavalry, a regular army of 80 regiments of infantry, 40 regiments of cavalry and 100 batteries of artillery. The police force consists of 30,000 men, and the tribal auxiliaries are about 50,000. When placed on a war footing it is thought that the Amir could put in the field at least a half million men, because every Afghan is by birth and education a soldier, a man of war from his youth.

History.—For many centuries this country was the centre of history. First, as the seat of powerful Buddhist kingdoms, and then as the highway of Moslem conquest. In the time of Darius Hystaspes, B.C. 515, these regions embraced the Achemenian Satrapies, and among them a district known as Paktyes, which must have been on the right bank of the River Indus now known as the district of Yusufzai, and the Peshawar valley. This is undoubtedly the origin of Pukhtun which is the oldest name of the country of the Afghans, and is still retained in the designation of their language.

Alexander the Great marched to Herat, the ancient Artacoana, the capital of Aria, and proceeded to Zarangae on the banks of the Helmand. He then advanced to "a country among the snows in a barren land," which seems to have been the mountain regions of Kabul and Ghazni. After retiring to the foot of the Caucasus for the winter he advanced to Bactria, the modern Balkh, and proceeded to Kabul, from whence he marched down the left bank of the Kabul River and crossed the Indus probably at Hund near Attok.

The Ariana mentioned by Strabo, about the beginning of the Christian era, must have occupied the limits of the present Afghanistan. In 250 B.C. an Indian king named Yandrob ruled the province of Kabul. In 250 B.C. there was an independent Greek dynasty in Bactria (Balkh). The ancient coins, and the old Buddhist ruins show evidences of this, and when the old ruins at Balkh have been excavated very interesting historical facts will be made known
regarding this Greek kingdom in Central Asia. At present we know but little regarding it.

Demetrius, B.C. 190, reigned in Arachosia after Alexander's death. Eucratides, B.C. 181, reigned in the mountain region. Under Heliocles, B.C. 147, the Parthians extended their conquests through the country into India. In B.C. 126 Meander invaded India. The Chinese accounts of the time when Bactria was overrun by Scythian invader are supposed to be very extensive although they have not yet been translated into western languages. Chinese historians say there was a nation called Yuchi settled in the Oxus valley in B.C. 126. In the tenth century the Chinese pilgrim Huen Tsang in the 7th century we have accounts of the country now known as Afghanistan. In 630 A.D. he says there were both Indian and Turk rulers in the Kabul valley.

The first attempts of the Moslem conqueror to bring these regions to the faith of the Prophet of Arabia were unsuccessful. It was not until 977 A.D. that Subuktigin the Turk conquered the country and established his capital at Ghazni and founded what is known as the Ghaznevi dynasty. His son was the famous Maimun who captured Delhi in 1001 invaded India, and in course of time established Afghan rule both at Lahore and Delhi. He is credited with having made 12 expeditions to India. His tomb is still to be seen at Ghazni. The Ghaznevi dynasty was succeeded by that of Ghor or Ghur which transferred the capital of the empire to Herat. Muhammad Ghori ruled Afghanistan in the 13th century and made Delhi the capital of his kingdom. About 1220 Genghiz Khan, the great Mogul ruler of the Tartars, marched through Afghanistan and displaced the Ghor dynasty. In 1398 Timur made himself master of Central Asia, and crossing the Indus plundered the Panjash as far as Delhi.

Baber, who was sixth in descent of Timur, captured the city of Kabul in 1504, and made it the capital of his empire. He was eventually killed and his body was carried from Agra and interred in Kabul where his tomb is still to be seen. His son Humayun was defeated and driven out of India in 1540, but in 1555 he again made the throne at Delhi, and at his death in 1556 was succeeded by Akbar, the greatest of the Mogul emperors of India. The Afghans gave Akbar much trouble. When the power of the court of Delhi was weakened, Kandahar with a large part of Afghanistan fell under the power of the Shah of Persia. Nadir Shah was proclaimed King of Persia in 1736. He seized the city of Kabul as one of the main gates of India, and then leading his army through the Khybar Pass entered the Peshawar valley and there defeated the imperial forces. Ahmad Khan, generally known as the Durrani, was confirmed by the treasury at Kandahar, and was crowned King of the Durans about 1747. With Ahmad Shah commences the history of Afghanistan as an independent nation. He reigned 26 years and was succeeded by his son Timur, who in 1773 removed the seat of government from Kandahar to Kabul. He reigned 20 years, and died in 1793 leaving three sons. The youngest son, Shah Shujah, eventually ascended the throne and made Peshawar his capital. In 1800 the Tsar of Russia and Napoleon Bonaparte concocted a scheme for the invasion of India, and consequently the British government sent Mr. Monstuart Elphinstone as ambassador to Shah Shujah at Peshawar and concluded a treaty in 1803.

The Barakzai tribe, under the leadership of Fateh Khan, deposed Shah Shujah, who fled from Peshawar to seek protection at Lahore, where the Sikh ruler Runjit Singh extracted from him the famous koh-i-nur diamond, which eventually became the property of the English sovereign. In 1826 Dost Muhammad became Amir of Afghanistan, founding the present dynasty of Afghan rulers. Dost Muhammad obtained supreme power, and establishing himself as Amir, entered into negotiations with Russia. This led to the invasion of Afghanistan by a large British force in 1838 and the establishment of Shah Shujah as king. Dost Muhammad was sent to India a prisoner of the British government. In November 1841 Sir Alexander Burnes and his suite were assassinated and a few days later Sir William MacNaughten shared the same fate. In January 1842 the British army retreated to India and was completely annihilated, with the exception of Dr. Bryden, who was brought in half dead to Jalalabad on 13 Jan. 1842, the number of British casualties was 5,000 men and 12,000 camp followers. In April two British forces were sent to avenge the massacre, a column under General Pollock by way of the Khyber Pass and another column under General Nott by way of the Bolan Pass. The British evacuated Afghanistan in October 1842 leaving Shah Shujah ruler of the country. Shah Shujah was assassinated, and the British having released Dost Muhammad from prison, he was restored to the throne. During the mutiny of the native army in India in 1857 Amir Dost Muhammad proved a valuable ally to the British. The British government engaged in war with Persia in behalf of the ruler of Afghanistan and eventually restored the province of Herat to Afghan rule.

Dost Muhammad died June 1863 and was succeeded by his son Shir Ali. Consequent on the nomination of Shir Ali, who was not the eldest son of the deceased Amir, a rebellion broke out and for a time Afzal Khan and Azim Khan, the elder sons, were jointly as Amirs. Eventually Shir Ali became firmly established on the Afghan throne and in March 1869 visited Lord Mayo, viceroy of India, at Umballa.

Amir Shir Ali Khan being suspected of intrigues with Russia a British force commanded by Gen. Donald Stewart invaded Afghanistan in 1878. On the death of Shir Ali February 1879 he was succeeded by his eldest son, Yakub Khan. A treaty with Amir Yakub Khan and the British government was signed at Gandamak by Colonel Cavagnari representing the English government and the Amir in May 1879. By this treaty an extension of the British frontier was secured and the residence of a British envoy in the city of Kabul was sanctioned. In accordance with this treaty Sir Louis Cavagnari proceeded to Kabul accompanied by his secretary, Mr. Jenkins, Dr. Ambrose Kelly and Lieutenant Hamilton. On 4 September the troops of the Amir demanded payment and attacked the British embassy, killing Cavagnari and his three companions.

As a result of this outrage a third Afghan
war began on 6 Sept. 1879 and an expedition under the command of General Roberts marched to Kabul arriving 28 September. The British embassy was executed and Amir Yakeb Khan was deposed and sent to India. Afghanistan for a few months was under British military rule, but in July 1880 Abdur Rahman Khan, the eldest son of Afaq Khan, who was the eldest son of Amir Dost Mohammad Khan, was recognized as Amir at a durbar in which the British government was represented by Sir Lepel Griffin. On 27 July 1880 occurred the "disaster" of Maiwand when the British force under the command of General Burrows was totally defeated by Sadar Ayub Khan, a brother of the late Amir Shir Ali. General Roberts made his celebrated march for the relief of Kandahar, leaving Kabul 8 Aug. 1880 and arriving at Kandahar 31 August, he totally defeated Ayub Khan on 1 September. On 30 Sept. 1881 the British evacuated Kandahar and Amir Abdur Rahman took possession of the province. In 1883 the Amir was granted a sum of 12,100,000 rupees. In 1885 Amir Abdur Rahman attended a conference with Lord Dufferin, viceroy of India, at Rawalpindi, and received the British decoration of G. C. M. G. Numerous boundary commissions were held during the years 1888-93 when the frontiers of Afghanistan were defined. A final agreement was reached by negotiations carried on by Sir Mortimer Durand in Kabul 1893 and the subsidy granted to the Amir was increased by six lakhs of rupees. In 1894 the Amir was invited to England by Queen Victoria, but being unable to leave his country, he sent his second son, Sadar Nasr Ullah Khan. On 1 Oct. 1901 the Amir died and was succeeded by his eldest son, Habib Ullah Khan, who, in a treaty with the British, assumed the position of the independent sovereign of Afghanistan and is now honored with the title of "His Majesty" in all treaty documents. In January 1907 Amir Habib Ullah visited Calcutta to meet Lord Minto, the viceroy of India. The Amir fled his country at the instigation of Sardar Inayat Ullah Khan, who was born 1888.

HENRI F. KLEIN.

AFIUM-KARA-HISSAR, "a'fī-ooccup'kā-rā'his-sār, Turkey in Asia, city of Anatolia, 180 miles northeast of Smyrna by rail; also connects with Konieh, Angora and Constantinople. At the junction of several caravan routes it lies on an extensive Oriental and European trade in general merchandise. It manufactures of saddlery, carpets, felts and arms, and opium is largely produced in the neighborhood. Pop. 20,000.

AFRICA, second in size of the six continents, with a continental area of 11,262,000 square miles and islands of 239,000 more, has the Mediterranean north, the Atlantic west, the Red Sea and Indian Ocean east, the Antarctic Ocean south; and lies nearly due south of Europe and southwest of Asia. It extends from lat. 37° 20' N. to 34° 51' S., and long. 17° 32' W. to 51° 28' E., being nearly equal in length and breadth from its extreme points; from Cape Blanco in Tunis to Cape Agulhas in Cape Colony is nearly 5,000 miles; from Cape Verde in Senegal to Cape Guardafui in Somalia about 4,600. The northern section, however, has an average breadth nearly double that of the southern, owing to the great northern projection of the upper part, the western coast taking a sudden inward turn and facing south for nearly 20 degrees of longitude, forming the Gulf of Guinea.

General Topography.—From its junction with Asia at the Isthmus of Suez, the north coast runs west by a little north to the Strait of Gibraltar, its nearest approach to Europe, whose Mediterranean shore it faces, and whence for many centuries it derived its principal civil and narrow expance of the Red Sea; further south the Gulfs of Cabes and Sidra. From the Isthmus south the coast runs somewhat southeast, parallel to Arabia, separated by the long narrow expance of the Red Sea; further south it projects well to the east, overlapping the south coast of Arabia and again running nearly parallel to it, the two forming the Strait of Bab el-Mandeb and the Gulf of Aden. From the terminus of this projection at Cape Guardafui, the coast trends southwest with slight undulations to the southern extremity of the continent. About midway, separated from the mainland by the Mozambique Channel, 250 miles wide, lies the great island of Madagascar. Save those named, Africa has no great indentations, and the coast line is very small relatively to its size; about 16,000 miles, a fifth less than that of Europe absolutely, and between one-fourth and one-fifth as great relatively. The southern extremity presents to the Southern Ocean a coast line of nearly 400 miles excluding indentations, comprehensively known as the Cape, first doubled by Bartholomew Diaz and Vasco da Gama. Its principal indentations are Algoa Bay and False Bay. The islands belonging to Africa are not numerous, and except Madagascar none of them large. In the Atlantic Ocean there are Madiera, the Canaries, the Cape Verde Islands, the Bissagos, the islands off the coast of Guinea, Fernando Po, St. Thomas, Annobon, etc., Ascension Island, St. Helena and Tristan d'Acunha; in the Indian Ocean, Soelotra, Zanzibar, Amirante, Comoro Isles, Madagascar, Mauritius, Reunion, with their dependencies; and some small islands in the Southern Ocean.
Northern Africa.—The interior of Africa forms two great divisions nearly corresponding with the external diversity of form already indicated. The northern section has its greatest extension from east to west, the southern from north to south. The northern division lies for the most part above the 6th degree of north latitude, extending from the Atlantic on the west to the Somali coast and the Red Sea on the east. Its principal feature is the Sahara and Great desert, which is inclosed on the north by the elevated plateau of Barbary and that of Barca, on the east by the Nile valley, on the west by the Atlantic Ocean and on the south by the Niger and the countries of the Sudan. The north coast region (plateau of Barbary) is traversed by the Atlas system and its continuations, rising to the height of 13,000 feet or even more. Exclusive of the mountains it has an elevation of from 1,500 to 3,000 feet. From Barca, where the former level prevails, it descends gradually toward Egypt. The character of the desert, though sufficiently inhospitable, is much less uniformly monotonous than till recent researches it was commonly reputed to be. Sandy plains, irregularly interspersed with spec-like oases it contains elevated plateaux and even mountains with more or less permanent streams, and habitable valleys which lose themselves in the vast low-lying tracts of sand, with which the more elevated regions alternate. The desert itself is furrowed with wadis (dry river-beds) radiating in all directions; while under the sand collections of water have been found, which by means of artificial wells have been turned to account by the French in their dependency, Algeria. A considerable nomadic population is thinly scattered over the habitable parts of the desert, and in the more favored regions there are settled communities. (See Sahara). To the south of the Sahara, and separating it from the plateau of southern Africa, a belt of pastoral or steppe country extends across Africa. This region has received the general name of the Sudan and includes the countries on the Niger, around Lake Tchad, and east to the eastern parts of Tanzania.

Southern Africa.—From Lake Tchad the country begins to rise till below the 10th degree of north latitude, where the edge of the elevated plateau of high or southern Africa begins. This division of the continent is, as far as known, completely surrounded, at a distance of 50 to 300 miles from the coast (which is usually low but rising inland), by what look like ranges of mountains varying in breadth and height; but which are really the escarpment of a tableland, or series of tablelands, of considerable elevation and great diversity of surface and direction, having hollows filled with great lakes rivaling those of America in extent, and terraces over which the rivers break themselves in falls and rapids. The southern division, on the west, and the eastern edge of the Kalahari desert—but it is of small extent compared to the Sahara. In some respects it resembles the Sahara, but possesses more vegetation. The mountains which inclose the south tableland are mostly much higher on the east than on the west, and the edge of the land and the flow of the principal rivers, with the exception of the Zambesi, is from east to west. The east edge of the plateau reaches its highest elevation and greatest extent in the mountainous country of Abyssinia, with heights of 10,000 to 14,000 or 16,000 feet. From this the system extends northwards and southwards, and the escarpment of the elevations between the valley of the Nile and the Red Sea, with gradually diminishing height to the very delta of the Nile. The east edge of the Abyssinian plateau presents a steep unbroken line of 7,000 feet in height for several hundred miles, and it extends southward toward Lakes Rudolf and Stefanie and thence in a narrow belt and at a lower average level to the northeast of the Victoria Nyanza; it then proceeds in a south direction to Kilima-Njaro, beyond which the plateau merges into the Paré Mountains in the neighborhood of the Pungani River. Immediately to the south of Lake Rudolf, Mount Nyrio rises to a height of 10,000 feet; Mount Elgon, to the northeast of Victoria Nyanza, 14,100 feet; Mount Kenia, 18,370 feet; Kilima-Njaro, 19,200 feet; Mount Meru, to the west of Kilima-Njaro, 14,000 feet. The general level of the plateau between Mount Kenia and the lake is from 5,000 to 7,000 feet. To the west of Victoria Nyanza, between Lakes Albert and Edward, the country rises to a height of 16,600 feet, and the active volcanic Kirungu Mountains, south of Lake Albert Edward, to 13,000 feet. All these mountains are volcanic in origin, and between Kilima-Njaro, and the lake signs of volcanic activity are still visible. The central plateau reaches its greatest average height, over 4,000 feet, in the region embracing the Lakes Victoria, Tanganyika and Nyassa; it forms a broad belt reaching close to the east coast and in an equally broad belt extends from Lake Nyassa to the west coast. Above this are numerous detached heights, like the Rubeho Mountains, west of Zanzibar, the Livingstone Mountains around the north of Lake Nyassa, and the Manjane heights south of that lake, Mount Manjane being 9,680 feet. South of the Zambezi occur the Mashona and Matoppo highlands, rising in places to from 5,000 to 7,000 feet. Immediately to the south of the Middle Limpopo a series of mountains begins which, under various names—Zoutpansberg, Zombi, Drakensberg, Comberg, Compassberg, Schneeberg, etc.—extends along the east and south coast and north to some distance beyond Cape Town. In Natal these rise to 10,000 and 12,000 feet, and in Cape Colony to 7,000 and 8,000 feet; the interior plateau averaging about 4,000 feet, but falling to a lower level in the Kalahari desert. Between the Orange River and the Kunene, and the latter river and the Kongo, the escarpment continues, rising in places to 6,000 and 8,000 feet. The general level lowers considerably as the Congo is reached. The low coast region extends some distance into the interior along this part of the west coast, the descent from the interior plateau giving rise to the cataracts which so seriously interrupt navigation on the lower Congo. On the south coast, the Congo extends a considerable area which sinks from the generally high level of the interior to an average of only about 1,000 feet. From the Kongo and Kameruns the general level of the coast plateau is broken by the Crystal and other mountains rising 3,000 to 6,000 feet, culminating in the Kameruns Peak, a volcanic mountain rising to 13,000 feet. On the south of the Bencu, in the Atlantica group, and be—
between the Benue and the Niger, we find a broken mountain group with heights of from 6,000 to 10,000 feet; while in the interior north of the Gulf of Guinea there is a broad plateau, beginning at various distances from the coast, extending across the upper Niger, and rising to 2,000 and 3,000 feet with irregular ranges rising to 5,000 feet. The Kong Mountains, in the region where the Niger has its sources, as a range do not exist. As the middle Niger is approached the general level lowers to that of the Sahara, while north the low coast region extends far into the interior till the Atlantic is reached.

**Rivers.**—The Nile is the only great river of Africa which flows to the Mediterranean. It is now known to receive its waters primarily from the country drained by the great lakes, the Victoria Nyanza, the Albert Nyanza and the Albert Edward Nyanza and especially from the Victoria Nyanza, which itself receives numerous streams. The Victoria Nile connects the Victoria and the Albert Nyanza; and on leaving the latter the river flows in a winding course, often on a meander. Without further lake expansion, to the Mediterranean. In descending from the lake elevations (of the Victoria 3,900, of the Albert 3,200 feet, the latter connected by the Semliki River with the Albert 2,300 feet) it makes, both between the lakes and in its subsequent course, numerous falls. Those in upper Egypt are known as the Cataracts. Between lat. 5° and 10° north, under the name of Bahr-el-Jebel, it receives numerous tributaries, mostly from the country to the south and west; the principal on the left bank being the Bahr-el-Ghazal, on the right the Sobat. After this it takes the name of the White Nile, and receives through the Bahr-el-Azrek and Atbara, or Blue Nile and Black River, the drainage of Abyssinia. The Atbara brings the mud which forms, so precious a deposit in Egypt. After this the Nile flows for 1,200 miles to the sea without receiving a tributary. Altogether it drains an area of more than 1,600,000 square miles. The Indian Ocean receives numerous African rivers, many of which are shoals, the drainage merely of the external slopes of the escarpment of the interior plateau. Among the most considerable rivers on this coast are the Juba, which is formed by several streams rising in the border slopes near Abyssinia, is navigable with difficulty to Bardera, and enters the ocean at the equator; the Webi Shebeli, formed by streams rising on the southeast slopes of Abyssinia, and losing itself in the sands on the coast near the mouth of the Juba; the Tana from Mount Kenia discharging at Witu; the Sabaki south of the Tana; the Roxuma, which flows from the mountains east of Lake Nyassa; the Beira; and the Limpopo or Crocodile, which enters the ocean north of Delagoa Bay. The only great river flowing from a distant point of the interior which breaks the mountain barrier of the east is the Zambezi, which has its embouchure between the Beira and Roxuma. It is the fourth in size of the continent. It drains a large part of the great tract of pastoral country south of the well-country, and discharging from the swampy plateau on the borders of Lunda and the Garenzane country unite to form the Zambezi, the principal being the Liva from the southwest edge of the Garenzane country. In its middle course it is joined by the Kafue and Loangwe from the north and the Shiré from Lake Nyassa, and by the Chobe and some smaller streams from the south. Below the Chobe are the Victoria Falls, one of the greatest cataracts in the world; from which the river flows in a semi-circular course to the ocean, breaking through the Lupata Mountains, and discharging by several mouths, the most navigable of which is the Chinde. The river is navigable by vessels of some size to the Lavora-Basa Rapids beyond the Shiré, but above that only by boats and canoes. The drainage area of the Zambezi is 350,000 square miles.

Of the Atlantic rivers, the Senegal, Gambia and Niger have their origin in the mountains near the coast of Senegambia. The Senegal flows in a northerly and westerly direction, its volume varying much according to the season. In the rainy season it swells to 700 miles, in the dry season for about a fourth of that distance. The Gambia takes a winding course to the west, and is navigable for about 400 miles, nearly its whole extent. The greatest of these rivers, the Niger, rising due north without further lake expansion, to the Mediterranean, descends from the mountains south of Lake Chad. The upper part of the Niger is called the Jofa, and is flanked by several great swampy lakes; it after- wards takes the name of Quorra or Kawarra. In the northern part of its course it touches on the great desert. It is navigable for light vessels above Timbuctu. Between the Sokoto and the Benue it is interrupted by shoals and rocks to below Bossou. From the junction it flows due south to the ocean, where it forms a wide alluvial delta and enters by a number of mouths, the most distant of which are 200 miles apart. The main channel is called the Nun. The drainage area of the Niger is 810,000 square miles. The Kongo, the second in extent of basin and the greatest in volume of the African rivers, flows from different slopes of the same watershed as the Zambezi. Its identification with the Luilaba, the great stream, by Livingstone in the centre of the continent, was established by Stanley in 1876–77, this enterprising traveler having descended the river to the Atlantic from a point in the interior west of Tanganyika. The Lukuga, the outlet of Lake Tanganyika, discovered by Cameron, is a tributary of the Luilaba. The Chambeze, which rises in the mountains between Lakes Nyassa and Tanganyika, is the remotest source of the Kongo system. It falls into Lake Tanganyika, from which it issues under the name Luapula and flows north to Lake Mweru; from the north side of this lake issues the Luilaba, which passes through a magnificent series of lake-like expansions and receives numerous tributaries. Below Stanley Falls it receives the Lomami, and above Stanley Pool the Kwa, which is formed by the junction of the Kasai-Sankanuru system with the Lukuallu or Kwango. Other tributaries come from the south and in the north it is fed by the Ubangi, which, under the name of the Wella-Fang, comes from the water-parting between the Nile and Kongo systems. The total length of the Kongo is about 3,000 miles, and its drainage area 1,450,000 square miles. Unlike most of the African
rivers, the mouth of the Kongo forms an estuary. It is estimated to pour into the ocean a body of water greater than the Mississippi. The Kwanza rises in the Mossamba Mountains and curves northwest to the ocean. Like most African rivers, its upper course is interrupted by cataracts, and its mouth closed by a bar. The Kuni flows north on the opposite side of the same watershed and flows southwest to the Atlantic. From it south to the Orange River follows a dry belt, through which no considerable river flows to the sea. The Orange, though it rises near the east coast, and flows nearly across the south part of the continent, passes for the greater part of its course through a desert region, receiving no tributaries, and is a shallow stream. Its headwaters, the Vaal and the Nu Gariep, rise on opposite slopes of the Drakensberg Mountains and flow to their junction route both sides of the Orange River Colony. The Great Fish River, which drains Great Namaqualand, enters the Orange River near the termination of its course.

The rivers which reach the ocean do not accordingly the whole drainage of Africa. There are two great and numerous smaller tracts from which no large river reaches the sea. The two great areas of internal drainage correspond with the two great deserts. That of the north desert is estimated at 4,000,000 square miles. As already indicated, it is furnished with water courses in every direction, which lose themselves in the sand. The Bahr-el-Ghazal, which is usually dry, but intermittently flows out of Lake Tchad, terminates in a salt lagoon on the border of the desert to the north of the lake. In the south the Zega or Botlele, which forms the outlet of Lake Ngami, in the Kalahari desert, loses itself in salt lagoons at greater or less distance, according to the supply of water. A region of inland drainage, with salt lagoons also exists between the Victoria Nyanza and the coast range of mountains. In the low coast land east of Abyssinia the Hawash River loses itself in the sands before reaching the sea; and the Webi, as already stated, which flows south from the Somali Peninsula to near the equator, likewise terminates in a salt lagoon on the border of the ocean. The Omo flows into the north end of Lake Rudolf.

Lakes.—The only lake of considerable extent north of lat. 5° N. is Lake Tchad, an enormous flooded swamp subject to great variations of level and area (10,000-20,000 square miles), which until 1911-12 seemed to be drying up but since then has slowly increased in size. Lake Tsana in Central Abyssinia, the salt Lake Assal in the east and Lakes Dembel and Abayo in Gallaland, are comparatively small. Between 5° N. and 15° S. is a series of lakes forming one of the most striking features of the continent. Almost in a line, beginning in the south, are Lakes Nyassa, Tanganyika, Lifu, Albert Edward, Albert, all lying in more or less elongated rifts or gorges. The series is continued by Lakes Rudolf (salt) and Stefanie in the northeast, and, according to some authorities, by the ancient lake now the Red Sea and by the Dead Sea in Palestine. The great Victoria Nyanza (32,000 square miles), the largest fresh water lake in the world after Lake Superior, which touches the equator on the north, is of a different type, as are Lake Bangweolo (another flooded swamp) on the south of Tanganyika and Lake Mweru in the north of Bangweolo. Lake Rikwa or Leopold, between Nyassa and Tanganyika, is partly of the rift type, while Lake Ngami in the Kalahari region is a swamp which sometimes dries up. Lake Leopold II and Lake Malumba are attached to the lower Kongo. Lake Dilolo is in the swamps region forming part of the water shed between the Kongo and the Zambezi. There are numerous salt lagoons in the northern portion of the Sahara.

Climate.—The climate of Africa is mainly influenced by the fact that, except the countries on the north and south coasts, it lies almost entirely within the tropics. The equator, as already observed, cuts it nearly through the middle, so that it belongs in latitudinal, though unequally in longitudinal extension, to the north and south tropics. It is therefore conditioned by circumstances which extend unbroken from the north to the south tropics and is consequently the hottest of all. The two sections north and south of the equator have, as has already been observed, in some respects a very considerable resemblance to each other, the main distinguishing circumstances being the greater elevation and the smaller longitudinal extension of the southern division, which, by bringing it more within the influences of the ocean, tends to modify its climate. In the belt immediately under the equator, both north and south, vegetation is intense and rain abundant. For about 10 degrees north and south we find true tropical forests, mainly to the west of the great lakes, on the middle and upper course of the Kongo and its affluents and along a belt of the west coast in the Niger region. To the east of the great lakes, where the rainfall is not so abundant, are considerable areas of poor steppe and scrub country, and generally over the tropical region the trees are scattered and the country more park-like than forestal. Animal life, from herds of elephants to innumerable swarms of insects, abounds in these luxuriant regions. To the north and south of the equatorial belt, as the rainfall diminishes, the forest region is succeeded by open pastoral and agricultural country. This pastoral belt extends, in the north, across the Sudan, from Senegambia to Abyssinia; on the south from Angola and Benguela to the Zambezi. This is followed by the rainless regions of the Sahara on the north and the Kalahari on the south, extending beyond the tropics and bordering on the agricultural and pastoral countries of the north and south coasts, which lie entirely in the temperate zone.

The winds and rainfall in Africa, which are chiefly produced by the successive exposure of the various intertropical belts to the vertical rays of the sun. The south winds on the west coast and the monsoons of the Indian Ocean exercise the principal modifying influence. From March to September the southwest monsoon blows from Africa to Asia, and during the remaining months the northeast monsoon blows toward the African coast. The indraught of air charged with moisture, at the seasons when the sun is overhead, produces the rainy season within the tropics, and as the incessant rain lowers the supply of water by heat continually draws in fresh supplies, the rainfall is on the whole abundant, varying from 50 to 100 inches in the region between 10° N. and the Tropic of Capricorn.
on the Gulf of Guinea the rainfall exceeds 350 inches, though in Somaliland there are almost rainless patches. Near the tropics, to which the sun comes only once a year, there is only a single rainy season, while in the central part of the zone, which the sun traverses twice in its passage between the tropics, there are two distinct rainy seasons, a greater and a less, according as it is nearer or more remote from the equator. The rains are more or less moisture, except in some places in the interior, where two rainy seasons are so protracted as to blend into one, lasting, as in the Manyuema country, from September to July, or in some other parts even longer. The rainy season usually begins soon after the sun has reached its zenith, but on the east coast the monsoon charged with the moisture of the Indian Ocean brings it earlier. In the deserts, as already observed, there is hardly any rain; and this applies also to Egypt, which but for the Nile would be no better than the Sahara. The chief cause of the rainlessness of the deserts is the direction of the winds, which causes the chief moisture-bearing currents to pass, before reaching them, over hot and dry regions. Near the tropics the atmospheric conditions are favorable to the condensation of these winds, and especially the mountain screens which intercept the moisture of the winds both from the northeast and southwest. Another cause is the want of elevated regions to attract the moisture actually contained in the atmosphere, as in the higher regions of the desert periodical rains do occur. The high mountains of the east plateau and the intervening tropical regions deprive the northeast monsoon of all its moisture before it reaches the Kalahari desert. Hence the intensification of the heat, and especially the mountainous area at great heat is found after the equatorial region is passed. The rapid radiation of heat in the desert causes a very great fall of temperature after the sun is down, so that sometimes frosts are generated, and this in some measure supplies the want of rain by condensing the moisture in dew. In the desert, too, scorching winds are generated full of fine particles of sand, those of the north afflicting Egypt, and the countries on the Mediterranean coast and those on the west coast known as the harmattan. The harmattan sweeps, so strongly depopulated is the Sahara, 97 degrees or more; the hottest part is in Nubia, where the Arabs say the soil is like a fire and the wind like a flame. The coasts of tropical Africa, especially the west coast, where colonial settlements have been formed, have been found to have a deadly climate for foreigners.

Geology and Minerals.—The geology of Africa is little known. Very ancient crystalline rocks are found rising into mountain ranges and sometimes spread over large areas. Most of the rocks that overlie them belong to the older formations, so that the continent as a whole is supposed to be of very ancient date. The sands which cover so large an area are believed to be mainly of aeolian origin, and not to have been formed by the action of water. The porous clay found so abundantly in West Africa is of comparatively recent date. The region around Tanganyika is of Jurassic origin. Around the great lakes are abundant evidences of enormous volcanic activity at no very remote date; and, as already mentioned, active volcanoes are not unknown. Tanganyika, according to recent views, may at one period have been connected with the sea. Salt is abundant, though often scarce from with the sun comes only once a year, there is only a single rainy season, while in the central part of the zone, which the sun traverses twice in its passage between the tropics, there are two distinct rainy seasons, a greater and a less, according as it is nearer or more remote from the equator. The rains are more or less moisture, except in some places in the interior, where two rainy seasons are so protracted as to blend into one, lasting, as in the Manyuema country, from September to July, or in some other parts even longer. The rainy season usually begins soon after the sun has reached its zenith, but on the east coast the monsoon charged with the moisture of the Indian Ocean brings it earlier. In the deserts, as already observed, there is hardly any rain; and this applies also to Egypt, which but for the Nile would be no better than the Sahara. The chief cause of the rainlessness of the deserts is the direction of the winds, which causes the chief moisture-bearing currents to pass, before reaching them, over hot and dry regions. Near the tropics the atmospheric conditions are favorable to the condensation of these winds, and especially the mountain screens which intercept the moisture of the winds both from the northeast and southwest. Another cause is the want of elevated regions to attract the moisture actually contained in the atmosphere, as in the higher regions of the desert periodical rains do occur. The high mountains of the east plateau and the intervening tropical regions deprive the northeast monsoon of all its moisture before it reaches the Kalahari desert. Hence the intensification of the heat, and especially the mountainous area at great heat is found after the equatorial region is passed. The rapid radiation of heat in the desert causes a very great fall of temperature after the sun is down, so that sometimes frosts are generated, and this in some measure supplies the want of rain by condensing the moisture in dew. In the desert, too, scorching winds are generated full of fine particles of sand, those of the north afflicting Egypt, and the countries on the Mediterranean coast and those on the west coast known as the harmattan. The harmattan sweeps, so strongly depopulated is the Sahara, 97 degrees or more; the hottest part is in Nubia, where the Arabs say the soil is like a fire and the wind like a flame. The coasts of tropical Africa, especially the west coast, where colonial settlements have been formed, have been found to have a deadly climate for foreigners.

Geology and Minerals.—The geology of Africa is little known. Very ancient crystalline rocks are found rising into mountain ranges and sometimes spread over large areas. Most of the rocks that overlie them belong to the older formations, so that the continent as a whole is supposed to be of very ancient date. The sands which cover so large an area are believed to be mainly of aeolian origin, and not to have been formed by the action of water. The porous clay found so abundantly in West Africa is of comparatively recent date. The region around Tanganyika is of Jurassic origin. Around the great lakes are abundant evidences of enormous volcanic activity at no very remote date; and, as already mentioned, active volcanoes are not unknown. Tanganyika, according to recent views, may at one period have been connected with the sea. Salt is abundant, though often scarce from with the sun comes only once a year, there is only a single rainy season, while in the central part of the zone, which the sun traverses twice in its passage between the tropics, there are two distinct rainy seasons, a greater and a less, according as it is nearer or more remote from the equator. The rains are more or less moisture, except in some places in the interior, where two rainy seasons are so protracted as to blend into one, lasting, as in the Manyuema country, from September to July, or in some other parts even longer. The rainy season usually begins soon after the sun has reached its zenith, but on the east coast the monsoon charged with the moisture of the Indian Ocean brings it earlier. In the deserts, as already observed, there is hardly any rain; and this applies also to Egypt, which but for the Nile would be no better than the Sahara. The chief cause of the rainlessness of the deserts is the direction of the winds, which causes the chief moisture-bearing currents to pass, before reaching them, over hot and dry regions. Near the tropics the atmospheric conditions are favorable to the condensation of these winds, and especially the mountain screens which intercept the moisture of the winds both from the northeast and southwest. Another cause is the want of elevated regions to attract the moisture actually contained in the atmosphere, as in the higher regions of the desert periodical rains do occur. Hence the intensification of the heat, and especially the mountainous area at great heat is found after the equatorial region is passed. The rapid radiation of heat in the desert causes a very great fall of temperature after the sun is down, so that sometimes frosts are generated, and this in some measure supplies the want of rain by condensing the moisture in dew. In the desert, too, scorching winds are generated full of fine particles of sand, those of the north afflicting Egypt, and the countries on the Mediterranean coast and those on the west coast known as the harmattan. The harmattan sweeps, so strongly depopulated is the Sahara, 97 degrees or more; the hottest part is in Nubia, where the Arabs say the soil is like a fire and the wind like a flame. The coasts of tropical Africa, especially the west coast, where colonial settlements have been formed, have been found to have a deadly climate for foreigners.
from its elevation, the vegetation of a temperate region. The swamps of the tropical region abound with papyrus. The cassava, yam, pigeon-pea and ground-nut are cultivated as bread plants.

Animals.—The fauna of Africa is extensive and varied, and numerous species of mammals are peculiar to the continent. According to a scientific view of the geographical distribution of animals, the northwest of Africa belongs to the Mediterranean sub-region, while the rest of the continent forms the Ethiopian region. Africa possesses numerous species of the order Quadrupaea (apes and monkeys), all of which are peculiar to it. They abound especially in the tropics. The most remarkable are the chimpanzee and the gorilla. The lion is the typical carnivore of Africa. Latterly he has been driven from the coast settlements to the interior, where he still reigns king of the forest. There are three varieties, the Barbary, Senegal and Cape lions. The leopard and panther rank next to the lion in the continent. Hyaenas of more than one species and jackals are found all over Africa. Elephants in large herds abound in the forests of the tropical regions, and their tusks form a leading article of commerce. These are larger and heavier than those of Asiatic elephants. The elephant is not a domestic animal in Africa as it is in Asia. The rhinoceros is found, like the elephant, in middle and southern Africa. Hippopotami abound in many of the large rivers and the lakes. The zebra and quagga were numerous in central and southern Africa, but the latter is said to be now entirely extinct. Of antelopes, the most numerous and characteristic of the ruminating animals of Africa, at least 50 species are considered peculiar to this continent, of which 23 used to occur in Cape Colony. The giraffe is found in the interior and is exclusively an African animal. Several species of wild buffaloes roam in the interior, and the Asiatic buffalo has been naturalized in the north. The camel, common in the north as a beast of burden, has no doubt been introduced from Asia. The horse and the ass are highly developed in the Barbary States. The cattle of Abyssinia and Bornu have horns of immense size but extremely light. In Barbary and the Sudan, the sheep of the breed are very fine-tailed; in Egypt and Nubia they are long-legged and short-tailed. Goats are in some parts more numerous than sheep, especially in the Sudan and in Abyssinia. Dogs are numerous, but cats rare, in Egypt and Barbary. The former in the northern towns as scavengers. Bears and foxes are found only in the north. The immense herds of game which formerly abounded in many parts of Africa were diminishing so rapidly that in 1900 measures for their protection were laid down by an international convention, and game reserves have been established in British Africa, Somailand and elsewhere. The birds of northern Africa are almost identical with those of the south of Europe and the Asiatic countries bordering on the Mediterranean. They show more resemblance to those of Australasia. Many of the African birds are famed for the brilliancy of their plumage, such as the sun-birds, bee-eaters, rollers, plantain-eaters, parrots and kingfishers. The ostrich is found nearly all over Africa in the desert. A remarkable bird of southern Africa is the secretary-bird or serpent-eater, which renders great service to the inhabitants by killing serpents. Another peculiar bird of South Africa is the little honey-guide (q.v.), which points out the nests of bees. The whale-headed stork, remarkable for its enormous beak, may also be mentioned. Other birds, such as eagles and vultures are numerous. Water-fowl are abundant on the lakes and rivers, and there are many species of quails and partridges. One species of gallinaceous bird, the guinea-fowl, has been domesticated in other countries. Reptiles, owing to the dryness of the climate, are comparatively few. The largest is the crocodile, which abounds in the great rivers and tropical lakes. There are several species of venomous serpents, including the horned viper and the African cobra. The chameleon is common. The rivers and coasts abound with fish of numerous species, and some of them of the most brilliant coloring. Insects are numerous. Among the more troublesome species are the locust, tsetse and whitefly.

Inhabitants, Civilization, etc.—There is a marked distinction between the races in the north and east of the great desert and those in central Sudan and the rest of Africa and the south. The main elements of the population of north Africa, including Egypt and Abyssinia, are Hamitic and Semitic, but in the north the Hamite Berbers are mingled with peoples of the same race as those of prehistoric southern Europe and other types of various origins, and in the east and southeast with peoples of the negro type. The Semitic Arabs are found all over the northern region, and even in the western Sahara and central Sudan, and far down the east coast as traders. The Somalis and Gallas are mainly Hamitic. In central Sudan and the whole of the country between the desert and the Gulf of Guinea the population is pure negro—people of the black, flat- or broad-nosed, thick-lipped type, with narrow heads, woolly hair, high cheek-bones and prognathous jaws. Scattered among them are peoples of a probably Hamitic stock. Nearly the whole of the narrow southern section of Africa is inhabited by what are known as the Bantu races, of which the Zulu or Xosa may be taken as the type. The languages of the Bantu peoples are closely related to the language of the negro type, some resembling the true negro and others having prominent noses and comparatively thin lips. The Bushmen of southern Africa are of a different type from the Bantu, probably the remains of an aboriginal population, while the Hottentots are apparently a mixture of Bushmen and Kaafs. Scattered over central Africa, mainly in the forest regions, are pygmy tribes, who are generally supposed to be the remains of an aboriginal population. The bulk of the inhabitants of Madagascar are of Malay affinities. The total population is estimated at about 140,000,000.

As regards religion, a great proportion of the inhabitants are heathens of the lowest type. Mohammedanism possesses a large number of adherents in the north of Africa. Christianity is spreading in the Sudan. Christianity prevails chiefly among the Copts of Egypt, the Abyssinians and the natives of Madagascar, the latter having been converted in recent times. Elsewhere the labors of the missionaries have been attended with promising success. It is estimated that about 1/5 of the popu-
The climate in Africa is a tropical one, with a hot and humid season in the north and a dry season in the south. The vegetation is varied, ranging from tropical rainforests in the equatorial regions to savannas and grasslands in the drier areas.

The human population of Africa is diverse, with a mix of cultures and languages. The continent is home to a variety of peoples, each with their own unique traditions and way of life.

The economy of Africa is varied, with a mix of agriculture, mining, and manufacturing. Many African countries rely on exports of raw materials such as minerals, oil, and timber.

The natural resources of Africa are vast, with significant quantities of minerals, oil, and gas. The continent also has a rich biodiversity, with many unique species of plants and animals.

Africans have a long history of civilization, with ancient cultures and empires such as the Meroitic and the Ancient Egyptian. The continent has also been home to a variety of religious and cultural traditions, including Islam and Christianity.

The people of Africa are diverse, with a mix of cultures and languages. The continent is also home to a variety of peoples, each with their own unique traditions and way of life.

lation are Roman Catholics and 1 9/10 per cent Protestants. Over a great part of the continent, notwithstanding European civilization, civilization is at a low ebb, and in the Kongo region cannibalism is still prevalent. Peculiar are the idioms; manioc, rubber, gold, diamonds, palm oil, ivory, wool, ostrich feathers, esparto, cotton, caoutchouc, etc. See paragraph Commercial Conditions at end of this article.

Languages.—The languages spoken on the continent may be divided into two great classes, those native to Africa and those brought in from outside; the former including the three great divisions of Negroid, Hottentot-Bushman and Hamitic, the latter Aryan, Malay and Semitic; and the latter again into the pure languages or *patois* of recent immigrants or traders and those which have become naturalized by time and change into virtually native tongues themselves.

The first division of the extra-African tongues comprises: (1) Pure English in South Africa and Liberia, pure French in Algeria and the scattered trading settlements elsewhere. (2) Four *creole* dialects: the Mediterranean *lingua franca* or trade jargon; the English creole or West African Kru-English; the Cape Verde Islands Portuguese creole; and the Boer and Hottentot Dutch creole. The last three are European in stock, but with much African phonetic, inflectional and syntactical mixture and influence. The second division includes the Malay or Malagasy of Madagascar and the Semitic tongues of the northeast. These last are (a) Pure Arabic (the Latin of Africa, the universal language of social intercourse and trade wherever Mohammedanism prevails, including the Egyptian, Sudani, Maghreb and Muscat dialects; (b) mixed, as the Arabian dialects, derived from the ancient Gez (q.v.), Tigré and Tigrinya, Amharic (originally of southern Abyssinia, but now the chief tongue of the country), Harari, Benin and the others. All these were brought in by Semitic invaders.

The native African stocks are classed in English books mainly according to the system adopted from Friedrich Müller by R. N. Cusin in his *Modern Languages of Africa*; later German Africanists prefer that of Lepsius, the chief difference being on the relations of Bantu and Negro or Nigric.

1. Negroid. This has three main divisions: (a) Bantu, a pure language. This immense group occupies, with enclaves of Hottentot-Bushman and Pygmy, the whole vast triangle from the Kamerun west and Zanzibar east down to the Cape, or pretty much all Africa south of the equator. All its components (for which see Bantu) have one grammar though different vocabularies; the greatest and perhaps purest representatives of it are the Zulus or Kafrirs and their neighbors the Se-chuanu. (b) Nigrite, Negro or Sudan-Negro, between the Sahara and the equator. Ethnologically, the races speaking this group of tongues are the purest types of the Negro stock; but linguistically, they are only classed together from the utter impossibility of grouping them with any others, though Lepsius thinks them degenerated Bantu, —a conclusion scouted by others, the affinities being very faint. They are many and to all appearance totally unrelated, so diverse and peculiar are the idioms; manioc, rubber, gold, diamonds and other products now widespread in their use.

AFRICA

Systems of Writing.—Africa has four living systems (not counting the fossil Coptic or the European used by those races) and has had four now represented only by inscriptions or practices: (1) Ancient Egyptian, passing from hieroglyphics (a mixture of ideograms and syllables) through the cursive hieratic to the more cursive demotic, the ordinary script of business life. A few of the demotic characters are preserved in the ritual Coptic. (2) Ancient Libyan, also known as the Coptic, the ancestor of all Western alphabets. (3) Ancient Ethiopian, used for the native tongue around Napata and Meroë. It was cursive and borrowed, but it is not known from whence, nor what language it represents. (4) Ancient Libyan or Numidian, borrowed from southern Arabia and read from the bottom up. There are many inscriptions in it in Algeria and Tunis, some of which have been deciphered; the first was the celebrated bilingual inscription of Talka. The living systems are principally those of the Hamites and Semites, the others being mostly below the grade of civilization which uses such things; and both the former use Semitic systems. The four are:

1. The only one developed in a Negro tribe, and the only one not in active use and not popularly used within historic times; that of the Ve, on the west coast near Cape Town, devised about 1834 by Doalu Bukere, a native with a rough knowledge of European printing. It was not an alphabetic system, but a syllabary, with complicated characters like hieroglyphics. It was later used for Mohammedan missionary work, but has been supplanted by the European system, the Christian missionaries refusing to employ it.

2. That of the Touaregs or Saharan Berbers, called tifnakdeh. It seems to be a descendant of the ancient Libyan, to which it is similar in reading from the bottom up.

3. The Arabic, used by all who wish to write the great language of Mohammedan Africa, the general medium of social and business communication. It is also widely used to write other African languages: by the Berbers and Arabic for Libyan; by the people of Sho in Amharc and those of Harar for Harari; by the people of Mr. Buran and by the Kufi of Egypt.

4. The Amharic, used largely in and around Abyssinia; it is an extension and modification of the ancient Geez or Ethiopic, which therefore have not classed as dead, any more than the Greek and Roman alphabets can be so called. It is written from left to right like the European languages, the other Semitic systems being the reverse; and the vowels are indicated by modifications of the consonants or marks added to them, making it a semi-syllabic rather than pure alphabetic system. It was borrowed from southern Arabia, and can be traced back to the 4th century on the monuments at Axum, the ancient capital of Abyssinia.

History of Discovery.—Although in Egypt and along the Mediterranean coast (see Carthage and Egypt) Africa was the seat of remote and comparatively high states of civilization, up to the middle of the 19th century the whole of central Africa was a blank; it is now at least as well known as South America. The civilized nations of the ancient world approached Africa from the Mediterranean and the Red Sea; there is reason to believe that till the introduction of the camel in the 7th century A.D. the desert was an insuperable barrier between the Mediterranean countries and central Sudan.

The name Africa is mythologically associated with Afer, a son of the Libyan Hercules; but this is a libel concocted by the Egyptians, Phoenicians, and probably meant "nomadic," a term applied by the Carthaginians to the tribes around. It was the name given by the Romans at first only to a small district of Africa in the immediate neighborhood of Cartage, and nearly corresponding with the modern Tripolitanian on the destruction of Cartage. The Greeks called Africa Libya, and the Romans often used the same name. The first African exploring expedition on record is that mentioned by Herodotus as having been sent by Pharaoh Necho about the end of the 7th century B.C. to circumnavigate the continent. The navigators, who were Phoenicians, were absent three years, and according to report they accomplished their object. The story has been the subject of much controversy, and was for long generally the case and recent authorities of weight have pronounced in its favor. The next important voyage recorded is that of Hanno, a Carthaginian, down the west coast, probably 50 or 100 years later. He passed a river which is either the only one actually invented and popularly used within historic times: that of the Ve, on the west coast near Cape Town, devised about 1834 by Doalu Bukere, a native with a rough knowledge of European printing. It was not an alphabetic system, but a syllabary, with complicated characters like hieroglyphics. It was later used for Mohammeidan missionary work, but has been supplanted by the European system, the Christian missionaries refusing to employ it.

That of the Touaregs or Saharan Berbers, called tifnakdeh. It seems to be a descendant of the ancient Libyan, to which it is similar in reading from the bottom up.

The Arabic, used by all who wish to write the great language of Mohammedan Africa, the general medium of social and business communication. It is also widely used to write other African languages: by the Berbers and Arabic for Libyan; by the people of Sho in Amharc and those of Harar for Harari; by the people of Mr. Buran and by the Kufi of Egypt.

1 Cecil Rhodes Monument, Table Mountain, near Cape Town, South Africa
2 Cape Town Breakwater and Harbor
made to geography under its auspices by Mungo Park, Hornemann, Burckhardt and others.

Modern African exploration may be said to begin with James Bruce, who penetrated through Abyssinia and Sennar to the headwaters of the Blue Nile (1770-72). He was followed by Mungo Park, who reached the upper course of the Niger or Joliba, and whose efforts to explore the river to its mouth cost him his life (1795-1805). Dr. Lacerda, a Portuguese, about the same time reached the capital of Cabembe, was sent to Bateke's country, and discovered, with the help of Hornemann, who traveled for the same society as Park, perished in the desert after sending home accounts of Bornu and the neighboring states. In 1802-06 two Portuguese traders crossed the continent from Angola, through Cabembe's dominions, to the Portuguese possessions on the Zambezi.

In 1816 Captain Tuckey, in command of a British expedition, sailed up the Kongo, which he took to be the mouth of the Niger, for 280 miles. About the same time Major Peddie, and after, in 1822, Captain Clapperton, with Captain Day of the Fula or Fellatah territory, returning to Kakundy on the Nunez. In 1817 Mr. Bowditch explored the country of the Ashantis. In 1818 a French traveler, Gaspard Theodore Molon, discovered the sources of the Senegal, Gambia and Rio Grande. In 1819 Ritchie and Lyon traveled from Tripoli to Murzuk, and in 1821 Major Laing made some important journeys in the Mandingo district of western Africa. In 1822-24 extensive explorations were made in northern and western Africa by Major Denham, Captain Clapperton and Dr. Oudney, the last of whom died on the way. The travelers proceeded from Tripoli by Murzuk to Lake Chad. While Denham examined the south and west coasts of the lake, Clapperton proceeded west through Bornu to Sokoto, the capital of the Fellatah country, on the Sokoto, an affluent of the Niger. Impressed with the importance of establishing political and commercial intercourse with this district, Clapperton organized another expedition for the purpose of reaching Sokoto from the west coast. Setting out from Badagry, on the east of Cape Coast Castle, 7 Dec. 1825, and passing through the kingdom of Yoruba he reached the No. 20, resident. He died. His servant, Richard Landor, returned to Kano and attempted to proceed south through the kingdom of Zegzeg, but was compelled by the natives to return to Darroro, from which he reached the coast.

W. Allen, a naval officer, about this time accompanied a mercantile expedition up the Niger, which he surveyed for a certain distance, and in another expedition in 1848 the same officer revised and corrected his survey. Major Laing in 1826 crossed the desert from Tripoli to the Cassabi River, and in his return and his papers lost. René Caillé, after living for some years on the Senegal coast learning the language and initiating himself into the religion and manners of the Arabs, made in 1827-28 a journey to Timbuktu, and thence through the great desert to Morocco. Richard Landor, accompanied by his brother, leaving Badagry for Bussa in March 1830, ascended the river Niger to Yauri, and descending from thence reached the mouth called the Nun in November. In 1832 he traced other mouths of the river up to the main stream; and the identity of the great river which passes under various names in different parts of its course was thus established.

In the south, Livingstone, who was stationed as a missionary at Kolobeng in 1849, passed through the desert of Kalahari, reached the Zuka or Botetle, and discovered the Zuka on the 19th of December 1849. He here discovered its source in Lake Ngami. In 1851 he went north again, proceeding from the Zuka in a more easterly direction. In lat. 17° 25' south, and between long. 24° 30' and 26° 50' east, he came upon numerous rivers flowing north, which were reported to be affluents of a larger river, the Zambezi.

In 1848 and 1849 Krapf and Rehmans, missionaries stationed near Mombasa, saw the Kilima-Njaro and the Kenia Mountains. In 1851 Francis Galton, starting from Walvisch Bay, made an extensive journey through the Mopane and Ovambo countries, in which he found high pastoral and agricultural table-lands. An expedition under the patronage of the British government started from Tripoli in 1850 to visit the Sahara and the regions around Lake Chad. Richardson, the originator of the expedition, was joined by two Germans, Drs. Overweg and Barth. In crossing the desert from Murzuk to Ghat they found some interesting sculptures. From Ghat to Air they found the country wholly desert and uninhabited. On reaching Lake Tchad Richardson went to Kuka, capital of Bornu, Barth to Kano, Overweg to the native states of Maradi and Guber. Barth and Overweg met again at Kuka in April 1851, but in the meantime Richardson had died. Overweg explored the lake and Barth proceeded on another journey south to Massena, in the kingdom of Bagirimi. On his return the death of Overweg left him to prosecute the enterprise alone. He proceeded to Timbuktu via Kano, and after collecting much information about the Niger and its tributaries, over a great part of the course of which he traveled on his return to Kuka, he reached Tripoli in August 1855. Dr. Vogel, who was sent to join Barth, was put to death at Wadai and is the only one who reached the coast.

Dr. Livingstone began another journey from Kolobeng on 15 Jan. 1853. After staying a month at Linyante, capital of the Makololo, he proceeded down the Chobe to Sesheke, and thence ascended the Leamboye (Zambezi) to the junction of the Liba. After returning to Linyante, and taking with him a party of Makololo, he again set out 11 Nov. 1853, reached the Liba 27 December and proceeded to Lake Dilolo, where he found the watershed of the streams which flow north and south (feeders of the Kongo or the Zambezi) at a level over 4,000 feet above the sea. On his return journey he was confirmed in the belief that an elevated plateau here crosses the country and forms the watershed of the whole continent. He next crossed the Cassabi River, and after ascending the banks of the Kuango, both these rivers being affluents of the Kongo. Crossing the Kuanga, he reached Loanda on 31 May. On 20 September he set out on his return journey, and following pretty nearly the route by which he had gone, arrived at Linyante. Starting from this
place on 3 Nov. 1855, he reached the Zambezi, and proceeding down the river, and visiting its falls, called by him the Victoria Falls, arrived at Kiliman at its mouth on 20 May 1856, and sailed for England. Thus was accomplished by Dr. Livingstone the remarkable feat of crossing the entire continent from sea to sea—the first time, so far as is known, that this was done by any European. In 1858 Livingstone returned to resume his exploration of the Zambezi regions. Entering the Kongoni mouth of the river in May, he ascended with its tributary, the Shire, to Murchison Cataraaks, visited Lake Shirwa and Lake Nyassa, travelled on or near the Zambezi to Victoria Falls, established the identity of the Leambie and the Zambezi, sailed up the Shire to Lake Nyassa, also sailed 156 miles up the Rovuma River, and returned to England in 1864.

Between 1856 and 1865 Paul du Chaillu traveled extensively on the west coast, in the neighborhood of the river Ogowe (or Ogob). In 1860 (after leaving Burton) he also traveled on the west coast. He ascended the Kamerun Mountains and confirmed some of the observations of Du Chaillu. A French expedition visited the delta of the Ogowe in 1864. After the river had been very fully explored, the principal expeditions being those of Walker, 1866, 1873; Lieutenant Aymes, 1867-68; the Frenchmen Compiègne and Marché, 1872-74; Dr. O. Lenz, 1876; and another French expedition under Savorgnani de Brazza, 1876, who took possession of a large stretch of territory for France. This territory now forms part of French Congo, which had been traversed by various Frenchmen, including Brazza, Mizon, Le Maistre, Monteill and others.

In 1866 Livingstone entered on his last great series of explorations, the main object of which was to settle the position of the watersheds in the interior of the continent south of the equator, and to discover the source of the Nile. Landing at the mouth of the Rovuma he proceeded southwest round the south end of Lake Nyassa, and then traveling north reached the south end of Lake Tanganyika (discovered by Speke and Burton in 1858). He afterward visited Lakes Mweru and Bangweolo in the basin of the Chambere, then gave up to a headwater of the Luapula river. In 1869 he reached Uijji, on the Tanganyika, and crossed the lake, making extensive journeys in the Manyuema country, and reached the Lualaba or upper Kongo, but could not explore it for want of boats. Henry M. Stanley, who had been specially sent by the proprietor of the New York Herald to search for Livingstone, met him at Uijji on his return from the Manyuema country, relieved his necessities and examined along with him the northern end of Lake Tanganyika. Livingstone afterward started on a fresh journey (in 1872) to determine the course of the Lualaba, intending to travel round the south side of Lake Bangweolo; but after suffering much from illness he died on the shore of this lake on 1 May 1873.

In 1872 the Royal Geographical Society organized two expeditions to go in search of Livingstone. The one, under Lieutenant Grandy, sailed some distance up the Kongo; the other, under Lieutenant Cameron, started from Zanzibar for Tanganyika. On ascertaining the depth of Livingstone he proceeded to Lake Tanganyika, where he secured Livingstone's map and sent it to Zanzibar. He ascertained the height of the lake; found an outlet, the Lukuga, on the west side; traversed the Manuema country; reached Nyangwe, Livingstone's farthest point on the Luabala; proceeded south up the east side of the valley of Lomane to Kilemba in the Ulima country, and reached Benguela, on the Atlantic coast, 2 Nov. 1875. The identity of the Kongo and Lualaba was at last settled by Stanley, who, between October 1876 and August 1877, descended from Nyangwe on the latter river to the mouth of the former. After helping to establish the Kongo Free State (1879-85) Stanley proceeded in 1887 with an expedition to relieve Emin Pasha. Gordon’s lieutenant, who, after the fall of Khartum, had retreated into the interior. Following the Kongo and its tributary the Arwumi, Stanley hewed his way through a vast forest, arrived at the Albert Nyanza, met Emin there, returned for his rear-guard and stores, and at last brought Emin and his followers, the Blue Nile and the Arzak and in 1889. He also discovered Lake Albert Edward and the lofty mountain of Ruwenzori, on the Semilki, between that lake and Lake Albert. The Portuguese Major Serpa Pinto journeyed from Benguela to Nata in 1879; the Germans Wissmann and Pogg, crossed from St. Paul de Loanda to Zanzibar in 1881-82; in 1879-80 (after the death of his leader, Keith Johnston), Joseph Thomson crossed from the east coast by the north of Lake Nyassa to the east of Tanganyika and back to Zanzibar; again in 1883-4 he explored the Masai country between the coast and Lake Victoria; Capello and Ivens went from Angola to Mozambique by way of Bangweolo in 1884-85.

One of the most interesting problems connected with African geography was the tracing of the source of the Nile. Among the first of the famous explorers in this direction was James Bruce, who, in 1770, reached the source of the Blue Nile. But in 1877 the Germans Wissmann and Pogg, crossed from St. Paul de Loanda to Zanzibar in 1881-82; in 1879-80 (after the death of his leader, Keith Johnston), Joseph Thomson crossed from the east coast by the north of Lake Nyassa to the east of Tanganyika and back to Zanzibar in 1883-4 he explored the Masai country between the coast and Lake Victoria; Capello and Ivens went from Angola to Mozambique by way of Bangweolo in 1884-85.

from Algeria and French explorers, prominent among them was Marchand during 1896–98, crossed the continent from Loanga, in French Congo, to Fashoda on the Nile, and Foureau, who, in 1900, crossed the Sahara from Algeria to Lake Tchad, have added greatly to our knowledge of the Sahara. Dr. Junker devoted several years to exploring the country between the basin of the Nile and the Kongo. Mr. Stanley, in his great journey across Africa in 1876, added largely to our knowledge of Lake Victoria and of Uganda, the country between Victoria and Lake Albert. After 1890 the work of the various international commissions, which traced the frontiers of the protectorates of the various European powers, added greatly to the topographical knowledge of Africa. Since the British occupation of Uganda, Colonel Lugard and many other officers have mapped the country between the coast and the lakes, Uganda itself and the country to the west. Italian and British explorers have added to our knowledge of Abyssinia and of the desert between the Nile and the Red Sea. Lakes Hagen and Stefanie have been discovered and explored by Count Teleki and Lieutenants von Höhnel from the south, James, Donaldson Smith, Cavendish, Robecchi, Bottego and others have explored Somaliland, and ascertained that the Omo flows into Lake Rudolf. Gregory has investigated Mount Kenya; Meyer has ascended Kilima-Njaro; Baumann and other German explorers have visited the region to the west and south of that mountain, round by the south of Lake Victoria, and on to Lake Albert Edward. In 1894 Count Götzén crossed from east to west, discovered Lake Kivu to the south of Lake Albert Edward and a lofty active volcano near its shores, coming out by the Kongo. Many other Germans have been busy in German East Africa, while in British Central Africa Johnston, Sharpe, Joseph Thomson and others have filled in many blanks, and British naval officers have charted Lake Nyassa.

The unique distinction of being the first white officer to cross Africa south to north on foot fell to the lot of an undergraduate of Cambridge University, Ewart Scott Grogan, who, in February 1898, started from Cape Town with one white companion and a few servants and 18 months later reached Cairo, having traveled the greater part of the distance with only the servants, as his white friend left him before the journey was half done. Mr. Grogan brought back a mass of ethnological information, having carefully investigated and described the various tribes with which he came in contact and cleared up a number of disputed geographical points. Consult "From Cape to Cairo" (London 1900).

Several German explorers also traversed and mapped Damaraland and Namqua-land and established the Uganda region of Gibbons and others traversed the Barotse country. The officials of the Kongo Free State laid open the courses of the numerous rivers that feed the main stream; Hinde found the Lukuga flowing into the Luabafa; Grenfell and others completed the connection of the Ubangi or Mobangi tributary on the north with the Makua-Welle higher up, which had been explored by Junker and others. Under the auspices of the Royal Niger Company, Joseph Thomson and others further explored the Niger; while the Benue and its tributaries and the German sphere in the south were actively explored by British, French and German travelers.

All these three nationalities, moreover, were busy in the vast area between the Guinea coast and the great bend of the Niger. Prominent among them was Binger, who contributed more than any single individual to our knowledge of this region. The French occupation of Timbuktu led to the navigation and exploration of the upper and middle river by gunboats; while a French expedition followed the river from Timbuktu to its mouth. Monteil crossed from Senegal to Lake Tchad and traversed the desert to Tripoli, and the Lake Tchad region was further explored by Lenfant and Loeffler (1902–04) and Alexander and Gosling (1904–05). French expeditions crossed from the Kongo to the Nile and all the river systems are now mapped in their main features. It may indeed be said that the pioneer exploration of Africa has been completed, and by 1910 geographic maps existed of all the colonies. What remains to be done is the filling up of the meshes between the vast network of explorers' routes, and this is a task which cannot be completed for many years.

International and Diplomatic Relations.—Early in the history of the United States American shipping trade in the Mediterranean suffered in common with the rest of commercial navigation from the piracies of the Barbary States. In 1784 Congress sought to safeguard American commerce by the negotiation of treaties. In 1787, Thomas Barclay signed a favorable treaty with the Emperor of Morocco for a period of 50 years, giving the United States the most-favored nation privileges, with consular representation. The treaty of 1797 with Tunis, like that of Morocco, was also favorable, and, with modifications in 1827, remained effective after the French occupation in 1881.

The treaties negotiated with Algiers in 1795 and with Tripoli in 1796 proved unsatisfactory and expensive. Failing in their obligations, the American naval blockade of Tripoli in 1805, and of Algiers in 1815, led to new treaties of peace and friendship. By compulsion and the expenditure of nearly $3,000,000 the United States gained the commercial freedom of the Barbary shores for the world. See BARBARY POWERS, U. S. TREATIES AND WARS WITH.

While the slave trade early in the 19th century was a subject of international discussion, and its suppression was advocated in the Treaty of Ghent in 1814, it was not until 1842 that the United States joined with Great Britain in a patrol of the west coast of Africa, which ended with the abolition of slavery in America in 1865.

In 1886 the Sultan of Zanzibar confirmed the extra-territorial rights granted Americans under a treaty made with the Sultan of Muscat in 1833, which lasted until the British occupation and the Anglo-American convention of 1905.

In 1903 a most-favored nation commercial treaty was effected by the United States' representative with Abyssinia.

The United States had shared in the most-favored nation treaty arranged in relation to
Moroccan affairs by the Madrid conference of 1880, and at the Algeciras conference in 1906, precipitated by German intervention, its representatives signed the treaty "without assuming obligation or responsibility for its enforcement," the Senate ratifying "without purpose to depart from the traditional American foreign policy." See AMERICAN DIPLOMACY; TREATIES; UNITED STATES — DIPLOMACY OF THE MODERN HISTORY — INTERNATIONAL INTERVENTION AND COLONIZATION. — Before 1875 the only European powers with considerable interest in Africa were Great Britain, France and Portugal, the first being predominant. After the Franco-Prussian war (1870-71) the unified German nation desired to build up a colonial empire, France also sought compensation for her loss of European prestige by colonial expansion, while Italy, recently become a united kingdom, likewise desired colonies. South America being protected by the Monroe Doctrine, Africa was the only field open to these conflicting ambitions. Great Britain and Portugal, seeing their influence threatened, determined to guard their possessions. Matters were brought to a head by Leopold II, King of Belgium, who conceived the project of forming a great state in the recently discovered Kongo territory in central Africa. The initiative the "International African Association" was founded in 1876, with headquarters at Brussels, ostensibly to place the exploration and commercial development of Africa on an international footing. This association finally resulted in the Berlin Conference of 1884, by which the Kongo Free State was established under the sovereignty of the Belgian King, and the general spheres of influence of the other Great Powers were defined. Meantime Germany had established a footing in East Africa and Italy on the Red Sea, France had secured the conquest of Algeria and established a protectorate over Tunisia, and Great Britain had consolidated her influence in South Africa. The possessions of the powers were added to and the boundaries more or less defined by subsequent agreements, most important of which are those of 1 July 1890 between Germany and England; of 5 Aug. 1890 between France and England; of 11 June 1891 between Portugal and England; of 24 March and 15 April 1891 between England and Italy, and of 15 March 1894 between France and Germany. As a result of the Fashoda incident in 1898, England secured control of the Upper Nile valley; by the Boer war (1899—1902) she gained possession of the South African Republic and Orange River Free State, which in 1910 were united with Natal and Cape of Good Hope Colony under the name of Union of South Africa, while by the conventions of 1899 and 1904 she strengthened her already dominant position in Egypt. The latter, however, remained nominally under Turkish control until 18 Dec. 1914, when a British protectorate was declared. Belgium annexed the Kongo Free State in 1907-08; Italy annexed Tripoli 1911-12, and France declared a protectorate over Morocco 1912. In 1915 territory under British control in Africa included: North and South Nigeria and protectorate, Gold Coast and protectorate, Sierra Leone and protectorate, Gambia and protectorate in West Africa; Mauritius and dependencies; Seychelles Islands, Somaliland, East African protectorate, Uganda protectorate, the islands of Zanzibar and Pemba in East Africa; Nyasaland, Union of South Africa, Rhodesia, Swaziland, Basutoland and Bechuanaland in South Africa; Egypt and Anglo-Egyptian Sudan; the islands of Ascension and Saint Helena; in all an area of 3,514,271 square miles, with a population of 30,681,243. Territory under French control included: Algeria and Algerian Sahara, Tunisia, Morocco, French Kongo, Madagascar, Mayotte and the Comoro Islands, Reunion Island, French Somaliland and French West Africa in which are comprised Senegal, French Guinea, Ivory Coast, Dahomey, Upper Senegal and Niger Territories and Mauretania; in all an area of 4,403,401 square miles (including Morocco), with a population of 30,681,243. Territory under German control before the European war included: Togo, Cameroon, German Southwest Africa, German East Africa; in all an area of 931,460 square miles, with a population of 14,890,000. German Southwest Africa was conquered by Great Britain 1915, Togo in 1914, Kamerun in 1915. Territory under Italian control included: Cape Verde Islands (1912), Guinea, Principe and Saint Thomas Islands, Angola, Mozambique; in all an area of 793,980 square miles, with a population of 8,245,032. Territory under Italian control included: Eritrea, Italian Somaliland, Tripoli and Cyrenaica; in all an area of 591,230 square miles, with a population of 1,378,176. Territory under Spanish control included: Rio de Oro and Adrar, Spanish Guinea and islands of Fernando Po, Annobon, Corisco, Golf of Guinea, and Little Elloby; in all an area of 84,814 square miles and a population of 235,844. The Belgian Kongo has an area of 909,654 square miles, with a population of 15,000,000. Liberia (area 40,000 square miles, population 1,500,000-2,100,000) being under the supervision of the United States as regards finances, military organization, etc., Abyssinia (area 350,000 square miles, population about 8,000,000) is the only independent nation remaining in Africa. For further details see separate country articles.

Commercial Conditions. — Necessarily in so large an area with so many tribes and peoples who keep no accounts of their transactions, a considerable amount of commerce must pass without being recorded in any way, yet the annual commerce of Africa, of which statistics are available, amounts to over $1,440,000,000. The principal imports were distributed as follows: Into British territory (1913-14), $441,516,990; French territory (1913), $174,250,765; Portuguese territory (1913), $74,000,000; German territory (1912), $30,000,000; into the Kongo Free State (1912), $11,000,000; into Italian territory (1912), $10,500,000. They consist largely of manufactured goods, especially cotton goods. Of the exports a large share, especially of gold and diamonds; in the tropical region ivory, rubber, palm nuts and gums and in the north a fair share of the exports are products of agriculture, cotton, coffee, cacao, spices, dates, etc. Exports from British Africa amounted (1914) to increased: £40,000,000; from Portuguese Africa to $42,000,000; from German Africa (1912) to $25,000,000; from Belgian Congo (1912) to $12,000,000.
Railroad development in Africa has been rapid in the past few years and seems but the beginning of a great system which must contribute to the rapid development, civilization and enlightenment of the "Dark Continent." Already the proposed "Cape to Cairo" railroad runs north from Cape Colony to Elisabethville in Katanga, Belgian Congo, about 2,300 miles, and south from Cairo to Sennar in the Anglo-Egyptian Sudan with branches to Port Sudan on the Red Sea and to El Obeid, the capital of Kordofan. All the important railroad lines skirt the Mediterranean coast, especially in the French territory of Algeria and in Tunisia, aggregating about 3,134 miles; while the Egyptian railroads are, including those of the Sudan, 3,779 miles in length. Those of the Union of South Africa are 8,833 miles and of Rhodesia 2,481 miles in length, and those of Portuguese East Africa are another 1,000 miles in length. In British West Africa there are about 1,500 miles open; in the Belgian Congo, now supplied 98 per cent of the diamonds and before the European war, there were over 1,700 miles in operation. The Great Lakes Railway in the Belgian Congo (total length 165 miles) was completed in 1915 and links the lakes with the German railway from Ujiji to Dar-es-Salaam on the Indian Ocean. The Upper and Middle Niger are connected at three points with the Atlantic Ocean.

Including all of the railroads now constructed and under construction, the total length of African railways is about 22,900 miles. A large proportion of the railroads thus far constructed are owned by the several colonies or states which they traverse, about 279 miles of that of Egypt and nearly all of the Union of South Africa and Rhodesia systems belonging to the state.

That the gold and diamond mines of South Africa have been and are still wonderfully profitable is beyond question. The Kimberley diamond mines, about 660 miles from Cape Town, now supply 98 per cent of the diamonds of commerce, though their existence was unknown prior to 1867 and the mines have thus been in operation scarcely 50 years. It is estimated that over $900,000,000 worth of diamonds has reached South Africa up to the end of 1913; the output in that year alone having been valued at over $56,500,000, and this enormous production would have been greatly increased but for the fact that the owners of the various mines there formed an agreement to limit the output so as not to greatly exceed the world's annual consumption.

Equally wonderful and promising are the great Witwatersrand gold fields of South Africa, better known as the Johannesburg mines. Gold was discovered there in 1883 and in 1884 the value of the gold product was about $5,000,000. It increased with startling rapidity, the product of 1888 being about $5,000,000; that of 1890, $10,000,000; 1892, over $20,000,000; 1895, over $40,000,000; and 1897 and 1898, $100,000,000. The value of the gold produced and output from the Union of South Africa was valued at over $178,300,000 and that of Rhodesia at over $17,900,000, and it seems probable that South Africa will for many years continue to be, as it is now, the largest gold-producing field of the world. Agriculture and farming have also made considerable progress in many parts of Africa, white immigration has steadily increased, as has the trade between the colonies and their mother countries. Plans for industrial training of the natives have been devised by the colonial governments, and the slave-trade, which has been a canker in the growth of Africa since the 'end of the 17th century, though still prevalent in many parts, has been checked to a certain degree by the extension of European control and improved economic conditions.

AFRICA, Colonization and Intervention

In—It is difficult to summarize the origin and development of the latter recent colonial expansion movements of European nations seeking territory and economic concessions in Africa, the efforts to secure strategic positions, the persistent work in the conquest of natural obstacles, the penetration of the wilds to stop slave-hunting and the slave trade and to establish peace and security, the enterprises and plunderings which furnish lessons of statecraft, and the evolution of adjustments in administration based on scientific study of people and conditions. Merging into a part of world politics chiefly relate to the founding of the Congo Independent State and its transition to the Belgian Congo, German colonization in Southwest Africa, British and German East Africa (and Uganda), French colonial expansion in West Africa (and the Sudan and Sahara), Nigerian enterprise, South African expansion and union, and the reoccupation of northern Africa (Algeria, Tunisia, Morocco, Tripolitania, Egypt and the Soudan) and various phases of vast world movement which none of the great European Powers had seriously considered in 1870 when their African possessions were still confined to seaport towns and adjacent territory—which were regarded as mere trade centres and not as bases for colonial expansion. Although French colonial enterprises in Africa began in 1636 and were extended and consolidated between 1854 and 1865, France really did not conceive dreams of a great Mediterranean-Kongo colonial empire until the early eighties when the Senegal colonists reached the Niger. She evolved a more progressive policy after the acquisition of Tunis. England, with the spirit of conservatism, and without any preconceived policy of expansion, was led to extension of territory by unexpected developments. In 1884, although forced by circumstances of 1882 to interfere in Biafra, she was still undecided on a policy of colonial expansion until forced to act by new conditions. Under Gladstone’s leadership she would never have consented to turn Egypt into a British protectorate. Until 1884, she had been in no haste to enter upon a race for colonies in West Africa, but, under pressure of French and German activities, she realized the necessity of formulating a definite policy of expansion there, and in June 1885 to protect British interests on the Niger she proclaimed a British protectorate over the region the beginning of a policy which by 1914 resulted in the amalgamation of all Nigeria into a single united protectorate. Her period of indecision and uncertainty was not fully ended until about 1885 after the fall of the Gladstone ministry. Although Germany was under strong pressure after 1878 to enter the field of international politics, Bismarck postponed action until he had firmly secured the position of Germany in Europe through a tariff agreement and the formation of the triple alliance of 1882. Alarmed at conditions resulting from the industrial revolution and increase of population at home, and partly influenced by the delay of the British government to establish a protectorate over Atlantic coast territory (north of Cape Colony) in which German missions had been established, Bismarck in 1884 determined upon colonization. In 1884, he sent a war ship to take possession of territory in Southwest Africa in which England promptly recognized German rights; and in 1885 he officially proclaimed in East Africa a German protectorate which, through the influence of England, was recognized by the Sultan of Zanzibar. Aroused by the entrance of Germany into Southwest Africa and the expansion of the Boers westward, England took under her protection Basutoland in 1884 and Bechuanaland in 1885—the latter in order to keep the way open to the north of the native districts of Natal and Bechuanaland, which attractions attracted the attention of Cecil Rhodes (and John Hays Hammond) by 1888. The later attempt (after 1890) of Germany to secure the Uganda region by treaties with the natives was frustrated by the prompt action of the British East African Company which, from 1890 to 1892, obtained a control which made permanent the British protectorate in East Africa and won the key to the Nile. By the new treaties (after 1895) the British government secured the Nile as the frontier of Uganda and proceeded to safeguard her interests in that region by a railroad which was begun in 1895 and which reached Lake Victoria at the close of 1901.

In South Africa also, forced by new factors which changed completely the situation, the British government after 1884 adopted a policy of forward movement. After the circumstances by which England was led to intervene in Egypt in 1882, and to undertake the reorganization of the Egyptian government after 1883, the British scheme of European extra-legal advisers acting with a gov-
ernment of native Egyptian officials worked admirably, securing a slow but steady progress of reforms and affording the people every chance to learn the elements of national self-government. The Gladstone government was justly criticized for failing properly to support General Gordon with force sufficient to make the contemplated attack on Khartoum practicable. The fall of the city in 1884. The tragedy of 1884 temporarily shattered the confidence of the Egyptians in the integrity and ability of the British government and multiplied the dangers and difficulties of the later reoccupation of the Sudan—an event which was finally accomplished by Kitchener in 1898. Considering the prospective economic benefits of European colonies in Africa, the possessions controlled by France and England are the most fertile and promising; those of Spain and Italy are of questionable value; while some parts of those controlled by Germany and Belgium and Portugal are promising. Although, as a financial proposition, Algeria does not pay, its future possibilities are excellent; and its position as an adherent since the definite and final settlement of the frontier question in 1911 by the acquisition of Morocco to which France is now applying the general principles of her Tunisian system of administration. Although Italy, adopting French methods in the preservation of local customs, has made a good beginning in orderly government in Turkish-ridden Tripoli, she will find a long and painful process necessary to secure a self-supporting and prosperous colony. British East Africa promises soon to become self-supporting. The two protectorates, recently lost in the World War, have never been satisfactory, although the most constant irritation which existed between settlers and natives was greatly lessened in 1907 under the leadership of Dermberg who inaugurated more scientific methods of government. In the German East African protectorate, on which the German government has spent large sums, no remarkable progress has been achieved either in colonization or in development of the resources.

JAMES M. CALLAHAN,
Professor of Political Science, University of West Virginia.

AFRICAINE, L' (Die Afrikanerin), an opera in five acts by Jacob Meyerbeer (1791-1864); text by E. Scribe; first performed at Paris 28 April 1855 and in New York 1 Dec. 1865. The plot revolves around Vasco da Gama, the famous Portuguese navigator (b. 1469), who is betrothed to Donna Inez, daughter of Admiral Diego. While da Gama is away with Diaz on a voyage of discovery by way of the Cape of Good Hope, reaches Lisbon that he has been shipwrecked and lost at sea. Her father insists that Donna Inez shall marry Don Pedro, a councillor of the king. In the first scene, which is laid in Lisbon, the council of state is sitting when da Gama suddenly appears before them and describes his adventures as the sole survivor from the wreck. He produces maps to show that other undiscovered lands lie beyond Africa. On his way home he had picked up a man and a woman of some unknown race who refused to give the name of their country. Henry VIII assumed the existence of countries not mentioned in Holy Writ, da Gama is thrown into prison, together with the two mysterious natives, and Selika. For having rescued her from a slave ship, Selika has fallen in love with da Gama. Her passion is not returned. Her companion, Nelusco, is jealous and attempts to stab da Gama in the cell while asleep, but Selika frustrates his design by awakening da Gama in time. She finally points out her country on the map, for which the navigator vows eternal gratitude. Then Inez enters the cell and announces that da Gama is free; she has purchased his liberty by marrying Don Pedro, having been told that da Gama was enamored of the dusky queen, Selika. Denying infidelity on his part, da Gama immediately makes Inez a present of the two slaves. Don Pedro had meanwhile gained possession of da Gama's maps and plans and been commissioned by the government to undertake the voyage of discovery. He decides to take the two natives with him. The third act plays on board of Don Pedro's vessel in the Indian Ocean. He is accompanied by his wife, Inez, and his native, Nelusco, is steering the ship; a somewhat broad stretch of imagination. On board of a small sailing ship Vasco da Gama is following them. He overtake them and, fearing only for the safety of Inez, he adds his warning to that of Don Alvar. But Don Pedro orders him to be shot; Inez pleads for his life; suddenly a storm breaks out and the vessel strikes upon a rock close to a cannibal island—Madagascar. A horde of savages overwhelm the ship and rescue their queen, Selika, whose influence alone saves the Christians from being massacred. In the fourth act Selika is restored to her position as queen. Her priests clamor for the white men's blood as a sacrifice to the gods; the white women are to inhale the deadly manzanillo-tree. Desiring to save Vasco from death, Selika proclaims that he is her husband and Nelusco is prevailed on to vouch for the statement. The marriage rites are about to be performed. Believing Inez to be already dead, da Gama is soon reconciled and once again swears eternal fidelity to Selika. But, believing the voice of Inez, who is being led to death, he turns pale and betrays that he still loves her. In the final scene Selika determines that Inez shall die. In an interview, however, her jealousy fades away, and she orders that Inez and Vasco be placed on a ship to return home. As the departing vessel sinks on the horizon Selika herself inhales the deadly perfume of the manzanillo-tree and dies. An invisible chorus consoles her with the assurance that all are equal in love's eternal realms.

AFRICAN INTERNATIONAL ASSOCIATION. King Leopold of Belgium called a conference of geographers and explorers at Brussels in 1876 to consider the development of Africa. This was the first definite step in the modern partition of the continent. King Leopold summoned representatives of Great Britain, Austria-Hungary, France, Germany, Italy and Russia to deliberate on the best methods to be adopted for the
exploration and civilization of Africa and the opening up of the interior of the continent to commerce and industry. After deliberations lasting many months, a conference formed the "International African Association," with its headquarters at Brussels; committees were to be established in the various countries represented and the central idea was apparently to place the entire matter of the exploration and development of Africa on an international footing. The greed of the different nations, awakened by the commercial prospects of the Kongo, led to various disputes, and at length it was decided by consent of all the Great Powers, including the United States, to adjust the several difficulties at an international conference in Berlin. This conference opened 17 Nov. 1884 and closed its session 26 Feb. 1885. Prince Bismarck presided at its deliberations. Fifteen countries were represented. It was decided that the regions forming the basin of the Kongo River and tributaries shall be neutral territory, free trade shall exist there, national of any country may undertake transportation therein, the powers exercising sovereign rights in adjacent territory shall not exercise any monopoly of trade and all shall bind themselves to suppress slavery. The central association became gradually more and more Belgian in character, while the territory in question at last developed into the Kongo Free State under the personal sovereignty of King Leopold. See AFRICA; BELGIAN KONGO; STANLEY, H. M.

AFRICAN METHODIST EPISCOPAL CHURCH, The. Work among the negroes was begun by the Methodist Episcopal Church at an early date. Bishop Asbury was much interested in the race and often preached to them. "Black Harry," a noted colored preacher, often accompanied Bishops Asbury and Coke and preached to white congregations as well as congregations composed almost entirely of black men. For a considerable number of years the two races worshipped together, but gradually they separated. As early as 1787 a society was organized among the negroes in Philadelphia as the result of ill-treatment received. The formation of the society was opposed by the whites. In 1793 Richard Allen erected a church on his own lot and at his own expense. This brought the church into controversy with the authorities. The whole involved story is given in the historical preface to 'The Doctrines and Discipline of the A. M. E. Church,' the last edition of which appeared in 1916. Dr. Benjamin Rush, the noted physician, sympathized with them and helped them. Bishop William White, bishop of the Protestant Episcopal Church, was appealed to and ordained Rev. Absolom Jones, one of their number, to be their pastor. However, when the new meetinghouse was completed it was dedicated by Bishop Asbury and was named Bethel. The subsequent history of the church was one of persecution and litigation. The members of Bethel were victorious in the suit brought against them.

A similar time of trial and persecution was experienced by the colored people of Baltimore and other places. The feeling produced made a division necessary. In 1816 a general convention was called to meet in April in the city of Philadelphia. Seventeen delegates responded to the call, representing congregations in Philadelphia, Baltimore, Attleborough, Pa., and Salem, N. J. At this first convention it was resolved: "That the people of Philadelphia, Baltimore and all other places who should unite with them, should become one body under the name and style of the African Methodist Episcopal Church." Articles of incorporation were prepared and until May 1900. The trustees are 12 and consist of four bishops, four ministers and four laymen. Rev. Richard Allen, who 17 years previously had been ordained deacon by Bishop Asbury, was elected bishop and served in that capacity until his death, 26 March 1831. He was not, however, the first choice of the convention. Rev. Daniel Coker was first elected, but resigned the next day. On 11 April 1816 Mr. Allen was ordained bishop by Rev. Absolom Jones, mentioned above. The convention adopted the Book of Discipline of the Methodist Episcopal Church, rejecting, however, the article relating to the office of presiding eldership. Later they adopted this officer in their polity and he remains as one of their executives to this day. They also used the hymnal of the Methodist Episcopal Church until 1826, when they prepared one of their own.

At the time of the convention about 3,000 members were numbered as belonging to the various churches represented. The growth of the new church was very rapid. The church spread south and southwest in its growth. As early as 1822 there was a strong church of 3,000 members in Charleston, S. C. It was suppressed by the authorities as dangerous to the community interests. Probably some of the leaders had been too outspoken to please the white authorities at that time it was the only church organization in the South not under white leadership. After the Civil War ceased the membership of the denomination greatly increased. As early as 1865 there were 10 annual conferences, 180 pastors, 206 churches and 50,000 members. These are now, according to the latest statistics available, 81 conferences, including a conference in Bermuda, one in Nova Scotia, one in Ontario, seven in Africa, one in the West Indies and one in South America; 5,000 preachers, 6,000 churches and over 650,000 members.

In 1856 the members of the African Methodist Episcopal Church residing in Canada formed the British Methodist Episcopal Church and elected Willis Narrey, then bishop of the A. M. E. Church, as their bishop. In 1884 the church was reunited and the British M. E. Church ceased to exist except in a very small minority.

The General Conference is the supreme governing body and, as in other Methodist bodies, it has the power of legislation to the church. It is composed of all the bishops, General Conference officers, college and university presidents and deans of theological schools, two ministerial and two lay delegates from each annual conference. If a conference has more than 60 members it is entitled to an additional ministerial delegate for each 30 members or fraction of the same exceeding 15. The Annual Conference is composed of all the traveling elders, deacons and licensees and
all the local elders and local deacons and two
laymen from each district in the bounds of the
county. The members of other conferences
visiting the session of the conference have the
right to speak in debate but cannot vote.

The District Conference is composed of all
county traveling ministers, local preachers and one
steward from each quarterly conference in a
presiding elder's district. The District Con-
ference does considerable work done by the
Annual Conferences in other churches, such as
the preliminary examination of candidates for
admission to the ministry.

The Quarterly Conference is the governing
body of the local church. The women of the
church have a large share in the local govern-
ment. There are not only stewards but stew-
ardesses as well. From three to nine belong
to each local Quarterly Conference. The church
also makes use of the services of deaconesses.
The bishops, however, are spe-
cifically prohibited from ordaining women to
the ministry.

The present Board of Bishops consists of 16
members, 15 of whom are in active service.
The church is divided into 15 episcopal dis-
tricts over each of which a bishop presides for
a period of four or more years, as the Gen-
eral Conference shall direct. The limit of
service of presiding elder or pastor is five
years.

The educational work of the church in-
cludes 20 institutions of which 10 are of col-
legiate grade, two are normal schools and one
an industrial school. For the training of their
ministry they have two theological sem-
inaries: Payne Theological Seminary, located
at Wilberforce, Ohio, and connected with
Wilberforce University; and Turner Theolo-
ogical Seminary, connected with Morris Brown
College, Atlanta, Ga.

The Missionary Society was organized by
the General Conference of 1844 and includes
both foreign and home missions in its work.
Previous to that date, however, the church had
conducted mission work in Hayti, sending
Samuel Beane as missionary in 1827. In 1830
mission work was begun in Santo Domingo.
In 1820 missions were established in Sierra
Leone by Rev. Daniel Coker. In 1878 work
was begun in Liberia and in 1889 in the Trans-
vaal. In 1912 Bishop Heard was
sent to Africa as resident bishop. In 1912
Bishop Johnston was resident bishop of South
Africa. In 1916 Bishop Ross succeeded Bishop
Heard, while Bishop Beckett succeeded Bishop
Johnston. The headquarters of the Mission-
ary Society is located in New York City.

AFRICAN SLAVE TRADE. See Ne-
gro, The.

AFRICAN WAR. The, in Roman history,
Cæsar's campaign against the Pompeians who
after Pharsalia kept up the war in Africa, and
were crushed at Thapsus, 46 B.C. The history of
it printed as Cæsar's is not his, and the author is
unknown.

AFRICANUS, Sextus Julius, Christian
historian of the 3d century. b. in Libya,
traveled in Asia Minor, and from 195 to 240
lived at Emmaus near Jerusalem. No copy
exists of his 'History of the World' in five
books from the Creation to A.D. 211, a period
which he computed at 5,723 years, but it is
known by considerable extracts made by Euse-
bius for his 'Chronicon,' and by Syncellus
and Cedrenus. A letter to Origen on the book
of Susanna and Origen's reply exist. Consult
Geizer, H. 'Sextus Julius Africanus und die
Byzant.' Chronographie' (2 vols., Leipzig
1880-85).

AFRIDS, af-rē'dē-z, a tribe of Afghans or
Pathans on the northwest Indian border near
the Khyber Pass, who after exactly contrary
the customary border raids were dignified into
almost a great power by the ill-advised policy of
the Indian government in sending out an
imposing army against them in place of the usual
small punitive expeditions. The inhabitants
women into the English camp to be cared for
and protected, fought for some months in their
mountains till the planting season was come,
then submitted and promised an indemnity, hav-
ing enjoyed the highest glory and felicity their
natures could appreciate.

AFRIKANDER ("Taal" Dutch for Af-
ican), a native South African; commonly used
for the Dutch stock alone.

AFRIKANDER BOND, or BUND, bōnt,
an association of white natives of South Africa
to make native influence paramount there and
ultimately secure its independence; formed in
1879, but thus named in 1880. The Cape Col-
ony wing supported Cecil Rhodes till after the
Jameson Raid in 1895, which it considered as
fostered by him with objects exactly hostile
to its own. It carried the elections in 1898, and
while advising Kruger to grant concessions to
the Outlanders for safety's sake, its sympathies
were hostile to them; in the ensuing war it was
a heavy handicap to the English, seeming likely
to stop at one time to add Cape Colony to the revolt;
indeed, it held a convention, 6 Dec. 1900, at
Worcester, C. C., condemning the war and Eng-
lish policy, insisting on the recognition of the
South African Republic, and censuring the pol-
cy of the high commissioner. The success of
the British and the annexation of the territory
to the empire of Great Britain brought about
dissolution of the organization.

AFTER-DAMP, the gaseous product
formed by an explosion of fire-damp (q.v.) in
a coal mine. It consists largely of nitrogen
from the air, and carbon dioxide formed by
the explosive combustion of the hydrocarbon
gas given off by the coal. It seldom contains
sufficient free oxygen to support respiration.
Hence its danger to the miners.

AFTERGLOW, a display of brilliant
colors in the western sky after sunset. The
colors are usually various shades of red, al-

AFRICAN SLAVE TRADE—AFTERGLOW
though yellows and grays are sometimes visible. Afterglows follow volcanic eruptions of explosive character and are generally ascribed to the presence of minute dust particles in the air. The eruption of Krakatoa in 1883 was accompanied by most gorgeous afterglows which were observed throughout the world and persisted for several years. Similar effects were seen over a larger area after the outbursts of Mont Pelée and La Soufrière in May 1902. The name foreglow is given to such displays in the eastern sky before sunrise.

**AFTER-IMAGE, AFTER-SENSATION** and **AFTER-PERCEPT** are the terms used to denote the direct after-effects of the stimulation of a sense organ. These after-effects occur in almost all of the sense departments. A brief stimulation of the sense organ gives a primary sensation, then a pause of a fraction of a second, followed by a secondary sensation of the same quality as the primary sensation. After-images of touch follow after brief contact. They do not appear under ordinary circumstances, but may be observed if special conditions are produced; for example, a gentle tap on the point of a needle will be followed by a pause, then an after-sensation which differs from the primary sensation in that it seems to be produced from within the body, not from without. The effects of a temperature stimulus may persist for a time in the same quality as the primary sensation. After-taste and after-smell have been observed, but have not been studied. Auditory after-sensations, analogous to after-sensations of touch, are very weak and of brief duration.

After-images of vision are stronger and more permanent, consequently have been given much more attention by experimentalists. It has been found that after the retina has been stimulated by light for one second, or less, the primary image disappears quickly; an interval of less than two seconds is then followed by a positive after-image, that is, an after-image of the same quality as the primary image.

A stimulus of longer duration is followed immediately by the positive after-image, and this image may itself be followed by a negative after-image, an image which differs very much in brightness from the primary image, or is of a different color. With some observers a brief stimulus is followed immediately by a negative after-image, which fades away quickly to be followed after an interval by a more permanent positive after-image. Several images may succeed each other immediately or be separated by an interval of time. A stimulus of still greater duration is followed directly by a negative after-image. In such cases the after-image is usually of a color that is complementary to the color of the primary image, especially if observed with closed eyes or if projected upon—that is, seen while looking at—a gray background. The duration of the after-image varies with the intensity, duration and area of the stimulus. The results of experiments, under conditions such that the intensity of the light does not vary, have not as yet shown that any one color has more power to produce after-images than any other color. The angular distance of the portion of the retina stimulated, from the fovea, the less distinct and the less durable is the after-image. There seems to be no after-image at an angular distance of 45 degrees or more from the fovea. The explanation for this fact may be physiological, or psychological; that is, it may be due to the fact that the periphery of the retina is more easily fatigued than the fovea, or it may be due to lack of ability to attend to those portions of the retina which are not customarily attended to. When an object occupies the eye for some time, the mind does not normally attend to images that are not over or very near the fovea.

A blow on the head may cause the after-image to become less intense or to cease entirely. Electrical stimulation of the eye and optic nerve will change the character of the after-image and shorten the time of its duration. General fatigue will shorten the duration of the after-image; for example, it has been found that an after-image lasts about 30 per cent longer in the morning than in the evening. The distraction of attention in any manner has its effect on the course of the after-image; when the attention is directed wholly upon the after-image the duration is one-third longer than when the attention is not concentrated upon it.

If one eye only is stimulated, an after-image may appear in the unstimulated eye. Four hypotheses have been offered to explain this transfer of the image from one eye to the other: (1) The appearance is a phasenois of binocular contrast. When one eye is stimulated by a bright colored light, and the other eye is stimulated by a very little gray light or is protected from all light, the contrasted color may be seen in the unstimulated eye during the time of stimulation, and this may leave an after-image in that eye. (2) A second hypothesis is that the eyes are accustomed to function together, and whatever affects one retina affects the other also. This may be considered as a modified form of the first hypothesis. (3) Another hypothesis is that the after-image has its seat in the centres in the brain, not in the end organ or retina, and that it may be seen in whichever eye is open. This hypothesis seems to be overthrown by the observation that an electrical stimulation of the optic nerve produces a sensation like that produced by a flash of light, but no after-image follows. Another fact difficult for this hypothesis to explain is that if one eye be stimulated the after-image appears in the other eye only in case that eye be well darkened. (4) A fourth hypothesis is that the transfer of the after-image is not real but only apparent. In support of this hypothesis it has been found that when the portion of the right eye which corresponds to the blind spot of the left eye was stimulated (Franz), there was an apparent transfer of the image to the left eye; also if the unstimulated eye be disturbed or interfered with during the course of the after-image no change in the image may be observed, whereas if the stimulated eye be interfered with the image disappears. Consult Fechner. 'Elemente der Psycho-physik'; Franz, S. I., 'After-Images' (Monograph Supplement, Vol. III, No. 2, 1889. Psych. Rev.); Titchener, E. B., 'Über binoculare Wirkungen monocular Reize.' See EYE: VISION.

**AGABUS, a-ga-bûz,* a prophet residing in Jerusalem in the time of Paul and said by tradition to be one of the 70 disciples of Jesus**
PHYSICAL—AGARUS

AGARUS, a work, a project

in fact, but in the time of Gaul and...
LIZARD (Agama colonorum) BEETLE (Ateuchus sacer) HORNY VIPER (Cerastes cornutus)
Christ. He predicted a famine in the year A.D. 43, which occurred in the next year (Acts xi, 27, 28) but was probably confined to Judea. According to Josephus many poor Jews were relieved of their distress by Adiabene, who purchased corn in Egypt for them. Later Agabus predicted to Paul that he should suffer if he went to Jerusalem (Acts xxx, 10-12). The Greek Church holds that later Agabus suffered martyrdom, and observes his festival on 8 March.

AGADES, ā-ga-dèz, Africa, a town near the middle of the Sahara, capital of the oasis kingdom of Air or Asen; at one time a seat of great traffic, probably containing 60,000 inhabitants. It has a population of about 6,000.

AGADIR, ā-ga-dèr', an Atlantic seaport of Morocco, northwestern Africa, 375 miles from Tangier and 64 miles from Mogador, in lat. 30° 27' N. and long. 9° 36' W. It is famous simply because its name has been so prominently associated with the Franco-German crisis of 1911. In the summer of that year, while France was establishing a protectorate in Morocco against the wishes of the inhabitants, the German Panther was suddenly sent to Agadir. The most powerful of the Moroccan chiefs were entertained aboard and were promised German support in resisting French control. For a time war seemed imminent between France and Germany, both nations mobilizing troops on their frontiers. After some delay an accord was published on 3 November in which Germany recognized the right of France to establish a protectorate in Morocco, and France ceded to Germany about 250,000 square kilometers of land in the French Congo, bordering the German colony of Kamerun, and other commercial and economic provisions were added. Both nations engaged to obtain the adhesion to this accord of the other nations who were signatories of the Algeciras act. At the waterfront there is a miserable hamlet of fishermen called Fonti; the town itself, built on the crest of a hill about 660 feet in height and a short distance away, is surrounded by walls with Saracenic towers. It was a barren outpost of Saracen power — closed, that is, to general commerce. Pop. about 1,000. Consult: Albin, P., 'Le "Coup" d'Agadir: origines et développement de la crise de 1911' (Paris 1912); also 'Agadir et la stratégie navale' (Rev. de Paris, 18th year, Vol. VI, pp. 809-822).

AGAG, ā-gag. (1) In Jewish history, a king of the Amalekites saved by Saul out of the slaughter of his people, and hewn in pieces by Samuel before Yahwe's altar; evidently a survival of human sacrifice. (2) A character in Dryden's Absalom and Achitophel, representing Sir Edmund Berry Godfrey, the London magistrate found murdered shortly after taking Titus Oates' deposition concerning the imaginary Popish Plot.

AGALACTIA, a deficiency, either of quality or quantity, in the secretion of milk after delivery. It may be due to a number of causes, as poor diet, hemorrhage, or exhausting diseases such as phthisis, or phthisis, or even by emotional disturbances. An abominable diet with plenty of milk and cream will often increase the secretion of milk. Malt liquors (porter, stout) are helpful in small quantities. Drugs are of no value. Agalactia is contagious in sheep and goats. It is accompanied when acute by a high fever and has a mortality of 15 per cent. It is very frequent in Italy, France and Spain.

AGALMATOLITE, ag-al-mat'-ô-lit (from the Greek words agalma, image, and lithos, stone), a soft, massive stone, grayish or greenish in general hue, and often yellow, brown and red, or streaked with those colors. It is soft enough to be cut with a knife and it takes a good polish. The Chinese use it for carving images, notably small pagodas and grotesque figures of animals and men; ingenious advantage often being taken of its varied colors for the production of odd effects. The hardness of the Chinese variety is mostly from 2.0 to 2.5, and its specific gravity about 2.8. It is not a definite mineral, some specimens being silicious pinite, while others are referable to pyrophyllite and steatite.

AGAMA (Caribbean name), a genus of lizards, typical of the large and important family Agamidæ, which is distributed over all Africa (except Madagascar), Arabia, Asia south of the Caucasus and Himalayan Mountains, the Malayan Islands and Australia. None are found in the New World. They are closely related to the iguanas, and are characterized by acrodont dentition (that is, the teeth surmount the ridges of the jaw), a broad and short tongue, and the absence of bony tubercles (osteoderms) in the skin, but large and numerous spines are often present. They may have brilliant colors, but many are dull, desert-dwelling species. Some have parachutes, as the flying dragon, and others defensive appendages, as the frilled lizard. Prominent examples are the dragons, bloodsuckers, false chameleons, frilled lizards, spiny-tailed desert lizards, dabs, molochs and related forms elsewhere described under their own names. The family contains about 200 species arranged in about 30 genera, and is most numerous in the region from India to Australia.

AGAMEMNON, in the Iliad, is the Greek "great king" or "king of kings," the overlord of Greece both north and south of the Gulf of Corinth; the royal seat is at Mycenæ in the Peloponnesus. He is represented as a rather weak man, presiding over a turbulent assembly of practically independent feudal chiefs, who will not openly defy him because he is consecrated to his position by Zeus, but who are entirely independent as regards their individual districts, though bound to follow him to war when ordered. His character is of course purely the invention of the poet, and its relation to that of Achilles and other chiefs is curiously like that of Charlemagne to Roland and the peers in the chansons; the dashing noble being the real hero, and the monarch slurred as rather petty, unjust and capricious, king by grace rather than special merit. In fiction is not fictitious. Archaeology has proved that Mycenæ was really the seat of a wealthy and powerful monarchy, probably about 1500 B.C. and somewhat after, as well as that several Troy flourishing and perished; and these proofs that the basis of the tradition and not mythical naturally tempt the sanguine to hope for further points of truth,
which research tends steadily to justify. As to the character of the monarchy, later theorists take the reverse view from the earlier. Grote held that the account in Homer showed the germ of a developing constitutionalism, the crisis of commons, who were becoming thorn in the monarch's flesh being satirized and caricatured in Thersites, and the king only an Aryan chief elected by his equals; Mahaffy thinks it the decay of a monarchy of the Oriental type, the feudal archaic state, indwelling and showing down instead of growth. In the legend he is the son of Atreus (q.v.), and brother of Meneleus, King of Sparta, whose wrong in the seduction and carrying away of his wife Helen by Paris, son of Priam, King of Troy, he avenges by a levy of all the Greeks to make war on Troy, when its King, Priam, will not give up Paris or make him give up Helen. (See Helen; Iliad; Troy). The sacrifice of his daughter Iphigenia (q.v.), to secure a passage from Aulis, is a later fiction and recalls Jephthah and his daughter curiously. His quarrel with Achilles is the theme of the Iliad. When Troy was sacked he received Priam's prophetic daughter Cassandra (q.v.) among his share of the spoils. Returning home after 10 years' absence, he was murdered by his cousin Ægisthus, son of Thyestes (see Atreus), aided by Agamemnon's wife Clytemnestra (q.v.) with whom he had been living in adultery for a short time previously; and his son Orestes on growing up avenges him by killing his mother, his sister Electra abetting. In Homer the motive for Agamemnon's murder is simply that of any adulterous pair in ridding themselves of an inconvenient husband; in Æschylus' 'Agamemnon,' Clytemnestra slays him with her own hand, professing in revenge for his sacrifice of Iphigenia, obviously sharpened by jealousy of Cassandra, and throwing the ultimate responsibility on Nemesis, who is pursuing the house of Atreus.

AGAMENTICUS, Mount, a noted landmark in County Clare, near which one of the earliest settlements in this territory was made in 1631. It is a few miles back from the shore and rises to the height of 673 feet.

AGAMIDE, a large family of lizards, including about 200 species, all dwelling in the warmer parts of the Old World. They are of moderate size, active, with well-developed limbs, are of both terrestrial and arboreal habits and mostly insectivorous. The tongue of all is broad and short; the skin often spiny and changeable in color. In this family are many common and familiar lizards of the Mediterranean region as well as of the East, including the flying dragon, the moloeh, the frilled lizard of Australia and others elsewhere described by name.

AGAMOGENESES. See PARTHENOGENESIS.

AGAÑA, ag-ān'yə, the principal town of Guam, the largest of the Ladrone Islands, 1,500 miles east of Luzon, Philippines and 1,300 miles south of Yokohama. The Ladrone, or Marianne, group belonged to Spain; but, as a result of the war between the United States and Spain in 1898, the former took possession of the island of Guam. In 1899 a United States naval station and seat of administration at Agaña, with Capt. Richard P. Leary, U.S.N., as first governor. The town contains the usual public buildings of a military station, and a college.

AGANIPPE, -nip'é, a fountain on Mount Helicon, in Greece, sacred to the Muses, which had the property of inspiring with poetic fire whoever drank of it.

AGAPE, ag'a-pé (Gr. ἀγάπη, love), in ecclesiastical history, the love-feast or feast of charity, in use among the primitive Christians, when a liberal contribution was made by the rich to feed the poor. During the first three centuries love-feasts were held in the churches without scandal, but in after-times the heathen began to tax them with impurity and they were condemned at the Council of Carthage in 397. Some modern sects, as the Wesleyans, Sandemanians, Moravians, etc., have attempted to revive this feast.

AGAPEMON, ag-a-pem-o'nē (lit. "the abode of love"), the name of a singular conventual establishment which was founded at Spaixton, near Bridgewater, Somersetshire, in 1859, the originator of it being a certain Henry James Prince, at one time a clergyman of the Church of England, who called himself the Witness of the First Resurrection. The life spent by the inmates appeared to be a sort of religious eremiticism. Some of the proceedings of the inmates of the "Abode of Love" resulted in applications to the courts of law, where parties formerly members of the society having returned to the world sought to regain their rights from Prince and his followers, such cases naturally causing some scandal; but the sect has been scarcely heard of for some years.

AGAPHITE, a name given to the turquois (q.v.) by Fischer in 1806, in compliment to the naturalist Agaphe. It is no longer in general use.

AGAR-AGAR, āgār-āgār, also known as Bengal isinglass. A dried seaweed or vegetable gum obtained from Singapore. It is almost completely soluble in water, dissolving to a tasteless and odorless mass. It is much used as a culture medium in bacteriology.

AGARIC (Agaricus), a genus of fungi, characterized by having a fleshy cap or pileus and a number of radiating plates or gills on which are produced the naked spores. The majority of this species are furnished with stems, but some are attached to the objects on which they grow by their pileus. Over a thousand species are known, and are arranged in five sections according as the color of their spores is white, pink, brown, purple or black. Many of the species are edible, like the common mushroom (A. campestris), and supply a delicious article of food, while others are deleterious and even poisonous. See FUNGI; MUSHROOMS.

AGARICIC ACID, agar-ar-is'ik, a substance having the formula C₆H₂O₆, which is obtained from certain species of mushrooms by extraction with ether or strong alcohol. It is also soluble in hot glacial acetic acid and oil of turpentine. It crystallizes in flat, four-sided plates, and also in prisms, according to the solvent from which it is deposited, and melts at about 200° F. It dissolves in boiling water, but crystallizes out again upon cooling. A
similar substance, known as agaricin, is obtained from the fly-agaric by extraction with alcohol, and Jahn states that it is identical with agaricic acid. Several salts of agaricic acid are known. See AGARIC RESIN.

AGARIC MINERAL, a-gar'ik, or a-gar'ik. (1) A soft, white variety of calcite, breaking easily in the fingers and occurring in caverns and in the clefts of rocks in regions where the ground water contains much lime. (2) A variety of silicate of magnesium found in Tuscany and also known as mountain-milk or rock-milk. Bricks made from it will float in water hence it is supposed that this is the material from which the ancients made their floating bricks.

AGARIC RESIN, a red resinous substance obtained from certain mushrooms, together with agaricic acid (q.v.) by extraction with alcohol or ether. It melts at 194° F. It is insoluble in water, alcohol, ether, wood alcohol, chloroform and alkalies.

AGASSIZ, Alexander, a-gä'siz, American scientist, son of Louis: b. Neuchatel, Switzerland, 17 Dec. 1835; d. 27 March 1910. Taken to America in 1848 and educated at Harvard College. In 1859-60 he made biological studies along the coast of California and Mexico with the United-States coast survey. Later he became wealthy through investment in coal and copper mines, to which he was led by scientific knowledge and experience. On his father's death he was appointed curator of the Museum of Comparative Zoology at Harvard, but resigned in 1885 on account of ill health. In 1896 he was made an officer of the Legion of Honor. He belonged to many scientific associations, did much important work in marine dredging and the zoology of the deep sea, as well as on other subjects. His most important publications are: 'North American Acalpea' (1865); 'Marine Animals of Massachusetts Bay' (with Elizabeth Agassiz, 1871); 'Revision of the Echii' (1872); 'North American Starfishes' (1877); and 'Report on the Echii of the Challenger Expedition' (1881).

AGASSIZ, Louis, American naturalist: b. 28 May 1807 at Motier, Canton Fribourg, Switzerland; d. 14 Dec. 1873. From childhood he showed a strong bent toward zoology and, after a preparatory training at Lausanne, studied medicine and natural history at Zurich, Heidelberg and Munich, taking a degree in philosophy at Heidelberg and graduating in medicine at Munich, 1830. After this he went to Paris and worked under Cuvier until 1832, when he was called to a professorship at Jena, but resigned his professor of natural history, and remained there until 1846, when invited to give a series of lectures in the Lowell Institute course at Boston. The success of these lectures and his desire to study the natural history and geology of America determined his permanent removal to the United States; in 1848 he was given the chair of natural history in the Lawrence Scientific School of Harvard University. With the interval of three years (1851-54) as professor in the medical college in S. C., he continued his connection with Harvard until his death. His enthusiasm, eloquence and clearness of thought made him a pre-eminent teacher, but in his later years he was relieved from the regular duties of the school.

His first great work, 'Recherches sur les Poissons Fossiles' (5 vols., 311 plates, 1833-42) was accomplished during his professorship at Jena. This was followed by 'Fossil Fishes of the Old Red Sandstone of the British Isles,' written after making several visits to England, and by the 'Nomenclator Zoologicus Index' (Soldans, 1842-46), which, revised and brought up to date by Scudder, was reissued in 1882 as Bulletin No. 19 of the United States National Museum. During this same period he had studied both living and fossil echinoderms and had spent many summers in observing glacial action. The most eminent European biologists, botanists and geologists were among his friends, and he came to America with the hope not only of advancing science by his own researches, but of waking a deeper interest among American students who had yet shown in the natural sciences. His first wife had died in the Atlantic Ocean and he married in America and became so engrossed with the work he had undertaken as to refuse the most flattering offers of positions in Europe. In constant demand and traveling widely as a lecturer as long as his health permitted, he was nevertheless constantly forwarding his original work. In 1848 he made a geological and biological survey of the northern and eastern shores of Lake Superior; in 1850-51 he studied the coral reefs of Florida; later he visited Brazil and the coasts of California.

His zeal was untiring, even after his health failed; besides working through all his later life on his great series, 'Contributions to the Natural History of the United States,' which he had planned on so large a scale that the four quarto volumes completed were but a beginning, he directed constant efforts toward the establishment of the Museum of Comparative Zoology at Harvard, giving more attention to it than to any other of his later interests. The plans for it were perfected in 1838, and through his influence the original endowment was supplemented by generous appropriations; he gave his own valuable collections to it, and his time and money as well; before his death the opportunities which he had created were not only a great addition to the wealth of the Smithsonian Institution (to which he had contributed the sum of $50,000), but had attracted a group of young men who were to become the foremost American biologists. The founding of a summer school where zoology could be studied out of doors was another of his projects, and this he accomplished on the island of Penikese, Buzzard's Bay, in 1873, just before his death.

Among his more important American publications are: 'Methods of Study in Natural History,' 'Geological Sketches,' 'The Structure of Animal Life,' in the Journal, at Bremen and 'An Essay in Classification' (the first volume of his unfinished 'Contributions'). The amount and scope of his work, together with his great gift of awakening interest in the natural sciences and advancing new views without rousing the opposition of the dogmatic, gave him rank as the most influential of American naturalists, although many of his opinions and theories have been superseded by the Darwinian idea of evolution, which he opposed. He was buried in Mount Auburn Cemetery, where his monument is a bold and sturdy "A" glacier in Switzerland. Consult 'Life and Correspondence of Agassiz' (Boston 1886).
AGASSIZ, Mount, a remarkable extinct volcano situated in Arizona about 70 miles northeast of Prescott. It has an altitude of more than 10,000 feet above the sea, and belongs to the ranges of the Rocky Mountains. As a place of resort it has numerous attractions—grand scenery, elevation and proximity to the Colorado Cañon.

AGASSIZ ASSOCIATION, an organization for the promotion of nature study among youth. The society was established in 1875, and in 1893 had a membership of more than 12,000. The headquarters are at Pittsfield, Mass. The official publication is *The American Boy*, and the badge is a Swiss cross. Consult Guyot, *Memoir of L. Agassiz* (Princeton, N. J. 1882).

AGATE, a variety of chalcedony, or cryptocrystalline quartz, distinguished by its banded or clouded appearance or by the presence of visible impurities. *Achatas* was the Greek name of a river in Sicily near which, according to Pliny, agates were first found; but the name was earlier used by Theophrastus in his *On Stones* (c. 270 B.C.), and published about 130 B.C., while agate is mentioned in Exodus xxviii, 17 as one of the precious stones in the breastplate of the high priest. Its history, therefore, extends over a period of at least 3,400 years.

The method of formation of banded agates has been carefully studied by numerous investigators. M. F. Heddle (consult *Nature*, Vol. 29, p. 419) assumes the existence of a cavity in a trap rock which is lined during its solidification with a thin layer of green celadonite or delesite. The rock subsequently rots, and its feldspar is decomposed by water containing carbonic acid, which thus becomes highly charged with silica. This is trans fusated into the cavity, coagulates and is deposited on its walls. The banded structure is due to the intermittent deposition of successive layers of silica from the highly silicious solution. It was long supposed that after the earlier layers were deposited fresh supplies of the solution passed inward through a hole called the "inlet of infiltration." This canal is often distinctly seen in agate, but the weight of evidence now seems to favor the hypothesis that the external solution supplies the silica by osmosis (q.v.). The internal solution becomes less dense as it is relieved of silica by its deposition on the walls of the cavity, and it is then replaced by the denser external solution which passes through the layers of agate already formed. If the conditions remain unchanged the process continues until the entire cavity is filled, but agates are not infrequently found with a cavity in the centre, or with crystallized quartz (often amethystine) lining the interior. Such distinctly crystallized portions may be succeeded by further deposits of the cryptocrystalline chalcedony. The successive layers often differ much in density, hardness, color and transparency. Sir D. Brewster has shown that some of the layers are so exceedingly thin that it would take 55,700 to measure an inch. (*Philosophical Magazine* (3) XXII, p. 213). These layers are deposited all around the cavities, following all of the contours, and the beauty of agates is thus greatly enhanced by extreme delicacy of their banding. Sometimes these bands concentrically encircle a dark spot, forming a "bull's eye agate," or again they parallel a cavity with sharp angles, as in the "fortification agate." Other agates show horizontal layers, suggesting the query as to whether the silica had settled upon the floor of the cavity from a solution at rest. Such agates are known as onyx (q.v.), or if the colors are red and white, as sardonyx (q.v.). In clouded agates there is no distinct banded structure, but the colors shade gradually from one into another.

The natural colors of agates vary greatly, being usually gray or either red or brown. The colors are due to the presence of organic impurities or to the oxides of iron, manganese or titanium. Nearly all the agates now offered for sale are, however, artificially colored. The success of the process is due to the varying degrees of porosity of the different layers of agate, some of which readily absorb the fluid in which the stones are immersed, while others are impervious to it. To prepare the agate it is immersed in a warm syrup of honey and water, then immer sing them in sulphuric acid, which carbonizes the honey absorbed by certain of the agates, thus making them dark brown or black. The red or carnelian agate is produced by a process of "burning." A grayish stone is heated in an oven for several weeks, at first gently, then it is moistened with sulphuric acid and the temperature is gradually raised to redness. Blue or "sapphire" agates are produced by steeping the stones first in a solution of a ferric salt and then in potassium ferrocyanide, thus depositing Prussian blue in the more porous layers. A green agate is secured by the aid of chromic acid or a nickel salt, while hydrochloric acid yields a yellow agate. The red and the black are much the most popular.

For over four centuries the headquarters of the agate industry has been in the valley between Idar and Oberstein, some 40 miles from Bingen on the Rhine. There are probably 150 agate mills working an average of three to five stones each in this little valley. These are chiefly operated by water-wheels 10 to 18 feet in diameter and modern power being secured from the rapid mountain streams of the neighborhood. The millstones are of red sandstone, each about five feet in diameter, and rotate in a vertical plane, making about three revolutions per second. The workmen lie stretched in an almost horizontal position upon a low wooden grinding stool fitted to the chest and abdomen, leaving the limbs free. The hands are engaged in holding and grinding the agate, while the feet are firmly pressed against short stakes screwed into the floor, the black anvil, white stone, the grinder to press the agate with much force against the moving millstone. During the process the agates glow most beautifully with a bright red phosphorescence. After having been ground the agates are polished with tripoli on cylinders of wood or a metal disc. Consult *Popular Science Review*, New Series, Vol. 1, p. 23.

Moss-agate or "Mocha-stone" is a variety of chalcedony through which are scattered black or brown masses, more or less resembling moss. These impurities greatly enhance the beauty of agates in such agates the beauty is thus greatly enhanced by extreme delicacy of their banding. Sometimes these bands concentrically encircle a dark spot, forming a "bull's eye agate," or again they parallel a cavity with sharp angles, as in the "fortification agate." Other agates show horizontal layers, suggesting the query as to whether the silica had settled upon the floor of the cavity from a solution at rest. Such agates are known as onyx (q.v.), or if the colors are red and white, as sardonyx (q.v.). In clouded agates there is no distinct banded structure, but the colors shade gradually from one into another.
AGATES
1. 4. 5. Carnelian Agate or Sard Agate
2. Moss Agate
3. Onyx Agate
6. Bull's Eye Agate
Beautiful dendrites are sometimes found in chalcedony. The name dendritic-agate or tree-agate is given to these highly prismatic forms. Moss-agates abound at many localities in the United States, especially in Wyoming.

In the "melaphyre" of the hills around Idar, agates of considerable beauty are found. Formerly they were extensively quarried there, but since 1877 the owners of the mines have secured their supplies largely from Uruguay and Brazil, which countries have long furnished nearly the entire commercial supply, though Scotch agates are marketed to some extent. Small banded agates of much beauty abound on the shores of Lake Superior; large and fine specimens occur plentifully in western Texas. Agates abound in many other regions, while very many localities yield choice agates sparingly. Most of the polished agate specimens and novelties of the tourist resorts, though often purporting to be of local origin, come from Brazil or Uruguay and are polished in Germany.

Agate is used in making burnishers and agate mortars and pestles and, owing to its hardness, forms the heaviest of chessmen. It is worked up as a decorative stone into vases, dishes, ashtrays, paper weights, paper cutters, etc., and is mounted as a semi-precious stone in a great variety of objects, such as jewel boxes, glove or shoe buttoners, watch charms, letter openers and scarf pins. Every boy is familiar with agate marbles, but the cheaper grades of these are only glass. From the earliest times the black and white banded agates (see ONYX) and the red and white (see SARDONYX) have been used for seal rings and for carving cameos. The ancients also regarded agate as a charm against the intoxication of love. Consult Ruskin, "On Banded and Breechiated Concretions" (in Geological Magazine, 1867 to 1870); "Ethics of Dust," p. 190; "The Vale of Idar," by S. Weisse (in Blackwood's Magazine, Vol. cxlviii, pp. 75 and 208).

GEORGE LETCHWORTH ENGLISH.

AGATE-SHELL, or AGATE-SNAIL, a land-snail of the carnivorous genus Achatina of the family Helicidae. They are abundant in tropical Africa; the largest of all land-snails are found among them, and many species have brightly colored shells.

AGATHA, Saint, a lady of Palermo, martyred by Quintilian, the pro-consul of Sicily, in the persecution of Decius, because she would not perform idolatrous worship or submit to his impure desires, c. 251 A.D.

AGATHARCHIDES, ág-a-thár'kí-déz, or AGATHARCHIDES, ág-a-thár'kí-déz, a Greek writer on geography: b. at Cnidus in Asia Minor; lived 250 B.C. and wrote numerous works; among them, one on the Erythraean Sea, of which some extracts have been preserved. He is the earliest extant writer who attributes the annual rise of the Nile to the periodical rains in the upper regions of that river.

AGATHARCHUS, ág-a-thár'kúz, Greek painter: b. Samos, about 430 B.C. He worked at Athens between 455 and 415 B.C. He is regarded as the first scene-painter, having painted a scene in a drama for the first time. His work was important because of the development of perspective. He is said to have written a treatise on this subject.

AGATHIAS, á-gá-thí-as, Greek poet and historian, about 536-81. He collected a Cycle of contemporary poems, in which there were a few of his own compositions. We have still 101 of his Epigrams and the whole of his History of the years 553-58.

AGATHO, ag-ath'ó, Saint, Pope of Rome from 678 to 681, surnamed Thaumaturgus—the Wonderworker, from the many miracles he wrought. He was born in Sicily and was over 100 years when he was elected Pope. He was instrumental in arranging the 6th Ecumenical Council held at Constantinople in 680 which practically ended the Monothelite heresy. His feast-day is celebrated by both the Greek and Roman churches. He died at Rome 10 Jan. 681.

AGATHOCLES, ag-ath'ó-kléz, Syracusan of low extraction, who became ruler of a great part of Sicily. He was remarkable for beauty, strength and capacity for enduring labor. In the outset of life he belonged to a band of robbers; afterward he served as a private soldier, rose to the highest honors, and made himself master of Syracuse. He conquered the greater part of Sicily, 317 B.C. Being defeated at Himera by the Carthaginians, he carried the war into Africa, where for four years he extended his conquests over his enemy. He afterward passed into Italy and made himself master of Crotone. In his 72d year he was poisoned by his grandson Archagathus, 289 B.C., after a reign of 28 years of great prosperity mingled with the deepest adversity. His son-in-law, Pyrrhus, King of Epirus, inherited his influence in Sicily and southern Italy.

AGATHON, ag-a-thón, Greek tragic poet (448-402 B.C.). He was a close friend of Euripides and of Plato; and the famous Symposium of Plato immortalizes the banquet given on the occasion of Agathon's dramatic triumph, 416 B.C.

AGAVE, ag-a've, daughter of Cadmus and Hermione, married Echion, by whom she had Pentheus, who was torn to pieces by the Bacchans. She is said to have killed her husband while celebrating the orgies of Bacchus. She received divine honors after death.

AGAVE, a genus of remarkable and beautiful plants, of the family Amaryllidaceae, having a tubular perianth with 6-partite limb and triangular many-seeded capsule. They resemble aloes in their growth and general appearance, and the best-known species, Agave americana, is sometimes known as the American aloe. This is a large plant, the leaves of which are thick, fleshy and spiny-toothed at the edge, and the stem branched and of great height. The flowers have the tube of the corolla narrowed in the middle, the stamens longer than the corolla and the style longer than the stamens. This magnificent native of North America, probably of Mexican, is by no means an uncommon plant in gardens, but is seldom seen there in flower. There is indeed a notion, but an erroneous one, that the American aloe does not bloom until it is 100 years old. The fact is that the time of flowering depends almost wholly on the rapidity of its growth. In hot countries it will flower in a few years, but in colder climates, the growth being slower, it is necessarily longer in arriving at maturity.
The stem, which bears the blossoms, rises from the centre of the leaves and when the plant is in a vigorous state it frequently exceeds the height of 20 feet. Branches issue from every side and in such a manner as to form a kind of pyramid, composed of greenish-yellow flowers, which stand erect and are seen in thick clusters at every joint. When in full flower its appearance is extremely splendid; and if the season be favorable, and the plant be sheltered from the cold in autumn, a succession of blossoms will sometimes be produced for nearly three months. In the warmer parts of Europe the American aloe is cultivated as an object of considerable utility. They are frequently set out in rows as fences for inclosures, particularly in Spain, Portugal and Italy. In some parts the leaves are employed for scouring-pewter, kitchen utensils and floors. The juice of these leaves is made into cakes, which are used for washing and will make lather with salt water as well as with fresh. The sap of certain species when fermented yields a beverage resembling cider, called by the Mexicans pulque. By distillation it yields two intoxicating beverages very widely used in Mexico—mescal and tequila. The leaves are used for fodder; the fibres of the leaves (called pita, xaxal hemp or henequen) are formed into thread, cord and ropes. The leaves also, roasted, were formerly used for food by the Indians.

AGE, any period of time attributed to something as the whole, or part, of its duration; as the age of man, the several ages of the world, the Golden Age.

In law, the time of competence to do certain acts. In the male sex 14 is the age when partial discretion is supposed to be reached, while 21 is the period of full age. Under seven no boy can be capitally punished; from seven to 14 it is doubtful if he can; at 14 he may. At 12 a girl can contract a binding marriage; at 21 she is of full age. In mediavals times, when a girl reached seven, by feudal custom or law a lord might distrain his tenants for her to marry, or rather, betroth her; if she were not dowerable; at 12 she could confirm consent to marriage which she had previously given; at 14 she could take the management of her lands into her own hands; at 16 she ceased, as is still the law in England, to be under the control of her guardian; and at 21 she might alienate lands and tenements belonging to her in her own right. At common law the age of discretion for female infants was 12 and the age of consent to unlawful carnal intercourse was 10, but by recent legislation the age of consent has been raised in the United States to 14, 15, 16 and, in several States, to 18 years. For the modern law of infancy consult Schouler, 'Treatise on the Domestic Relations' (Boston 1870). In the United States at 25 years of age a representative in Congress, and at 30 a Senator and at 35 he may be chosen President. The age of serving in the militia is from 18 to 45 inclusive.

In England no one can be chosen a member of Parliament under 21 years of age, nor be ordained a priest under the age of 24, nor made a Judge until he has become 20 years of age. The age of serving in the militia is from 16 to 45 years. The sovereignty of the realm is assumed at 18; though the law recognizes no minority in the heir to the throne.

In French law, a person must have attained the age of 40 to be a member of the legislative body; 25 to be a judge of a tribunal de première instance; 27 to be its president, or to be judge or clerk of a cour royale; 25 to be a justice of the peace; 30 to be judge of a tribunal of commerce, and 35 to be its president; 25 to be a notary public; 30 to be a juror. At 21 both males and females are capable of performing all the acts of civil life.

In Archaeology.—The Danish and Swedish antiquaries and naturalists, MM. Nilson, Steen-dentrup, Forchammer, The Age of Bronze and the Age of Iron. During the first mention of these he is supposed to have had only stone for weapons, etc. Sir John Lubbock divides this into two—the paleolithic, or older, and the neolithic, or newer, stone period. At the commencement of the age of bronze that composite metal became known and began to be manufactured into weapons and other instruments; and the age of iron came in, bronze began gradually to be superseded by iron. Consult Lyell's 'Antiquity of Man' and Lubbock's 'Prehistoric Times.'

In Physiology.—If the word age be used to denote one of the stages of human life, the physiology clearly distinguishes six of these, viz., the periods of infancy, of childhood, of boyhood or girlhood, of adolescence, of manhood or womanhood and of old age. The period of infancy terminates at two, when the first dentition is completed; that of childhood at seven or eight, when the second dentition is finished; that of boyhood or girlhood at the commencement of puberty, in temperate climates from the 14th to the 16th year in the male and from the 12th to the 14th in the female; that of adolescence extends to the 24th year in the male and the 20th in the female; that of manhood or womanhood stretches on till the advent of old age, which comes sooner or later, according to the original strength of the constitution in each individual case and the habits which have been acquired during life. The precise time of human existence similarly varies. See Longevity.

In Geology.—Age, as used by geologists, represents a subdivision of time variously evaluated. It has been used as the equivalent of Era (q.v.), but as now generally understood constitutes a subdivision of an epoch.

Ages of the World.—We find the ages of the world mentioned by the earliest of the Greek poets. Hesiod speaks of five distinct ages: (1) The Golden or Saturnian Age, when Saturn ruled the earth. The people were free from the restraint of laws; they had neither ships nor weapons, wars nor soldiers; the fertile fields needed no cultivation, and perpetual warfare blessed the earth. In which he describes as licentious and wicked. (3) The Bronze Age, violent, savage and warlike. (4) The Heroic Age, which seemed an approximation to a better state of things. (5) The Iron Age, when justice and honor had left the earth 20 years of age. The age of serving in the militia is from 16 to 45 years. The sovereignty of the realm is assumed at 18; though the law recognizes no minority in the heir to the throne.
AGEN.—AGE OF REASON 395

religious sentiments of various nations. We
find examples of it in the thousand years of
the Milennarians and in the four yogas or
ages of the Hindus. The first or Krita Yuga,
a kind of Golden Age, lasted, according to
their tradition, 4,000 divine years, each equal
to 360 solar years, and adding its tone and
after "twilight," 1,728,000 solar years in all;
men then lived 100 years and were all giants;
the second, or Brähma Yuga, which lasted a
day—2,000 divine years, men lived only 300 years and vice began to creep
into the world. During the third age or
Dwapär Yuga, which lasted 2,000 divine years
and 864,000 solar years, men lived only 200 years
owing to the increase of vice. The last age,
the Káli Yuga, that in which we now live, is
to last for 1,000 divine or 432,000 solar years
and the life of man is sunk to one-fourth of
its original duration.

Age of Animals.—The duration of life in
animals is generally between seven and eight
times the period which elapses from birth till
they become adult; but this rule, besides being
very vague, is practically unvalid, because it
affords no scale of gradation which
would enable us to ascertain the precise age of
individuals, the only inquiry of real importance
or of practical application to the interests of so-
ciety. More certain and scientific principles are
derived from observing the growth and decay of
the teeth. See CATTLE; HORSE.

AGÉN, a-zhan, one of the oldest towns in
France, capital of the department of Lot-et-
Garonne, on the Garonne, 74 miles southeast of
Bordeaux. A fine stone bridge of 11 arches
spanning the river, and the aqueduct bridge of
the Canal Lateral is another striking
structure. The town has been an episcopal see with a
 cathedral since the reign of Clovis, prior to
which it was a Roman station. It commands
an extensive agricultural trade, owing to its
position between Bordeaux and Toulouse.

AGENCY, in its widest sense includes ev-
ery relation in which one person acts for or
represents another by his authority. In the
more restricted sense in which the term is used
in the law of principal and agent, agency may
be defined as the relation which results where one
person, called the principal, authorizes an-
other, called the agent, to act for him, with
more or less discretionary power, in business
dealings with third persons. It is a representa-
tive relation, its fundamental maxim being,
Quis facit per alium facit per se. The agent
represents, acts for, and derives his authority
from another, his principal; he is an attorney
standing in the place of his employer. It is
also a fiduciary relation which is one of trust
and confidence. See Agent.

AGENT, in law, one person who acts for
another, called the principal. If a person acts
as agent without authority, the subsequent rati-
fication of the act will make it binding on the
principal just as if he had originally directed it.
When an agent acts within the scope of his
employment he may bind his principal, and the
principal is liable for any fraudulent acts or
wrong-doings of the agent so acting. If the
agent, having power to bind his principal, does
so expressly, he is not liable; but if he exceeds
his authority he becomes personally responsible.
The agent is bound to obey the instructions of
the principal, and if, in violating them, he binds
his principal to a third person, he is personally
liable to make compensation. He cannot deal
in his principal's affairs to his own profit. The
right on the part of an agent to act is called his
authority or power. The authority or power
must in some instances be exercised in the
name of the principal, and the act done is for
his benefit alone. As a general rule, an agent
cannot delegate his authority without special
authority from his principal, consequently an
agent cannot create a subagent without special
permission. Any person may act as agent
whom the principal wishes to appoint. So
broad is this rule that married women and
infants, who are incapable of acting in their
own behalf, may act as agents, for the ap-
pointment takes away the legal insufficiency
and permits them to bind their principals when
they could not bind themselves. The mode of
appointment depends upon the nature of the
agency. By a rule of law the evidence of
appointment must be of as high a nature as
the thing to be done. Thus, to execute a
deed must be written as a deed, under seal.
When the authority or power is
coupled with an interest, or when it is given
for a valuable consideration, or when it is a
part of a security, then, unless there is a
special agreement that it shall be revocable, it
cannot be revoked. Death, insanity, bankruptcy,
the extinction of the subject-matter of the
agency or the execution of the trust will
usually terminate the agency unless the au-
thority is coupled with an interest. Upon the
law of agency is based to a large degree the
law of partnership.

AGENTS-GENERAL, representatives in
London of the self-governing British colonies.

AGE OF CHIVALRY. The, or THE
LEGENDS OF KING ARTHUR, by
Thomas Bulfinch, was published in 1858. More
than 20 years after an enlarged edition appeared
under the editorship of Edward Everett Hale.
In Part I the legends of King Arthur and his
knights are considered; Part II deals with the
Mabinogion, or ancient prose tales of the
Welsh; Part III with the knights of English
history, King Richard, Robin Hood and the
Black Prince. From the time of its first publi-
cation the popularity of the book has been
great. No more sympathetic and fitting intro-
duction could be found to the legends of
chivalry.

AGE OF FABLE, The, or THE BEAU-
ties of Mythology, by Thomas Bul-
finch, was published in 1855, and republished
in 1882 under the editorship of Edward Everett
Hale. It has become a standard work upon
mythology, by reason of its full and extensive
treatment of the Greek and Roman myths.

AGE OF REASON, The, by Thomas
Paine, was first published in a complete edition
25 Oct. 1795. In 1793 the first part, appeared,
but no copy bearing that date can be found.
Part I consists of an inquiry into the bases of
Christianity; its second part deals with claims of
revelation. The process is destructive and
revolutionary. In Part II the author makes
critical examination of the Old and New Testa-
ment, to support the conclusions and inferences
of Part I. Yet the work is not wholly negative. "The Word of God is the creation we behold."

**AGERATUM**, a-ger'-a-tum, a genus of plants of the family Asteraceae (belonging to the Eupatorium tribe of the order), chiefly natives of the warmer parts of America. One species, A. houstonianum, is an annual plant of flower borders and has densely clustered heads of lavender-blue flowers. Several others are also grown in gardens, some of them with purple, white or pale blue flowers.

**AGESANDER**, a Greek sculptor of the Rhodian school, who with Polydorus and Athenodorus, 42–21 B.C., are mentioned by Pliny as authors of the famous Laocoon group, discovered near the baths of Titus in 1568, and now in the Vatican at Rome.

**AGESILAUS**, King of Sparta: b. 442 B.C., and elevated to the throne after the death of his brother Agis II, in 398. Called by the Ionians to their assistance against Artaxerxes, he commenced his glorious career by defeating the Persians and defending Sparta against the united attack of Thebes, Corinth, etc. In a subsequent war with Thebes he had to contend against Pelopidas and Epaminondas, the greatest generals of those times. His prudence, however, saved Sparta without the hazard of a battle. He delivered it anew at the age of 80 years, though it was actually in the hands of Epaminondas. In the spring of 361 he crossed over to Egypt with a body of Lacedaemonian mercenaries, and there, after displaying much of his former ability, he died while preparing for his voyage home, in the winter of 361–360. Though small and insignificant in person he was a noble prince and almost adored by his soldiers.

**ALLOMEREATE**, in geology, a name applied to a rock consisting of angular fragments of other rocks, united or bound together by a matrix of similar materials but of finer texture. The rock is of volcanic origin, but the fragments may be either volcanic or sedimentary, having been ejected from some volcano.

**AGGLUTINATE LANGUAGES**, languages in which the modifying suffixes are as it were glued on to the root, both it and the suffixes retaining a kind of distinctive independence and individuality, as in the Turkish and other Turanian tongues. Consult Max Müller's "Lectures on the Science of Language."

**AGGLUTINATION.** See IMMUNITY.

**AGGREGATION.** See GRADATION.

**AGGREGATION, States of,** an expression sometimes used to signify collectively the various physical states in which matter can exist. For ordinary purposes it is sufficient to distinguish two fundamentally different states of aggregation, the solid and fluid; fluids being further subdivided into liquids and gases. A solid body may be defined as one that is capable of resisting a considerable shearing-stress. It is important to note, however, that a true solid does not yield continuously to a small deforming force; it resists deformation, and its resistance increases as the deformation increases. A fluid body, on the other hand, having almost no shearing-strength and offering very little resistance to forces that tend to change its shape. A fluid yields continuously to a deforming force, and a force that will deform it at all will deform it indefinitely, so long as it is allowed to act. Considering the subdivision of fluids into gases and liquids, it may be said that a gas is a fluid that presses continuously in every direction on the walls of the vessel containing it, and which follows them indefinitely if they retreat. A gas, if left to itself, tends to expand infinitely in every direction. A liquid may be defined as a fluid which does not follow the walls of the containing vessel if they retreat, and which has no tendency to sudden and indefinite expansion when freed from all restraint.

These distinctions between the various states of aggregation in which matter occurs are to a certain extent arbitrary, elastic, indefinite and inexact. For example, certain kinds of pitch resist the action of deforming forces that are applied for a short time only, and are brittle enough to fracture, like glass, under the influence of a sudden stress; yet they yield slowly but continuously to very small deforming forces, when those forces act for a long time. A body of this sort, strictly speaking, is neither a solid nor a liquid, and to avoid general classification we should have to have a "semi-solid" division. The distinction between liquids and gases is even more artificial than that between solids and liquids; for a liquid may be made to pass into its vapor in such a manner that it is impossible to state at what moment it ceases to be a liquid. Thus, if water is heated under a sufficiently great pressure up to 700° F., and is then allowed to expand by a sufficient amount at this temperature and is finally cooled at constant volume, we shall find, at the end of this operation, that it has been entirely transformed into steam, although we cannot say at what stage the transformation took place. See CRITICAL POINT; EQUILIBRIUM, CHEMICAL; MOLECULAR THEORY; THERMODYNAMICS; MATTER.

**AGHA KHAN,** title of the spiritual head of the Indian Ismailites or Khodjas, a Mohammedan sect. The office is vested in a very ancient and sacred family said to be descended from Mohammed's daughter Fatimah; but more directly from the Samh, founder of the Ismailiah dynasty in Persia (d. 1124). This weird but mighty personage became chief of the dreaded Assassins (q.v.), well known by the Crusaders and completely exterminated by the Tartar King Halaku of Persia in 1256. The present holder of the title is the third in succession. A remarkable feature of the three Agha Khans is their absolute and whole-hearted devotion to Great Britain. Agha Khan I, Hasan Ali Shah, b. Persia 1800; d. Bombay, 12 April 1881, was governor-general of the province of Kerman under the Shah Fath Ali. He fled from Persia in 1840 after an attempt to gain the throne, at which his family aimed, and settled in Bombay. Here he held a royal court for 30 years. He assisted the British with his private cavalry in the Afghan War, 1842, and later rendered numerous valuable services to the British government, which granted him a pension. A recognized "king without a country," he exercised over his followers, collected a large annual tribute, and became a keen sportsman, with a special fondness for horse racing. Agha Khan II, Agha
Ali Shah, son of the preceding, reigned only four years; he continued in his father’s policy, received a knighthood from Queen Victoria, and became a member of the Bombay legislative council. He died in 1885 and was succeeded by his son: Agha Sultan, Sir Muhammad Shah, K.C.I.E., G.C.S.I., LL.D., Agha Khan III, b. 1875. He holds a spiritual sway over some 60,000,000 followers in India, central Asia, East Africa, Morocco, and China. At the outbreak of the European War, he was visiting his adherents in Zanzibar; he not only exhorted all his people to place their personal services and resources unreservedly at the service of the British government, but himself volunteered to accompany the Indian Expeditionary Force as a private in any infantry regiment, since he had not had any military training to justify a commission. When Turkey entered the war he issued a powerful manifesto to Moslems throughout the empire strongly condemning her action. At the risk of his life, he visited Egypt in the critical period immediately following Turkey’s adherence to the Central Powers, insisted on a thorough reorganization which followed the deposition of Abbas Hilmi II (q.v.). During 1911-13 he was instrumental in soothing the grave disquietude of Indian Moslem sentiment in respect of the Turkish war, and, with a masterly touch, urging upon his coreligionists the imperative duty of resignation to the inevitable waning of the Turkish power in Europe and of acquiescence in British policy. An enthusiastic supporter of the Allies against Germany, he has upheld their cause in public speeches and writings. In April 1916 King George, Emperor of India, granted to His Highness the Agha Khan a salute of 11 guns and the rank and status of a first class chief of the Bombay Presidency for life. This very exceptional honor is the more noteworthy as his authority is entirely spiritual and there is no state in India where he holds sway as ruler. In 1902 he was the guest of the British nation at the coronation of the King. In 1905 the Kaiser conferred on him the First Class Prussian Order of the Royal Crown.

AGINCOURT, á-jí-nô’kt, or AZINCOURT, á-zhahn-koor, France, a village, department of Pas-de-Calais, famous for a battle fought there 25 Oct. 1415. Henry V, King of England, eager to conquer France, landed at Harleuf, took the place by storm and wished to march through Picardy to Calais, in order to fix his winter quarters in its neighborhood. With a powerful force the Dauphin advanced against him. Henry V, retreated to the Somme. The French followed to harass his retreat and to defend the passage from Abbeville to Saint Quentin, which he gained only through the inattention of the enemy. The English, however, being destitute of everything and reduced by sickness, Henry asked for peace on advantageous terms. The English refused his proposals and succeeded in throwing themselves between Calais and the English. These latter consisted of 2,000 men-at-arms and 12,000 archers, and were arranged in order of battle between two hills, with archers on the wings. Stakes, of which every man carried one, were fixed in front of them. The French, commanded by the Constable d’Albret, numbered 50,000 troops, of whom 8,000 were men-at-arms; but other estimates make the French strength much greater. They arranged themselves in two divisions, with the men-at-arms, of whom 2,000 were mounted, in front. The English first put themselves in motion. The French horse instantly hastened to meet them, but were received with such a shower of arrows by the archers that they fell back on the first division and threw it into confusion. The light-armed English archers seized their clubs and battle-axes and broke through the ranks of the French knights, who could hardly move on account of their heavy coats of mail and the closeness of their array. The English horse rushed to assist the archers; the first French division retreated; the second could not sustain the charge of the victors; and the whole French army was soon entirely routed. The victorious army, in the pursuit of the flying enemy, took 14,000 prisoners in addition to those previously captured; 10,000 Frenchmen lay dead on the battlefield. Among them was the Constable of France, with six dukes and princes. Five princes and two dukes of Orleans and Bourbon, were taken prisoners. The English lost 1,600 men killed; among them the Duke of York, Henry’s uncle, whom the Duke d’Alençon slew at his side while pressing toward the King, d’Alençon had dashed the crown from Henry’s head and lifted his hand for a more effectual blow, when the King’s attendants surrounded him and he fell covered with wounds.

AGIRA, à-jérà, Italy, a town of Sicily, 35 miles west of Catania. It stands over 2,000 feet above sea-level and is four and one-half miles from its railway station to the south of the town. In the neighborhood are fine marble quarries which yield its chief industry. It is famous as the site of ancient Agrigium, ruled by Sicel tyrants, notably Agrisius, who became the leading ruler of central Sicily, and an ally of Dionysius I when they overthrew Gela. The Carthaginian invasion 392 B.C. Hercules visited Agris according to Diodorus Siculus the historian who was born here, and Timoleon 339 B.C. expelled the last tyrant, and erected several fine buildings. Pop. 22,500.

AGIS, á’tis, the name of four Spartan kings. Agis I, son of Eurysthenes, founder of the family Agida, and reputed conqueror of Helos. Agis II, son of Archidamus II, and reigned either in 427 or 426 B.C. to 400 or 399 B.C. He was active in the Peloponnesian war; invaded Attica several times and conquered the Athenians at Mantinea in 418 B.C. Agis III, son of Archidamus III, reigned in 338-331 B.C. He endeavored to overthrow the Macedonian power in Europe, but was routed and killed in a battle with Antipater in 331 B.C. The most important of the four kings was Agis IV, who succeeded to the throne in 244 B.C., and reigned four years. He attempted a reform of the state—his plan comprehending a redistribution of the land, a division of wealth and the canceling of all debts. Opposed by his colleague, Leonidas, advantage was taken of his absence in an expedition against the Ætolians to depose him. Agis at first took sanctuary in a temple, but he was entrapped and hurriedly executed by his rivals.
AGLIARDI, a-lyar'dé, Antonio, Catholic cardinal and diplomat: b. Cologno (Bergamo), Italy, 4 Sept. 1832. After service in Canada as bishop’s chaplain, on his return to Rome in 1884, he was appointed secretary of the Propaganda, created archbishop of Caesarea in Palestine, and proceeded to India to investigate conditions. In 1887 he returned to India as apostolic delegate to settle the Goa controversy with Portugal. He was appointed papal nuncio to Munich in 1889 and to Vienna in 1892. In 1896 he was recalled at the request of the Hungarian government for being involved in the disputes which had arisen with the church authorities. The same year he was created cardinal-archbishop of Ferrara, and in 1903 vice-chancellor of the Catholic Church.

AGLIPAY, Gregorio, archbishop and head of the Independent Catholic Church of the Philippines: b. about 1864. An Ilocano by birth, he was educated in a Roman Catholic seminary and ordained in Manila about 1890. He was trusted by his superiors and rapidly advanced. At the time of the insurrection he was excommunicated by the church authorities for some irregularity in church order. He then cast his lot with the insurrecto movement, and Aguinaldo made him vicar-general. On 4 April 1899 he *came in* and took the oath of allegiance. In October 1902 he with others formed the Independent Catholic Church of the Philippines. The movement spread rapidly. One million five hundred thousand soon joined it. He recommends the reading of the Bible by his people. Consult H. C. Stuntz, 'The Philippines and the Far East,' to which we are largely indebted.

AGLOSSA, á-glos'sa (Gr. α, priv.; glossa, tongue), a group of the order Anura (toads and frogs) containing only two living families, the South American Pipidae and the African Xenopidae, and characterized by the lack of any tongue and the union of the eustachian tubes into one opening far back in the palate. The pipa toads and South African plathandlers are herbivorous. The group is interesting for its antiquity and primitive relationships.

AGNADELLO, an-a-de'llo, North Italy, a village 10 miles east of Lodri, near which Louis XII of France completely defeated the Venetians, on 14 May 1509, and the Duke of Veneto gained a victory over Prince Eugene in 1705.

AGNAO, an-yá'nō, till 1750, small lake, three miles west of Naples, about 60 feet in depth, and without visible outlet. As it was supposed to cause malaria it has been drained. The surrounding country is volcanic and mountainous. On the right lies the Grotta del Cano, where the carbonic acid is dense enough to kill dogs, and on the left are found the sulphurous vapor baths of San Germano, which are valuable for gout and blood disorders.

AGNES, Saint, a saint who, according to the received account, because she steadfastly refused to yield the iron of the prefect of Rome, was adjudged to be burnt with the stake, but as the flames did not injure her she was beheaded. Her festival is celebrated on 21 January. Domenichino painted a picture representing her at the moment of her execution.

AGNESI, á-ný'sē, Maria Gaetana, a learned Italian lady: b. Milan 1718; d. 1799. In her 9th year she was able to speak Latin, in her 11th, Greek; she then mastered Oriental languages, and next geometry and philosophy, mathematics having latterly engaged her chief attention. She was appointed, in 1750, professor of mathematics in the University of Bologna, ultimately taking the veil. Her sister, Maria Theresa, composed several cantatas and three operas.

AGNES OF SORRENTO, a romance by Harriet Beecher Stowe. The scene is laid in central Italy during the papacy of Alexander VI (1492–1503). Agnes is the daughter of a Roman prince who secretly marries and then deserts a girl of humble parentage. The young mother dies of grief, and Elsie, the grandchild, takes Agnes to Sorrento, where she lives by selling oranges in the streets. Her beauty and her purity attract to her many lovers, worthy and unworthy, and involve her in many romantic and dramatic incidents.

AGNEW, Cornelius Rea, American physician: b. New York, 8 Aug. 1830; d. 8 April 1888. Professor of diseases of the eye and ear in New York College of Physicians and Surgeons. He was a graduate of Columbia College, and later studied in Europe; was surgeon-general of the State of New York at the beginning of the Civil War, when he became medical director of the New York State Volunteer Hospital. As member of the United States Sanitary Commission he contributed largely to its success. In 1868 he founded the Brooklyn Eye and Ear Hospital. He was interested in the public schools of New York; became founder of the Columbia College School of Mines, and in 1874 one of the trustees of the college. His writings are chiefly monographs on diseases of the eye and ear.

AGNEW, David Hayes, American surgeon and medical writer: b. 24 Nov. 1818; d. 22 March 1892: for many years surgeon of surgery at the University of Pennsylvania. He was also the operator in several important cases, notably that of President Garfield. He published 'Practical Anatomy' (1867); 'Anatomy and Its Relation to Medicine and Surgery,' 'Principles and Practice of Surgery' (1878);

AGNO, ag'nō, important river in the northwest part of Luzon, Philippine Islands. It is about 90 miles in length, describing a circuitous course, parallel with a range of coast mountains, and emptying into Lingayen Gulf. The town of Lingayen is at the mouth of the river, which is accessible by railway from Manila.

AGNOSTICISM (Gr. ἀγνωστός, unknowing), a school of thought which holds that man can know nothing of ultimate realities, or whether they exist; since, his only means of knowledge being through comparison of phenomena, the absolute could not be known in this sense on assuming phenomenal traits, and would then be grasped as a phenomenon and not as absolute, the knowledge of which is therefore a contradiction in terms. We cannot know anything outside our own mental processes and the
existence of other minds; in popular phrase, we cannot get behind the looking-glass. This does not, however, deny the absolute any more than affirm it; and most agnostics (as Clifford, one of the greatest) consider the diversity of phenomena as probably indicating a diversity in their causes. The agnostic position involves refusal to accept *evidences* of the origins of the universe, of unseen powers, of a future life, or in general the metaphysical bases of religious belief. The probable is more probable than the inferences. The current idea that it involves rejection of these beliefs, however, is entirely wrong; the agnostic does not admit that either the affirmative or the negative of them can be a subject of knowledge, and regards the atheist as less intellectually respectable than the devout. In point of fact, Professor Huxley, the inventor of the term, thought the existence of beings higher than man rather probable than otherwise, and the government of the universe by a *divine syndicate* of great spiritual essences quite logical. The theory is practically that of the Pyrrhonist or Skeptical school of Greek philosophers. See Epistemology; Huxley, Thomas Henry; Spencer, Herbert. 

**AGONY COLUMN**, a jocular name given to the column in newspapers set aside for advertisements of missing or runaway persons, lost property, help appeals, etc. Some of these are often couched in agonizing terms.

**Agoracritus**, Greek sculptor; b. Paros in the 5th century; the favorite pupil of Phidias. His chief work, by some attributed to his master, was the colossal statue of Nemesis at Rhampus, the head of which is in the British Museum and fragments of the pedestal reliefs in the Athens Museum.

**Agnes Dei.** See Sacramentals.

**Agoraphobia**, a type of phobia in which the patient experiences great anxiety and distress when in open spaces, such as an empty theatre, a very large room, an open square, etc. It is but one symptom found among a number of related neurotic signs in many neuroses and phychoneuroses. It is found, however, in its most striking form in that psychoneurotic group known as the Compulsion Neurosis (q.v.).

**Agosta, a-gosta, or Augusta**, a seaport on the southeast coast of Sicily, in the province of Syracuse. It was a scene of some importance before the earthquake of 1693, which buried a third of the inhabitants in its ruins, and at the same time ignited the powder magazine, and blew up the citadel. It was off this port that De Ruyter, the famous Dutch admiral, in command of his Dutch and Spanish fleet, 22 April 1676, was defeated by the French under Duquesne, and received his death wound. Pop. about 16,400.

**Agoult, a-goo', Marie Catherine Sophie de Flavigny, Comtesse d', French author: b. Frankfort-on-Main, 31 Dec. 1805; d. Paris, 5 Mar. 1867.* Daniel Stern. In 1827 she married Comte Charles d'Agoult, but separated from him to live with Franz Liszt who was the father of her three children; a son who died young, and two daughters Blandine, who became Mme. Emile Olivier, and Cosima who married Hans von Bülow and later Richard Wagner. She is the *Arabella* in the *Lettres du voyageur* of *George Sand* with whom she frequently associated during her European travels. Under the royal régime of Louis Philippe, she was associated with the literary and artistic side of Parisian life; after the creation of 1848 with its political life. Her best known works are *Équises morales et politiques* (1849); other works include *Lettres republicaines* (1848), on the government of Louis Philippe; *L'Historie de la Revolution de 1848* (3 vols., 1850-53); the novels *Herve* (1841), and *Néilda* (1845) describing her rupture with Liszt; *Jeanne d'Arc*, a national drama (1857); and *Mes Souvenirs, 1806-1833* (1877). Consult Rochelaure, S., *Une amitié romanesque: George Sand et Mme d'Agoult* (Paris 1895).

**Agouti, a-go'oo', AGOUTY or AGOUTI**, South American and West Indian rodents of the Dasyprocta family and genus *Cavia*. They are nocturnal woodland prowlers feeding on nuts, fruits and roots and frequenting sugar cane and banana plantations, where with grunting enjoyment they frequently dig considerable damage. Several species are black, from 15 to 20 inches long, with slender limbs, five front and three hind toes, and short nails, they hide in the day in the hollows of trees and in burrows among the roots. There are a dozen species of which the West Indian variety, black and brownish with yellow hind quarters, and Azara's *acuñi* of Guiana, are the best known. In Brazil and southward to Patagonia, the *pampas hare,* *cavy* or *agouti* is hunted as game.

**Agra, a-gra**, India, a city in the North-west Provinces, on the right bank of the Jumna, 841 miles by rail from Calcutta. It is a well-built and handsome town and has various interesting structures, among which are the imperial palace, a mass of buildings erected by several emperors; the Moti Masjid Mosque (both within the old and extensive fort); the mosque called the Jama Masjid (a cenotaph of white marble); and above all, the Taj Mahal, a mausoleum of the 17th century, built by the Emperor Shah Jahan to his favorite queen, of white marble, adorned throughout with exquisite mosaics. There are several Protestant and Roman Catholic churches, a government college and three other colleges or high schools, besides a medical college. Agra has a trade in grain, sugar, etc., and some manufactures, including beautiful inlaid mosiacs. It was founded in 1566 by the Emperor Akbar, and it was a residence of the following emperors for over a century. Pop. 185,500.

**Agram, a-gram**, Austria-Hungary, capital of the crownland of Croatia-Slavonia, between the banks of the Save and the foothills of the Agram Mountains rising in the background to 3,400 feet, 188 miles by rail south of Vienna. Of Roman origin, Agram was made the see of a bishop in 1094. It was ravaged by the Mongol-Tartars in 1242, but after their expulsion it was rebuilt and created a royal free city. It was made the capital of Croatia-Slavonia in 1867 and is an important Slavic
AGRAPHA — AGRARIAN PARTY

national centre. Earthquakes in 1880 and in 1901 did considerable damage. Divided into the Kapitel-Stadt or Bishop's town, and the upper and lower towns, the city has numerous fine buildings, including the cathedral of the 15th century, the governor's palace, the Academy of Sciences, the Franz-Josef University and the national theatre. Street railways connect the different districts. Active trade is carried on in wine, grain, silk, porcelain, etc., and there are thriving manufactures of cannons, ammunition, carpets, tobacco, leather, linen, etc., besides important state railroad works. Pop. 80,000.

AGRAPHA, ág'rāfə, signifying "unwritten," sayings not recorded in the New Testament, but found in the MSS. of early Christian writers, and ascribed to Jesus. I. G. Körner first used the term in 1776, but its general adoption dates from 1889, when Alfred Resch used 'Agrapha' for the title of his work on the 'Sayings' in Gebhardt and Harnack's 'Texte und Untersuchungen.' Among early debated examples of the sayings are: "That which is weak shall be saved by that which is strong"; "Wretch destroyeth even wise men"; "A man is unapproved if he be untempered," and "Jesus on whom be peace, has said: The world is merely a bridge; you are to pass over it, and not to build your dwellings upon it," this last found inscribed in Arabic on the gateway of a mosque at Fathpur Sikri, by Rev. Alexander Duff, missionary to India, 1839. The most important of the sayings are those found in 1897 and 1903 by Grenchell and Hunt at Bahnasa, ancient Oxyrhyncus in Egypt, all beginning "Jesus saith." Among these are: "Jesus saith, Except you fast to the world, you shall in no wise find the Kingdom of God"; "Jesus saith, I stood in the midst of the world, and in the flesh was I seen of them, and I found all men drunken and none found I aithrist among them, and my soul grieved over the sons of men, because they are blind in their heart, and see not," etc. "Whenever there are two they are not without God, and wherever there is one alone, I say I am with him. Raise the stone, and there thou shalt find me; cleave the wood and there am I." Besides Resch's work consult also Grenchell, B. P. and Hunt, A. S., 'Logia Jesu: Sayings of Our Lord from an Early Greek Papyrus' (London 1897); 'New Sayings of Jesus and Fragment of a Lost Gospel from Oxyrhyncus' (London 1904); Pick, B., 'Paralipomena: Remains of Gospels and Sayings of Christ' (Chicago 1908).

AGRARIAN LAWS, enactments framed at different times by the Romans to regulate the public domain. In the first epoch of the growth of Rome, before the city had extended beyond the Palatine Hill, the whole soil of the state was undivided public property, and from this consisting exclusively of citizens, every citizen received a share for his private use. In principle all the land was therefore undivided public property, and the citizen could only acquire possession as tenant at will of the state. In course of time, however, the descend- analogues of the original holdings, or the patricians transformed these primitive concessions into an absolute right called in the Roman law de jure acquirere. During the entire existence of the republic the principle was recognized that all lands and personal property acquired by conquest were acquired for the state, and could only become the property of individuals through the cession to them of the rights of the state. As conquest increased the public property, and the class of plebeians was formed, the Roman government gave them an interest in the public domain as private property on condition of their paying a tribute and undertaking other public services. The patricians, however, always preserved their ancient right of receiving in possession and using portions of the public property on paying to the public treasury a tithe of its product. From the earliest period of Roman history lands thus held fould patr since the land was not an inheritance to children, and were even sold under this uncertain tenure, while the state always reserved the power to resume possession. Spurius Cassius, a patrician, on becoming consul in the early period of the republic, caused a law to be enacted that persons holding the public lands, long before conquered, but occupied by the Roman nobles, shall be surrendered to the state and assigned to the needy citizens. The law remained a dead letter because of the resistance of the patricians, who not only prevented any new issue of public lands, but by violence or usury acquired those of the plebeians. The keeping of large flocks of cattle practically ruined the common pasture lands, and in fact excluded the small farmers from them. This caused the publication, in 367 a.c., of the Licinius law, so called from Licinius Stoto, its originator. For a brief period this law was put in force, after which it was neglected for nearly 200 years, when it was renewed by Tiberius Gracchus with some additions and modifications in favor of the patricians. The attempt to execute these laws caused the death of the two Gracchi (133 and 121 b.c.). Not one of the Agrarian laws was ever executed, and it is said by the ablest writers that they had none of that leveling and beneficent character which the framers of them attributed to them. It is believed by able writers that none of the laws aimed at the equal division of real estate owned by individuals in their own absolute right, or intended any limitation upon the ownership of land. The most prominent advocates of the Agrarian laws, Cassius, Licinius and the Gracchi, all belonged to the class which would have been injured by their operation had they led to an undue interference with the right of private property.

AGRARIAN PARTY, a political organization in Germany, representing the interests of the landlords (in political life). The first steps toward the formation of the party were taken by an assembly called together at Breslau, in May 1869, by M. A. Niendorf (d. 1878), and Elsner von Gronow, but the theory on which the party was based had already been formulated by Johann Karl Rodbertus. The organ of the party was Die Deutsche Landeszeitung, edited by Niendorf. In February 1876 a constitutional assembly of agrarian reformers was opened, and adopted the official name of "Steuer und Wirtschaftsreformer." Their program was especially devoted to the abolition of taxes on land, buildings and trades. At first especial emphasis was laid on free trade, but this object fell more and more into the back-
ground after 1879. Since that date they have sought to limit the importation of food stuffs, and have opposed several commercial treaties supported by the government; they have also opposed the Emperor’s project for a canal system, and have been hostile to his naval policy. As the Agreats dominate the Conservatives in the Reichstag they have frequently obtained important concessions in commercial matters and forced the government to turn to the Radicals for support for its measures.

**AGRAVIADOS.** The Catalan insurgents in 1825 called themselves by this name, or men with a grievance.

**AGREDA,** a-grá’dá, Maria (Coronel) de, Spanish abbess and author: b. 2 April 1602; d. 24 May 1665. Extremely devout. From an early age, she entered a convent at Greda when 17 years old, under the name of Sor (Sister) Maria de Jesus, and eight years later was appointed abbess. Her prominence is due to her posthumously published writings, chief of which is ‘La mistica ciudad de Dios, historia divina de la Virgen, Madre de Dios,’ (The mystic city of God, the divine history of the Virgin) printed in Madrid in 1670. When translated in French and published at Marseilles in 1697, it created an international controversy which lasted over half a century. Her lengthy correspondence with Philip IV from 1642 to 1655 was printed in Madrid in 1885, and is distinguished by its excellent style and valuable illustrations of contemporary Spanish life.

**AGREEMENT,** a mutual bargain, contract or covenant. Agreements may be either express or implied. Express agreements are those openly stated and avowed by the parties at the time of their making. Implied agreements are those which the law supposes the parties to have made although the terms were not openly expressed. There must be an agreement by the parties, a definite offer made by one party and accepted by the other, and they must assent to the same thing in the same sense. The assent must be mutual and obligatory, and there must be a request on one side and an assent on the other. The assent must be broad enough to cover the whole proposition. It must be exactly equal to its extent, sense, and division, and it must not qualify them by any new matter, and even a slight qualification destroys the assent. The agreement must be based upon a sufficient consideration (q.v.), and against third persons this consideration must be good or valuable. It need not be adequate provided it has some real value. If the consideration is impossible, or illegal either in whole or in part, the agreement will be void. The assent may be to do anything permitted by the law, as to sell and buy real estate or personal property. The evidence of the sale of real estate, however, must be by deed, and sealed. In many instances agreements in regard to personal property must be reduced to writing.

A hire-purchase agreement is a contract, usually in writing, by which one agrees to hire or purchase goods on instalments, the title to the same remaining in the lender or vendor until the last instalment has been paid, and in case of default in any payment or breach of any part of the contract by the hirer or vendee, the prior payments are forfeited to the lender or vendor. It is virtually a conditional sale, and has become of increasing importance during recent years. See CONTRACTS; SALE.

**AGREEMENT OF THE PEOPLE, The,** a document proclaimed by the Council of the Army, 15 Jan. 1649, a fortnight before the execution of Charles I of England. It is based on the Heads of the Proposals of the Army, 1 Aug. 1647, except that no reference is made to royalty. It is, in fact, the rough draft of a constitution for a republic. It provided that the existing Parliament was to be dissolved and that a representative assembly, composed of not more than 400 members, was to be elected by the people every two years on the first Thursday in May. The franchise was conferred on all who were assessed ordinarily toward the relief of the poor, over 21 years of age, and housekeepers dwelling within the division for which the election is held. There was also to be a Council of State for the management of public affairs. Christianity was adopted as the religion recommended as the public confession, but the Papists were tolerated. The assembly was given the supreme trust in order to the preservation and government of the whole, but six points were reserved from its legislative action. Except for the constitutions of the Connecticut and New Haven colonies this is the first record of a republican constitution. But as its promulgators, the Levellers, were defeated by Cromwell, it was never put into effect. A full text of this remarkable document may be found in Gardiner’s ‘Constitutional Documents’ (Garrick’s Works, 1839).

**AGRIGOLA,** Gnaeus Julius, lived from A.D. 37 to 93, and was a Roman general and governor in Britain, the greater part of which he brought under the dominion of Rome. His life (which extended through the reigns of the nine emperors from Caligula to Domitian) has not been excellently written by his son-in-law, Tacitus, who holds him up as an example of virtue. Agricola was born at Forum Julii (now Fréjus in Provence), and was the son of Julius Gracchus, a senator put to death under Caligula. He served his first campaign in Britain in 60, and after serving in Asia Minor and again in Britain, and governing Aquitania a prætor for three years, he was raised to the consulship in 77, and the next year went to Britain as governor. Agricola was the twelfth Roman general who had been in Britain, but was the only one who effectively subdued it; partly by his consummate military skill, partly by his policy in reconciling the Britons to the Roman yoke and by teaching them the arts and luxuries of civilization. In his fourth campaign he built a chain of forts between the Forth and Clyde to help to keep in check the peoples to the north of this. His seventh and last campaign (A.D. 84) was marked by the total defeat of the Caledonians under Calgacus, at a place called by Tacitus Muro, or Grampius. In this campaign his fleet sailed northward from the coast of Fife round Britain to the Trutulensian harbor (supposed to be Sandwich), thus for the first time proving that the country was an island. His death was either caused or hastened by the munitions of the jealous tyrant Domitian.
AGRICOLA, Gnaeus Julius, Life of. The story of Agricola's life is told by his son-in-law, the historian Tacitus, in what is, perhaps, the most artistic biography that has come down to us from ancient times. It was avowedly written to do honor to its subject, and is in no sense a critical estimate of his character and achievements. The state had fallen on evil days. Was it possible for men to be treated even under bad rulers? The question has often arisen in the history of the world, and has been variously answered by honest men. Tacitus was himself convinced that political martyrdom is inexpedient unless the resultant gain to one's country is beyond all comparison. "Conscripti, moderando," he holds (Agr. 42) "if combined with diligence and energy, attain those same heights of glory to which very many have climbed by perilous paths, gaining fame, without any risk of injury to the person, by an honorable death." It is in this spirit that he describes the career of an upright and highly efficient public servant who knew when it was prudent to avoid futile opposition to the inevitable, and who did his duty unobtrusively under a tyrant in order to prepare the way for a better rule. The style in which this memoir is written represents an early stage of that unique manner which is associated with the name of Tacitus. There is already a tendency to compress the thought, sometimes to the point of obscurity, a preference for short independent sentences rather than the intricately balanced period, a readiness to modify almost any accepted rule of prose structure, and a remarkable mastery of pointed phrase. A very famous specimen of this last power occurs in the speech of the Gallician chief tainy, Caligatus, before the battle at the Graupian Mount: "To robbery, murder, pillage, they (i.e. the Romans) give the false name of empire, and when they make a solitude, they call it peace." The "De re metallica" has been of very little importance. One admirable rendering is by W. H. Fyfe. Of the "De Re Metallica," consisting of 12 volumes, covering mining, metallurgy and geology, was completed in 1850 and went to press three years later. Originally written in Latin, it was later translated into German, Italian and English, the latter version being published in 1812, in the latter version being published in 1850 and included five volumes on geology. In 1530 he published "Bermannus," his first work on mining. Aside from these, his chief works, he wrote copiously on the same and kindred subjects. In 1560 Agricola, at the request of Duke Maurice, entered public life in a diplomatic and advisory capacity. Though a Catholic himself, he was elected a Burgher by the Protestant electors of Chemnitz, and in the same year was appointed Burghermeister. During the Thirty Years' War he made various missions to Emperor Charles, King Ferdinand of Austria and other potentates. 

AGRICOLA, Johann, German reformer: b. 1492; d. 1566. He was one of the most active among those who propagated the doctrines of Luther. He studied at Wittenberg and Leipzig, and was afterward rector of the university at Eisleben, his native city, and in 1526, at the Diet of Spires, was chaplain of the Elector John of Saxony. He subsequently became chaplain to Count Albert of Mansfeld, and took part in the diet of Augsburg, and in the signing of the articles of Schmalkalden. When professor at Wittenberg, whither he went in 1537, he stirred up the Antinomian controversy with Luther and Melanchthon. He afterward lived at Berlin, where he died after a life of controversy. Besides his theological works he composed a work explaining the common German proverbs. Its patriotic spirit, strict morality and pithy style place it among the first German prose compositions of the time, by the side of Luther's translations of the Bible.

AGRICOLA, Martin, German composer and writer: b. Soran, Silesia, 1486; d. 1556. After 1524 and until his death he was musical director of the Protestant school at Magdeburg. He wrote much on musical subjects. His "Musica Instrumentalis" is invaluable as a source of information in regard to old instruments. It contains many illustrations and explanations of the mechanism and instructions for playing each instrument. It was reprinted by Eitner as volume XX of the publication of the Gesellschaft für Musikforschung. He also wrote "Rudimenta Musice" (1529).

AGRICOLA, Rudolphus, the foremost scholar of the German learning in Germany: b. 23 Aug. 1443, near Groningen, in Friesland; d. 28 Oct. 1485. His real name, Ropold Huyssan (husbandman), he Latinized into Agricola; and from his native place he was also called Frisius, or Rudolf of Groningen. From Groningen he passed to Louvain, then to Paris and then to Italy, where, during the years 1473-80, he attended the lectures of
the most celebrated men of his age, and where he entered into a close friendship with Dalberg, afterward bishop of Worms. On his return home he endeavored, in connection with several of his former codisciples and friends, to promote a taste for literature and eloquence. Several cities of Holland vainly strove with each other to obtain his presence, but not even the enticements of Rome could induce him to follow the Emperor Maximilian, to whose court he had repaired in connection with affairs of the town of Groningen, could induce him to renounce his independence. At length yielding (1483) to the solicitations of Dalberg, he established himself in the Palatinate, where he sojourned alternately at Heidelberg and Worms, dividing his time between private studies and public lectures, and enjoying high popularity. He distinguished himself also as a musician and painter. With Dalberg he revisited Italy (1484), and shortly after his return died at Heidelberg. Most of his works were collected by Alard of Amsterdam (2 vols., Cologne 1539).

AGRICOLITE, a mineral having the same composition as eulytie, but crystallizing in the monoclinic system. It also occurs in globular formed masses, and the crystals, when they occur, are indistinct. The species needs further examination.

AGRICULTURAL ANT, a remarkable species of ant (Myrmica molefaciens) that cultivates fields of grass around its hill, allowing only one kind of grass (Ardisia) to grow in a field, the ants sowing the seeds and storing them away as food. The fields may be as large as 15 feet across; roads are laid out from the hill to the outer margin of the plantation, so that the crop may not be trampled, and any weeds which appear among the grass blades are cut off. These colonies are often found in large grain fields, which they injure in proportion to their numbers.

AGRICULTURAL ASSOCIATION, the voluntary association of farmers with the object of promoting a knowledge of the science of agriculture. The first instance on record of such an organization is that of the Society of Improvers in the Knowledge of Agriculture, founded in 1723 by a group of Scotch agriculturists. It continued its activities for over 20 years and has left behind its 'Select Transactions,' published in 1743. In 1777 the 'Bath and West of England Society' was established, followed by the 'Highland Society' in 1784. The later organization exists to this day as the 'Highland and Agricultural Society of Scotland,' carrying on much the same work as the United States Department of Agriculture. In England the same functions in the development of agriculture were performed by 'The Royal Agricultural Society,' founded in 1838. Its present membership is considerably over 10,000 and at its annual agricultural fairs it distributes as much as $50,000 in prizes. It maintains an experimental station at Woburn and a veterinary college at Camden Town, London. Another organization is the Agricultural Organization Society, Ltd., founded in 1901 to co-operate among the agricultural societies of England and Wales. It has affiliated with it about 400 societies and its membership includes over 20,000 individuals. In Ireland a society of the same name and the same purposes has been very active of recent years, under the guidance of Sir Horace Plunkett, who by some has been termed the father of modern Irish agriculture.

In the United States the activity of the Department of Agriculture has made the extensive organization of such societies needless, but in 1885, before there was any thought of the government taking over such work, a society for the promotion of agriculture was founded in Philadelphia. In the same year another society of the same nature was organized in South Carolina. Then followed other societies in Kennebec, Me. (1877), New York city (1791) and the Massachusetts Society for the Promotion of Agriculture (1792). By 1809 these societies attempted the beginnings of a national federation, whose work should be of nation-wide scope, in the Columbian Agricultural Society, with headquarters in Washington, D. C. The holding of agricultural shows or county fairs had its origin in Washington, in the efforts of Elkanah Watson, of Massachusetts. Such exhibitions are now held all over the country by nearly 3,000 organizations, ranging from international to local scope in their characters. In many of the States agricultural societies have developed to large proportions. Other societies have for their purpose the organization of co-operative buying and selling among farmers. But in 1913 the Department of Agriculture assumed a function approaching this very much in character—the rural organization service to assist farmers in forming organizations for the betterment of agricultural and country life.

AGRICULTURAL CHEMISTRY. Agricultural chemistry deals with the chemical composition of plants and of animals and of their foods, and with the chemical changes involved in the life processes. It therefore includes the chemistry of air, water, soil, manures, fertilizers, insecticides, fungicides, plants, animals and metabolism or the chemical changes taking place in living things. Some of the problems of agricultural chemistry do not lie strictly in the field of chemistry but border on other branches of science such as physics, geology and physiology.

Composition of Plants. The number of definite chemical compounds occurring in plants is very large, and excluding water which may constitute from 75 to 90 per cent of the weight of the plant, most of them can be classified under one of the following heads:

1. INORGANIC SALTS.
   a. Organic compounds without nitrogen.
   b. Organic compounds containing nitrogen.

2. ORGANIC COMPOUNDS.
   a. Carbohydrates.
   b. Fats and waxes.
   c. Amines, terpenes and resins.
   d. Organic acids.
   e. Proteins and amino acids.
   f. Alkaloids.
   g. Chlorophyll and coloring matter.

Carbohydrates, including cellulose, starch and sugars, or fats or proteins make up most of the dry matter of plants. Except for certain terpenes which contain only carbon and hydrogen the organic compounds all contain carbon, hydrogen and oxygen, and some also contain nitrogen. Sulphur occurs mainly in one of the amino acids which are the constituents of proteins. Phosphorus occurs in conjugated proteins and also as inorganic and organic...
phosphates. Potassium and calcium are present as salts of inorganic and of organic acids. Iron, magnesium and manganese occur in organic combination, magnesium being present in the green pigment chlorophyll. Sodium, chlorine and silicon are also found in most plants, but they do not seem to be essential to plant life.

The Air.—The growth of plants is greatly influenced by temperature and rainfall, both of which are controlled by the atmosphere. The nitrogen of the air is one of the elements essential for plant and animal life, but it can be utilized only when it is in combination with other elements. Except for a small amount which is combined with oxygen during lightning discharges and brought to the earth by the rain, and that which is now artificially fixed by chemical processes and added to the soil in commercial fertilizers, all nitrogen that is used by plants has been fixed or combined with other elements by micro-organisms which are present in fertile soils and especially in the nodules on the roots of leguminous plants, or by certain very low forms of plant life. The nitrogen is then taken from the soil by the roots of the plant in the form of nitrates. The oxygen of the air oxidizes organic matter in the life processes to furnish energy and also oxidizes waste matter during decomposition. The main products of complete oxidation are carbon dioxide and water. The source of all the carbon in organic compounds in plants is, with few exceptions, the carbon dioxide of the air. In the presence of chlorophyll, the green pigment of plants, and under the influence of light, carbon dioxide and water are converted into organic compounds which occur in plants. During this process a volume of oxygen equal to the volume of the carbon dioxide is returned to the air.

The Soil.—Plants obtain from the soil, in addition to nitrogen which comes originally from the air, water and inorganic salts containing phosphorus, sulphur, potassium, calcium, magnesium, iron and manganese. Soil is formed by the disintegration of the rocks which make up the earth's crust, mostly by the mechanical and chemical action of water and air, and the elements necessary for plant food are made available by chemical decomposition of the mineral compounds of which the rocks are composed. The soil then consists of decomposed rocks, mainly in the form of sand, clay and limestone with small amounts of unchangeable minerals and of the salts necessary for the growth of plants. In addition to these, an important constituent of fertile soil is humus, which is decaying organic matter, either of plant or animal origin. Humus benefits the soil both on account of its physical and its chemical properties. It contains the elements required by plants, which are made available for plant food during decomposition, and it is able to retain ammonia and some other bases, thus preventing their loss from the soil by leaching. It has a lower density, a higher specific heat and a greater capacity for holding water than the other constituents of soil, thus making a moist warm soil in which the air can circulate. These conditions of temperature and air circulation are most suitable for factory not only for the growth of plants but also for the action of nitrifying bacteria which oxidize different forms of nitrogen into nitrates which can be utilized by plants. When the air is excluded from the soil either because the soil is too compact or because it is not well drained, the conditions are more favorable for the action of bacteria to convert nitrogen compounds to free nitrogen which is then lost as a plant food. An important property of fertile soils is the ability to retain plant food by forming insoluble compounds which are not washed out by water but which are soluble in the plant juices. In addition to the retention of ammonia by humus, which is mentioned above, phosphates, potash and ammonia are retained by clay, the phosphates in combination with oxides of iron and aluminium, the bases in combination with complex silicates.

Manures.—Soils gradually become poorer in plant food as crops are removed every year. If the crops removed are fed to farm animals and the manure returned to the land the soil may be maintained in a fertile condition. The manure from an adult animal not giving milk contains practically all the nitrogen, potassium, phosphorus and calcium that was present in the food, but growing animals and those giving milk use a large amount of these elements, so the amount in the manure is not over 80 per cent of that in the food. On a farm where milk is the only product sold and where some feed is bought for the animals the manure will return to the soil all that the crops take from it, providing the manure is used in such a way that nothing is lost from it by fermentation or leaching. In addition to returning plant food to the soil manure furnishes humus and so greatly improves the physical condition of most soils that its beneficial effect is lasting, so that the soil remains fertile for several years after the application of manure.

The condition of a soil is improved by green manure as well as by farm manure, especially when the latter is not obtainable. It has been known for ages that the growth of leguminous crops such as red clover is to a great extent equivalent to the application of nitrogen fertilizers for the growth of cereals, and in 1886 Hellriegel and Willfarth demonstrated that this was due to the fact that micro-organisms in the nodules on the roots of leguminous plants assimilate free nitrogen from the air and make it available for plant food. Growing and plowing in leguminous crops therefore not only returns to the soil the plant food used by the crop but it also increases the supply of combined nitrogen in the soil.

Commercial Fertilizers.—When crops are continually taken from the soil and plant food is not returned in manure, it is necessary to supply the necessary elements in commercial fertilizers. These are used mainly to supply nitrogen, phosphorus, potash and lime, as the other elements are required in such small amounts that most soils have a sufficient supply. The principal nitrogen fertilizers are either organic matter such as dried blood, meat waste, fish scrap, tankage, sewage sludge and cottonseed meal, or inorganic compounds including ammonium sulphate recovered from coal gas, nitrates from the natural deposits in Chile, and artificially fixed nitrogen in the form of calcium nitrate and calcium cyanamide. Nitrogen is assimilated by plants in the form of nitrates, so the nitrate salts are most readily available for plant growth, but in fertile soils there are bacteria to ammonify
organic nitrogen and to nitrify ammonia. Some kinds of organic matter such as leather and wool waste decompose very slowly and so the nitrogen is released slowly. The phosphate fertilizers are phosphate rock, bones, superphosphate and basic slag. The first two are insoluble, consisting mostly of tricalcium phosphate, and it was Liebig who in 1840 first suggested making a more soluble product by treatment with sulphuric acid to make superphosphates which consist of monocalcium phosphate and calcium sulphate. In the last few years some phosphate rock has been treated in the electric furnace to get a soluble concentrated product which may be used either in combination with ammonia, potash or lime. Basic slag contains the phosphorus removed from iron by limestone in the blast furnaces. Except for tobacco stems and wood ashes, most potash fertilizers have been salts from the Steatsturt mines in Germany. In 1894, when the supply from Germany was cut off, many attempts have been made to obtain potash supplies in this country. Two methods of obtaining large amounts at a reasonable cost appear to be successful. The first, the recovery of potash from potassium salts from the kelp of the Pacific Ocean by processes in which other by-products are also recovered. The second is the recovery of potash from flue gas and clay in connection with the cement industry by the use of the Cottrel process for precipitation from the flue dust. By this method a large amount of potash which has previously gone to waste is now recovered at a slight cost.

Applications of lime are often of benefit on soils which are not deficient in calcium, on account of the effect on the physical condition of the soil and the chemical action on the soil constituents. Lime flocculates clay and so improves the drainage of a heavy soil, it liberates potash from flue gas, makes certain phosphates more available for plants and aids bacterial nitrification by neutralizing acidity and maintaining a neutral or slightly alkaline condition. Lime is applied either as quick lime, slaked lime or finely ground limestone.

Crops.—The different fertilizers have different effects on the growth of plants and different crops require different amounts of the plant foods, so commercial fertilizers should not be used indiscriminately. Analyses of plants show how much of each of the necessary plant foods is removed by any crop and this gives an indication of how much fertilizer should be added to the land to keep the soil from becoming deficient in any element. Nitrogen generally tends to delay maturity by causing more growth. Maturity is also delayed by a lack of phosphorus which is especially needed for the growth of the seeds. While potash tends to delay the maturity of grains it hastens the maturity of root crops. While the use of fertilizers may materially increase the yield, the composition of the mature crop is influenced very little by the amount or kind of fertilizer used.

On account of the fact that different crops use different amounts of the several plant foods and so deprive the soil of different elements, a plan of rotation is necessary. The soil loses rapidly than growing a single crop continually on the same land and allows the soil to be enriched occasionally by the growth of a leguminous crop. Some plants have short roots which take their food from the surface soil, while others have long roots which bring up their food from the deeper soil. When the crop is harvested and the root decays it enriches the top soil by a certain amount of potassium, phosphorus and nitrogen.

That the climate influences the composition of crops more than other factors has been shown by several experiments. Among them is LeClerc's experiment with wheat in which it was found that the same wheat planted in different parts of this country gave crops with very different amounts of protein and starch, while wheat from different parts of the country when planted in one place gave crops which were approximately alike and quite different from the seed from which they were planted. With regard to the effect of rainfall on the composition of wheat it was found that an abundant water supply produces a large starchy grain, while a dry climate produces smaller grains with a larger proportion of protein. Wiley's experiments with sugar beets showed a considerable variation in the composition of the crop grown in different parts of the country from the same seed, a larger yield of sugar being obtained in the northern part of the country. In experiments with sweet corn Wiley found that the climate has less influence on the composition of the crop than the amount and distribution of the rainfall. From such chemical studies it is possible to find out in what part of the country to grow certain crops with the best results and also to select for development the varieties that will produce more of a given desirable constituent, either protein, fat or carbohydrate. It is evident that for the improvement of crops by selection it is necessary that the experiments be carried on in the climate in which the crop is to be grown.

Insecticides and Fungicides.—Plants have many insect enemies and it is often necessary to use poisons to kill them. These poisons must not be such as to harm the plant and must not be used in a way to make it poisonous as a food for the higher animals. The poisons used for spraying on leaves which insects eat are mainly insoluble compounds such as Paris green and lead arsenate. Among the sprays that poison by contact are lime sulphur and tobacco extract or nicotine solution. For destroying insects in stored grains poisonous gases are frequently used, such as hydrocyanic acid and carbon disulphide. Copper salts are commonly used for destroying fungi and the most generally used fungicide is Bordeaux mixture which is made from copper sulphate and lime.

Animals.—The animal body contains besides from 50 to 70 per cent of water, inorganic salts and organic matter which is mainly protein and fat. The inorganic salts include phosphates and chlorides of calcium, sodium, potassium and magnesium in the skeleton and body fluids. The organic matter includes fats and containing carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus, iron and iodine. Small amounts of fluorin and silicon are also found but it is not known that these are essential to animal life. The organic matter required by animals comes directly or indirectly from plants which have synthesized their organic compounds from the inorganic matter in the
air and soil. The organic matter required for growth and repair of tissues is protein, and the energy required for keeping the animal warm and performing the functions of the organs and muscles is obtained by oxidation of organic compounds, mainly fat and carbohydrate. Protein in excess of that required for building new tissue or replacing wasting tissue is also used as a source of energy, but the energy obtained from protein is more than twice as much as is derived from the same weight of energy than fat or carbohydrate, and they are generally used in a diet only in amounts necessary for tissue-building. Any excess of food over that required for growth and for energy is stored as fat. Not only must a diet contain protein, fat, and carbohydrates enough to furnish the necessary energy, but it must have a sufficient variety and amount of inorganic salts, and there are also certain other organic compounds, known as vitamins or as the essential factors in diet, which are present in small amounts in food from plant and animal sources and without which animals either do not grow or they develop certain diseases such as poliomyelitis or scurvy, which are therefore known as deficiency diseases.

The energy requirements of animals have been carefully investigated by three methods: First, by determining the balance between the intake of energy in the food and the output; second, by observing the amount of oxygen consumed during respiration and the amount of carbon dioxide exhaled; third, by direct measurement of the heat given off by the body in a calorimeter. The three methods are combined in experiments made with the respiration calorimeter devised by Atwater. These latest methods have been established, especially by Armsby, for different animals under different conditions such as growing, working, fattening and giving milk.

Besides the importance of the required amount of different food substances it is now known that the quality of the protein has some effect on its availability for animal use. Work by Osborn has shown that some proteins do not furnish nitrogen in a form that can be used by growing or adult animals. Analyses of these proteins show them to be deficient in certain ones of the amino acids of which proteins are composed.

Carbon and Nitrogen Cycles.—The study of agricultural chemistry shows interesting cycles for carbon and nitrogen. Carbon is taken from the air as carbon dioxide by plants and synthesized into organic compounds which are then used by animals and returned to the air by oxidation during respiration or decomposition. Some carbon is returned to the air by plants by oxidation during respiration or decomposition or combustion, and there are other branches to the cycle, but in the main it may be represented as air—plant—animal—air—plant—animal, etc.

In the same way combined nitrogen as nitrates is taken from the soil by plants and synthesized into organic compounds which are then used by animals and returned to the soil in manure or the dead body. Here also some of the nitrogen is returned to the soil by decaying plants, but the main cycle is soil—plant—animal—plant—animal—animal, etc.

Dairy Chemistry.—Dairying is an important agricultural industry not only commercially but also because dairy farming tends to keep the soil fertile by returning to it all the plant food taken from it except for the small amount used up in producing the milk. Chemical investigations have been directed to the composition and character of milk from different cattle and under different conditions, to the chemical changes taking place during souring and curdling, to the processes of making butter and cheese used in producing the milk. The Association of Official Agricultural Chemists, organized in 1880, is composed of the Federal and State officials who are enforcing the laws regarding foods, drugs, feeding stuffs, fertilizers, insecticides and fungicides, and those who are carrying on investigations along these lines under the Federal or State governments. The main work of this association is the improvement of the methods of analysis of agricultural products and it thoroughly supports its results of collaborative work carried out on these methods. Its analytical methods are official in many of the Federal and State laws. The proceedings of the meetings and the methods of analysis are published in the Journal of the Association of Official Agricultural Chemists.

AGRICULTURAL COLLEGES. As a result of National and State co-operation, which enables the ordinary farmer to profit from the experiments of widely separated individuals interested in scientific farming, the United States stands foremost in the matter of agricultural developments made. As of 1882, Congress passed the first of a series of acts whereby extensive grants of national lands were made and converted into trust funds for the support of at least one agricultural college in each State, the grants being contingent upon a certain percentage of assistance by the States. Our Department of Agriculture renders the greatest
service imaginable to the country; but its facilities are greatly improved by the co-operation of the different State agricultural institutions, while the faithfulness of each section in relying upon their special State colleges to supplement the work of the national institution.

The Massachusetts Agricultural College is one of the foremost representatives of the typical institution devoted to practical agricultural education. It is devoted chiefly to the training of students in modern scientific farming. The work is conducted in the class-room, on an experimental farm and in co-operation with farmers’ organizations. The institution is located on a farm of 400 acres at Amherst, and its buildings, land and equipment are valued at $1,530,465. Its annual income from the State and United States for extension work and its experiment station alone amounts to $100,000. There are buildings for nearly every imaginable specialty pertaining to agriculture—a chemical laboratory, botanical laboratory, plant-house, creamery and dairy laboratory, veterinary buildings, barns, museum, library, and entomological laboratory and insectary.

Instruction is given by a corps of 60 professors and assistants in chemistry, botany, agriculture, horticulture, zoology, veterinary science, mathematics, civil engineering and similar studies and in extension work. Practical work on the farm is a part of the course, and the students cultivate the whole farm, experimental orchard and nursery. There are 100 acres devoted to orchards, vineyards and the cultivation of small fruits; 150 acres under cultivation with field crops and nearly as many more allotted to grass and hay for the cattle which are kept on the farm. Considerably over 2,000 men have been educated at the Massachusetts Agricultural College. A recent census of them showed that nearly 400 are to-day engaged in agricultural pursuits; more than a score are in important positions in government, and others have drifted into a variety of callings.

The effect of the college on the agriculture of the country must prove of immeasurable value if a similar proportion of its graduates adopt farming for their life’s work, and perform their duties in a scientific manner, as they were taught to do at the institution. During 1915 a new building, costing $210,000, was dedicated.

The State agricultural and mechanical colleges which have sprung up in most of the leading agricultural States of the East and West, and in many parts of the South, in recent years, have in view the training of young men for scientific and practical agriculture, and also for mechanical and manufacturing arts and sciences. They are endowed by the State and the Federal Government (see Department of Agriculture) and also by private individuals. They are for the most part under the control of the State Board of Agriculture, the governor and other State officers; but the president and faculty of each institution practically have all the liberty they demand in carrying out the work according to well-defined policies. Some of these State agricultural colleges are remarkably well equipped and endowed for the work they have in hand. Thus, the Iowa State College of Agriculture, which has been erected by the State at a total cost of $500,000, There are nearly 1,000 acres of land attached to the institution. A corps of 250 professors and instructors and over 1,700 students are engaged in study and work. All kinds of crops raised in Iowa are cultivated on the farm, and cattle, horses and poultry are kept by the students. Experiments are constantly being carried on by the professors and students in agriculture, horticulture, chemistry and general farming, and the results of these experiments are published in bulletins and papers for the benefit of the world.

The Pennsylvania State College, called the Agricultural College of Pennsylvania, is even broader in its educational aims than the Iowa college. Almost all studies from agriculture, chemistry, physics, engineering, mining and mathematics up to philosophy, general literature and languages are taught there. In recent years this college has steadily broadened as a high-grade technical, scientific and classical institution. Nevertheless agriculture, in all its wide fields of application, is one of the chief studies emphasized at the college. A correspondence course has in late years been organized for the purpose of instructing students on farms who cannot attend the college, but who wish to avail themselves of the research and facts obtained at it. Forestry is one of the most useful branches of work carried on at this college; and it not only trains young men to appreciate the value of cultivating orchards and woods, but also turns out practical foresters capable of taking charge of large forests and converting them into profitable possessions, without destroying and denuding them of trees.

The Michigan State Agricultural College is another institution which, for more than 45 years, has endeavored to help the farmers in their struggle to wrest from the soil a fair compensation for their labors. The original idea of this college was to perfect in their studies all graduates of the common schools who wished to possess a complete practical and theoretical knowledge of the art of agriculture. They bore directly upon agricultural and kindred pursuits. Economic zoology, meteorology, physics, veterinary science, entomology, bacteriology, chemistry, geology, and agriculture and horticulture are a few of the subjects pursued by graduates can pursue advanced studies in the sciences, and in the library of 38,000 volumes they can find nearly all the literature of value pertaining to their particular studies. There is also an arboretum, a botanical garden, a grass garden and a weed garden, where 100 or more noxious weeds are grown to show their destructive possibilities to the students. There are some 1,400 students at the college, and more than half of them take the full agricultural course.

The South has a good institution of this class in the Mississippi Agricultural and Mechanical College, with a faculty of some 60 members and a student membership of nearly 800. The college is under the management of a board of trustees, with the governor of the State an ex officio member. The students who attend this college are paid eight cents per hour for their work in the fields or orchards, which enables them to pay for a part of their living while studying.

The Kansas State College, with its 300 acres of land, buildings valued at $965,000 and a faculty of 190 professors and assistants, has
become an important factor in the middle West in developing the agricultural possibilities. Agriculture, engineering and general and household economics are taught in the schools. There is a dairy, blacksmith-shop, foundry, machine-shop, printing-office, and woodwork and painting shop connected with the college, where practical work can be followed by the students.

With agriculture as our leading industry, many of the large universities have in recent years established an agricultural course and experimental farms for work in the regular college course. When this subject is mentioned, one turns instinctively toward Cornell University, with its admirable agricultural and forestry departments; toward the Ohio State University, with its buildings and equipments aggregating nearly $5,000,000 and with an income of $1,250,000; or toward the University of Wisconsin or the University of California. These typical universities, which have given agriculture and horticulture a prominent place in their curriculums, send forth annually hundreds of students to teach practical farming to new communities which may still be under the disadvantage of old methods and ideas of agricultural production. The Ohio State University at Columbus has over 2,500 students and a corps of 250 professors and assistants; but it aims to give a scientific and classical education to both young men and women. It is divided into six colleges, with one devoted to agriculture and domestic science and another to veterinary science. Students pursuing other studies can take courses in these departments, and there are also opportunities for graduate studies in the sciences of agriculture. There is a well-stocked farm connected with the university, a dairy department and a large laboratory for student work.

At the end of 1914 there were 69 State agricultural colleges, some of them being conducted in connection with the State universities. Their total endowments amounted to $60,000,000; the value of their farms amounted to $24,000,000 and their buildings to $1,800,000. Toward their maintenance the Federal Government was contributing $3,592,198 (see States Relations Service in article DEPARTMENT OF AGRICULTURE) and the States were contributing $17,997,765. The rest of their incomes, mostly from tuition fees, amounted to $13,301,000. The total number of students enrolled amounted to 115,654. During the four years from 1910 to the beginning of 1915 the increases in their equipment, faculties, student bodies, etc., have amounted to 67 per cent. During the year 1915 progress was especially notable; the State legislature of California appropriated large sums for additions to the group of agricultural buildings at the State University, Nebraska gave $100,000 for similar purposes and Cornell University completed a new Soils Building which cost $100,000.

AGRICULTURAL EDUCATION. See Education, Agricultural.

AGRICULTURAL EXPERIMENT STATION. An institution for scientific research in agriculture. The modern agricultural experiment station owes its origin chiefly to the work of Boussingault and Liebig, born respectively in 1802 and 1803, although the earlier work of Sir Humphrey Davy, De Saussure and others had prepared the way for that of these great chemists. During the third decade of the century Boussingault determined for ten years maintained a chemical laboratory on his farm, and there began the combination of field experiment with laboratory investigation which characterizes the experiment station of to-day.

In 1837 a young Englishman, John Bennett Lawes (q.v.), began making experiments in the use of bone superphosphate on his ancestral estate at Rothamsted, near St. Albans, Hertfordshire, about 25 miles northeast from London. The success of these experiments led him to engage in the manufacture of superphosphate and also stimulated a desire for further investigation, and after some years of preliminary work, in 1843 he associated with himself Dr. Joseph Henry Gilbert, a young chemist and a recent pupil of Liebig, and the two entered upon a systematic line of research which has been continued without material change of original plan until the present day. For more than half a century these two men worked together; both received marks of knighthood, and before his death, which occurred in 1900, Sir John Lawes made provision for the permanent continuance of the work, under what is now known as the "Lawes Agricultural Trust."

The feature of the work of Lawes and Gilbert which distinguished it from anything that had previously been undertaken, except the work of Boussingault, was the combination of systematic and long continued field and feeding experiments with parallel investigations conducted in the chemical laboratory, in which the principal agricultural plants adapted to the English climate were grown both continuously on the same land and in various rotations, the composition of the crops and of the soils upon which they were grown being determined from time to time, and in which large numbers of animals have been fed over long periods and under such conditions that it was possible to determine the chemical elements consumed in the food and the proportion of each utilized by the animal. Extensive detours have also been made into other fields of chemical research, especially that of the assimilation of nitrogen by plants. For many years several general assistants have been employed, including chemists, botanists, computers and other helpers. The entire expense of this work has been met by the originator, except that a chemical laboratory was presented to him some years ago in recognition of the value of his work.

In 1851 a small company of farmers, organized as the Agricultural Society of Leipzig, incited by the revelations of Liebig and Boussingault (q.v.), who were then in the full zenith of their work, employed a young chemist, Emil von Wolff, and started him in the experimental study of agricultural problems, especially those related to the feeding of animals. In a few years the government was induced to assume the cost of this work, and thus was established at Moeckern, near Leipzig, the first public agricultural experiment station in the world.

In the United States attempts at experimental research in agriculture were undertaken at the Agricultural High School, afterward State College, of Pennsylvania; at the Michigan Agri-
cultural College and at the Maryland Agricultural College, all established between 1854 and 1858, and later several of the institutions organized under the National Agricultural College Act of 1887. In 1888 Dr. O. Atwater, a young chemist who had become enthused with the idea while studying in Germany, for the inauguration of this work private initiative was necessary; Mr. Orange Judd, then editor and proprietor of the American Agriculturist, contributed $1,000 on condition that the State should appropriate $2,800 for the support of the station for two years. This offer was accepted and work was begun in October of that year. In 1887 at the expiration of the statute the State assumed entire support of the station, and it was removed to New Haven.

Similar stations were established by North Carolina in 1877; by New Jersey in 1880; by Nebraska and Oregon in 1883; and by New Mexico and Minnesota in 1893. During this period also several of the agricultural colleges organized their research work on a more definite basis, and by 1887 there were 17 stations in operation in 14 States.

In 1883 a bill was introduced in the House of Representatives of the National Congress by C. C. Carpenter, of Iowa, providing for the establishment of experiment stations in connection with the colleges of agriculture, but it was not voted upon. In the next Congress Mr. Cullen, of Illinois, introduced a bill providing for a grant of $15,000 annually to each State and Territory for this purpose. This bill was re-introduced in the following Congress by William H. Hatch, of Missouri, and after being so amended as to authorize States, in which experiment stations independent of the agricultural colleges had been previously established, to use the grant in support of such independent stations—a proviso applying to the five States mentioned—the bill became a law on 2 March 1887.

Under this law experiment stations have been established in every State and Territory in the United States, 60 such stations being enumerated in 1914—the fund being divided between two stations each in Connecticut and New York; while additional stations have been established under State or Territorial support in Alabama, Louisiana, Missouri, New Jersey, Pennsylvania and Virginia, and in several of the Northern States of the Union. In all, there were 852 persons in the work of administration and research, and published 1,330 reports and bulletins, which were sent to over 1,000,000 addresses.

The following are among the principal subjects under investigation by the American stations: (1) The soil: its physics, chemistry and biology; including tillage, drainage, irrigation and the maintenance of fertility by rotation and the use of manures and fertilizers. (2) The plant: its physiology, chemistry, nutrition and pathology; the introduction of new varieties; improvement in productivity by selection and breeding; the control of fungous and bacterial diseases and injurious insects; the various phases of forestry. (3) Animals: the special adaptations of the various breeds; the chemistry of animal foods and the economics of feeding; dairying and its manifold problems; the control of animal diseases.

In addition to the work above outlined, several States have laid upon the stations certain lines of police work, such as the inspection of fertilizers, seeds, drugs, foods and animal feeding stuffs for the prevention of fraud; that of live stock to prevent communication of animal diseases, and that of orchards and nurseries for the control of insect pests and fungous and bacterial diseases; but such work is not scientific research; it is merely incidentally with the conduct of such research, and is more properly an executive function of the State government. In some States it is so recognized.

Under the provisions of the Hatch Act the stations are governed under the laws of their respective States, the National Government exercising no control except to make sure, through annual financial reports from the stations and through personal visits by officers of the Office of Experiment Stations of the Department of Agriculture, that the money appropriated by Congress is being expended for the purpose designated in the national law.

The stations, in connection with the colleges of agriculture, have organized an Association of American Agricultural Colleges and Experiment Stations, which meets annually at some point in the United States for the discussion of matters pertaining to their work, and the Office of Experiment Stations publishes a monthly journal, the Experimental Station Record, in which notices or summaries are given, not only of the publications of the American stations, but also of the scientific agricultural publications of the world.

While this work has been thus extending in the United States it has also spread over most of the civilized world, 728 such institutions being enumerated in other countries in a bulletin of the Office of Experiment Stations, published in 1904. The only countries in which experiment stations were not found in that year were Greece, China, Turkey, Russia, Afghanistan, Beluchistan, Mexico, Central America, Bolivia, Colombia, Ecuador, Patagonia, Peru, Uruguay and Venezuela. As was natural, there has been a decrease in the kind of activity which has characterized the European stations in normal times. The information available has been drawn on to a hitherto unprecedented degree. The forces of many of the stations have been drawn for the war and considerably depleted.

The European stations as a rule are confined to single lines of research, and very often to inspection work merely, whereas the American station generally embraces several co-ordinate departments, each with a chief and
AGRICULTURAL IMPLEMENT INDUSTRY; LEGISLATION

one or more assistants and helpers, all working under the general supervision of a single director. Many of the European stations would be impossible without this method. In America, however, the position of the stations is very generally limited to laboratory work, whereas in America, England and the English colonies the laboratories are generally used as adjuncts to field investigation.

The rapid extension of this work throughout the world and the large and constantly increasing sums of money devoted to it are sufficient evidence that it has obtained and holds the confidence of the people; but this position has been attained rather through the gradual substitution by the stations' investigations of demonstrated facts for the theories which had previously held sway in agriculture than by epoch-making discoveries, although a few of these also are to be placed to the credit of these institutions.

It was the Rothamsted Station which demonstrated that leguminous plants do not absorb and fix the free nitrogen of the air through the root system but which cleared the way for the solution of a mystery which had puzzled the student of plant growth for many years, and Dr. S. M. Babcock, of the Wisconsin Station, perfected a method of determining the fat in milk, which has been adopted throughout the world, and for which a medal was voted to him by the legislature of his State; but it is the patient, plodding work, by which a body of exact knowledge in agriculture is being slowly accumulated, which has been the chief factor in maintaining confidence and support.

On 15 Feb. 1906 a bill, introduced by H. C. Adams of Wisconsin, passed the House of Representatives by a unanimous vote, increasing the national allotment to the experiment stations by $5,000 for each State for 1906, this amount to be increased by $2,000 annually until the total should reach $15,000. This bill became a law 16 March and the experiment stations receive $720,000 annually under it in addition to the same amount appropriated under the Hatch Act.

CHARLES E. THORNE,
Director Agricultural Experiment Station,
Wooster, Ohio.

AGRICULTURAL IMPLEMENT INDUSTRY. The. One of the largest classified industries of the country, including the establishments whose products of greatest value are machines or implements designed for use in agriculture. Such implements fall naturally into four groups: (1) Implements of cultivation; (2) seeders and planters; (3) harvesting implements; (4) seed separators. The first group includes plows, harrows and cultivators; the second, seeders, drills, planters and listers; the third, mowers and reapers, harvesters and hay rakes, hay tedders, hay forks, hay stackers, etc.; the fourth, threshers, fanning mills, corn huskers and rollers. Besides the production of new machinery there is a very large output of parts for replacement or repair of worn-out mechanisms, amounting to some $60,000,000 annually.

A special census of manufactures made for the year 1914 shows that in that year there were 772 establishments engaged wholly or partly in the making of agricultural implements. Their combined product amounted to 3,318,175 implements of cultivation; 634,929 seeders and planters; 1,076,769 harvesting implements; and 140,803 seed separators. Their aggregate value was $1,010,120.32, which, as compared with the value in 1909—$149,318.54—shows an increase of 12.6 per cent in the five years. These totals include a value of $90,211.32 for parts and miscellaneous implements and $1,460,598 for completed implements.

The industry, as might be expected, is widely distributed over the country, every farming community constituting a centre of demand. Of the 772 establishments engaged in the industry in 1914, 86 were located in Illinois, 67 in Ohio, 61 in Wisconsin, 58 in New York, 49 in Pennsylvania, 45 in California, 42 in Indiana, 40 each in Iowa and Michigan, 35 in Minnesota, 27 in Missouri, 25 in Tennessee, 22 each in North Carolina and Virginia, 18 in Georgia, 14 in Vermont, 12 in Kansas, 11 in Maine, 10 each in Alabama and New Jersey, 7 each in Kentucky, Massachusetts, Nebraska and Washington, 6 each in Connecticut and Mississippi, 5 in Texas, 4 in Colorado, 3 each in Arkansas, Florida, Maryland, New Hampshire, Oregon, South Carolina and South Dakota, 2 each in Idaho, Oklahoma and West Virginia, and 1 each in Louisiana and Montana.

There is some concentration of the industry, however, the first five states named doing fully 75 per cent of the entire business. Agricultural implements constitute one of the most important classes of export from the United States. The value of such machinery exported before the European war ranged from $30,000,000 to $40,000,000 annually. For the fiscal year ending 30 June 1915 the value exported dropped to about $10,000,000. See FARM MACHINERY.

AGRICULTURAL LAND BANKS. See FEDERAL FARM LOAN ACT; LAND CREDIT.

AGRICULTURAL LEGISLATION. United States.—The history of agricultural legislation in the United States dates back to 1802 when Congress granted to the several States 30,000 acres of land for each senator and representative in Congress with which to endow at least one agricultural college. In the same year the United States Department of Agriculture was established by law of 15 May. The first State to pay serious attention to agriculture as a scientific subject worthy of serious study on the part of the people was Connecticut which established the first agricultural experimental station at the Sheffield Scientific School in 1877; and it was not until 11 years later that the United States Department of Agriculture was created by law as an executive department (21 May 1888) and the Secretary of Agriculture made a member of the Cabinet. In 1891 the Weather Bureau was transferred from the Department of War to that of Agriculture; and in 1905 the National Forest Reserve Department was handed over from the Department of the Interior to that of Agriculture, which, from this time on, continued to gain control of every part of the government activities related in any way to agriculture. Thus strengthened, it soon began to show its power for good. Chiefly through its instrumentality the Meat Inspection Law of 1906 was passed, and the National Pure Food Law, after a long and bitter struggle, finally became a fact. Control was also secured over
AGRICULTURAL LEGISLATION

interstate transportation. The sum of $150,000 was secured from Congress, in 1907, to fight the Texas cattle fever in the South, and the moth pest in the Eastern States. The tendency of the Federal laws passed from this time on, is the interest of the development of agriculture, was to give more power and resources to the Department of Agriculture, and to place in its hands the control of products intended for interstate shipment. The Appropriation Act of 1908 provided large sums for the continuance of the agricultural work already in hand and its rapid extension throughout the country. The appropriation was intended to increase the effectiveness of the various State governments, and to receive more money for the support of its work. The appropriation of $3,820,420 (in addition to the $20,000 previously granted for State aid) for the work in hand. By the close of the year, 1908, had been passed in every State of the Union and in all the Territories including Hawaii, Guam, Alaska and Porto Rico, for the establishment of experimental agricultural stations maintained or supported in part by Federal funds. The Adams Act raised the level of the appropriation made available for the agricultural stations and induced the States to undertake more practical operations. A Federal law passed in 1910 regulated the manufacture, sale and interstate transportation of adulterated or misbranded insecticides and fungicides; and it was adopted by 15 States. In 1911 the sum of $2,000,000 was appropriated until July 1915 for the purchase of lands located at the headwaters of navigable streams, and their maintenance as national forests; and stringent measures were provided for the safeguarding of seeds, feeding stuffs, fertilizers, seeds and other agricultural interests.

In 1912 agriculture received unusual consideration from Congress. Numerous bills, though not then passed, were introduced and with others already pressed vigorously discussed. Among those actually adopted were, (1) an act providing for plant quarantine, (2) making it necessary to secure a permit from the Secretary of Agriculture before importing nursery stock; the law also put up a certificate of inspection from the proper authorities of the exporting country. Interstate movement of nursery stock was required to be reported to the Secretary of Agriculture. This requirement might also be exacted, when considered necessary, of imported fruits, vegetables and seeds. The Secretary of Agriculture was empowered to stop importations from, and to quarantine against shipments from, any State or section thereof in the interest of protection against any pest. The administration of this work, which had already assumed large proportions, was entrusted to a Federal horticultural board composed of officials of the Federal Department of Agriculture, while the inspection was left in the hands of the State authorities. In 1913 agriculture continued to receive also very special attention from Congress, the chief interest centring in bills to improve the economic status of the farmer, to regulate markets, to provide increased facilities for agricultural credit and co-operative drainage, irrigation and general farm improvement. Steps were taken to better and increase the dissemination of agricultural information; and the police duties of the Federal Department of Agriculture were extended to include the protection of migratory and insectivorous game birds and the inspection of viruses and serums for the treatment of animal diseases.

The Smith-Lever Agricultural Extension Act, which had been in being for several years, was finally passed in 1914. It provides for extra-mural instruction and recognizes the agricultural colleges as the proper agencies in which such work should center; and it is specially intended to aid in diffusing among the people of the United States information on agriculture, home economics and the practical application of both; and to give instruction and practical demonstration in these subjects to non-college students, through field demonstration, publications and otherwise; The act provides a permanent appropriation of $480,000 per annum ($10,000 for each State); and, in addition to this, $600,000 for the second fiscal year of operation, and thereafter an increase each year of $500,000 for seven years, reaching finally $4,500,000 as a permanent annual appropriation. Additional appropriations are to be allotted annually by the Secretary of Agriculture to the several States in proportion of the State rural population to that of the whole rural population of the country, conditional upon the provision by each State of an equal sum; thus making, when the act finally matures, $8,680,000 annually.

The United States Cotton Futures Act was also passed in 1914 to minimize speculative manipulation of the cotton market. This activity of the Federal government in promoting the welfare of agricultural interests was reflected in the activities of most of the States of the Union, for the provision of better rural credit facilities. Though no State agricultural bills became law in 1914, the good work done in the State legislatures was seen in the following year in the constant stream of State agricultural legislation and in the closer co-operation of farming interests throughout the country. In 1915 the interest in providing, by law, better rural credit facilities continued; and the Federal appropriation for the study of marketing problems was increased to $238,000 annually. Congress provided a standard barrel for fruit, vegetables and other dry commodities handled in
AGRICULTURAL LEGISLATION

interstate commerce. This barrel must contain 7,056 cubic inches.

The Federal Farm Loan Act (q.v.), which had long been before Congress, in one form or another, finally became law in 1916. It created a Federal Farm Loan Board controlling a system of national and land banks empowered to make long-time loans on favorable terms on farm mortgages. See Farm Loans.

State Legislation in the United States.—The years 1908 and 1909 were prolific in legislation for the control and improvement of agriculture. Florida, South Dakota, Tennessee, Mississippi, Texas, Utah, Vermont, Wyoming and several other States made legal provisions for the protection of various phases of agriculture, including the inspection of live stock, butter, cheese and other farm products, nursery stock brought into the country, sanitary conditions in rural districts, conservation of natural resources, protection against insect and other diseases in plant life, regulation of the sale of agricultural seed and the supervision of nurseries. Florida provided, by legislative act, for the teaching of elementary agriculture in the public schools of the State. Mississippi directed the County Department of Agriculture to furnish information to agriculturists and develop the agricultural resources of the State; and provided agricultural high schools and inspection by the State entomologists. Louisiana provided for experimental agricultural stations in the great rice belt of the southwestern part of the State, for scientific investigation into rice growing. It also fixed a standard for cotton classification. Vermont created a State Board of Agriculture and Forestry; Texas, agricultural experiment stations and training in agriculture, in certain schools; Kansas, a Dairy Commission with power to enforce the sale of only pure butter, cheese, ice cream and dairy products in general; Porto Rico, a completely new program of agricultural education. Massachusetts had the establishment of the maintenance of schools of instruction throughout the State, in gardening, fruit growing, floriculture, poultry keeping, animal husbandry and other branches of agriculture and horticulture, with the approval of the State Board of Education; and provision was also made for the protection and encouragement of forestry. South Carolina passed an act to encourage the joint action of Consolidated Schools in practical class-room and field work in agriculture; and provided that when trustees of three or more approved schools raise $750 for agricultural instruction the districts shall be entitled to a like sum from the State, the total amount to be used to pay the salary of a qualified teacher of agriculture or of horticulture.

The distribution of hog cholera serum was regulated by law and stallion registration was provided for in many States. Ohio made agriculture obligatory in all the State non-city schools; Kansas prescribed a knowledge of agriculture for all teachers; Indiana and North Carolina instituted systems of rural agricultural high schools; Massachusetts, Maine and North Dakota extended additional State aid to schools giving agricultural instruction. New York appointed a State advisory board to promote agricultural education and the advancement and improvement of country life. In 1912 Arizona and New Mexico provided new irrigation codes; New York passed a law to encourage the preservation of forests, and authorized use of the several State school timber for the benefit of villages and the acquisition of timber and lands for the benefit of the same.

The year 1913 saw a decided movement on the part of many of the States to encourage market co-operation and to improve rural credit. Long-time loans were authorized in Vermont from munificence and the consolidation of projects. Michigan provided for the inspection and testing of sugar-beets at the factories, and numerous States regulated weights and measures and fruit containers, and provided for the employment of farm experts for advisory and demonstrative work throughout the counties. Irrigation and drainage received serious atten-
tion in many States. In New Hampshire, Washington and Montana new agricultural departments were established. Co-operative efforts during this legislation, consisting of local savings and loan associations with a central State bank in New York city, provided $1,000,000 school fund for long-time farm loans at 6% legislative session of 1914. New York authorized a system of land banks, consisting of local savings and loan associations with a central State bank in New York city, with power to issue shares to locals. Colorado provided $1,000,000 school fund for long-time farm loans at 6% legislative session of 1914. New York authorized a system of land banks, consisting of local savings and loan associations with a central State bank in New York city, with power to issue shares to locals. Colorado provided $1,000,000 school fund for long-time farm loans at 6% legislative session of 1914. New York authorized a system of land banks, consisting of local savings and loan associations with a central State bank in New York city, with power to issue shares to locals. Colorado provided $1,000,000 school fund for long-time farm loans at 6%

Much recent agricultural legislation has taken place in the various States of the Union, but nearly all of it has been improvement, extension or definition of that already mentioned or described in this article.

LEGISLATION IN FOREIGN COUNTRIES.

Germany.—The German government early recognized the importance of agricultural education properly directed and encouraged by the State. It was among the first nations of the world to establish agricultural colleges and experimental agricultural stations; and to carry on intensive farming along scientific lines. The only serious competitors in this latter work being Belgium and Holland. Extensive investigations were made, in Germany, by legislative action, into crop rotation; and laws were passed providing for detailed study of diseases incidental to plant and animal life. The broad and scientific work done in this field inspired the governments of other countries to greater effort along these and other lines of agricultural endeavor. The works of the German scientists, in the form of translations, were scattered broadcast over the entire scientific world by the agricultural societies, bureaus and agencies of the various governments and thus helped vastly the work of furthering the interests of agriculture.

France.—After several years of very effective work, all the French government agencies interested in agricultural education and experiment stations in the country were unified in 1911, in one Department of Agriculture, with bureaus of General Administration, Agricultural Instruction and Service, Waters and Forests, Breeding, Inspection, Agricultural Credit, and other co-operative agencies; and also a department for the protection of horticultural interests from insect pests and plant diseases. In 1912 the pure food laws were revised and extended to cover practically all the interests of the country. The system of national agricultural education was reorganized and made vastly more efficient; and commissions were ordered to study and combat plant and animal parasites and to classify useful and injurious birds. The following year the Ministry of Agriculture was reorganized along the administrative lines of 1914. New and its Advisory Superior Council of Agricultural Education authorized the expenditure of 12,000,000 francs for agricultural loans. Laws were also passed to encourage reforestation and the conservation of mountain lands.

In Germany and France, Great Britain saw the importance of legislative help to agriculture, and her influence had begun to be felt in the colonies and at home. The relation of the Board of Agriculture and Fisheries to that of Education had been clearly defined, with co-operation of agricultural interests; and, in 1909, provision was made for aiding and developing agricultural and rural industries by promoting agricultural research, instruction and experiments in the methods and practices of agriculture. In the same year the Development and Road Improvement Funds Act gave much prominence to the aiding and development of agricultural and rural industries by encouraging research, agricultural education and experiment, the organization of co-operative enterprises and the extension of the provision of small holdings. The improvement of rural transportation, the development of forestry through teaching and experimentation, the afforestation of lands, reclamation and drainage were all provided for; and horse breeding was subsidized. In the following years, among much active legislative attention to agriculture, special care was given to the registration and sale of fertilizers, feed stuffs and other agricultural commodities, and the inspection of seeds and nursery plants of all kinds. A Commissioner of Agriculture was appointed for Wales in 1912. Numerous restrictive and directive measures relative to agriculture were put into force, owing to the war, for the period of its duration.

Cuba.—The budget estimate for 1910 provided $112,200 for the maintenance of six agricultural schools authorized for the several provinces by the Agricultural Act of 12 July 1909, since which time the island government has had a very active and efficient Department of Agriculture.

Brazil.—In 1909 Brazil organized, under the Federal government, a Bureau of Agricultural Inspection, which was empowered to make a special study of agricultural conditions, collect and disseminate useful information among farmers and to promote crop introduction and production. This bureau is also, by law, required to compile agricultural statistics (still then completely lacking in Brazil), to make crop estimates and to inspect agricultural schools; and a new bureau was also authorized to be used in the northern Brazilian states for the introduction of irrigation and dry farming. A later law makes provision for opening up remote agricultural regions by rail and public highways; and it also provides for irrigation plants, reservoirs, artificial wells, river dikes and drainage in certain coast lands, in order to make them suitable for agriculture. Both the Federal and States' legislatures were active in the promotion of laws favorable to the betterment of agriculture throughout Brazil from 1909 to 1918.

Canada.—Ontario, Quebec and the Maritime Provinces early had each its department for looking after agriculture; and the Dominion government has long had a very active and efficient Department of Agriculture. The eastern provinces, notably Ontario, have had agricultural schools in active and efficient operation for years; and much good work has been done in spreading abroad scientific methods in farming and in the organization of farm authorities. The central and western provinces have followed the lead of the eastern and they threaten
soon to surpass them in the extent and breadth of their legislation in aid to agriculture. In 1909 Alberta provided for a Department of Agriculture in the Provincial University at Strathcona; and, in connection with it, demonstration farms "in those sections of the province not coming within the immediate scope of the work of the college itself." All the provinces followed in the steps of the Dominion government, providing special agricultural legislation. New Brunswick, by legislative act of 1913, established a system of agricultural schools; and British Columbia arranged to make long-time loans to agricultural associations.

In 1909 President Roosevelt invited Canada, Newfoundland and Mexico to a North American Conservation Conference at Washington. The invitation was accepted by the Dominion government and resulted in the creation by Parliament through the law of 19 May 1909 of a Commission of Conservation; and by an Order-in-Council (3 September) 32 members of the Commission were appointed, the ex officio members being the Ministers of the Interior, of Agriculture and of Mines, and the member of each provincial government of Canada charged with the administration of the natural resources of the provinces. At least one of the members of the Commission from each province must be a member of the faculty of a university in the province. The Commission has to collect, assimilate and digest exact information and to make it of practical benefit for the country, and to advise the government upon questions relative to the administration and conservation of natural resources with regard to their effective and economic use. The Commission set for itself two broad aims: "the taking of an inventory of Canada's natural resources, the molding of public opinion and the advising of administrative authorities with regard to the more intelligent management of the same." To this end the Commission formed itself into seven committees dealing respectively with Lands, Forests, Waters and Water Powers, Minerals, Fisheries, Game and For-bearing Animals, Public Health, and Press and Co-operating Associations; and field investigations were ordered to be undertaken by these committees and a staff of technical experts respecting various natural resources. The committee on lands set itself to study and improve farming methods throughout the Dominion; and constructive measures were undertaken in 1912 to supplement the survey work done up to that date. In each agricultural district "illustration farms" were conducted at the government expense to demonstrate practically the benefits to be derived from scientific agriculture.

Latin America.—Practically all the countries of Latin America had, in 1918, departments of agriculture, commissions or other bodies dedicated especially to the promotion, each of the agricultural interests of its own national territory; and all had one or more agricultural schools with experimental agricultural stations established by legislative act and maintained by public funds, state or Federal, or both. Most of the Latin American countries extend both State and Federal aid and encouragement to agriculture and offer supervision and inspection covered by protective laws.

Mexico.—In 1909 the Mexican Federal Agricultural Commission, by direction of Congress, completed the reorganization of the agricultural department of the republic and created a General Bureau of Agriculture with five departments; and provided for the establishment of national chambers of agriculture in various states, of which 11 were opened that same year. All public land was also withdrawn and was to be diverted to special agricultural uses contemplated by the Federal government. Since then the Carranza government has made provision for the subdivision of large estates in widely different parts of the country, into small holdings, with a view to encouraging the great body of Indians and mestizos composing the laboring and peon class of the republic, to become independent homestead holders and agriculturists. These small tracts of land are offered at exceptionally low prices and favorable conditions of payment. Provision has also been made for the further extension of agricultural teaching and more attention is being paid yearly to the broadening and making practical of the National Agricultural College, near Mexico City. An effort is being made to teach agriculture more extensively in the public schools. Uncultivated lands, of which there are still vast tracts in Mexico, have been taxed with a view to forcing their cultivation. Export duties have, in some cases, been put upon cattle to prevent their going out of the country in regions where, owing to the ravages of the revolution, there are not cattle enough. Legislative enactments have also been made to encourage the settlement of agricultural colonies in various parts of the republic.

disadvantage in the production of these crops. There is, therefore, a tendency for each crop to be grown in marketable quantities in those sections where the soil, climate and other conditions are best suited to it, rather than in those sections which are nearest the centres of consumption. Therefore, we have what may be called belts of production such as the cotton belt, the corn belt, the wheat belt, etc. To attempt to grow wheat, for example, in Massachusetts would prove uneconomical. Although the wheat grower in this State would be very close to a vast consuming population, he would save comparatively little in freight rates in competition with the wheat grower of the far West. The latter, having such a marked advantage in the quality of his land, can easily pay the slight difference in freight rates and still drive his Eastern competitor out of the market. Even some of the more bulky and perishable products show the same tendency. Apples from the far West are regularly marketed in large quantities in the Eastern cities in competition with apples that are grown in the immediate neighborhood. Here again the advantages of a favorable climate and virgin soil seem to be sufficient to overcome the difference in freight rates.

Some of these producing belts or crop areas are fairly well defined and easily described; others are not. About 90 per cent of the orange crop of southern California is produced in a strip 10 miles wide and 60 miles long, lying at the foot of the Sierras. The cotton belt is a strip beginning in North Carolina and extending southwestward and westward to central Texas, lying in its eastern extremity midway between the mountains and the sea, widening as it approaches the Mississippi River and extending westward until it reaches the arid belt where lack of moisture prevents its further spread. Small areas devoted to Egyptian cotton grown under irrigation are found in the far West, particularly in the Salt River valley of Arizona. The wheat belt is divided into two parts, the northern and the southern. In the northern belt where spring wheat predominates, though winter wheat is gaining ground, we find its greatest concentration in the valley of the Red River of the North. The southern belt, where winter wheat predominates, is noticeable in southern and Illinois, north central Missouri, but finds its greatest concentration in west central Kansas and Nebraska, along the border between what is conventionally called the humid and the arid belts. Another large producing area not included in either of these belts is found in eastern Washington. The corn belt is more difficult to describe for the reason that corn is grown in practically every county in the United States. That which is known as the corn belt, however, is the territory in which corn is the leading money crop and where it is grown on the largest percentage of the total acreage under cultivation. The belt thus defined is first noticeable in western Ohio. It extends through north central Indiana and Illinois, covering the whole State of Iowa, part of western Missouri, and corn approaches the Missouri River and extending beyond that river to the borders of what is known as the humid belt,—that is, approximately to the hundredth meridian of longitude. It reaches its greatest density, however, in north central Illinois, particularly in a remarkable strip of prairie extending from the Wabash to the Illinois River. Its next greatest area of concentration is along the Missouri River from about the latitude of Sioux City, Iowa, on the north to St. Joseph, Mo., on the south. It is not customary to speak of an oats belt, probably for the reason that oats is nowhere grown as the principal crop, but it is largely grown in the corn belt in rotation with corn. Thus it happens that the area of largest oats production is identical with that of the largest corn production, with the same centres of concentration. There is nothing that could be called a potato belt, though there are several detached areas of large production, notably the eastern half of Aroostook County, Me., western New York, central Wisconsin and a small area in Minnesota just north of the twin cities. The greatest centre of apple production in the country is western New York. The Ozark region of northwestern Arkansas and southwestern Missouri is another area of concentration, as are also several valleys in southern Washington, northern Oregon and western Colorado.

The corn crop of the country exceeds in value any other crop, and in most years any two other crops. It so much exceeds the demand for it for purposes of direct consumption that the greater part of it has had to be sold in more concentrated form. Various corn products have recently been manufactured, large quantities of it have been used for the purpose of manufacturing alcoholic drinks; but by far the largest part of it has been used for the production of meat. It therefore happens that the areas of pork production are almost identical with the corn belt. The fact that the corn belt lay contiguous to the great ranges of the arid West built up a great cattle-feeding industry, especially in the Missouri River valley. It would not be quite accurate to say that the corn belt is therefore the centre of beef production because much beef is produced outside the corn belt; but the centre of high-class beef production or the centre of the business of fattening beef is in the corn belt.

A small but rapidly increasing minority of American farmers are engaged in growing agricultural specialties for which there is no well-organized market or distributing system. These products are too numerous to mention, but they include most perishable fruits and vegetables and fancy products of various kinds, including fancy horses and breeding stocks. These products cannot be thrown on to the market as can the large staple products for the reason that there is no well-organized distributing system ready to handle them. Therefore the grower of such products must give a great deal of attention to their marketing and distribution. In some respects this is a more difficult if not a more important problem than that of growing them. The following figures show the totals in millions of bushels of the different crops harvested in 1916: Winter wheat, 665; spring wheat, 206; maize, 2,673; oats, 1,141; barley, 195; rye, 43; buckwheat, 17; hemp, 16; apples, 253; peaches, 54; hay, 70,000-000 tons; and tobacco, 1,035,000,000 pounds.

A glance at the railroad map of the United States shows that the main lines run east and west instead of north and south. This is only an indication of a much larger economic fact,
AGRICULTURAL PRODUCTION AND DISTRIBUTION

namely that the territorial division of labor is between East and West rather than between North and South. There is a natural and permanent division of labor between different climatic zones. This gives rise to transportation lines running north and south. The division of labor and exchange of products between East and West are due in part to difference of soil and other physical conditions, but mainly to the fact that the East is older and the West younger. The older communities develop the highly technical industries first, leaving to the younger communities the task of producing raw materials and the cruder products. In short, the division of labor and exchange of products between East and West are mainly between the manufacturing and commercial regions on the one hand and the agricultural, mining and lumbering regions on the other.

This fact, in so far as it affects agriculture, derives considerable significance from its bearing upon the problem of distributing farm products. It means that the bulk of our agricultural produce is grown at a distance from the centres of consumption. Another fact which points in the same direction is that our railroads have given great attention to long distance freight and almost none to local freight. These may be said to be the dominating factors in the organization of our agricultural markets. The amount of produce which is grown within hauling distance of the consumer is so small as to be negligible. Accordingly very little account is taken of it and very few provisions have been made for handling it. Dealing on a large scale have planned their business primarily with a view to handling produce from a distance shipped in by rail, and only secondarily, if at all, with a view to handling produce which is hauled to town by farmers nearby. Nor have many cities made provision for an open market where local producers might sell directly to consumers.

From the standpoint of the city consumer this situation has certain advantages as well as disadvantages. It relieves him of dependence upon local sources, giving him a wider choice among large numbers of producers scattered over wide areas. Again, it lengthens the season over which a perishable fruit or vegetable may be consumed. But it tends to discourage the local producer who yields only a superior, because fresher, product in its proper season. Lacking adequate machinery for handling and distributing his product, he is often at a positive disadvantage in competition with a more distant producer who sends his product through a well-organized system with well-worn channels.

The predominance of this system of long-distance marketing has necessitated certain changes both in method and machinery. When the farmer could haul his produce to town and show it to the consumer, marketing was simple and its methods could be crude without great loss of efficiency. The method was that which is known as selling on inspection. It becomes, however, a very expensive and laborious process when producer and consumer are widely separated. It requires a chain of middlemen, each of whom must make a profit. Selling by sample is an improvement upon selling on inspection because it is less expensive and laborious, but it is possible only where there is confidence in the seller, that is, confidence that the whole quantity offered for sale will be like the sample submitted for inspection. This is a case where confidence makes economy possible. A still more economical method, but a method which requires still more confidence, is that which is known as selling on grade. If the product is properly graded he can sell it at the grade of the grade of the grower of a sample so that it is not even necessary to submit a sample for inspection. This requires confidence not only in the honesty of the seller but also in the scientific accuracy of the one who does the task of grading the samples and the producer raw materials and the cruder products. In short, the division of labor and exchange of products between East and West are mainly between the manufacturing and commercial regions on the one hand and the agricultural, mining and lumbering regions on the other.

The nearer to the farm the process of grading can take place the better it will be for the farmer. Except in the case of the very large farmer who sells on a scale large enough to make an impression on the market, selling on grade is an impossibility for the farmer. The small farmer operating alone cannot establish confidential relations with large numbers of dealers nor can he gain such a reputation on the market as to secure the general acceptance of his grade of produce. But a group, however, acting co-operatively, may achieve this result. Every great co-operative selling organization among farmers which has achieved notable success owes its success to its system of grading as much to any other single factor. Not every farm product can be graded accurately enough to permit of its being sold by grade. Selling by sample or on inspection is then the only method. In these cases it is sometimes necessary to sell rapidly, economically and on a large scale. The auction method, Horses, for example, are not easily graded. So far as the writer knows they are never sold on grade. Selling by sample is obviously impossible. The auction method seems to have demonstrated its superiority over other methods in every large horse market where horses have to be sold at wholesale and in large numbers. The same method is being tried in a large number of other cases including such diverse products as cheese, apples, fish, meat, coffee, grains, and vegetables.

The commission merchant is a peculiar and more or less temporary development growing out of the necessity of selling products on a distant but badly organized market. To him the produce is a commodity and it is his business to find for whatever it will bring, the commission merchant deducting a fixed commission on the price received and returning the balance to the producer. Under this method the producer assumes all the risk and the commission merchant none. Besides, this method invites abuses because the producer has very few and very inadequate checks upon the commission merchant. This presents temptations which human nature is not always strong enough to withstand. In a disorganized and uncertain market the distant producer frequently has no other recourse than to consign to a commission merchant. As soon, however, as the market becomes organized and the demand fairly calculable the commission merchant gives place to the jobber who buys from the producer and sells again, thus assuming the risk and relieving the producer of it. During the transition stage, however, many houses practice both methods, becoming jobbers when the market is firm and prices advancing and commission merchants when the market is unstable or
prices falling, thus playing the time-honored game of "heads I win, tails you lose."

The parcels-post and express companies are beginning to serve as agencies through which the farmer can sell directly to distant consumers. The success of this method is obviously limited to those products which can be accurately graded and put up in standardized packages, in short, to those articles which can be sold on grade rather than by sample or on inspection. There is no reason, however, why there should not be a great increase in the use of these agencies in this restricted field. Moreover, this is an expanding field. The tendency is more and more toward grading and standardizing all products which are capable of being graded and standardized. Before much can be done in this direction it will be necessary for the government, either State or Federal, to define grades more fully and accurately. To define a grade is merely to establish a standard of quality. This is coming to be quite as important as to establish standards of quantity as is already done when the government defines weights and measures.

A large factor which must be remembered in any discussion of the problem of getting agricultural products from producer to consumer—that is, three-fourths of all the telephones in the world are in the United States and Canada. This means that American housewives, more than any others, have formed the habit of ordering goods by telephone. It is not likely that this habit will decline. It is more likely to grow. If it does, it means that direct selling by the farmer to the consumer is possible only within a very limited field. The store which can always be reached by telephone and which can make a prompt delivery will have an advantage in getting the trade of the telephone-using housewife.

This paper may be summarized as follows: (1) From the standpoint of distribution two classes of products are grown in the United States, first, the great staple crops for which there is a well-organized market and which sell at a quotable price; second, agricultural specialties which sell at a very limited market and which do not sell at a quotable price. The latter class presents the difficult problem in distribution. (2) There are two distinct problems in the marketing and distribution of farm products, especially the minor crops and agricultural specialties. The first is that of distributing the products where they are grown within a wagon-haul of the consumer. The second is where the products are grown at such a distance from the consumer that the producer cannot accompany them to market. Of these, the latter is much the larger problem in the United States. (3) There are three distinct methods of selling products: First, selling on inspection; second, selling by sample; and third, selling on grade. Of these three methods the last is the most efficient where the product can be satisfactorily graded; but the conditions are more exacting, requiring confidence not only in the honesty of the seller but also in his skill and accuracy as a grader. (4) These are four characteristic agencies through which the producer who is distant from the market may sell his products. The first and crudest is the commission merchant, the second is the auction house, the third is the jobber and the fourth is the parcel-post and the express service. Of these the last is the most direct but it requires confidence between buyer and seller, besides an efficient and accurate system of grades and standards.

THOMAS N. CARVER,
Professor of Political Economy, Harvard University.

AGRICULTURAL SYNDICATES, differing from agricultural associations in that they take on more the character of co-operative societies and act as commission merchants for their members in the sale of their produce. It is estimated that they now number 5,000 in Europe with a membership of 800,000 individuals. Their most complete development has been reached in France among the vineyardists. Their funds are usually derived from a commission charged their members on the business transacted for them, whether in selling their produce or buying fertilizers, farming machinery or seeds. They are also sometimes active in politics in promoting the farming interests. In some countries their influence has been potent enough to obtain subsidies from the government.

AGRICULTURAL TRACTORS. See Tractors.

AGRICULTURE IN THE UNITED STATES. Land and Labor.—The two factors which, more than any others, have given character to American agriculture are: First, an abundance of land, second, a scarcity of labor. These two factors almost necessarily belong together because land is abundant whenever and wherever there is not enough labor to cultivate it thoroughly, and labor is scarce whenever and wherever there is more land than can be thoroughly cultivated. The necessary and logical result of this combination of abundant land and scarce labor is extensive as opposed to intensive farming. Extensive farming consists in using a small quantity of labor on a large quantity of land, whereas intensive farming consists in using a large quantity of labor on a small quantity of land. As extensive farming is the logical system in a country where land is abundant and labor scarce, so intensive farming is the logical system in an over-populated country where labor is abundant and land scarce.

Not only was the character of our agriculture largely determined by this combination of scarce labor and abundant land, but many of our political and social institutions, and much of our political and social history as well. It gave rise, for example, to the institution of slavery which was primarily an agricultural institution, together with all that grew out of that institution. Scarcity labor and abundant land mean necessarily dear labor and cheap land. This is a situation extremely favorable to those farmers who expect to work with their own hands. Cheap and abundant land means free opportunity for self-employment on the part of the agricultural laborer, whereas scarcity and dear land mean self-employment for self-employment, most of those who work the land being compelled to work for others. Scarcity and dear labor means necessarily a
Agriculture in the United States

liberal income for the self-employed laborer. On the other hand, this is a situation which is very unfavorable to the proprietary farmer who does not expect to work with his own hands but has to depend upon the labor of others to cultivate his lands. The cheapness of land reduces his income from that source and the scarcity and dearth of labor makes it difficult for him to cultivate it.

In Virginia and the other southern colonies this difficulty was increased by the exceedingly liberal land policy. In Virginia, for example, there were three methods by which an individual might acquire title to land: One was to buy a share of the stock of the London Company, to which the land had been granted by the British Crown. These shares were called Bills of Adventure and the holder of each share, besides participating in the profits of the company, was entitled to receive without further cost a set number of acres of land. The second method was by meritorious service. Ministers of religion, physicians and other public servants, including those who had performed valuable manual labor, were sometimes granted tracts of land as rewards. The third method, which was really the one generally used, was known as head right. Under this right anyone who transported to the colony any person, including himself, at his own expense, could secure, without further expense, 50 acres of land for every person so transported. Later on this method became so laxly administered that any free person could secure land under it without much regard to the original requirements.

This liberal policy made it extremely difficult for any large landowner to keep sufficient help to cultivate his land. No man was willing to work for wages when he could, practically without money and without price, secure a tract of land and become a landowner himself. The difficulty was first met by the system of indentured servants. An indentured servant was simply a person who was too poor to pay for his own transportation to the colony. In order to get there he would agree to work for a set number of years for someone who would advance the money. After his term of service had expired he became a free man and could become a landowner on the same easy terms as anyone else. This gave the large landowner an opportunity to keep a laborer for a short term of years but his labor supply had to be constantly renewed. Under these conditions African slavery seemed to furnish a solution of the problem which confronted the large landowner. It was the ruin of the small white farmer who made his own land and who thereafter had to sell the products of his own labor in competition with that of slave labor. If they had been awake to the situation they would at once have prevented the establishment of slavery or, later, have abolished it, since they vastly outnumbered the large landowners who alone found slavery profitable.

The conditions in New England were more favorable to a continuation of free labor for several reasons. In the first place the soil and climate were less favorable to the production of great staple crops such as tobacco and cotton. Consequently there was less farming for profit and more farming for a living. In the second place there were fewer large landholders who needed an abundant supply of cheap labor. In the third place the land policy was a little less liberal. That is to say, there were more restrictions and obstacles in the way of the necessary help. The colonies frequently granted directly to individuals but generally to companies or groups of individuals, who founded towns. The individual settlers generally received their grants from these companies or towns. Some of the earlier towns were settled as church communities. The formation of a town amounted practically to the organization of a church congregation and then settling as a congregation upon a tract of land and calling it a town. Weeden, in his Social and Economic History of New England, makes a creditable economic land tenure which shaped the early towns; without this, even their religious and political systems might not have established their distinctive system of living. The restrictions and provisions made the land less easy for the landless man to become a landowner and the harshness of the climate, the sterility of the soil and the difficulty of reducing it to cultivation made landownership a little less desirable in New England than it was in the South. Consequently it was, on the one hand, easier to keep a supply of labor for those who needed it, and, on the other, there was less demand on the part of landowners for a large supply of cheap labor in New England. Therefore, slavery never appealed to the New Englanders as an economic necessity as it had to the wealthy landowners of Virginia. Nevertheless there were, in limited numbers, both indentured servants and negro slaves in New England. But neither class ever figured prominently as factors of agricultural production, being kept rather as domestic servants by wealthy townsmen.

Labor-saving Devices.—Another characteristic of American agriculture which grew out of the original factors of scarcity of labor and abundant land was the large use of labor-saving devices and, until recently, the general absence of land-saving devices. This was a logical and natural result. Labor being scarce and hard to get it was necessary to economize it. Agricultural machinery in America was consequently designed almost exclusively with a view to enabling a given amount of labor to cultivate a larger area of land rather than to enable a larger population to subsist on a given area. Neither the reaper, the thresher, the twine-binder, the thrasher, the corn planter, the grain drill, the cultivator, the corn-husker nor any other characteristic American farm machine is calculated to increase materially the product per acre. They are designed to increase the product per man by enabling each man to cultivate more acres. In the use of labor-saving devices American farmers have shown themselves to be the most scientific and progressive farmers in the world. In the use of land-saving devices they have not kept up with some of the other more thickly populated countries, as shown by the fact that our product per acre is noticeably lower than theirs. However, our product per man is

AGRICULTURE IN THE UNITED STATES

noticeably higher which, from the economic standpoint, is of the utmost importance. It is generally true the world-over that intensive cultivation and a large product per acre are found in proportion with the poverty of the agricultural workers. This is a necessary result of a small product per man.

During the period of slavery labor-saving devices were not much used in the South, mainly for the reason that slave labor was so cheap that it was not necessary to economize it. In another sense, slaves took the place of machinery.

However, further expansions of our agricultural area must come slowly in the future as compared with the rapid expansion of the past. Then it was merely a matter of moving westward and settling upon land that was easily tillable. Hereafter it must depend upon the progress of discovery—the discovery of methods of using lands hitherto unappropriated for cultivation. Vast areas of dry land west of the one hundred and second meridian and considerable areas of the South, especially in the coastal plain, may yet be reduced to profitable cultivation, besides smaller areas here and there. Up to the present time the progress of discovery in these fields has not been rapid. A great many experiments and failures must be recorded before many successes can be achieved. If the expansion of our tillable area continues to be retarded and if, at the same time, the number of our farmers should increase, a change must come in our methods if we would maintain a large product per man. Instead of merely increasing our acreage in proportion as the number of farmers increases, we must hereafter increase the product per acre, otherwise the product per man must decline.

Native Crops.—Another outstanding fact regarding American agriculture is the extent to which it is a continuation of that of the aboriginal Indian. Of course, on the plains of the northern United States was the corn, or as it is universally called in this country, corn. It exceeds in value that of any other two field crops combined. The first European settlers found it growing here under conditions that enabled them to learn from the Indians how to grow it. The potato is another product native to the American continent. Next to wheat and rice, these are the two most important of the world’s food products. Sweet corn, as it was, until it was superseded by cotton about 1803, the principal money crop of the South and it was, like corn and the potato, a product of native agriculture.

The earliest colonists, both in the North and the South, found that the hog flourished in the woods, feeding on the mast and the roots. Accordingly, the raising of hogs was one of the first branches of animal husbandry to be developed. Corn proved to be admirably adapted to the fattening of hogs. With the development of the great prairie States of the Midwest, which now form what is known as the corn belt, hog-raising increased rapidly and pork-packing became one of the leading industries of the cities of that region. From about 1830 to 1863 Cincinnati was the greatest center of pork-packing. In the latter year it was surpassed by Chicago, which has held first place ever since.

The raising of cattle has always been, since the earliest settlements, a frontier industry. Before the soil was broken by the plow the natural grasses furnished cheap and abundant pasturage. Accordingly, the cattle ranges, since the first settlement of Jamestown, have tended just west of the line of permanent settlement. They moved through the Southern States in advance of tobacco and cotton until they reached Texas. There the rangers from the United States came into competition with those from Mexico, producing complications which afterward led to the Mexican war.

Immediately after the Civil War the wide ranges of Texas having become overstocked, there began a vast migration of cattle from the southern to the northern ranges. The route, known as the "Old Cattle Trail," was merely a strip of land of indefinite width fringing the western settlements. After the building of the transcontinental railways the points at which the trail crossed these railroads became great shipping points from which cattle were sent to the great markets and packing towns of the corn belt.

Wheat, like beef, has been primarily a frontier crop. Both these products are most economically produced by extensive and intensive methods; that is, by the use of little labor on much land. Accordingly, under what is known as the territorial division of labor, those sections where labor is relatively abundant and land relatively scarce are given over to the crops which can be cultivated economically by intensive methods, while those which require extensive methods, migrate to those sections where land is relatively more abundant and labor relatively scarcer. The wheat belt, in accordance with this law, has gradually migrated westward, first through western New York and Pennsylvania, later through Ohio, Indiana and Illinois. Here it split, the spring wheat belt moving northwestward through Wisconsin, Minnesota and the Dakotas, while the winter wheat belt moved southwestward through Iowa, Missouri, Nebraska and finally into Kansas.

A clearer idea of our present agricultural situation can be gained through a brief survey of our agricultural history. This history may be divided into five main periods. The first is the same as our colonial period and may be called the period of trial and adaptation. The second is that comprised between the dates 1789 and 1830 and may be called the period of the conquest of the forest. The third is the period from 1830 to 1860 and may be called the period of the conquest of the prairies. The fourth is the period from 1860 to 1888 and may be called the period of the settlement of the Far West. The fifth is the period from 1888 to the present time and may be called the period of reorganization.

The Period of Trial and Adaptation.—The colonial period was necessarily a period of experiment and adjustment; of trial and adaptation. The settlers faced conditions of which they had had no previous experience and they had to acquire their own experience through bitter trials and disappointments. The summers were hotter and the winters far colder than anything with which they were familiar. The plant and animal life was also different from that of the Old World. What crops to grow and how to grow them was consequently an
unsolved problem for the first settlers except in so far as the practices of the Indians gave them a clue.

Jamestown, for example, is in the same latitude as the northern coast of Africa. The first English explorers had visited the coast of Virginia in summer when the heat was more intense than in England. A natural inference was that the new country would be adapted to a semi-tropical agriculture. The fig and the olive were tried and there were numerous experiments with silk culture. These were soon given up in favor of stock-raising and the growing of corn and tobacco. In New England, besides cattle and hogs, most of the English grains and garden fruits and vegetables were tried out. In the middle colonies wheat was grown successfully and exported to the West Indies. So successful were the colonists in this work of trial and rejection that the main features of our present agriculture were all fixed. Until our present Federal government began sending its plant explorers to the ends of the earth in search of new crops, not a single new crop was introduced into this country since the colonial period except sorghum and alfalfa.

The Period of the Conquest of the Forest.

Before the War of Independence being some of the Colonial population had spilled over the Alleghanies into the great interior basin. The movement westward on a large scale began soon afterward. The various colonies sold to the Federal government their claims to the western lands. The government then began a land policy which encouraged settlement. This policy began as a financial policy and ended, through a series of transitions, as a social policy. That is to say, the government began selling the public land as a means of filling the treasury and of paying off the Revolutionary War debt. It ended by giving the land in small farms, without money and without price, to landless men who would actually live upon and cultivate it.

The first general ordinance for the sale of the national domain was passed in 1785. Among other things it provided for the rectangular system of surveying, which has been followed ever since. Until 1800 the land was sold by the large tract, 640 acres being the smallest unit. During the next 20 years (1801-20) the smallest unit was 160 acres and the lowest price was $2 per acre. From 1821 to 1840 the lowest price was $1.25 per acre and 40 acres was the smallest unit. In 1841 was passed the first general pre-emption act. This withdrew public lands from sale to the general public, reserving them for sale to actual settlers. These were allowed to purchased limited areas, upon which they had actually settled, at the uniform price of $1.25 per acre. The first general of the transition was reached in the Homestead Acts of 1862 and 1864. Under these acts the actual settler who lived on his land and cultivated it for a period of years was given a tract not exceeding 160 acres without money and with a low price. There have been other supplementary acts, such as the Timber Culture Act, the Desert Land Act, all designed to make it easy for the landless man to become a proprietor.

The beginnings of this public land policy form by far the most important phase of our national history during the period we are now studying. With it began the real history of the Great West. Getting the people on to the land, bringing the land under subjection, laying the foundations of a future civilization, are the most fundamental and far-reaching enterprises of any government.

In 1793 the saw gin for separating the seed from the cotton was invented. This followed a remarkable series of inventions for the manufacture of cotton cloth which had created a great demand for cotton. The cotton gin enabled the Southern States to supply that demand and greatly stimulated the growing of cotton. Cotton therefore soon rose to first place among the products of the South, superseding tobacco as the main crop. An unfortunate result was to give a new lease of life to slavery, which was beginning to be unpopular even in the South.

The beginnings of an improved live stock industry were made during this period. The famous sire "Morgan," was imported from England in 1788. The great "Justin Morgan," the sire of the Morgan breed, was foaled about the same time, probably in 1789. George Washington began the breeding of mules of a superior quality, having received two in 1792 as presents from Lafayette and the King of Spain. Several importations of cattle for breeding purposes, particularly of the Shorthorn and Hereford breeds, were made about this time. Merino sheep, having arrived in small numbers from Spain. There had been restrictions upon their exportation from their native country, but during the disturbances growing out of the Napoleonic wars, particularly the Peninsular war, these restrictions were ineffective. Many bands of sheep were broken up and sold and American buyers were not slow to take advantage of these opportunities. There were said to be 3,000 Merinos in the United States by 1809. The growing of hogs in the Ohio valley became a leading industry. In 1805 fat cattle began to be driven across the Alleghanies to the Eastern markets.

The movement for the organization of agricultural societies began during this period. Societies for agricultural improvement were organized in Connecticut in 1768, in New York in 1791, in Massachusetts in 1792. An exhibition of agricultural products was held in Georgetown, D. C., in 1810 and another in Pittsfield, Mass., in the same year. In 1816 a somewhat larger one was held in Brighton, Mass. These were the forerunners of the State and county agricultural fairs which have since played a very important part in our agricultural development.

Period of the Conquest of the Prairies.

The third period, which we have called the period of the conquest of the west, well have been called the period of transformation. The period between 1830 and 1860 witnessed, on American soil, a transformation of farming methods such as no previous period of 30 years had ever witnessed. It was a period of the introduction of farm machinery driven by horse power. At the beginning of this period practically every farm operation except plowing, harrowing and the drawing of carts was performed with human muscles. By the end of this period, corn was planted and
cultivated, wheat and other small grains were drilled, harvested and threshed, hay was mown and lifted into the mow or on to the stack by horse power—that is, on the more progressive farms.

The first factor in this transformation, aside from the native ingenuity of the American farmer, was the opening up of the great prairies of the West. At the beginning of this period the vanguard of the great army of settlers was just emerging from the great forest which extended continuously from the Atlantic coast to the western end of Lake Erie and the Wabash River in the middle streak, and to the Mississippi and beyond on the north and on the south. These prairies, though regarded as of doubtful value by the first settlers, soon proved themselves to be more fertile than the timber lands previously settled. Besides they were smooth and comparatively level and free from stones and other obstructions. They were therefore well adapted to, the use of horse-drawn machinery. This fact, together with their seemingly boundless expanse, offered a challenge to the inventor which he was not slow to accept. The reaper, the mower, the thresher, the corn planter and the cultivator followed one another in quick succession.

Another important factor in bringing about this transformation was the coming of the railroad. In 1830 there were no railroads in the United States. In 1860 there were 30,000 miles in operation and they had penetrated every State east of the Missouri River. They brought the markets of the world near to the Western fields and furnished an outlet to all that could be produced by means of the new farm machines. Through the repeal of the English corn laws, English markets were opened to American farm products in 1849. New England factory towns were growing at the same time, so that the factory populations of both Old and New England began to be fed with food grown in our great West.

The joint result of all these changes was an agricultural revolution, not only in this country, but in Europe as well. A flood of agricu-
lultural products began to pour into the Eastern markets and later into the European markets. The Eastern farmers and the European farmers began to feel the pressure of the new competition. On the more broken and stony farms of New England the farmers were unable to stand the pressure and public attention began to be called to the abandoned farms. This pressure, which began during the period we are now studying, continued and increased during the next quarter century.

The Period of the Settlement of the Far West—The period from 1860 to 1888 begins with the use of horse-drawn machinery well established. Many improvements were made, particularly in reaping and threshing machinery, during this period. The Marsh harvester, the wire binder and the twine binder followed in quick succession. The roller process of manufacturing flour made it possible to manufacture excellent flour out of Northern spring wheat, a process previously been considered impossible. This, together with the improved harvesting and threshing machinery, made it possible to cultivate the vast prairies of the Northwest, making Minneapolis the centre of the flour manufacturing industry. The building of the transcontinental railway lines, most of them projected in advance of settlement through subsidies of government land, still further hastened the settlement of the far West. More important, possibly, than any of these were the homestead laws of 1862 and 1864, already referred to, which gave the land free of charge to actual settlers. The tide of settlement literally swept across the prairies during the seventies, the eighties and the early nineties, all but exterminating the buffalo and crowding the Indians into reservations where they could be protected against the competition of the white man. The settlers were mainly people from the Eastern and middle West settlements, but their numbers were greatly increased by the immigrants from northern Europe who began coming to the United States in unprecedented numbers after the close of the Civil War. During the decade from 1860 to 1870 there arrived more than 2,000,000 immigrants; during the decade from 1870 to 1880, and 5,250,000 from 1880 to 1890. During the decade from 1870 to 1880 more than 297,000 square miles were added to the cultivated area of the United States. The population had increased to that of Great Britain and France combined.*

One result of this rapid expansion of our agricultural area was the disorganization of agriculture in the older States and in Europe. Wheat began to be exported in enormous quantities, and its price, in consequence, fell to unremunerative levels. While this, and a similar fall in the price of other products, tended to discourage the farmers of the older sections, it did not deter the western settler from the work of extending the agricultural frontier farther and farther west. Many of the settlers, in fact, had no intention of remaining in the farming business, planning rather to get a piece of government land, hold it for a few years and then sell it at a price which would remunerate them for the time spent. Crops were grown and sold, meanwhile, in order to live until a buyer with a satisfactory price arrived. They lived literally by mining the soil and selling it, rather than by farming. Against this kind of competition the recent burners of farms found it hard to strive. The result was a vast amount of agricultural discontent. Shameless demagogues flourished and fattened on this discontent, telling the farmers that it was the fault of the monetary system, or that it was due to some other more or less occult force rather than to the over-supply of agricultural products. The seventies, the eighties and the early nineties witnessed several political movements among the farmers of the South and the West, none of which, however, succeeded in seriously modifying the financial system.

The complete reorganization of the cotton-growing industry constitutes the most violent agricultural change of this period. In 1860 the bulk of the cotton crop was grown by slave labor. After the Civil War cotton prices were soaring because of the cotton shortage of the war. It sold for 43 cents a pound in 1865 and for 30 cents in 1866. Under the stimulus of these prices many planters undertook to grow cotton on a large scale with hired negro help and with borrowed capital. The price fell rapidly and brought bankruptcy to many of the

Agriculture in the United States

Planters. But both the landowners and the negroes had to live, and to live mainly on cotton. It was therefore necessary that some useless system should be devised. This was found in the one still in vogue throughout the greater part of the cotton belt, at least in the eastern half of it. The land is worked by negro tenant-farmers who cultivate small tracts on shares. Thus both landowner and laborer share in the risk and the danger of complete bankruptcy is avoided.

The Period of Reorganization. — The year 1888 is chosen as the beginning of the fifth period in our agricultural history, not because any profound change was noticeable on that date, but because there began about that time a series of changes which are destined to produce, — which have, in fact, already begun to produce, — profound agricultural changes. Congress had, in the preceding year, passed the famous Hatch Act, or the Experiment Station Act, as it is sometimes called. Agricultural experimentation began at once on an enlarged scale. This led to a more comprehensive and systematic application of the principles of experimental science to agriculture than had ever been undertaken before.

Another large fact is that through the rapid occupation of the public lands the available free lands in the humid belt were nearing exhaustion. The old pioneering period in American agriculture was therefore drawing to a close and a new period was opening, wherein the farms must first be created by considerable outlay of labor and capital before profitable farming can begin. During the old period waste land was merely land which lay to the west. It was only necessary for the settlers to move to it in order to bring it within the cultivated area. From now on waste land is land which goes to waste not because of geometrical distance, but because of bad physical, chemical, or political conditions. Bad physical conditions may be described as (1) too wet; (2) too dry; (3) too stony; (4) too sandy. The cure for the first is drainage; for the second, irrigation; for the third, the clearing of the stones; for the fourth, the supplying of humus through the application of manure and green crops.

Bad chemical conditions may be described as (1) too much acid, and (2) too much alkali. The cure for the first is lime. The second is a complicated problem too difficult for discussion within the limits of this article. * Bad political conditions may be described as (1) bad taxation; (2) undesirable social surroundings; (3) poor educational facilities; (4) poor sanitation. The cures are obvious.

The point to remember is that it is no longer possible for the landless man who can acquire a team, a wagon, plow, harrow and a few other implements, to begin farming on free public land. The drainage of wet land, the irrigation of dry land, the clearing of stony land, the supplying of humus to sandy land are laborious and expensive processes. These opportunities are consequently open only to men with some capital, either of their own or advanced to them on easy terms by others. The same may be said of land which is either too sour or too alkaline. Land which is going to waste through bad political or social conditions is more abundant than is commonly supposed. A detailed description here would provoke resentment and do no good.

In the early settlement of the continent, when serious difficulties had to be overcome, experience showed that the colony system rather than the system of individual settlement was the practicable method. The system of individual settlement flourished under the easy conditions found in the Mississippi valley. Now that we are again face to face with difficult conditions, the lesson of history shows that we must again return to the colony method. In the field of irrigation the Mormons and the Greeley colony of Colorado have furnished us with excellent examples.*

The tendency, which has almost become a habit, of well-to-do farmers to leave the farms and retire to the towns, is primarily a result of bad social conditions in the open country. These call peculiarly for the colony idea as a corrective. Though the physical difficulties in the way of the new pioneering call for united or community effort, such as can only be found where the colony idea prevails, these do not point so unerringly toward the colony system as do the social difficulties. Where families of unlike ideals, customs and traditions are thrown together, higgledy-piggledy, in the same neighborhood through the method of individual settlement, it is difficult to secure effective community action. Such a settlement may succeed in overcoming the physical difficulties where they are as easy as they were in the middle-western prairies, but it can never succeed where they are as great as they are in most of the lands which remain to be subjugated, and it is utterly incapable of handling the social difficulties which are found in very many of our rural communities.

Unity of sentiment and feeling, or like-mindedness, which is the condition of all effective community work, may grow out of a feeling of common and pressing necessity, as in the case of the early pioneers in time of physical danger; it may be based upon a common kinship, nationality or language, as in the case of some Scandinavian communities of our Northwest, or it may be based upon a common religion, as in the case of the early New England towns, many Pennsylvania German communities, a few Quaker communities, a few Scotch Presbyterian neighborhoods, and especially the Mormon settlements of the Far West. A combination of all these unifying factors gives the best results. The agricultural statesmen of the future must build our agricultural civilization on community action. Effective community action must have some unifying sentiment to give it body and consistency. Therefore, the problem of agricultural statesmanship is to discover or create these unifying sentiments.

In almost every agricultural region there is one crop which, under the conditions of soil, climate and markets, is more profitable than any other, such as cotton in the South, corn in the Middle West and wheat, oats and barley in the Northwest and in the Middle Southwest. In the early development of every such region there is a tendency toward what is called the *one crop

*Consult Katharine Coman, 'The Economic Beginnings of the Far West.'
system, under which all the labor of the farmer is concentrated on his most profitable crop. Later on there is, in every progressive community, a tendency toward diversification. This is not the case that one crop has ceased to be more profitable than any other. There are two reasons which combine to force the change. The first is the necessity of economizing the soil, and the other is that of economizing the labor time of the farmer. Growing one and continuously on the same soil tends not only to exhaust those elements in plant food which are required by the crop in question, but to multiply the enemies and parasites which prey upon or injure it. A change of crops not only gives the soil a rest, but interferes more or less with the development of the enemies of each crop. The crops which are introduced into the rotation need to be chosen very carefully in order to give the soil the maximum rest and also in order to afford the most effective check upon the enemies of the major crop.

Quite as important, however, is the necessity of economizing the labor time of the farmer and his labor force. No crop requires equal treatment year after year. When the major crop requires all the time of the labor force it would be uneconomical to turn aside to work on a less profitable crop. But if the farmer grows as much of the major crop as he can handle when it demands the most attention, he will have time to spare at other seasons of the year. This time will ordinarily be wasted unless he has other crops which require his time then. If minor crops can be found which do not demand attention when the major crop is requiring it, but can be handled at other times and seasons, the farmer can obviously make a more economical use of his labor force by growing some of these minor crops.

Neither of these reasons in favor of rotation are very strong in a new and undeveloped farming community. In the first place the soil is usually so rich as not to require immediate conservation. In fact, the pioneer farmer was usually in great need of other forms of capital, while food was in superabundance and manure was cheap. From his point of view it was not unbusinesslike to reduce his over-supply of one form if by so doing he could increase those forms which he lacked. Therefore he would be inclined to grow only his most profitable money crop. In the second place, on a pioneer farm there are so many other things to do besides growing crops that the farmer need never spend an idle day from the beginning to the end of the year. Paving, draining, erecting buildings, clearing stones, stumps and other obstructions and a multitude of other improvements have to be made. Under such circumstances it is natural and economical that he should grow only his most important money crop, and spend his time during the slack seasons making these necessary improvements.

In case, however, as in some portions of the South, the labor force is not inclined toward steady and continuous work the year round, the tendency to stick to the principal money crop rather than to rotate and diversify persists long after the pioneering period has been passed. Seasons of strenuous work followed by periods of idleness seem to be preferred by the negro farmer. This is one of the chief obstacles to the proper diversification of crops in the South. There is probably no other crop which the cotton farmer could grow which is so profitable as cotton. Therefore, if diversification meant less cotton, it would probably reduce his income. But if he will equip himself with first-rate teams and tools he can grow more cotton than he can possibly pick. There is a tendency, therefore, to work with inferior teams and tools — with one mule per gun. For example, instead of with two, three or four, because one man can usually grow as much cotton with one mule as he can pick. The way for the cotton farmer to increase his income is to cultivate more land, growing as much cotton as he can pick, and some other crops besides, provided he can find crops which can be handled when cotton does not demand the full time of his labor force. In order to do this each hand should work at least two mules, though four would be better. The cotton belt is fairly smooth and free from obstructions. This habit of working with large teams and tools has had a great deal to do with the prosperity of the farmers of the upper Mississippi valley. It is also one of the factors in the increasing tendency toward rotation and diversification.

The principal crop areas of the country must be defined in terms of the principal money crops rather than in terms of the subsidiary crops. The cotton belt, the corn belt and the spring and fall wheat belts are fairly well defined, provided we observe the above definition. There is, for example, scarcely an agricultural county in the United States in which corn is not grown, but it is grown as the principal money crop in what is known as the corn belt. Wheat is widely grown, but only in restricted areas as the principal crop. Potatoes are grown as the principal money crop in small areas scattered here and there, such as Aroostook County, Maine, parts of western New York, of Michigan, Wisconsin, Minnesota, Montana and Colorado; barley in parts of Wisconsin and California; buckwheat in a few counties in Pennsylvania and New York; hops in a few counties in New York and Washington; tobacco in many scattered areas from Louisiana to Vermont, particularly in the Connecticut valley, southern Ohio, eastern Pennsylvania, southern Wisconsin and the border States between the cotton belt and the corn belt.

Turning from field crops to farm animals, we find the hog in greatest numbers in the corn belt, cattle are widely scattered, dairy cattle being found in greatest numbers in the thickly populated States of the east, and beef cattle in the corn States and the contiguous grazing States to the west. Horses are raised in greatest numbers in the corn States, though Kentucky, Tennessee and Texas raise considerable numbers. Sheep are diminishing in numbers, but are grown in considerable numbers in Ohio, Michigan, Wyoming and the Pacific Coast States.

If one were to describe American agriculture in terms of the size of the business unit, one would say that the characteristic farm is the middle-sized farm, or the one-family farm. That is, it is a farm of such size as can be worked by the labor force of one family, with an occasional hired man, when equipped with
the best teams and tools that are to be had. It differs from the small peasant farm of Europe in that it includes a larger area, and because of the larger area makes use of larger teams and tools. The tendency toward this type of farming is growing, as shown by the fact that the large farms—those of above 1,000 acres—are diminishing in number, and that the smaller farms also—those under 100 acres—are diminishing in number. In other words, the tendency is toward the farm of from 160 to 320 acres. From the standpoint of production, this middle-sized, or one-family farm is the most efficient unit yet discovered in this country. From the trading point of view it is less efficient than the larger unit. In other words, where the farmer's success depends primarily upon his efficiency in production, the middle-sized one-family farm will beat all others in competition. But where the farmer's success depends primarily upon his efficiency in bargaining, that is, in buying and selling, the large farm has the advantage. In the growing of staple products for which there is always a well-organized market where they always sell at a quota price, the farmer's success will depend more upon his skill as a producer than upon his skill as a bargainer. But in the growing of specialties, which do not sell at a quota price and for which there is no organized market, the farmer's success will depend much more upon his success in selling than upon his success in producing. This is the field where the large farm has a handicap. On the other hand, where there is a much larger middle-sized farmer more than holds his own in competition with the big farmer.

AGRICULTURE, Department of, an executive department of the United States, whose head is a member of the Cabinet with the title secretary of agriculture. It was formed early in 1889 under President Cleveland, the first secretary being Norman J. Colman of Missouri; he was succeeded in the same year, under President Harrison, by Jeremiah M. Rusk, of Wisconsin; in 1893 President Cleveland in his second term appointed J. Sterling Morton, of Nebraska; in 1897 President McKinley appointed James Wilson, of Iowa, who was succeeded in 1913 by David F. Houston, of Missouri, the present incumbent (1916). Its germ was a distribution of seeds to farmers by the Commissioner of Immigration (1863); Eberle in 1839 to include the prosecution of agricultural investigations and collection of agricultural statistics; in 1854 a special appropriation was made and an entomologist employed; in 1853 a chemist and botanist were added and
a propagating garden begun. In 1862 the Agricultural Bureau was established separate from the Patent Office, and President Lincoln appointed Isaac Newton, of Pennsylvania, Commissioner of Agriculture; the last commissioner was Mr. Colman, the first secretary. The Department's quarters in Washington are in a large park near the Washington Monument. Its functions are expressed by statute as: "To acquire and diffuse among the people of the United States useful information on subjects connected with agriculture in the most general and comprehensive sense of that word; and to procure, propagate and distribute among the people new and valuable seeds and plants; but scientific and administrative duties have been heaped upon it till it has become not only an enormous workshop and museum of every class of scientific research relating to plant and animal life and that of agricultural animals, but an establishment of practical services in trade and commerce, diseases dangerous to live stock, tree planting, road-making, irrigation, insecticides and almost everything that can affect the interests of those engaged in raising and marketing all articles that grow from the ground or living things that feed on them. Even the Weather Bureau was transferred to it, in 1891, from the War Department.

Its cost is over $20,000,000 a year, of which about $2,200,000 goes to extension work. The detailed statement below will give a full conception of its activities.

**Organization and Functions.**

**Office of the Secretary.**—Supervision of public business relating to the agricultural industry and management of department subdivisions; advisory supervision over government agricultural experiment stations; control of quarantine stations for imported cattle and of interstate cattle quarantine, including inspection of cattle ships; also carrying into effect the interstate game laws and those on importation of noxious animals, with authority to control that of other animals.

**The Weather Bureau.**—Records daily existing atmospheric conditions and formulates the general distribution of probable weather during the succeeding 48 hours. It maintains a central office in Washington, and 197 subordinate stations in the United States and West Indies, whose work is supplemented by the services of 4,500 voluntary observers. It also receives daily telegraphic reports of observations in Canada, Mexico, the Azores and the western coast of Europe.

**The Bureau of Animal Industry.**—Investigates the nature and prevention of communicable diseases dangerous to live stock, and takes measures for their extirpation; inspects live stock and their food products in interstate and foreign commerce, also the transport vessels for exported and quarantine stations for imported animals; disseminates information on our dairy interests and their foreign markets; and reports on our animal industries and means of improving them.

**The Bureau of Chemistry.**—Studies the chemical problems of agriculture; soils, fertilizers, irrigation waters; agricultural products and industries; insecticides and fungicides; foods of man and beast; raw materials, products and processes of agricultural-chemical industries; chemical relations which modify the results of environment—as soil, latitude, altitude and meteorological conditions; on agricultural products; inspects food products imported or for export; and examines quality of materials used in road construction. The chemical problems of other departments are turned over to it. It has under its charge the inspection of foods and drugs, as authorized by the Pure Food Act.

**The Bureau of Plant Industry.**—Studies plant life in relation to agriculture, including vegetable, pathological and physiological, botanical, pomological, grass and forage plant investigations and experiments; has charge of experimental gardens and grounds, the Arlington experimental farm, Congressional seed distribution, seed and plant introduction and tea culture experiments.

**Forest Service.**—Prepares and executes plans for conserving lumbering of woodlands, public or private; fire laws and tree planting, road-making, irrigation, insecticides and almost everything that can affect the interests of those engaged in raising and marketing all articles that grow from the ground or living things that feed on them. Even the Weather Bureau was transferred to it, in 1891, from the War Department.

It is over $20,000,000 a year, of which about $2,200,000 goes to extension work. The detailed statement below will give a full conception of its activities.

**The Bureau of Soils.**—Studies physical and chemical properties of soils, and materials and methods of artificial fertilization, with their influence on the original soils; classifies and maps soils in agricultural districts to show the distribution of soil types for adaptability to certain crops and their management; investigates alkali problems and their relations to irrigation and sewage waters; reclamation of abandoned lands; studies tobacco soils and methods of cultivation and curing, introduction of improved varieties and methods of exporting tobacco. The total area covered by detailed soil surveys in the United States from 1899, when the work began, to 30 June 1915 amounts to 369,928 square miles.

**The Bureau of Crop Estimates.**—Collects and digests statistics of agricultural products; area annually sown to each of the leading crops, their condition on the first day of each month, the quantitative results at close of the crop year, and estimated farm value 1 December. Supplementally it collects periodical information on minor crops of importance, meadows and pastures, and the principal foreign crops. The stock of corn, wheat and oats on United States farms at certain regular fixed dates is estimated, with the proportion shipped out of the country when; magnitude; number and value, by species, of animals on United States farms at the beginning of each year, and the annual losses from disease and exposure; also the annual clip of wool and average weight of fleeces, by States and Territories. It computes the world's production of the chief crops, by countries, and prices of principal agricultural products in various United States markets.

**The Division of Publications.**—This is the publishing house of the Department. The general charge and assignment of expenditures under the appropriation for printing and distributing agricultural documents, preparation
and distribution of the 'Year-Book,' 'Farmers' Bulletins,' and other bulletins, reports and circulars; supervises the Department's printing and binding in the government printing office, provides for the drawings for illustrations, and prepares and distributes official information and advance notices to agricultural writers. During 1915 the Division issued 913 new bulletins, pamphlets, circulars, reports and documents of all kinds, the printed copies aggregating 20,496,661.

The Bureau of Entomology.—Studies the entire field of insect life in its relation to humanity; primarily, insects injurious directly to man, to agriculture and horticulture, and to stored products; the geographic distribution of such insects, and their relations to climate. It conducts field and laboratory experiments with different classes of remedies, and reports thereon. It also studies beneficial insects—both those which are the sources of industries, like the honey-bee, the silkworm and the fig-fertilizing insect and those indirectly beneficial by preying on injurious ones. It makes large collections of insects and of insecticidal machinery.

The Bureau of Biological Survey.—Studies the geographic distribution of animals and plants, and maps the natural life zones of the country; also investigates the economic relations of birds and mammals, recommends measures for the preservation of beneficial and the destruction of injurious species, and carries into effect the Federal laws concerning the importation of wild birds and other wild animals, and the interstate game laws.

The Office of Public Road and Rural Engineering.—Investigates the United States system of road management and the best methods of road-making and maintenance; experiments on best methods of road-building and analyzes chemical and physical qualities of road materials; co-operates with agricultural colleges, experiment stations and local authorities in building short sections of road as object lessons, and conducts investigations into proper methods of irrigation and drainage.

Office of Dividends and Disbursements.—Audits and pays all accounts and adjusts claims against the Department; decides questions involving the expenditure of public funds; prepares advertisements, schedules and contracts for annual supplies, leases, agreements, letters of authority and all letters to the Treasury Department and Department of Justice; issues requisitions for the purchase of supplies and requests for transportation; prepares the annual estimates of appropriations, etc.

The Library.—The librarian purchases books and periodicals, supervises their arrangement and cataloguing, and has charge of the preparation of catalogues, indexes, bibliographies, etc.

Federal Horticultural Board.—Established to administer the Plant Quarantine Act of 20 Aug. 1912, regulating the entry of foreign nursery stock and other plant products into the United States and providing for domestic and foreign quarantines on account of plant diseases and insect pests.

Office of Markets and Rural Organization.—Enforces an act of 18 Aug. 1914 which taxes the privilege of dealing on exchanges, boards of trade and similar places in contracts of sale of cotton for future delivery, whose object is to curb speculation. The office also makes a study of co-operative organizations among farmers with the object of extending such organization more widely and it requires and spreads information regarding improved methods in the marketing and distribution of farm products.

States Relations Service.—A department which was formally established by Secretary Houston on 1 July 1915, in accordance with the provisions of the Smith-Lever Agricultural Extension Act of 8 May 1914, providing for a wide extension of the co-operative activities carried on with the various State colleges on a permanent basis. The Smith-Lever Act appropriates money as follows: The sum of $10,000 of Federal funds is granted to each of the 48 States. In addition to the $480,000 in the act there are $600,000 additional, which will be increased annually by $50,000 until 1923, when the annual government appropriation will be $4,580,000. The additional appropriation is divided among the States in the same proportion that the total population of each State bears in relation to the rural population of the country as a whole. Each State, on its part, must grant a sum of money toward the funds equal in amount to the Federal grant. The money from the States will bring the joint extension work funds up to $1,680,000 in 1916. In addition to all these provisions, however, the Department of Agriculture will, during 1916, spend from its own appropriations $1,025,000 for farmers' co-operative demonstration work and other field instruction in special subjects. The new States Relations Service will include within its jurisdiction the former Office of Experiment Stations, which superintends the work of the experiment stations and sends its agents all over the world in search of useful plant life that may be introduced into the United States. Since the Service was established all the States have assented to the provisions of the Smith–Lever act. A single agricultural college in each State is named as the beneficiary of this act. In several where the college is not coeducational a co-operative arrangement for work in home economics has been made with the State college for women. All the State agricultural colleges receiving the benefits of the States Relations Service have entered into co-operative relations with the Department of Agriculture, and in 46 States these institutions and the Department are conducting all their extension work in agriculture and home economics under a general memorandum of understanding, which is used as a basis for a great variety of co-operative project agreements.

One of the chief works which is being undertaken is the establishment of the "county agent" system. The county agent is an agricultural expert who acts as the joint representative of the local community, the State through its agricultural college and the Federal Government through the Department of Agriculture. The functions of the county agent are various: he advises the individual farmers in their work, instructing them in all modern and scientific methods of planting or stock raising, assists them in the buying of their supplies on
a co-operative basis and advises them in the marketing of their products. His business is, in fact, to do all in his power to further the interests of his local community as an agricultural centre. Already 1,200 counties have established such county agent headquarters. Another line of extension work which will be greatly stimulated by the States Relations Service is the organization of agricultural clubs among school children, in connection with the work of the elementary schools. The same is true of the agricultural economic, which will now be extended to the colleges which number girls among their students.

The following figures will give an idea of the relative attention that is being paid to the various fields of this work. Of a total of $4,782,270 the following sums will be spent on: Administration, $391,652; publications, $107,980; county agents, $2,497,426; home demonstration, $542,732; movable schools, $218,000; school children's clubs, $235,917. It will be seen that the largest item, over one-half of the total, is county agent work. The rest of the appropriation will be spent in minor sums on pig, poultry and live-stock associations.

Agrigentum, ág'i-jên'tüm, a town in Sicily, of which this was the Roman name, the Greek name having been Agragas and the modern Italian name being Girgenti. It is thought to have been founded by Dorian colonists about 552 B.C. Its situation on the southern shore of the island was peculiarly strong and imposing, standing as it did on a bare and precipitous rock about 1,000 feet above the level of the sea. During the Greek period Agragas rose to a position of great wealth and importance and was adorned with splendid temples and public buildings. Among Sicilian towns it was second only to Syracuse. In 406 B.C. the city received a blow from which its dignity and power never recovered, in its capture by the Carthaginians. Under the Roman dominion we do not hear much of it, which, however, seems to have always been prosperous, having mines as well as the most fertile territory. The town is celebrated in Greek history as the birthplace of the famous philosopher Empedocles, and the celebrated and almost legendary tyrant Phalaris was ruler there—in what capacity is not clearly recorded. In the history of fine arts Agragas was famous as the centre of a school of sculpture and refined architecture. We still have vestiges of this in the extraordinary group of temples, that dedicated to Hera Lacinia, that called the Temple of Concord, a remarkably well-preserved monument of the Doric style; that called the Temple of Hercules, much ruined; and, finally, the gigantic Temple of Zeus, a building wholly unique in Greek art as having columns engaged in the walls of the cella and a great interior evidently treated as a public hall.

Agrimony (Agrimonia), a genus of plants belonging to the family Rosaceae, distinguished from the other genera of the same tribe (Rosae) by having but two carpels enclosed in the deep tube of the calyx, from 7 to 20 stamens and small notched petals. A. eupatoria, or common agrimony, is an erect, hairy, herbaceous plant, native of Europe. Several species are widely distributed in eastern North America.

Agrippa von Nettesheim, Heinrich Cornelius, a versatile German diplomat, historian, philosopher and author: b. Cologne, 14 Sept. 1486; d. Grenoble, 18 Feb. 1535. He led a remarkably diversified life in France, Italy, Switzerland and the Netherlands, and wrote among other works: 'De Occulta Philosophia' (1510) which describes and defends magic; 'De Nobilitate et Præcelentia Feminc Sexus,' dedicated to Margaret of Burgundy (1532); and 'De Incertitudine et Vantitate Scientiarum et Artium, Atque Excellentia Verbi Dei Declamatio' (1527), a satire on sciences and on the pretensions of scientists. Consult Morley, H., 'Life of H. C. Agrrippa,' (London 1856); Prost, A., 'Corneille Agrippe, sa vie et ses oeuvres' (Paris 1881).

Agrippa I and II. See Herod Agrippa I; Herod Agrippa II.

Agropyron, a genus of grasses including about 50 species, mostly perennials. The best known are A. repens, couch grass or twitch grass; A. caminum, bearded wheatgrass; A. divergens, wire bunch grass; A. pseudorepens, western couch grass. A. lanigerum, slender wheat grass; A. repens is in some districts considered a pest to agriculture. It is extremely hard to eradicate. It is considered a good hay grass in western United States. The species are common in America, Europe and Australia. A. repens is considered a good binder grass for railroad embankments and places liable to washouts and its roots are used in medicine, having aperient properties.

Agtelek, ág'té-lék, or Aggtelek, Hungary, a village in the County of Gömör, 40 miles southwest of Kaschau, on the road from Budapest to Dobosna. Pop. 500. It is a famous tourist resort on account of the neighboring Baradla ('steaming place') stalactite cavern, which with its remarkable chamber, passages and subterranean stream extends underground for over five miles.

Aguailla, á'gwá-él'ya, Porto Rico, capital of a municipality on the western coast, near the northern extremity of the island from Mayaguez. The town, founded in 1775, is well built on a spacious bay forming an excellent trading outlet for the sugar, tobacco, coffee, coconuts, etc., of a fertile agricultural district. Pop. of municipality 21,500; of town 6,200.

Agua, á-gwá'ðó, Alejandro Maria, Marquis de las Marias del Guadalquivir, Spanish financier and millionaire: b. Seville, 29 June 1784; d. Gijon, 14 April 1842. Of Jewish parentage, he early became a soldier, fighting in the war for Spanish independence. Exiled, he went to Paris in 1815 and in colonial trade and banking with Cuba and Mexico acquired great wealth. From 1823 to 1831 he negotiated four loans which saved Spain from bankruptcy. For these services he was ennobled by Ferdinand VII. He acquired large estates in France and became a naturalized citizen in 1828. He left a fortune of over $12,000,000 (60,000,000 francs), and a collection of splendid pictures which were acquired by the French government.

Aguaras Calientes, á'gwá's kâl'ê-én'tás, Mexico, capital of the state of the name, on the line of the Mexican Central Railroad, 800
miles south of El Paso, Tex., 364 miles north of the City of Mexico and 415 miles northwest of Tampico, on the Gulf of Mexico. Elevation 6,106 feet above the sea. It is especially noted for its hot springs (the name Aguas Calientes signifies hot waters), which have been highly prized ever since their discovery. Here are located the principal stores and one of the division headquarters of the Mexican Central Railroad, the result of which has been the establishment of a considerable colony of Americans. Here, also, is located one of the greatest silver-copper smelting plants in the world, employing a multitude of men, and adding materially to the business prosperity of the community. In the city and its immediate vicinity are several woolen factories, a flouring mill, a starch factory and other important manufacturing enterprises. Perhaps the most notable social industry, and for which the place has become really famous in domestic circles, is the making of drawnwork table cloths, napkins, doilies, handkerchiefs, dresses trimmings and accessories of every description, in which a considerable part of the female population is employed. Imposing church edifices and beautiful parks or plazas greet the eye on every side. The cause of education,—both primary and advanced,—has long received great attention in Aguas Calientes. The educational institutions are most creditable, not only in numbers and capacity but in the thoroughness and progressiveness of the professors and teachers by whom they are conducted. The local financial institution—the Bank of Aguas Calientes,—has a capital of $600,000. The National Bank and the Bank of London and Mexico maintain branches here, and there is an agency of the Bank of Zacatecas. The library of the Institute of Sciences contain over 4,000 volumes. As a place of residence the city has long been a prime favorite.

AGUE. See MALARIA.

AGUESSEAU, âgé-sô. Henri François d', chancellor of France: b. 1688; d. 1751. According to Voltaire, he was one of the most learned of Frenchmen and his long and honorable career is distinguished chiefly by his defense of the Gallican Church and the rights of the people, in opposition to the imposition of the "Union Révolutionnaire," favored by Louis XIV and his councilors. He also ranks high as a reformer of French jurisprudence. A complete edition of his works, edited by Pardessus, J. M., was published in 16 volumes (Paris 1818-20). Consult Butler, C. 'Memoir of the Life of H. F. d'Aguesseau.' (London 1830).

AGUILAR y CORREA, âgé-lâr, Antonio, Marqués de la Vega de Armijo, Spanish statesman: b. Madrid, Spain, 30 June 1824; d. 1909. He studied law in the universities of Seville and Madrid, then became prominent in the politics of the Union Liberal party. His first office was that of governor of Madrid and during his term of office he distinguished himself by his severity against vice. He next became minister of public works, then minister of the interior. On the downfall of his political party, 22 July 1866, he insisted in the preparations for the revolution, which was successful. In 1873 he was sent as the representative of Spain to France. After the restoration he recognized Alfonso XII. In 1883 he passed over to the opposition and the following year was elected "Concejal" for Madrid. On the death of the King, Alfonso XII, his party returned to power and he was elected deputy for Madrid and Lucena. In 1889 he became minister of state, but a year later his party fell from power. Late in 1892, under the presidency of Sagasta, he was again made minister of state, in this position he resigned a few months later in order to be elected president of the congress, a position he held until March 1895, when Sagasta fell from power. In 1898 he was elected president of the congress of deputies. Aguilar was a member of the Royal Academy of Moral Sciences and Politics and the Royal Academy of History; and was for a time director of both.

AGUILAR, Grace, Anglo-Hebrew author: b. London, 2 June 1816; d. Frankfort-on-Main, 16 Sept. 1847. 'The Spirit of Judaism' (1842); 'The Jewish Faith' (1846) and 'Home Influence' (1846), of which over 30 editions were issued, are her chief works. 'The Vale of Cedars, (1850); 'A Mother's Recompense' (1850) and 'The Days of Bruce' (1852), edited by her mother, appeared under her name.

AGUILAR DE LA FRONTERA, âgé-lâr dah lâ fрон-tâ-râ Spain, city of Cordova province, Andalusia, on the river Cabra, 26 miles by rail southeast of Cordova. A former fortified town on the Moorish frontier, it has an interesting history. Its modern importance is derived from its olives and white Montilla wine and the thriving agricultural and manufacturing trade carried on. Pop. 13,000.

AGUILAS, âgé-lâs, Spain, seaport town of Murcia province on the Mediterranean, the terminus of the Huercal-Overa Railway, 38 miles southwest of Cartagena. It is the commercial outlet for the iron, minerals and agricultural produce of the region, and imports large quantities of coal. Pop. 16,000.

AGUILERA, Ventura Ruiz, âgé-lârâ, ventoo-râ roo'-eth, lyric poet, the Spanish Beranger: b. Salamanca, 2 Nov. 1829; d. Madrid, 1 July 1881. After returning home he became a Madrid journalist (1843) and an important official under Liberal governments; later a director of the Madrid Archaeological Museum. His bold incisive editorials endeavored to instil fervid national patriotism into the masses, an aim also of his poems like 'National Echoes' and 'Satires.' His 'Elegies' (1862) were masterpiece translated into nearly all European languages. He wrote also 'The Book of the Fatherland' (1869); 'A Christmas Legend' (1872); 'The Modern Arcadia'; collections of novelettes, etc.

AGUILLOW, dâ'gé-lyôn', François d', Belgian Jesuit, philosopher and mathematician: b. 1566; d. 1617. He became rector of the Jesuit College at Antwerp and was the author of an important work on optics, containing the earliest description of stereographic principles, published in 6 volumes (Antwerp 1613). AGUINALDO, âgé-nâl-dô, Emilio, leader of the insurgents 1896, he assisted in the preparations for the revolution of 1896, and their chief in the Spanish-American war of 1898: b. Imus 1870 of Chinese and Tagalog parentage. His father was a planter and he received his early education at the
College of St. Jean de Lateran and the University of St. Tomas in Manila. Later he became the protégé of a Jesuit priest, and was for a time a student in the medical department of the Pontifical University of Manila. In 1886 he had some conflict with the authorities and went to Hongkong, there becoming interested in military affairs and acquiring a knowledge of warfare. He quickly learned something of the English, French and Chinese languages, together with various native tongues, acquired a reputation for intelligence, ability, shrewdness and diplomacy and had a personal magnetism which gave him great influence among his countrymen. On the outbreak of the rebellion against Spanish authority in 1896 Aguinaldo became a commanding figure with the insurgents. He was at the head of the diplomatic party, which succeeded in making terms with the Spanish government, the latter paying a large sum to induce the Filipino leaders to lay down their arms. Aguinaldo quarreled with his associates in Hongkong over the division of this money and went to Singapore, where he came in contact with the United States consul shortly before the breaking out of the war between the United States and Spain. On the representations of the consul Commodore Dewey telegraphed to have Aguinaldo sent to him and the insurgent leader arrived at Cavite shortly after the battle of Manila Bay. Aguinaldo was given opportunity to organize the Filipinos against the Spanish authority; but no promises were made to him and the insurgents were never officially recognized by the Americans. Friction early arose and the Americans protested against the cruel treatment of Spanish prisoners by the Filipinos. The strain became serious at the capture of Manila, the insurgents claiming the right to sack the city, which the Americans denied. On 12 June 1898 Aguinaldo organized a so-called Filipino republic, with himself as president, but very soon proclaimed himself dictator. He proceeded against the Spanish-American treaty of peace, which ceded the Philippine Islands to the United States, and claimed the independence of the islands. Organizing an extensive conspiracy among the native population of Mindanao and other islands, he tried to throw off the Americans, together with the entire European population of the city, while yet at peace with them. The plot was discovered in time and failed. The intention of Aguinaldo to oppose by force the American occupation had by then been growing increasingly evident and on the evening of 4 Feb. 1899 his forces attacked the American lines in the suburbs of Manila. The news of this overt action caused the prompt ratification of the Spanish-American treaty by the United States Senate. Aguinaldo made a determined resistance to the Americans and the rainy season soon prevented the latter from following up their uniform successes in the open field; but early in 1900 organized insurrection, which was chiefly confined to the Tagalog nationality, was broken up. Aguinaldo was captured and his correspondence, order books, etc., captured by General Funston, who captured Aguinaldo himself at Palawan, Luzon, 23 March 1901. On 2 April he took the oath of allegiance with the Consult Wildman. 'Aguinaldo' (Boston 1901); 'Aguinaldo et les Philippines' (Paris 1900).

AGULHAS, á-goál'yáhs, Cape, the most southern point of Africa, lies about 100 miles east southeast of the Cape of Good Hope, in lat. 34° 49' S.; long. 20° 0' 40" E. The point is very dangerous for ships; fogas are frequent, the currents are uncertain and there are many rocks to seaward.

AGUR, a-goor, the name of an unknown Hebrew sage mentioned only in Proverbs xxx, 1. There he is called the son of Jakeh. Much discussion has arisen concerning the name. Jerome and many Jewish rabbis of his time held the name to be a pseudonym used symbolically. Agur is not mentioned as the author but as the collector of the book of Proverbs. It is thought by some that he was one of Hezekiah's men. Another theory is that he was the son of the Queen of Massa, whose kingdom was located near the head of the eastern branch of the Red Sea.

AGUTI. See AGOUTI.

AHAB, King of Israel 875-853 (7) B.C., son and successor of Omri (1 Kings xvi-xxxii). He found his kingdom in extreme peril; whole districts in the north had been swallowed up by the growing Syrian kingdom with capital at Damascus, which menace was ever a lurking danger. Moab and Edom were possessions only to be held down by force, with Syria constantly inciting them to revolt. He proved a prince of great energy and ability; twice he drove back Ben-hadad of Damascus and he held down Moab with a strong hand, crushing a wholesale insurrection, as proved by the inscription on the Moabite Stone (q.v.); he made the kingdom of Judah an ally and perhaps a vassal, and gained at least the neutrality and perhaps some of the resources of the kingdom of Tyre by marrying the Princess Jezebel. Unfortunately this involved letting her establish the worship of the Tyrian Baal, called Melkart, and made the extremists of the Yahwe priesthood his irreconcilable enemies and defamers. Yet he was no deserter of Yahwe, but merely a cool politician, who felt that his first duty to his country and even to its national religion was to save it from absorption in Syria, which would end Israel and the Yahwe cult at once; and 400 priests of Yahwe prophesied before him from the face of the next campaign. His entire internal policy has been blackened by the affair of Naboth's vineyard, and Jezebel is a name of execration. Certainly the judicial murder was a great crime, but it shows at least that even an Oriental monarch 2,750 years ago could not expropriate an obstinate holder by sheer violence; defiance of royal orders was not as safe to let go for a precedent then as now and more than one king has had his hand forced by his queen. Nor in fact did these things prejudice the larger interests of his reign. In 854 we find him strangely allied with his old enemy Ben-hadad against Shalmaneser (q.v.) of Assyria, though one would suppose he would gladly have seen Ben-hadad crushed, and Assyria no immediate danger; possibly he was fettered in alliance with quarters and dared not refuse. At any rate, Shalmaneser inflicted a crushing defeat on the allies at Karkar near the Orontes in 854 and Ahab recovered liberty of action if he had lost it; for the next year he engaged in a new campaign against Ben-hadad in Samaria with Jehoshaphat, King of Judah, and was killed in
battle. The Biblical narrative is taken from two opposed sources; one embodying the pop-
ular tradition of Ahab as a brave, capable and pop-
ular king, the other the priestly view of him as a bad man and monarch. His contest
with Elijah (1 Kings xxvii–xix) is a picturesque
rendering of the latter.

AHASUERUS, a-hāzû-ê-rūs, Scripture history, a king of Persia, the husband of Esther, to
whom the Scriptures ascribe a singular de-

erance of the Jews from extirpation, which
they commemorate to this day by an annual
feast, that of Purim, preceded by what is
called the fast of Esther. Different opinions
have been entertained as to which of the kings
of Persia mentioned in other historical books
may be the Ahasuerus of the Bible. He is
probably the same as Xerxes. Ahasuerus is
also a Scripture name for Cambyses, the son
of Cyrus (Ezra iv, 6) and for Astagyes, King of the Medes (Dan. ix, 1). The word
Ahasuerus is merely the Latin form of the Heb-

rew Ahasuervos and is believed by some to be

the Persian Khosrovsharsha ("venerable king") and this name may be reasonably supposed to have been originally

an appellative, so that its application by for-

eigners, like the Jews, to different royal person-

ages is explained.

AHAVA-va, the name of a stream and a
district or town in Babylonia, mentioned in
the book of Ezra. The river was probably
one of the canals of the Euphrates near the
city of Babylon. On its banks Ezra assembled
his company and camped for three days be-

fore returning to Jerusalem. The site and the
river still remain unidentified although many
conjectures have been made. In the apocry-
phal book of First Esdras the name is given
as Theras.

AHAZ, the 12th King of Judah, succeeded
his father Jotham, 742 B.C. Forsaking his fa-
ther's religion, he gave himself up so completely
to idolatry that he is said to have caused his
own son to pass through the fire to Moloch, and
plundered the temple to obtain presents for
Tiglath-pileser, King of Assyria, whose assist-
ance he desired to obtain. His powerful ally
freed him from his most formidable foe by
invading Syria, taking Damascus, killing Rezin,
the King, transporting the inhabitants of Kir,
thus putting an end to the Syrian kingdom of
Damascus, and by stripping Israel of the whole
country east of the Jordan.

AHAZIATH, two kings referred to in the
Bible. The first was the son and heir of Ahab,
and the 8th King of Israel, from 851 to 849 B.C.
On assuming power the Moabites refused to
pay tribute, but before he could march against
them they fell from a window of his palace and
was badly injured. He sent messengers to the
god Baal Zebub of Ekron to consult him in
regard to his injuries, but the messengers were
met by Elijah, the Prophet of Yahwé, who
sent them back with the information that the
King would die. He was succeeded on the
throne by Jonadab. The second
Ahaziah referred to was the son of Jehoram
and of Aráb's daughter, Athaliah, the 6th
King of Judah. In 2 Chron. xxi, 17 he is
called Jehoahaz and in 2 Chron. xxii, 6 Azariah,
which is an error of transcription, as indicated by the Greek version. With his uncle, Jehoram,
he served in the latter's campaign against
Hazael, King of Syria. Later he was slain by
Jehu, after having been on the throne only a
year.

AHIKAR, a-hékär, the vizier of Sennach-
erib. The story of Ahikar has recently been
published. Scholars claim for it a greater an-
tiquity than that of the Book of Tobit or the
Book of Daniel. Both seemed to have bor-
rowed from it. Ahikar being childless, adopted
a boy named Nadan and treated him as his
own son. He was not worthy of the care laid
upon him. He fell into thievery and deposited
in Ahikar's name, thus procuring Ahikar's
condemnation to death. The executioner spared
him but imprisoned him. In time he was
restored to royal favor and Nadan delivered
to him for punishment. The text of the story
is in a volume issued from the Cambridge
University Press (1898). In condensed form
the reader is referred to the American Journal
of Semitics (Vol. 16).

AHITh'OPHEL, privy counselor to King
David, native of Gilo (Judg and supposed to
be the grandfather of Bathsheba. He was
implicitly trusted by David and Absalom and
joined the latter when he revolted. It was he
who advised Absalom to take possession of
David's throne and concubines. In despair be-
cause Absalom took other advice than his, he
went home and hanged himself.

AHMADABAD, a-ma-da-bad', chief town
in the district of the same name, in the presi-
dency of Bombay, India. It is situated on the
banks of the river Sabarmuti, 309 miles north
of Bombay. It was founded in 1412 by Ahmed
Shah. In 1818 it came under British rule. It
has always been the centre of the skilled handi-
crafts, being famous for the manufacture of
silk fabrics, objects of the goldsmith's art and
pottery. It is now also the centre of a big
trade in cotton, indigo and opium. The Jumna
Masjid, a magnificent mosque, shoots its two
lofty minarets above the centre of the city.
Here too is the mosque of Sujaat Khan and
the modern Jain temple of Seth Hathí Sinh.
The city walls, once a very complete system of
fortifications, have been completely restored
in 1834. Ahmadabad has now a modern
system of water works installed and con-
tains quite a number of educational institutions,
the most important of which is the Rat Guza
College. The population is estimated at a little
over 216,000.

AHMED FUAD, 2d Sultan of Egypt; b. 1868.
He is the youngest son of the Khedive
Ismaël Pasha, and succeeded his brother Hus-
sein Kamel (q.v.) on the death of the latter in
October 1917. He received most of his edu-
cation in Italy and is regarded as a broad-
minded and progressive ruler. Always noted
for his consistently friendly attitude toward
the British connection, he is expected to pur-
sue the same steadfast and loyal policy as his
predecessor. He is strongly interested in all
matters of national importance, particularly
education and agriculture. He is a direct
descendant of Muhammad Ali, the founder of
the dynasty, and has two brothers and three
sisters living.

AHMED MIRZA, ahméd mirzá, Shah of
Persia; b. Tabriz, 8 Jan. 1898. He is the son
of Mohammed Ali, whom he succeeded on the
Persian throne when the latter was deposed, 16 July 1909. Although not the eldest son, his father nominated him heir-apparent because the mother of his eldest son was not of the Jadjar, or royal, house.

AHMED, Prince, hero of one of the Arab-Rus campaign. Tou-ba supplies him a tent large enough to shelter an army, yet so fine in texture that it could be folded up and hidden in one's pocket. She also presented him with the apple of Samarcand, which insured its possessors perennial good health.

AHMEDNAGAR, ām-ed-nāg'ār, an importation in British India, presidency of Bombay, 122 miles east of Bombay, on a branch of the Great Indian Peninsular Railroad. It was founded in 1494 by Ahmad Nizam Shah. During the reign of his son, Boorhan Nizam Shah, it reached a high degree of prosperity, but the political anarchy following his death brought about its decay. In 1797 it fell into the hands of the Maharrat, but in 1803 was taken by General Wellesley. The town has increased in size and prospered since coming into British possession. It is noted for the curious defense works that have been laid about it, walls consisting of prickly pear hedges 20 feet high, so full of sap that no fire can burn them and so thick that it is impossible to force a way through. Some fine pieces of native architecture still survive the past glories of the town. It has a modern water supply, brought in by means of aqueducts. The population is about 43,000.

AHMED SHAH, āh'méd sháh, 1st Ameer of Afghanistan: b. 1724; d. 1773. He was a chief of the Abdali tribe, but later extended his sway over the other chieffains by taking advantage of their feuds. He thus liberated them from the dominion of Persia and founded the Douranee dynasty. He became noted for his wealth, among which was included the famous Kohinoor diamond. In 1748 he captured Lahore and Kashmir and in 1756 defeated the Great Mogul and sacked Delhi.

AHMED TEWFIK PASHA, Turkish diplomat and statesman: b. 1843. Having served in the army some years he was sent to Athens as ambassador in 1882, to Britain as ambassador in 1884, then became minister of foreign affairs in 1895, holding this office until 1899. Under the Young Turk regime he was again minister of foreign affairs, becoming grand vizier for a short time in 1909.

AHRENS, Carl, Canadian landscape painter: b. Winfield, Ont., 15 Feb. 1866. A Normane by descent, he studied art under William Chase, Edwin Ellwell and George Inness of New York. One of his pictures, 'The Day is Done,' received much favorable notice at an exhibition of the Ontario Society of Artists in 1890; another, 'The Fisherman's Child,' was given the place of honor in the biennial exhibition of the Royal Canadian Academy in 1893; and still another, 'Ripe Corn Field,' purchased by the Ontario government to hang in the Parliament buildings, Toronto 1896. Afterward he attracted the attention of Elbert Hubbard, who was greatly impressed by his originality in atmospheric effects, and persuaded him to throw in his lot with the brothers at East Aurora, N. Y.; separating from them he spent three years painting the ruins of the old Spanish missions in southern California. He returned to Canada in 1907. His distinguishing traits are his feeling for color and his handling of the problems of light and air. His composition is always simple and effective, there is, however, no real resemblance to any other than himself; his style is an amalgam absolutely his own. In addition to the works mentioned above the following are well known: 'Cradled in the Net,' 'The House in the Clearing,' 'Glean on the Woodlands,' 'The Woodcutters,' 'The Glade in the Woodland,' 'Passing Showers' and 'The Coming Storm.' He is also a writer of short stories for the periodical press.

AHRENS, ār-ens, Franz Heinrich Ludolf, German classical philologist: b. 1809; d. 1881. For 30 years, from 1849 to 1879, he was director of the Lyceum at Hanover, and became known as an authority on the scientific study of Greek dialects. His principal work, an important standard treatise, is 'De Greece Lingua Dialectis' (1839-43; new ed. by Meister, 1882-89).

AHRIMÁN, ār-ī-mān, the devil of the ancient Zoroastrian religion, poetized in the holy spirit of all the sources of evil. Under him are hordes of other evil spirits, but next to him come the six arch-demons, chief of whom is Aeshma.

AHUACHAPÁN, ā-hoo-ach'tsh-a-pá'n, a department of the Republic of El Salvador. It is divided into two districts, the first of which includes the departmental capital (pop. 15,000), also called Ahuachapán, together with Apaneca, Ataco, Jujuilita, Guaimango, San Pedro Pustla and Tacuba (in all 48,840 inhabitants), and the second district embraces Atiquizaya, San Lorenzo, Turin and Refugio (all told 15,168 inhabitants). It is bounded on the north and northwest by Guatemala, on the east by the departments of Santa Ana and Sonsonate, and on the south and southwest by the Pacific Ocean. The climate is considered healthful, the agricultural products are uncommonly varied, and in commerce and industry this department takes the leading position in the republic. Total pop. 64,008. See Salvador, El.

AIBONITO, ā-bōn-ē-to, Porto Rico, capital of a municipality of the Guayama electoral district, 25 miles northeast of Ponce. Coffee and tobacco are cultivated in the neighborhood, and the town, located over 2,000 feet above sea-level in a cool and healthful situation, is the seat of an acclimatizing station and sanatorium for visitors. Pop. of municipality, 8,600; of town, 2,100.

AICARD, ā-shār', Jean François Victor, French author: b. Toulon, 4 Feb. 1843. Many of his works are extremely popular and he is especially noted for his finished style. He was elected member of the French Academy in 1909. Among his later works are 'Poèmes de Provence' (1874); 'La chanson de l'enfant' (crowned by the Academy of France 1895); 'Cantique de Noré' (1880); 'Lamartine' (1883); 'Jésus' (1896-1912); 'Tata' (1901-10); 'L'âne d'un enfant' (1903). His plays: 'Legende du cœur' (1903); 'Benjamine' (1906); 'L'illustre Maurin' (1908); 'Maurin des Maures' (1908); 'Hollande; Algére' (1915).

AÏDA, grand opera in four acts by Giuseppe Verdi (libretto by Camille du Locle and
AIDE-DE-CAMP — AIGUILLON

Antonio Ghislanzoni), first produced at Cairo, Egypt, on 24 Dec. 1871. Verdi was in his 59th year at the time, but, as the event showed, not yet in the full maturity of his powers. He was still later to astound the musical world with 'Gowlel' and 'Aida' and to add to the unique exhibit of the ultimate flowerings of genius. Aida typifies Italian opera at its best. Never has there been a richer or more breathless outpouring of melody that carries the listener on its very crest from beginning to end. Verdi's original order and for an honorarium: a major-general, three aidae (either captains or lieutenants); and a brigadier-general two aidae (lieutenants). Before an officer below the rank of major can receive such appointment he must have served at least two of the six preceding years with his troop, battery or company. The appointment is for four years and may not be exceeded. In the British service, before an officer can be appointed as aide-de-camp, he must have been two years with his regiment and must pass an examination.

AIDIN, i-dén, Turkey in Asia, capital of a sanjak of the same name, in the vilayet of Smyrna, on the classic river Meander, 70 miles by rail northeast of Smyrna. It is noted for the beauty of its situation, its tree-shaded streets, its churches, synagogues and mosques, and its ruins, especially of the Exedra, Gazel-Hissar and for its interesting history. A large transit trade is carried on in cotton, figs, dates, raisins and important candy and leather manufactures. Pop. 35,000.

AIGRETTE, ă-grét', a French word, used to denote the down, or plume, that is attached to many vegetable seeds, as the thistle or the dandelion. It is also used in reference to the feathery tufts found on the heads of some birds, as the heron and the egret, whence the term came also to cover a tuft of feathers employed as an ornament in a woman's head-dress. More specifically it means such an ornament of egret plumage, the long, slender white feathers that spring from the back of the egret during the breeding season and for which these birds have been much hunted. As the feathers cannot be procured without killing the bird, thus causing the death of the nestlings, the result has been that it has become more and more rare and now threatens to become extinct. To protect the birds their feathers are prohibited from importation into the United States.

AIGUES-MORTES, āg-môr't, town in the department of Gard, 25 miles by rail southwest of Nîmes. Isolated amid the salt marshes of the Rhône delta, three miles from the Mediterranean, with which it communicates by a canal, it is remarkable for the fine mediaeval fortifications, crenellated walls, bastions and towers surrounding the town. These were begun by St. Louis IX who sailed from here in 1248 and again in 1270 for the seventh, and the eight crusade in which he lost his life. The fortifications were completed under Philip III. Trade is carried on in oranges, fruits, wine and coal and the manufacture of soda, fishing and the entertainment of tourists are the chief industries. Pop. 4,000.

AIGUILLON, dâ-gwé'yôn', Armand de Vignerot du Puy, born 1592 in Paris, died at Fontainebleau in 1661. A French statesman: b. 1720; d. 1782. In 1754 he became governor of Brittany. His administration of the province was so bad that he brought upon himself the condemnation of the Parliament of Rennes. But his friendship with Madame du Barry, the mistress of Louis XV, not only saved him from punishment but was the influence
which caused his appointment as minister of foreign affairs, in 1771. But so incompetent was he that even the complacent monarch could no longer tolerate his performance, and in office three years he was removed.

AIGUILLON, Marie de Vigneron, Duchesse d': b. 1604; d. 17 April 1675. In 1620 she was married to the Marquis de Combalet, and after his death in action in 1622 she devoted her time and fortune to works of piety and charity. Her interest was aroused in the Jesuit mission to Canada by Father Le Jeune's 'Relation' of 1635, and in 1639 she founded the Hotel Dieu at Quebec, entrusting it to Augustinian nuns from Dieppe.

AIGUN, Convention of (1858), between Russia and China, by which the former obtained all the territory eastward of the Ussuri River to the Japan Sea, and fixed her southern boundary at the frontier of Korea.

AIHUN, i‘hun, or AIGUN, China, town of northern Manchuria, of historical importance, owing to the Aihun treaty effected here by Count Muraviev in May 1858, by which the left bank of the Amur was ceded to Russia. An active transit trade is carried on in grain, flour, mustard, tobacco and oil. Pop. 20,000. See AIGUN, CONVENTION OF.

AIKEN, Charles Francis, American educator: b. Boston, Mass., 8 April 1863. He was educated at Harvard University, St. John's Theological Seminary, Brighton, Mass., and the Catholic University, Washington, D. C. In 1884-86 he was teacher of the classical languages in Heathcote School, Buffalo, N. Y., from 1892 to 1895 was engaged in parish work, studied abroad for the next two years, and in 1897 was appointed instructor, in 1900 assistant professor, in 1906 ordinary professor of apologetics at the Catholic University, Washington. He was dean of the faculty of theology in 1913-14. In the latter year he lectured at the Catholic Summer School, Cliff Haven, N. Y. He is a member of the Advisory Council of the Simplified Spelling Board, is a contributor to the Catholic University's American Ecclesiastical Review, the American Catholic Quarterly Review and has published 'The Dhamma of Gotama the Buddha and the Gospel of Jesus Christ' (Boston 1900; French trans., Paris 1903).

AIKEN, William, American congressman: b. Charleston, S. C., 1860; d. Flat Rock, N. C., 7 Sept. 1885. In 1825 he was graduated from the College of South Carolina. Having been elected, in 1838, to the State legislature he served his term and was then, in 1844, elected governor of South Carolina. In 1851 he was sent to Congress as democratic representative, where he remained for six years and was short only one vote from becoming Speaker of the House of Representatives. He opposed secession, and after the end of his term he retired from politics, until 1866, when he was again elected to Congress but was not admitted to a seat. Aiken, S. C., is named for him.

AIKEN, S. C., city and county-seat of Aiken County, on the Southern Railroad, 17 miles northeast of Augusta, Ga., and 120 miles northwest of Charleston. It is one of the most picturesque and attractive towns in the United States, being located at an elevation of 600 feet above the sea, in the midst of numerous pine forests. The dryness of the atmosphere and the comparative mildness of the climate have combined to make Aiken the most noted health resort in the South. The town is the centre of a large and important agricultural district and does a thriving cotton trade. There are also artificial stone works, planing and lumber mills. There is located here the Histric Club and the Robertson Training School for colored youth, and several private schools and academies for both sexes. Many Northern families of wealth and culture have winter homes here. Aiken was first incorporated in 1835, and is governed by charter, secured in 1890 and revised in 1897, which provides for a mayor elected every two years, and a city council composed of the mayor and six aldermen. The town officials are elected annually at town meetings. The water supply and sewerage system are controlled by the town. There are two national banks here, numerous large hotels, a number of manufacturing and several newspapers. Pop. about 5,000.

AIKINE, John, English physician and miscellaneous writer: b. 1747; d. 1822. He attained considerable popularity by 'Evenings at Home' (6 vols. 1792-95), instructive reading for the family circle which were translated into almost every European language, and which he issued in collaboration with his sister Mrs. A. L. Barbauld. His 'General Biography' (10 vols., 1799-1815), was another important work. His daughter, Aiken, Lucy, b. 1781; d. 1804, was the author of court memoirs of 'Queen Elizabeth' (1818); 'James I' (1822); 'Charles I' (1833), which had considerable vogue. She also wrote 'Lorimer,' a novel (1814), and 'A Life of Addison' (1843).

AIKINITE. See NEEDLE ORE.

AIKINS, Sir James (Albert Manning), Canadian lawyer and administrator: b. Grahamsville, Peel County, Ontario, 10 Dec. 1851. He was educated at Upper Canada College and Toronto University, where he graduated in 1875. He was called to the Ontario bar in 1879, and settled in Winnipeg in 1879. He represented Brandon in the Conservative interest in the House of Commons 1911-15, and resigned to lead his party in the provincial elections for Manitoba, in which they suffered defeat. In 1916 he was appointed lieutenant-governor of Manitoba. He was knighted in 1914, and was president of the Canadian Bar Association, 1914-15.

ALANTHUS, a genus of trees of the family Simaroubaceae, including eight or nine species of central and southern Asia and northern Australia. The trees have large deciduous pinnate leaves and small greenish flowers in large panicles, followed by flat-winged fruits. A. glandulosa, the Tree of Heaven, the best known species, is common in cultivation in the United States and in some places has run wild. It is better able to endure smoke and dust than most trees and has few enemies. The trees are short-lived and are somewhat objectionable because of their malodorous flowers, the pollen of which is said to cause catarrhal troubles.
AILLY, a'ly, Pierre d' ("Petrus de Allaco"), French cardinal and philosopher, sur-
named "the eagle of France and the indefati-
gable". b. at Compiègne Feb. 1350; d. at Avignon 1420. Distinguished as a
preacher and philosophical disputant, he led an active
and diversified life mainly devoted to the
promotion of church unity and the healing of the
schism. He was made cardinal by
John XXIII and was appointed papal legate to
Germany. He was a prolific author and among
his writings are 'Concordantia Astronomiae
cum Theologia'; and 'Imago Mundi'; the
latter of American significance as in it he writes
of the possibility of reaching the Indies by sail-
ing west, citing as authorities Aristotle, Pliny
and Seneca. Columbus' personal copy of
d'Ailly's 'Imago Mundi' now in the Columbine
library at Seville has numerous marginal notes
in the navigator's own handwriting, and Las
Casas in his 'Historia de las Indias' (Vol. I,
xi, 89) states that of all "modern writers
of Ailly exercised the greatest influence
on the realization of the plans of Columbus." 
AILSA CRAIG, àl'sa kråg, Scotland, a
remarkable rock islet, at the mouth of the Firth of
Clyde, off the west coast of Ayrshire. Scarcely
two miles in circumference, it rises
precipitously to a height of 1,114 feet. On
the northern side is a columnar basalt cave. The
rock is the chief source of supply for "curling"
stones, which are popularly called "Ailsa Craigis" or "Ailsa clarets." The rock is immortalized in literature,
notably in Keats' 'La Belle Dame sans' (1818).
AIMARD, a'mär, Gustave, French-American
novelist; b. 1818; d. 1883. His real name
was Olivier Gloux and he became known as the
"French Fenimore Cooper." After a voyage to
America as a cabin-boy he spent an early
adventurous life for 10 years among Indians in
Arkansas and Mexico. He afterward traveled
as a soldier of fortune in Turkey, the Caucasus
and Spain, served as an officer of the Garde
Mobile in the Paris revolution of 1848, and as
commander of the "francs-tireurs of the press" in
the Franco-German war 1871-72. Based on
his varied experiences he wrote numerous
novels, many of which have been translated into
English. The best are 'Les trappeurs de l'Arkansas' (1852); 'Le grand chef des Incas' (1858); 'Les pirates de la prairie' (1859); 'Le grand filibuste' (1860); 'Nuits mexicaines' (1863); 'L'Araucan' (1864); 'La forêt vierge' (1870); and 'Les sappeurs blancs' (1873).
AIN, an administrative department of
the French government, on the French and Italian
frontiers. In the south and west the country is
marshy, but in the north are the Jura Moun-
tains, much frequented by foreign tourists. The
soil produces bituminous limestone. The area
is about 2,250 square miles and the population
342,482. The chief town is Bourg.
AINGER, aing'or, Alfred, English clergy-
man and author; b. London, 9 Feb. 1837; d.
8 Feb. 1904. In 1887 he was appointed a
bishop in Bristol Cathedral; in 1894 he became master of
the Temple, London; chaplain-in-ordinary to
Queen Victoria in 1896; and to King Edward
VII in 1901. He was distinguished by an
attractive personality, and was called well known as an authority on Charles
Lamb, Crabbe and Thomas Hood. His chief
works are 'Poems of Thomas Hood' (with
biographical introduction, 1897); 'The Life
and Works of Charles Lamb' (12 vols., 1899-
1900); 'Crabbe' (1903); 'The Gospel and
Human Life' (1904); 'Lectures and Essays' (2
vols., 1905).
AINMULLER, in'mool'er, Maximilian
Emmanuel, German artist, founder of
the modern school of stained glass painting: b.
Munich, 14 Feb. 1807; d. 9 Dec. 1870. After
studies in architecture and decoration, he
became designer in the royal factory at Nymphenburg and later inspector and
head of the royal manufactury of stained
glass at Munich. Among his master works are
the windows representing St. Peter and St.
Paul in the Vatican at Rome; windows in the
cathedrals of Cologne, Glasgow, St. Peter's
College, Cambridge, St. George's Chapel, Wind-
sor, St. Paul's Cathedral and Westminster
Abby, London.
AINO, in nó, or AINU, sometimes called
"hairy Ainu," people of northern and
eastern Yezo, on the Island of Hokkaido, in
the southern Kuriles, numbering in all about
18,000. They are supposed to be the descend-
ents of the original inhabitants of the Japanese
archipelago. They differ very much in appear-
ce from the present inhabitants of Japan, especially in the heavy beards of
the men. Their language resembles the Japanese
in structure, but differs radically in vocabulary.
Authorities differ widely in their theories re-
garding the origin of the Ainu, one of them
being that they were a small branch of the
Caucasian, or white, race, which was driven
out into the archipelago by the Mongols. Con-
sult Batchelor, 'The Ainu and Their Folk Lore'
(London 1901); Chamberlain in the Journal of
Race Development for 1903.
AINSWORTH, an'sworth, Fred Crayton,
American soldier; b. Woodstock, Vt., 11 Sept.
1852. He was appointed first lieutenant and
assistant surgeon, U.S.A., in 1874; major and
surgeon 1891; colonel and chief of Record and
Pension Office in 1892, where he devised and
introduced many important improvements in
the business methods of the War Department
and the army and compiled the compilation
and publication of the 'Official Records of the Union
and Confederate Armies.' In 1899 he
received the rank of brigadier-general. In 1904
he became the military secretary of the army
with the rank of major-general, and in 1907
the adjutant-general of the army with the
same rank. In 1912 he was retired from active
service, at his own request, after more than
37 years' service.
AINSWORTH, William Harrison, Eng-
lish novelist; b. 4 Feb. 1805; d. 3 Jan. 1882. He
was the son of a Manchester solicitor. He
wrote 'Rookwood' (1834); 'Jack Sheppard'
(1839); and about 40 other novels, including
'Guy Fawkes,' 'Tower of London,' 'Windsor
Castle,' 'Lancashire Witches,' 'Fitch of
Bacon,' etc.
AINTAB, in-tâb, Turkey in Asia, town in
the villayet of Aleppo, on the southern foothills of
Mount Taurus and on the right bank of the
river Sajur; 70 miles northeast of Aleppo.
Its strong fortifies are an anastomosing line of
an important military station. There is an
active trade in the tobacco, grain and fruits of
the region, and in the local manufactures of
cotton goods, striped cloths and pelmeez conserve made from grapes; also in "Hittite" antiquities from ancient Doliche, the site of the cult of Baal, to the northwest. Aintab is the seat of American, Anglican and Franciscan missions. Pop. 45,000.

AINU. See Aino.

AIR, the gaseous substance that envelops the earth and forms its atmosphere. (See Atmosphere.) It consists almost entirely of the gases oxygen and nitrogen, which are merely mixed and not chemically combined; but in addition it contains many other substances in small amounts, among which are water-vapor, carbon dioxide, nitric acid, ammonia, ozone, argon, neon and neon-like matter, as well as dust, germs and other solid particles held in suspension. In certain localities other components may occur. Near the sea, for example, salt can always be detected in it, and over the land it contains sulphates in small amounts. The quantity of water-vapor present in air varies greatly with time and place, and in all analyses of the composition of the air, its water-vapor is supposed to have been removed first. The quantity of carbon dioxide is subject to considerable variation also. It is very constant in the open country, where it constitutes about 0.043 per cent (by weight) of the air or 3.65 per cent (by volume). In the cities the percentage is higher, rising to 0.07 and occasionally to 0.10. In crowded rooms, especially where artificial lights are burning, the quantity of carbon dioxide present may be even greater than this. In country air the percentage of carbon dioxide is subject to a diurnal change amounting to about one-eighth of its total amount, more being present at night than in the daytime. This is undoubtedly due to the fact that plants absorb the gas by day and exhale it during the night. The proportion of nitrogen and oxygen in air is subject to variation also, though within much narrower limits. In general, 100 volumes of air contain about 21 volumes of oxygen and 79 of nitrogen. Regnault analyzed air collected in different parts of the world, and found that the volume-percentage of oxygen in the air of Europe varied from 20.903 to 21.0 per cent. The average of 17 samples collected from over the Arctic seas gave 20.91 per cent. Regnault was of the opinion that sea air is saturated with nitrogen, but Lewry considered that no distinct difference could be proved except in the tropics, where sea air exhibited a slight diurnal variation. Argon constitutes about 1 per cent of air, and neon about 0.001 per cent. The nitric acid present in the air is so small in amount that it can be detected only in rainwater, by which it is dissolved and brought down. It is very likely formed partly by the direct combination of oxygen and nitrogen under the influence of electric discharges, and partly by the action of ozone upon ammonia. The quantity present is greatest in summer and least in winter. The ammonia of the air occurs partly as carbonate and partly as nitrate. Its amount is exceedingly variable, varying from 0.1 to 15.0 parts per million (calculated as carbonate) in 1,000,000 parts of air, the average amount being perhaps 6. The amount present decreases during a heavy rain, but within a few hours it returns to the normal amount again. No ozone can be detected in city air, and air over marshes and in malarial regions contains very little of it. Normal country air contains not more than one volume of this gas to 700,000 of air. It is more abundant in summer than in winter, and is most noticeable during thunderstorms and hurricanes. In the laboratory ozone is produced by the action of electric discharges upon oxygen, and it is probably produced in the air in the same way. Hydrogen peroxide has been detected in the air, and some authorities consider that it may be present in greater abundance than ozone, and that it may sometimes be mistaken for ozone. (For further information on the composition of the air, see Angus Smith's "Air and Rain"). According to Regnault, one cubic centimetre of air that has been freed from water-vapor, carbon dioxide, and ammonia, weighs 0.0012932 gramme when the air is at the temperature 0° C. and under a barometric pressure of 760 millimetres of mercury at Paris (lat. 48° 50' N.), and at a height of 60 metres above the sea. In English equivalents this means that at 760 millimetres of mercury pressure and at the temperature of melting ice (32° F.) a cubic foot of air weighs 0.080681 pound; "ordinary atmospheric pressure," signifying the pressure that would be exerted by a weight of 14.7 pounds, resting upon an area of one square inch at sea level in the latitude of Washington. When a mass of air, originally at atmospheric pressure and at the freezing-point (32° F.), is heated to the boiling-point (212° F.) without changing its volume, its pressure becomes 1.36728 atmospheres according to Balfour Steward, or 1.36706 according to Wiebe and Böttcher. The average of these is 1.36717, which agrees well with the value 1.36719 as given independently by Morley and Miller. The older estimates of Regnault and Magnus are probably too small. The specific heat of air (the pressure being kept constant) is 0.2375 according to Regnault, and 0.2389 according to Wiedemann. The specific heat (the volume being kept constant) is 0.1715 according to Joly's direct measurement with the steam calori- meter. Air cannot be liquefied by any pressure whatever so long as its temperature is higher than about 220° F. below zero (−140°C.); but if it be first cooled to a temperature slightly below this it condenses to a liquid upon the application of a pressure of 39 atmospheres. (See Critical Point.) If it be cooled to a temperature materially lower than 220° F. below zero, it can be liquefied by a correspondingly smaller pressure. Liquid air is opalescent at first, probably from particles of solid carbon dioxide held in suspension. These can be separated by filtration, or they will rise to the surface in a short time, leaving the clear, transparent air beneath. When liquid air is exposed in a glass vessel it absorbs heat rapidly from surrounding objects, and boils actively until it has entirely evaporated. The nitrogen that it contains evaporates faster than the oxygen, however, and the liquid remaining in the vessel becomes increasingly rich in oxygen until toward the last it resembles liquid of that gas. Liquid air may be frozen to a clear, transparent solid by surrounding it with liquid oxygen and then forcing the evaporation by means of an air-pump. Liquid air is of great interest to the physicist for many reasons; but its importance in the arts has been grossly ex-
aggregated. In particular, the process that is put forth from time to time, to utilize liquid air for running a motor that shall condense more liquid air than it consumes, is impossible of realization, because although such an action would not necessarily imply perpetual motion it would violate the second law of thermodynamics. (See THERMODYNAMICS) If liquid air is confined and allowed to become warm through the absorption of heat from its surroundings its expansion gradually generates an enormous pressure. This fact, together with the safety with which liquid air can be handled, has led to its use to a limited degree for blasting in tunnels and mines, where the presence of the irrepressible products of combustion of ordinary explosives is objectionable; but even this application has been discontinued, owing to certain grave and apparently insuperable practical difficulties that were encountered. See LIQUID AIR.

The scientific study of the air has been much stimulated in recent years by the establishment of the Hodgkins Fund. In October 1891 Mr. Theodore Hodgkins of Steauket, N. Y., made a donation to the Smithsonian Institution, the income from a part of which was to be devoted to the *increase and diffusion of more exact knowledge in regard to the nature and properties of atmospheric air, in connection with the welfare of man.* The first prize of $10,000 from this fund was awarded on 6 Aug. 1895 to Lord Rayleigh of London, and Prof. William Ramsay of University College, London, for their discovery of the previously unknown element argon in the atmosphere. (See ARGON.) A prize of $1,000 was also awarded at the same time to Dr. Henry de Varigny of Paris, for his 'L'Air et la Vie' ('Air and Life*), which was considered to be the best treatise upon atmospheric air, its properties and relationships. Further information concerning the Hodgkins Fund may be had from the Smithsonian Institution, Washington, D. C. For information concerning dust and germs, consult Tyndall's 'Fragmente of Science,' and Dr. T. Mitchell Frudden's 'Dust and Its Dangers.'

Dephlogisticated Air, in the old chemistry, was air that had been deprived of phlogiston (q.v.) in modern terminology it is called oxygen. Fixed air was Dr. Black's name for carbon dioxide, suggested by the fact that certain alkaline substances can fix this gas, or combine with it to produce a solid substance.

The word *air* also occurs as an element in a host of compound words. The significance of many of these is evident, but some few are for special mention and they will be found below in their respective order. See AERODYNAMICS; AEROSTATICS; AERONAUTICS; ATMOSPHERE; BAROMETER.

Allan D. Risteen.

AIR, in music (in Italian, *aria*), means a continuous melody in which some lyric subject or passion is expressed. The lyric melody of a single voice, accompanied by instruments, is its proper form of composition. The word also designates the entire composition in such expressions as "national air," "operatic air," etc. In the 16th and 17th centuries the word was used in England to denote a lively, cheerful strain. It is fast becoming obsolete as a technical term synonymous with *aria.* Many of the Italian airs of the period, together with too great a proportion of the popular music of the day, are destitute of meaning and character. The songwriters of Germany strive to construct their airs in direct conformity to the meaning of the words. Air is also the name given to a song often given at the end of a part in a concerted piece, and is thus equivalent to treble, soprano, etc. *Arietta* signifies a short, less elaborate air than *aria,* and is designed to express a more simple and transient emotion.

AIR, ā-ér, or ASBEN, French West Africa, an oasis of the desert of Sahara, called by Dr. Barth 'the Switzerland of the desert and the frontierland of negridom.' In the north, inhabited by the savage and treacherous Tuaregs, the mountain group of Gunje rises 5,000 feet above the level of the sea. On the south a desert plateau, rising 2,000 feet, the home of giraffes, ostriches, and wild oxen, divides Air from the Sudan. Palm nuts, dates, figs, melon, senna and indigo are the chief products; camels, zebra, asses, cattle and goats are raised. The salt caravan trade to southern regions, and pilgrim caravans traveling to Mecca, are the means of commercial intercourse, yielding in tribute much of the revenue of the reigning suzerain sultan whose capital is at Agades (pop. 50,000), and of his emir who governs at Oudjebat (pop. 60,000). Ashuri, the native designation of the region which under the name of Air, was first described by Leo Africanus in 1526.

AIR-BATH, an apparatus designed for drying substances by exposing them to air of any desired temperature.

AIR BEDS AND CUSHIONS, often used by the sick and invalids, are composed of india-rubber, or of cloth made air-tight by a solution of india-rubber, and when required for use filled with air, which thus supplies the place of the usual stuffing materials. They tend to prevent bedsores from continuous lying in one position. They are also cheap and easily portable, as the bed or cushion when not in use can be packed in small compass to be again inflated with air when wanted.

AIR-BLADDER. See Fish.

AIR-BLAST, a stream of air, issuing from a nozzle or other aperture under pressure. Such blasts are used for throwing sand or other abrasive material against a body that is to be eroded or polished; for forcing the fires of forges or furnaces, and for burning out the impurities in pig iron in the manufacture of Bessemer steel; for removing dust from grinding-machines and saws; for cleansing woven fabrics and for multitudes of other purposes.

AIR-BLAST TRANSFORMER. This transformer is particularly well adapted to all installations where the use of oil is not permissible, or where, on account of the size of the units, self-cooling is impracticable and the cost of water refrigeration prohibitive. Their high efficiency at all loads, low fire risk, economy of floor space and other desirable features have resulted in a large and increasing demand for this apparatus for those installations in the foundry and arsenal in which large amounts of power must be continuously handled.
Electric transmission lines for moderate distances are usually operated at the following potentials: 2,200, 6,600, 11,000, 16,500, 22,000 and 33,000 volts. The standard lines of air-blast transformers are designed for these voltages and on account of the drop in potential on the transmission lines, taps are brought out from the high tension winding at such points that the transformers can be operated on potentials approximately 3/5, 6/9 and 10 per cent lower than their normal voltage. This arrangement of taps on the high tension winding permits the use of duplicate transformers at either end of transmission lines and at intermediate points, which is of great advantage in many cases, particularly on large systems.

Air-blast transformers are cooled by a forced blast of air delivered by a blower. One blower usually supplies all of the transformers in any particular station; but it is strongly recommended that a duplicate blower equipment be installed on the principle that should one unit fail to be held in reserve. The transformers are generally placed above an air-chamber in which a pressure is maintained slightly above that of the surrounding air; and the blower may deliver air directly into this chamber, or, if it is more convenient, the blower can be located at a distance from the transformers, feeding into a conduit which leads to the air-chamber.

AIR-BOX, a flue or other form of conduit conveying air to or from a furnace or into a mine for ventilation.

AIR BRAKE. A brake operated through the medium of compressed air, and extensively applied to railroad trains and street railway cars. Originally this brake was devised merely as a safety device, but is now considered invaluable as a dividend-earning asset also. This latter consideration is based on the principle that the better the brake, the higher the scheduled speed; consequently, the more frequently the car or train can traverse a given road so that fewer cars need be purchased and less labor employed. The air brake permits high scheduled speed because of the short emergency stopping distance made possible from high velocities and because a train or car may be run at high speed within a short distance of the stopping point, which is a highly important feature where stops are frequent. The first type of this appliance, designated as the straight-air, or non-automatic, brake, was invented in 1869 by the well-known American engineer and inventor, Mr. George Westinghouse. It consisted of a steam-driven, direct-acting air compressor (see Fig. 1), carried on the locomotive, which forced compressed air into a reservoir. This reservoir was connected through a three-way valve, in the engine cab, to the rear of the locomotive tender where it terminated in a flexible hose with a coupling. Throughout the length of every car a pipe was extended, with a similar hose and coupling at each end. To combine a number of cars and a locomotive into a train the respective couplings were united, making the brake pipe continuous throughout the train. The brake pipe at the rear of the train was closed by a cock. On each car, the brake pipe communicated with one face of its respective brake cylinder piston. On the other face were located brake rods and levers holding the brake shoes almost up against the treads of the car wheels. Normally the three-way valve connected the brake pipe to the atmosphere. To apply the brakes, the engineer turned the three-way valve to a position which cut off the brake pipe from the atmosphere and permitted compressed air to flow into it from the reservoir (now known as the main reservoir) on the locomotive. This air, thereupon, forced the brake cylinder pistons on each car outward, actuating the brake rods and levers, and thereby forcing the shoes against the treads of the car wheels. Whenever the desired pressure was developed in the brake pipe, the engineer turned the three-way valve into a position (lap position) which cut off the main reservoir from the brake pipe and, at the same time, vented the latter to the atmosphere. This operation removed the pressure from the faces of the brake cylinder pistons and permitted the brake cylinder release springs to pull the shoes from the treads of the wheels, through the medium of the rods and levers.

This brake, while being far superior to any vehicle brake heretofore invented, required improvements in the following respects: (1) The brake pipe pressure, being higher on the front than on the rear cars during the period the brake pipe pressure was being built up, caused the rear cars to run violently into the head

---

Fig. 1
cars and produced a rough stop. (2) The stop with a long train was prolonged through a considerably greater distance than with a single car because of the time necessary to transmit the required air through the long brake pipe to the respective brake cylinders. (3) For a long train, an impractically large size main reservoir was required to fill all brake cylinders to standard maximum pressure without the assistance of the compressor. (4) In case a train broke in two, or a hose burst, the brake would be lost. This would be especially dangerous on grades.

In order to improve these conditions, Mr. Westinghouse invented the automatic brake in 1872 (see Fig. 2). With this scheme, air was stored in a reservoir on each car at a time when a brake was not required. When a brake application was desired the stored air, being at the spot ready for use, was caused to flow from the reservoir on each car to its respective brake cylinder. In order to apply the brakes with this arrangement, it became necessary to employ a device for controlling the flow of this stored air, known as a plain triple valve, on each car. This device had to be operated just the reverse of the straight air brake, viz., to release the brakes, air was put into the brake pipe, and to apply them, the brake pipe air was vented to the atmosphere. This scheme had the added advantage of operating on the closed circuit principle, in that, whenever a train broke in two, or a hose ruptured, the resultant reduction in brake pipe pressure caused the brakes to apply automatically. Experience with the air brake to this time indicated that two rates of applying the brakes were desirable for train control—one, a comparatively slow rate (service rate) for ordinary use, through which the train would be stopped as quickly as consistent with the comfort to passengers and freedom from damage to lading and equipment; the other, a rapid rate (emergency rate) through which the train would be stopped at a rate as great as conditions would permit, to be used only when a short, quick stop became necessary. To utilize these new functions, the engineer’s three-way valve was developed into a form designated as a brake valve. With this automatic system, as with the straight air system, compressed air was forced into the main reservoir by a compressor. Normally, however, when the train was running free over the road, the compressed air, after passing through a valve which reduced its pressure, was admitted by the brake valve into the brake pipe. The air then passing to the outer face of each triple valve piston held each in its innermost position, where this air was able to flow by the piston through a groove into a storage reservoir (auxiliary reservoir), charging it until the pressure on the two faces of the triple valve piston became balanced. In this innermost position of the triple valve piston, a slide valve, controlled by the piston, locally connected its respective brake cylinder to the atmosphere. To retard partially, or stop a train under ordinary conditions, the brake valve was moved into “service” position whereby the main reservoir air supply was cut off from the brake pipe and the air in the latter vented to the atmosphere. The rate of reduction in brake pipe pressure, while slow, was nevertheless faster than air could flow from the storage reservoir through the groove past the triple valve piston back into the brake pipe. Consequently, a differential pressure, thus developed in the triple valve piston, forced it outward to a position where its accompanying slide valve cut off the brake cylinder from the atmosphere and connected the brake cylinder to the auxiliary reservoir in such a manner that the pressure in the auxiliary reservoir dropped at the same rate as the pressure in the adjacent section of the brake pipe.

Whenever it was desired to stop the brake application from developing to its fullest possible magnitude, the engineer, by placing the brake valve in “lap” position, interrupted the reduction in brake pipe pressure. The auxiliary reservoir pressure, having been reducing up to this time at the same rate as that of the brake pipe, immediately dropped slightly below the now constant brake pipe pressure, whereupon the triple valve pistons were forced slightly inward, thereby resulting in cutting off further flow of air from the auxiliary reservoirs into the brake cylinders. In releasing the brake, the brake valve was moved into “release” position where air at full main reservoir pressure was permitted to expand into the brake pipe through a large opening, in order to transmit a quick impulse through the brake pipe. The triple valve pistons were thereby forced to their innermost position whereupon the auxiliary reservoirs were recharged and the brake cylinder air exhausted, as previously explained. After a short period elapsed, the engineer placed the brake valve in “running” position to prevent
the system from charging to a pressure higher than permitted by the reducing valve, which is operative in "running" position and is used to govern the maximum pressure carried in the brake pipe. To produce an emergency brake application, the operator moved the brake valve pipe air to flow to one outlet (the brake valve port) at the extreme end of the brake pipe, and furnishing, in addition, a local outlet on each car, the time to apply all the brakes throughout the train was materially reduced. This decreased the length and improved the

into "emergency" position where the brake pipe air was vented to the atmosphere through a large opening. The resultant sudden reduction in brake pipe pressure caused the auxiliary reservoir air to force the triple valve pistons and slide valves into their outermost positions where auxiliary reservoir air was admitted into the brake cylinders rapidly. This operation produced a short, quick stop. While the automatic brake with the plain triple valve made the air brake safe, and the stops quicker and shorter than with the straight air brake, yet as train lengths and weights increased, the stops smoothness of the emergency stop. In other respects, the quick action automatic triple valve was similar to the plain triple valve. From the time of this invention, train speeds and weights were gradually increased and the train stops accordingly began to lengthen once more. It was known that this increase could be offset for emergency application by raising the brake pipe pressure, because this, in turn, would cause an increase in brake cylinder emergency pressure. The greater retarding force thus developed would not have been objectionable at high speeds on account of the coefficient of

again began to become rough and longer, particularly with emergency applications.

This condition led Mr. Westinghouse to invent the quick action triple valve (Fig. 3) in 1887, which, in assuming "emergency" position, locally reduced the brake pipe pressure. By thus avoiding the necessity for all the brake friction between the shoe and the wheel being low, but as the velocity of the train decreased the accompanying increase in the coefficient of friction would have caused the wheels to slide. Mr. Westinghouse overcame this difficulty in 1894 by inventing the high-speed reducing valve (Fig. 4), which was connected direct to the
brake cylinder. This valve permitted the use of high brake cylinder emergency pressure, which it gradually reduced throughout the stop to compensate for the increase in the coefficient of friction between the shoe and the wheel. The high-speed reducing valve did not operate for brake cylinder pressures supposed to be developed for service brake applications. Up to, and shortly after, 1900 substantially the same type of equipment was employed for all different classes of steam and electric railway service; but about this time the characteristics of these different classes became so distinctive that it became necessary to develop specific types of air brake appliances for each.

A classification of air brake equipment with reference to service requirements resulted as follows: (1) Locomotive brake equipment; (2) Passenger brake equipment; (3) Freight brake equipment; (4) Electric traction brake equipment. In each of the above classifications quite a number of epoch-making inventions were brought out between the years 1900 and 1918 by Mr. Walter V. Turner, an eminent American engineer and inventor, which form the basis of rapid developments and improvements in the art, thereby not only advancing the status of the air brake, but contributing largely to the marked progress in railroad transportation during the years mentioned. These inventions are described in sequence of their development as follows:

Locomotive Brake Equipment.—In the earlier days of railroading, no brakes were installed on the locomotive; then straight air brakes were applied to the engine; next straight air brakes to both engine and tender; and finally, as all the braking force possible had to be developed within a safe limit of wheel sliding, quick action instead of plain brakes were placed on the tender. The necessity of braking the engine as part of the train, under some conditions, and independently, as in switching, grade work, etc., under other con-

Fig. 5

ditions, and of avoiding the difficulties experienced from variations in braking ratio, due to non-uniformity of piston travel and loss of brake cylinder air through leakage from the locomotive brake cylinder (which unfortunately often had to be located near the hot boiler) resulted in the development of the No. 6-ET equipment (Fig. 5) during the period from 1903 to 1905, which overcame all these objections.

Freight Brake Equipment.—When freight trains were composed of less than 50 cars, the automatic quick action type of triple valve invented in 1887 fully met the braking requirements. With the later practice of operating
60 and 80 cars per train, however, it was found that, during a service brake application, the brake pipe pressure reduced so slowly toward the rear of the train that the auxiliary reservoir air would leak past some of the triple valve pistons without actuating them and would thus cause a brake failure; that, during a release and recharging operation, the auxiliary reservoirs on the front cars would absorb so much of the air delivered to the brake pipe that the small quantity which reached the rear end of the train would leak past some of the triple valve pistons without forcing them to "release" position so that "stuck" brakes would result; and further, that, if the rear brakes did release, it would be so long after the front ones did so, that in the case of a slow-down, produced by an application and release of the brakes, the front cars would violently run out from the rear. During the period from 1903 to 1905, there was also developed the "K" triple valve, which eliminated the objections developed by the increasingly severe freight brake requirements. The "K" differed from the former type of quick action triple valve by quickly and positively transmitting a service brake pipe reduction by locally reducing the brake pipe pressure in its adjacent section of the brake pipe at a moderate service rate as soon as it assumed "service" position; by automatically restricting the communication between the brake pipe and auxiliary reservoir on the front cars during the release and recharging period and thereby enabling far more air to be transmitted toward the rear of the train than heretofore, so thus the releasing of the rear brakes and a uniform recharge of all the auxiliary reservoirs throughout the train were ensured; and by automatically restricting the release passage at the head end of the train in order to compensate for the time interval required to start the release of the rear brakes, so that all the brakes tended to release uniformly. To maintain the speed of a given train constant on a given grade requires a certain braking force for every pound weight of the train. This exact braking force cannot be obtained by merely making one brake application, for two reasons:—First, because it would be almost impossible to reduce the brake pipe pressure the exact amount required; and second, if this were possible, the brake cylinder pressure obtained would soon be lost due to leakage, etc. Consequently, the method employed in practice to secure the proper train control was to make a brake application to reduce the train speed; to release the brake cylinder air on each car through a restricted "retaining valve" port (until the retaining valve cut off the exhaust after the brake cylinder air had reduced to a predetermined pressure), while the brake system, in the meantime, was being recharged and the train speed increased; to make another brake application followed by a release; and to continue to repeat this cycle as long as the train was on the grade. Such operation necessitated that the train be sufficiently short to enable the brake system to be recharged in time to obtain another effective brake application before the train speed developed to an uncontrollable degree; and that the maximum speed reached through the braking cycle be sufficiently slow to ensure that the train could be
stopped at any time. Furthermore, the braking force available on the loaded cars alone was insufficient to control the train speed on some grades of ordinary steepness, so that the practice of distributing empty cars throughout the train had to be resorted to, in order to secure the greater force per pound weight provided by the empty cars. As a result, trains on grades were short, only partly loaded and operated at slow speeds. Consequently, in various sections, grades restricted, and in fact limited, the traffic. To obviate this condition, the freight empty and load brake was devised, which provides substantially the same per cent retarding force for a loaded as an empty car and requires less air to produce a given braking force (the train considered, at least, partially loaded) than heretofore. This invention, therefore, made train stops smooth and greatly improved grade traffic by permitting higher speeds, longer trains and loading to car capacity. The recent introduction of heavy high capacity freight cars in service (weighing 70,000 pounds empty and 315,000 pounds loaded) required so much air per car, even with the empty and load brakes, that another type of an empty and load brake (Fig. 6) substitute economical in air consumption and especially adaptable to these cars was developed.

Passenger Brake Equipment.—About the year 1900, a speed of 60 miles per hour with long heavy passenger trains became common. For this condition the brakes then in service were inadequate to ensure the safety required. The energy to be dissipated was also so great that high shoe temperatures were developed which caused the shoes to soften as the step continued, so that under these new conditions the coefficient of friction between the shoe and the wheel remained constant throughout the entire stop. This fact made the invention of the 

air brake
class possible. In addition to the auxiliary reservoir the 

air brake
type triple valve employs a large storage reservoir, known as the supplementary. The air in the supplementary reservoir is not used for service applications; but during emergency applications it equalizes with the air in the auxiliary reservoir and the brake cylinder. The high brake cylinder emergency pressure then realized, and the maintenance of the full brake cylinder pressure throughout the stop (possible because the coefficient of friction between the shoe and the wheel remains constant), greatly shortened the emergency stop and hence made it safe to run the train at high speeds. The 

air brake
type triple valve has four other important advantages, namely, quick recharge of the auxiliary reservoir after a service application, through the undisturbed air in the supplementary reservoir restoring the pressure in the auxiliary reservoir as fast as the pressure rises in its adjacent section of the brake pipe (up to the pressure at which the supplementary and auxiliary reservoirs equalize, which is very close to the maximum brake pipe pressure carried); uniform and quick release, after a service brake application, possible because the air is fully delivered immediately; the brake application need only expand through the brake pipe on account of being relieved by the supplementary reservoir of the first stages of recharging the auxiliary reservoir; graduation of release secured by the supplementary reservoir charging the auxiliary reservoir to a slightly higher pressure than that in the brake pipe, when the recharging of the latter is cut off at the brake valve, so that the auxiliary reservoir pressure moves the triple valve pistons outward sufficient to cause the exhaust of brake cylinder air to be cut off; and a provision for each valve to reduce the pressure in its respective brake pipe to a moderate service rate after the respective triple valve piston and slide valve have assumed service position.

With triple valves, including the 

air brake

type, up to this time, however, the following conditions prevailed: (1) Since the brake pipe pressure reduced during a service brake application at a faster rate than it is restored during a recharging period, less air may leak past the triple valve piston for a given change in brake pipe pressure in the former case than in the latter. This action, combined with a greater frictional resistance of the triple valve piston and slide valve in service than in release position as sometimes existed, occasionally prevented a triple valve piston and slide valve, which assumed "service" position upon a slight reduction in brake pressure, from being fully returned to its release position. Thus a stuck brake resulted. (2) The device which normally tended to maintain the brake pipe pressure (feed valve) when in bad condition, permitted the brake pipe pressure to fluctuate through a range of several values, so that the fluctuation caused a brake application, which thereupon could not be released, as explained above. (3) The brake cylinder pressure developed from any application gradually reduced, due to the brake cylinder air changing in temperature and leaking past the brake cylinder piston to the atmosphere. (4) The pressure intended for any brake pipe reduction depended on the brake cylinder volume which in turn depended on a certain fixed predetermined travel of the brake cylinder piston. With poor designs and lack of maintenance of brake rigging, this piston travel varied on the different cars, so that different brake cylinder pressures were obtained on various cars throughout the train for the same brake pipe reduction. This condition often produced rough stops. In addition, even the 

air brake
type of triple valve, while representing the highest development in the air brake art up to this time, still afforded possibilities of improvements in the following respects: (1) If the 

air brake
type triple valve were used on the same train with triple valves which did not have the graduated release feature (that is, triple valves which did not have supplementary reservoirs to recharge the auxiliary reservoirs to a slightly higher pressure than the brake pipe, when the latter was cut off at the brake valve, so that the higher auxiliary reservoir pressure could force the triple valve piston outward, thereby cutting off the brake cylinder exhaust) a rough stop would be produced when an attempt was made to apply the brakes fully at the beginning of a stop and then to "graduate off" the brake cylinder air; the brake application would be rough because the triple valves, without the graduated release feature, would release their car brakes at once due to the immediate and entire exhaust of the brake cylinder air and thus permit their respective cars to lunge
AIR BRAKE

forward, while the other triple valves would release their brakes by steps, and thus tend to hold their cars back. If the supplementary reservoirs were cut off to eliminate the graduated release feature, then their respective triple valves would lose their quick recharge feature and high emergency brake cylinder pressure secured through these reservoirs; (2) The *L* was the first triple valve to develop a higher brake cylinder pressure for emergency than for service brake applications. This higher pressure was secured from air in the supplementary reservoir being introduced into the auxiliary reservoir, and the brake cylinder through the operation of a piston valve actuated by the supplementary reservoir exposed one piston valve face forcing the piston valve in the direction of the brake cylinder pressure on the opposite piston valve face. Due to this arrangement, the differential pressure after a full service brake application was insufficient to actuate it, even if the triple valve piston assumed "emergency" position. In other words, the other valve functions; the emergency function was made independent of the service so that an emergency could be made after a service brake application; the depletion of brake pipe pressure to a predetermined low degree produced an emergency brake application; and a shorter, quicker emergency stop was secured by quicker transmission of the brake pipe reduction, quicker delivery of air to the brake cylinders and high brake cylinder pressure. To obtain what may be termed "ideal" train control in a practical way with methods that are fundamentally safe and sound, the *UCE* Universal valve with electrical appliances was perfected in 1912 (Fig. 7). This valve possesses substantially all the features of the "PC" equipment, previously mentioned, except the obtaining of brake cylinder pressure irrespective of piston travel and maintaining it against leakage (provision is made for the addition of these features, when desired) with the addition of the following: Simultaneous application of every brake throughout the train, electrically initiated by the brake valve, resulting in a smooth and quick stop, smooth because each car is braked at the same instant, and quick because the time of transmission of the brake application is eliminated; a more powerful brake than heretofore possible without the danger of rough stops on account of all cars being retarded simultaneously; ability to recharge the brake system while the brakes are held applied by closing the exhausts with a magnet valve; same degree of flexibility of brake control as possible with the straight air brake on even a single car realized by electrical appliances on each car; elimination of the possibility of the valve assuming emergency position when not intended by making the service and emergency valve mechanisms separate and distinct; simultaneous application of all brakes throughout the train in case of a break-in-two or rupture of the brake pipe obtained by a pneumatic switch on each car, which, when energized by electrical actuation, causes each valve throughout the train to assume emergency

Fig. 7
AIR BRAKE

position; and the ability to secure a relatively small rise of brake cylinder pressure per pound of brake pipe reduction when a reapplication is made before the brake cylinder air from previous applications has been entirely exhausted by automatically placing only a portion of the auxiliary reservoir under the control of the equalizing piston during this period; ability to cut out any features without interfering with others; ability of assembling valve so as to give the equivalent of any past standard valve; and ability to make one size of valve suitable for all sizes of equipment by using removable choke plugs to govern the flow of air instead of permanent restriction in the valve structure.

Electric Traction Equipment.—When all electric traction cars were operated singly, straight air brakes were used almost exclusively in this service. After two cars were employed as a unit, "straight air" became dangerous because, whenever the cars broke apart, no braking force could be maintained due to the brake cylinders being connected direct to atmosphere through the open straight air pipe. As a consequence in 1905 there was developed the semi-automatic equipment with the "A" emergency valve. With this device straight air applications were secured as heretofore, but the straight air connection was made through only the straight air pipe to be filled from the brake valve while the brake cylinders were charged by a reservoir located on its respective car, and controlled by a valve actuated through the medium of the air in the straight air pipe. This arrangement overcame to a considerable extent the serial time difference in the application of the various car brakes. It also developed the proper brake cylinder pressure irrespective of the brake cylinder piston travel and maintained this pressure against brake cylinder leakage. A late development of this particular type of equipment was of electro-pneumatic semi-automatic character, having as its main new feature the electrical control of straight air, with provision for a brake application in case any portion of the electrical equipment failed. A special phase of this type of equipment, recently developed, is the one-man car, or safety control equipment (Fig. 9). With this equipment the entire control of the car can be efficiently handled by one man. The opening and closing of the doors, as well as the folding and unfolding of the door steps, is controlled from the brake valve. The incapacitation or negligence of the operator, or breakage of any of the pipes at either end of the car, will cut off the power, make an emergency brake application, sand the rails and unlock the car doors.

the emergency slide valve. The emergency brake application was obtained by reducing the pressure in the "emergency" pipe, thus enabling the main reservoir pressure to force the emergency slide valve piston outward, which thereby cut off the straight air pipe from the atmosphere and thereupon connected the main reservoir direct to the brake cylinder. The accidental separation of cars produced a similar brake operation.

When more than two cars began to be operated as a unit, the serial time difference required to develop the braking force on the different cars was objectionable. The "D" type of emergency valve (Fig. 8) was therefore provided in 1906 to meet this new condition. This valve possessed substantially the same emergency feature as the "A" type of emergency valve; but for service application required

Another phase of the electric traction-road development consisted in the use of purely automatic devices as in steam-road service. Some roads which operated a number of cars as a unit at times ran the individual cars separately. To obtain flexibility of brake control realized with straight air in single cars and also to operate the head car of the train separately, when desired, a combined straight air and automatic system was developed in 1906. A recent development for electric traction service is the universal type of valve with an exhaust cut-off valve. This valve possesses all the features previously outlined for the universal valve for steam-road service and, in addition, permits the simultaneous delivery of air, for service applications direct from the reservoirs to their respective brake cylinders and simultaneous exhaust of brake cylinder air direct to the atmos-
They are connected with the respiratory system, and are situated in the cavity of the thorax and abdomen, and sometimes extend into the bones. They are most fully developed in birds of powerful and rapid flight, such as the albatross.

AIR-CHAMBER, a reservoir in a hydraulic apparatus, in free communication with the water. The chamber or reservoir is filled with air, which by its elasticity diminishes the shocks that would otherwise be produced by sudden changes in the speed of flow of the water, and also equalizes the flow. When the pressure in the pipes is momentarily greater than the normal pressure, water enters the air-

ments have been developed. One of particular note is the type of electro-pneumatic governor for electrically-driven air compressors—the first satisfactory electro-pneumatic governor ever developed for electric compressor control. Consult 'Development in Air Brakes for Railroads'; 'The Air Brake as Related to Progress in Locomotion'; 'The Vital Relation of Train Control to the Value of Steam and Electric Railway Properties'; 'The Development of the Electro-Pneumatic Brake'; 'Brake Performance on Modern Steam Railroad Passenger Trains'; also various other publications issued by the Westinghouse Air Brake Company, Pittsburgh, Pa.

Westinghouse Air Brake Company.

AIR-CELLS, cavities in the cellular tissue of the stems and leaves of plants which contain air only, the juices of the plants being contained in separate vessels. They are largest and most numerous in aquatic plants, as in the Vallisneria spiralis and the Victoria regia, the gigantic leaves of which latter are buoyed up on the surface of the water by their means. There are also air-cells in the bodies of birds.

AIR-COCK, a cock placed upon a water- or steam-pipe (notably upon a steam radiator) to allow of the escape of air from the piping.

AIR COMPRESSOR, a device used for compressing air, or, in other words, which makes the same weight of air occupy a less volume or a greater weight occupy the same volume. Any device which reduces the volume of air with a pressure increase is an air compressor. When released from the containing reservoir the air tends to resume its volume and this tendency is utilized by making the air perform mechanical work as it expands. Although compressed air has been used for working engines in confined situations, it is not at all likely that it will ever come into extensive use, owing to the great waste of power attending it. This waste arises from two causes: (1) The friction due to forcing the compressed air along a great length of pipe, and (2) the
loss from the dissipation of the great heat which results from its compression. The greater the original compression of the air the higher its temperature will rise; and as this caloric, which cannot be kept from escaping, is practically a part of the bulk of the air, it follows that the loss of power from this cause will increase with the pressure or tension of steam engines there is always a small quantity of water in the cylinders and slide-valves, arising from the condensation of a portion of the steam, and this suffices to lubricate the piston and valves. It is well known that when steam is superheated so highly as to prevent a slight condensation in the cylinder and slide-valves, they are very rapidly destroyed. Air rises in the air. Even were it possible to prevent the escape of the heat by covering the vessels and pipes with some non-conducting substance, it would not be practicable to use the hot air in the same way as steam is used, because the lubricating material necessary to keep the piston and slide-valves from tearing would be decomposed by the high temperature. In temperature when very much compressed, and we cannot use it until its temperature falls; and as this involves a great waste of power, it follows that where economy is of great consequence, air cannot be used as a mode of transmitting mechanical power. Indeed, no fluid can be economically used for transmitting power for any considerable distance.
In its early history compressed air as a motive power for vehicles was not successful due to the fact that the storage tanks in use would admit of only small pressures. With its continued use and the development of storage tanks permitting the air to be compressed to an initial pressure of about 5,000 pounds per square inch it has made that class of motive power available for trucks used in manufacturing plants and for other vehicles designed to carry heavy weights for short distances. The extensive plants necessary for compressing the air and the fact that the storage tanks must be refilled frequently, as well as the inconvenience of transporting a large number of charged cylinders, make it impracticable as a motive power for vehicles used for commercial or military purposes.

The air compressor consists essentially of a cylinder in which atmospheric air is compressed by a piston, the power for driving which may be derived from a steam engine, water-wheel or electric motor. The air cylinder is generally double-acting and is provided with inlet and discharge valves in each cylinder head. The usual types of compressors are straight-line and duplex. Direct-connected compressors are driven by direct-current induction or synchronous motors, the rotors of which are of large diameter to produce a proper relation between the peripheral and rotative speeds.

The work performed by a compressor is, broadly speaking, that of increasing the pressure of air (or other gas) by reducing its volume or compressing it into a smaller space. Usually the lower or initial pressure is the "atmospheric pressure" at the point of location of the compressor, while the higher or terminal pressure is fixed by the requirements of the particular case, and may be anywhere from 10 to 30 pounds (gauge pressure) per square inch as in blowing engine practice, up to 80 to 125 pounds per square inch for rock drills, pneumatic tools, etc., and up to 1,500 to 2,000 pounds per square inch, or even higher, for special purposes. Atmospheric pressure (or zero gauge pressure) equals 14.7 pounds absolute pressure per square inch at sea-level (equivalent to 30 inches barometer) and becomes less as the altitude above sea-level increases, the decrease being approximately one-half pound, or one inch in mercury column, for each 1,000 feet increase in altitude. As the work of compression depends upon the initial and terminal absolute pressures (absolute pressure being equivalent to gauge pressure plus atmospheric pressure) the altitude at which the compressor is to work is of great importance and must always be taken into consideration.

When air is compressed into a smaller volume, if the temperature remains constant, the pressure increases directly in proportion to the decrease in volume; that is, if the volume is reduced one-half the pressure will be doubled; if reduced to one-third the pressure will be trebled, and so on for any decrease in volume. There is, however, another and most important fact which must be considered in all cases, particularly where high pressures are concerned, viz., the increase in temperature and consequent increase in volume due to the heat developed during compression. When air is compressed, part of the work done during compression is converted into heat, which must

- AIR COMPRESSOR

- 287

be taken up by the air compressed, the result being to very materially raise its temperature and increase its volume, thus adding largely to the work required to be done.

The single stage compressor consists primarily of an air-cylinder, in which the air drawn from the atmosphere is compressed, a steam cylinder, located above the air-cylinder, the two being connected by a suitable centre piece, steam and air pistons mounted on a common piston rod, and a valve motion controlling steam admission and exhaust. The compressor is double acting, steam being admitted alternately on either side of the steam piston which, being directly connected with the air piston, causes both to move up and down. On the upward stroke of the air piston the air above

- Air Reheater.
9½-inch single stage compressor, the steam consumption per 100 cubic feet of air compressed is very small.

While it is advantageous to keep the air as cool as possible during compression, heating it is an advantage, as soon as it leaves the receiver, for the reason that by this heating its volume or its pressure is increased. So important is this advantage, theoretically, that devices called reheaters are frequently employed to heat the air just before it passes to the motor or tool which it operates. Reheaters are made in many forms, the usual one being a kind of stove or oven through which the air passes by means of a spiral pipe or some other arrangement which allows it to be quickly heated.

The air reheater shown in the sectional drawing consists of a series of hollow annular rings bound together by four tie rods, the upper and lower rings having flanged openings projecting through the shell for pipe connections. These rings are surrounded by a sheet steel shell, the space between being filled with asbestos packing, which prevents loss of heat by radiation. Air enters at the bottom ring and leaves at the top, the openings connecting the rings being so arranged that the air is forced to travel through the heater in a circuitous passage. These heaters should be placed as near as possible to the work and the outlet pipe should be of large diameter, short and carefully covered, to prevent losses by radiation. See Air-Pump; Compressed Air; Condenser.

Edward S. Farrow,
Consulting Military and Civil Engineer.

AIR ENGINE. See Internal Combustion Engine.

AIR-CYLINDER. A pneumatic buffer used to absorb the recoil of large guns. For 10-inch guns, one cylinder is used; for 15-inch guns, two. They are placed between the chassis-rails, to which they are firmly secured by diagonal braces. A piston traversing the cylinder is attached to the rear transom of the top carriage. When the gun recoils the piston-head is drawn backwards in the cylinder, and the recoil is absorbed by the compression of the air behind it. Small holes in the piston-head allow the air to slowly escape while the gun is brought to rest. The hydraulic buffer, largely used above, operates in the same manner, water being used instead of the air. See Pneumatic Buffer.

AIRD, ird, Thomas, Scottish poet who has won praise from high critics, but little popular acceptance: b. Roxburghshire 1802; d. 25 April 1876. He studied in the University of Edinburgh, and formed a lifelong intimacy with Carlyle; contributed to 'Blackwood's,' and won the warm good will of Wilson; edited the Weekly Journal 1832-35, and the Dumfriesshire and Galloway Herald (Dumfries) 1835-64. He published 'Religious Characteristics,' prose essays (1827); 'The Captive of Perizy,' a narrative poem (1830); a character story, 'The Old Bachelor in the Scottish Village' (1845), very popular at the time; etc.

AIRDRIE, Scotland, a municipal and parliamentary burgh in Lanarkshire, 11 miles east of Glasgow. It depends chiefly on the collieries and iron-works in its vicinity, but has also a large cotton-mill and factory, several extensive foundries and machine-shops, tube-works and a number of hand-loom weavers. Pop. about 25,000.

AIR-DRILL, a rock drill or other form of drill actuated by compressed air.

AIR-ENGINE. See Turbine.

AIR-ENGINE, an engine in which air is the working body. Such an engine may be operated by air previously raised to a high pressure by a compressor, as in the storage and transmission of power by compressed air; or it may derive its power directly from the burning of fuel. In the latter case it is often called a hot-air engine. For the elementary theory of the hot-air engine, see Thermodynamics.

AIRE-SUR-LA-LYS, àr-sur-là-le, a town of France, department of Pas-de-Calais, 10 miles southeast of Saint Omer. It stands at the junction of the Lys with the Laquette, on a low marshy site, but is well built, and possesses several beautiful fountains, a handsome Gothic church and barracks for 6,000 men. Its trade is chiefly in linens, fustians, hats, thread, starch, soap, Dutch tiles, osier work and grain.

AIR-GAS, an inflammable gas produced by charging air with the vapors of naphtha, gasoline or some similar volatile hydrocarbon.

AIR-GATE, in foundry work, an opening left in the mold for the escape of air and other gases as the molten metal enters.

AIR-GUN. An instrument resembling a musket, used to discharge bullets or darts by the force of compressed air instead of gunpowder. Various forms of construction have been adopted. The most usual plan is to insert a condensing syringe in the stock of the gun.

The piston of this syringe is worked by an apparatus which passes through to the exterior of the gun, and this working causes a small body of air to be condensed into a chamber. The chamber has a valve opening into the barrel just behind the place where the bullet is lodged. The gun is loaded from the muzzle, as ordinary muskets or fowling-pieces. The trigger opens the valve; the highly compressed air rushes
forth and propels the bullet. By a certain management of the trigger, two or three bullets, such as the cartridges of a revolver, can be fired off—if firing it can be called—by one mass of condensed air. Another form of air-gun contains several bullets in a receptacle or channel under the barrel; by the movement of a rod, the mass of these bullets can be made to be shifted into the barrel; and thus several successive discharges can be made after one loading—on a principle somewhat analogous to that of the revolving pistol. Some varieties of air-gun have the condensing syringe detached, by which means a more powerful condensation of air may be produced. This done, the air-chamber is replaced in its proper position behind the bullet in the barrel. Those air-guns which present the external appearance of stout walking-sticks, and are hence called air-canes, have a chamber within the handle for containing condensed air, which can be unscrewed and subjected to the action of the condensing syringe. One inventor has devised a form of air-gun with two barrels—one of small bore for the reception of the bullets, and another of larger bore for the reservoir of condensed air; the condensing syringe being within the stock of the gun. An attempt has more recently been made to combine the action of elastic springs with that of compressed air in an air-gun; springs of gutta-percha, or of vulcanized india-rubber, are employed in substitution of, or in cooperation with a condensing syringe. No form of air-gun hitherto made has had power enough to propel a bullet to any considerable distance, and therefore the instrument is scarcely available in war. The air-gun was known in France over two centuries ago; but the ancients had some kind of apparatus, by which air was made to act upon the shorter arm of a lever, while the larger arm impelled a bullet.

AIR-HOLE, or BLOW-HOLE, a fault in a casing, due to the presence of a bubble of air or other gas.

AIR-LOCK, an air-tight chamber used in tunnelling, when the tunnel has to be kept filled with compressed air to prevent the entrance of water. The air-lock communicates with one door, and with the outside air by another. It serves the double purpose of permitting the workmen to enter and leave the tunnel without undue loss of air, and of partially mitigating the physiological effects of a too sudden transition from the high pressure in the tunnel to lower pressure outside.

AIRPLANE ENGINE. See INTERNAL COMBUSTION ENGINE.

AIR-PLANT, more properly epiphyte, a plant growing upon the trunk or top of another plant (the host), but not anatomically connected with it. Air-plants derive their nutriment chiefly from the air and rain, commonly by means of vessels on their roots. In Florida, on the other hand, are directly connected with the plant upon which they grow and extract their food from the host. Air-plants are most common in moist tropical forests, often completely covering the trunks and branches of trees. They belong chiefly to the ferns, mosses, bryeliads, orchids and aroids, and are mostly herbaceous, but sometimes shrubs are epiphytic upon tropical trees. In the United States air-plants are found chiefly in Florida, but one, Spanish moss (Dendrophiogon usneoides), is common throughout the Southeastern States.

AIR-PUMP. A machine by means of which air or other gas, water or other liquids may be removed from an enclosed space. The essential part is a hollow cylinder, in which an air-tight piston is made to move up and down by a rod. From the bottom of the cylinder a connecting tube leads to the space which is to be exhausted, which is usually formed by placing a bell-glass, called the receiver, with edges ground smooth and smeared with lard, on a flat, smooth plate or table. When the piston is at the bottom of the barrel, and is then drawn up, it lifts out the air from the barrel, and a portion of the air under the receiver, by its own expansive force, passes through the connecting tube and occupies the space below the piston, which would otherwise be a vacuum. The air in the receiver and barrel is thus rarefied. The piston is now forced down, and the effect of this is to close a valve placed at the mouth of the connecting tube and opening inward into the barrel. The air in the barrel is thus cut off from return to the space below, and, as it becomes condensed, forces up a valve in the piston, which opens outward, and thus escapes into the atmosphere. When the piston reaches the bottom and begins to ascend again, this valve closes; and the same process is repeated as at the first ascent. Each stroke thus diminishes the quantity of air in the receiver; but from the nature of the process it is evident that the exhaustion can never be complete. Even theoretically there must always be a portion left, though that portion may be reduced to any assignable quantity; and practically the process is limited by the elastic force of the remaining air being no longer sufficient to open the valves. The degree of rarefaction is indicated by a gauge on the principle of the barometer. By means of the partial vacuum formed by the air-pump a great many interesting experiments can be performed, illustrating the effects of atmospheric pressure and other mechanical properties of gases. The air-pump was invented by Otto von Guericke; and though many improvements and varieties of structure have been since devised, the principle of all is the same. Two barrels are generally used, so as to double the effect of one stroke. In some air-pumps, stop-cocks turned by the hand take the place of valves, and in others the entrance of the connecting tube into the cylinder is so contrived that the valve through the piston is not required. The air-pump used in connection with the densimeter is of the ordinary construction.

The use of compressed air for pumping water, oil or other liquids from wells, vats and tanks, is now general. The simplicity and ease of maintenance attending its use make it far superior to any other means of conveying liquids. In deep wells particularly, great economy is found in the use of air as compared with the old time deep-well pump. No valves, no reciprocating rods and plungers, and no wasteful steam cylinder at the top to operate them are required. The air may be compressed at any convenient point, such as an existing power-house, and yet do pumping at an isolated or distant place; several separate wells, if necessary, being pumped from one central station.

Westinghouse compressors have been found.
well adapted to this class of work and are largely employed for furnishing the compressed air used in breweries, tanneries, oil wells, dairies, hospitals, chemical laboratories, acid plants and especially all kinds of water wells.

The Latta-Martin displacement pump is an efficient and reliable device designed to pump water by air pressure. Extremely simple in construction, it requires no packing nor lubrication, has no dead centre, no pistons, no plungers, will not freeze in the severest weather, and is entirely automatic. It will pump from any distance, to any elevation, in any quantity, handling muddy or gritty water without injury. In the general design of the apparatus, the two cylindrical chambers are connected at the top by an automatic air-valve mechanism and at the bottom by suitable piping and check valves. The air pressure entering at the top is delivered alternately to the respective chambers, discharging the water contained therein through the check valves and discharge pipe. As a chamber is emptied of water, the remaining air is exhausted through a port in the upper valve gear, while water simultaneously replaces it through the check valves below. This simple operation is repeated alternately upon each side of the pump and is entirely automatic. The pump may be placed at any point of water supply— in a dug well or in a river—and can be operated and controlled by the engineer even though situated several miles from the source of power. A modified form of these displacement pumps can be used in driven wells having casings six inches or more in diameter. This form is particularly valuable for cases where the water level in the well falls a considerable amount, either during the pumping operation, or at different times of the year, as the action of the pump is not affected by the position of the water level. See Air-Compressor; Condenser; Compressed Air; Power; Power, Transmission of.

AIRSHIP. See Aeronautics, History of; Airplane; Dirigible; Military Aeronautics.

AIR-THERMOMETER, a thermometer in which temperature is measured by determining the change of volume of a mass of air that is kept at constant pressure, or the change of pressure of a mass that is kept at constant volume. See Thermometry.

AIR-TRAP, in steam and hydraulic engineering, a place where air can accumulate in a line of piping; as at the highest point of a line of water pipe. Air-cocks are placed at these points to permit of the removal of the accumulated air. Also called air-bond.

AIRY, âr^i, Sir George Biddell, English astronomer-royal: b. Alnwick, 27 July 1801; d. 2 Jan. 1892, in Greenwich. He was graduated at Trinity College in 1823. In 1826 he was appointed professor of mathematics at Cambridge, a chair once held by Newton, and he was the first actual director of the Cambridge Observatory, holding in connection with this post the Plumian professorship of astronomy. In 1835 he succeeded Pond as director of the Greenwich Observatory, and retained this office till 1881, when he retired on a pension. He initiated at Greenwich the plan of immediately and completely reducing observations; introduced the regular observation of magnetic phenomena, and of sun-spots by photography; invented new instruments for lunar observation and for measuring the heights of objects; and made astronomical observations in all parts of the world of the transit of Venus in 1874. His chief works are Mathematical Tracts (1826); Ipswich Lectures on Astronomy (1849); Undulatory Theory of Sound (1863); Treatise on Magnetism (1870).

AILSE, ël^e, in architecture, one of the lateral and usually lower divisions of a building which is divided lengthwise, as by rows of columns or piers, so that the roof is supported while still the interior is one large hall broken only by the uprights. The basilicas of the Romans were built in that way, as had been the small interiors of many Grecian temples; and when the first Christian churches were built in Italy and in the East, this basilican form rivaled the round or polygonal plan and the plan of the Greek cross in popularity. At a later time Christian churches were nearly always built with aisles and a higher central part called usually the nave. Most churches have an aisle on either side of the nave, and are called three-aisled churches, but there are few with five. And the famous Cathedral of Antwerp in Belgium has seven aisles, being almost alone in this respect. It is a mistake to count an outer row of chapels as another aisle.

By extension the term covers such a long and narrow compartment of a building as is found in one of the great mosques of Cordova and Damascus. These buildings have generally flat roofs intended always to be of masonry, and that structure is carried by a great number of parallel rows of columns. The resulting aisles are, of course, of the same height. In the mosque of Cordova there are 17 such aisles left open, besides two outer ones which are largely enclosed for chapels; all the aisles opening by doors or windows upon a large court.

AILSENE, âl^en, France, a northeastern frontier department which takes its name from the river Aisne, a tributary of the Oise. Area, 2,866 square miles; pop. 530,300. The surface is level; the soil fertile; drained and watered by the rivers Ourcq, Marne, Oise and Aisne, names celebrated in the great European War and the battles that raged on their banks. Together with several canals, these rivers carry a considerable traffic. Owing to numerous small lakes and stretches of forest the climate is cold and humid, though well adapted to agriculture and pasturage. The principal crops are cereals, but hemp, flax, potatoes and oil-seeds are also largely cultivated. Cotton and other textiles are manufactured at Saint Quentin, and at Saint Gobain the plate-glass works have been in operation since 1655. Laon, Soissons, Saint Quentin, Chateau-Thierry and Vervins are the chief arrondissement towns, with Laon as capital of the department. See War, European.

AISNE, ân, a river in northern France, with a total length of 280 miles. A tributary of the Oise, the Aisne rises in the Argonne Forest, flowing north-northwest, and after joining the Oise above Compiègne (on the left bank) after passing Vouzières, Rethel and Soissons, taking in on the way its affluents the Aire and Vesle, on the latter of which stands Rheims.
It flows through the departments of Marne, Ardennes, Aisne and Oise. From Moulon for about 170 miles the river is used for floating lumber and in parts it is navigable for 75 miles, and from Neuville-Chatel, about 15 miles below that point, there is considerable traffic. A lateral canal runs from Vouzier to Conde—above Soissons. The Canal des Ardennes (62 miles long) begins at Conde, below it joins the Aisne at Soissons and connected with the Meuse. The lateral canal of the Aisne is connected with that of the Marne at Conde-sur-Marne by a 36-mile canal. On its north side the Aisne has a line of steep ridges, the scar of a great plateau, at an average of a mile or more from the stream. The height of the scarp varies from some 200 feet, where the uplands begin on the west above Compiegne from the Forest of the Eagle, to more than 450 feet 30 miles east in the high bluffs of Craonne. Beyond this latter place the Aisne takes a wide sweep to the northeast toward its source, and the banks fall to the lower level characteristic of the shallow dales of Champagne. From Compiegne to Craonne there is everywhere of the same type, with occasional deeper ravines. For the most part the lower slopes are steep and clothed with grass. The plateau stretches back for some miles, till at La Ferre and Laon it breaks down into the plains of northeastern France. It was the crest of this plateau that the German armies had chosen—at an average of two miles from the river bank—on which to make a stand after they had been hurled back on the Marne (op.) in September 1914. The position was well chosen, for it was one of enormous strength, extending from a point on the heights of the Meuse north of Verdun westward across the Argonne and the plain of Champagne to Rheims, where it turned northwest along the Forts de la Pompelle, Nogent l'Aisne, Berru and Brimon, and across the Aisne near its confluence with the Siuppe to Craonne, whence it ran westward along the heights of the Aisne to the Forest of the Eagle, north of Compiegne. During their advance to the Marne the Germans had left parties of sappers behind to entrench the Aisne position—in case of necessity. How that necessity actually arose from the historic battle of the Marne is told elsewhere (See War, Europe). That battle began 6 Sept. 1914; on 8 September General von Kluck's army was in full retreat and on the 9th von Buelow's army followed. On the 10th the battle was over and the British and French became the pursuers. On the 12th the Germans were in position on the Aisne, and on the 13th the Allies began the passage of the river. The first phase of the battle of the Aisne closed on 18 Sept. 1914, and from that day began the remarkable trench warfare that became so prominent a feature of the great war.

AISSE, â'é-sa, or HAIDEE, Made-moiseelle, French-Circassian author: b. Circassia 1694; d. Paris 1733. The daughter of a Circassian chief, captured at four years of age in a Turkish raid, she was brought in the slave market to Constantinople by Count de Ferriol, French Ambassador to the Sublime Porte, and educated, where, later, introduced by the Count's sister-in-law to the Regent's receptions, she was greatly admired for her beauty and her wit. Count de Ferriol took advantage of her innocence, but she repulsed the French Regent's advances, and made a love match distinguished by great affection and fidelity, with Chevalier d'Aydie, a Knight of Malta, and had a daughter. Her latter years were marked by sincere devotion and piety. Her 'Letters,' published with annotations by Voltaire (1787), contain interesting pictures of court life of the period and anecdotes of contemporary personages, notably Madame du Deffand and Madamé de Tencin. They also reveal the great charm of the author's personality. She is the original of the Haidee in Dumas's 'Count of Monte Cristo,' and has been the subject of at least three plays. The best editions of her 'Letters' are those of M. Ravenel, with introduction by Sainte-Beuve (1846), and by Eugene Asse (1873). Consult Courtaulet, 'Une idylle au XVIIIe siècle; Mademoiselle Aisse et le Chevalier d'Aydie' (Macon 1900) and Gosse, E., 'French Profiles' (London 1905).

AITKEN, ã-tken, Robert Grant, American astronomer: b. Jackson, Cal., 31 Dec. 1864. In 1887 he was graduated at Williams College, then became instructor of mathematics at Livermore College, California. In 1891 he was appointed professor of mathematics and astronomy at the University of the Pacific. In 1895 and four years later he became astronomer at the Lick Observatory. In 1898 he was a member of the expedition sent by the Lick Observatory to the Flint Islands to observe an eclipse. He has discovered over 2,400 double stars, for which the Academy of Sciences of France awarded him the Lalande prize in 1906. From 1897 to 1908 he edited the publications of the Astronomical Society of the Pacific, besides which he has contributed many articles to German and American journals on astronomical subjects.

AITKIN, Robert, American printer and publisher: b. Dalkeith, Scotland, 1734; d. Philadelphia, July 1802. Emigrated to America, 1769; settled in Philadelphia as a bookseller, becoming later a bookbinder and publisher as well. He published the Pennsylvania Magazine (1775–76), and printed numerous documents and state papers for the Continental Congress, among them the 'Journals of Congress' from 5 Sept. 1774 to 1 Jan. 1776 (Phila. 1777–80). At his own expense he published in 1788 the first English Bible printed in America. This is now the rarest of all early Bibles printed in America, not more than 25 copies being known to exist. In 1777 Aitkin was imprisoned for his attachment to the cause of independence. His daughter, Jane Aitkin, was one of the first business women of America. After her father's death in 1802, she carried on his business as printer and publisher. Among other books she published in 1808, in four volumes, the translation of the Septuagint made by Charles Thompson, secretary of Congress.

AITON, ã-ton, William, Scotch botanist: b. Hamilton, Scotland, 1731; d. Kew Palace 1793. In 1759 he was appointed director of the botanical garden at Kew, and in 1789 published the work by which he is remembered, 'Hortus Kewensis' (3 vols.), in which, under the Linnean system of nomenclature, 1,660 species are described, indicating their origin, mode of culture and date of introduction in
England. His assistants in this monumental work were Dr. Solander and Mr. Jonas Dryander, who also cultivated Sodier.

Aitzema, at-zem-a, Lieuwe (Leo) Van, Dutch official and historian: b. 1600; d. 1669. An expert in politics and political science, he was resident-agent of the Hanseatic League at The Hague for 30 years, and author of the most valuable work on the eventful epoch of Dutch history covering the years 1621 to 1668, entitled ‘Zaaken van Staat en Oorlog in Eend omtrent de Vereenigde Nederlanden’ (14 vols., 1637-71; 7 vols., 1685-99, continuing the history to 1697).

Aivali, ai-vah-li, or Kidonia, ki-doh-nee-ah (the ancient Heraclea), a town of Asiatic Turkey, on the western promontory of the Gulf of Adramyti, 66 miles northwest of Smyrna. In the beginning of the present century it was a place of considerable note, but in June 1821, during a contest between the Greeks and Turks, it was set on fire by the latter and reduced to ashes. It has again revived, however, and possesses a population of about 35,000. The olive is extensively cultivated in the district, and much oil and soap manufactured.

Aivazovskii, Ivan Konstantinovitch, Russian painter: b. Feodociya 1817; d. 1900. From his earliest years he showed a remarkable talent for painting. Koch, the architect of his native town, discovered his gift and also gave him a few private lessons in perspective and architectural designing. Thanks to the influence of Koch and some other friends, Aivazovskii succeeded in entering (1833) the Academy of Fine Arts where he learned the art of aquarelles from Philippe Tonneur. His first work, which attracted general attention, was the ‘Study of Air above the Sea’ (1835) for which he was awarded a silver medal. Henceforth Aivazovskii pursued exclusively this field of painting and, in order to acquire adequate impressions of light on the nature of the sea, he sailed extensively over the Gulf of Finland and the Black Sea. His extraordinary memory enabled painters to retain and reproduce with great vigor and fullness the most singular moments at sea, hence there is a complete absence of monotony or repetition in his works. He traveled extensively through Italy, France, Germany and England where his fame as a sea painter was already well established by his remarkable paintings made in Rome: ‘Neapolitan Night,’ ‘Storm,’ and ‘Chais.’ The ‘Boat of the Tcherkessian Pirates,’ ‘Stillness on the Mediterranean’ and ‘Island of Capri’ won prizes at the Exposition of Paris (1843) and gained him the title of academican. In 1857 at the Exposition of Paris, he was awarded the order of the Légion d’Honneur for his remarkable ‘The Four Wealths of Russia.’ Of his later paintings the best known are: ‘Universal Declaration,’ ‘The Medal of the World’ (1864); ‘The Chain of Caucasian Forests’ (1871). At the Exposition in Florence the Academy of Fine Arts there asked him to paint his own portrait for the gallery in the Palazzo Pitti where are kept portraits of the most celebrated painters of the Renaissance. At the time of the Russo-Turkish war 1877 Aivazovskii painted a new series of episodes and in 1880 there was held an exposition of his works illustrating different episodes from the life of Columbus. On 20 Sept. 1887 Aivazovskii celebrated his 50th jubilee on which occasion he presented the Saint Petersburg Academy of Fine Arts with ‘Pushkin on the Sea-Shore’ painted in co-operation with L. E. Ryspyn.

Aix, aks, France, town and capital of an arrondissement, department of Bouches-du-Rhône, 17 miles by rail north of Marseilles. Its interests chiefly historical. It was the ‘Aquae Sextiae’—Baths of Sextius—founded 123 B.C. by the Roman consul Sextius Calvinus around the thermal sulphur spring. In the Middle Ages it was the capital of Provence and became a great seat of learning, renowned for its faculties of law and theology. Both baths and university under modern development continue their usefulness; and fine historical and modern buildings attract the attention, notably the cathedral dating from the 11th century, and the archiepiscopal palace. Pop. 20,000; including suburbs, 30,000.

Aix-la-Chapelle, ahs, or aex-leh-sha-pehl’ (German, Aachen; Latin, Civitas Aquensis, Aquigranum), capital of a district of the same name in the Prussian province of the Rhine, 38 miles west by south of Cologne; pop. 156,150. It is a well-built town, pleasantly situated in a fine vale watered by the Wurm, and surrounded by the Venn Hills. It was formerly surrounded by ramparts, but these have been converted into pleasant promenades. The town-house (built in 1533 on the ruins of Charlemagne’s palace) contains the coronation room with portraits of the German emperors, half-size portraits of Napoleon and the Empress Josephine, painted by David, and many relics of old German art. The nave of the cathedral, erected by Charlemagne as a palace chapel between 796 and 804, was rebuilt on the old model by Otto III in 983, after having been almost destroyed by the Normans. It consists of an octagon, surrounded by a 16-sided gallery, and terminating in a cupola. The Gothic choir was begun in 1353 and finished in 1413; it is of prodigious height (115 ft. from floor to ceiling), and the large windows are filled with stained glass. Besides the tomb of Charlemagne, the cathedral contains many relics, the most sacred of which — such as the robes worn by the Virgin at the Nativity, the swaddling-cloths of the infant Jesus, the scarf He wore at the crucifixion, etc. — are shown only once in seven years, and attract many thousands of pilgrims from all countries. As the chief station of the Belgio-Rhenish railway, which connects it with Antwerp, Ostend and Cologne, Aix-la-Chapelle affords an extensive market to the commerce of Prussia; it is also a grain market for Belgium, and the seat of commercial and other courts. Electric street railways connect with handsome suburbs and neighboring towns. Aix-la-Chapelle was presented the Saint Peter’s fire, especially of cloth and needles, as early as the 12th century; and its prosperity in this respect still continues. Its woolen cloths are highly esteemed on the continent of Europe and are also exported to America, China, etc. All trading centers in the United States have consulates in the city. It is estimated that over 30 per cent of the inhabitants are employed in the manufactures of the city. Although Aix-la-Chapelle is an extensive seat of
manufactures and has considerable commercial relations, it derives its celebrity chiefly from its historical associations, and a considerable portion of its importance and prosperity from the influx of visitors to its baths. There are in all eight mineral springs here, six of them warm. The most famous is the Imperial Spring or Konerspergelle, which has a temperature of 143°F., and the vapor of which, when confined, deposits sulphur. For the accommodation of strangers there are a number of bathing-houses. The rooms for bathing are excellently fitted up, with baths from 4 to 5 feet deep, built in a stately style such as in the old Roman style. About a half mile north of the city is the Louisberg or Lousberg, rising nearly 300 feet higher than the city. It is a favorite summer evening resort of the citizens.

Aix-la-Chapelle was known to the Romans as early as the time of Caesar, and is mentioned by Pliny under the name of Vetera. It was, after 768, the favorite residence of Charlemagne, who made it the capital of all his dominions north of the Alps and spared no expense in improving it. Here he died in 814, and in the cathedral his tomb is marked by a large flat slab with the inscription Carolo Magno. During the Middle Ages it was a free imperial city, and its citizens throughout the empire were exempt from feudal service, from attachment of their goods and persons and from all tolls and taxes. Thirty-seven German emperors and 11 empresses have been crowned in this city, and the imperial insignia were preserved here till 1795, when they were carried to Vienna, and are now in the imperial treasury. By the Treaty of Lunéville (9 Feb. 1801), which separated the left bank of the Rhine from Germany, the city was transferred to France, in whose possession it remained till 1814, when it was restored to Prussia. It was a busy base for military operations during the Franco-Prussian War 1870-71, and during the European War from 1914 was also an important aerial station.

AIX-LA-CHAPELLE, Congress of, an important congress held in October and November 1818. By this congress the army of the allies, consisting of 150,000 British, Russian, Austrian, Prussian and other troops, which, since the second peace at Paris, had remained in France to watch over its tranquillity, was withdrawn after France had paid the contribution imposed at the peace of 1815. Thus the Congress of Aix-la-Chapelle restored independence to France, and readmitted her as one of the Great Powers to the councils of Europe.

AIX-LA-CHAPELLE, Treaties of Peace Concluded at. The first, 2 May 1668, put an end to the war carried on against Spain by Louis XIV in 1667, after the death of his father-in-law, Philip IV, in support of his claims to a great part of the Spanish Netherlands, which included both the city of Liége and the Infanta Maria Theresa, pledging the jus devolutionis prevailing among private persons in Brabant and Namur. The second peace of Aix-la-Chapelle, 18 Oct. 1748, terminated the Austrian War of Succession in which the parties were at first Louis XV of France and the Empress Maria Theresa and, in the sequel, Spain on the one side and Great Britain, Maria Theresa and Charles Emmanuel, King of Sardinia, on the other.

AIX-LES-BAINS, -lì bah'n, France, town in the Savoie department near Lake Bourget; 848 feet above sea-level; 18 miles by rail north of Marseilles. It is a fashionable watering place visited annually by thousands for the hot sulphurous springs, used internally and externally for bathing ever since the establishment there in Roman days of the 'Aquae Gratianae — the Baths of Gratian.' Resident pop. 5,000.

AJACCIO, ā-yä'chō, or AJAZZO, ā-yä'tso, France, capital of the department and island of Corsica, on its southwest coast, on a tongue of land projecting into the Gulf of Ajaccio. It is sheltered by mountains from the north and east winds; and the town and bay are defended by a citadel. The entrance into the harbor is rendered unsafe by projecting rocks. Ajaccio is the birthplace of Napoleon; the house in which he was born is still in a state of good preservation and has become a national relic. It is the handsomest city of Corsica and the seat of a bishop. It contains a cathedral, a communal college, a public library, a botanical garden, etc. In the commercial world it is famous for its coral and sardine fisheries, and it has also a trade in wine, grain, olives and fruits. During the European War its importance was increased as a naval base for the allied fleets operating in Mediterranean waters.

AJALON, ā'jä-lō'n, said to be the modern Yâlo, a village 14 miles west-northwest of Jerusalem, was the town rendered memorable by Joshua's victory over the five Canaanitish kings, and still more so by the extraordinary circumstance of the miraculously lengthened day.

AJAX (Greek, Aias), the name of two of the Grecian chiefs who fought against Troy, distinguished as Ajax Oileus and Ajax Telamonius. The former, the son of Oileus and Etiopas, a Locrian, was called the Less. When the Greeks had entered Troy, Cassandra fled to the temple of Pallas, whom Ajax fell upon and dragged along, bound as a captive. Some accounts add that he violated the prophetess in the temple of the goddess. Ulysses accused him of this crime, when he exculpated himself with an oath. But the anger of the goddess at last overtook him and he perished in the waves of the sea. The other Ajax was the son of Telamon, from Salamis, and a grandson of Æacus. He understood not how to speak, but how to act. After the death of Achilles, when his arms, which Ajax claimed on account of his courage and relationship, were awarded to Ulysses, he was filled with rage, and, driven to frenzy, threw himself on his sword, after having slaughtered the sheep of the Greek army, which he fancied were his enemies.

AJMERE, āj'mér', India, capital of the district and province of Ajmere-Merwara, on the Rajputana Railway, 275 miles south of Delhi. Ajmere was founded 145 A.D., and the ancient section is rich in historical interest. The modern city is well laid out with broad streets, fine stores and handsome residences. It is the seat of the Mayo Rajputana College established in 1875 for the sons of native nobles. Pop. of city, 86,500. Area of province, 2,700 square miles; pop. of province, 501,500.
AKABAH, ā'ka-bā', Arabia, town of historic and strategic interest at the head of the Gulf of Akabah, identified with the Græco-Roman Ἡλανα and the scriptural Elath, whence Solomon sent Ophir. A branch line joining Akabah to the Mecca Railway from Beirut was begun in 1906. The Gulf of Akabah, the Ἡλανιτic Gulf of the ancients, is the eastern of the two inlets into which the Red Sea divides at its northern end. It is from 12 miles wide and 10 miles in a northeast direction, bounding the mountainous peninsula of Sinai on the east.

AKBAR, ā'khr, the Great, properly ʿE-LAL ED DIN MOHAMMED, most noted of the Great Moguls, Emperor of Hindustan: b. Amerkote, 14 Oct. 1542; d. Agra 1605. His father, Humayun, was driven from the throne by usurpers and fled to Persia. It was during this flight that Akbar was born. After an exile of 12 years the father returned and succeeded in recovering his throne, but died within the year. Akbar succeeded him at the age of 14 and at first the administration was placed in the hands of a regent, but in 1560 he asserted his strong personality and took the reins of power into his own hands. At this time the territory under the rule of Delhi was limited to a few provinces. Within 12 years Akbar had conquered and consolidated under his administration the whole of Hindustan north of the Deccan. But although great in war, he was even more able as an administrator, being unequaled, or even unequaled, by any of his predecessors or successors. He threaded his dominions with roads, established a uniform system of weights and measures and organized a vigorous civil police system. His powerful influence rested more on his strong sense of justice than on the military power with which he had first subdued his enemies. The proper levying of taxes, the lands were accurately surveyed and a careful census of the population taken. He forbade child marriages, encouraged widows to remarry and attempted to put an end to the hideous practice of suttee, whereby wives were burned on the funeral pyres of their husbands. Although a Mohammedan by faith, he was wonder-fully tolerant of other forms of belief and even invited Christian missionaries into the country. Schools were established for Hindus as well as for Mohammedans and numbers of Hindu works were translated from the Sanscrit into Persian. Abu-I Fazl (q.v.), his able vizier, has left detailed records of the entire administration of his reign in a work which has been translated into English by Gladwin under the title 'Institutes of Akbar' (3 vols., Calcutta 1786 and London 1800). He was succeeded by his son Selim, also known as Jehangir, in 1605. Consult Malleson, 'Akbar' (Rulers of India series, Oxford 1891-1901); Garbe, 'Kaiser Akbar von Indien' (1909); Modr, 'Parcises at the Court of Akbar' (1903).

AKED, ā'kɛd, Charles Frederick, Anglo-American clergyman: b. Nottingham, England, 27 Aug. 1864. He began his career as a musician to the sheriff of Derbyshire, but later entered as a student in the Midland Baptist College. He first attracted attention in Liverpool as a speaker and his congregation there became one of the largest in England. During the Boer war he was one of those who founded the Passive Resistance League whose object was to put an end to that war, and this made him, for a time, very unpopular. In 1907, through the influence of John D. Rockefeller, he received a call to the pastoral of the Fifty Avenue Baptist Church, New York. In 1911 he went to San Francisco, where he became pastor of the First Congregational Church. In 1913 he became a citizen of the United States. Among his published writings are: 'The Courage of the Coward' (1905); 'A Ministry of Reconciliation' (1907); 'Mercies New Every Morning' (1907); 'Wells and Palm Trees' (1908); 'Old Events and Modern Meanings' (1908); 'The Lord's Prayer: Its Meaning and Message for To-day' (1910).

AKEE (Blighia sapida), fruit tree of the family Sapindaceae. It is a native of tropical Africa, reaches a height of 25 feet or more, with numerous branches. Its leaves resemble those of the ash. The fruit is about the size of a goose's egg, contains three seeds and has a grateful flavor. With sugar and cinnamon it is used as a sauce for game. The distilled water of the flowers is sometimes used as a cosmetic. Sometimes by cramping the roots in pots the akee produces fruit in hot-houses.

AKENSIDE, Mark, English physician and poet: b. 9 Nov. 1721; d. 23 June 1770. He achieved literary fame at the age of 23 with his poem 'Pleasures of the Imagination' (3 vols., London 1744), didactic verse based largely on Addison's essays on the imagination and on Lord Shaftesbury's writings. Among his minor verse are 'Ode on the Winter Solstice' and 'Hymn to the Naiads,' Consult Buckle, C., 'Life, Writings and Genius of Akenside' (London 1832).

AKERS, Peter, American clergyman and educator: b. Campbell County, Va., 1 Sept. 1790; d. Jacksonville, Ill., 21 Feb. 1866. He received his education in the common schools and pursued a classical course in higher institutions of learning in Virginia and North Carolina. In 1817 he was admitted to the bar and formed a partnership with Maj. W. P. Fleming of Kentucky. In 1822 he entered the ministry of the Methodist Episcopal Church, served many years as presiding elder. In 1827 and 1831 he was financial agent of Augusta College. In 1833-34, 1852-57 he was president of McKendree College, Lebanon, Ill. He was a delegate to six General Conferences of his church.

AKHALTSIKH, ā'k ál-t'sk, Russia, chief town of a district in the government of Tiflis, the former capital of Turkish Armenia from 1579 to 1828, 70 miles by rail east of Batum. The river Kura divides the old town and fortress on the left bank from the new town on the right. Coal and lignite are mined, firearms, small weapons, silver filigree work are manufactured, and a thriving trade in these and in the silk, grain, honey and wax of the neighborhood is carried on with Black Sea ports. Pop. 15,000.

AK-HISSAR, ā'k his-sar, Turkey in Asia, a town in the vilayet of Smyrna, 50 miles by rail northeast of Smyrna. It is the biblical 'Thyatira,' one of the 'seven churches of Asia,' a Macedonian colony founded by Seleu-
CUS about 290 a.c., and later an important Ro-
man station on the highway from Pergamum
to Laodicea. The modern town carries on a
busy export trade in locally-grown cotton, wool,
silk cocoons, grains and cereals, and has a high
reputation for its scarlet dyes. Pop. 20,000.

AKHMIM, ak'-mém', or BAKHMIM, Egypt,
town on the right bank of the Nile, almost
opposite the Suhaq station on the Cairo and As-
sian Railway, 68 miles by river south of Assiut.
Its archaeological interest is great. It was the
ancient Egyptian Apy or Khen-min, the Coptic
Shmin, known to the Greeks through Herod-
otus, Strabo and other travelers, as Chemmis
or Panopolis, the seat of the pagan worship of
the ithyphallic Min (Pan) as “the strong
Horus.” Christian monasteries were early
founded here and the pagan temples destroyed.
Modern Akhmin is a busy trading centre in
cotton and linen goods, and in Coptic and
Egyptian antiquities. Pop. 24,000.

AKHTYRKA, ak'-tir'-ka, Russia, town in
the Kharkov government, on the Vorskla River,
82 miles by rail northwest of Kharkov. Its
miraculous icon of the Virgin in the beautiful
cathedral, built in 1753, and the annual fair,
attract numerous pilgrims and visitors. A
busy agricultural trade is carried on and
woolens are manufactured. Pop. 26,000.

AKIBA BEN JUDAH, ak'-ba ben jô-da, a
Jewish rabbi who was executed during the reign
of Hadrian, about 135, because it is said
he taught a law within it was forbidden
to be taught. He was a great scholar in Jewish
law and a Mishnah bears his name. He de-
defended the Song of Solomon and interpreted it
allegorically. He was an allegorist in his
method of interpretation, finding a meaning in
even the letters of the law. Aquila, who trans-
lated the Old Testament into Greek, is said to
have been a pupil of Akiba. The school of
which he was head exerted a wide influence.

AKKA, ak'ka, a tribe of dwarfs inhabiting
the Belgian Congo. The first to report their
existence was the Franco-American ex-
plorer and writer, Paul du Chaillu, but because
his books were written in a simple style, which
made them popular with young people, his ac-
counts were not accepted by the scientific world,
being regarded as fiction. Later the Akka were
discovered by Schweinfurth, who corroborated
du Chaillu in every detail. In height these
peculiar people average four feet and six inches
and though their features are distinctly negroid
they are of a dark yellow complexion. They
are extremely retiring by nature, do not mix
with the neighboring tribes though often they
will seek the protection of the tall negroes.
They hunt their game with poisoned arrows,
their favorite prey being the python. Their
main diet, however, is composed of nuts and
berries.

AKKAD, ak'kad. See ACCAD.

AKKERMANN, ak'ker-mán', Russia, fortifi-
ted town of the Bessarabian government, on the
right bank of Dniester estuary, 12 miles from
the Black Sea. The harbor has been made
salvageable for large steamers and an export
trade is carried on with Odessa 60 miles dis-
tant, in wine, fruits, fish, salt, wool and tallow.
The town is noted for its beautiful gardens
and vineyards. It dates from the Genoese col-
ony Mauro Castro, founded on the site of Ty-
ras, an ancient Milesian colony. In disputes
with the Turks it was repeatedly taken and
returned by Russia until its final annexation
in 1881. Pop. 34,000.

AKMOLINSK, ak'mö-lénsk, Asiatic Rus-
sia, a province organized 2 Nov. 1868 from
the Kirghiz Steppe. Central. The Trans-Siberian
Railway runs along its northern border and the province extends southward to the Chu River. Akmolinsk, the former capital, a
city of 12,000 inhabitants, is an important
trading centre for the caravan trade with Bok-
vara and Tashkend. Of note, in 1862, the most important city, is since 1882 the
capital of the province. Coal, iron, copper and
gold are mined and among the chief industries
are horse-breeding, cattle- and sheep-raising,
fishing, hunting and the cultivation of grain,
flax and tobacco. The stationary population
live mostly in the northern and central hilly
section. The Kirghiz nomads who constitute
about half the population wander and encamp
over the southern regions. Area of province
218,490 square miles; pop. 1,100,891.

AKRON, Ohio, city and county-seat of
Summit County, situated in a range of hills
overlooking the Big and Little Cuyahoga Rivers,
35 miles southeast of Cleveland and 130 miles
northeast of Columbus. Akron is entered by
the Baltimore & Ohio, Pennsylvania, Erie, Akron, Canton & Youngstown, and Northern
Ohio railroads. The town was settled about
1818 but its growth dates from the construction of
the Ohio Canal in 1825, here mounting to the
watershed between Lake Erie and the Ohio River by a series of 21 locks. (q. v.) surplus water
used in lockage furnished by a system of reser-
voirs on the Summit level supplying the power
for large flouring mills then located here.
Akron was incorporated as a village in 1836 and
as a city in 1855. Situated in a location
advantageous for diversified industries and
the northern edge of the grain belt and on the
southern border of the dairy section of the
State, with beds of fireclay and coal fields
close by, Akron has developed the largest
cereal mills in the country. Being a
clay-product plants, has taken the lead in
books, fishing-tackle, matches and agricultural
implements, and is the largest rubber-manufac-
turing centre in the world. Besides im-
mense quantities of rubber clothing, hose,
surgical and other goods, 20 companies have a
daily capacity of 40,000 automobile tires and an
increasing output of aviation and aeronautical
material. The aggregate capitalization of its
104 industries is $175,000,000; combined value of annual sales (1915) $156,177,993. Akron is
governed by a mayor, council, board of public
service, board of public safety, board of edu-
cation and subordinate officers. The school
system alone involves the annual expenditure
of $350,000 in salaries, and is of a high and
efficient grade. The University of Akron, a
free city institution, dates from 1913 and was
previously known as Buchtel College (Univer-
salist) (q.v.), founded by John R. Buchtel,
the cornerstone of which was laid by Horace
Greeley in 1872. Akron has fine public insti-
tutions and residential buildings, large depart-
ment stores, a completely motorized fire de-
partment, a municipal water system completed
AKSAKOFF — AKTIAN DEPOSITS

(1915) at a cost of $4,580,000; a municipal garbage and sewage plant which cost $550,000, 17 parks covering 219 acres, four public playgrounds, and a ‘white way’ system of lighting three miles long. It is the centre of a lake district famous for its scenic attractions, including Portage Path, an Indian trail between the Cuyahoga and Tuscarawas rivers, which formed part of the western boundary of the United States in 1785. Akron was once the home of John Brown, where the councils of his associates in the abolition cause were held. It was also the residence of Sidney Edgerton, first chief justice of Idaho Territory and first territorial governor of Montana. Pop. (1915) 100,079, an increase of 45 per cent in five years from (1910) 60,067. Pop. of Greater Akron, including suburbs (1916), 120,000. Consult Lane, S. A., ‘Fifty Years and Over of Akron and Summit County’ (Akron 1892); ‘Akron — The City of Opportunity’ (Akron Chamber of Commerce 1916).

AKSAKOFF, ak-sä'köf, Ivan Sergeyevich, Russian writer and leader of the Pashkhov detachment of the Moscow troops. After the war he founded a weekly journal called Des, which he edited for four years, after which he founded and edited a daily paper called Moskva. This latter paper was suppressed three times by the government within two years. He was one of the leaders of the movement toward the union of all the Slavic peoples into one great empire and he had not a little influence in precipitating the Russo-Turkish war of 1877, which resulted in the liberation of Rumania and Bulgaria. From 1880 until his death he published the weekly Rod. Rassvet, the organ of the ‘Panslavics’; and the political organ of the Sultan Bajazet I died while a prisoner in the fortified camp of Tamerlane. The modern city manufactures carpets of repute and is an important trading-centre between Constantinople and Syria. Pop. 15,000.

AKSU, ak-soo’ (‘white water’) China, a town of East Turkestan, on the AkSU River and the southern slope of the Tien-shan Mountains, about 250 miles northeast of Kashgar. It is a great caravan-centre for Chinese, Russian, West Turkestan, Kashmir and Indian traders and its industrious and hospitable inhabitants manufacture unglazed ‘bias’ cotton cloth, ornamented saddlery of deerskin, jewels and jasper ornaments. Copper, iron and lead deposits nearby are mined by Chinese convicts. Aksu was the former capital of the Khans of Kashgar and Yarkand. In 1867 the Khan of Kashgar regained it, only to lose it to the Chinese in 1877. It was almost destroyed by an earthquake in 1716 and in 1800 was flooded by a freshet in which 3,000 lives were lost. Pop. 25,000.

AKTIAN DEPOSITS. See CONTINENTAL SHELF.
AKYAB, ak-yāb', India, seaport town of Burma, capital of the district of Akyab and of the province of Arakan, 190 miles southeast of Calcutta on the eastern coast of Akyab Island, at the confluence of the Kuladan, Myu and Lemyu rivers. A former fishing village, it has become a flourishing town since its selection in 1869 as a port and the capital of the province. The chief exports are rice and oil. Pop. 40,000.

AL, or EL, the Arabic definite article; also means "of the:" al abdu = the slave; abu 'l malik = slave of the king. In Arabic the following consonants are called "sun letters." Tā, thā, dāl, ḍāl, zā, sin, shin, sad, dad, tā, tsa, nun. When a noun or a name beginning with one of these letters follows the article, the l is then dropped and the sun letter is doubled, e.g. Noor-el-deen (light of the faith), becomes Noorreddeen; koh-el-noor (mountain of light), is pronounced koh-en-noor. Similarly, Abu el Rahman (slave of the merciful) is pronounced Abdurrahman; el shems (the sun), esh-shems.

ALABAMA. A Gulf State of the United States, the ninth in order of admission to the Union. It is bounded on the north by Tennes- see, Florida and the Gulf of Mexico; east by Georgia, west by Mississippi. Its extreme length is about 336 miles from north to south; its greatest breadth 200 miles; its area 51,998 square miles, of which 719 square miles is water. Its population, as estimated in 1910 was 2,332,608, of which 58 per cent are white. In 1910, Alabama ranked as the 18th State of the Union in population and the 27th in area. It is divided into 67 counties. The capital is Montgomery.

Topography.—The State lies partly in the Gulf Coastal Plain and partly in the Appalachian Highland which extends in the United States from Maine to middle Alabama. A southward bending arc drawn from the northwestern corner of the State to Columbus, Ga., divides it into two distinct regions, the northwestern, the southern extremity of the Appalachian, a mountainous section; the southwestern, belonging to the Gulf Coastal Plain. The mountain portion Contains all the features of the Appalachian system: (1) A Piedmont region in the east, called the Ashland Plateau. (2) Adjacent to the Piedmont, a number of parallel mountain ridges, with valleys between, extending from northeast to southwest, which gradually reduce in elevation to the southern plains. (3) On the west a hilly region, the southern end of the Cumberland Plateau. The average elevation of the State is approximately 600 feet. In the north and east the surface is generally above this level; in the south and west, below it. The greatest elevation is 2,500 feet, found in the sharp crested Talladega ridges composed of granite, slate and marble. These represent the extreme southern end of the Blue Ridge of the Appalachians. The great Tennessee River enters Alabama at the northeastern corner from the State of Ten- nessee, and flowing northeast it turns abruptly to the northwest and flows through the valley which it has made across the Cumberland Plateau and emerges from the State at its northwest corner.

The coast line of the State is about 120

miles in length including both shores of Mobile Bay, an inlet 36 miles long and from 8 to 18 miles in width with a channel 30 feet deep in course of construction. The smaller bays are Perido, Grand and Bon Secours.

Hydrography.—There are three major and two minor drainage basins in the State:

Major.—(1) The Mobile; (2) the Tennessee; (3) the Chattahoochee.

Minor.—(1) The Conecuh, forming the Escambia of Florida; (2) the Choctawhatchee.

The Mobile system drains the greater part of the State. Mobile River, 44 miles long, is formed from the Alabama and the Tombigbee, both crooked alluvial streams. The Alabama is navigable 320 miles to the junction of its two chief tributaries, the Coosa and the Tallapoosa. The Coosa, since the completion of several great locks by the Federal government, is navigable to Rome, Ga., and its falls are the source of immense water power. The Cahaba, another tributary of the Alabama, enters it from the north and flows through important coal fields.

The Tombigbee, 500 miles in length, has its remotest sources in Mississippi. Its chief tributary in Alabama is the Black Warrior, 300 miles long, rising on the divide near the great bend in the Tennessee River. This tributary flows through the greatest coal measures of Alabama, and has been made navigable by a series of locks and dams built by the Federal government.

The Tennessee, chief affluent of the Ohio, is navigable from its mouth to Knoxville, Tenn., about 700 miles, 300 of which lie in Alabama. Navigation on this is originally interrupted by mussel shoals, but now a canal with nine locks is in operation, extending 28 miles between Decatur and Riverton. The power available at the foot of the shoals in this mighty stream is second only to that of Niagara.

The Chattahoochee, flowing between Georgia and Alabama, is navigable to the "Fall-line" where the stream leaves the Piedmont and enters the Coastal Plain, a distance of about 200 miles.

The Conecuh and Choctawhatchee are shallow streams of the Coastal Plain, used for floating rafts of logs to the Gulf. Alabama is classed as one of the four great river States of the United States. Its streams furnish steam navigation for nearly 3,000 miles.

Climate.—Lying between parallels 31°-35°, the State has a range of climate from temperate in the northern mountainous portion, to semitropical in the low-lying counties of the southern part bordering the Gulf. The annual mean temperature for the entire State is 63°; average rainfall, 52 inches. Throughout the State there is an average of six months without frost. All the climate conditions favor the growth of cotton, corn, peanuts and other leguminous plants.

Geology.—All the Appalachian formations are found here in three divisions: (1) A northwest section showing great stone masses and coal measures, with strata practically horizontal. (2) A northeast section having metamorphic and calcareous rocks, —Silurian quartzites, marbles, granites and gneisses, the strata often broken into masses of
clay interlaminated with quartz seams; the Coosa and Cahaba coal fields showing strata of sandstones, conglomerates, shales and coal beds. (3) A southern section, part of the Gulf Coastal Plain, having drift beds over Cretaceous and Tertiary rocks. The angle between the Alabama and Tombigbee rivers is rich in fossil remains of the Tertiary Age. Consult Geologic Map published by Geological Survey of Alabama.

Soils.—The soils are (1) residual, and (2) sedimentary. The residual soils, being derived from underlying rocks, vary from clay to sand according to the substratum. The Coosa and Tennessee valleys underlain with limestone are overlaid with fertile red clay, while the adjacent highlands are covered with sandy soil varying in color. The Coastal Plain is composed of many overlapping strata of sedimentary material, limestone, sandstone, clay, each outcropping stratum being overlaid with its appropriate soil. Overlying the western and southern part of the State is the remnant of a mantle of sand, gravel and loam in the form of gravelly hills of moderate fertility, but chiefly forested. Between the northern mountainous region and the southern plain lies an inner lowland extending across the State from east to west. This strip about 25 miles in width, has been eroded out of the belt of chalky limestone of the Cretaceous deposits, the rock of which has weathered into a dark soil of great depth and fertility. This lowland is the famous Black Belt, having a soil of enduring quality. Most of the rivers of the lowlands have made flood plains of rich alluvial soil.

Fisheries.—Oyster-dredging is the chief branch of the fishing industry, an average annual yield being 535,000 pounds valued at $108,500. Red snappers, catfish, mullet and shrimp also furnish considerable yields. The average annual value of the total product of the Alabama fisheries amounts to $387,000.

Minerals and Mining.—The mineral wealth of Alabama is enormous, practically all of it lying in (1) and (2) of the geologic regions. The advantage of vast coal, iron, limestone and dolomite (magnesian limestone) deposits lying close together has within the past 20 years raised the State from an almost purely agricultural sector to one of the chief manufacturing districts of the Union with its centre at Birmingham. It is said that iron products can be manufactured more cheaply there than anywhere else because of the proximity of coal, iron and fluxing material. The mineral wealth of Alabama lies chiefly in her rich deposits of coal and iron ore. The former brings her two-thirds of her annual income from mines and quarries, and the latter about one-fourth. Beyond the first value of these raw materials, however, they form the bases of two thriving industries — the manufacture of pig iron and of coke — through both of which the State takes high rank among the mineral-working States in the Union. In 1916 Alabama produced 5,976,018 tons of iron ore, which, three and a quarter per cent of the total yield of the whole country, placed the State in third place among the iron ore producers — following Minnesota and Michigan — and the yield was five times as much as that of Wisconsin, the fourth in rank in that industry. The incompleteness of the returns for 1910 of the mineral industries of Alabama at this writing (October 1917) makes it necessary to revert to the record of 1915 for a unified statement. In 1915, then, the production of raw mineral substances in the State reached a total value of $29,457,407. This was distributed as follows:

Some of these items, as the clay products, cement and lime, are advanced by treatment beyond the raw stage; the stone is more or less dressed before being placed on the market; and the graphite is milled. But it is the custom of the Geological Survey to enumerate such productions among the mineral products of the several States and this practice is followed here. A very considerable secondary value arising from the conversion of coal into coke, and of iron ore into pig iron should be noted, as inseparably connected with the mineral output of the State. In 1915 the pig iron produced was valued at $23,775,000 and the coke production was valued at $8,505,555.

Coal.—The great Appalachian coal region which includes the world-famous mining section of Pennsylvania and Ohio, trends south-westward through eastern Kentucky and Tennessee, having its southern limit in a broad area in the northern half of Alabama. The coal formations in this State underlie about 8,400 square miles distributed in four distinct measures: the Warrior, the Cahaba, the Coosa and the Platte. The first named includes all of Walker County and most of Jefferson, Tuscaloosa and Fayette counties, with parts of Blount, Culman, Winston and Marion counties. This great area embraces about 4,000 square miles and supplies over 80 per cent of all the coal mined in the State. The Cahaba measures underlie St. Clair, Tuscaloosa and Shelby counties, and supply more than 18 per cent of the State's total output. The other two measures though they are known to contain immense quantities of coal, have but a small output. The total supply less than 5 per cent of the coal mined in the State. Nearly half of the entire output is mined in Jefferson County, nearly one-fourth in Walker County and about one-eighth in Bibb County. About 35 per cent of the product is mined by machines, 31 per cent by hand and 33 per cent is blasted off the solid. The coal production of Alabama in 1915 was 14,927,937 tons, valued at the mines at $19,065,043. The highest output was in 1910 when 16,111,462 tons were mined. In 1870 the output was 13,200 tons. Of the coal output of 1915, 49 per cent was consumed in the State, 34 per cent by railroads, 14 per cent was shipped to other States and 3 per cent was shipped to tidewater. The amount consumed by the railroads was 5,792,435 tons; 4,608,932 tons were used in the manufacture of pig iron and of coke; 2,389,397 tons were consumed in industrial plants; 1,592,932 tons were used for domestic and local purposes; 535,340 tons were used in the manufacture of gas; and 480,258 tons were shipped to tidewater as bunker coal. of the coal production of the State were first made, and including the 1915 output, Alabama has mined a grand total of 285,475,717 tons of coal, valued at $1,48 per ton, and produced 3,071,811 tons of coke valued at $2.78 per ton. The yield of coke was 62.4 per cent of the coal consumed and the value of coal per ton of coke, $2.26. Of the whole coke production, 2,889,268 tons were of furnace quality and 172,991 tons of foundry quality. The entire product was valued at $8,545,555. At the close of 1915 there were 8,568 beehive ovens and 750 by-product ovens in the State, but during the year only 2,506 beehive ovens and 732 by-product ovens had been active. Of the by-product ovens, 450 are of the Koppers type and 300 of the Semet-Solvay type. No reports are available as to the coal products recovered, but it is known that some tocoul was produced.

Iron Ore.—The output of iron ore in Alabama in 1915 was 4,374,309 tons of hematite ore or red ore and 935,045 tons of limonite ore or brown ore. In the early days of iron-making in the State only the brown ore was used and the furnaces reduced it with charcoal. Later it was discovered that the red ore could be made into good iron at a considerably lower cost, using coke for fuel. The limonites, however, continue to be regarded as the best ores in Alabama and bring a higher price. They make a tougher iron than the red ore and are frequently used with the red ore to improve the quality of the product. The limonite deposits are very numerous and widely distributed over the State, and in some localities are very extensive. The most important occurrences are those overlying the Knox dolomites, the Weiser quartzite, the Lauderdale chert and the Lafayette strata. The brown ore in 1915 brought at $1.25 per ton, when the red ore was selling at $1.25 per ton.

All the hematite ore mined in Alabama comes from the Clinton or Red Mountain formation. It is found on both sides of the anticlinal valleys which lie between the coal fields. In spots, owing to faults, the red ore ridges are missing on the western side of the valleys, although in some places and from the same cause the ridges are duplicated on the eastern side. The moderate dips are generally on the eastern side, and it is in these localities that nearly all the active mines are found. The hematite seams are exposed in outcrop along a distance of about 50 miles, but for the greater part of this distance they are not rich enough for profitable working. The most important development in the State has been along the easterly side of East Red Mountain, Jefferson County, in the stretch of about 15 miles between the cities of Birmingham and Bessemer. Here there is an almost continuous string of active mines. A new mine, opened in 1915 in Shades Valley, gives promise of being the largest producer in the State. That rank is now held by the Red Mountain mine (a group), which also holds third rank among the iron mines of the United States, with the record for 1915 of 2,138,015 tons of ore, only 170,000 tons behind the leading mine in the country—the Mahoning, of Minnesota. The average tonnage of the new mine at Shades Valley analyzes as follows: Metallic iron, 39.5 per cent; calcium carbonate, 24.20 per cent; silica, 9.94 per cent; alumina, 3.34 per cent; magnesium carbonate, 0.78 per cent; phosphorus, 0.32 per cent; metallic manganese, 0.20 per cent.

Pig Iron.—In 1915 there were 27 blast furnaces in operation in Alabama and they produced 2,049,453 tons, about 7 per cent of the 29,916,213 tons which was produced by the whole United States. With this output Alabama took fourth place among the iron-producing States, following Pennsylvania, Ohio and Illinois. The average value for the year was $10.24 per ton. In the latter part of the year the price began to rise and in the early part of 1916 reached $13. Later the price of Southern foundry No. 2 at Birmingham rose to $22 per ton. A general advance in the price of ore followed the rise in iron and the tendency was still upward at the close of 1916.

Clay and Clay Products.—In 1915 there were mined in Alabama 31,520 tons of fire clay, and 250 tons of other clay, which were sold as such in the market. The remainder of the clay mined was manufactured into brick and tile and pottery, and no records were kept as to its amount. The clay products made during the year were valued at $1,177,725, of which $1,177,725 was the value of the brick and tile produced and $15,297 of the pottery. The brick industry centers in Jefferson County, where 68 per cent of the State's entire output was made. A total of 70,681,000 common brick, 29,018,000 vitrified brick, and fire brick to the value of $145,535 was made by 65 operators; and 13 other firms made the red earthenware and the stoneware which constituted the pottery output.

Cement.—Large supplies of the limestone, chalk, clay and shale required for the manufacture of Portland cement exist throughout the State. With coal and labor cheap, the cement industry flourishes. In northern Alabama the limestone used is the hard Trenton limestone, with shale from the Clinton formation or from the coal measures. In central Alabama the soft Cretaceous limestone is used, with the residual clays which overlie it. In southern Alabama the Saint Stephen's limestone is combined with clays from the Grand Gulf formation. In 1915 the cement output of the State was 1,114,386 barrels, valued at $891,183. In North Birmingham is located the principal Puzzolan cement works in the United States; there are built two other such plants in the country. Furnace slag is used in the manufacture of this cement.

Stone.—Alabama has for many years had a thriving industry in stone, principally in limestone. Some very fine building stone of this material has been quarried in the area north of Franklin County. It has proved very durable under weather and wear, and has found an ever-widening market outside of the State. Alabama produces also some notable marbles, both crystalline and non-crystalline. The former, known as statuary marble, occurs as a belt 50 miles long, crossing Coosa and Talladega counties. In quality it compares favorably with the best Vermont marble and many public buildings
have been faced with it. In Shelby County there are deposits of variegated marble, red, pink, black and white, and at Prattville on the Cahaba River, in Bibb County, there is another deposit of varicolored marble, ranging from gray through pink, red and brown. A very handsome black marble is also found near Anniston, and at Piedmont in Calhoun County. The total stone production in 1915 was valued at $719,452; of this, $375,000 represented marble. The total includes the value, $289,167, of 523,066 tons of limestone flux, mined for use at the furnaces. Lime was burned in 14 plants in 1915, with a combined output of 60,332 tons, valued at $250,227. Three of the plants produced hydrated lime.

Sand and Gravel.—In 1915 Alabama mined 169,663 tons of molding sand, 157,581 tons of building sand, 6,942 tons of engine sand and 7,294 tons of other sands, and 547,656 tons of gravel. A high grade of glass sand is found in Jefferson and Etowah counties, but no development has yet been made. The value of the sand and gravel production in 1915 was $242,336.

Graphite.—Alabama produces annually about half the crystalline or "flake" graphite mined in the United States, and this production is 47 per cent of all the graphite of all kinds which is mined in the United States. The mineral is found in a schist in the form of lenses in a series of metamorphic rocks traversing parts of Clay, Coosa and Chilton counties in the Piedmont region. The average graphite content of this schist is 3 to 4 per cent, but the recovery in mining is rarely more than 2 per cent of the tonnage of ore handled. The industry centres about Ashland, in Clay County, with one or two establishments near Goodwater, in Coosa County, and one near Mountain Creek, in Chilton County. In 1915 only four mines were in operation producing 3,474,800 pounds, valued at $204,572. Three more mines began operations during the year and in 1916 the output of the seven mines was 5,226,940 pounds, valued at $492,407. Two mines began production in the early part of 1917 and 23 other companies have made preparations to begin mining before the year is out. This marked activity is due to the scarcity of Ceylon graphite in the market because of the shut-down in shipping facilities and the high ocean freights. The price of the Ceylon graphite doubled and the demand for domestic graphite became insistent. The larger parts of the crystalline graphite produced in the country, and imported, is used by crucible makers, whose business has increased enormously through the manufacture of munitions.

Miscellaneous.—The mineral productions of Alabama which are of minor importance when ranked according to the value of their annual output are gold and silver, mica, millstone, mineral paint, petrified wood, fuller's earth, bauxite, barytes, natural gas and petroleum. In 1915 the value of their combined output was $92,300. There are known to be auriferous lodes in Turkey Hendricks, Montgomery county, but they have not been developed. Some new prospecting was done during the year and a new placer was discovered and worked near Heflin. The year's output of gold was $5,243; and of silver, $6. Mica was mined in Randolph, Cleburne, Clay and Talla-posa counties. The total output amounted to 5,750 pounds of sheet mica and two tons of scrap. It was sold to local and out-of-state markets. The natural gas wells in Fayette County and two in Walker County supplied a total of 441 customers. Small quantities of petroleum have been found at several localities in the State, the latest and most promising being the new well at Cordova, in Walker County. Oil was struck in this well in December 1916, and it has the record of being the first well in the State to yield enough oil to be measured in barrels. At Hamilton, in Marion County, and at Atwood, in Franklin County, oil-saturated sands have been found and small quantities of oil secured. The strike at Cordova has revived interest in oil exploration in that part of the State. There is one mine near Rock Run, Cherokee County, producing bauxite; one mine in Calhoun County producing barytes; one quarry at Dutton, in Jackson County, producing millstones; and one mine producing ochre, in Clarke County. There are 14 mineral springs in the State producing medicinal waters. The total output reached 86,499 gallons, valued at $8,912.

Forest Products.—Beech, hickory, white oak, yellow, long leaf pine, walnut, ash and elm cover the State in sufficient quantity to be a factor of prime commercial importance. The products from this source include firewood, material for fences, logs, railroad ties, telegraph, telephone and power-conduit poles, materials for barrels, bark and naval stores. The total value of these reaches annually to about $6,500,000, of which about $4,000,000 worth is used on the farms and the remainder sold off the lands.

Agriculture.—Alabama is pre-eminently an agricultural State with a wide range of soils admirably adapted to cultivation. The number of farms in 1910 was 262,901, an increase of 17.8 per cent over 1900 when 223,220 farms were reported. The farm area in 1910 was 20,732,312 acres, of which 9,693,581 acres were improved land. The average acreage per farm was 78.9 in 1910 against 92.7 in 1900. The value of all farm property was $370,138,429, including land, buildings and live stock. The average value of land per acre was $10.46 in 1910 against $4.84 in 1900, an increase of 116.1 per cent for the decade. These values have greatly increased (1917) but no statistics are available.

In Alabama, as in other southern States, there is a great tendency to lease farms to tenants or on shares. Of the 262,901 farms in the State in 1910, 158,326 were operated by tenants and 104,575 by the owners. The leasing contracts vary considerably; of the total number in 1910, 83,300 were cash tenants, 2,428 share-cash tenants, and 67,352 were shareholders.

Another matter of great interest in connection with farming in Alabama is the relative amount of land held or leased by whites and negroes. Silkia, the steam plants, fullers' earth, bauxite, barytes, natural gas and petroleum. In 1915 the value of their combined output was $92,300. There are known to be auriferous lodes in Turkey Hendricks, Montgomery county, but they have not been developed. Some new prospecting was done during the year and a new placer was discovered and worked near Heflin. The year's output of gold was $5,243; and of silver, $6. Mica was mined in Randolph, Cleburne, Clay and Talla-
held by colored tenants. Of 103,929 farms owned in 1910, 74,504 were free of incumbrance while 27,457 were under mortgage and the status of 1,908 was unknown. In 1900 80.8 per cent of the farms were free of mortgage while in 1910 only 73.1 per cent were free. Two-fifths of the entire farm area of the State is in farms of from 20 to 49 acres; one-fifth are from 50 to 99 acres, and about one-eighth from 100 to 174 acres. Of the farmers in Alabama in 1910, 152,458, or 58 per cent, were white and 110,443 were non-white, of which number all but 56 were negroes. In 1915 the area under cotton was 3,219,000 acres; the yield was 525,000 bales of cotton valued at $48,956,000. In 1911 Alabama produced 1,716,534 bales of cotton. Due to ravages of the boll weevil cotton is greatly reduced since 1914. Velvet beans and peanuts are replacing its acreage. In 1917 velvet beans were planted on 2,334,000 acres, and peanuts on more than 900,000 acres. The chief crops are maize, 46,688,000 bushels in 1916; wheat, 1,045,000 bushels; oats, 10,400,000 bushels; peas, 1,000,000 bushels. Other important crops are hay, 362,000 tons in 1916, and vegetables, peanuts to the value of about $1,500,000 annually; sweet potatoes and yams to the value of $3,500,000; cottonseed valued at $6,000,000 annually; orchard fruits valued at $1,800,000; bush fruits valued at $175,000; tobacco, 60,000 pounds in 1916. Sugar cane is largely grown and manufactured into syrup. In January 1917 the live stock comprised 150,000 horses, 278,000 mules, 410,000 milch cows, 534,000 other cattle, 121,000 sheep and 1,850,000 hogs. In 1910 the total value of live stock, including domestic animals, poultry and bees, was $65,955,000. Strong efforts have been made in recent years to diversify the State's agriculture more, and not without success: but the system of renting farms by merchants to small occupiers, largely negroes, who are supplied with necessaries by the merchant on a crop mortgage, makes it difficult to effect the change, as the cotton is a less experimental crop; and the merchant wishes to sell the occupier other products himself. The partial exhaustion of even the fertile cotton land, however, by continuous planting for many years, has awakened much anxiety for the agricultural future; and the planting of cow-pease, alfalfa, etc., to enrich the soil and feed greater quantities of stock has shown a considerable advance.

Manufactures.—According to the special census of manufactures made by the Federal government for 1914, the figures show that although the number of manufacturing establishments in the State had decreased by 156 since the preceding census (for 1909), the number of the wage-earners had increased in the five years by 6,569; the amount paid in wages had increased by $6,613,000; the capital invested in the State's industries had increased by $54,325,000; and the value of the yearly production of manufactured articles had increased by $32,836,000. Incidentally it may be mentioned that the horsepower employed in the manufacturing industries in the same five-year period had increased by 87,925. The number of establishments engaged in manufacturing in the State in 1914 was 3,242; the number of persons employed was 88,931, of whom 78,717 were wage-earners who received an aggregate of $33,897,000 in wages in the year, an average of $430 each. The combined capital invested amounted to $227,505,432 and the value of the year's output was $178,793,634. More than one-third of this, $71,386,000 was the value added by the processes of manufacture. The total horsepower employed aggregated 445,762, of which 375,114 was steam and turbine energy, 98,189 electric and 9,621 power from water wheels and water motors.

The principal industries, arranged in the order of the value of their output in 1914, were as follows: Cotton goods, 57 establishments, employing 13,697 hands, $25,623,000; lumber and timber, 1,355 establishments, 21,646 hands, $21,333,000; iron and steel blast furnaces, 15 establishments, 3,547 hands, $20,066,000; cottonseed oil and cake, 84 establishments, 2,028 hands, $14,982,000; railway car and repair shops, 22, with 7,008 hands, $12,522,000; fertilizers, 80 establishments, 1,416 hands, $10,870,000; coke, 18 establishments, 2,209 hands, $10,353,000; iron pipe, 20 establishments, 3,696 hands, $6,754,000; foundry and machine shops, 79 establishments, 1,866 hands, $4,033,000; printing and publishing, 278 establishments, 1,286 hands, $3,993,000; planing mills, 76, with 886 hands, $2,772,000; flour and grit mills, 73, with 125 hands, $2,179,000; mineral- and soda-water bottlers, 161 establishments, 520 hands, $2,162,000; bread and bakery products, 97 establishments, 651 hands, $2,056,000; turpentine and resin, 160 establishments, 3,411 hands, $2,047,000; brick and tile, 51 establishments, 1,599 hands, $1,622,000; ice manufacture, 55 establishments, 478 hands, $1,201,000; illuminating and heating gas, 14 establishments, 214 hands, $1,125,000. No other industries reached the million mark in their combined output for the year.

The chief manufacturing centre was Birmingham, where 10,863 wage-earners found employment. No other city in the State approached this figure, Mobile ranking next with 2,604.

Of the total number of wage-earners in the State 69,849 were males over 16 years of age and 5,735 were females over 16 years. The number of persons under 16 years engaged in the manufacturing industries of the State was 3,133—about 4 per cent. Of the whole number of workers, 36,131 had a 60-hour week; 12,797 worked from 60 hours to 72 hours a week; 9,804 worked 54 hours a week; 6,765 worked 48 hours a week; 4,777 worked from 54 to 60 hours a week; 3,507 had a 72-hour week; and 3,372 worked more than 72 hours a week.

Transportation.—The great streams of the State, never closed by ice, afford fully 1,500 miles regular steam navigation, besides smaller boats in reaches; and improvements under way will increase this. The Mobile River and its two great constituents are navigable to Montgomery on the Alabama, 320 miles from the Mobile (the Coosa has also small steamers on it), and to Columbus, Mississippi, 300 miles. The Chattahoochee is navigable to Columbus, Ga., about 300 miles. Navigation on the Tennessee was hampered by the Mussel Shoals near its western end.
in the State, but a canal 23 miles long cut around the shoals has obviated this difficulty. It is navigable to Chattanooga, Tenn., and for small craft as far as Knoxville. The Mobile Basin and Tennessee River Association was organized in 1907 to work for the improvement of Alabama waterways and in 1910 the United States government began extensive improvements in the Alabama and Coosa Rivers to Wetumpka and also in the Warrior and Tombokhe.

Alabama was a leader in the pioneer period of railroad building. As early as 1830 the legislature charted a two-mile line from Tuscumia to the Tennessee River and in 1832 another road was chartered which extended to Decatur from Tuscumia. On both roads were iron bars laid on wooden stringers and the cars were drawn by mules. The stockholders were the cotton planters of the locality who found an ample supply of labor in the plantation negroes. A prosperous commerce developed on the navigable rivers at an early period and in 1858-59 Mobile had become the third exporting port in the United States ("Statistical Abstract, United States Treasury, Washington 1886").

The railroad mileage increased from 127 miles in 1859 to 6,415 in 1916, exclusive of over 300 miles of electric street railroads. The great railroad centre of the State is Birmingham, through which passes nearly every trunk line in the South. The Louisville & Nashville Railroad had an early and potent influence in making available the landlocked mineral resources of the State and the Southern Railroad has been equally active and beneficent in promoting agriculture. The harbor of Mobile, the chief commercial outlet of Alabama and neighboring States, has been greatly improved; the harbor channel is being deepened to 30 feet, making it possible for seagoing ships to be loaded at their wharves. The port is available for the entire commerce of the State, either by rail or river.

**BANKS AND FINANCE.** — The imports at Mobile arrive mostly from Mexico and comprise tropical fruits, chiefly bananas and sisal grass. Total in 1911 was $4,031,737. Raw cotton, the principal export, averages annually over $12,050,000; timber, lumber, etc., $6,800,000; cereals and flour, $2,900,000; lard, $1,800,000; besides cattle, mules, swine and sheep, flax-seed and oil, tobacco, sugar, hops, fruits and nuts. Total export 1911 equaled $30,151,501.

**Banks and Finance.** — There are in the State 93 national banks with resources of $60,746,000; 205 State banks with resources of $32,189,445; 41 loan and trust companies with resources of $22,534,555; and 11 savings banks with resources of $1,572,282. The capital of the national banks aggregates $9,700,000, and they make annual deposits totaling $53,187,760. In 1915 there were seven banks in Birmingham with deposits of $24,147,379; five banks at Mobile with deposits of $11,724,786; seven banks at Montgomery with deposits of $6,031,383; and five banks at Selma with deposits of $3,763,169. The State now has an officer, the bank examiner, charged with stated and frequent examinations of private banks. Some of the more lately constructed bank buildings are equal in magnificence of appointments to the best in the United States. Alabama, according to the council of the Corporation of Foreign Bondholders, has a defaulted debt estimated at $30,000,000, but the State denies any liability for such estimated indebtedness, having legally adjusted all claims. Unauthorized charges for which no warrants were issued make up the amount claimed. The bonded debt in 1915 amounted to $9,057,000; the assessed value of real property was $389,741,082; of personal property, $2,436,417,740; total assessed value, $2,652,150,822. The revenue is derived mostly from taxes on property of all kinds and partly from occupation taxes. The assessment is made at 60 per cent of the cash value for State and county purposes by the county assessors on the sworn statements of the taxpayers. The receipts in 1914-15 (year ended 30 Sept. 1915) amounted, with the previous year's balance of $180,196, to $6,874,734; disbursements amounted to $7,830,045, leaving a deficit of $955,311.

The present State Constitution limits the power of the legislature to levy in any one year a greater rate than 6 per cent on its obligations and State taxes. No county may levy a tax exceeding one-half of 1 per cent by State assessment, except for old debts and school purposes. Incorporated cities are subject to some limitation of power of taxation that applies to counties. The State can contract no new debt except that the governor may borrow $300,000. The governor has authority under the State Constitution to extend the present bonded debt of the State. The State bonds of all classes are non-interest-bearing. Of the State taxes, 30 cents on $100 is applied to the maintenance of the public schools and 25 cents is applied to general purposes, including pensions to indigent Confederate soldiers and widows of Confederate soldiers, salaries, etc. The State revenue is derived as follows: Tax on property and polls, 60 per cent; licenses, 23 per cent; proceeds of convict labor, 18 per cent. About 50 per cent of the disbursements is applied to schools and charitable institutions; 16 per cent to pensions; 10 per cent to penal institutions; about 6 per cent to interest on the bonded debt, and the remainder for miscellaneous subjects, including salaries of chieft and employees of the State, the judiciary, the National Guard, etc.

**Education.** — There is a State superintendent of education, an elective office, the term of which is four years. He has general supervision of the public schools and teachers. The public school fund is derived from a State tax of three mills on the $100 assessable values, interest upon the sixteenth section fund and from appropriations by the State legislature together with certain smaller amounts fixed and provided by the legislature. Each county is authorized by a vote of its qualified electors to levy a county tax equal to four mills, 40 cents on each $100 of taxable values. The incorporated towns and cities share in all State taxes and in all county taxes. Each of them is also permitted to levy a municipal school tax of not more than three mills, 30 cents on each $100 of taxable values. The total expenditures for the year ending 30 Sept. 1917 from the above sources and including small incidental fees collected amounted to nearly $5,000,000. Each of

the 67 counties may establish and maintain under the management of the State high school commission a county high school of standard grade to which an additional, annual appropriation of $3,000 is provided by the State. All but about half a dozen counties have availed themselves of this privilege. Ten agricultural high schools, one for each congressional district, are also maintained under State management. Each receives a State appropriation of $3,000. The institutions for the training of white teachers are conducted in all the counties each year, under institute conductors appointed by the State superintendent of education. The term of compulsory attendance is 80 days annually, including all children 8 to 15 years, unless they have completed the common school course of seven grades. The State appropriates funds for the Alabama Industrial School for white boys and the Alabama Reform School for juvenile negroes. It aids the Alabama Home of Refuge for white girls and supports the Alabama School for Deaf and Blind. S

6 normal schools for the training of white teachers are supported and controlled by the State, as well as one normal school for negro teachers. The Alabama Polytechnic Institute, the Polytechnic Institute (coeducational) and the State University (coeducational) are controlled and managed each by a separate board. Tuskegee Institute for the education and training of negroes, coeducational, is the most extensive educational plant in the State and the largest in the world for negroes. It was founded and developed by the late Booker T. Washington. The State makes an annual appropriation to this school but exercises no control over its policies and management. A majority of its trustees are non-residents of Alabama. The Agricultural and Mechanical College for negroes is supported jointly by State appropriation and national funds. The governing board is self-perpetuating and local. All these State-supported institutions are in a satisfactory condition and are meeting the growing needs of the Commonwealth. In addition to the State schools and colleges there are many flourishing institutions under private or denominational control. Among them should be mentioned, either wholly or partly of college grade: Alabama Presbyterian College, Presbyterian (male); Alabama Synodical College, Presbyterian (female); Athens Female College, Methodist; Birmingham College, Methodist (male); Howard College, Baptist (male); Judson College, Baptist (female); Loulie Compton Seminary, private (female); Marion Institute, private (male); Marion Female Seminary, Presbyterian; Saint Bernard College, Catholic (male); Spring Hill College, Catholic (male); Talladega College (colored), Congregationalist; Woman's College of Alabama, Methodist (female).

Religion.—The Protestant churches, notably the Baptists and Methodists, are in the ascendency in Alabama as throughout all the South. The other religious bodies in order of numerical strength are Roman Catholics, Presbyterians, Christians or Disciples, and Episcopalian.

Charity.—The hospitals, orphanages, homes for the aged and other benevolent institutions, including asylums for the deaf, dumb, blind and insane, number 48. The charitable institutions include insane hospitals at Tuscaloosa and Mount Vernon, the Confederate Soldiers’ Home at Mountain Creek, the Industrial School at East Lake, School for the Deaf and Blind at Lineville and a school for the negro deaf and blind. Rules for the support of the poor are made by county commissioners. Within certain degrees, relatives are liable for the support of the poor. For infirm and necessitous Confederate veterans and their families' annual pensions are allowed according to rating: First-class, $100; second-class, $80; third-class, $64. On 1 Jan. 1910, the number of paupers in almshouses was 759, being 34.6 per 100,000 of population.

Punishment.—Although the harsh conditions formerly governing the convict system have been greatly modified, prisoners are still hired out to contractors. Since 1907 special provision is made for dealing with juvenile offenders and in 1911 a State prison inspector was appointed. There is a State cotton mill and cotton farms where women and boy convicts are employed, a penitentiary, a reformatory for wayward women, a reform school for juvenile negro offenders and State convicts are kept. On 1 Jan. 1910 there were 3,687 prisoners in penal institutions, being 172.4 per 100,000 of the population.

Population, Chief Towns.—From 127,901 in 1820 the population had increased to 908,932 in 1870, to 1,828,697 in 1900, and to 2,138,093 in 1910, the increase being 16.9 per cent in the last decade, or 41.7 inhabitants per square mile as against 35.7 in 1900. Alabama ranks 18th in population among the States. In 1910 the population comprised 625,891 white males, 602,941 white females, 447,794 colored males, 460,488 colored females, 454 Indian males, 455 Indian females and 70 male Asians. The foreign-born included 3,599 Germans, 2,348 English, 1,167 Irish, 1,120 Scotch. The capital, Montgomery, has a population of (1910 est.) 42,879. The other large cities are: Birmingham, 174,108; Mobile, 56,336; Selma, 13,640; Anniston, 12,794; Bessemer, 10,804, and Gadsden, 10,557. There were 22 cities with a population in excess of 4,000 in 1910. The total gain in population in 1916 was estimated at 2,332,600.

Constitution.—The Territory of Alabama was organized in 1817 by act of Congress. Population from the Southern Atlantic States from Maryland downward flocked there rapidly. By authority of act of Congress 45 deputies from 23 counties assembled in convention at Huntsville in July 1819, and framed the State Constitution that was accepted and the State was admitted to the Union 14 Dec. 1819. The census of 1820 gave the population, not including any Indians, 127,901. The total of that year showed 142 per cent increase, of which 18 per cent was slaves and 124 white. No white wage class appeared. Increase of population not Indians fell from 1830 to 1840 to 90 per cent that slaves increased by 118 per cent and natural increase to 115 per cent. The first State Constitution, that of 1819, was made by cotton planters, university men fresh from their forest-opened plantations. It was an aristocratic democracy. The general assembly contained the kernal. The lower house met every year; the higher once in three years. It met every year. The governor was chosen at
the polls every two years. The general assembly elected all courts of record for life. The deputies to the constitutional convention were mostly South Carolinians, North Carolinians, Virginians or Georgians. The Constitution, with certain amendments, endured until by convention an ordinance of secession from the United States made expedient a new Constitution in 1861. The scheme of government was not changed. The original right of emancipation of slaves by individual masters was forbidden. The third State Constitution was framed in 1865, within six months of the collapse of the Southern Confederacy. The President of the United States ordered the convention. The Constitution thus framed revoked the ordinance of secession and emancipated slaves within the borders of the State except for crime convicted. This Constitution went into effect two months prior to the 13th article of amendment of the Federal Constitution emancipating slaves. The electoral vote was given to white males only. Special provisions secured to negroes the civil rights possessed by white women and minors. This third Constitution was set aside by the act of Congress in 1867. By that act the army took control of the Southern States, Alabama becoming part of a Military District No. 3. Maj.-Gen. John Pope commanding. General Pope ordered an election to be held during several days in October for the selection of delegates to a constitutional convention. Under this act of Congress the free men were eligible voters. The Fourth State Constitution was made under military authority by outsiders, mainly chosen by followers left from the army of occupation, a few citizens and illiterate negroes. In 1875 by State election a fifth Constitution was made. The object was to curtail the power of taxation hitherto held by the general assembly. The military constitution of 1867 had been in force from 1868 to 1875. Under the Constitution of 1875 a debt commission of three made readjustment of the State debt contracted under the military constitution. The debt of about $30,000,000 was reduced to $9,057,000. The debt commission reported that assessable values of the State, which in 1860 exceeded $700,000,000, had been reduced by 1875 to something like $200,000,000. The electoral vote created by the military constitution was not disturbed by that of 1875. Under that the State government was administered for 33 years. Toward the close of the last century State elections had become impracticable. The belt of white counties were upon the verge of insurrection. The negroes, uneducated, were politically dominant in the black belt, and their votes either purchased or suppressed at option of partisans. The sixth and last State Constitution was framed by convention in 1901, and ratified at the polls after severe opposition from white leaders and the solid negro sentiment. The only registration list is of date 1908. That presents white electors, 250,361; negro electors, 3,742 (Official and Statistical Register of the State, Archives and History, 1915, p. 363). The Constitution of 1901 practically eliminates negro suffrage through several of its provisions, such as that requiring an applicant for registration prior to 20 Dec. 1902, to be the descendant of one who took part in the early wars of the nation, the Spanish war or as a member of the Confederacy. Another provision requires that the applicant be able to read and write in English and be physically able to work.

Alabama (1917) has had six State Constitutions, each of conventional product and each the vital essence of the times in which it was written. The State was one of the groups in the period, 1812–21, when Congress introduced the sanction of that body to membership in the Union. Vermont, the first new State, that is the 14th State, but in both cases before two years before she had established any State Constitution at all, Kentucky came next into Congress by authority of Virginia only. In 1796, the third new State, Tennessee, offered a State Constitution to Congress but in the House it was decided the application should have gone to the Supreme Court only. There the matter was abandoned. Ohio was the fourth, 1802. The State Constitution presented to Congress was referred in the Senate to a special committee but it never reported. The Supreme Court is elected for six years. The State is represented in the Senate of the United States by two senators elected by the people and in the House of Representatives by 10 representatives elected each two years in a prescribed district. The militia is known as the National Guard, composed of the three arms of service, infantry, artillery and cavalry, with special corps. There were (1916) about 4,400 enlisted men and officers in camp, well disciplined and equipped. The functions of executive character in the State are, the convict bureau, controlling the penitentiary, under the governor; the department of archives and history, under a director, the governor, ex officio president of the board of trustees, composed of one in each Congress district; State tax commission of three; State board of health; State department of fish and game; State inspector of prisons and cotton mills, three persons; State banking department, seven persons; State highway commission; State geological survey; State board of examiners of public accounts; State coal mine inspector and his associates; State live-stock and sanitary board; State board of Confederate pensions; State board of mediation and arbitration and various other commissions intended to promote the public weal.

Of those enumerated the Alabama public service commission ranks first in importance. It is made up of three citizens elected by the people. It controls railroads, telegraphs and telephones, and services, telephone, telegraph, etc., and regulates their rates and charges. It has general supervision of firms, corporations and persons engaged in business. Except in the interregnum of military authority, 1867–74, all senators in Congress have been Democrats of the Jackson school. Senator Gabriel Moore, Democrat, 1832, having offended the Jackson sentiment, was requested by the legislature, in vain, to resign. In 1840 the legislature abolished the congressional district for a general election in order to eliminate two Whigs from Whig districts. In 1844 the Democratic State Convention recommended Van Buren for President against Calhoun. For Alabama political history preparatory to the founding of the Southern Confederacy, consult Du Bose's 'Life and Times of Yancey.'

Alabamaans with national and world-wide reputation won in the succeeding generations under the various political constitutions are: William R. King, senator; Ambassador to France; Vice-President of the United States; Josiah C. Nott, M.D., author of voluminous, illustrated works on "Type of Mankind"; James Marion Sims, M.D., surgeon; William Lowndes Yancey, political orator and leader; Mrs. Augusta Evans Wilson, novelist; John Peter O'Leary, a loyal soldier, and John Tyler Morgan, senator of the United States.

History.—In 1519, the Spanish governor of Jamaica sent Pineda to explore the gulf coast of Florida. Pineda soon reached a fine body of water, supposedly Mobile Bay, which he called the Espiritu Santo. He ascended the broad stream emptying into it for six leagues and saw many houses and natives on the banks. Nine years later, Panfilo de Narvaez, a Spaniard, set out westward from Florida on an exploring expedition. He skirted along the coast, but soon drifted out to sea and he and all but three of his men were lost. In 1539, Ferdinand de Soto, governor of Cuba landed in Florida with a thousand men equipped for fighting their way into the unknown West. The Indians who met De Soto were an interesting type of the American aborigines, and were more savage than our historians report that in the later time of the white settlements. The men were fairly intelligent, possessed splendid physical forms, were athletic, brave and resourceful. The women were smaller, with marked personal beauty in individuals. These Indians, Samuel B. Moore, Thomas Moore, and Joseph Moore, and others of his family, with Colonel William Weatherford, one-fourth Indian, three-fourths Scotch, led the Creek warriors to the massacre of Port Mims. In a few hours, most of the 540 white occupants of this place, men, women and children, were butchered indiscriminately. Only

bark and grass. At Mauvilla, an Indian village near the junction of the Tombigbee and Alabama rivers, De Soto won a hard-fought battle with the Indian chief, Tuscaloosa. After this, De Soto made his way westward to the Mississippi River, and Alabama was undisputedly the white men for 160 years.

After LaSalle's exploration of the Mississippi River, Alabama was included in French Louisiana. In 1702, a young French-Canadian, Jean Baptiste La Moyne, Sieur de Bienville, founded Mobile. To checkmate the British from South Carolina who sought to monopolize the Indian trade, he built Fort Toulouse near the place where the Tallapoosa and Coosa join; and to protect the colony against the Chickasaws, he built Fort Tombecbe where the Great Southern Railroad now crosses the Tombigbee. The French colony did not succeed. The settlers sickened in their effort to cultivate the soil; so 15 years after Bienville came, the home government chartered the West India Company to settle Louisianna with a vague idea of its boundaries. During 1721, three slave ships brought negroes to Mobile, and slavery began in Alabama. The colony now took on a new face. Whites, who had been reduced to that last extremity because of labor in the hot climate, now began to trade in timber, tar and turpentine, and to produce from the soil plentiful crops of corn. Cotton was successfully grown, and many decades before Whitney's invention, a crude machine was put in use near Mobile which served to separate the cotton seed from the lint.

Early in the 18th century, the English had planted trading posts north of Mobile, and when the French posts east of the Mississippi were ceded to England, that part of Alabama north of 32° 28' was added to the Illinois country, and that part south of the line was added to west Florida. Many English and Scotch settlers came here, and the French remained loyal during the Revolution. Spain seized the province of west Florida in 1789. On account of her treaty with England, the United States laid claim to all territory down to 31°. Spain, however, held all south of 32° 28' until 1798. The land lying between 31° and 32° 28' on the east, 31° on the south, the Chattahoochee River on the east, and the Mississippi River on the west, was organized into Mississippi Territory in 1798. In 1804, land claimed by Georgia and South Carolina, extending to 35°, was added to Mississippi Territory. The Mobile district was taken from Spain in 1812. In 1817, Mississippi Territory was divided. The western half became the State of Mississippi, and the eastern half the Territory of Alabama. On 14 Dec. 1819 Alabama became a State.

At the outbreak of the War of 1812, the chief Tecumseh and his brother, the Prophet, came south to inflame the tribes of Alabama against the whites; and Colonel Nichols came from London to Pensacola with ample freight of arms and ammunition to distribute among the tribes of Alabama and allies of the British army. On 30 Aug. 1813, Chief William Weatherford, one-fourth Indian, three-fourths Scotch, led the Creek warriors to the massacre of Port Mims. In a few hours, most of the 540 white occupants of this place, men, women and children, were butchered indiscriminately. Only
a few made good their escape. General Andrew Jackson, a fierce avenger, hastened to the field, and on 27 March 1814, he attacked the Creeks in their fortified position on the Talla-
poooa, 20 miles north of Montgomery, and almost annihilated the tribe. Near the battle-
field on the site of old Fort Toulouse, he built Fort Jackson, assembled the warriors, prophets and deputies of the Creeks and made a treaty with them by which they surrendered most of the tribal lands in Alabama and Missis-
sippi. The British War Office now conceived a plan for invading the South. Major Lawrence, of the regulars, was placed at Fort Bowyer at the entrance of Mobile Bay with 160 men. The English assailed the fort with perseverance, but were defeated and re-
treated with loss.

The total white population of Alabama at the beginning of the decade of 1860 was 526,431. The slave population was 435,080. There were 52 counties. In each of the 15 great cotton plantation counties which formed the Black Belt there were from 25,700 to 100,000 slaves, an average of 16,608 slaves and an average of 9,363 white population. The most influential men of the State came from the Black Belt, Mobile and the Tennessee Valley.

As one of the earliest Southern States to engage in the secession movement, and Montgomery was the first capital of the Confederacy, The Ordinance of Secession was passed 11 Jan. 1861, by a vote of 61 to 39. The division of the vote on the adoption of the Ordinance of Secession was not be-
tween a disunion and a union party. The two parties in this convention were the Im-
mediate Secessionists, led by William L. Yancey, and Co-operationists, who believed in the right of secession, but hoped in some way through the co-operation of the Southern States to pro-
tect their rights without secession. These Co-operationists were led by William R. Smith. When the State seceded, Governor Moore or-
dered the seizure of Forts Morgan and Gaines which guarded Mobile harbor. The senator and representatives from Alabama resigned their seats in Congress on 21 Jan. 1861. On the 4 February the government of the Con-
federacy was organized at Montgomery by delegates from the seceding States. Selma was made a leading Confederate arsenal and ship-
ing yard. The Tennessee Valley was occupied by Union forces early in 1862; the fleet in Mobile was destroyed and the forts were re-
taken by Farragut in 1864; and the whole State was recaptured April 1865.

A provisional government was established by President Andrew Johnson by the appoint-
ment of Lewis E. Parsons, a native of New York, who had long resided in Alabama, to be governor. Governor Parsons ordered an elec-
tion by the full body of electors, but the several classes not yet pardoned by the Presi-
dent, of delegates to assemble at the Capitol at Montgomery, September 1865. This conven-
tion made a new State Constitution revoking the Ordinance of Secession, abolishing slavery and providing for the equality of the freed-
men in the rights of person and property; but restricted the electorate to the white males eligible. The State government set up by the new Constitution was recognized by the Presi-
dent as soon as the legislature had ratified the 13th Amendment, and went into effect Decem-
ber following. The general assembly of Ala-
abama, however, refused to ratify the 14th Amendment. Thereupon, the senators and rep-
resentatives from Alabama to Congress were denied seats by that body, and by the Acts of March, 1867, the State government was abol-
ished and military rule restored. Under mili-
tary supervision, the Constitution of 1868 was made by carpet-baggers, scalawags and negroes and a civil government was set up. The Con-
istitution of 1868 remained in force until 1875. The State was bankrupt under the carpet-bag-
ner régime, and there was great disorder in the attempt to bring the government once more into the hands of the better classes. But these conditions have long since passed away, and the reorganizing of the public debt in 1876 made industrial progress possible. The re-
markable industrial changes in the mineral region of Alabama since 1870 have greatly af-
ected the life of the State. To the agricul-
tural life of early days has been added the city life of mining, iron and other manufac-
turing, and commercial people. Great attention has been given to road building. The steel and cotton indus-
tries, lumbering and mining have developed enormously and agriculture is now improving rapidly.

During the Spanish-American War, Ala-
abama furnished two white regiments and one negro regiment. President McKinley overcame what was left of sectional ill-feeling by ap-
pointing Joseph Wheeler, a representative in Congress from Alabama, as Confederate genera-
l, major-general of volunteers, and giving him command of all the cavalry at the battle of Santiago de Cuba. In the last dec-
ade the burning question in Alabama has been prohibition. After waiving between local option and State-wide prohibition, the State adopted State-wide prohibition in 1915. The State has always been Democratic, except dur-
ing the carpet-bagger régime.

The construction of the Panama Canal has greatly enhanced the importance of Mobile as a port. Since the United States declared the war against Germany, Mobile has been selected as a centre of important naval con-
struction work. The Tennessee valley in the extreme northern part of the State is one of the most prosperous sections of Alabama. In 1915, the United States government appropriated $20,-
000,000 for the purpose of manufacturing nitrates. An experimental nitrates plant has been located at Sheffield, and a permanent plant is being constructed near South Florence at Mistle Shuolts post office, established February 1918. In addition, a great dam across the Tennessee River at Florence for the purpose of developing the enormous power of the Mistle Shuolts is to be built by the government. So great will be the increase of the power developed that Florence, Sheffield, and Tusculum will be-
come important industrial centres.

C.); Fish and Game Laws of Alabama (Department of Game and Fish, Montgomery); Official and Statistical Register-Director of Archives (Montgomery); Booklets issued by Industrial Departments of all RAs, Cahawba and Clifton; Special Publications issued by Commercial Clubs of the larger cities of Alabama.

HENRY J. WILLINGHAM,
President State Normal School, Florence, Ala.

ALABAMA CITY, Ala., town in Etowah County, 56 miles north of Birmingham on the Louisville and Nashville, the Alabama Great Southern and Cleveland and Gulf. Situated on the banks of the Ohio and Southern railroads. Large steel works and a cotton mill form the industrial resources of the city. Coal is found in the vicinity and corn, oats, cotton and wheat are raised extensively in the surrounding country. Pop. 4,513.

ALABAMA POLYTECHNIC INSTITUTE, at first known as the Alabama State Agricultural and Mechanical College. This institution is a college at Auburn, Ala., organized in 1872, under the Federal Land Grant Act of 1862. The value of its grounds, buildings and general equipment is estimated to be about $1,000,000. It has a campus of 304 acres. The library contains 25,000 volumes, and the students number more than 800 in the various courses.

ALABAMA RIVER. An important river of the State of Alabama. Formed by the union of the Tallapoosa and Coosa rivers, about 10 miles direct northeast of Montgomery, it winds its way for miles west to Selma, then south, until about 50 miles above Mobile, it joins with the Tombigbee to form the Mobile River. On its banks are valuable timber, some of the largest southern cotton plantations and the towns of Montgomery, Selma, Cahawba and Clifton, which carry on an active river transit trade.

ALABAN’DITE, an iron-black, submetallic mineral. It is usually granular-massive, while its rare isometric crystals exhibit very perfect cubical cleavage. The black color of a fresh surface tarnishes to a dark brown, while its streak is green. Its hardness is 3.5 to 4 and specific gravity 4.0. Alabandite is a manganese monosulphide MnS, and contains 63.1 per cent of manganese. Some of its most important localities are in Austria-Hungary, Peru and Mexico. It also occurs in Summit County, Cal., and at Tombstone, Ariz.

ALABASTER, a name applied to two substances, the one a stalagmitic or stalactitic carbonate of lime, the other a kind of gypsum or sulphate of lime. The first is often called Oriental alabaster, and is that which is mentioned in the New Testament. It occurs in caves in limestone regions and is a translucent stone of yellowish milky color or of a deeper tinge of yellow and sometimes marked with lighter and darker streaks like an onyx. It is found in the cave of Antiparos, the Bauman's cave in the Hartz and is now worked in the province of Oran in Algeria. The gypseous alabaster has a fine granular texture and is usually of a pure white color. It is softer than the other alabaster, and indeed so soft that it may be scooped out with the nails; while the other kind cannot be so treated. It is found in many parts of Europe; in great abundance and of peculiarly excellent quality in Tuscany and Piedmont in Italy, also in England. It is extensively carved into statuettes and vases and often sold as Florentine marble.5 Many museums contain ancient vases and similar articles of alabaster, for which the Romans often employed this material.

ALACOQUE, a’la-kok’, Marguerite Marie ("the Blessed"), a French nun: b. 1647; d. 1690; to whom, according to Catholic faith, was revealed through visions of Christ, the command to confirm the Church of Louis and the Southern railroads. Large steel works and a cotton mill form the industrial resources of the city. Coal is found in the vicinity and corn, oats, cotton and wheat are raised extensively in the surrounding country. Pop. 4,513.

ALADDIN, or THE WONDERFUL LAMP, one of the stories in 'The Arabian Nights' Entertainments.' Aladdin, the son of a poor widow, comes into possession of a magic ring and lamp, and thus becomes the master of the powerful jinns who are the slaves of the lamp and ring. Through their powers he amasses great wealth and becomes sultan.

ALAGOAHS, a’la-gw’ash, Brazil, a maritime province, deriving its name from the first vowel of the Portuguese name. It is a mountainous coast province with numerous small communicating lakes for which it is noted; capital Maceio. It is bounded on the north and west by the province of Pernambuco, on the south by that of Sergipe del Rey and on the east by the Atlantic; area, 11,040 square miles. This province has several lakes, none of them of great extent, frequented by a great variety of birds; and in the west several ridges of hills, none of them of great elevation, but generally well wooded, and inhabited by abundance of game, ounces, macaws, etc. From the extent of surface covered by lakes and by forests the climate of Alagoas is on the whole moist. The plains near the sea are generally sandy and not very fertile; but inland the soil is good, producing besides tobacco, cotton and sugar, which are exported to Bahia and Pernambuco, rice, cocoaanuts, oranges, jack-fruit and abundance of fine timber used for ship-building in the above-named ports and in Maceio. The forests furnish excellent building and dye woods and much ipecacuana. Limestone, granite and various kinds of clay abound in the province. Pop. 75,000.
ALAIS, aîla, France, town of the department of Gard, situated in a fertile plain on the right bank of the Gardon at the base of the Cevennes Mountains, 23 miles by rail northwest of Nîmes. Alais is a very flourishing community, owing much of its prosperity to the abundance of mineral wealth of the district surrounding it which produces coal, iron, lead, zinc and manganese. Blast furnaces, mines and factories of various kinds give employment to large numbers of men, and Gard may therefore be truly styled a beautiful miniere of the Old World and the New. There is also an extensive trade in silk, glass, bricks and tiles. There are in Alais monuments to Florian the novelist, and to Pasquier, who became famous after his studies of the silk worm disease then prevalent in Alais. The town sided with the Protestants in the religious wars of the 17th century and Louis XIII I in person, accompanied by Cardinal de Richelieu, besieged it and, having captured it in 1632, demolished its walls. Three years later the Bourbon of Alais having taken part in the rebellion of Montmorency, the castle was destroyed. Protestantism still prevails to a considerable extent. Consult 'Mémoires et Comptes-rendus de la Société Scientifique et Littéraire d'Alais' (Pop. 24,940; 1911, 29,831).

ALAI, Peace of, a treaty which closed the Huguenot wars in France. It was signed on 28 June 1629, immediately after the capture of Alais by the royal forces, La Rochelle having fallen as a result of Richelieu's policy the year before. In accordance with its terms the fortifications of the Protestant towns were razed and Catholic worship re-established in them, but amnesty and freedom of conscience were granted to the rebels.

ALAJUELA, aîl-ah-w’hâ’la, city of the state of Costa Rica, Central America, 23 miles west northwest of Cartago, and a little on the western side of the watershed between the Atlantic and the Pacific. It is connected with Cartago by rail and carries on a considerable trade in cattle, coffee, sugar and bananas. Pop. 6,300.

ALAMAN, a-lâ-mân’, Lucas, Mexican historian and statesman; b. 18 Oct. 1792; d. 2 June 1853. He was educated in Spain 1814–20, and served as minister of foreign affairs, 1823–25, 1830, 1837, 1853. He introduced European machinery; founded a museum of antiquities and natural history, and was an active official encourager of industry and agriculture, but reactionary in religion and politics. His works are 'Dissertations on the History of the Mexican Republic from the Conquest to Its Independence' (3 vols., Mexico 1844–49), an introduction to his 'History of Mexico,' 1808–30 (5 vols., Mexico 1840–52), of scholarly impartiality in the main, filled with documentary proofs, but with a tendency to belittle the actions of those not of pure Spanish blood.

ALAMANTE CREEK, N. C., Battle of, 16 May 1771, sometimes termed the first battle of the American Revolution. Official correspondence between Gen. Cornyn in North Carolina roused public sentiment so that the colonists banded themselves into 'Regulators' to reform conditions. The rough element resorted to riot and violence, whereupon the assembly passed the Johnson bill (better known as the Bloody Act), which made rioting treason. Governor William Tryon (q.v.) collected 1,200 militia and on 16 May 1771, at Alamance Creek, near Hillsboro, encountered and defeated about 2,000 Regulators (of whom only about 1,000 were armed), inflicting a loss stated at from 9 to 200, while his own loss was about 60 or 70. Twelve Regulators were tried for treason and condemned, but only six were executed. The others submitted and ultimately nearly 6,500 took an oath of allegiance to the royal government.' Consult J. S. Bassett's article in 'Report of the Freemen's Historical Association' 1894, pp. 141–212; F. William E., 'Some Neglected History of North Carolina'; 'North Carolina Colonial Records' (Vols. VII–IX); Haywood, Marshall de L., 'Goverm Tryon and His Administration'; Stockard, 'History of Alamance'; Husband, Harmon, 'Affairs of North Carolina'; 'The South in the Building of the Nation' (Vol. I, pp. 452–456).

ALAMANNI, a-lâ-mân’i, or ALE-MANNI, a confederacy of several German tribes which, at the commencement of the 3d century after Christ, lived near the Roman territory, and came then and subsequently into conflict with the imperium of the Cæsars. The first fought with them in 211, but did not conquer them; Severus was likewise unsuccessful. About 250 they began to cross the Rhine westward, and in 255 they overran Gaul along with the Franks. In 292 a body of them was defeated in Italy at Milan, and in the following year they were driven out of Gaul by Postumus. But the Alemani did not desist from their incursions, notwithstanding the numerous defeats they suffered at the hands of the Roman troops. In the 4th century they crossed the Rhine and ravaged Gaul, but were severely defeated by the Emperor Julian and driven back. Subsequently they occupied a considerable territory on both sides of the Rhine; but at last Clovis broke their power in 496 and deprived them of a large portion of their possessions. Part of their territory was latterly formed into a duchy called Alemannia or Swabia, this name being derived from Suevi or Swabians, the name which they gave themselves. It is from the Alemanni that Austria derived their names for Germans and Germany in general, namely, Allemands and Allemande, though strictly speaking only the modern Swabians and northern Swiss are the proper descendants of that ancient race.

ALAMANNO, Luigi, Italian poet; b. Florence 1495; d. 1536. His father was zealously devoted to the party of the Medici, and he himself stood in high favor with the Cardinal Giulio, who governed in the name of Pope Leo X; but conceiving himself to have been injured he joined a conspiracy formed against the life of the cardinal. The plan was discovered; Alamanno fled to Venice; and when the cardinal ascended the papal chair, under the name of Clement VII, he took refuge in France. But the misfortunes which befell this Pope gave occasion to the revolution in North Carolina roused public sentiment so that the colonists banded themselves into 'Regulators' to reform conditions. The rough element resorted to riot and violence, whereupon the assembly passed the Johnson bill (better known as the Bloody Act), which made rioting treason. Governor William Tryon (q.v.) collected 1,200
mании, now proscribed by the Duke Alessandro, went to France (1530) where the favors of Francis I retained him. Here he composed the greater part of his works. The King treated him so highly that after the peace of Crespy in 1544 he sent him as ambassador to the Emperor Charles V. Alamanni discharged his office with great skill. He was held in like estimation by Henry IV. who also esteemed him in all his negotiations. He followed the court and was with it at Amboise, where he died in 1556. His principal works are "Opere Toscane," "La Coltivazione," "Girone il Cortese," etc. The English poet Wyatt imitated some of his satirical poems. The writings of Alamanni are recommended by ease, perspicuity and purity of style, but often want strength and poetic elevation.

ALAMEDA, á·lã-mâ·dã, Cal., a coextensive city and township in Alameda County, on San Francisco Bay and the Southern Pacific, Santa Fe and the Western railroads, 11 miles east southeast of San Francisco. It is the seat of the College of Notre Dame (Roman Catholic); a popular summer resort, and the place of residence of many San Franciscans engaged in business pursuits. It has numerous banks, electric lighting and street railways, large borax works, extensive potteries, oil refineries, ship-building yards, engine, motor, pump, moving picture and aero-plane manufacturing plants. According to the United States census 1914, there were in that year 53 manufacturing establishments of factory grade, employing 1,267 persons, of whom 1,092 were wage earners receiving an aggregate of $1,029,000 in wages. The total capital employed was $3,737,000, and the value of the output $2,794,000, of which $1,789,000 was the value added by manufacture. The commission of government was adopted in 1913. Alameda grew from a population of 100 in 1854 to 23,383 in 1910; (1916) 26,500.

ALAMINOS, á·lã-mê·nôs, Antonio de, Spanish painter, born in Paim, Spain, about the end of the 15th century. He is said to have been with Columbus in 1599, and was the principal pilot for the expeditions of Cordova, Ponce de Leon and others in the early part of the 16th century. The earliest map of North America is ascribed to him. The islands of Alambo and Alaminos have been mentioned in 1562.

ALAMO, á·lã-mô, The, San Antonio, Tex.; a Franciscan mission house built about 1722 and called San Antonio de Valero; after 1793 used on occasion as a fort and renamed Fort Alamo. It consisted of an oblong plaza some 2½ acres in area, enclosed by walls 8 feet high and 33 inches thick, a church, a hospital building, a convent and a walled convent yard about 100 feet square. It has enduring celebrity as the scene of the battle and massacre of 6 March 1836, in the war for Texan independence. The fort was held by about 140 men under William B. Travis, and on 23 February was invested by a considerable Mexican army (probably about 4,000) under Santa Anna, who at once began a bombardment scarcely intermitted for the next 3 days. The little garrison, contended to man the defense by day and night and fed to relieve each other, sent desperate appeals to their outside comrades for help; but to break through the dense Mexican forces was so difficult that the only reinforcement received was 32 men on the 1st of March. At last a breach was made in the walls, and shortly after daylight on the 6th a general assault was ordered. Twice the storming party were repulsed with heavy loss of lives; the third time they gained the parapet and entered the enclosure. No surrender was offered, and the result showed that the Texans knew their foe too well to expect quarter; worn with fatigue and privation, they fought to a finish, till only 180 of the left were taken prisoners, and the savage Santa Anna had them slaughtered on the spot. Three women, two white children and a negro boy were the sole survivors of about 180 inmates. Santa Anna stated the Mexican loss at 70 killed and 300 wounded, but it is believed to have been much greater. The news of the heroic fight, "The Thermopylae of America," nerved the Texans in all their future efforts, and their slogan was "Remember the Alamo!" Santa Anna himself was defeated and captured at San Jacinto a few weeks later. Consult Corners, "San Antonio de Bexar" (1890); Williams, "San Houston and the War of Independence" (1893); Ford, J. L., "Origin and Fall of the Alamo" (1896).

ALAMOSA, Col., city and county-seat of Conejos County, 110 miles south of Pueblo, on the Rio Grande, and on the Denver and Rio Grande Railroad. It has a Carnegie library and an opera house. Its industrial establishments comprise a flouring mill and railroad repair shops. The surrounding region is a prosperous agricultural and stock raising section, in the products of which the city has a large trade. The city owns the waterworks and sewage system. Pop. 3,013.

ALAND ISLANDS, á·lân, a group of about 80 islands and islets between the Gulf of Bothnia and the Baltic Sea, and near the mouth of the Gulf of Finland, area 468 square miles. The principal islands are Aland, which is the largest and gives name to the group; Lemoland, Lammarland, Ekeroe, Fogloe, Kumlingo, Braenoe, Vordoe and Hannoe. Aland, distant about 30 miles from the Swedish coast, is 25 miles long and about 22 broad. In this island is a harbor capable of containing the whole Russian fleet. The chief towns are Aland and Castelholm. The islands are now included in the province of Finland, and with Aland. After the World War broke out in 1914 the islands were not fortified. Their strategic importance was beyond question, as properly fortified, they form virtually an impassable barrier between the Baltic and the Gulf of Bothnia and provide a naval base commanding the entrance to the Gulf of Finland. According to the North Sea Baltic Treaty of 1908 they were not to be fortified or used for military or naval purposes. Through the intermediary of Great Britain and France, apprehensions of the Swedish government were removed, Russia readily giving definite assurances that any defenses would be purely for war emergencies, and that any such military works would be removed at the conclusion of peace. Pop. about 19,000.

ALANI, or ALANDS, one of the warlike tribes which migrated from Asia westward at the time of the decline of the Roman empire. They are first met with in the region east of Mount Caucasian, where Pompey fought with them. From this centre they spread over the south of modern Russia to the confines of the
Roman empire. They were engaged in war with Rome in the time of Hadrian, but were defeated by Arrian, the general of that Emperor. Marcus Aurelius had much difficulty in keeping them out of the empire, and Tacitus concluded a treaty with them (275 A.D.). About a century later those on the banks of the lower Danube were conquered by the Huns, after which most of them joined the ravaging expeditions of that people. They accompanied Radagaisus on his march into Italy, and after his defeat they settled first on the Rhine, afterward (about 411) in modern Portugal. Being there completely defeated by the Visigoths, they joined the Vandals, among whom they have become lost to history.

ALANUS AB INSULIS, a-lán’us ab in’stú-lis, or ALAIN DE LILLE, a-lán de lill, a French scholastic philosopher: b. 1114; d. 1203. Of his voluminous theological writings the 'Arithmetica' is chief. His poem, 'Anti-Claudinus, or On the Duties of a Good and Perfect Man,' is one of the most celebrated poetic compositions of the Middle Ages.

ALARCON, Pedro Antonio de, Spanish novelist, poet and politician: b. Gaúchos, 10 May 1836; d. 19 July 1891. His critical contributions to papers, political and literary, his description of the Moroccan campaign, but especially his novels and short stories, are among the best of their kind and present a picture of modern Spanish society as true to life as it is variegated. His clever essay, 'The Poet's Christmas,' went through over 100 editions. An imposing number of his stories appeared under the collective titles 'Love and Friendship,' 'National Tales,' 'Improbable Stories,' Among them 'The Three-Cornered Hat' and 'The Scandal' deserve special mention. See EL SOMBRERO DE TRES PICOS (The Three-Cornered Hat).

ALARCON Y MENDOZA, a-lár-kón e man-dó’-tha, Don Juan Ruiz de, Spanish dramatist: b. Tasco, Mexico, about 1588 or 1590; d. 4 Aug. 1639. Little is known about his early life or where he went to school in 1600 and became royal attorney in Seville. From 1608 to 1611 he was in Mexico; then he took up his residence in Madrid, where he was appointed reporter of the royal council of the Indies, about 1628. Elevated sentiment, harmony of verse and correctness of language distinguish his works, the principal of which are 'The Weaver of Seville'; 'Suspicious Truth,' the model for Corneille's 'Liar'; 'Walls Have Ears'; 'The Proof of Promises'; 'The Anti-Christ.' A complete edition of his works was published by Hartzenbusch in Madrid 1866.

ALARIC I, King of the Visigoths: b. about the middle of the 4th century; d. 410, and is first mentioned in history in 394 A.D., when Theodosius the Great gave him the command of his Gothic auxiliaries. The dissensions between Arcadius and Honorius, the sons of Theodosius, inspired Alaric with the intention of attacking the Roman empire. In 396 he ravaged Greece, from which he was driven by the Roman general Stilicho, but made a masterly retreat to Illyria, of which Arcadius, frightened at his successes, appointed him governor. In 400 he invaded Italy, but was defeated by Stilicho at Pollentia (403), and induced to transfer his services from Arcadius to Honorius on condition of receiving 4,000 pounds of gold. Honorius having failed to fulfill this condition, Alaric made a second invasion of Italy, during which he besieged Rome thrice. The first time (408) the city was saved only by paying a considerate sum to the Huns, after which most of them joined the ravaging expeditions of that people. They accompanied Radagaisus on his march into Italy, and after his defeat they settled first on the Rhine, afterward (about 411) in modern Portugal. Being there completely defeated by the Visigoths, they joined the Vandals, among whom they have become lost to history.

ALARIC II, King of the Visigoths from 484 to 507 A.D. At the beginning of his reign the dominions of the Visigoths were at their greatest extent, embracing three-fourths of the modern Spain and all western Gaul to the south of the Loire. The warlike character induced Clovis, King of the Franks, to invade the kingdom of the Visigoths. In a battle near Poitiers (507) Alaric was slain and his army completely defeated. The 'Breviarium Alaricenum,' a code of laws derived exclusively from Roman sources, was compiled by a body of Roman jurists at the command of this King of Alaric.

ALA-SHEHR, a-la-shèr, ancient Philadelphia, a town in Turkey in Asia, 76 miles east of Smyrna, famous as the seat of one of the first Christian churches, and still having a vast number of interesting remains of antiquity, consisting of fragments of sarcophagi, fountains, etc. It is a place of some importance, carrying on a thriving trade, chiefly with Smyrna, to which runs a railway. Pop. 20,000.

ALASKA. The greatest of the Territories of the United States in area and in prospective resources. It practically is divided into three distinctive regions—the main territory, the panhandle or southeastern Alaska, and the Aleutian Archipelago. The main territory includes all that part of the continent of North America to the west of the 141st meridian of west longitude; its other boundaries are the Arctic Ocean to the north, Bering Sea to the west and the Pacific Ocean to the south. The panhandle of southeastern Alaska comprises a narrow fringe of continental coast—with the outlying and adjacent islands—extending from Portland Canal north to Mount St. Elias. The Aleutian Archipelago consists of all the islands westward from the Alaskan Peninsula to include Attu, off the Asiatic coast. Under American jurisdiction also are the islands of Bering Sea—the Pribilofs, Saint Lawrence and others near the Alaskan mainland. The geographical extension of Alaska is very great, from 51° N. in the Aleutian Archipelago to about 72° N. latitude at Point Barrow, and from 130° W. longitude, in Portland Canal, westward to Attu Island in 173° E. longitude.

Physiography. Since Alaska, with its area of about 590,000 square miles, is one-third greater in size than the Atlantic States from Maine to Florida, its detailed geographic description would involve much space. Sitka, Alaska, the land of tourists, is a narrow region intersected by long, deep fjords, which are dom-

inatated by lofty, glacier-covered mountains rising precipitously hundreds, and in places thousands of feet from the water's edge. All visible land surfaces are very rarely level. Southwestern Alaska, from the Alaskan Peninsula eastward to the Saint Elias region, has coasts of the fjord type, which are rather more open through the greater waterways of Cook Inlet than from Yakutat Bay. These mountainous coasts are, however, broken by the Copper River and the debouching streams at the head of Cook Inlet. This well-wooded country of surpassing beauty from Yakutat Bay to Cook Inlet hence shades westward to the desolate Alaskan Peninsula, a treeless, volcanic, upturned region, where lakes are interspersed. Southeastward of this region are the fertile islands of Afognak and Kodiak. The Aleutian Archipelago stretches from the Peninsula a thousand miles westward toward Kamchatka in the form of some 70 treeless volcanic islands, of which less than a third are inhabited. The best known are the Fox group (Uminak and Unalaska), the Nearer (Atru), Rock (Seward Peninsula), and the mountains facing them. Isolated in the middle of the Bering Sea are the Pribilofs, the wonderful breeding grounds of the fur-seal. The Bering Sea district from Bristol Bay north is a barren coast, usually a treeless and tundra country. The Seward Peninsula, about 20,000 square miles in area, rises from low, sandy coasts to flat-topped uplands, rarely above 2,000 feet. The Arctic coast is low, sandy, shoal-bounded and practically uninhabited, though the forest-clad hills of the north are much frequented by Eskimo hunters. The Yukon watershed, about 200,000 square miles in area, comprises far greater part of the habitable regions of the Territory. In its bow-shaped course of 1,500 miles from the Canadian frontier to Bering Sea the Yukon receives three large and navigable affluent—the Porcupine, Tanana and Koyukuk. The Yukon watershed is separated from the Arctic slope by low (Endicott) mountain ranges, and from the Gulf of Alaska by lofty, snow-clad ranges of the Alaskan chain, the Saint Elias, Wrangell and McKinley groups—which range from 9,000 to 19,000 feet. Extensive areas in the Yukon and other valleys are tundra—flat, undrained lands covered with a dense, rank growth of mosses, sedges and shrubs. Apart from the Bering Sea coast the Yukon Basin has extensive forest growths in its valleys, principally alders, birches, cottonwood, hemlock, poplar and spruce.

Mountains.—Some 200 miles inland and nearly parallel with the Arctic shores is the Endicott range, low mountains from 1,000 to 1,800 feet in elevation. The Coast Range, north of Cross Sound, consists of the Fairweather and Saint Elias groups—more picturesque than any other part of Alaska—over which lies the most extended glacier of America. Twelve of its peaks exceed 10,000 feet in height, while Mounts Saint Elias and Logan rise respectively to 18,024 and 19,540 feet above the sea. The Wrangell group, to the east of Copper River, is an irregular uplift of volcanic formation, which has an area of 12,000 square miles. Eight of its summits rise above 10,000 feet, Mount Blackburn reaching 16,140 feet. The Alaskan Range, the southern boundary of the Yukon Basin, extends in an unbroken chain about 200 miles from the Canadian border to the Alaskan Peninsula. Its crest line exceeds an average of 8,000 feet with peaks of 10,000, among which is Mount McKinley with an elevation of 20,464 feet—the highest peak of America. South of this range are the less important Chugach Mountains. Finally the Aleutian volcanic range forms the backbone of the Alaskan Peninsula. Among these peaks, and the continuation of the range through the Aleutian Isles, are the active volcanoes of Alaska, perhaps the most remarkable group in the world, Akutan, Bogoslof, Grewingk, Katmai, Korovin, Pavlof, Redoubt, Shishaldin, etc. The eruption of Katmai in 1912 is the most violent volcanic outburst known in the history of the Alaskan mainland. On the Aleutian Chain the existence of 48 volcanic craters on 25 islands indicates the frequency and violence of such disturbances in past ages.

Glaciers.—The most extensive remnants of the ice-age in North America are those found in Alaska. Along the coast from Portland Canal north and west to the Alaskan Peninsula, the mountains face an area covered with perpetual snow, from which project huge glaciers, increasing in size and in frequency as one goes north. Though the least extensive of the glacial formations, the tourist-visited glaciers of southeastern Alaska are the most widely known. Noteworthy among them are the numerous ice-streams of Sumdum Bay and Taku Inlet, the 40 or more dead glaciers of Lynn Canal and the enormous accumulations in Glacier Bay, where the Muir glacier has a surface of about three miles in width and 600 feet in height. Much vaster, however, are the névés which cover the coastal mountains from Glacier Bay northwestward to Kenai Peninsula, as on these shores are to be seen ninetenths of the permanent ice-fields of America. Of the 31 live glaciers (those which reach the sea) no less than 25 are in these regions—three in the Saint Elias group, 11 in Prince William Sound, and 11 in the Fairweather region. Prince William Sound is especially notable for its ice phenomena, since in Harrison and College fords there are 11 live ice-rivers, the largest being Columbia glacier with a front about four miles wide, and 300 feet or more high. The greatest ice mass, however, is the Malaspina glacier, which rests on the southern flank of Mount Saint Elia as a seaward flowing ice-mass of some 1,200 square miles in area. Separated from the ocean for a score of miles by a forested moraine about five miles wide, it finally reaches the open sea at Icy Cape. There must be at least 400 glaciers in Alaska, as more than 250 have been visited, definitely located and considered important enough to be named.

Climate.—Owing to its great range of latitude, from 54° 30′ to 72° N., it is difficult to briefly describe the various climates of this vast territory. From Portland Canal northward to the Alaska Peninsula the coast type prevails; much cloudiness, heavy rainfall and equable temperature through warm winters; and cold summers; of which Sitka and Valdez are representative. June through July are the months of average temperature and yearly rainfall (including melted snow) as follows: Sitka, February, 33°, August, 57°, rainfall 112 inches; Valdez, January, 20°, July 51°,
rainfall 73 inches. The Bering Sea coast, little affected by the ocean temperatures, has smaller rainfall and increased range of temperature, as shown by Saint Michael, February, 2°, July, 54°, rainfall 15 inches. The interior regions have a continental type of climate, with very cold winters, warm summers and also light rainfall. The following are typical: Copper Center, January, 14°, July, 55°, rainfall 9.3 inches; Ft. Gibbon, January, 18°, July 59° rainfall, 12 inches. The climatic conditions of the Aleutian archipelago are of the insular type, at times appearing as a desert climate in winter. The Aleutian Islands, 20°, July, 50°, rainfall 109 inches. Point Barrow is typical of the entire Arctic coast, with its polar climate modified by the adjacent sea, January, 21°, July, 39°, rainfall 6.6 inches. It may be added that the heaviest rainfalls occur along the southern coasts during October, in the interior during July, on the Arctic coast during August and in the Aleutian Isles during January.

**Fauna and Flora.**—The species of animals, birds, fishes, etc., are varied and numerous. The Harriman expedition collected along the coast more than 1,000 species of insects. More than 150 kinds of plants are known and nearly 50 different fishes and over 200 habitant birds. Over 471 species of birds from the Yukon River region alone. At sea the more important species are the fur-seal, sea-otter, hair seal, walrus and whale. On land are found five kinds of bear and six of foxes. Other animals of economic value are the beaver, caribou, ermine, goat, hare, lynx, martin, mink, moose, otter, reindeer, sheep, squirrel, wolf and wolverine.

**Commerce.**—The entire volume of traffic shipments in and out of Alaska for the fiscal year ending 30 June 1916, amounted to $97,646,430, including copper, gold and silver. The shipments increased enormously in value for the fiscal year ending 30 June 1917, the aggregate being $121,265,947. Articles to the value of a million dollars or more were shipped into the Territory as follows: Breads, $19,283,218; copper manufactures, $1,530,197; explosives, $1,278,026; machinery, $3,932,189; other iron and steel, $6,209,227; meat and dairy products, $3,493,676; oils, $1,385,186; tin manufactures, $3,162,165; wood manufactures, $1,822,549. The comparative shipments out of Alaska for the years 1916 and 1917 of the most valuable articles were: Furs and fur-skins, 1915, $588,035; 1917, $711,550; fish, $19,629,431, and $23,833,662; copper, $26,488,288 and $33,058,150; gold ores, etc., domestic $16,195,635 and $15,409,529. The salmon industry has increased greatly from shipments of $17,590,317 in 1915 to $21,195,612 in 1917, and will be very materially increased for the fiscal year 1917-18. The most phenomenal growth has been in the shipments of copper ore, etc., which has risen in value from $5,182,004 in 1915 to $26,488,288 in 1916 and $33,058,150 in 1917. The increase in pounds has been from 35,994,812 to 117,338,937, and finally 120,637,707 pounds in 1916 and 1917.

**Commercial Development. Fur-Seals.**—Three products have in turn dominated the commercial interests of Alaska—furs, fish and gold. Copper now forges to the front, while coal looms up in the near future. The development of these industries will be separately considered. In the minds of the multitude Alaska was for many years associated only with the furs of the otary or eared-seal. The breeding grounds of these mammals are almost exclusively confined to the Pribilofs—four isolated, barren islets in the middle of Bering Sea, of some three miles in circumference. At a distance 200 miles from the Aleutian Isles, the Alaskan mainland and the Nome region. Set apart as a reserve by Congress in 1868, the Pribilofs were leased from 1870 to 1890 to the Alaska Commercial Company, with authority to kill furs. In 1889 the Pribilofs were leased to 1889 inclusive the company took 197,273 pelts, valued at $29,473,050. The maximum productivity, including seals killed outside of the Pribilofs, was in the two years, 1888 and 1889, when 272,568 pelts were taken at $4,333,809. In 1890 the concession passed to the Northern Commercial Company with the right to take 40,000 pelts annually. As early as 1885 pelagic or open-sea sealing by various nations in the waters adjacent to the Pribilofs, seriously affected the fisheries. In 1885 363,000, killed outside of the Pribilof reserve. The annual means of 136,000 pelts taken (1888-89) fell to less than 20,900 for the five years ending 1908. The Paris convention for the correction of the evil proved to be of little value. In 1911 the governments of Great Britain, Japan, Russia and the United States agreed to a convention which promises to restore the seal herd to large proportions. Until 1926 pelagic sealing is prohibited in the seas of Bering, Japan, Kamchatka, Okhotsk and to the north of the 30th parallel of latitude in the Pacific Ocean. Aborigines living on the coasts of these regions are permitted to take native-fashion such seals as are needed for local use. Under the convention the products obtained by sealing on the islands are to be equitably divided between the countries named, and during close seasons an indemnity must be paid by the United States to Great Britain and Japan. By the Act of 24 Aug. 1912, Congress established a close season for five years, with a proviso that resident natives may kill such seals as are necessary for food, clothing and boat-making. Under such conditions the product of fur-seals cannot average much over $300,000 annually. In round numbers the annual reproductive numbers from 1868 to 1915 inclusive have a value of $65,000,000, the fur-seal products amounting to about $51,000,000. The beneficial effects of the closed season at the Pribilofs are already apparent. The seals were enumerated at the rookeries with the following results: 1912, 215,738; 1913, 268,305; 1914, 294,687; 1915, 363,822; and 1916, 417,281. With the same rate of increase the seal herds should number about 550,000 when the open season begins in 1918. Land Furs.—In comparison with the sea furs those obtained from land mammals are of minor importance, though considerable in value. The value of land furs by decades are as follows: 1871-80, $1,596,494; 1881-90, $2,360,115; 1891-1900, $2,335,967; 1901-1910, $2,381,925. The aggregate values to include 1915 amount to $11,518,188. The enormous slaughter of land animals threatened at one time the destruction of the industry, as in 1899 the product was only $45,725. Under restrictions as to close seasons, prime skins, use of
poison, etc., the trade has very much improved and the maximum year of products was 1914, $632,063. The furs taken in 1914 were as follows: Ermine, 6,893; red fox, 14,967; white fox, 6,530; lynx, 6,530; marten, 6,467; mink, 6,623; muskrat, 11,202; and others, 1,008. In October 1915 the United States sold to auction 513 blue-fox skins at an average of $114.45, an advance of $72 over the last sale. Selected lots ran from $245 to $273 per pelt. The white fox pelts averaged $24.55. The value remained materially unchanged. In 1916 and 1917 a novel industry was introduced about 1894, the breeding of foxes. Thirty or more uninhabited islands, principally situated from Prince William Sound westward to the Fox Islands, have been leased by the United States to the breeders. Few of these enterprises have resulted in returns adequate for the labor and capital therein involved.

Fisheries.—With the marked decrease in the fur products—from $3,054,414 in 1888 to $2,591,755 in 1897 during the same period from $1,447,478 to $2,856,742 annually, thus making it temporarily of primary importance in Alaskan trade. To include 1916 the product of Alaskan fisheries aggregates 4,200,000, figures, $250,000,000. Of this amount $20,000,000 came from cod, herring, halibut, etc., in contradistinction to the far more productive of all branches—the salmon industry. From 1888 to 1880 the average output of all fisheries was about $170,000. The following decade saw the product quintupled, the income from 1888-90 averaging $850,000 annually—almost half the value of the furs—of which nine-tenths were derived from the salmon. The subsequent growth in the salmon industry has been constant and astonishing. The average annual values in periods of five years are as follows: 1891-95, $2,100,000; 1896-1900, $3,400,000; 1901-05, $6,700,000; 1906-10, $11,000,000; and 1911-15, $16,900,000. Except for one year (1913) the increase has been uninterrupted from 1906 to 1915. The maximum productivity for this period was 1914, $19,474,393, followed closely by 1915 with values of $19,053,905. The output is again steadily increasing, the values for 1916 for canners and packers were $25,869,929, with a reasonable probability that this sum will be very largely increased in 1917. Although temporarily surpassed by the gold output, the salmon is now the most valuable single product of Alaska, and affects industrially the maximum number of persons. The plants are elaborate, including at least 100 canneries, and five hatcheries. The entire fisheries give employment to about 22,000 persons, of whom some 4,000 are natives. The entire investments exceed $37,000,008, of which the salmon industry alone amounts to $35,000,000.

Mineral Resources. Gold.—In 1880 Alaska began gold mining, but the yearly product was not considered of importance until it passed the million-dollar mark for 1892. The deposits are in Alaska, and as shown by the average annual output for decades: 1881-90, $462,000; 1891-1900, $2,821,000; 1901-10, $14,572,000, and for the five years ending with 1915, $16,418,485. The total products to include 1915 aggregate $200,958,943, divided by districts as follows: Pacific Coast belt, $60,500,000; Copper River, $135,000; Inoko, $190,000; Koyukuk, $300,000; Seward Peninsula and Northwestern Alaska, $71,562,700. The mining operations of 1916 added to these figures a value of $11,140,000 in placer gold and $5,912,736 from the lode mines, a total value for the year of $17,052,736.

Of the total yield of gold in Alaska, 72 per cent is obtained from placers, 27.6 per cent from lode-mines, and 0.4 per cent from copper ores. Juneau is the most important of the lode-mining centres, although some lode-mines are in operation at Fairbanks, and in the Assokokwim and Nome districts. In the season of 1916, 42 dredges were operating in the streams of Alaska, 37 of these being in the waters of the Seward Peninsula. These great machines recovered 94 per cent of the entire value won from Alaska’s gold placers, the output of the small workings reaching little above $600,000. The Territory of Alaska, as regards its mining interests, is classified as follows: (1) The Pacific Coast Belt includes all mines in southeastern Alaska and the districts of Juneau and Berner Bay regions. Far greatest in productivity are the quartz mines of Juneau, where the famous Treadwell lode mines on Douglas Island, the largest gold mines in the world, with their plant of stampers, workshops, etc., have produced nine-tenths of the gold of the Pacific belt. The yield of its three largest mines in 1905 exceeded $2,000,000, and in 1908 was $3,000,000, and in 1916 attained an output of $4,500,000. Second in importance are the quartz mines on the mainland near Juneau. In 1916 there were 13 lode mines producing ore, and the output was $5,912,736, an almost uninterrupted yearly increase from 1897. The average of the past five years exceeds $5,500,000 annually. (2) The Copper River district has averaged an output of $300,000, which has increased for the past five years to $450,000, with its maximum of $605,590 in 1915. (3) The Yukon Basin has produced a larger amount of gold than any other Alaskan district. Of surpassing importance were the placer diggings of the Tanana watershed, where the Fairbanks yield of $350,000 in 1904 rose to $3,750,000 in 1905, and then gradually to $2,000,000 in 1908. The maximum for the Yukon Basin was $1,450,000 in 1906, at which time, despite the discovery of new placers in the basins of the Innoko and upper Kuskokwim, the production has fallen very gradually to $7,367,776 in 1915, of which more than $300,000 came from lode-mines. (4) The Seward Peninsula is better known to the public as the Nome region. This district sprang into fame when the unimportant output of $75,000 in 1898 rose to $2,800,000 in 1899. The yearly output reached a maximum of $7,500,000 in 1906; after that it decreased steadily to $2,535,000 in 1913, but is again tending upward, the product of 1915 being $2,920,000. The gold production from 1901 to 1907 amounted to $37,000,000, the Nome district yielding about $28,000,000. Thirty-six deep mines were operated in 1915 in the Nome district, whose average annual output for decades was about $1,500,000, while some $700,000 came from the Council district. (5) Among smaller isolated districts the most promising for future increases with their outputs in 1915 are: Tolovana, 50 miles northwest of Fairbanks, $60,000; Kuskokwim, $110,000; Chisana, $135,000; Inoko, $190,000; Koyukuk, $300,000;
Hot Springs, $550,000, and Iditarod, more than $2,000,000. These are placer mines, in which some steam dredges are at work.

Silver.—The silver production of Alaska in 1916 was the highest on record, at 1,391,291 ounces, Wilksdorff, valued at $907,554. About nine-tenths of this was secured incidentally in the mining of copper, the amount being not far from 1,200,000 ounces. The remainder was gained in the mining of gold. An undeveloped source of silver in Alaska exists in the 1,391,291 ounces of argentiferous galena, which up to 1916 were still lying idle. Since 1880, including the output of 1916, Alaska has yielded a grand total of 6,302,459 ounces of silver, valued at $3,729,465.

Copper.—While gold has for 20 years shown the largest value among the mineral products of Alaska, it bids fair to be surpassed in importance by copper in the immediate future. For a few years prior to 1903 copper was profitably mined, to the value of about $200,000 annually, in the Ketchikan district on Prince of Wales Island. The number of working mines reached 10 in 1906 with an output of $920,000. Later rich veins were discovered on the adjacent Kasaan Peninsula, where more than 30 mines were opened. Very rich deposits of sulphide copper ore were discovered scattered over the country from the Saint Elias region to Cook Inlet. Rich and easily worked veins were found on the eastern shores, and adjacent islands, of Prince William Sound. The richest and most productive deposits are those in the watershed of the Chitina, on the southern flank of the Wrangel Mountains, where there are several mines and scores of prospecive drifts. These deposits were so extensive and valuable that the Copper River and Northwestern Railway, 197 miles long, was built to transport the ores of the Bonanza copper mines from the northeastern terminus at Kennicott. In connection with the Bonanza, Jumbo and Mother Lode mines there have been installed tramsways, concentrators, etc., for handling the immense quantities of ore produced. The production of 1914 was great, but it was quadrupled in 1915, in which year the product was 40 per cent of the grand total mined in Alaska from the beginning. From 13 mines, 1,391,291 ounces of copper were discovered, including the 139 tons gained in 1916, has been 767 tons. Most of this has been obtained incidentally by dredges operating for gold in the stream beds. Two lode mines are in operation in the York district, with a small annual output. There are a number of known tin-bearing placers in York district, and stream tin is widely distributed throughout the Hot Springs district, but few miners make any attempt to save it. The York tin mining is carried on only through the summer season, and the Hot Springs placers can be worked only about three months.

Tungsten, in its ore scheelite, has been for a considerable period recognized in the gold placers of Fairbanks, Iditarod and Nome. In 1915 a scheelite-bearing lode was opened near Fairbanks, and in 1916 others were located and opened in that vicinity and also near Nome. Most of the dredges in the Nome and Iditarod districts separate the scheelite from their concentrates. But scheelite has been found in some of the gold placers of the York district, and wolframite has also been found in some of the gold placers of the Yukon-Tanana region. In 1916 the total output of tungsten ore in Alaska was 4,070 tons.

Platinum began to attract the attention of the Alaskan placer miners in 1916, and 10 or 12 ounces were recovered, most of it in the newly developed Koyuk district, in the southeastern part of Seward Peninsula and in the Slate Creek placer in the upper Copper River Basin. Platinum has also been reported as in considerable quantity in the gold-bearing gravels of the Kahlita River, and in the beach placers of Lituya Bay and of Red River, Kodiak Island.

Quicksilver occurs as cinnabar in lodes in the lower Kuskokwim region, and in nearby localities in the Yukon Basin. The extent of the deposits has not yet (1917) been defined.

Nickel and cobalt have been found in a copper-bearing lode near Pinta Cove, on the west side of Chicagoof Island, in the Sitka district. There are deposits of molybdenite at several
points in southeastern Alaska, and in the Willow Creek district, but no attempt to develop them had been made up to the close of 1916. A bismuth-bearing vein occurs on Charley Creek in the Nome district, and this metal is also found in connection with gold at two points in the Tanana valley. No output was reported for 1916.

Coal.—Coal occurs in Alaska in many widely separated sections, and in many grades, ranging from a fair quality of anthracite to lignite. Much of the larger part of the coal area is remote from transportation lines as to be available only for local uses. The only area at present accessible is the Matanuska field, yielding high grade steam and coking coals, and low grade bituminous coal. This field is reached by the Matanuska Branch of the government railroad. The Bering River field, yielding high grade steam and smelting coal, and perhaps coking coal, with some anthracite, can be made accessible by the completion of the rail- road now under construction, and its extension into the central and western parts of this field, where the best coal is found. The Cook Inlet field lies practically at tidewater, but yields only lignite.

Notwithstanding the extensive areas of its coal-fields, the amount mined in Alaska has been insignificant, amounting to less than 50,000 tons. The withdrawal of coal-lands from public entry in 1907 ended all mining, but legislation in 1914 provided for utilization of the coal. Over 1,200 square miles of area have been determined by survey to be coal-fields, while there are good reasons for the belief that 11,400 other square miles are underlaid by coal-bearing rocks. About 58 per cent of the known fields are of lignite, while 7 per cent are high-grade coal—there being 26 square miles of anthracite, 7 of semi-anthracite and 50 of semi-bituminous. No considerable area of high-grade coal has been found outside of the fields in the basins of the Bering and the Matanuska Rivers. By far the greater amount is in the Bering River field—22 square miles of anthracite and 28 square miles of semi-anthracite and semi-bituminous. The coals vary from 84 per cent of fixed carbon in the anthracite to 74 per cent in the bituminous. Workable Bering beds are known from 3 to 25 feet in thickness. In the Matanuska field of 46 square miles the seams vary from 3 to 50 feet in thick- ness. The estimates for these two fields indicate the presence of at least 3,554,390 tons of high-grade coal, which estimates will doubt- less be largely increased when detailed surveys are made. Bituminous coal exists in large quantities in the Alaska Peninsula. Throughout the Yukon Basin coal is widely distributed, the principal fields being the Nulato (the best coal), the Washington (upper Yukon), and the very extensive Nenana lignite coals, where 66 square miles are covered by veins from 500 to 1,800 feet in thickness at many points. Three fields are known on the Arctic coast — Cape Lisburne, Wainwright Inlet and the Colville Basin. Under the Act of 16 July 1914, the Alaskan coal lands were opened for public use. The act empowers the President to reserve for governmental purposes coal-bearing lands not exceeding 3,120 acres in the Bering River Basin, 7,560 acres in the Matanuska field and one-half of the other coal-fields. Unreserved coal lands are to be divided into blocks of 40 acres, and no combined blocks exceeding 2,560 acres in the aggregate shall pass under any one control, the leases to run for 50 years only. Limitations are imposed on aliens, corporate settlers, railroads and other common carriers. Royalties of not less than two cents per ton are to be levied, while annual rentals rising from 25 cents per acre for the first year to $1 in the sixth and succeeding years are provided for. The royalties and rentals are to form funds for the construction of railways and for other public utilities in Alaska. Leases must contain pro- visions for an eight-hour day as well as other welfare restrictions in favor of the miners. For strictly local or for domestic use permits may be granted covering the mining for 10 years, without royalties, of areas not exceeding 10 acres. No less than 47,742 tons of coal were imported by Alaskans during the fiscal year 1917, which indicates the inadequacy of the coal law of 1914. See COAL LANDS.

Agriculture.—The United States has fos- tered agricultural interests through four experimental stations: Sitka, nursery, etc.; Kodiak, dairy, etc.; Rampart, grain; and Fairbanks, farm demonstration. Despite much effort agri- culture is only successful near large settlements and to a moderate degree. The growing sea- son of six months on the southern islands drops to four in the interior valleys. The most im- portant products are vegetables on favored grounds in the valleys of the Susitna, Koyukuk, Copper River, and especially the Tanana. The reduced importations of vegetables, despite large increase of population, indicates the in- creasing volumes of these products. The values of all vegetable shipments into Alaska aggregated $790,000 in 1906, but was only $522,000 in 1915; imported hay fell from 16,044 tons in 1913 to 8,780 in 1917.

Manufactures.—Apart from the canneries the manufacturing establishments of Alaska are few. The census of 1910 reported the fol- lowing additional: 22 with 178 persons engaged in lumber products; 16 with 89 persons in printing and 68 with 250 persons in miscel- lanceous work.

Forests.—The forestal resources have been conserved by congressional legislation. Originally about 40 per cent of the Territory was wooded, of which the coastal woodlands are now protected. The Chugach forest, over 800 square miles in area, includes most of the valu- able timber in the neighborhood of Prince William Sound and on the adjacent island of Afognak. Some considerable areas in this forest have spruce and hemlock ranging from 20,000 to 50,000 feet per acre. The Tongass forest, with an area of 100 square miles, brings under national control the timber of the Sitkan Archipelago and the adjoining mainland. The timber is heavier and more valuable than elsewhere. It consists of Sitka spruce, western hemlock, western red cedar and yellow cypress. The exportation of timber from the Territory is forbidden. Wood that is not needed is free to all living on or near the national for- ests, as is the timber needed by prospectors while developing their claims. Nearly 40,000,000 feet of timber were sold from the national for- ests in 1915, which returned a net revenue of $7,265. While the woodlands of the interior are inferior in quality, consisting mainly of
small cottonwood, birch and spruce, yet they are of great economic importance in the mining districts where they are indispensable for the easy working of the frozen placers, which are thawiag for exploitation. See FORESTRY IN THE UNITED STATES.

Game.—Alaska is the only part of the United States where large game is yet to be found in quantities. Under the provisions of the act of 11 May 1906, game has been conserved through closed seasons, hunting and shipping licenses, and the system of licensed guides. During the breeding seasons the law protects caribou, deer, goats, bears, sheep, sea-lions, walrus and game birds. Hunting is free to residents, but non-residents must obtain licenses from the Secretary of Agriculture, ranging from $50 to $150. While game can be killed for necessary food it cannot be shipped out of the Territory. Licensed hunters are permitted to kill not more than one walrus or seal, two moose, three bears, caribou, deer or sheep, and not more than 25 birds on any single day. Special permits are granted for scientific purposes.

Reindeer.—As far as the natives are concerned, reindeer-raisinig is the most important of the indigenous industries. It has gradually transformed large numbers of natives from wandering hunters into domesticated stock herders. In general the reindeer herds are scattered through the tundra of the coast regions of Bering Sea, of the valleys of the lower Yukon and Kuskokwim, along the Arctic coast from Kotzebue Sound to Point Barrow, and on a few of the outlying islands. The deer are widely and systematically distributed to the natives under definite regulations, which foster the spirit of personal ownership and inculcate skilled methods of herding. Young natives, trained as herders by an apprenticeship of four years, ultimately receive from 24 to 29 deer as the nucleus of a personal herd. On 30 June 1914, there were 57,872 reindeer, herded at 65 separate points, these no less than 37,828 deer were owned by 980 natives, whose income for the year amounted to $77,934, exclusive of domestic uses. The missions and the Lapp settlers owned 15,931 head. In 1916, the herd had increased to 82,151, and by 1918 will undoubtedly exceed 100,000. Female deer can be sold only to natives and within the Territory. Male deer can be slaughtered, when over four years old, not exceeding 2 per cent of any herd. Experiments have been made and plans are in progress for the exploitation of reindeer meat commercially, and it is thought that shipments will soon attain such proportions as to be a factor in the meat supply of the entire Pacific coast.

Reservations.—Many reservations have been made by the United States in the interests of conservation and for public utilities. The army, the navy, the fishery and the lighthouse bureaus have thus been insured proper facilities for administration, free from unauthorized interferences. Mentioned are the Chugach and Tongass forests, the Pribilof fur-seal islands and nine for native villages. Others of importance are a sea-otter reserve on Afognak Island, a reindeer station on Saint Lawrence Island, a moose reserve on Fire Island. General and very extended reservation is that of the Aleutian Archipelago, for the development of fisheries, the propagation of reindeer and for the protection of birds and fur-bearing animals. Special bird-reservations are the Bering Sea, the islands of Bogoslof, Chamisso, Forrester, Hazy, Saint Lazaria, Tuzedini and the great delta of the Yukon, the last named being a favorite breeding region for ducks and geese. The fox-farming islands are not reservations, although leased for exclusive use.

Transportation.—In summer transportation in the interior of Alaska is largely by boats on the great rivers. The principal streams are the Yukon, with its important tributaries, the Porcupine, Koyukuk and especially the Tanana, Copper, Kuskokwim, Susitna, Yentna and Kobuk. They are all navigable for steamboats from 100 miles upward. The Yukon, 1,865 miles in length, is the fifth river in size of North America. The Tanana, besides 750 miles of navigable waters, has tributaries also navigable—the Chena, Kantishna, Tolovana and Volkman Charles Bar. For this route at Copper City, from the mouth of the Tanana, may be called the centre of river transportation. From that point boats ply to and from Dawson, from the end of May to 1 October; Fairbanks from the same point to Tanana, except for the middle of June to 1 October. Occasional boats navigate the Koyukuk and the Kuskokwim. Skagway and the Prince William Sound country are reached weekly by steamer from Seattle throughout the year, and Nome from early June to October. The railroads (see Railroads) are almost entirely operated in connection with mines. Land travel has been greatly facilitated by the labors of the Army Roads Commission. Under its administration there have been built to 30 June 1916, 3,759 miles of wagon roads, sled roads, pack-trails and winter trails. A stage route is operated throughout the year from Valdez to Fairbanks, about 375 miles; stages from Chitina on the Copper River Railroad connect with this route at Copper City. From Fairbanks there are sled roads (for winter travel) to Ft. Gibbon and Circle on the Yukon. Pack-trails extend westward from Gibbon to Nome and eastward to the Canadian border. The northern route, northward within the Arctic circle to Candle on Kotzebue Sound, Coldfoot on the Koyukuk, Ft. Yukon on the Yukon and Barrow on the Arctic Ocean.

Railroads.—Practically all the railroads of Alaska have been constructed as adjuncts to mining enterprises. They aggregate 466 miles in length, as follows: White Pass and Yukon, from Skagway, 205 miles; Yakutat Southern, between Minio and Situk bays, 9; Tanana Valley, from Fairbanks, 46; Council City, from Solomon, 32.5; Golovin Bay, from Cordova to Kennicott, 195; Alaskan Northern, from Seward, 72 miles. Conditions of taxation and the necessity of the bodies of these roads were 1913, and in the year only 261 miles of these roads were operated. The necessity of additional railroads for the development of the Territory was so evident that Congress authorized such a system at public cost. Public Act 69, 12 March 1914, empowered the President to locate, construct and operate railroads in Alaska, at a cost not to
exceed $35,000,000. After surveys and studies by a commission, the President approved of what is known as the Susitna route, a line from Seward to anchorage running through the Tanana River, about 471 miles in length, with a branch line of 38 miles to the Matanuska coal fields. The route is from Seward to the head of Turnagain Arm to Knik Arm, up the drainage valley of the Susitna and Chulitna rivers, over Broad Pass, and down the valley of the Nenana River to the Tanana valley. In order to develop as early as possible the Matanuska coal fields, work was begun on Knik Arm, where a town site was surveyed and settlement made. It is known as Anchorage, is connected with the main line by a branch of five miles, and will be the shipping point save for four months in the winter when Knik Arm is usually frozen. During the remainder of the year freight and passengers will necessarily be handled to and from Seward, with which the Matanuska section will soon be connected by rail. During 1914 about 70 miles of the Alaskan Northern Railway were rebuilt, and about 30 miles of the Matanuska section graded and bridged. The line from Anchorage to the Chugach coal, and the Matanuska coal field is now connected by rail with Seward. Construction has so far progressed that there are now being operated about 75 miles of new line, 65 miles of which is located north of Anchorage. Some of the heaviest work on the line is found between Anchorage and Kern Creek, on account of it being necessary to bench in the line on precipitous cliffs in that locality. It is estimated that the 50 miles of line from Seward to Fairbanks can be built for $27,000,000, exclusive of the $1,150,000 paid for the Alaskan Northern. Passenger service has been fixed temporarily at 12.5 cents per mile, while the freight rate for 35 miles operated is 1.25 cents per pound. Timber for construction purposes will be taken free from the Chugach forest, while local needs will be met from the timber reservation made by executive order, five miles wide on each side of the railway route from Turnagain Arm to Chichakoon to and Fairbanks.

Twentieth Century Telephone.—Ninety per cent of the towns and mining camps of Alaska, even to Kotzebue Sound, can be reached readily from any part of the world. The Signal Corps of the Army constructed, and now operates, a system of more than 4,000 miles of cable, wireless and land lines, which connects Seattle, via Sitka and Valdez, with Nome to the extreme north-east, Circle City to the central north, and along the immediate southern coast to Skagway. These lines are open to commercial use, and transact a business of the volume that the tariffs approach $225,000 annually. Private companies operate a telephone system, which from the centre at Nome reach Candle and other stations on Seward Peninsula. Similarly the mining camps of the Fairbanks district are connected with Fairbanks. The United States Navy operates radio stations at Cordova, Dutch Harbor, Saint George, Saint Paul Island and Sitka.

Education.—The whites and the natives are educated at schools supported by local and the latter at Federal expense. In 1915 schools for the white children were maintained in 14 incorporated towns and in 31 other settlements, with a force of 105 teachers and 2,503 children. Under acts of Congress the education of the Eskimo and Indians is conducted under the direction of the Secretary of the Interior, the expenses of the system being met by appropriations. In 1915 such appropriation amounted to $200,000, from which were maintained 71 schools with 106 teachers. There were 3,666 pupils enrolled, while the average attendance was 1,991. The instruction is along thoroughly practical lines, and covers the moral, physical and mental training of both adults and children. Elementary English subjects, domestic science, industrial handicrafts, personal hygiene and village sanitation are the principal subjects. Nearly three-fourths of the native children between 10 and 14 years of age can read and write English. The teachers are debarred from trade. Besides their school work they aid in the reindeer service, and actively engage in the care of the sick and distressed, distributing food and clothing to the absolutely destitute and affording hospital care. In the special hospitals at Kankanuk, Kotzebue and Nulato is employed part of the force of doctors and nurses. Contract hospital service is also had through hospitals at Candle, Juneau, Nome, Seattle and Valdez.

Missions.—The Presbyterians began missionary work in 1877, and though the establishment of independent churches in the larger towns has materially modified the needs, they yet maintain three missions, as well as the hospital at Haines and the training school at Sitka. The Baptists, Congregationalists, Friends, Lutherans, Moravians and Methodists have contributed largely to religious training in Alaska. The Catholics have labored assiduously and successfully, especially in the Yukon Valley at Nulato and Holy Cross; the latter is a station monumental for its success in agriculture, stock-raising, and industrial training. The Greek Church has gone its own way with the natives near their stations. Although the Episcopalian entered the field late they have pursued their work to a greater extent than any other denomination. About $50,000 are spent annually on their 24 missions, and four hospitals, those at Fairbanks, Iditarod, Ketchikan and Valdez.

Natives.—The Indian population of Alaska has fallen from 29,336 in 1900 to 25,331 in 1910, and was estimated to be about 24,000 in 1915. As far as their racial distribution was determined in 1910 they were divided as follows: Aleuts, 1,491; Athabascans, 3,916; Eskimo, 12,652; Haidas, 530; Tlingits, 4,458; and Tsimshians, 729. The Aleuts occupy the Aleutian Archipelago, where they barely maintain life by fishing. The few Haidas live in the Ketchikan region, being offshoots from the tribe on Queen Charlotte Islands. The Tsimshians, generally known as the Metlakatlas, are for the most part living in community on the reservation of Annette Island, granted them by Congress; they are industrious, temperate and thriving. The Tlingits are the natives living principally in the Sitkan Archipelago, and along the coast northward to the Saint Elias region. Known to tourists through their totems and other objects, they have gradually abandoned old ways, many being employed in mines, fishing, etc. Living in the interior of the country, in the valleys of the Copper, Kuskokwim, Tanana and Yukon, the
Athabascans are rapidly disappearing. Both game and fish are scarce, and regular labor in mining has drawn up a large number of Indians under mission control. The Eskimo are a coastal people, whose habitat extends from the Canadian border of the Arctic shore westward to Cape Barrow, thence south and easterly along Bering Sea and the Alaskan Peninsula to Columbia Island. Only about one-fifth live on the shores of the Polar Sea. About two-fifths occupy permanently the hunting and fishing grounds between Bristol Bay and Norton Sound, where game is abundant in some form summer and winter. The education and care of the natives are treated under the head of Education and Missions. Their conditions have materially improved during the past few years, as far as selected communities are concerned. The United States has set apart certain reservations, thus freeing them from obtrusive and demoralizing surroundings: Annette Island, Saint Lawrence Island, Hydaburg, Klawock, Klukwan, Port Gravina, Long Bay, Ft. Yukon, and on Kotuk River. The Territorial legislature has enacted laws granting citizenship, and establishing separate self-governing towns to Indians under certain restrictions. Co-operative stores have been conducted with success by natives at Hydaburg, Atka, Klawock and Saint Lawrence Island, and are being organized elsewhere. Efforts, so far unavailing, have been made to induce Congress to bring about the betterment of the 5,000 Eskimo in the Yukon delta through the abolition of the liquor traffic and the development of industrial training. In 1915-16, however, an appropriation of $25,000 was made by Congress for the relief of natives, supplementary to the funds used in education.

Government.—Alaskan government is that of a modified territorial form. Appointed by the President, the governor has strictly limited powers. The territorial legislature, consisting of eight senators and 16 representatives, meets biennially in Juneau, the capital. Its acts are subject to veto by the governor, and only have the force of law when approved by Congress. The course of justice, administered through territorial courts, is carried out by the governor. The courts are supplemented by commissioners whose powers are restricted to cases involving values of not more than $1,000, and to crimes whose punishment does not exceed imprisonment for one year. The fisheries, forests, fur seal, game and largely the natives are under Federal control, so that local administration is complicated, uncertain and not always efficient.

Population.—According to the census of 1910 the population then numbered 63,700, of whom about 36,000 were white. The government officially estimates the white population in 1915 at 44,000. The incorporated towns and their population in 1910 were: Fairbanks, 3,541; Nome, 2,600; Douglas, 1,722; Juneau, 1,044; Cordova, 1,152; Skagway, 872; Valdez, 810; Wrangell, 743; Petersburg, 385; Seward, 534; Haines, 445; Tanana, 398; Eagle, 178 and Chena, 138. The new railway town of Anchorage, founded at the head of Cook Inlet in 1915, is estimated to have a population of 2,500. The largest native town is Metlakahtla, 602; Chinig, 566; Karluk, 549; Sitka, 500; Kodiak, 438; Saint Michael, 415; Ft. Yukon, 331; Unalaklik, 247; Kosefesky, 231; Nulato, 230.

History under Russia.—The discovery of Alaska was due to the enterprise of Peter the Great, who a few days only before his death drew up a decree conferring on the Indians under mission control. The Eskimo are a coastal people, whose habitat extends from the Canadian border of the Arctic shore westward to Cape Barrow, thence south and easterly along Bering Sea and the Alaskan Peninsula to Columbia Island. Only about one-fifth live on the shores of the Polar Sea. About two-fifths occupy permanently the hunting and fishing grounds between Bristol Bay and Norton Sound, where game is abundant in some form summer and winter. The education and care of the natives are treated under the head of Education and Missions. Their conditions have materially improved during the past few years, as far as selected communities are concerned. The United States has set apart certain reservations, thus freeing them from obtrusive and demoralizing surroundings: Annette Island, Saint Lawrence Island, Hydaburg, Klawock, Klukwan, Port Gravina, Long Bay, Ft. Yukon, and on Kotuk River. The Territorial legislature has enacted laws granting citizenship, and establishing separate self-governing towns to Indians under certain restrictions. Co-operative stores have been conducted with success by natives at Hydaburg, Atka, Klawock and Saint Lawrence Island, and are being organized elsewhere. Efforts, so far unavailing, have been made to induce Congress to bring about the betterment of the 5,000 Eskimo in the Yukon delta through the abolition of the liquor traffic and the development of industrial training. In 1915-16, however, an appropriation of $25,000 was made by Congress for the relief of natives, supplementary to the funds used in education.

The new railway town of Anchorage, founded at the head of Cook Inlet in 1915, is estimated to have a population of 2,500. The largest native town is Metlakahtla, 602; Chinig, 566; Karluk, 549; Sitka, 500; Kodiak, 438; Saint Michael, 415; Ft. Yukon, 331; Unalaklik, 247; Kosefesky, 231; Nulato, 230.
and by the act of 24 Aug. 1912; the Territory was accorded a measure of home government by the creation of a territorial legislature. Although for a period of five years, almost, under governmental administration, Alaska has been free from murders and other serious crimes to an extent unsurpassed by any other part of the United States.

ALASKA BOUNDARY. See BOUNDARIES OF THE UNITED STATES.

ALASKA, Explorations in. Under Russia.—In carrying to completion the project of Peter The Great for explorations to the east of Kamchatka, Vitus Bering discovered Alaska in 1741, when he visited the Saint Elias region, while his lieutenant Chirikoff landed at Cross Sound. Incited by reports of fur wealth, enterprising Russian hunters, between 1743 and 1762, discovered and visited the chain of Aleutian islands and the peninsula adjoining. In pursuit of the North-West Passage, James Cook in 1778 followed the greater part of the coasts from the Sitkan Archipelago northward to Icy Cape, Arctic Ocean. Taking possession of the country, the Russian-American Company, 1790 to 1860, established trading posts at many points,—the principal stations being Kodiak, Saint Michaels, Sitka and Unalaska. From these centres desultory and infrequent efforts were made to explore the adjacent regions. The principal journeys were as follows: 1791, Bechereff on the Alaska Peninsula; 1796, Shultz, Lituya Bay and Lynn Canal; 1803, Bazaroff, the delta regions of Copper River; to carry out the orders of the company to explore the country to the north of Cook Inlet, in 1818, Korsakoff crossed overland from the Inlet to Bristol Bay, and thence by ship to the Kuskokwim Bay, and two years later Kalmakoff visited the valley of the lower Kuskokwim River. Ascents up the Yukon River were made by Glazunoff, 1835, to Anvik; by Malakoff, 1838, to Nulato; by Zagloskin, 1843, to Novikakat; while in 1863 Lukeen was the first to make the long journey to Ft. Yukon and return. Along the coasts Vancouver surveyed in 1794 Cook Inlet and the shores thence southward to Chatham Strait; Kotzebue discovered and explored Kotzebue Sound in 1816; while Beechey in search of the Northwest Passage in 1818 reached Elson Point, Barrow by boat. From the Hudson Bay Territory, in 1847, came a factor, Murray, who descended the Porcupine River and near its mouth established and built the trading post Ft. Yukon. In 1826 Franklin explored the Arctic Coast from the Mackenzie River northward to Return Reef, Alaska. In a renewal of the journey in 1837 Thomas Simpson filled in the unknown coast between Return Reef and Point Barrow. Between 1853 and 1865 the Kennicott party, constructing the Western Union telegraph line, surveyed the country overland from Norton Sound to the mouth of the Koyukuk River, and thence along the north bank of the Yukon as far as Ft. Yukon. When Alaska was transferred to the United States in 1867, the mainland was an unknown country except narrow fringes along the coasts, and the immediate banks of the Yukon River.

American Explorations.—The explorations from 1869 to 1898, made entirely by officers of the army, are recorded in ‘Compilation of Narratives of Explorations in Alaska’ (Senate Report 1023, 56th Cong., 1st Sess.). In 1869 Capt. Raymond, corps of engineers, made a reconnaissance of the Yukon River from its mouth to Ft. Yukon. His astronomical observations disclosed the fact that the Hudson Bay station at that point was in American territory, and its removal was demanded. On the 1st of May the weather stations at Saint Paul, Pribilofs and at Saint Michael, the signal corps began research work, which was eventually carried on at 29 stations, until Congress forbade continuance. The most important of the labors of the corps was the maintenance of an international polar station at Point Barrow, 1881–83. Its commander, Lieut. P. Ray, supplemented his scientific work by field explorations, during which he discovered Meade River and the adjacent Endicott Mountains. In 1883 Lieut. P. Schwatka explored the country between Chilkoot Inlet and Ft. Selkirk, B. C. The most important and extensive of any reconnaissance is that of Lieut. H. T. Allen in 1885. Starting from the coast at the mouth of the Copper River, with Corporal Fickett, signal corps, he ascended the Copper Valley, crossed the mountains, descended the Tanana to its mouth, and following the Yukon to the mouth of the Koyukuk ascended that valley overland to the junction of the Kanuti, and then by boat reached the mouth of John River. The journey was one of great danger and privations. Allen's discoveries added some 240,000 square miles of territory hitherto unknown, although under the control of Russia and the United States for a century. The maps of these three rivers were recognized as authoritative for 12 years, when they were revised by the geological survey. The gold discoveries of 1896 stimulated activity in exploration. In 1898–99, Abercrombie explored the country from Prince William Sound to Copper Valley for a military road. Glenn's expedition of 1898 extended from Cook Inlet toward the Tanana Basin, and that of 1899 around Cook Inlet. Burnett and Mitchell, signal corps, explored the regions of
the upper Copper and upper Tanana for telegraph routes in 1902-03. The explorations of the basins of the Noatak and Kobuk Rivers have been made by the navy, the revenue marine and the geological survey. These unknown tributaries of Kotzebue Sound were first explored by Lieut. G. M. Stoney, U.S.N., who from 1885 to 1886 made extended voyages up those rivers, supplemented by land trips in adjacent regions. Lieutenant Cantwell, revenue marine, further explored in 1884 and 1885 the Kobuk, reaching Walker Lake. Engineer McNegan, revenue service, first visited the Noatak, traversing an extended part of the valley in 1885. Systematic surveys were made by W. C. Mendenhall, geological survey, who explored the country from Ft. Hamlin, on the Yukon, to Kotzebue Sound, traveling in 1901 via the Dall, Kanuti, Koyukuk, Alatna and Kobuk rivers. Ft. Hamlin to Kotzebue Sound (Survey Prof. Paper 19.) The latest explorations, under P. S. Smith, geological survey, in 1910 and 1911, appear in Survey Bulletin 536, "The Noatak-Kobuk Region." By far the most important explorations from an economic standpoint are those made by the United States Geological Survey, whose labors have contributed enormously to the material development and prosperity of Alaska. Working primarily in the interests of mining, the survey covered, from 1898 to 1915, 202,391 square miles of area, divided as follows: Detailed surveys, 3,731 miles; exploratory, 31,680 miles; and reconnaissance, 146,960 miles; thus including in its work one-third of the Territory. The geological surveys aggregated 177,963 square miles. The National Geographic Society's expedition of 1917 under the direction of Dr. Robert F. Griggs, explored the Mount Katmai region, called by the Indians "the valley of ten thousand smokes," and reported the Katmai crater the largest in the world, nine miles in circumference, and 3,600 feet deep. The region has over a thousand active volcanic vents within an area of 100 square miles, and is declared by Dr. Griggs to be one of the wonders of the world.

Bibliography.—Among the many valuable publications of the survey the following cover the more important phases of exploration:
Brooks, "Geography of Alaska" (Prof. Paper 45); "In Northern Alaska Across the Rocky Mountains" (Prof. Paper 20); Brooks, "Mount McKinley Region" (Prof. Paper 70); "The Koyukuk-Chandalar Region" (Bull. 532); Brooks, "Railway Routes to Fairbanks" (Bull. 520). Major-Gen. A. W. Greely.

ALASKAN BOUNDARY COMMISSION, a mixed tribunal which met in London, England, 3 Sept. 1903 to arbitrate on the contents of the Canadian government with regard to a line between Alaska and Canada, from Mount Saint Elias to the Portland Canal. The commission consisted of three Americans and three Britons, the American commissioners being Secretary Root, Senators Lodge and Turner, while the British commissioners were Justice Haldane (formerly Mr. Justice Richard Webster), English, Sir Louis Jetté and Mr. A. B. Aylesworth, Canadians. Ex-Secretary Foster was counsel for the American side and Mr. Clifford Sifton for the British side.

In May 1898 the United States and Great Britain agreed to appoint an Anglo-American Joint High Commission to consider and put on a satisfactory basis the regulations of the North Atlantic fisheries, commercial reciprocity, the Bering Sea fishery question and other disputes which disturbed relations between the United States and Canada. When the questions for the deliberation of this commission were fixed, no mention was made by Great Britain of any divergence of opinion regarding the Alaskan boundary,—but on 1 Aug. 1898 the British government informed the United States that a difference of views existed as to the provisions of the treaty of 1825, which defined the Anglo-Russian boundary. On 23 August Great Britain submitted its claims, enumerated below. It was proposed to arbitrate the matter, but the High Joint Commission could not agree. The United States rejected a European umpire for American territory and the Canadians would not agree to an American judge. The final compromise was the above-mentioned, and

Previous to the discovery of gold in the Yukon region there was no dispute; or occasion for dispute, as to the course of the boundary line defined by the Anglo-Russian treaty of 1825. For 73 years it had been tacitly recognized by all nations, including Great Britain. The history of that treaty is interesting. The government of the Tsar had from time to time by ukase asserted exclusive jurisdiction over the coast lands and the waters of Alaska, to prevent any encroachment by the British Hudson's Bay Company upon the monopoly of the Russian-American Fur Company which had established its stations and carried on its trade in the islands and along the coast of Alaska extending northward from the Portland Canal. Disputes arose, and in the attempt to settle them the negotiations were begun which led to the signing of the treaty of 1825. The purpose of Russia in that negotiation was altogether to shut out Great Britain from the coast and the waters in which the Hudson's Bay Company was carrying on its business. The attempt of Great Britain was to secure a foothold upon the coast with the obvious purpose of getting an opportunity for the Hudson's Bay Company to establish its stations there, which was the very thing Russia sought to prevent. The negotiations lasted from 1822 to 1825, Count Nesselrode and M. de Poletica conducting the Russian case, and Sir Charles Bagot first and Lord Stratford de Redcliffe finally, the British case. At that time Great Britain feared that the United States would insist upon retaining possession of the whole Oregon territory up to the Russian line at the historic parallel of 50° 40'. This would have shut off Canada from the Pacific coast entirely, and the British, therefore, made strenuous efforts to get an outlet through the American coast strip, making various propositions, one after the other which the Russians rejected, stubbornly adhering to their original proposition, which in the end prevailed.

The British first asked to have the boundary line drawn straight down the 141st meridian to the sea at Mount Saint Elias, thus depriving Russia of the entire panhandle of Alaska, and
causing her even to relinquish Sitka, the colonial capital. This was peremptorily rejected by Russia without serious consideration.

The British next proposed Christian Sound, Chatham Strait, and Lynn Canal as the boundary, leaving Baranof Island to Russia, but giving to the British Juneau, Admiralty Island, and everything to the south and east thereof. This was also rejected. Then Clarence Strait and the Stikine River were proposed, leaving Baranof Island to Russia, but giving Great Britain the islands of Wrangell and Revilla-Gigedo. This also the Russians rejected. Finally the British commissioners condescended to Russia the whole strip down to 54° 40', but sought as a last resort to have the coast line drawn straight across such arms of the sea as Glacier Bay and Lynn Canal, from headland to headland, so as to give the British access to tidewater. This, too, the Russians, in exorable refused to grant, and in the end they won on this point as on all the others. From first to last the constant and inflexible Russian contention was for Russian possession of an unbroken strip of coast from Mount Saint Elias to Portland Canal, and in the treaty of 1825 that contention was explicitly upheld and confirmed.

That Russian title was transferred to the United States in 1867, and from that time to the present the United States has stood for precisely what Russia stood for in 1822-25.

In 1898, however, as already stated, following the discovery in 1896, of the rich gold deposits in the Klondike district, the Canadian government set up a claim based upon a new understanding of the Anglo-Russian treaty. The main contention, which, by the way, never had any cordial support from qualified experts in Great Britain, was whether the line of demarcation between the southeastern end of Alaska and the British northwest possessions cut through the inlets and estuaries of the Pacific or went around them, leaving all these waterways in American territory and permitting Great Britain from access to the sea. The British contended that the boundary line, which was defined by treaty as running parallel with the sinuosities of the coast at a distance of 30 miles, except where parallel mountain ranges were nearer, when it was to follow these ranges, was to be construed as running parallel to the coast of the Pacific and not parallel to the shores of the inlets of that sea, thus constituting a political rather than a physical coast line. If the British contention had been granted, Dyea and Skagway, two important ports on the Lynn Canal, and the prominent places of export and import for the Yukon and Klondike gold fields, would be in Canadian territory. So would the Porcupine gold fields.

On account of the apparent clearness of the terms of the Anglo-Russian treaty in 1825 it may seem difficult to imagine how any interpretation different from that argued for by the United States could have been put forth. The original treaty, however, was in French, and dispute arose as to the precise translation of "côte," meaning crest, "lisière," meaning strip, and "côte," usually translated as coast.

The treaty also laid down the boundary on supposed topographical conditions which did not exist. When the treaty was drawn up the framers relied upon some of the maps of Captain Vancouver, and from observations in the small section of British Columbia which the treaty covered, it seemed apparent that the whole coast was bordered by a range of mountains which ran parallel to and at a distance of from 25 to 30 miles from the sea.

As a matter of fact there is a jumble of mountains in various places along the coast, but in no case is there a well-defined watershed. The "cristes" mentioned in the treaty were even more difficult to decide upon, and with the difference of opinion as to whether the coast line as intended in the treaty ran through the inlets or around them there were grounds for disputes, for the settlement of which an international tribunal became necessary.

The treaty between the United States and Great Britain, of which the appointment of the Alaska tribunal was the consequence, therefore decided that the following questions should be decided upon:

1. What is intended as the point of commencement of the line?
2. What channel is the Portland Channel?
3. What course should the line take from the point of commencement to the entrance to Portland Channel?
4. To what point on the 56th parallel is the line to be drawn from the head of the Portland Channel, and what course should it follow between these points?
5. In extending the line of demarcation northward from said point on the parallel of the 50th degree of north latitude, following the crest of the mountains situated parallel to the coast until its intersection with the 141st degree of longitude west of Greenwich, subject to the condition that if such line should anywhere exceed the distance of 10 marine leagues from the ocean then the boundary between the British and the Russian Territory should be formed by a line parallel to the sinuosities of the coast and distant therefrom not more than 10 marine leagues, was it the intention and meaning of said convention of 1825 that there should remain in the exclusive possession of Russia a continuous fringe or strip of coast on the mainland, not exceeding 10 marine leagues in width, separating the British possessions from the bays, ports, inlets, havens and water of the ocean, and extending from the said point on the 50th degree of latitude north to a point where such line of demarcation should intersect the 141st degree of longitude west of the meridian of Greenwich?
6. If the foregoing question should be answered in the negative, and in the event of the summit of such mountains proving to be in places more than 10 marine leagues from the coast, should the width of the "lisière" which was to belong to Russia be measured (1) from the mainland coast of the ocean, strictly so-called, along a line perpendicular thereto, or (2) was it the intention and meaning of the said convention that where the mainland coast is indented by deep inlets, forming part of the territorial waters of Russia, the width of the lisière was to be measured (a) from the line of the general direction of the mainland coast, or (b) from the line separating the waters of the ocean from the territorial waters of Russia, or (c) from the heads of the aforesaid inlets?
7. What, if any exist, are the mountains referred to as situated parallel to the coast, which measurements from the line of the coast are declared to form the eastern boundary?

The United States made no actual claim. She reiterates her right to territory which she maintained had been recognized as hers by Great Britain and by various official acts of Canada. Various maps were produced to show that Russia had been entitled to the disputed territory and that after the purchase of Alaska that same territory was mapped and charted as belonging to the United States.

Among the maps put in evidence was the British Admiralty Chart No. 787, corrected to April 1898, in which the boundary line follows the sinuosities of the actual sea-coast, and deprives Canada of the inlets which cut into the continent. It was proved also that post offices have been maintained on various points of the disputed strip; that custom-houses have been established there and have collected duties, and that government and mission schools, particularly the school at the Lynn Canal, have been maintained for nearly 20 years. The fact that the possession of the territory by Russians and later by Americans had not been disputed from 1825 until 1898 was also put forth by the United States in support of her claim.

The British contention rested primarily on the claim that it would have been impossible to trace at a distance of 30 miles the intricate convolutions of the line forming the edge of the salt water, and that therefore a general coast line, including many of the islands and disregarding many of the inlets, was the intention of the framers of the Anglo-Russian treaty. If the 30-mile limit were applied to such a coast, the boundary line would, of course, cut across all the deeper inlets, giving the British immediate access to the interior.

The British also submitted an argument placing a new interpretation of that clause of the treaty which provides that where the boundary line follows the mountain ranges, the crests of those mountain peaks shall mark the precise line of demarkation. It was demonstrated in the rush to the Klondike that there was no general line of mountains anywhere near the coast, but a number of peaks and small mountains were scattered disconnectedly close along the coast.

The British claim that the boundary line should follow the crests of these isolated peaks, had it been allowed, would have deprived the United States of a great portion of their 30-mile "isles." The British cited the action of American surveyors in 1893 in support of their interpretation of "coast."

Dr. T. C. Mendenhall, superintendent of the United States Coast and Geodetic Survey, in that year directed his subordinates to carry their operations inland 30 nautical miles from the coast of the mainland in a direction at right angles to its general trend. In regard to the mountains it was contended that a gap does not continue the general line of the range.

The official report of the tribunal was signed and issued on 26 Oct., 1903. The signatories were Lord Alverstone, the British commissioner, and the three American commissioners, who constituted a majority of the tribunal, the Canadian commissioners refusing to sign.

All the American claims were granted with the exception of those in regard to questions 2 and 3, in which the British contentions were upheld. The original treaty specified that the line should run from the north end of the Prince of Wales Island (Cape Muzon) to Portland Channel. The course of this line, according to the United States, is due east about 70 miles.

The British locate it a little north of east about 66 miles to what they call Portland Channel, and what the Americans call Pearse Channel. The American claim is made on the map of Captain Vancouver, who first scientifically investigated the territory, and the British claim was made upon the text of Captain Vancouver's book, which differed slightly from the map.

A substantiation of the American contention would have given to the United States Pearse and Sitkiok islands, which command the entrance to Fort Simpson, to which point Canada proposes to build a new transcontinental railway.

The decision in regard to Portland Channel or Canal gave Canada Pearse and Wales islands, excluding many of the islands and disregarding many of the inlets. The decision lay in the conclusion upon the fifth or main question of Lord Alverstone, who by his impartial and high-minded course refused the assumption on which was based the principal objection to the former treaty, that the decision lay in the conclusion upon the fifth or main question of Lord Alverstone, who by his impartial and high-minded course refused the assumption on which was based the principal objection to the former treaty, that not even on the bench could a British subject be found who would not persist in upholding the supposed interests of his country, no matter how cogent might be the appeals to his sense of justice or of equity.

The following is an abstract of Lord Alverstone's conclusions:

"The broad, undisputed facts are that the parties were engaged in making an agreement respecting the archipelago and islands off the coast and some strip of land upon the coast itself. The western limit of the islands extends in some places about 100 miles from the coast and the channels or passages between the islands and between the islands and the coast are narrow waters, their widths varying from a few hundred yards to 13 miles."

"In ordinary parlance no one would call the waters of any of these channels or inlets the ocean. I agree with you as presented on behalf of Great Britain that no one coming from the interior and reaching any of these channels, particularly the head of Lynn Canal or Taku Inlet, would describe himself as being upon the ocean, but on the other hand, it is quite clear that the treaty does regard some of these channels as the ocean. This consideration, however, is not sufficient to solve the question. It still leaves open the interpretation of the word coast, to which the mountains were to be parallel..."

"There is, as far as I know, no recognized rule of international law which would by implication give a recognized meaning to the word
coast as applied to such sinuosities and such waters different from the coast itself. As I have said more than once, the locus in quo to which the treaty was referring precludes the possibility of construing the word coast in any particular article in any special way if it does not refer to the coast line of the continent. I think the words upon the border of the continent comprised within the limits of the Russian possessions in Article V rather confirm the view that Russia was to get a strip all along the coast properly and I do think that much reliance can be placed upon this because of the provision regarding the rivers and streams in Article VI.

"Turning from the language of the treaty to the record of the negotiations, I have been unable to find any passage supporting the view that Great Britain was directly or indirectly putting forward a claim to the shores or ports at the head of inlets. This is not remarkable inasmuch as no one at that time had any idea that it would become of any importance.

The language of both the British and Russian representatives in reporting the conclusion of the treaty to their respective governments is in accordance with the view I have suggested ... I have little doubt that if shortly after making the treaty in 1825 Great Britain and Russia had proceeded to draw the boundary provided by the treaty, the difficulties and in certain events the impossibilities of drawing the boundary in strict accordance with the treaty would have been evident.

"I can, therefore, understand and appreciate the contention of Great Britain that under existing circumstances difficulties in delineating the boundaries described must arise in one view and might arise in any view. But these contentions, strong as they are in favor of a just and equitable modification of the treaty, do not, in my opinion, enable one to put a different construction upon the treaty. I think the parties knew and understood what they were bargaining about and expressed the terms of their bargain in terms to which effect can be given. The fact that when, 75 years later, the representatives of the two nations attempted to draw the boundary in accordance with the treaty they were unable to agree as to its meaning does not entitle me to put a different construction upon it.

"In the view I take of the terms of the treaty itself it is unnecessary to discuss the subsequent action. Had the terms of the treaty led me to a different conclusion and entitled me to adopt the view prescribed by Great Britain, I should have felt great difficulty in holding that anything done or omitted to have been done, by or on behalf of Great Britain, prevented her from insisting upon a strict interpretation of the treaty, nor do I think the representations of the map-makers that the boundary was assumed to run around the heads of the inlets could have been properly urged by the United States as sufficient reason for depriving Great Britain of any rights she had under the treaty had they existed."

**ALASKA RAILROAD, The.** See *Alaska—Railroads; Alaska Railroad Act.*

**ALASKA RAILROAD ACT,** approved April 1915, for the building of the Susitna or Seward route, extending from Seward on Resurrection Bay to Fairbanks, 471 miles inland on the Tanana River. It includes the existing Alaska Northern Railroad, purchased for $1,150,000, running from Seward through the Kenai Peninsula almost to Knik on the Matanuska River, a distance of about 100 miles. A side line is projected from Matanuska Junction to the Matanuska coal region, perhaps the most valuable field of high-grade coal in Alaska. The estimated cost of construction of the line from Seward to Fairbanks including the 38-mile Matanuska branch, was $26,800,000. The road eventually will probably be extended to the Yukon, tapping the great interior valleys with their vast agricultural resources.

**ALASKA TREATY.** See *Alaskan Boundary Commission.*

**ALASSIO,** ā-lasْ-seْ-ô, small seaport and summer resort in the province of Genoa, Italy, situated on the Gulf of Genoa, about 48 miles southwest of the city of Genoa. Pop. 6,000.

**ALASTOR,** in Greek mythology, a surname given to Zeus as the avenger; also the name of an avenging demon who follows the sinner and drives him to fresh crime. In the Middle Ages the name was given to a house-demon, the skeleton in the cupboard.

**ALATAU,** ā-la-tou, a range of mountains in central Asia, forming the boundary between Mongolia and Turkestan.

**ALATYR,** ā-la-tir' Russia, a town in the government Simbirsk, at the confluence of the Alatyr with the Sura, with a considerable trade. Pop. about 15,000.

**ALAUDA,** a genus of inesserial birds, which includes the larks. See *Lark.*

**ALAUX,** al-ô', Jean, called "Le Romain," a French painter: b. Bordeaux 1786; d. 3 March 1864. He was a pupil of Vincent and Guerin; in 1815 took the Prix de Rome with the painting of 'Briseis Finding the Body of Patroclus in the Tent of Achilles.' He executed many portraits and other works. His historical paintings in the Museum of Versailles are famous: 'Battle of Villaviciosa,' by Assault by Louis XIV, 'States-General of Paris under Philippe de Valois,' 'Assembly of Notables at Rouen under Henry IV,' 'States-General of Paris under Louis XIII' and the 'Reading of the Will of Louis XIV.' He spent nine years in painting the 80 pictures which decorate the hall of the States-General of Paris. He was director of the Academy of France from 1847 to 1850, and in 1851 became a member of the Academy. His brother, Jean Paul Alaux, called 'La Gentil,' born in 1788, was director of the School of Design at Bordeaux.

**ALAVA,** Spain, a hilly province in the north; one of the three Basque provinces; area, 1,175 square miles; covered by branches of the Pyrenees, the mountains being clothed with oak, chestnut and other timber, and the valleys yielding grain, vegetables and abundance of fruits. There are iron and copper mines, and inexhaustible salt springs. Capital, Vitoria. Pop. about 98,000.

**ALB** (from Lat. albus, white), a clerical vestment worn by priests while officiating in the
more solemn functions of divine service. It is a long robe of white linen reaching to the feet, bound round the waist by a cincture and fitting more closely to the body than the surplice.

ALBA, the name of several towns in ancient Italy; the most celebrated of which was Alba Longa, a considerable city of Latium, according to tradition built by Ascanius, the son of Æneas, 300 years before the foundation of Rome. It was at one time the most powerful city of Latium and the head of a league of the Latin cities, but fell during the reign of Tullus Hostilius when the town was destroyed and the inhabitants removed to Rome. It was long believed that the modern Albano occupies the site of Alba Longa, but Cluver disproved this in 1624. It is probable that its site was on the western side of the Lacus Albanus, where the modern Castel Gandolfo stands, immediately to the north of which a prehistoric necropolis was discovered in 1817, buried under volcanic ashes and containing burial urns shaped like round nuts. Alba Pompea (modern Alba), an episcopal city in the province of Cuneo, on the Tanaro, 30 miles southeast of Turin. It contains rare collections of ancient coins, manuscripts, household utensils, etc. The district produces grain, cattle, wine, silk, cheese and truffles. Pop. (1911) 14,176. Another Alba, called Alba Fucensis, was near the Lacus Fucinus. The cyclopean walls of the old town are still to be seen in excellent preservation. Consult Promis, C., 'L'Antichità di Alba Fucensia' (Rome 1836).

ALBA, Duke of. See ALVA.

ALBACETE, ál-ba-thé-té, Spain, town and capital of the province of the same name, on the highway and railway between Madrid and Cartagena. It lies in a fertile but treeless plain. Albacete, from its position, is a place of considerable business; and carries on trade, both direct and transit, with Murcia, Alicante, Valencia and Murcia. It has a tanning and printing, salting, softening and cooking, and cattle; and importing codfish, sardines, rice, sugar, wine, iron, clothes, etc. A good deal of cutlery is made here. Pop. 25,000.

ALBA LONGA. See ALBA.

ALBAN, ál-bán', Saint, protomartyr of Britain, 303. A native of Hertfordshire, he was tortured and executed at Verulamium by command of the prefect, Asclepiodotus. When tranquillity was restored a chapel was erected over his grave; in 795 Offa, King of the Mercians, founded a large monastery upon the spot and Pope Adrian IV (1154-59) directed that he should hold the first place among the abbots of England and that the festival is celebrated by the Roman Catholic Church on 22 June, and by the Anglican Church on 17 June.

ALBANEL, ál-bán-él', Charles, Jesuit: b. Auvergne 1616; d. Sault Ste. Marie 1696. He entered the order in 1633, arrived in Canada in 1649, and accompanied the first French expedition from Quebec to Hudson Bay 1671-72, designed to take possession of that region in name of the French King. In 1674 he revisited the bay, was taken prisoner by the English, sent back to Europe, and on his release returned to mission work in Canada.

ALBANI, ál-bá-ni, a powerful family of Rome, which has supplied the Roman Catholic Church with several cardinals. Two of them are well known as patrons of the fine arts: (1) ALBANI, ALESSANDRO, b. 1692; d. 1779; he was a great virtuoso and possessed a collection of drawings and engravings which at his death was purchased by George III for 14,000 crowns. (2) ALBANI, GIOVANNI FRANCESCO, nephew of the former, b. 1720; d. 1843; a great friend of the Jesuits, and in every respect liberal and enlightened. His palace was plundered by the French in 1798, when he made his escape to Naples stripped of all his possessions.

ALBANI, Emma (stage name of Marie Louise Cecilia Emma Lajeunesse), Canadian dramatic soprano: b. Chamogey, near Montreal, Canada, 1 Nov. 1852. After studying with Lamperti, at Milan, she made her début at Messina (1870), in 'La Sonnambula,' under the name of Albani, in compliment to Albany, N. Y., where her public career began at the age of 17. In 1878 she married Ernest Gye of the Covent Garden Theatre. She sang in opera in London, Berlin, Paris, Saint Petersburg and in the principal cities of the United States. Among her principal roles were Elsa in 'Lohengrin,' Elizabeth in 'Tannhäuser,' Sieglinde in 'The Ring,' Dutchman, Marguerite, Mignon, Lucia, Isolde and Ophelia. Madame Albani has sung also in oratorio. Consult her memoirs, 'Forty Years of Song' (London 1911) and Edwards, H. S., 'The Prima Donna' (ib. 1888).

ALBANI, Francesco, famous painter: b. Bologna 1578; d. 1660. He entered the school of Dionysius Calvaert, a Flemish painter, who had a great reputation in Bologna. Albani was one of his most distinguished scholars, but quitted him for Ludovic Carracci, under whose instruction he made a rapid progress; and, after spending here several years in connection with Domenichino, to whom he was closely attached by friendship and love of art; and some resemblance is perceptible in their manner of coloring. But in invention he surpasses his friend, and indeed all his rivals of the school of Calvaert. His female forms Mengs places above those of all other painters. Among the best known of his compositions are the 'Sleeping Venus,' 'Diana in the Bath,' 'Danaë Reclining,' 'Galatea on the Sea,' 'Europa on the Bull.' The Flemish subjects he has less frequently selected, but when he has, the paintings are principally distinguished for the beauty of the heads of the angels. He had a prosperous school in Rome and Bologna. The scholars of Guido, with whom he vied, accused him of effeminacy and weakness of style, and maintained that he knew not how to give any dignity to male figures. He has been called the Anacreon of painters.

ALBANIA, ál-bá'ni-a. The geographical region known as Albania before the Balkan war (1912-13) was made up of the Turkish provinces of Scutari (the ancient Illyrium) and Yanina (the ancient Epirus), and parts of the Ottoman vilayets of Kossovo and Monastir. It lies in the western part of the Balkan Peninsula and was bordered on the west by the Adriatic, on the northwest by Montenegró, on the north and northeast by Serbia, on the east by Macedonia and on the south by Greece. The southern part of Albania is of a volcanic character and earthquakes are very frequent, although not very intense. Since the independence of Albania was proclaimed in November 1912 its frontiers have been ill-defined and
constantly changing. The eastern natural boundary is a mountain range, which attains in its highest peak an altitude of 8,858 feet. Westward of this range lie parallel chains enclosing long, elevated valleys sinking to level strips along the coasts, which, while fertile and well watered, are very unhealthy and swampy. The highlands advance to the sea, forming steep, rocky coasts. One promontory, the Glossa (ancient Aeroceramia), projecting in Cape Linguetta far into the sea, reaches a height of 650 feet above the water. The principal rivers are the Boyana, Drin, Shkumbi, Maç (Matul), Voyussa and Devol. The climate in the highlands is healthful but subject to violent changes and excessive cold in winter. The sea-coast is malarial in parts and exposed to the violent bora or north winds. The principal ports are Drač (Durazzo) and Sinjzin (S. Giovanni di Medua). The inhabited valley is from some 10 to 15 miles wide and is between 10,500 and 11,500 square miles, and the population between 800,000 and 850,000 souls.

Industries.—The Albanians, especially in the north, have never been an agricultural people, and although the soil, apart from some chalky regions, is fertile, great tracks remain uncultivated. In the cultivated areas the methods used are exceedingly primitive, and agricultural and industrial development is further hindered by lack of transportation, there being no railways, few roads and few bridges. In the north little is cultivated but maize; the mountain terraces are used as pastures for horses, cattle and sheep. In the south the slopes of the lower valleys are covered with olives, fruit and mulberry trees, intermingled with patches of vines and maize, while the densely wooded mountain ridges furnish valuable supplies of timber. The plateau of Janina yields abundance of grain; and in the valleys opening to the south the finer fruits are produced, along with maize and wheat. In 1902 the chief exports were wool, hides, olives, fish, fruit and maize. Durazzo, Valona and Scutari are the chief towns. Industries are primitive and include fishing, extraction of sea-salt, gold and silk embroideries and similar manufactures. The Turks have recently abandoned and is of excellent quality. The mountains are thought to be rich in minerals, especially copper and coal, but mining is practically unknown.

The People.—The inhabitants (called by the Turks 6Arnauts, by the Serbians "Arbanasi" and by themselves "shkipetar") are the descendants of the ancient Pelasgs and are divided into two main groups: the Ghegs, who live in the north, and the Tosks, who live in the south. They have an hereditary aristocracy, and a kind of feudal system. The Ghegs are divided into tribes, the principal of which are the Malisori and Minirdis. They are half-civilized mountaineers; frank to a friend, vindictive to an enemy and treacherous. The Tosks are more educated, live in perpetual anarchy, every tribe being at war with its neighbor, and manage their affairs according to their own peculiar customs and code of honor, so called "besa." They are haughty, simple and brave and have always been excellent soldiers. The Tosks are more civilized and have hitherto been under the guidance of a system of boys or chiefs and acknowledged the Ottoman code of law.

In reality their tribes ("fisses") have self-created an administration of a somewhat aristocratic-republican character with a "voyvoda" (duke) as chief leader in war and peace and at the same time the head of a council of chosen senators. At the beginning of the 15th century the Tosks had a legislator called Dukashin. Their ancestors, the Pelasgs, were at first subjugated by the ancient Hellenes and later by the Romans. About two centuries after the Albanians are Moslems; the northern Christians are mostly Roman Catholic, the southern Orthodox Greek. There are a few Roman Catholic and Orthodox schools, but education may scarcely be said to exist as yet. The free schools, which were founded by a Serbian scholar and celebrated writer, Dositay Obrodivo, in the beginning of the 18th century, died out as soon as their founder left the country.

History.—The Albanians are among the oldest peoples in Europe. Their country formed part of the Roman provinces of Illyria and Epirus, and after the dismemberment of the Roman Empire it became part of the Byzantine Empire. In 640 A.D. northern Albania was invaded by the Serbians, who remained later (1288) the Christian faith, and in the 9th century southern Albania was conquered by the Bulgarians. The Normans, Venetians, and Byzantines disputed the territory with them, but until the 14th century the Albanians remained the greater part of the time nominally under Serbian rule, never, however, losing in any high degree their nationality. Upper Albania and part of southern Albania were ruled by the Montenegrin princely family of Balsa or Balsi of Provençal origin. In 1360, after the death of the Serbian Emperor Dušan the Mighty, they regained complete independence under native chiefs until 1431, when the Turks captured Yania. The Albanians, united for the first time under their great leader George Kariot, or Skanderbeg (1404–27), successfully resisted in 1443 the Turkish invasion, but on the death of Skanderbeg (1467) the principality he had founded was taken over by the Venetians, and after the fall of Scutari in 1478 the Albanians passed nominally under Turkish rule. They still preserved their national characteristics and maintained a large degree of independence augmented by their conversion to Mohammedanism in the 16th and 17th centuries. This was a cause of further estrangement from their neighbors, the Bulgarians, Greeks and Serbs, who remained Christians, and their aloofness was encouraged and utilized by the Turks, who in the second half of the 18th century through the pashas of the notorious Bushal family succeeded in acquiring from the Sublime Porte the hereditary right of succession in northern Albania and Kara-Mahmut Pasha made himself an absolute satrap after several battles which he won from the Turks. But in 1796 he perished in a battle against the Montenegrins, the Albanians being unable to clear their arms, live in perpetual anarchy, every tribe being at war with its neighbor, and manage their affairs according to their own peculiar customs and code of honor, so called "besa." They are haughty, simple and brave and have always been excellent soldiers. The Tosks are more civilized and have hitherto been under the guidance of a system of boys or chiefs and acknowledged the Ottoman code of law. But in reality their tribes ("fisses") have self-created an administration of a somewhat aristocratic-republican character with a "voyvoda" (duke) as chief leader in war and peace and at the same time the head of a council of chosen senators. At the beginning of the 15th century the Tosks had a legislator called Dukashin. Their ancestors, the Pelasgs, were at first subjugated by the ancient Hellenes and later by the Romans. About two centuries after the very...
Ottoman sovereignty but the liberty-loving Albanians rose in rebellion against their oppressors in 1833, 1836 and 1842. The Albanians in the south followed the example of their northern brothers and rebelled in 1843 and 1847, but were mercilessly suppressed and crushed by Omer Pasha. Among other rebellions that took place in Albania mention must be made of that of 1872 when the Merediths joined hands with the Montenegroins and resisted stubbornly Dervish Pasha. Stimulated by the Turkish revolution of 1908 and the downfall of the Young Turks the powerful Malemsori contributed to bring about the Balkan war (q.v.) of 1912. The Balkan allies wished to divide Albania among themselves, but were opposed by Austria-Hungary and Italy. At Valona 28 Nov. 1912 Albania was declared independent, a provisional government was set up under Ismail Kemal Bey and on 20 Dec. 1912 the London Ambassadorsial Conference of the Great Powers acknowledged the autonomy of Albania, and later approximately defined the frontier and appointed Prince William of Wied sovereign (in Albanian "M'pret," a corruption of Imperator) of the new country, to be supported by an International Commission of Control of six members. The Prince arrived at Durazzo March 1914, but after the outbreak of the European war fled from the country with most of the members of the commission. An attempt made by Essad Pasha to set up a military form of government failed (5 Oct. 1914) and Albania fell into a state of anarchy. On 25 Dec. 1914 the Italians captured Valona. Had the new principality survived its area would probably have been 10,000 to 11,500 square miles and its population between 800,000 and 850,000. But the total Albanian population is computed to 1,700,000, of which number 250,000 live in Greece, 100,000 in southern Italy, while many thousands live in Asia Minor and in European Turkey.

Language.—Authorities are not in complete accord over the origin of the Albanian language. By some it is thought to be the speech of the ancient Pelasges, but Gustav Meyer and most of the later philologists believe it to be one of the eight chief Indo-Germanic groups, representing the ancient Illyrian; it is found not only in Albania, but in southern Italy and Sicily. The former notion that its affinities were prevailing Greek was derived from the number of Greek loan-words in its southern branch, the Toskish, the northern and the more primitive being called Gegish; the affiliation of the whole is rather to Slavic than any other. While retaining its grammatical structure, its vocabulary has been largely transformed by borrowing from its neighbors; Latin most, then Greek, Serbian and Turkish. The many suffixes of Latin origin, the simple and compound verbs made in accordance with Latin models, the formation of plurals by inflexion, etc., are the best proof that the Albanian language has been affected most by Latin influence. It has almost no literature, except folk songs, fables and tales. The Gegish use the Roman alphabet, the Toskish the Greek, with some changes, there being a Greek-written alphabet. Apart from a few writings of the Roman Catholic propaganda (Varibabba with his 'Life of the Virgin Mary') mention should be made of de Rada's attempt to collect Albanian national poetry and rhapsodies (19th century). In the most recent times Koustuban Kristoforidhis has written the grammar of the Albanian language, and de Rada devoted himself to translate the Old and New Testaments.

ALBANS, St. See ST. ALBANS.

ALBANY, al'bâ-ni, Louisa Maria Caroline, or Aloysia, Countess of, a princess of the Stolberg-Gedern family; b. 1755; d. 29 Jan. 1824. She married in 1772 the English pretender, Charles Edward Stuart, afterwards Bonnie Prince Charlie, and bore the above title. Her marriage was unfruitful and unhappy. To escape from the barony of her husband she retired in 1780 to a cloister and afterward to the house of her brother-in-law at Rome where she met the poet, Alferi, to whom, soon after the death of her husband, she was privately married. Alferi attributed to her his poetic inspiration. (See ALFIERI.) She died at Florence, her usual place of residence, in her 72d year. Her ashes and those of Alferi now repose under a common monument in the church of Santa Croce at Florence.

ALBANY, Ga., city and county-seat of Dougherty County, on the Albany & North Seaboard Air Line, Central Ga. and Plant System railroads, at the head of navigation on the Flint River, about 175 miles west from Savannah. The city has large manufacturing interests in lumber, brick, etc., and is the centre of one of the most productive agricultural regions in the State. It is governed by a mayor and a council and maintains municipal
gas and electric lighting plants and waterworks. Pop. (1910) 8,190; (1916) 12,500.

ALBANY, Mo., city and county-seat of Gentry County, on the Chicago, B. & Q. Railroad, about 82 miles northeast from Kansas City. The Central Christian College and the Northwest Missouri College are situated there. The city, first settled in 1845, is governed by a mayor and council. Pop. 2,000.

ALBANY, N. Y., State capital and seat of Albany County, on the right (west) bank of the Hudson, 143 miles north of New York, 200 miles west of Boston, 297 miles east of Buffalo. Besides its political importance as the capital, its commercial and manufacturing status is high. For many years the starting point of all the enormous eastern travel and traffic to the West, over the Erie Canal (q.v.), connecting it with the Great Lakes at Lake Erie, and the several lines of the new State Barge Canal System, it is an important port and the intersecting point of the great western as well as northern rail and water routes. With New York and the ocean it is connected by the Hudson, of which it is the head of navigation, and by the steamers (smaller ones going on to Troy, six miles above). The Barge Canal is a great commercial advantage and will soon be more so; while the Champlain-Barge Canal gives access not only to western Vermont, but to the Saint Lawrence and the heart of Canada, with the foreign business centring at Montreal. It joins the western and northern traffic of the New York Central Railroad system (the Adirondack region, Vermont and Canada) and that of the Delaware & Hudson Railroad with the western traffic of central New England over the Boston & Albany branch of the New York Central road, the Fitchburg branch of the Boston & Maine Railroad and the Rutland Railroad.

Trade and Manufacturing.—The thorough freight lines now leave little transshipment to be done at Albany, but the city still remains an important passenger centre, and is the second largest express and the third largest mail station in the United States. Commerce and industries are conservative and it retains much of both given it by its position in earlier times as a distributing point and terminal. In particular, the great Canadian and Adirondack forests to the north have made it an immense lumber market. Its manufactures are of wide and well-known importance, the greatest being iron goods,—foundries and stove works,—wood and brass; combined wood and metal, as carriages and wagons; brass wire, galvanized iron, nails, india-rubber goods, shoes, flour, tobacco and cigars; and brewery products, billiard balls, dominoes, checkers and embossed blocks. The United States census (1914) reported 477 manufacturing establishments of factory grade, employing 11,405 persons, of whom 9,339 were wage-earners receiving a total of $5,652,000 in wages. The capital employed aggregated $26,683,000 and the value of the output $25,289,000; the value added by manufacture being $13,564,000. In addition there are also the extensive car and locomotive shops of the New York Central Railroad.

Finances.—The assessed valuation of real property in 1917 was $104,701,690 and the net public debt in 1910 was $2,458,644.08. The annual and municipal outlay is about $2,283,000, of which $492,285 was for schools, $244,685 for police and $250,610 for the fire department. There were four discount banks and trust companies with aggregate capital of $3,000,000, and seven savings banks with a surplus (at market value) of $4,621,941, and amount of deposits of $83,973,602. Tax rate (1917) per $100 was $2.56 (includes State, county and city taxes).

Interior.—The city has a river frontage of little over four miles and extends west about nine miles, from a narrow alluvial strip often flooded in the spring, over a steep rise to a sandy tableland 150 to 200 feet above tidewater, divided into four elevations and their corresponding valleys. It has 97.5 miles of streets, paved with granite, asphalt and brick; gas and electric light plants; and about 42 miles of electric street railways within its limits, several subways of the new State Barge Canal System, it is an important port and the intersecting point of the great western as well as northern rail and water routes. With New York and the ocean it is connected by the Hudson, of which it is the head of navigation, and by the steamers (smaller ones going on to Troy, six miles above). The Barge Canal is a great commercial advantage and will soon be more so; while the Champlain-Barge Canal gives access not only to western Vermont, but to the Saint Lawrence and the heart of Canada, with the foreign business centring at Montreal. It joins the western and northern traffic of the New York Central Railroad system (the Adirondack region, Vermont and Canada) and that of the Delaware & Hudson Railroad with the western traffic of central New England over the Boston & Albany branch of the New York Central road, the Fitchburg branch of the Boston & Maine Railroad and the Rutland Railroad. Trade and Manufacturing.—The thorough freight lines now leave little transshipment to be done at Albany, but the city still remains an important passenger centre, and is the second largest express and the third largest mail point in the United States. Commerce and industries are conservative and it retains much of both given it by its position in earlier times as a distributing point and terminal. In particular, the great Canadian and Adirondack forests to the north have made it an immense lumber market. The capital employed aggregated $26,683,000 and the value of the output $25,289,000; the value added by manufacture being $13,564,000. In addition there are also the extensive car and locomotive shops of the New York Central Railroad.

Finances.—The assessed valuation of real property in 1917 was $104,701,690 and the net public debt in 1910 was $2,458,644.08. The annual and municipal outlay is about $2,283,000, of which $492,285 was for schools, $244,685 for police and $250,610 for the fire department. There were four discount banks and trust companies with aggregate capital of $3,000,000, and seven savings banks with a surplus (at market value) of $4,621,941, and amount of deposits of $83,973,602. Tax rate (1917) per $100 was $2.56 (includes State, county and city taxes).
buildings are the County courthouse; the State armories; the old Schuyler Mansion, once used as an orphan asylum, but dedicated in 1917 as an historical monument; the Albany Institute and Historical and Art Society, containing many archives of Albany history; the Hotel Ten Eyck; the Delaware and Hudson building; and the new High School. In 1893 the second Van Rensselaer manor-house, built 1765, was removed to the Williams College campus, of Williamstown, Mass.

Religion, Education, Etc.—Albany is the seat of both Roman Catholic and Protestant Episcopal bishoprics, and has 74 churches. Very notable are the cathedrals of the Immaculate Conception (R. C.) and All Saints (P. E.). St. Peter's Church (P. O.) is reputed one of the finest specimens of the French Gothic type of architecture in the United States. The Madison Avenue and First Reformed churches were organized in 1642, incorporated in 1720 and continued as one church until 1799 when separate edifices were built; these two churches continued under one government until 1815.

The State Education Building is exceeding attractive, four stories and basement. The materials used on the front and ends are for the most part white marble, terra cotta and dark granite. The building contains offices for the Board of Regents and Department of Education, the State Library, with an attractive reading room, and a stock room capable of accommodating 2,000,000 volumes, the State Library School, and the State Museum, which contains the State collections in geology, mineralogy, paleontology, archaeology, botany and zoology. There is also a large auditorium in the building. Several large and attractive mural paintings adorn the walls.

The public school property is valued at nearly $2,000,000. Other institutions of learning are the law and medical departments of the Union University at Schenectady (originally independent academies of 1851 and 1839), Albany Academy, the State College for Teachers, Saint Agnes School, the Albany Female Academy and the Convent of the Sacred Heart; also the Dudley Observatory and the Bender Hygienic Institute.

Public buildings are the City hall, a spacious city hall built in 1899 on the pavilion plan and covering 16 acres with 150,000 feet of floor space; the Homeopathic and Saint Peter's hospitals; the Albany penitentiary, dating from 1849—from three to four hundred prisoners a year are confined in this institution.

Government—Biennial mayor; city council, the president elected at large, the aldermen by wards; and boards constituted as follows: (1) Finance, comptroller, treasurer and a board of estimate composed of the mayor, comptroller, corporation counsel, president of the common council, city engineer and treasurer; (2) Public Works, commissioner who appoints superintendents of waterworks and parks; city engineer; a board of contract and supply; (3) Public Safety, commissioner who appoints chiefs of police and fire departments with their subordinates and a health officer with assistants; (4) Public Instruction, three commissioners of education, term six years, who appoint superintendents of schools and city schools; (5) Assessment and Taxation, four assessors, two elected every two years for a term of four years; (6) Charities and Correction, commissioner who appoints overseer of the poor and assistants; (7) Judiciary, one police court justice who holds office six years and three city court justices; (8) Law, corporation counsel, assistant and subordinates. Of the three city court justices, the comptroller, treasurer, assessors and police and city court justices are elected. All others are appointed by the mayor.

History.—Albany, as an old frontier town and strategic post against the French settlements in the 18th century wars, is of much historic interest. Next to Jamestown, Va., and Saint Augustine, Fla., it was the oldest settlement in the Union; if the 13 colonies only are included, and Jamestown thrown out as deserted since 1676, it may perhaps be called the oldest with a continuous life, though its actual settlement as a residence is later than Plymouth. (For early discovery, see AMERICA; HUDSON; VERASSANO). About 1540 a French trading-post was set up there for a time. In 1614 the Dutch, following Hudson's lead, established a factory on Castle Island, called Fort Nassau, in 1617 removed to the mainland and called Beverwyck. The first settlers were 18 Walloon families (Huguenot refugees from Belgium—Peter Minuit, the first director-general of New Amsterdam, was a Walloon), and Fort Orange (Latinized Aurnia) was built the same year near the present capitol. In 1626 a war with the Mohawks forced the temporary abandonment of the village. In 1629 Killian Van Rensselaer, having obtained from the Dutch government a large land-grant near by, colonized it with Dutch settlers and rented the land to them as patron. (See Anti-Rent War; PATROON). This, as always, ended in a chronic dispute over the extent of his legal rights and jurisdiction, which was not settled till after the ownership of the Dutch settlements was transferred by the English conquest to the Duke of York and Albany (later James II) after whom Fort Orange was renamed. In 1686 it received a city charter. In its bi-centennial year (1886) former Gov. Thomas Dongan; its first mayor (appointed by the governor, though the council was elected) was Peter Schuyler. The English settlers rapidly increased, but Albany was long a Dutch city. In the French and Indian wars it was a stockaded rendezvous, arsenal and hospital, the refuge of the border. In 1754 it was the meeting-place of the first Provincial Congress, which formed a plan of a proposed union of the several colonies. (See Albany Congress). In 1777 it was Burgoyne's objective point, where he was to meet the expeditions up the river and from Canada. After being for many years the occasional seat of State government, it became the permanent capital in 1797, the centennial of which it celebrated 6 Jan. 1897. Its rapid growth began with the opening of the Erie Canal in 1825, making it the terminal for western business. Within 35 years it had increased five-fold. In 1848 the city was partially destroyed by fire. Bibliography: Rapin, The History of the City of Albany (Albany 1884); Munsell, J., The Annals of Albany (10 vols., Al-

EDWIN TRISTRAM COFFIN, Secretary Albany Chamber of Commerce.

ALBANY, Ore., city and county-seat of Linn County, on the Southern Pacific and the Cowalli & E. railroads, and the Willamette River, about 25 miles south by west from Sa-

lem. The city has good water-power from the Willamette River, and has large manufac-
	
turing interests. It ships both grain and flour. Pop. (1916) 8,000.

ALBANY, West Australia, in Plantagenet County, on King George’s Sound. It has one of the finest harbors in Australia and is a port of call for the steamers of the Peninsula & Oriental Company. It is a consular station of the United States. Pop. about 3,600.

ALBANY CONGRESS, an assembly of representatives of the seven northern British-

American colonies (Massachusetts, New Hampshire, Connecticut, Rhode Island, New York, Pennsylvania, and Maryland), called together in 1754 by the British government to consult in regard to the threatening French war. It met 19 June, and two plans were pro-

posed: (1) A league with the Five Nations, which was carried out; (2) a proposal offered by Franklin for a political union. In this a common president was proposed, and a great council representing the different colonies. The president was to be appointed by the Crown; to be also commander-in-chief, to com-
mission all civil officers and appoint all military ones and have a veto on the council. The council was to consist of three-year members, two to seven from each colony; not to be ad-
journed or dissolved or kept over six weeks in its will; it could lay taxes, maintain troops, build forts, nominate civil officers, manage Indian affairs and authorize new settlements; and its acts were to be valid unless vetoed within three years by the Crown. This plan was rejected by the British Crown because it gave too much power to the colonies and by the colonies because it gave too much power to the Crown. The significance of this congress lies in the fact that it stimulated the union of the colonies which was afterward accomplished.

ALBANY REGENCY, in American political history, the nickname of a powerful group of Democratic leaders in New York State, who controlled the party machinery there and acted together for influence in State and na-

tional affairs about 1820 to 1854. The name was generally restricted to a body of men of the Regency either lived near the capital or held offices which made the city their headquarters. Its origin and essence as an aristocracy of ‘bosses’ lay in the system of frequent electoral districts; a Democratic ‘boss’ puts nominations into the hands of professionals who will be paid in some shape, creating a permanent standing army of professional managers. The Regency was the unofficial staff of this army and was larger than in other States from the imperial field which New York offered for great careers; but it could not have perpetuated its power but for the means of rewarding friends and punishing enemies by the “spoils system” (a name derived from the saying of one of its members, William L. Marcy, in 1833, that “to the victors belong the spoils”). While personally upright, and strong opponents of corruption, they held power to this date; the very spring of corruption: the giving or taking away of offices, the use of public contracts for printing or other work or supplies, etc. That this was its cement is shown by the fact that after the bitter factional split of 1848 (see Barnburners) had given the other party this patronage to use against it, the Regency was reduced in a few years to unorganized indi-
