viduals. The members of course kept themselves in high or profitable positions according to their capacities or preferences; several alternating between State and national office, but never neglecting the former basis even in the latter service. The earliest and greatest leader was Martin Van Buren, State attorney-
general, United States senator 1821–28, resigning to become governor of New York. Polk’s secretary of state, Pierce’s secretary of state; Silas Wright, congressman, State comptroller, United States senator 1833–44 (succeeding Marcy); resigning 1844 to become governor of New York; John A. Dix, State secretary of state, United States senator 1845–49, Buchanan’s secretary of the treasury, again governor of New York 1872–74; Benjamin F. Butler, Van Buren’s attorney-general and acting secre-
etary of war; while others held only State offices.—Azariah C. Flagg, State secretary of state and afterward twice mayor of Albany; Josiah C. Crosswell, State printer, editor of the Albany Argus, leading Democratic organ; Benjamin Knowler, State treasurer; and others held no offices.—Dean Richmond, Roger Skinner, Peter Sagger, Samuel A. Talcott, etc. Afterward Samuel J. Tilden, Daniel Manning and others of high stamp, by sagacity of central manage-
ment, preserved in a manner the traditions of the older group, though they never had its patronage to use for discipline.

ALBATROSS (corrupted from Portu.

guese alcatraz, the cormorant; from Ar. al, the; qudus, bucket, on account of its pouch), a large, almost exclusively pelagic bird of the family Diomedeidae, a feature of the lonely southern oceans. They are rarely seen on the north At-

lantic, but frequent nearly all other seas, and are never seen ashore except on the barren Antarctic islands where they breed. They have great powers of flight and follow ships for long distances to pick up offal. Their appetites are rapacious, their natural diet consisting of any fishes, mollusks or other animal matter which they find at the surface of the water; they do not dive. Sailors have a strong superstition against killing them. Like their allies, the petrels, the albatrosses have three fully-webbed toes, while the hind toe
is either entirely wanting or represented by a claw. The bill of an albatross is four inches or more long, very thick and finished by a powerful, curved tip. The nostrils open five round horizontal tubes placed one on each side of the bill, but at its base, instead of together on top as with the petrel. The wings are extremely long and pointed, the tail short and somewhat rounded. The feathers of the body form so thick a coat as to withstand both water and severe, long-continued cold; owing to the extreme length of the wing the number of flight feathers on it is greater than on the wing of any other bird. The single large white egg of the albatross is usually hatched on the bare earth. Two rather small species of albatross, the short-tailed (Diomedea albatrus) and the black-footed (Diomedea nigripes), occur on the western coasts of North America; these are about three feet long and seven feet across the wings. The sooty albatross (Phoebetria fuliginosa), of much the same size, belongs broadly to the Pacific Ocean. There are from seven to nine other species, of which the largest is the wandering albatross (Diomedea exulans) of the Southern oceans. It is five feet long and 10 to 12 feet from tip to tip of wings. Its color is white, with black bars across the wing coverts and across part of the back. This is probably the best known species in the family.

AL-BATTANI (MOHAMMED IBN JAHIR IBN SWAN), Arab astronomer and mathematician: b. 850; d. 929. He began his astronomical observations at Rakka in 878 and continued them for over 40 years. In pure mathematics he also made important investigations. He used the sines of an angle instead of the chord of double the angle, computed a table of cotangents and formulated several propositions in spherical trigonometry. Plato of Tivoli translated his astronomical works under the title 'Mahometis Albateni de Motu Stellarum.' This work made him known to Europeans. This work was edited by C. A. Namilo in Arabic and Latin and published at Milan (1899). Al-Battani corrected numerous errors of astronomers; he gave the length of the tropical year as 365 days, 5 hours, 46 minutes, 24 seconds; too short by 2 minutes, 26 seconds, and he stated the obliquity of the ecliptic as 23° 35' instead of 23° 51' 20''.

ALBAY, ál-bí', Philippine Islands, province in the southeast of Luzon, and the richest hemp-growing district on the island; area, 997 square miles; pop. 241,000. It has yielded as much as 40,000 tons of hemp in a season. The province contains a picturesque volcano, Mayon, which has had several destructive eruptions, the last in 1889. In January 1900 Brig.-Gen. William A. Kobbe, United States Volunteers, was appointed military governor of the province and Catin- duanes Island, with temporary authority over Samar and Leyte Islands for the purpose of controlling the hemp-growing country and occupying and opening to trade the various hemp ports. The principal towns in the province are Albay (the capital, pop. 42,000), Tivi, Malinao, Tabaco, Malilipot, Bagacay, Lobig, Legaspi, Manito, Ligab, Polangui, Ligao, Oas, Guinoba- tan, and H. Cacabu. Vico is almost the exclusive language of the province. The industries are hemp-growing (annual value $4,750-217), shipbuilding, gold, silver, coal and iron mining.

ALBEMARLE, The, a Confederate ram, which for a long time did great damage among Union shipping, but was finally destroyed by W. B. Cushing in 1864. The nozis open five round horizontal tubes placed one on each side of the bill, but at its base, instead of together on top as with the petrel. The wings are extremely long and pointed, the tail short and somewhat rounded. The feathers of the body form so thick a coat as to withstand both water and severe, long-continued cold; owing to the extreme length of the wing the number of flight feathers on it is greater than on the wing of any other bird. The single large white egg of the albatross is usually hatched on the bare earth. Two rather small species of albatross, the short-tailed (Diomedea albatrus) and the black-footed (Diomedea nigripes), occur on the western coasts of North America; these are about three feet long and seven feet across the wings. The sooty albatross (Phoebetria fuliginosa), of much the same size, belongs broadly to the Pacific Ocean. There are from seven to nine other species, of which the largest is the wandering albatross (Diomedea exulans) of the Southern oceans. It is five feet long and 10 to 12 feet from tip to tip of wings. Its color is white, with black bars across the wing coverts and across part of the back. This is probably the best known species in the family.

ALBERONI, ál'ba-rón'ě, Giulio, cardinal and minister of the King of Spain: b. Firenznoila, Parma, 1654; d. Rome 1752. He soon gained the favor of powerful patrons, especially the Duke of Vendôme, whom he accompanied to Paris and then to Spain, the Duke being appointed generalissimo of the armies of Philip V. Having made himself a favorite of the Spanish King, he rose to be prime minister, became a cardinal, was all-powerful in Spain after the year 1715 and endeavored to restore it to its ancient splendor. He reformed abuses, created a naval force, organized the Spanish army on the model of the French and rendered the king-dom of Spain more powerful than it had been since the time of Philip II.

ALBERS, Petrus Henricus, German ecclesiastical historian: b. Cranenburg, Cleves, Germany, 13 April 1856. He was educated at the gymnasium of Gemert, North Brabant; emigrated with his family to Holland in 1870 and entered the Society of Jesus in 1880. After completing his studies in the Jesuit scholasticates he took a course in church history at Innsbruck under Ludwig Fischer. In 1896 he became professor of church history at the Jesuit college of Maastricht. He is a member of the Historical Society of Utrecht, the Leyden Literary Society and of the administrative board of the Historical and Archaeological Society of the Province of Limburg. He has published: 'Het Herstel der Hierarchie in de Nederlanden' (2 vols., Nijmegen 1904); 'Handboek der Algemeene Kerkgeschiedenis' (2 vols., ib. 1905-07), translated into French, Latin, Spanish, Italian and English; 'Levensgeschiedenis van Pater Roothaan.' He was a collaborator in 'Vivat's Encyclopédie'; 'Nederlandsch Biographisch Woordenboek'; 'Het Jaarboekje van Alberdingk Thijm'; and 'Ar- chief voor de Geschiedenis van het Aartsbisdom Utrecht'; and for many years has been a contributor to the Studien.

ALBERT, Prince (ALBERT-FRANCIS-AU- GUSTUS-CHARLES-EMMANUEL), Prince of Sax- Coburg-Gotha and Prince Consort of England, second son of Ernest I, Duke of Saxe-Coburg, was born at the Rosenau, a castle near Coburg,
ALBERT I

King of the Belgians: Albert Leopold Clément Marie Meinrad, Duke of Saxony, Prince of Saxe-Coburg and Gotha, second son of Prince Philip Baldwin, Count of Flanders, and Princess Charlotte, Countess of Hesse-Homburgh. b. Brussels, 8 April 1875; married 2 Oct. 1900 to Elizabeth, Duchess of (in) Bavaria, daughter of the late Duke Karl Theodor, the physician and oculist. They have three children: (1) Prince Leopold, Duke of Brabant, b. 3 Nov. 1901; (2) Prince Charles, Count of Flanders, b. 10 Oct. 1903; (3) Princess Marie José, b. 4 Aug. 1906.

King Albert succeeded his uncle, Leopold II (d. 17 Dec. 1909) and was crowned on 23 Dec. 1909. The condition of Belgium at that time was far from promising. Leopold II had gone to his grave "unwept, unhonoured and unsung." His profligate vices, ambitions and autocratic magnificence, his domestic tyranny and private scandals had aroused almost universal disapprobation, not merely amongst the French, but amongst the Flemish, in his own country. In addition, the Kongo atrocities perpetrated in his name and with his knowledge had lowered the repute of Belgium. Hence the new King inherited sentiments of distrust, enmity and anger at home and abroad, besides a country saddled with enormous expenditures. A barrier of estrangement and contempt had grown up between King and people; it was the task of Albert I to break down that barrier and replace it by a bond of democratic sympathy and confidence. But Albert I, the man of great stature and masterful will; but there the resemblance ends. Before he had been two weeks on the throne his people realized that something essential had been changed in the executive of the State, the virtual dictatorship constantly disregarded by the late King—love of children, of family and country, honesty and simplicity—had been restored, as it were by magic, into the scheme of national life. One of the King’s actions was to allow or rather, invite—Princess Louise, Leopold’s eldest daughter, to return to Belgium, whence her father’s wrath had expelled her. He also authorized Leopold’s youngest daughter, Princess Clementine, to marry Prince Victor Napoleon—a love romance which her father had sternly opposed. King Albert quickly gave proof of his genuine interest in the welfare of the people, in their labor and their pleasures; in the sympathetic encouragement he extended to art, literature, science and industry—all subjects treated with contemptuous indifference by his predecessor. He reduced the royal ceremonials and etiquette to their lowest expression; with his consort he moved among his people with an easy, unpretentious friendliness, qualified by a natural modesty almost akin to bashfulness. He abolished Leopold’s custom of driving through the streets surrounded by loaded rifles and pistols. The success of his endeavors to win public confidence was not, however, the result of mere tactful good nature, but of deep understanding, systematic study and first-hand knowledge. He had been trained in sociology and economics by his father; as heir presumptive for 18 years (since the death of his elder brother in 1891) he strove to learn facts for himself regarding the life and labor of the people. With this object he worked in the mines, drove railway engines and was mixed with the working classes in all their activities. In the guise of a newspaper reporter he had visited the principal ports and shipyards of Europe, and in 1898 traveled in the United States, where he made a study of our railroad methods with the assistance of the late James J. Hill. Some months before his accession he returned from an extensive tour through the Belgian Congo and plainly opened his mind on the necessity for reforms to his royal uncle, who, it is said, never spoke to him again.

On his accession King Albert ordered the release of 2,500 prisoners detained for minor offenses. He attended the funeral of King Edward in London (May 1910) and a week later with the Queen was in Berlin and Potsdam, receiving expressions of good wishes from the German people and their ruler. As the Kaiser was indisposed at the time, the Imperial Crown Prince acted as host. In the official speeches peculiar stress was laid on the commercial relations between the two countries and the absence of any evil between Germany to annex Belgium. On 25 Oct. 1910 the German Emperor and Empress and their daughter visited Brussels. At the state banquet that night the Emperor, replying to the King’s French speech, spoke in German—which few of those present understood—and said, in conclusion, "that your Majesty’s reign may spread happiness and prosperity in your Royal House and among your people, is the wish which arises from the deepest depth of my heart, and with which I concur as the King and Queen of the Belgians. Hurrah!"

Long before he was called to the throne, King Albert had resolved to remedy a serious defect in the equipment of his country: Belgium had a great overseas trade and the port of Antwerp was the chief port in Europe, namely, Antwerp; but its merchandise was carried in foreign ships, mainly English and German, not only a source of commercial weakness, but also a political menace. The Germans were gradually acquiring a predominant influence in Antwerp, capturing the chamber of commerce, the marine insurance business, the
control of the banks, possession of the navigation companies, ship-broking, etc., etc. To alter this he had decided on a Belgian mercantile marine and during the first year of his reign a shipping scheme was put forward, by which a new service to South America and one to the Congo was established with a capital of $2,000,000, of which $800,000 was supplied by the Woermann Line of Hamburg and the British Elder-Dempster Company. In 1911 two new steamer services were started to Brazil — from Ghent to Rio Grande do Sul and from Antwerp to Brazilian and River Plate ports. Despite labor troubles, election riots and political strife, King Albert and his government introduced a number of useful reforms, including free and compulsory education, equal rights for the Flemish and French languages, and a scheme for the reorganization of the army.

The great world conflict turned the eyes of the world upon the little kingdom and its monarch; the tragedy of Belgium became the central constellation of tragedies. In a few days Albert I was a king without a country. Only four and a half years earlier he had uttered these words in Brussels: "Belgium is mistress of her destiny. . . . Belgium is a land happy. . . . Perhaps the first vision of coming disaster was conveyed to King Albert as early as November 19, by no less a person than the German Emperor himself, in an interview at which von Moltke, chief of the General Staff, was also present. The report of that interview first saw the light in the French Yellow Book published in December 1914 (see War, European — Diplomatic History). Thus the year before the war King Albert knew that the storm would ere long burst over his country, for von Moltke had prophesied to him the "irresistible enthusiasm with which the whole German people will be carried away when that day comes." Though he had no passion for military glory, though all his hopes centred in the commercial and industrial development of his country, King Albert unhesitatingly rejected the German demand for a free passage through Belgium and mustered his forces to resist invasion. He had studied the art of war with the same thoroughness that he had all his tasks; training began at the age of 17. Unfortunately, the army reorganization was barely half completed when the challenge came. German troops were already on Belgian soil when he made a "supreme appeal" for the diplomatic intervention of Great Britain. At 7 o'clock the same night the British ambassador in Berlin presented the ultimatum. The heroism of the Belgians and their King was not in vain; their spirited resistance held the avalanche long enough to enable the French and British to complete their mobilization and preparations for the victory of the Marne. After the fall of Antwerp the Belgian government withdrew to Le Havre, France (13 Oct. 1914). During the war Albert shared all the dangers of the field with his heroic army, defending the remnant of his kingdom, a corner of West Flanders. See War, European.

ALBERT, First Duke of Prussia, and the last Grand Master of the Teutonic Order, son of Frederick, Margrave of Ansbach and Baiersficht, and grandson of Albert Achilles, Elector of Brandenburg: b. 17 May 1490; d. 20 March 1568. He was educated under the care of Archbishop Hermann of Cologne. He accompanied Maximilian I in his expedition against Venice. In 1511 he was chosen by the Teutonic Knights grand master of their order. Being the son of Sophia, the sister of Sigismund, King of Poland, and descended from one of the leading German families, the Knights hoped by his means to be freed from the feudal superiority of Poland and placed under the protection of the empire. Being recognized by Poland he proceeded to Königsberg and assumed the government in 1512. He refused the oath of allegiance to Poland, which the previous grand master had evaded, and prepared for resistance. In 1520, after protracted negotiations, Sigismund attempted to enforce submission by an invasion of Poland. The contest was without decisive result and in the following year a truce of four years was agreed to at Thorn. Albert appeared before the Imperial Diet at Nuremberg as a German prince of the empire to solicit the aid of the other princes in his struggle against the Pope. He failed in this object and soon after espoused the cause of the Reformation. In order to preserve his possessions from becoming a prey to Poland, he, at Luther's advice, had himself proclaimed secular Duke of Prussia and placed himself under the sovereignty of Sigismund. He earnestly sought to promote the welfare of his duchy, established the ducal library, founded the University of Königsberg in 1544 and gathered about his person many literary men. In 1527 he married Dorothea, daughter of Frederic, King of Denmark. The latter years of his reign were troubled with many intrigues, foreign and domestic; in 1532 he was put under the ban of the empire, but succeeded in transmitting his succession to his son. Consult Lohmeyer, Herzog Albrecht von Preussen (Dantzig 1890) and Tschakert, Herzog Albrecht von Preussen (Halle 1894).

ALBERT I, Margrave of Brandenburg, surnamed the Bear, from his heraldic emblem, was the son of Otto the Rich, Count of Ballenstädt; d. 1170. As Marquis of Lusatia he served the Emperor Lothaire with credit in his war with Bohemia. In 1138 the Emperor Conrad conferred on him the duchy of Saxony, of which he had deprived Henry the Proud. This led to a war with Henry, in which Albert was deprived of Brandenburg, but was restored by an armistice negotiated by the ecclesiastical electors. On the death of Henry (1139) he resumed the title of Duke of Saxony. A combination was then formed against him, which, in spite of the favor of the Emperor, reduced him to extremities. Peace was concluded in 1142. Albert resigned Saxony and Brandenburg was raised to an immediate fief of the empire, at the same time by inheritance from Pribislas, a Vandal king who had taken his name in baptism, the country between the Elbe and the Oder. He made his new possessions a fief of the empire and in order the better to guard them removed his residence to Brandenburg.
ALBERT, KING OF BELGIUM
In 1148 he led an expedition into Pomerania and in the following year induced the duke of that country to embrace Christianity. In 1150 he was raised to the electoral dignity. In 1157 he made a third expedition against the Wends, driven out of their country and colonized it by agriculturists from Germany, Holland and Zealand. In 1164 he went on a crusade to the Holy Land. Another war broke out between him and Henry, Duke of Saxony, which was terminated by the mediation of the Emperor Frederick I. In 1169 Albert remitted his estates to his son. The origin of Berlin, Köln, Aachen on the Elbe and other towns is attributed to the colonies founded by him. Consult Heinemann, 'Albrecht der Bär' (Darmstadt 1873).

ALBERT I, Duke of Austria, and afterward Emperor of Germany: b. 1248; d. 1 May 1308; son of Rudolph of Hapsburg, who had a short time before his death attempted to place the crown on the head of his son. But the electors, tired of his power and emboldened by his age and infirmities, refused his request and chose as his successor the King of the Romans (the title of the designated successor of the Emperor). After the death of Rudolph, Albert, who inherited only the military qualities of his father, saw his hereditary possession, Austria and Styria, rise up in rebellion against him. He quelled by force this revolt which his avarice and severity had excited; but success increased his presumption. He wished to succeed Rudolph in all his dignities, and without waiting for the decision of the Diet seized the insignia of the empire. This act of violence induced the electors to choose Adolphus of Nassau Emperor. The disturbances which had broken out against him in Switzerland, and a disease which deprived him of an eye, made him more humble. He delivered up the insignia and took the oath of allegiance to the new Emperor. Adolphus, after a reign of six years, lost the regard of all the princes of the empire, and Albert was elected to succeed him. A battle ensued near Geisheim, in which Adolphus fell by the hand of his adversary. The last barrier had fallen between Albert and the supreme power, but he was conscious of having now an opportunity of displaying his magnanimity. He voluntarily resigned the crown conferred on him by the last election, and as he had anticipated was re-elected. His coronation took place at Aix-la-Chapelle in August 1258, and he held his first Diet at Nuremberg with the utmost splendor.

But a new storm was gathering over him. The Pope, Boniface VIII, denied the right of the electors to deprive Adolphus of the imperial dignity and bestowed it upon one who had caused the death of the legitimate sovereign. He accordingly summoned Albert before him to ask pardon and submit to such penance as he should dictate; he forbade the princes to acknowledge him and released them from their oath of allegiance. The archbishop of Mainz from a friend became the enemy of Albert and joined in the conspiracy against him. On the other hand, Albert formed an alliance with Philip le Bel of France, secured the neutrality of Saxony and Brandenburg, and by a sudden irruption into the electorate of Mainz forced the archbishop not only to renounce his alliance with the Pope, but to form one with him for the five ensuing years. In April 1301 Boniface forbade all submission to Albert until he would go to Rome and repair his crimes. The next year Albert entered into negotiations with the Pope, in which he again showed the duplicity of his character. He broke his alliance with Philip, acknowledged that the Western Empire was a grant from the last of the emperors, that the electors derived their right of choosing from the see of Rome and promised to defend with arms the rights of the Pope whenever he should demand it, against any one. As a reward Boniface excommunicated Philip, proclaimed him to have forfeited his crown and gave the kingdom of France to Albert. Philip in revenge annoyed and persecuted the Pope.

Albert was engaged in unsuccessful wars with Holland, Zealand, Friesland, Hungary, Bohemia and Thuringia. While preparing to revenge a defeat which he had suffered in Thuringia he received the news of the revolt of the Swabians and saw himself obliged to direct his forces thither. The Princes of Schwyz and Uri had broken out 1 Jan. 1308. Albert had not only foreseen this consequence of his oppression but desired it, in order to have a pretense for subjugating Switzerland entirely to himself. A new act of injustice, however, put an end to his ambition and life. Suabia was the inheritance of John, the son of his younger brother Rudolph. John had repeatedly asserted his right to it, but in vain. When Albert set out for Switzerland John renewed his demand, which was contemptuously rejected by Albert. John, in revenge, conspired with his governor, Walter of Echenbach, and three friends against the life of Albert. The conspirators took advantage of the moment when the Emperor, on his way to Rheinfelden, was separated from his train by the river Reuss, and assassinated him.

ALBERT, Peter Paul, German archivist: b. Steinbach, Baden, 29 Jan. 1862. He was educated at the universities of Freiburg, Würzburg and Munich. In 1895 he was assistant archivist of the Grand-Duchy of Baden Archives in Karlsruhe and in 1897 became archivist at Freiburg-im-Breisgau. He is a member of the Baden Historical Commission and has published: (Matthias Düring) (1899); 'Geschichte der Stadt Radolfzell' (1896); 'Steinbach b. Mudau' (1899); 'Baden Zwischen Neckar und Main' (1901); 'Das Geschichtsschreibung der Stadt Freiburg' (1912); 'Schloss Burgheim am Rhein' (1904); 'Die Schiller von Herder' (1905); 'Die Ursprungs-Mosbach-Mudau' (1906); 'Die Schneeburg ob Ebringen' (1909); 'Der Meister E. S.' (1910). He is editor of the Freiburger Münsterblätter and the Freiburger Zeitschrift für Geschichte—Altertums- und Volkskunde.

ALBERT. See ANKE.

ALBERT COAL. See ALBERTITE.

ALBERT LEA, Minn., county seat of Freeborn County, on the Chicago, M. & St. P., the Burlington, C. R. & N. and the Minneapolis & St. L. railroads, about 100 miles south of St. Paul and 10 miles north of the boundary of Iowa. The presence of many lakes and ar-
tesian wells of chalybeate waters make the
city and neighborhood a popular summer re-
sort. It is the market town for a large agri-
cultural and dairy region, is noted for its
State creameries and has considerable
manufacturing interests. It is the seat of a Pres-
byterian college for women and a Lutheran
Academy. Pop. (1910) 6,192; (1916) 12,000.

ALBERTA, ál-bár'ta, Canada, a north-
western province. A part of the present area
of the province was in 1882 given territorial
status and called Alberta in honor of H. R. H.
Princess Louise Caroline Alberta, daughter of
Queen Victoria and wife of the Marquis of
Lorne, 9th Duke of Argyle, at that time Gover-
nor-General of Canada. The country was
sparsely settled, what white population there was
being chiefly in the south and engaged in
ranching. For upwards of 15 years little
change took place, but subsequent to 1896 a
vigorous immigration policy was instituted and
settlers flowed in. By the autonomy acts of
1905 the old territories stretching from the
western boundary of Manitoba to the Rockies
were erected into the two provinces of Sas-
katchewan and Alberta. The boundaries given
to the latter were the 49th parallel—the United
States frontier—to the south, the 60th parallel
to the north, the 4th meridian to the east and
British Columbia to the west. This vast area of
253,540 square miles is 750 miles from
north to south and at its broadest part
400 miles from east to west. Though some-
what smaller than Texas, Alberta is more that
twice the size of Great Britain and Ire-
land and considerably more extensive than
France or Germany.

Physical Features.—Alberta is a vast
plateau ranging from 1,000 to 3,500 feet above
sea-level. The land lies higher in the south
and falls away toward the north. The coun-
try is well watered, both the great Mackenzie
and Saskatchewan river systems taking their
rise within the province. The Saskatchewan
system, with its north and south branches,
drains Alberta approximately from the Ed-
more district to the American boundary,
while the northern half of the province is
watered by the various rivers which ultimately
combine to make up the Mackenzie. The
chief streams flowing into the south branch of
the Saskatchewan are the Belly, Old Man, Saint
Mary’s, Bow and Red Deer, while into the
north branch debouch the Clearwater, the Bat-
tle, the Sturgeon, the Vermilion and other
smaller streams. The northern section of
the province is drained by three great waterways,
the Athabasca, Peace and Hay, which, united
on issuing from Great Slave Lake, become the
Mackenzie. Lakes also abound, especially in
the northerly part of the province. Among
the more important of these may be men-
tioned Gull, Buffalo, Wabamun, Saint Anne, La
Biche, Claire and Lesser Slave Lake. Some of
these are considerable bodies of water.
Clare and Lesser Slave cover respectively 405
and 480 square miles and Lake La Biche has
an area of over 100 square miles. Most of
these lakes teem with fish—the whitefish of
the northern lakes being much esteemed as an
article of diet. Mention should be made of
two small lakes that enjoy a world-wide reputa-
tion for beauty—Lake Louise in the Bow
Pass through the Rockies and Lake Malighe
in the Yellowhead Pass. While the southern
part of the province is characterized by vast
treeless prairies, the central section has been
aptly described as a park-like country, prairie
and wooded districts being intermingled. As
one goes farther north, prairie again becomes
predominant.

Climate.—Alberta has a continental climate,
warm in summer and cold in winter. In the
former season the thermometer usually
registers 90° during the daytime, but the nights
are always cool. The distribution of heat
varies little as regards latitude. At Fort Vermi-
lion (lat. 58° 29') the mean summer tempera-
ture is 61°; at Dunvegan (lat. 55° 56') 60°; at
Edmonton (lat. 53° 33') 61°; at Calgary (lat.
51° 2') and Cardston (lat. 49° 12') 59°. This
equality of heat seems the more extraordinary
when it is remembered that Fort Vermilion
and Cardston with two degrees difference in
mean summer temperature are in a northerly
and southerly direction roughly 700 miles apart.
It may be pointed out in this connection that
owing to its northerly latitude the summer
days are very long in Alberta. These are ac-
companied with a correspondingly large amount
of sunshine, which facilitates the growth of
field crops and vegetation of all kinds. At
midsummer there are 18 hours of sunshine.
In winter the weather is cold, but as the at-
mosphere, owing to the altitude, is dry, low
temperatures are easily supported. In southern
Alberta the winters are much more severe
by the warm chinook winds which, crossing the
mountains from the Pacific, bring in their train
periods of extremely mild and genial weather.
Alberta is a region of light rainfall. The sub-
joined table indicates the average precipitation
in the various months:

Though the foregoing figures yield only
23.71 inches for the year, it will be noted that
of this total 13.87 inches or 58 per cent comes
during the growing season and the crops are
thus amply supplied with necessary moisture
when it is most needed. In the southern por-
tion of the province snow falls during the win-
ter but soon disappears; in the more northerly
section the snowfall varies in depth from six to
18 inches and remains on the ground from the
beginning of December till the end of March.

Soil.—The soil of Alberta consists, gen-
erally speaking, of a marly clay subsoil over-
laid with a black or chocolate-colored mould.
The latter, the product of ages of decayed
vegetable matter, varies from six inches to
several feet in depth. The combination results
in a soil capable of storing moisture and at
the same time of extraordinary fertility.

Industries.—The chief industry is agricul-
ture. The immense crops returned by the
virgin land of Alberta have too often caused
the farmer to devote himself exclusively to
grain growing and to neglect stock. With the
establishment however, of extensive packing
plants and resultant steady markets, increased
interest is being taken in mixed farming, for
which Alberta is admirably fitted. The area
under crop and the production of cereals are
annually rapidly increasing. In 1900 the acreage of spring and autumn wheat was 30,361 and the product 583,806 bushels; in 1905 the acreage was 107,527 and the product 2,306,524 bushels; in 1910 the acreage was 592,960 and the product 7,904,520 bushels; in 1915 the acreage was 1,065,436 and the product 30,088,658 bushels. In 1900 the oat crop amounted to 2,625,581 bushels; in 1905 the return was 9,514,180 bushels; in 1910 the yield rose to 12,158,530 bushels and in 1915 with an acreage of 1,570,596 sown to oats the harvest totalled 91,852,704 bushels, averaging 57.66 bushels to the acre. The acreage of barley in 1915 was 374,062, and from this area 12,761,187 bushels were garnered. Flax in 1915 amounted to 569,762 bushels, the land under crop being 41,243 acres. In 1915 there were in the province 183,974 milk cows and 660,000 other cattle. Dairy farming is rapidly on the increase and excellent markets, both domestic and export, have been developed for dairy products. The production of butter for the year ending October 31, 1915, showed an increase of 2,000,000 pounds over the previous year. Much attention has been paid to the breeding of horses and with the introduction of such standard strains as the Clydesdale, Percheron, Hackney, Shire, Suffolk and Belgian the standard of horseflesh has reached a high pitch. In 1915 there were 544,772 horses in Alberta. The growing of sheep, both for slaughter and for the wool crop, has proved profitable. The number of sheep in 1915 in Alberta was 238,579. The raising of swine has also in recent years yielded handsome returns. Extensive packing plants affording steady markets are in operation in Edmonton and Calgary.

As has been said, the bulk of the precipitation in Alberta comes at the growing time and provides ample moisture for the crops. This remark applies to by far the greater part of the province, but there is a dry area in the southern section—particularly the region lying between the cities of Medicine Hat and Calgary and Lethbridge. The situation in regard to this section is not that there is inadequate rainfall, but that the rainfall cannot confidently be depended upon and recourse has been had to irrigation schemes as a species of insurance so that the farmer may be always sure of his crop. The most ambitious irrigation project is that of the Canadian Pacific Railway, which when complete will supply water to a block of land of 3,000,000 acres adjacent to the company’s right-of-way.

While Alberta is obviously not distinctly a lumber country, still the forest resources are very considerable. The chief merchantable timber is spruce, of which heavy stands are found here and there, especially in the northerly part of the province. The forest reserves of Alberta cover 26,112 square miles. Of this vast area, nearly 13,000,000 acres lie along the eastern slope of the Rocky Mountains and extend in a northwesterly direction some 450 miles from the international boundary. Under the inspiration of the Forestry Branch and the Dominion Commission of Conservation, intelligent measures are being enacted for the conservation of provincial forests. In 1912 the timber cut was approximately 50,000,000 feet. Of this 90 per cent was spruce. The remainder was made up of small quantities of pine, poplar, Douglas fir and tamarack.

Minerals.—Alberta is known to contain large deposits of minerals. Indications of petroleum have been found at many far-scattered points. Hitherto, however, only one region—that to the south of Calgary—has actually produced oil. Natural gas is found in large quantities in the Medicine Hat—Bow Island district and is piped into the city of Calgary. At Pelican rapids on the Athabasca River natural gas exists but owing to there being no developments of any size it has not yet been utilized. A new gas field has recently been discovered at Viking on the Grand Trunk Pacific Railway east of Edmonton. Several wells have been successfully sunk and it is expected that Edmonton will shortly be supplied with natural gas from this field. At McMurray on the Athabasca River are immense deposits of tar sands. The commercial value of these, whether for the paving of roads or for highly valuable extractive matter which may be wrested from them by chemical processes, is a question undergoing investigation in the laboratory. Other minerals are known to exist but owing to lack of transportation or other difficulties have not yet been developed. It remains to speak of coal, the one mineral industry whose exploitation has already assumed substantial and permanent form. Very wide areas of the province are underlain with coal. Anthracite is mined near Banff. Extensive deposits of bituminous coal, an excellent steam and coking coal, are found in the Crowfoot Pass as well as in the Palliser, Costigan and Bighorn fields. The commonest coal is lignite, and of this inexhaustible quantities occur. According to the report of D. B. Dowling submitted to the Geological Survey in 1909, coal underlies nearly 17,000 square miles of territory and the total quantity is estimated at upward of 90,000,000-000 tons. The production of coal is steadily increasing. Two hundred and eighty thousand tons were mined in 1901, while in 1914 the number of collieries operating was 264 and the production of coal had risen to 3,821,739 tons.

Transportation.—Three transcontinental railway lines traverse Alberta from east to west. The pioneer line, the Canadian Pacific, crosses the province in the southerly section. The main line running through Medicine Hat and Calgary ascends the valley of the Bow and threads the Kicking Horse Pass on its way to the Pacific coast. Leaving the main line at Medicine Hat, the Canadian Pacific Company also operates a line connecting Medicine Hat with Lethbridge, and crossing the mountains by way of the Crownest Pass, proceeds toward tidewater. Besides these through lines the company has constructed a complex system of branch lines. The chief of these are the line running north and south and connecting Edmonton with Calgary and that running east from Edmonton and giving the latter city direct touch with Winnipeg. The Canadian Pacific continues steadily its policy of expansion and during the decennial period, 1905-15, this company’s mileage in Alberta increased from 1,000 to 1,900. In 1906 a rival railway, the Canadian Northern, appeared on the scene laying down that year 178 miles of steel. In 1909 and the following years, encouraged by liberal finan-
cial support from the provincial legislature, the Canadian Northern carried out an ambitious program of construction. In 1915 the construction work in Alberta had risen to 1,000 miles. In this same year the Canadian Northern Railway transcontinental line following the valley of the North Saskatchewan, and connecting Edmonton via the Yellowhead Pass with Vancouver, was also put into operation. In 1908 the Grand Trunk Pacific Railway, the transcontinental, began to build in Alberta. With assistance from both the Dominion and provincial governments, this company's system steadily grew. In 1914 the main line connecting Winnipeg, Edmonton and Prince Rupert, was opened to traffic. At the close of 1915 the Grand Trunk Pacific Company was operating 707 miles of railway in the province. Apart, however, from the line running north from Edmonton some 90 miles to Athabasca, the Pr inconsistency of the vast system of northern navigable waterways. Under the name of the Alberta and Great Waterways, this group is also engaged in the building of a line in a north-easterly direction from Edmonton to McMurray on the Athabasca River. At this point great mineral resources will be made available and connection given also via the Athabasca River with navigable streams and lakes leading to the Mackenzie and thence to the Polar seas. The total mileage of railways in the province of Alberta at the close of 1915 was 4,423 miles—showing an average annual increase for the decennial period of 323.2 miles.

Population. —The population of the province has in large years shown rapid growth. According to the Dominion Census of 1911, it totalled 73,022. In 1911 official figures gave a return of 374,663. The population according to census of 1916 is 496,525. In recent years heavy immigration has taken place, especially from the British Isles and the United States. Settlers in considerable numbers have also come into the province from Germany, Austria-Hungary and the Scandinavian countries. The census of 1911 shows the chief religions to be represented as follows: 68,381 Pars, 20,314 Presbyterians, 62,621 Roman Catholics, 61,844 Methodists, 55,628 Anglicans, 43,311 Lutherans, 19,491 Baptists, 18,149 Greek Church, 2,682 Congregationalists, 1,524 Mennonites, 1,207 Jews. Numerous minor varieties of religious faith are also represented.

Education.—Education is by law free and compulsory. Owing, however, to difficulties arising from rapid settlement and imperfect transportation, it has proved neither always wise nor always possible rigidly to enforce compulsory attendance at school. Any section of the province may be erected into a school district provided (1) it does not exceed four miles in length or breadth; (2) it contains four persons liable to assessment and eight children between the ages of 5 and 16. The number of schools down to the close of the year 1914 was 2,027 and the number of children enrolled 89,910. All schools are inspected by government officials and the annual examinations in the upper grades are conducted directly by the provincial department of education. The school system is supported by direct taxation and by grants in aid made by the provincial government. By the terms of the British North America Act, a certain percentage of the Crown lands was set apart for the endowment of public education. In Alberta, sections 11 and 29 in every township are designated for this purpose. The money accruing from the sale of these lands is held by the Dominion government in trust for Alberta and the income paid to the province for the support of the school system. For the training of teachers two normal schools have been established—one at Calgary and one at Edmonton. Education in manual arts, domestic science and vocational training generally is provided for in the Institute of Technology and Manual Arts in Calgary. In 1908 the University of Alberta was founded in Edmonton and occupies a site of 258 acres fronting the Saskatchewan in the city of Edmonton. It is well equipped with buildings and laboratories. There are in operation faculties of arts and sciences, applied science, medicine, law and agriculture, and schools of pharmacy, accountancy and dentistry. The enrolment of students in 1915-16 was 418. Nowhere perhaps in America has professional education been brought so completely under direct and central public control as in Alberta. This has been accomplished by making the University of Alberta on behalf of the province responsible for the conduct of the licensing examinations of practically all the professional societies.

History and Government.—The history of Alberta may be summarized in a word or two. It has consisted largely in the efforts of the government to keep pace in the provision of educational and transportation facilities with the tide of settlement pouring into a new country. Buildings, the encouragement of methods of farming suited to the province, the organization of the country generally—in the record of these efforts consists the history of Alberta since the province came into being. The governmental system of Alberta resembles that of most of the Canadian provinces. Representing the Crown there is a lieutenant-governor appointed from Ottawa, a single popular chamber, known as the legislative assembly, of 55 members elected on a single vote. The executive power lies in the hands of a cabinet of seven members, who must hold seats in the legislature and are responsible to it. The Liberal party has been in power since the Autonomy Act of 1905. The first premier was the Hon. A. C. Rutherford, who as the result of a political crisis was succeeded in 1910 by the Hon. A. L. Sifton.

Chief Cities and Towns.—Edmonton, the provincial capital and seat of the provincial university, is situated on both banks of the North Saskatchewan. The city has handsome public buildings, is a very important railway centre and has a population of 53,846. Calgary is a substantial and prosperous
manufacturing and commercial city located at the confluence of the Bow and Elbow rivers and commanding a beautiful view of the Rocky Mountains. The population in 1914: 9,514. Lithium, parasite, bales, and Medicine Hat, population 9,272, are busy industrial communities. Other important towns are Red Deer, Wetaskiwin, Lacombe, Macleod, Camrose, Stettler, Olds, Cardston, Vegreville, Vermilion and Peace River.

William A. R. Kerr, Dean of the Faculty of Arts and Sciences, The University of Alberta.

Alberti, al-behr-te, Leone Battista degli, Italian architect, painter, poet, musician and philosopher: b. Venice, 16 Feb. 1404; d. Rome, April 1472. Excelling in physical and social accomplishments, a man of most attractive personality, master of almost all the arts, he ranked equally high as dramatist, poet, philosopher, and was one of the best of contemporary organists. While his essays on painting and sculpture are greatly admired, his most important work is De Re Aedificatoria (1455), which was freely translated into other languages. He was architect to Pope Nicholas V, and designed many fine edifices in different cities, notably the Church of Sant' Andrea at Mantua, and the fine church of San Francesco at Rimini. Consult Manzini, M., Vita di Alberti (Florence 1882).

Albertinelli, al-behr-te-nil-le, Marotto, Italian artist: b. Florence, 1474; d. there 1515. He was fellow-pupil, friend and partner of Fra Bartolommeo until the latter's retirement into a monastery. His pictures, ranking among the finest of the Renaissance period, include 'The Visitation of the Virgin' (1503), his masterpiece in the Uffizi Palace; a 'Holy Family', in the Pitti Gallery, and an 'Annunciation' (1510), in the Florence Academy.

Albertite, or Albert coal, a pitchlike mineral of brilliant jet black color first discovered by Henry W. Eskildon and other mining engineers in Albert County, New Brunswick. Like the district, it was named after Albert, Prince Consort to Queen Victoria. Albertite is found in the lower carboniferous group, consisting of red sandstones, green marls and beds of fossiliferous limestones accompanied by gypsum. It is not a true coal and is very much lighter in weight per bulk, compared with ordinary coal. It ignites freely from a match and burns like a candle, leaving a fine, almost insalvable ash. It analyses 82.67 per cent of free carbon, 9.14 per cent oxygen and nitrogen, 8.19 per cent. Albertite has sold at $45 per ton, and is used for enriching gas, in the preparation of fine varnishes, etc.

Albertus Magnus, Count of Bollstadt, German scholastic philosopher: b. Langen, Suabia, 1206; d. Paris, 25 Nov. 1280. He was educated principally at Paris, where he was instructed in the writings of Aristotle. In 1223 he joined the Dominican order and studied theology in the houses at the order at Bologna and elsewhere. He was appointed lecturer at Cologne, and later taught at Regensburg, Freiburg, Hildesheim and Strassburg. Thomas Aquinas was his pupil at Cologne. He went to Paris in 1245, received the degree of doctor and taught there with great success. He was appointed German Provincial of the Dominicans in 1254 and fulfilled the duties of the office with great care and efficiency, instituting many reforms in the monasteries and defending the mendicant orders against the attacks of the University of Paris. At this period he also answered the errors of Averroes, the Arabian philosopher. In 1260 he was appointed bishop of Regensburg by Pope Alexander IV, but resigned this office in 1263. He spent the remainder of his life in preaching throughout Bavaria and adjoining districts; in 1270 he preached the 8th Crusade in Austria. He attended the council of Lyons in 1274, and soon after at Paris publicly defended the orthodoxy of his former pupil, Thomas Aquinas. His great literary activity is attested by his works (published in 21 folio volumes by Pierre Jamy, Lyons 1651, and reproduced by the Abbé Borgeot, 36 vols., Paris 1890). He was the most widely read and most learned man of his time. He was the greatest student of Aristotle up to his time. His chemical and mechanical knowledge was remarkable in his age and brought upon him the imputation of sorcery. His best known works are 'Summa de Creaturis' and 'Summa Theologiae.' Consult Sigbart, J., 'Albertus Magnus, sein Leben und seine Wissenschaft' (Regensburg 1857; English trans. by Dixon, London 1876), and Erdman, J. E., 'History of Philosophy' (Vol. I, London 1890).

Albi, al-beh, France, city, capital of the department of Tarn, 48 miles by rail northeast of Toulouse, built on a height rising nearly 600 feet above the river Tarn. The fortress cathedral church of Saint Cecilia, dating from 1277 to 1512 and the 14th century fortress palace of the archbishop, are the most notable buildings. Albi as the home of the Albigensian Cathari of the 13th century suffered severely during the religious wars. A large agricultural trade is carried on and there are extensive manufactories of brick. Pop. 25,000.

Albina, Iowa, city and county-seat of Monroe County; 65 miles southeast of Des Moines, on the Chicago, Burlington and Quincy, the Wabash, the Minneapolis and St. Paul and other railroads. Considerable quantities of coal are mined in Monroe County and the city has a large trade in this commodity and also in the grain, livestock and other agricultural products of the district. Its industrial establishments consist of a telephone factory, metal works and a packing plant. Pop. 5,342.

Albicore, or Albacore. See Tunny.

Albigenses, al-beh-zen-say, a religious sect, coming first into prominence in the 12th century, and taking its name from Albi, their principal stronghold. What their doctrines were has not been determined, as no formal statement of them was ever drawn up. It appears that the Albigenses held beliefs similar to those of the Patarins in Italy, the Bulgarians in France and other similar sects. They styled themselves Cathari the Pure and traced their doctrines to the Manichean sect known as Paulicians, that settled in Bulgaria, whence their tenets spread to France. They taught the doctrine of the Manicheans, that there are two opposing creative principles,
one good, the other evil; the invisible word proceeding from the former, the body and all material things from the latter. Their teachers assumed a great simplicity of manners, dress and mode of life. They inveighed against the vices and worldliness of the clergy, and there was sufficient truth in their censures to dispose their hearers to believe what they advanced and reject what they derided. They added that the New Testament, said that infant baptism was useless, and denied marriage to the 'perfect' as they called their more austere members. (Addis and Arnold's 'Catholic Dictionary').

On the other hand, the license permitted to the imperfect gave rise to so much fanaticism and grave social and moral disorders as to threaten the destruction of Christian civilization in the heart of France. They had increased very much toward the close of the 12th century in the south of France, about Toulouse and Alba, and in Raymond, Count of Toulouse, they found a patron and protector. Innocent III, after trying in vain to reform the abuses prevalent among them, was so incensed by the assassination of the papal legate, Peter of Castelnau, in 1208, that he proclaimed a crusade against them, and was supported by the King of France.

An army was accordingly collected, large numbers of those composing it being mere mercenaries and adventurers brought together by the hope of plunder rather than by zeal for the Catholic faith. The chief leader was Simon de Montfort, father of the well-known Earl of Leicester. Raymond's territories were ravaged, and in 1209 the crusaders took Beziers by storm and put a number of the inhabitants to the sword. Simon de Montfort was equally severe toward other places in the territory of Raymond and his allies, of whom Roger, nephew of Raymond, died in a prison and Peter I, King of Aragon, in battle. The lands taken were presented as a reward for his services.

Simon de Montfort, who, however, was killed at the siege of Toulouse in 1218. When Innocent III heard of the cruelties of the invading armies he recalled his legate Milo for his weakness in not restraining Simon and restored to Raymond the title of Count. But, in 1218, however, Raymond once more espoused the cause of the Albigenese. He died in 1222, under excommunication, and his son, Raymond VII, was obliged to defend his inheritance against the legates and Louis VIII of France, who fell in 1229 in a campaign against the Albigenese. After thousands had fallen on both sides a peace was made in 1229 by the terms of which Raymond was released from the penalties in consideration of a large tribute. He ceded Narbonne, with several estates, to Louis IX, and made his son-in-law, a brother of Louis, heir of his other lands.

ALBINISM, a condition in which there is a congenital absence of pigment in the hair, eye and skin. Animals so affected are albinos. Albinism is also present in the flowers of many if not all plants, white flowers occurring among those of other color on the same plant. Albino human beings have been known among all races and all peoples, hence neither climate nor race are its causative factors. Rare in many races, it occurs frequently in others, as for instance in the Zuni and other tribes of Arizona. The most widely accepted theory is that the condition is due to an arrest of development of the pigment layers in the embryo. Affections of the eye are the most important disfigurable features for albinos.

ALBINUS (Weiss), Bernhardt Siegfried, German physician, one of the greatest anatomists of his time: b. Frankfort-on-the-Oder, 24 Feb. 1697; d. Leyden, 7 Sept. 1770. Besides editing the works of Harvey he published 'De Ossibus Corporis Humani' (1726); 'Historia Musculorum Hominis' (1734); and 'Tabulae Sceleti et Musculorum Corporis Humani' (Leyden 1747), illustrated with costly plates prepared under his own supervision. From 1718 he was professor of anatomy, and from 1745 professor of medicine at the University of Leyden.

ALBION, the earliest name by which the island of Great Britain was known, employed by Aristotle, and in poetry still used for Great Britain. The Greeks and Romans probably received the name from the Teutonic people whose language it would mean mountain-land or white-land, from the Celtic alp, alb, said to mean high or white (whence also Alps), the latter name being given to it in reference to the chalky cliffs on the coasts.

ALBION, Mich., city in Calhoun County, situated on Kalamazoo River, the Lake Shore and Michigan Southern and the Michigan Central railways, 28 miles south of Lansing. There are manufactures of farm tools, malleable iron, automobile cushion springs, automobile hubs, wire screens. Over 2,000 men are employed in the iron-working industries. It has two banks, with a combined capital of $100,000; six churches and good schools. Albion College (q.v.) is located here. Albion is governed by commission-manager form of government. Four commissioners, elected one a year for four-year terms, hire a city manager. First settled in 1831, became a borough in 1855, incorporated in 1885. Pop. (1916) 8,000.

ALBION, N. Y., the county-seat of Orleans County, on the New York Central and Buffalo, Lockport and Rochester railroads, and the Erie Canal, about 51 miles southwest of Buffalo and 31 miles west of Rochester. It has two national banks with a combined capital of $1,731,619, one high school and four public schools, public parks, a free library, several churches and five newspapers. The House of Refuge for Women is located here, and among other places of interest are the court house, surrogate and county clerk building, Pullman Memorial Church and Mount Albion Cemetery. It is a prosperous fruit and agricultural country and has important agricultural industries, three canning factories and large stone quarries. Cement, building blocks, etc., are also manufactured. The value of taxable property is $4,030,050. The city is lighted by electric light. The affairs of the town are administered by a mayor, elected triennially, and board of trustees. Albion was first settled in 1812, incorporated 1828. Pop. 6,000.

ALBION, New. See New Albion.

ALBION COLLEGE, a coeducational institution in Albion, Mich., established as a seminary under the auspices of the Methodist Epis-
copal Church in 1835, organized as a college in 1861. Professors and instructors in 1914, 26; students, 516; volumes in the library, 21,000; grounds and buildings valued at $250,000; endowment fund, $400,000; productive income, $405,000; income, $61,644. It has beside the college department a business department, preparatory department and schools of music and painting.

**ALBITE**, an important member of the feldspar group of minerals. It stands at one end of the albite-sanidine series of trichloride feldspars (see Feldspar Group). It is a sodium-aluminum silicate, NaAlSi2O6, and is often called "soda feldspar." It has perfect basal cleavage and also cleaves easily parallel to the brachypinacoid. It is brittle, breaking with an uneven to conchoidal fracture. Its hardness is 6 to 6.5, and specific gravity about 2.63. Its usual color is white, whence its name (from "albus," white), but it is occasionally gray or tinted with blue, green or red. The variety peristerite shows vitreous luster and pale blue or bluish white color similar to the "change of colors" of moonstone, which is also sometimes a variety of albite. Cleavelandite is a common lamellar variety, named in honor of the eminent mineralogist, Dr. F. Cleaveland, who died in 1858. Albite crystals present a great variety of forms, some of the simpler of which are quite similar to those of the monoclinc orthoclase, with which albite is often associated in parallel growths and intergrowths such as perthite. Twinning is common in albite than in orthoclase, and their analogy is shown by the occurrence of Carlsbad, Baveno and Manebach twins. Several other laws of twinning are, however, followed by albite, notably those known as the "albite law" and the "pericline law." Both of these types are very common and often manifest themselves by the polysynthetic twinning lamellae which are so characteristic of the plagioclase feldspars. Albite often occurs in tabular crystals and embedded masses in which this twinning is revealed by striations on the basal plane. Probably the most striking occurrence of albite is at Amelia, Va., this locality producing large groups of tabular crystals, each over a foot in length. It usually occurs in granite or gneiss, and less frequently in the crystalline schists. It is found but rarely in volcanic rocks and in limestones. Many of the most highly prized gem minerals, such as topaz, beryl and tourmaline occur in albite granite, while albite is often a guide mineral to columbite, allanite and other rarer minerals. It is also an essential constituent of diorite. There are many noteworthy localities in Switzerland, the Tyrol, Cornwall and elsewhere in Europe, while it abounds throughout the Atlantic Coast States, and is found in especially attractive specimens on amazonstone in Colorado.

**ALBOV, al̄bōv', Joseph, a Spanish-Hebrew traveler; born in Cordova, 1550; died 1390; d. 1444. His celebrated work 'Ikkarim' ('Principles'), published 1463, is described by Tanzer as a well-conceived contribution to the apologetics of Judaism'; it reduces the basic principles of Judaism to three: The existence of God, revelation, divine retribution, and is a standard popular treatise which has been of great importance in shaping Jewish thought and confirming Jewish religious faith. An English translation appears in the Hebrew Review, Vols. 1–III. Consult Back, S. ‘Joseph Albo’ (Breslau 1869); Tzunzer, ‘Die Religionsphilosophie des Joseph Albo’ (Pressburg 1860).

**ALBOIN, al̄bōin', King of the Lombards, conqueror of Italy; d. about 573; succeeded his father in Pannonia in 565; allied himself with Narses against the Ostrogoths; with the Avers against the Gepide, whose King, Cunimond, he defeated and slew, 567; invaded Italy, which he overran as far as the Tiber, and after a three-years' siege took Parma which he made the Lombard capital in 572. He had married as his second wife his prisoner, Princess Rosamond, daughter of Cunimond. At a feast in Verona he compelled her to drink out of her father's skull which he had transformed into a goblet trophy. In revenge she persuaded her paramour, Helmicis, to assassinate Alboin. Rosamond fled with Helmicis to Ravenna where, flattered by the attentions of the ex-arch Longinus, she administered poison to Helmicis. He, discovering it, compelled her to drink a similar fatal draught, and they died together. Alboin is one of the prominent figures in early German literature.

**ALBONI, al̄bōni′ Marietta, Italian contralto: b. 1823; d. 1894. At the age of 15 she made her début at Bologna as Orsini in 'Lucrezia Borgia,' and thereon to appear with distinguished success, in Paris and in Munich in 1872, was an artist of international reputation, ranking next to Malibran as the finest contralto of the period. Her range, of the most beautiful, true, equal and sonorous, extended over a compass of two and a half octaves from F in the bass to C in alt of the soprano. Her favorite parts were in the operas of her teacher and coach, Rossini, 'Gazza Ladra,' 'La Donna del Lago,' 'Demetri' and 'Cenerentola.' She appeared in the United States on a professional tour in 1852, and for over a year sang in opera, oratorio and concert in the principal cities. She married Count Pepoli, who died in 1866. In 1877 she married M. Zieger, a French emigre, and at the age of 13 wrote a story in the form of a diary, 'The Memoirs of an Underground Lodger,' which the Peterburski Listok accepted and published. Intoxicated by that success Albov abandoned school altogether and dedicated all his efforts to the literary field. It was then that his first novel, of considerable importance, 'On the New Road' (1860), appeared and attracted general attention. A few years later (1873) he re-entered the gymnasion, finished his course, matriculated at the university and was graduated from the Faculty of Law in 1879. He took a post in the civil service only to resign a few months later. Besides the above works he wrote in rapid succession 'The
Wretches of Petrograd," 'The Dog that Ran Away,' 'In the Rear of an Army,' 'The End of an Unknown Street,' 'A Chapter from an Unfinished Novel,' 'Transport,' 'A Terrible Word,' 'The Garden of Babel' and many others. His earlier novels show the powerful influence which Dostoyevsky exercised over the young author and are distinguished by a sombre character, a youthful subjectivism and a singular autoanalysis. But in his later works (especially in 'The End of an Unknown Street'), the dark colors disappear and a warm sincerity and a bright poetry are apparent throughout. However, he has not succeeded in developing into a true artist owing to his strong inclination toward a self-created psychiatry and rough naturalism. Consult Skabiech, 'Istoryia Nov. Lit.'; Arsenyed, K. K., 'Krit. Eyudy no Russk. Liter.'

ALBRECHTSBERGER, āl'brēkts-'bērk-'er, Johann Georg, Austrian organist, composer and theorist: b. 1736; d. 1809. Of the leading masters of counterpoint, among his famous pupils were Weigl, Seyfried, Hummel and notably Beethoven, whose vagaries, however, misled his teacher to declare that young man would never turn out anything in good style.) Albrechtsberger was appointed organist to the court of Vienna in 1772 and kapellmeister of Saint Stephen's Cathedral in 1792. His fame rests less on his numerous compositions than on his valuable theoretical works: 'Kurzgefasste Methode, den Generalbass zu erlernen' (1792); 'Gründliche Anweisung zur Composition' (1818), republished in 'Generalbassschule,' edited by I. von Seyfried (3 vols., Vienna 1826); English translation by V. Novello (London 1855).

ALBRET, āl'brēt, Jeanne d', Queen of Navarre, daughter of Henry II of Navarre and Margaret of Valois (sister of Francis I of France), was the mother of Henry IV of France and a zealous supporter of the reformed religion, which she established in her kingdom. She was b. in 1528; d. 1572. She married Antoine de Bourbon in 1548, succeeded her father on the throne of Navarre and Bearn in 1555, reigned in conjunction with her husband till his death in 1562, and afterward alone.

ALBUF ERA, āl'boo-fā'ra, a lake about nine miles square near Valencia, Spain, supposed to have been excavated by the Moors. It is separated from the sea by a strip of land. The revenues from the fisheries of the lake belonged at one time to the Duke of Wellington.

ALBULA, āl'bu-lā, Swiss river in the Canton Grisons, an affluent of the Rhine, 29 miles in length, in which distance it falls over 4,500 feet.

ALBULA PASS, at the head of the Albulaw Valley, about 7,600 feet above the sea. In this pass the most direct road from the valley of the Inn to the valley of the Hinter-Rhein. A railroad now runs through it.

ALBUM, among the Romans, a board or tablet on which official notices, such as the praetor's edicts, lists of the members of public bodies, etc., were written, and which was put up on a prominent public place. The term was so called either because it was of a white material ('albus, white) or a material whitened, or because the writing on it was in white. Album is a name now generally given to a blank book for the reception of pieces of poetry, autographs, engravings, photographs, etc.

ALBUMAZAR, āl'boo-mā-zör, or ABOU-MASCHAR, Djaifar Ibn-Mohammed, Arab astronomer: b. Balkh 805; d. Wasit 885. He lived in Bagdad and wrote books of some of which have been translated in Latin. In 'De Magnis Conjunctionibus' (Augsburg 1489) the theory is advanced that the world was created when the seven planets were in conjunction in the first degree of Pisces and the prediction is made that it will come to an end when the same conjunction occurs in the last degree of Pisces. His other notable works are: 'Flores Astrologici' (Augsburg 1488), and 'Introductorium in Astronomiam' (Venice 1560).

ALBUMAN, or ALBUMIN (Latin from albus, white), a substance, or rather group of substances, so named from the Latin for the white of an egg, which is one of its most abundant known forms. The albumins enter largely into the composition of the animal fluids and solids, are coagulable by heat or pressure and are soluble in water and dilute salt solutions. The albumins are present in the serum of the blood, the vitreous and crystalline humors of the eye, the fluid of dropsy, the substance called coagulable lymph, in nutritive matters, the juice of flesh, etc. The blood contains about 7 per cent of albumen. The albumins belong to the class of simple proteins, which are nitrogenous organic substances, widely distributed in nature. They consist largely of amino acids united by their carboxyl or amino groups. These simple proteins are divided into about seven groups, albumins, globulins, glutelins, prolamines, albuminoids, fustones and prolamines. (See PROTEINS.) Consult Matthews, 'Physiological Chemistry.'

ALBUMINOID, See PROTEINS.

ALBUMINURIA, a condition characterized by the presence of albumen in the urine, indicating some disturbance of the kidney function, mild or severe. Thus there may be a functional or physiological albuminuria, following excessive exercise, such as bicycling; febrile albuminuria as a result of fever, being especially common in pneumonia, diphtheria and typhoid; haemorrh albuminuria accompanying blood diseases, lukemia, anaemia; toxic albuminuria from poisoning by lead and mercury, sphyllis, etc. The presence of an albuminuria always calls for a determination of its causation. See KIDNEYS.

ALBUNOL, āl'boon-yōl, Spain, town in the province of Granada, near the Mediterranean, on which it has a harbor, some 35 miles to the south of the city of Granada. Pop. 18,000.

ALBUQUEQUE. Alfonsa d', al'bō-kēr's, the Great, viceroy of the Indies: b. near Lisbon 1453; d. Goa, 16 Dec. 1515. The Portuguese had discovered and subjugated a great part of the western coast of Africa and were beginning to extend their dominion over the seas and the people of India. Albuquerque, being appointed viceroy of these new possessions, with a fleet and some troops landed on the Malabar coast in 1503; conquered Goa, which he made the seat of the Portuguese gov-
ernment and the centre of its Asiatic commerce; and afterward Ceylon, the Sunda Isles, the Peninsula of Malacca, and the island of Ormuz at the entrance of the Persian Gulf. When the King of Persia sent for the tribute which the princes of this island had formerly rendered to him, Albuquerque presented bullets and swords to the ambassador, saying: "This is the coin in which Portugal pays her tribute." He made the Portuguese name profusely respected among the princes and people of the East; and many of them, especially the Kings of Siam and Pegu, sought his alliance and protection. He maintained strict military discipline, was active, far-seeing, wise, humane and equitable, respected and feared by his neighbors while beloved by his subjects. His virtues made such an impression on the Indian peoples that long after his death they resorted to his grave to implore his protection against the misgovernment of his successors. Yet he did not escape the envy of courtiers and the suspicions of impostors. Soize, a personal enemy of Albuquerque, was made to supersede him as vicerey. This news reached him just as he was leaving Ormuz, and gave a severe shock to his shattered health and he died a few days later.

ALBUQUERQUE, al'bu-kér'ke, N. M., largest city of the State and county-seat of Bernalillo County; situated on the Rio Grande and the Hutchinson, Texas and Santa Fe, and the Santa Fe and New Mexico Central railroads, 56 miles in a direct line southwest of Santa Fe. It has an elevation of 4,930 feet above sea-level; is an ancient and interesting settlement, divided into the Old and New towns and is the seat of the University of New Mexico and of a government school for Indians, the latter founded in 1881, the former organized in 1889. Under the Spanish régime, Francisco Cuervo y Valdez became governor of New Mexico 10 March 1705, and he established in 1706 a town or "pueblo" to which he gave the name Albuquerque (now Albuquerque) in honor of the vicerey of New Spain, the Duke of Albuquerque (not to be confused with the Portuguese Alfonso d'Albuquerque). The church of S. Felipe, which was built almost immediately, has never been entirely destroyed, and therefore the present edifice in the "Old Town" may still claim to be its continuation (consult Prince, "Spanish Mission Churches of New Mexico," Cedar Rapids 1915). The city is renowned as a health resort, the winter climate being exceptionally good, and six large sanatoriums have been located here. Noteworthy features are the Federal building and the Harvey Indian Museum with its large and truly representative collection of Indian beliefs. The Isleta Indian pueblo is about 13 miles distant, toward the south. The last census showed that 16.3 per cent of the total value of New Mexico's products must be credited to Albuquerque. The varied industries range from mining (gold, copper, lead, silver) and truck-farming. We mention also the extensive lumber interests, railroad shops, woolen mill, Indian trading company, foundries and machine shops, flour mills and tie-preserving plant. The United States has seven manufacturing establishments of factory grade employing 1,008 persons, of whom 847 were wage earners, receiving a total of $654,000 in wages. The capital employed aggregated $1,593,000, and the output was valued at $1,914,000; of this, $1,020,000 was added by manufacture. These figures show an increase of 45.6 per cent over the year of 1909. Pop. (1910) 11,020; (1916) 20,000.

ALBURNUM, the soft white substance which, in trees, is found between the liser or inner bark and the wood and, in progress of time acquiring solidity, becomes itself the wood. A new layer of wood, or rather of alburnum, is added annually to the tree in every part just under the bark.

ALBURY, Australia, town of Goulburn County, New South Wales, at the head of navigation of the Murray River, 1,800 miles from its mouth, and by rail 380 miles from Sydney and 200 miles from Melbourne. Albury was reached by explorers in 1824 and was created a municipality in 1859. It is a sheep-raisring and farming centre, noted for its manufactures of wine, which with wool, cereals, tobacco and grapes are its staples of commerce. Pop. 6,500.

ALCÆUS, ál'kä-ú’s, Greek warrior-poet and lyricist: b. Mitylene, Lesbos, in the 7th century B.C. From 606 B.C. he served in war between the Athenians and Milesians, and in the factions of his native city, which led to his exile for a considerable period. Contemporary with Sappho he was the author of numerous martial and patriotic hymns, love lyrics, bacchalian songs, epigrams and other poems, originally collected in 10 books. They are said to have exhibited the Æolian lyric in highest perfection, but fragments only exist; one of the latest discovered with some fragments of Sappho is mentioned in the "Classical Review" (May 1902). The Alcaic metres, admired and imitated by Horace, and in modern days by Tennyson and others, are claimed to have originated with him. Consult Bergk, T., "Poete Lyrici Greeci" (Leipzig 1832); Frennel, L. R., "Greek Lyric Poets" (London 1891); Smyth, T., "Greek Melic Poets" (New York 1900); Easby-Smith, J., "The Songs of Alceus" (Washington 1901).

ALCALA, ál'ka-lá', name of seven cities in Spain, but by far the most important in Spanish history is Alcalá la Real of Toledo. Cardinal Ximenes began the first building of the University of Alcala in 1500. Francis I, in 1517, declared that the cardinal had done for Spain what it had taken many kings to do for France. It was in Alcala that the famous Complutensian Polyglot Bible was brought forth.

ALCAMENES, ál'ka-mé'néz, Greek sculptor of the 5th century B.C., pupil and co-worker with Phidias at Athens on the Parthenon. His masterpiece, now lost, was the "Aphrodite in the Garden," at Athens, presumably reproduced in the well-known statues of "Venus Genetrix."

ALCAMO, ál'ka-mo, Italy, a town of Sicily, province of Trapani, 25 miles direct southwest and 52 miles by rail, from Palermo. A Saracen town dating from the existing castle built 828; it has several interesting medieval buildings, and in the neighborhood are the ruins of ancient Segesta. Mount Piana, on the south, 2,700 feet high, affords splendid views of Castellamare Bay. Quarries of yellow marble
are worked in the neighborhood and a considerable agricultural trade is carried on. Pop. 35,000.

**ALCANTARA,** al-kánˈtə-rə, Spain, fortified town of Estremadura, on the left bank of the Tagus, near the Portuguese frontier, noted for the Roman bridge built by Trajan in 105 A.D. Of uncemented stone, 616 feet long and 190 feet high, with six arches, it was partly blown up by the British in 1809 during the Peninsular war, and also suffered in the Civil war of 1836. A ferry was used until the bridge was restored in 1860. Here in 1215, when Alcantara had been recovered from the Moors, was organized for defense the celebrated order of monk-soldiers, the Knights of Alcantara. Pop. 3,700.

**ALCANTARA,** Brazil, seaport town at the entrance to S. Marcos Bay, 17 miles northwest of Maranhao. A coating trade is carried on in salt, cotton, rice, coffee, hides and sugar. Pop. 10,000.

**ALCAZAR DE SAN JUAN,** al-kāˈzahr de sán hwˈoːn, Spain, town and important junction of the Madrid-Albacete and Madrid-Manzanares railroads, province of Ciudad Real, 48 miles northeast of Ciudad Real. In the neighborhood are large iron mines, deposits of salt and alkali, and an important trade is carried on in local manufacture of soap, daggers, powder, chocolate and wines. The Roman Alcazr dating from the 2d century around Alcazar is much of the country described by Cervantes in his immortal "Adventures of Don Quixote." Pop. 14,000.

**ALCESTIS** (438 b.c.), the earliest extant play of Euripides, is one of the most touching dramas that have come down to us from antiquity; some of the scenes, in the opinion of Racine, are incomparable. Alcestis, the daughter of King Pelias of Iolcus, married the Thessalian, Admetus, King of Pherae, for whom she offered herself as a willing substitute when Thanatos (death) came to claim her husband. Admetus tried all his friends in turn, but

---

When Alcides dies, Admetus gives himself up wholly to his sorrow and remains inconsolable, until Heracles brings her back from the tomb and restores her to her husband. The theme has also been treated in modern literatures. (Wie-land, 'Gücksoper,' Handel's 'Admeto'). (Consult Ellinger, 'Alcest in der modernen Litteratur' Halle 1885). The supernatural side of the story is barely touched upon by Euripides. The beauty of the play consists in the portrayal of the emotions; the tenderness and piety of Alcestis, her firmness of soul, the sorrow of her husband, a sincere and affectionate though mediocre man, the naïve egoism of his father, Phere, the touching farewells of the servants—all are portrayed with truth and skill. Alcestis has hardly a peer for virtue and true beauty of soul; in the poet's galaxy of noble women—Minerva, Evarine, Praxithea—she stands pre-eminent. The chorus possesses greater unity and strength than in any other Euripidean drama, with the possible exception of the 'Bacchae'; it forms an integral part of the play. The comic element in the 'Alcestis' is more pronounced than in any other Greek tragedy, primarily, perhaps, because the play was intended as a trilogy. In the saddest part of the drama the spectators behold the garrulous Heracles, sage as a philosopher, giving advice of doubtful morality to a servant in such a comical manner that even those who have been touched by the touching scenes which they have just witnessed cannot refrain from smiling. This feature is an innovation of Euripides, who frequently makes use of comic elements in the most tragic situations.

**JOSEPH E. HARRY.**

**ALCHEMIST, The.** In 'The Alchemist,' the ensuing composition of that second period of Jonson's comedy which began about 1605, we have, in Coleridge's judgment, one of the three perfect plots of all literature, revolving around characters whose very extravagancies broaden our knowledge of human nature. The first of modern critics, Jonson, making his one thing, his own work and that of his fellows, as well as the life of his times to the censure of a "pitiful method." This critical faculty in Jonson explains both the rigors of his technical codes and the note of conscious didacticism with which his work is sharpened. As an artist Jonson apprehended those who come in "rustily," those who "seek to do more than enough," who "utter all they can, however unfit." In observing his ideal of "election and mean," he clings to the unities of time, place and action. Jonson's moral passions are the outgrowths of his rugged honesty of temper. His gallery of humors varies as it goes back to one of two sides of dishonesty and pretense, the commanding side which preys upon the weaknesses of its fellows; the weaker side of guilt and sycophants. Of the two it is not difficult to see for which Jonson has the greater sympathy. The dignity of Subtle's pretensions demands and secures a dignified going-out; and Face comes off scot-free because he enters the gulls are punished without pity. The personages of such a play as 'The Alchemist' have a double value. Subtle and Dol Common, Abel Dragger, Kastrill, Ananias and Tribulation Wholesome, are figures of London streets; but they are mental abstractions as well. In combing the pressure of personality with abstract qualities no writer is Jonson's equal.

Subtle, the Alchemist, belongs to an ancient order of cheaters that had been attacked by Chaucer as well as by Lyly. Alchemy as a science was no more believed in by London than were ghosts. To Jonson it meant the pretensions of learning, cozening the avaricious and fools. Subtle is the magnificent cheater. Face belongs to a very old family of sycophants in the history of literature. Only once is a burlesque Jew of Malta brought under the sway of the cheater and revelling in the poetry of avarice. Dapper and Abel Dragger, Kastrill and the men of the church, are figures from contemporary life. The two in the play who are neither cheats nor cheated are appropriately enough Surly and Lovewit. Like Shakespeare's women Jonson's women were written for men actors. He had none of
Shakespeare's witching power for putting womanhood over through the disguise. Do]. Common, perhaps on account of her jovial masculinity, is a real character.

The main features ('The Alchemist') is indebted to 'The Mostellaria,' or 'The Haunted House' of Plautus. First acted in 1610 the play was printed in 1612, and four years later, in the folio edition of his works, Jonson protests himself against the charge of imitating 'Alchemist.' A charge which in fact Dryden brought against the play 60 years later. The part of 'Dr. Common' was played by Cooke; and Robert Armin, the famous actor of clowns, played Abel Dragger. The play has had a long and honorable stage history. Revived after the Restoration Pepys rated it far beyond Shakespeare. In the 18th century Garrick played both Dragger and Face. The play was acted as farce at Drury Lane as lately as 1787. On account of the tender sensibilities of later times it is not now accounted suitable for the stage. Editions: Gifford, W. (Vols. 1816); Cunningham, F. (9 vols., 1871-75); Mermaid Series, ed. Nicholson, B. (3 vols., 1893-94); 'Everyman's Library,' (Vols. 489, 490); Rys, E., 'Cromwell and his Times' (1912). Consulting Ward, A. W., 'A History of English Dramatic Literature' (1889); Swinburne, A. C., 'A Study of Ben Jonson' (1889); Symonds, J. A., 'Ben Jonson' (1886).

Thomas H. Dickinson, Author 'The Contemporary Drama of England.'

ALCHEMY, or ALCHEMY, the art which in former times occupied the place of and paved the way for the modern science of chemistry (as astrology did for astronomy), but whose aims were not scientific, being confined solely to the discovery of the means of indefinitely prolonging human life, and of transmuting the baser metals into gold and silver. Probably the ancient nations, in their first attempts to melt metals, observing that the composition of different metals produced masses of a color unlike either — for instance, that a mixture like gold results from the melting together of copper and zinc — arrived at the conclusion that one metal could be changed into another. At an early period the desire of gold and silver grew strong as luxury increased, and men indulged the hope of obtaining these rarer metals from the more common. At the same time the love of life led to the idea of finding a remedy against all diseases, a means of lessening the infirmities of age, of renewing youth and repelling death. The hope of realizing these ideas prompted the efforts of several men, who taught their doctrines through mystical images and symbols. To transmute metals they thought it necessary to find a substitute which, containing the original principle of all matter, should possess the power of dissolving all into its elements. This general solvent or menestras universal, which at the same time was to possess the power of removing all the seeds of disease out of the human body and renewing life, was called the philosopher's stone, lapus philosophorum, putamen philosophorum. The more obscure the ideas which the alchemists themselves had of the appearances occurring in their experiments, the more they endeavored to express themselves in symbolical language. Afterward they retained this phraseology to conceal their secrets from the uninstructed. In Egypt Hermes Trismegistus was said to have left behind him many books of chemical, magical and alchemical learning. These, however, are of a later date. (See HERMES TRISMEGISTUS.) After his death alchemy received the name of the hermetic art. It is certain that the ancient Egyptians possessed considerable chemical and metallurgical knowledge, although the origin of alchemy cannot with certainty be attributed to them. Several Grecians became acquainted with the writings of the Egyptians, and initiated in their chemical knowledge. The fondness for magic, and for alchemy more particularly, spread afterward among the Romans also. When true science was persecuted under the Roman tyrants, superstition and false philosophy flourished the more. The prodigality of the Romans excited the desire for gold, and led them to pursue the art which promised it instantaneously and abundantly. Caligula made experiments with a view of obtaining gold from orpiment. On the other hand, Dio Chrysostom advised to be burned that taught to manufacture gold and silver by alchemy. At that time many books on alchemy were written, and falsely inscribed with the names of renowned men of antiquity. Thus a number of writings were ascribed to Democritus, and more to Hermes, which were written by Egyptian monks and hermits, and which, as the Tabula Smaragdina, taught in allegories, with mystical and symbolical figures the way to discover the philosopher's stone. At a later period chemistry and alchemy were cultivated among the Arabians. In the 8th century the first chemist, commonly said to be Geber, flourished among them, in whose works rules are given for preparing quicksilver and other metals. In the Middle Ages the monks devoted themselves to alchemy, although they were afterward prohibited from studying it by the popes. But there was one even among these, John XXII, who was fond of alchemy. Raymond Lully, or Lullius, was one of the most famous alchemists in the 14th and 16th centuries. A story is told of him that during his stay in London he changed for King Edward I a mass of 50,000 pounds of quicksilver into gold, of which the first rose-nobles were coined. The study of alchemy was prohibited at Venice in 1488. Paracelsus, who was highly celebrated about 1525, belongs to the renowned alchemists, as do Roger Bacon, Basilius Valentinus and many others. When, however, more rational principles of chemistry and philosophy began to be diffused and to shed light on chemical phenomena, the rage for alchemy gradually decreased, though many persons, including some nobles, still remained devoted to it. Alchemy has, however, afforded some service to chemistry, and even to medicine. Chemistry was first carefully studied by the alchemists, who whose labor and patience we are indebted for several useful discoveries, for example, various preparations of quicksilver, kermes, etc.

It is still impossible to assert anything with certainty about the possession of the philosopher's stone. Modern chemistry, indeed, places metals in the class of elements, and denies the possibility of changing an inferior metal into gold. Most of the accounts of such transmutation rest on
fraud or delusion, although some of them are accompanied with circumstances and testimony which render them probable. By means of the galvanic battery even the alkalies have been dissolved and a metallic base. The possibility of, obtaining metal from other substances which contain the ingredients composing it, and of changing one metal into another, or rather of refining it, must therefore be left undecided. Nor are all alchemists to be considered in this light. Many have labored, under the conviction of the possibility of obtaining their object, with indefatigable patience and purity of heart (which is earnestly recommended by sound alchemists as the principal requisite for the success of their labors). Designing men, however, have often used alchemy as a mask for their covetousness, and as a means of defrauding silly people of their money. Many persons even in our days, destitute of sound chemical knowledge, have been led by old books on alchemy, which they did not understand, into long, expensive and fruitless labors. Hitherto chemistry has not succeeded in unfolding the principles by which metals are formed, the laws of their production, their transformations and reappearances. The possibility of imitating this process of nature; consequently the labor of the alchemist is but a groping in the dark.

ALCIATI, al-chā’tē, Andrea, Italian jurist and poet: b. Milan, 8 May 1492; d. Pavia, 12 Jan. 1550. For many years an advocate in Milan, he treated the objects of legal science to keen criticism, and was founder of the so-called “elegant” school of law. He also wrote several antiquarian and historical essays, but his most popular work was the ‘Emblems’ (Milan 1522), epigrammatic poems on his contemporaries’ virtues and vices. Of the numerous editions of this work several are chiefly sought on account of their wood-engravings. Editions of his ‘Complete Works’ in Latin (4 vols., Basle 1546-49); (6 vols., Lyons 1560-61); (4 vols., Lyons, 1617). Consult C. Mignaut’s ‘Life of Alciati’ (Milan 1584).

ALCIBIADES, al’si-bi’dēz, son of Cleinias, an Athenian of high family: b. Athens 450 b.c.; d. 404 B.C. His father, who died a few years after his birth, had greatly distinguished himself in the Persian wars, and had taken a prominent part in the expulsion of the Peisistratidæ. Alcibiades was a relation of Pericles, who was his joint guardian along with Ariphon. He was remarkable in youth for the beauty of his person, the dissoluteness of his manners, the determination of his character, and the greatness of his abilities. He came under the influence of Socrates, who tried to lead him into the paths of virtue; but though their friendship was strengthened by mutual obligations, each having saved the other in battle, the passions of Alcibiades were too strong for advice, and little permanent effect was produced on his character. He acquired great popularity by his liberality in providing for the amusements of the people, and although guilty of many violent, extravagant and audacious acts, he had, after the death of Cleon, a political ascendency which left him no rival but Nicias. Both at first cultivated alliance with Sparta, to which Alcibiades had a hereditary partiality, but the Spartans trusting more to Nicias, he was offended, and induced the Athenians to break with Sparta and ally themselves with Argos, Elis and Mantinea (in the Peloponnesian war). In 419 he was chosen strategos, and led a small army into Thrace, to which some important operations were effected. In 415 he advocated the Sicilian war, and was chosen one of the leaders of the expedition appointed to conduct it; but before it sailed he was charged with profaning and divulging the sacred mysteries, and mutilating the busts of Hermes which were set up in public all through Athens. He was permitted to take his place in the expedition, but was recalled before his plans could be accomplished. He made his escape and went to Sparta, where he was well received. He divulged the plans of the Athenians, and assisted the Spartans to defeat them. Sentence of death and confiscation was pronounced against him at Athens, and he was cursed by the ministers of religion. He induced the Athenian dependencies of Athens to revolt, and made alliance with Tissaphernes, a Persian satrap. Soon after he abandoned Sparta and took refuge with the Persian, ingratiating himself by his affectation of Persian manners and in making and in admiring a similar affectation of Spartan simplicity. He now began to intrigue for his return to Athens, offering to bring Tissaphernes over to the Athenian alliance. His intrigue led to the establishment of an oligarchy (the Four Hundred), but they did not recall him. The fleet, however, which was stationed at Samos declared in favor of a democracy and recalled him. The revolution was effected at Athens without the return of the armament, and the banishment of Alcibiades was canceled. He remained abroad, however, for some years in command of the Athenian forces, gained several victories, and took Chalcedon and Byzantium. In 407 B.C. he returned to Athens, where all proceedings against him were canceled, but in 406, the fleet which he commanded having suffered a severe defeat, he was deprived of his command. He retired to the Thracian Chersonesus, where he made war with mercenaries on the Thracian tribes. On the establishment of the Thirty at Athens a few years before he was passed against him. He took refuge with Pharnabazus, a Persian satrap, and was about to proceed to the court of Persia when he was assassinated, probably through private revenge.

ALCINOUS, al-sin’ōos, said to have been king of the Preesians, in the island now called Corfu. See ULYSSES.

ALCIPHRON, al’si-frōn, Greek rhetorician who flourished in the 2d century of the Christian era and attained celebrity through his series of more than three hundred letters purporting to be written by the very dregs of the Athenian population, including courtesans and petty rogues. Their importance in literature is due almost wholly to the insight they afford into the social conditions at Spartan manners and morals of the day. The letters from the courtesans (hetairai) are based upon incidents in Menander’s lost plays, and the new Attic comedy was likewise drawn upon for material.

ALCIPHRON, or THE MINUTE PHILOSOPHER. See BERKELEY, BISHOP GEORGE.
ALCIRÁ, ál-thē'ra, Spain, a well-built and strongly-fortified town in the "garden" province of Valencia, on an island encircled by two arms of the river Jucar, some 25 miles from Valencia. It was founded by the Carthaginians. Pop. 22,000.

ALCMÉON, álk-mé'on, a son of Amphiaratus and Eriphyle, was one of the heroes who took part in the successful expedition of the Epigoni against Thebes. He was charged by his father to put his mother to death in revenge for her having urged her husband to take part in an expedition in which his foresight showed him he should perish. She had been gained over to urge this fatal course by a gift from Polynices of the fatal necklace of Harmonia. The matricide brought upon Alcméon madness and the horror of being haunted by the Furies, but at Psophis he was purified by Phegeus, whose daughter he married, giving her the fatal present. But the land became barren in consequence of his presence, and he fled to the mouth of the river Acheleus, the god of which gave him his daughter Callirrhoe in marriage. His new wife longed for the fatal necklace, and sent her husband to Psophis to procure it under the pretense of dedicating it at Delhi; but Phegeus, learning for whom it was really intended, caused his sons to murder the ill-fated Alcméon.

ALCMAN, álk'mán, one of the earliest and greatest of Greek lyric poets, belonging to the 7th century B.C. He is supposed to have been a native of Sardis, in Lydia, and to have been taken as a slave to Sparta and was made teacher of the state choruses. Only small fragments of his odes remain. He used the broad, homely Doric dialect. His poems were love ditties, hymns, peans, processional chants, etc. He was regarded as the founder of erotic poetry, and the bocolic poets considered him their predecessor. He was read widely even in the 2nd century A.D., but his dialect was then considered harsh. Consult Bergk, 'Poëte Lyrique Gréco' (4th ed., Leipzig 1852); Smyth, H. W., 'Greek Melic Poets' (New York 1900); and a fragment discovered in 1890 and published in 'Oxyrhynchus Papyri' (Vol. I, No. 8).

ALCMENE, or ALKMENE, álk-mé'nē, in Greek mythology, the daughter of Anaxo and Electryon, King of Mycenæ. She became the mother of Hercules through Zeus, who took the form of her husband Amphitryon. Finally Zeus bade Hermes guide her to the Islands of the Blest, where she was happily united with Rhamanthus.

ALCO, a small variety of dog, with a small head and large pendulous ears, found wild in Mexico and Peru, and also domesticated.

ALCOBAÇA, álk'o-bā'sa, Portugal, a small town in Estremadura, 50 miles north of Lisbon, at the junction of the Alcoa and Baça; is celebrated for a magnificent Cistercian monastery, the richest in the kingdom. It was founded in 1148 by Dom Alphonso I. The buildings include an early Gothic church, containing the tombs of some of the Portuguese kings, and a valuable library. Parts of the buildings are used for barracks. Pop. 1,600.

ALCOCK, ól'kōk, Sir Rutherford, diplomat: b. Ealing, 1809; d. London, 2 Nov. 1897. Educated as a physician, he served as surgeon with British troops in Spain and Portugal 1832-36; and was appointed consul at Fuchow 1844. On the way his services were requisitioned at Amoy, where, with Sir Harry Parkes, he succeeded in convincing the Chinese officials that treaty agreements were to be respected and kept. Transferred to Shanghai he showed courage and determination by proclaiming that English ships would pay no duties, and that 1,400 grain junks then waiting to sail would not be allowed to go until the murderers of some missionaries were punished. Though only one British sloop of war was in the harbor at the time, his bold attitude succeeded. He was appointed first consul-general in Japan 1858, and created K.C.B. 1862. As minister at Peking (1865) he conducted many difficult negotiations with tact and success. Retiring in 1871, he devoted himself to medical charities, promotion of geographical studies and the furtherance of a knowledge of Japanese art. Works: 'Medical History and Statistics of the British Legion in Japan' (1860); 'Japanese Grammar' (1861); 'Capital of the Tycoon' (1863); 'Art and Art Industries in Japan' (1878).

ALCOFORADO, álk'o-fō'rād-ō, Marianna, Portuguese nun and author: b. Beja 1640; d. 1723. She was betrothed and deserted by Noel Bouton, afterward Marquis de Chamilly and Marshal of France, who was in Portugal from 1655 to 1667, serving under Count Schomberg in the reorganization of the Portuguese army. Her five letters written to him between December 1657 and June 1658 have added her an imperishable position in literature, owing to the poignancy of their self-analysis, their unconscious self-abandonment and the revelation through passionate spirituality of a pure, single-hearted, tender and hopeless affection. Many human documents, spontaneous expressions of love, faith, hope and despair, the record of a nature tortured into a cry of anguish, they possess that quality of immortal dignity, melancholy and charm, which never fails to arouse sympathy and interest. The Letters of a Portuguese Nun, they were published anonymously in Paris, in 1669, by Comte de Guillermique, director of the Gazette de France, and while Chamilly was known as the recipient, it was not until 1810 that the much discussed identity of the author was revealed. Consult Prestage, E., 'The Letters of a Portuguese Nun' (Marianna Alcoforado) (3 ed, London 1903).

ALCOFRIBAS NASIER, álk'o-frē'bā nā-syã, pseudonym sometimes used by Rabelais (q.v.).

ALCOHOL. Origin of the word somewhat obscure. According to most authorities it is from the Arabic al-kohl, kohl, being the finely-powdered black sulphide of antimony used in the East for painting the eyebrows. First used to signify this powder, it afterward stood for any fine powder obtained by sublimation; then for any essence or spirit, and lastly for the liquid to which it is now applied. In the latter part of the 16th century spirit dried over powdered carbonate of potash was called spiritus alcobolae; but Kopp suggests
that this is a corruption of *spiritus alciatus*, signifying spirit that has been treated with alkali, and that alcalized (or alcoholized) spirit was then shortened to alcohol.

**Ethyl Alcohol.**—Unless otherwise qualified, "alcohol" is understood to mean the liquid known to the chemist as "ethyl alcohol," and to the trade as "grain alcohol," or "spirits of wine." It is colorless and inflammable, burning with a flame that is intensely hot but almost nondescript. Most of the alcohol used in the arts is produced by the fermentation of sugars or starches. A thin paste is made from molasses, finely ground corn or potatoes or other natural products containing sugars or starches, and a small quantity of malt or other agent containing diastase (q.v.) is added. The mixture is then allowed to stand until the diastase has transformed the starch into dextrose (glucose). Taking the chemical formula of starch as \((\text{C}_6\text{H}_10\text{O}_5)\), for the sake of illustration, we may have either of the following reactions as the primary effect of the diastase:

\[
\text{(C}_6\text{H}_10\text{O}_5) + \text{H}_2\text{O} = \text{(C}_6\text{H}_12\text{O}_6) + \text{C}_2\text{H}_5\text{OH}
\]

\[
\text{Starch Water Dextrin Dextrose}
\]

\[
\text{(C}_6\text{H}_12\text{O}_6) + 2\text{H}_2\text{O} = \text{C}_6\text{H}_12\text{O}_6 + \text{C}_2\text{H}_5\text{OH}
\]

\[
\text{Starch Water Maltose Dextrose}
\]

Neither dextrin nor maltose is directly fermentable, but each slowly becomes further transformed into dextrose, as appears from the following equations:

\[
\text{(C}_6\text{H}_12\text{O}_6) + 2\text{H}_2\text{O} = 2\text{C}_2\text{H}_5\text{OH} + \text{C}_2\text{H}_4\text{O}_2
\]

\[
\text{Dextrin Water Dextrose Carboxylic acid}
\]

\[
\text{C}_6\text{H}_12\text{O}_6 + \text{H}_2\text{O} = 2\text{C}_2\text{H}_5\text{OH} + \text{CO}_2
\]

\[
\text{Maltose Water Dextrose Carbon-dioxide}
\]

A certain amount of nitrogenous and mineral matter must be present, in addition to the starch and sugar, in order to furnish food for the yeast-plant. The next step in the process is to distill off the alcohol from the fermented product. This is usually done in a still heated by steam. One or more redistillations may be necessary in order to obtain the alcohol in a satisfactory state of purity and strength. The product of the original fermentation is weak in alcohol, but the subsequent distillations effect a great concentration, since alcohol is far more volatile than water and therefore passes off first. The British Pharmacopoeia requires rectified spirits (produced as described above) to have a specific gravity of 0.838, which is equivalent to 84 per cent of alcohol by weight. The United States Pharmacopoeia fixes the specific gravity at 0.820, which corresponds to 91 per cent of alcohol by weight. It is possible to obtain this latter degree of concentration by ordinary distillation; but it is not possible to free the alcohol entirely from water without distilling it with potassium-carbonate, quick-lime, calcium-chloride or some similar sub-stance possessing sufficient affinity for water to prevent the water from passing over. The best way to eliminate the last traces of water is to digest strong alcohol with quicklime for two hours at about 100° F., and then distil, rejecting the first and last portions of the distillate. The product is then subjected to the same treatment a second time, after which it will probably be free from water. Alcohol thus deprived of the last trace of water is termed "absolute" or "anhydrous" alcohol. Its chemical formula is \(\text{C}_2\text{H}_5\text{OH}\), and its specific gravity is 0.80625 at 32° F., and 0.79367 at 59° F. Absolute alcohol boils at 173.1° F., when the bunsen meter stands at 29.92 inches (760 mm.). It freezes at about 200° below zero F., first becoming very viscous. Its low freezing-point has led to its use as a thermometric fluid for the measurement of low temperatures. Its specific heat is variously estimated, but it is in the vicinity of 0.61. Absolute alcohol has a powerful affinity for water, and it is therefore used as an astringent, and (for certain purposes) as an antiseptic. When exposed to the air it quickly absorbs a sensible amount of aqueous vapor, and ceases to be "absolute." According to the experience of Atwater, the human body is capable of oxidizing about two ounces of it per day, since this amount can be administered without any evidence of alcohol appearing in the excreta. Alcohol mixes with water in all proportions, and is extensively used as a solvent for substances that do not dissolve in water: notably for organic substances and for alkaloids and drugs. When absolute alcohol is mixed with water the volume of the mixture is considerably less than the sum of the volumes of the constituents. The specific gravity of such a mixture therefore cannot be deduced by any simple formula; but it has been found by direct experiment, and tabulated, for all possible mixtures and temperatures. The strength of a given mixture of alcohol and water may be found by observing the specific gravity of the mixture at a definite temperature by means of a hydrometer (q.v.) and then referring to the tables. The greatest contraction of volume observed upon mixing absolute alcohol and water occurs when 49.8 volumes of water are mixed with 53.9 volumes of absolute alcohol, both liquids being at 32° F. The volume of the mixture is then 100, instead of 103.7, as it would be if there were no contraction. Mendeleff points out that this particular mixture corresponds to a possible compound having the formula \(\text{C}_2\text{H}_5\text{OH}_2\); but it has not been conclusively proved that such compound exists. An alcohol containing 49.3 per cent (by weight) of absolute alcohol is known in the arts and for excise purposes as "proof spirit." This term was originally intended to denote alcohol just strong enough to ignite gunpowder when burned upon it; but it was defined by law in the reign of George III of England to be spirit such as shall, at the temperature of 60° F., weigh exactly twelve-thirteen parts of an equal amount of distilled water (Watts). At 60° F. proof spirit has a specific gravity of 0.920. A mixture stronger or weaker than this is said to be (respectively) overproof or underproof. Distilled liquors, such as whisky, brandy and gin, contain from 40 to 50 per cent of absolute alcohol, wines from 7 to 20, ale and
porter from 5 to 7, and beer from 2 to 10. Alcohol coagulates albumen, and, partly for this reason and partly because of its action in arresting the development of micro-organisms, it prevents the putrefaction of dead animal matter. The alkali metals attack absolute alcohol with great avidity, a phenomenon of compounds variously known as alcohoxides, alcohoxides, and alcoates, but more definitely and correctly as ethylates. Thus alcohol may be regarded as water in which one atom of hydrogen has been replaced by a molecule of the organic radical ethyl, CH₃O, and, water being H-O-H, the formula for alcohol may be written (CH₃O)-O-H. An alkali metal, when it combines with alcohol, merely replaces the H at the right of this formula; and sodium ethylate (for example) is therefore (CH₃O)-O-Na, or simply CH₃ONA. The commonest test for alcohol in small quantities consists in warming the suspected liquid (or its distillate) with caustic potash and iodine. If alcohol is present itodiform comes down after a time as a precipitate. In England the use of alcohol in the arts is permitted without the payment of an excise tax, provided the alcohol contains 10 per cent of methyl alcohol (wood spirit). Alcohol so treated is known as "methylated spirit," it is unfit for drinking and the methyl alcohol that it contains cannot be readily removed. Alcohol can be prepared directly from its elements as follows: Acetylene (qv.), CH₃, will combine directly with hydrogen to form olefiant gas, CH₄; concentrated sulphuric acid will absorb olefiant gas with the formation of hydrogen-ethyl-sulphate, CH₃H₂SO₄; and if the product so obtained is diluted with water and boiled, alcohol is formed in accordance with the equation:

\[ \text{CH}_3\text{H}_2\text{SO}_4 + \text{H}_2\text{O} \rightarrow \text{H}_2\text{SO}_4 + \text{CH}_3\text{OH.} \]

This process is of considerable theoretic interest, and is said to be in commercial use in Russia. Until carbide of calcium (from which acetylene is prepared) can be had more cheaply, however, it can hardly be successfully used in the United States. (See Denatured Alcohol.)

2. Wood Alcohol, or Methyl Alcohol.—A colorless, inflammable liquid, strongly resembling alcoholic in all respects, it burns with a flame resembling that of grain alcohol, but with sensibly less evolution of heat. It is far cheaper than pure grain alcohol, because there is no excise tax upon it; in many uses it may be substituted for grain alcohol with success, its solvent powers being very similar. It cannot be used internally, however, as it is of a poisonous nature, and has a peculiar selective action upon the optic nerve, in which it often induces a condition of permanent atrophy with consequent total blindness. Methyl alcohol is obtained by the dry distillation of wood. The process, as carried out in New York State, is substantially as follows: Hardwood is cut into cordwood size and allowed to season thoroughly, two-year-old wood being dry enough as a rule, and both el and birch are most commonly used, birch being the poorest of the three, because it yields a larger proportion of objectionable tarry matter. The seasoned wood is placed in retorts of cast iron or sheet steel, which are cylindrical in general shape, and lined with a metal rather than more than half a cord each. A slow fire is then built under the retorts, its intensity being gradually increased as the distillation progresses, and regulated so that at the end of from 12 to 18 hours nothing remains in the retort but charcoal. The distillate is passed through a condenser, by which a portion is condensed into a watery fluid, while another and very considerable portion passes through in the form of a permanent, non-condensable gas. The non-condensable part consists largely of marsh gas, hydrogen, carbon-dioxide and carbon-monoxide, together with smaller amounts of acetylene and numerous other substances. No attempt is made to utilize this portion of the product except as fuel. The portion that condenses consists largely of acetic acid and methyl alcohol, together with acetate of methyl and acetone, and a considerable quantity of tarry matter. The condensed distillate is passed into settling-tanks, where it is allowed to remain until the greater part of the tarry matter has subsided. The lighter part is then drawn off and saturated with sodium acetate. A second distillation expels the methyl alcohol, which is recovered by means of a condenser and shipped to the refineries in iron tanks, being known to the trade in this form as "wood spirit." The acetate of lime remaining behind is then recovered by evaporation and spread out upon a heated floor to dry.

Acetate of lime, as it comes from the alcohol manufacturer, is brown in color, from the tarry impurities that it contains. It is used in the manufacture of acetic acid and the various acetates (notably those of iron and aluminum) that are used in dyeing and in printing upon cloth. The impure methyl alcohol, or "wood spirit," that is shipped from the factory to the refiner, usually contains 80 per cent of alcohol and 20 per cent of water. The yield of spirit of this strength varies greatly, according to the skill and care exercised by the manufacturer; but in the best plants it may be taken at from eight to nine gallons per cord of good wood. Crude wood spirit contains considerable empyreumatic matter as well as acetone, acetate of methyl and acetate of ammonia. Pure methyl alcohol may be prepared by saturating the crude spirit with fused calcium chloride (CaCl₂) and heating in a water-bath. Methyl alcohol combines with calcium chloride under these conditions, forming a product which can be readily purified, and from which the alcohol can again be recovered by distilling with water. A final distillation over quicklime will give the alcohol in its anhydrous or "absolute" state. Pure methyl alcohol, free from water, has a specific gravity at 32° F. of 0.8101. Its chemical formula is CH₃OH; it is the hydrate of the organic radical "methyli" (CH₃), being analogous in this respect to ethyl alcohol, which is the hydrate of the organic radical "ethyli" (CH₂). It boils at about 151° F. under ordinary atmospheric pressure.

3. Alcohol.—In organic chemistry, a member of a numerous class of compounds consisting of carbon, hydrogen, oxygen, and often nitrogen, derived from hydrocarbons containing an even number of hydrogen atoms by the substitution of one or more hydroxyl molecules (HO) for an equal number of hydrogen atoms. The alcohols, as thus defined, include the two substances described above (such as glycerin) whose properties at first
sight appear to be radically different from those of either ethyl or methyl alcohol. Alcohols are classified as monohydric, dihydric, trihydric, tetrhydric, pentahydric and hexahydric, according as they contain one, two, three, four, five or six molecules of hydroxyl (OH). Thus ethyl alcohol, C₂H₅OH, is monohydric, while glycerin, C₃H₈(OH)₂, is trihydric. In the present article both mono- and polyhydric alcohols will be considered. These are divisible into five general series as follows: (a) Those having the general formula CₙH₂ₙ₊₁OH; they are derived from the paraffins, CₙH₂ₙ₊₂, by the substitution of one molecule of OH for one atom of hydrogen and are known as the "fatty alcohols." (b) Those having the formula C₆H₅OH. Allyl alcohol is the most familiar member of this series. Its formula is C₃H₇OH. (c) Those having the general formula CₙH₂₉₋₁OH. No familiar example can be given. (d) Those having the general formula CₖH₄₋₁OH. This series is derived from the aromatic series of hydrocarbons, just as the first series given above is derived from the paraffins. Thus, when hydrogen peroxide, H₂O₂, acts upon benzene, C₆H₆, yielding C₆H₅OH+H₂O₂→HO·+C₆H₅OH, the last expression in this equation being the formula of phenyl alcohol, or (as it is more familiarly known) carboxylic acid. (e) Those having the general formula CₙH₂₉₋₁OH. Cholesterol belongs to this series. It will be evident that the complete discussion of even the monohydric alcohols would be impossible in the present place; hence in what follows attention will be confined to the fatty or paraffin series of monohydric alcohols, having the general formula CₙHₙ₊₁OH. No less than 17 distinct members of this series are known, the first five, when they are arranged in order according to the number of carbon atoms they contain, being:

- Methyl alcohol, CH₃OH
- Ethyl alcohol, C₂H₅OH
- Propyl alcohol, C₃H₇OH
- Butyl alcohol, C₄H₉OH
- Amyl alcohol, C₅H₁₁OH

The first two members of this series do not admit of any isomeric modifications; but the third admits of one such modification, and the following members admit of more than one. For example, propane has the formula CH₃CH₂CH₃ and an alcohol may be formed by substituting OH for any one of the H atoms in this formula. If a hydrogen atom at the end of the formula be replaced in this way, we shall obtain the same result whether the substitution be made at the right-hand end or the left; that much is evident from the symmetry of the formula. But if one of the hydrogen atoms in the central CH₂ be so replaced the alcohol thus formed may differ from the one previously obtained by an end substitution; and in fact experiment shows that two different alcohols do actually exist, both having the same formula C₄H₉OH. These are distinguished as "primary" and "secondary" respectively. In general, an alcohol is said to be "primary" if the carbon atom to which the OH is attached is itself attached to only one other carbon atom; it is "secondary" if the carbon atom to which the OH is attached is itself attached to two other carbon atoms; and it is "tertiary" if this carbon atom is attached to three other carbon atoms. If it is admitted that the valence of carbon is never greater than four, it follows that no carbon atom can be attached to more than three other carbon atoms; hence every alcohol in the class under consideration must be either primary, secondary or tertiary. The various radicals with which hydroxyl (OH) is combined in the alcohols are collectively called "alkyls." Thus CH₃ (methyl), C₂H₅ (ethyl) and C₃H₇ (propyl) are all "alkyls," and an alcohol may be briefly described as the hydrate of an alkyl. Other alkyl compounds are also known. For example, hydrochloric, hydrobromic, hydroiodic or hydrofluoric acid, when allowed to act upon an alkyl hydrate, yields the chloride, bromide, iodide or fluoride of that alkyl. Thus: CH₃OH+HCl=CH₃Cl+H₂O; and CH₃OH+HI=CH₃I+H₂O. CH₃Cl is "methyl chloride," and CH₃I is "propyl iodide." The oxides of alkyls are called "simple ethers." (See Ether). For example, (CH₃)₂O is ethyl oxide (or ether), often erroneously called "sulphuric ether" from the fact that sulphuric acid is used in preparing it. By the action of various acids upon these "alkyl hydrates" (or alcohols), the salts of these alkyls, entirely analogous to the metallic salts, are obtained. Thus acetic acid and ethyl alcohol react according to the equation:

CH₃COOH+CH₃OH=CH₃CO (CH₃)₂+H₂O.

Ethyl Acetic Acid Ethyl Water
Acid Acetate

This reaction is entirely analogous to the following familiar one relating to potassium:
KO₂+CH₃COOH=CH₃COOK+H₂O.

See Esters.

ALCOHOLISM. See Internal Combustion Engine.

ALCOHOLISM, a term applied to the symptoms produced by poisoning with ethyl alcohol (see Alcohol). Alcoholism may be acute, subacute or chronic, and in order to understand its phases a brief review of the more important features of the physiological action of alcohol is necessary. Locally alcohol is an irritant, and induces congestion and increased cellular activity. There appears to be some foundation for the popular view that taken before a meal alcohol increases the wish to eat, for although in any marked quantity it greatly reduces or altogether inhibits the action of the digestive ferments it is probable that the increased amount of gastric juice secreted under the influence of small amounts more than makes up for this effect. Some authorities maintain that while the alcohol remains in the stomach digestion is retarded, but that after absorption of the alcohol the process advances more rapidly than would otherwise have been the case. The most important effect of the administration of alcohol is manifested through the nervous system. There is no doubt that physiologically alcohol is always a poison. Its psychological effects, however, need special attention. Experimental columns of figures or reading series of disconnected syllables are performed less rapidly and more inaccurately when the person had taken moderate amounts of alcohol, though he usually feels increased self-confidence and is convinced
that the actually inferior work he is doing is especially good. It is in this way that alcohol often aids the after-dinner speaker, who by moderate amounts of wine is relieved of diffidence or embarrassment and is enabled to speak with a fluency apparently rare at his command under ordinary conditions. It is probable that the capacity for muscular work also is only apparently augmented by alcohol, the slight increase in efficiency at the start being neutralized by the earlier onset of fatigue. According to modern observers alcohol has but little direct effect on the circulation, though there is some change in the distribution of the blood through dilatation of the peripheral vessels. Respiration is little if at all affected. The question of whether or not alcohol is a food has elicited much controversy, but the experiments of Atwater, Neumann and others show beyond doubt that a certain amount of alcohol can be completely burnt in the body and serve as a source of heat and energy. In this way a saving of other food stuffs is effected, and in this sense alcohol is undoubtedly a food. The view upheld by some of the older authors that alcohol has the power of lessening the oxidation of the tissues is, however, unfounded. The modern tendency is to regard alcohol as a physiological stimulant but as a universal depressant. From the above it might be inferred that alcohol does not possess the traditional value ascribed to it in medicine, and to some extent this is true. On the other hand, there are many legitimate indications for its use that cannot be met by other drugs and few thoughtful clinicians would be willing to do without its aid. Alcohol is often used in popular medicine without a correct conception of its action. Contrary to general belief it does not raise the bodily temperature, but actually causes it to fall on account of the increased radiation of heat from the surface of the body accompanying the dilatation of the blood vessels of the skin. Consequently alcoholic drinks should not be taken before exposure with the idea of avoiding fatigue or chilling, though there is no objection to its use when the exposure is over and the individual has returned home wet or chilled through.

Alcoholic poisoning follows the taking of very large quantities of strong spirits in a short time, and is not often seen. The patient promptly becomes comatose, the face is congested or purplish, there is complete muscular relaxation, weak heart action and collapse, ending in death through paralysis of the heart or of respiration or both, unless medical aid is given.

Subacute alcoholism is the ordinary type of drunkenness or intoxication and produces different manifestations in different individuals. The first effect of moderate amounts of alcohol is to cause exhilaration, garrulity, inattentiveness and incoherence of speech, blunting of the sense of touch, and loss of muscular control so that the patient is unsteady on his feet and staggers when he walks. Dizziness and disturbances of sight and hearing may also appear, and finally a deep lethargy and stupor supervene. On awaking, nausea, vomiting, headache and mental depression remind the sufferer of his condition. Some individuals at the stage of hilarity does not appear and quarrelsomeness and moroseness are manifested from the start. The insensibility of alcoholic intoxication to some extent resembles that attending certain grave disorders like apoplexy, epileptic coma, fracture of the skull or opium poisoning, and mistakes in diagnosis on persons found unconscious in the street are not uncommonly fortunate. The true state of affairs is often extremely difficult to recognize, and it is always wiser to treat doubtful cases as if the more serious trouble existed. The fact that the breath smells of liquor or little value, as bystanders may have sought to aid a victim of other conditions in this way, or a man who has indulged in alcohol may also be suffering from some of the difficulties mentioned. Some persons instead of becoming stuporous pass into a condition of wild excitement and uncontrollable fury termed alcoholic mania, during which the most revolting crimes may be committed. In others convulsive seizures, or alcoholic epilepsy, may succeed the first stage. Delirium tremens is a form of mental disturbance in which the patient is subject to attacks of irresistible craving for liquor, though in the intervals he may be quite rational and alcoholic beverages may even be repugnant to him. It is most frequently a manifestation of a compulsive neurosis, and may be a form of depression psychosis. Delirium tremens is a state of nervous unrest sometimes following a protracted debauch, sometimes appearing in steady, but not necessarily excessive, drinkers, usually as the result of some physical or mental shock. There are distaste for food, intense restlessness, terrifying hallucinations and illusions and obstinate insomnia. The treatment of acute alcoholism comprises, first, elimination of the poison by washing out the stomach, purging, rectal irrigation with salt solution, and the Turkish bath; and secondly, the substitution of other stimulants such as ammonia, strychnine, caffeine, etc., until nourishment can be retained and strength returns. In delirium tremens the two great indications are to produce sleep and nourish the patient, problems that often tax the ingenuity of the physician to the utmost.

Chronic alcoholism is the result of long continued immoderate indulgence in alcoholic liquors and is a serious cause of disease. It is always due to mental causation. Various organs of the body are affected and exhibit a new growth of connective tissue. The blood vessels show the lesions of arterio-sclerosis, the heart is affected in a variety of ways, commonly becoming fatty and weak, the kidneys develop nephritis, the liver cirrhosis, and the stomach is the seat of a chronic catarrhal condition giving rise to nausea, vomiting and distaste for food. There are congestive and catarhal changes in the respiratory apparatus; the bodily strength is decreased and there is a tendency to obesity. There is also marked involvement of the nervous system leading to complete mental and moral deterioration with loss of will power, loss of memory and incapacity for the responsibilities of life. Chronic alcoholics have lessened or a complete lack of infectious diseases and readily break down under the stress of any mental or physical strain. The treatment of chronic alcoholism requires isolation of the patient, preferably in a sanitarium or an institution. Some individuals must have immediate withdrawal of all alcohol, others recommend a more gradual process of "tapering off."
Which method is preferable depends on the individual case. Hypodermic injections of nitrate of strychnine form the basis of some of the courses of treatment. The use of atropine, physostigmine, pilocarpine, as drugs which control the disturbance of balance in the vegetative nervous system, which is characteristic in chronic alcoholic states, is advisable. (See Crime; Pauperism; Temperance.) Consult also Tocqueville's "Philosophy of Reform" and "Therapeutics"; Jelliffe, S. E., "The Mentality of the Alcoholic" (New York Medical Journal, May 1917); Jelliffe and White, "Diseases of the Nervous System" (1917); "Modern Treatment of Nervous and Mental Diseases" (1913); Kelvynack, T. N., "The Drink Problem" (New York 1907); Phelps, E. B., "The Mortality of Alcohol" (ib., 1911). Consult also Economic Aspects of the Liquor Problem (Boston 1889); "The Relations of the Liquor Traffic to Pauperism, Crime and Insanity," in Twenty-sixth Annual Report of the Massachusetts Bureau of Labor Statistics (Boston 1895) and Economic Aspects of the Liquor Problem, in Tenth Annual Report of the United States Department of Labor (Washington 1898).

Karl M. Vogel, M.D.

ALCOHOLOMETRY, the process of estimating the amount of percentage of alcohol in spirits. Several methods are employed for this purpose, but the commonest consists in determining the specific gravity of the spirit. Every mixture of alcohol and water has a specific gravity of its own depending on the temperature and on the relative composition of the mixture. As liquors contain substances other than alcohol and water they must be carefully distilled before a test can be made. When the specific gravities of various mixtures have been determined, the composition of a sample is readily determined by finding its specific gravity and observing the temperature.

ALCORAN, ál'kó-rán or ál'kó-rán. See Koran.

ALCORN, al'korn, James Lusk, American statesman: b. near Golconda, Ill., 4 Nov. 1816; d. 30 Dec. 1894. He was educated at Cumberland College; served in the Kentucky legislature; in 1844 removed to Mississippi and began law practice and was in the Mississippi legislature 1846-65. He was a Scott presidential elector in 1852, declined a Whig nomination for governor 1857, and the same year was defeated for Congress by L. Q. C. Lamar. He founded the levee system in the State. In 1861 he was in the Secession Convention, and was elected brigadier-general, but Jefferson Davis refused his commission from political grudge. In 1865 he was elected United States senator, but not allowed to take his seat. In 1869 he was elected governor (Republican), but resigned on election to the United States Senate, where he served 1871-77. He was independent candidate for governor in 1873, but was defeated.

ALCOTT, al'kót, Amos Bronson, American philosopher and educator: b. Walcott, Conn., 29 Nov. 1799; d. 14 March 1888. In 1823 he set up an infant school, teaching it by conversation; and it gained much local fame. In 1828 he removed to Boston, and till 1836 conducted a school of the same sort, exciting wide attention by his genius for teaching, his revolutionary methods, and his exaggerated respect for the individual. He was favored by most people, and in 1836 he removed to Concord, Mass., thenceforward expounding reform views on all human subjects, society and theology, diet and education, politics, morals and metaphysics. He became an admired public lecturer in the great days of the lecture platform. In 1842 he visited England, where a Pestalozzian school near London had been named Alcott House. He returned with two English friends, one of which, Charles Lane, bought him. He was the leader among the Transcendentalists, and the others joined him; but it failed. Mr. Alcott lived in Boston for a while, but finally returned to Concord, where he spent the remainder of his life as a "peripatetic philosopher," as justly said; giving talks in, Crime and Insanity, in Twenty-sixth Annual Report of the Massachusetts Bureau of Labor Statistics (Boston 1895) and Economic Aspects of the Liquor Problem, in Twelfth Annual Report of the United States Department of Labor (Washington 1898).

A. L. M. Vogel, M.D.
entitled 'Hospital Sketches,' as the easiest available literary capital, not suspecting that she had found her kingdom. In these was first revealed her peculiar power of sketching common
people scenes in all their commonplace, yet by the play of genial humor and rare selective art making them as charming as the best creations of the fancy. The success of these stimulated the publication of 'Little Women' (written 1869, after return from a
year's European trip for impaired health, published 1868), which sold 60,000 copies the first year, and which still remains one of the best copyrights in American literature. It raised her at once and justly to one of the front places in
American authorship, and remains the one work of hers the world would much regret losing. In formal art it has no merits; there is no structure and no climax, merely detached scenes of an eventful life; little delicacy of touch, though bountiful of much tenderness and pathos; but the healthy sense and stereoscopic lifelikeness make it rather an addition to people's actual experiences than their memories of fiction; and the girls, despite the blunt portr
titure of superficial faults and even over-harsh lack of idealization, are loved like sisters by millions. It is the world-photograph of the New England home and the American girl. This was her great opportunity; her own family and friends to compose and adorn, with scant need for imagination, of which she had little, or plot, in which she was very deficient. After this, with the necessity of inventing a set story, and her personal life mostly wrought into
her previous work, her limitations were strongly apparent: 'An Old-Fashioned Girl' (1869), 'Little Men' (1871) and a series of later juveniles, though only less popular with the young than 'Little Women,' add nothing to her real reputation. They are also deformed by two unwholesome qualities: one derived from her
cradle,—representing grown people mainly as vexatious interferences with children's enjoyment and the latter as quite capable of teaching wisdom to their elders; the other a proof how much feminine craving lay underneath her space-taking. In its element a satire, to everything from the kindergarten up, and the world one vast scene of philandering. But these pot-boilers had a higher motive and result than most money-earning, for they enabled her father to live his serene life. She adopted at different times a son of her sister, Mrs. John Pratt ('Meg') and the orphaned daughter of her artist sister, Mme. Nieriken ('Amy'); and kept house for them and her father in vigorous New England fashion, caring for the latter like a baby. She had great passion, throughout her last hours laid her low with a fatal brain fever. Besides the books above mentioned she published 'Flower Fables or Fairy Tales' (1855); 'Moods' (1864, revised 1881); a series, 'Aunt Jo's Scrap Bag' (1877-82); 'Work, A Story of Experience' (1873); 'Eight Cousins' (1874); 'Rose in Bloom' (1876); 'Silver Pitchers' (1876); 'Under the Lilacs' (1878); 'Jack and Jill' (1890); 'Proverb Stories' (1882); 'Spinning-Wheel Stories' (1884); 'Lulu's Library' (1885).

ALCOTT, May (Mme. Ernest Nieriken), American artist, daughter of A. B. Alcott: b. Concord, Mass., 1840; d. 1879. She studied at the Boston School of Design, and under Krug, Rimmer, Hunt, Vautier, Johnston and Müller. Thenceforward she lived variously in Boston, London and Paris; after marriage chiefly in the last. She did good work in still-life painting, both oil and water-color, and copied Turner so ably that Ruskin had some doubt as to whether she had adopted for models at the South Kensington schools. She published 'Concord Sketches,' with a preface by her sister (1869); 'Art Studying Abroad' (1879).

ALCOY, òl-kó'e, Spain, a town in Valencia, 24 miles north by west of Alicante, near the source of the Alcoy, in a hollow encircled by hills. There is a Roman bridge over the river and the town has a very picturesque appearance. Its chief manufacture is paper and it is famed for the peladillas or sugar-plums of Alcoy, Pop. 34,000.

ALCUIN, àl'kwín, or FlACCUS AL-BINUS, an Englishman, renowned in his age for learning; the confidant, instructor and ad
viser of Charlemagne. He was born probably in York in 735 and was educated under the care of Archbishop Egbert, and his successor Ælbert, with whom he went to the continent, and who afterward gave him the management of the school at York. Having gone to Rome to bring home the pallium (see Pallium) for Ælbert, the successor of Ælbert, Charlemagne became acquainted with him in Parma on his return; invited him, in 782, to his court and made use of his services in his endeavors to civilize his subjects. In the royal academy he was called Flaccus Albimus. To secure the benefit of his instructions Charlemagne established at his court a school, called Schola Palatina, or the Palace School, and intrusted him with the superintendence of several monasteries, in which Alcuin exerted himself to diffuse a knowledge of the sciences. Most of the schools in France were either founded or improved by him; thus he founded the school in the abbey of Saint Martin of Tours, in 796, after the plan of the school in York. He himself instructed a large number of scholars in literature and outward spread the light of learning through the empire of the Franks. Alcuin took his leave of the court in 801 and retired to the abbey of Saint Martin of Tours, but kept up a constant correspondence with Charles to the time of his death in 804. He left, besides many theological writings, several elementary works in the branches of philosophy, rhetoric and philology; also poems and a large number of letters, the style of which, however, is not pleasing and plainly betrays the uncultivated character of the age; nevertheless he is acknowledged as the most learned and polished man of his time. He understood Latin, Greek and Hebrew. The best edition of his works is that published at Ratis
bon (1777, 2 vols.). Consult Lorenz's 'Life of Alcuin' (translated into English, London 1837).

ALCYONA'RIA (from Gk. alkyon ['e]ion, bastard-sponge, a sub-class of coral polyps (Anthozaa), including fang corals, *dendron men's fingers,* organ-corals, the red coral used for beads and ornaments and others. Eight tentacles around the mouth and the eight cells into which the body is divided are the characteristic elements of this group. See CORAL; GORGONIA.
ALCYONE, the brightest star of the Pleiades (q.v.). Also see KINGFISHER.

ALDAN, a river of eastern Siberia, a tributary of the Lena, 1,200 miles in length, navigable for 600 miles. The Aldan Mountains run along parallel to it on the right 400 miles.

ALDANA, Ramon, alda-na, rá-mó'n, Mexican poet: b. 1832; d. 1882. Besides four dramas, among which are 'Honour and Happiness' and 'Nobility of Heart,' he produced lyric poems and sonnets and contributed articles to journals.

ALDBOROUGH, ald'bôr, or locally âbrô, or ALDEBURGH, a small seaport and watering-place of Suffolk, 29 miles northeast of Ipswich by rail. It was disfranchised in 1832; but in 1885 it received a new municipal charter. It has a quaint, half-timbered moot hall; and in the church is a bust of the poet Crabbe, who described the place in his poem 'The Borough.' It has a two-mile promenade, golf links and lobster and herring fisheries. Pop. 2,400.

ALDEBARAN, a star of the first magnitude, forming the eye of the constellation Taurus or the Bull, the brightest of the five stars known to the Greeks as the Hyades. Spectrum analysis has shown it to contain ammonia, bismuth, iron, mercury, hydrogen, sodium, calcium, etc.

ALDEGIVER, al'de-gâr'vër, or ALDEGRAF, Heinrich, German artist: b. Paderborn, Westphalia, 1502; d. Soest before 1561; the most important artist of Westphalia during the 16th century and one of the great names in German art. The story of his life can only be gathered from fragmentary allusions which tell us that he was the son of Hermann Aldegiver (the family name was really Trippenmeker, which the artist used in signing some of his works), that he became a citizen of Soest, where he was highly esteemed and where he died, whose last date known on any work by him was 1555. Aldegiver was eminent as goldsmith, painter and engraver. In the first capacity he had such patrons as Duke Wilhelm of Cleve, and like most artists of his day, worked at various related crafts (glass, small sculpture, etc.). His paintings are not numerous but of a very high standard. The 'Portrait of a Young Man' now in the Liechtenstein Gallery in Vienna, perhaps his masterpiece in this art, or the 'Young Man with the Pink' in the National Gallery of London, shows the German school at almost its best level; the scrupulous exactitude of observation and of workmanship being informed by a spirit of human appreciation and a real sensitiveness to design. Other paintings of his quality by the master are 'The Resurrection' at Prague and a 'Portrait of a Man' at Berlin. Aldegiver's greatest importance is as an engraver, the number of works attributed to him in this medium being 289 (Bartsch). There is a good collection in the British Museum. One of his earliest plates is a free copy after Dürer, and the influence of the master persists for some time and is most fruitful of good. 'The greatest of all the 'Little Masters,'" says W. B. Scott, *Aldegiver is the most worthy successor to Albert Dürer.* His inventive power never fails and shows itself alike in purely ornamental designs, in landscape and in figure work, like the 'Wedding Guests' or the 'Melanchthon.' Aldegiver was apparently much stirred by the Reformation, and the gravity of its thought is translated by the severe and yet vital treatment which he accords to lines and masses, to the human face and figure. Consult 'Die Nürnberger Kleinmeister' (Leipzig 1911).

ALDEHYDE ("dehydrogenated alcohol," or alcohol which has been deprived of a portion of its hydrogen), a substance intermediate in composition between a primary alcohol and the corresponding acid. When an alcohol (q.v.) containing the molecular group CH₂OH is acted upon by oxidizing agents, it loses two atoms of hydrogen from this group and becomes transformed into a substance which no longer contains the hydroxyl group (OH), and which is known as the "aldehyde," of which it from which it was produced. In the laboratory aldehyde is formed by the oxidation of alcohol by air in the presence of platinum black or by manganese dioxide and sulphuric acid, and subsequent rectifying with calcium chloride. It may also be prepared by passing alcohol through an iron tube heated to 1,350° F. For commercial use it is collected from the first vapors which come over in the rectification of alcohol which has previously been filtered through charcoal. The largest yields are obtained from potato alcohol and from alcohol made from the juice of the sugar beet. The aldehyde is separated from the alcohol in a special still contrived for the purpose. If the formula of the original alcohol is R.C₃.H₅.OH, that of the corresponding aldehyde is R.CO.H. Aldehydes combine with bisulphites (or acid sulphites), producing compounds that are usually soluble in water, but insoluble in a solution of a bisulphite. Hence if a solution containing an aldehyde is shaken with a saturated solution of a bisulphite (such as HNaSO₃), the aldehyde is all thrown down in the form of an insoluble compound, from which the aldehyde itself may afterward be liberated by treatment with dilute sulphuric acid and distillation by steam. Alde- hydes are easily oxidized into their corresponding acids and on account of their affinity for oxygen they act as powerful reducing agents. An aldehyde may also be reconverted into the alcohol from which it was obtained, by the action of sodium amalgam. About 50 aldehydes are known, nearly all of which are volatile liquids.

The general relation of the aldehydes to their corresponding alcohols and acids may be illustrated by the following equations. The formula of methyl alcohol is CH₃.OH or H.CH₂.OH. In the presence of platinum black, air oxidizes methyl alcohol in accordance with the following equation:

\[ \text{H.CH₂.OH + O = H₂O + H.CO.H} \]

\[ \text{H.CO.H (or CH₂.O) is "formic acid" or} \]
\[ \text{"formaldehyde." This rapidly absorbs oxygen and undergoes the change} \]
\[ \text{H.CO.H + O = H.CO.OH} \]

\[ \text{Formaldehyde Formic acid} \]

Again, if ethyl alcohol (C₂H₅.OH or} \[ \text{C₂H₅.CH₂.OH) is treated in the same manner} \]
\[ \text{(or better, if it is oxidized with a mixture of} \]
potassium bichromate and sulphuric acid), we have
\[ \text{CH}_3\text{CH}_2\text{OH} + \text{O} = \text{CH}_3\text{COH} + \text{H}_2\text{O}. \]
Ethyl alcohol Acetic aldehyde
If allowed to absorb oxygen, acetic aldehyde then undergoes the further transformation
\[ \text{CH}_3\text{COH} + \text{O} = \text{CH}_3\text{COOH}. \]
Acetic aldehyde. Acetic acid.

Acetic Aldehyde or Acetaldehyde.—When not qualified in any way the term aldehyde is understood to mean acetic aldehyde, the substance whose formation from ethyl alcohol has just been described. It is found among the products of the dry distillation of sugar, in wines during the ageing process, in crude wood alcohol and in crude petroleum. Aldehyde (in this sense) is a colorless liquid with a suffocating smell, miscible in all proportions with water, alcohol and ether, boiling at 70° F. and having a specific gravity of 0.880 at 32° F. It is highly inflammable and burns with an almost non-luminous flame. It is capable of existing in several polymeric states, each having the same chemical composition as aldehyde, but differing from it in appearance and behavior. Thus although it may be preserved for a long time if kept in contact with excess of acid, in its pure state it soon deposits a solid substance in needle-like crystals known as metaldehyde, which sublimes at 240° F. without decomposition, and is recovered into aldehyde when confined and heated to 260° F. By treatment with sulphuric or hydrochloric acid, aldehyde may be converted into a liquid known as para-aldehyde, a colorless liquid which boils at 385° F., has a vapor density indicating the formula \(3\left(\text{CH}_2\text{O}\right)\) and crystallizes in large transparent prisms at about 50° F.

Aldehyde is used for silversing mirrors and other objects, on account of the property that it possesses (in common with other aldehydes) of throwing down a deposit of bright metallic silver when heated with a concentrated ammoniacal solution of silver nitrate containing a little caustic soda.

ALDEN, Alden, Bradford R., American soldier: b. Meadville, Pa., 1800; d. Newport, R. I., 10 Sept. 1870. Graduating at West Point 1823, he constructed the 1833–40 after several camp and garrison life; then for nearly two years aide to Winfield Scott; after three years more of garrison duty was commandant at West Point 1845–52. Sent to the far West for service in the Puget Sound Indian troubles, in 1853 he organized and led an expedition against the Rogue River Indians of southwest Oregon; and in the fierce battle at Jacksonville 24 Aug., was permanently disabled and forced to retire from the army. He was a man of culture and fine literary tastes.

ALDEN, Henry Mills, American magazine editor and author: b. Mt. Tabor, Vt., 11 Nov. 1836. He was graduated in 1857 at Williams College, in the class with James A. Garfield and Horace E. Scudder; in 1860 at Andover Theological Seminary and received license to preach, but was never ordained. He settled in New York in 1861; was manager-editor of Harper's Weekly 1863–69 and has been editor of Harper's Magazine since 1869. His earliest interests were classical, especially in regard to ancient thought, religion and literature; in the winter of 1863–64 he delivered 12 lectures at the Lowell Institute, Boston, on 'The Structure of Paganism'; his earliest writings published were two papers on the 'Eleusinian Mysteries,' in the Atlantic Monthly; and his classical scholarship is recognized as of a high type. In his editorial work he has sought to combine fresh intellectual outlook and the presentation of the latest results of scholarship with sound ethics and an elevating social tone; also to make the magazine American in the best sense and to bring forward new writers. He collaborated with A. H. Guernsey in Harper's Pictorial History of the Great Rebellion (1862–65); and has written 'The Ancient Lady of Sorrows' (poem, 1872); 'God in His World' (1890, anonymous), a Study of Death (1895), widely read and admired, and 'Magazine Writing and the New Literature' (1908).

ALDEN, (Mrs.) Isabella MacDonald, (Mrs) of 'Pansy.' American juvenile writer: b. Rochester, N. Y., 3 Nov. 1841. She was educated at Ovid and Auburn, N. Y., and while she has written fiction for adults and 'The Prince of Peace,' a life of Christ, her chief note is as the author of the 'Pansy Books,' a Sunday-school juvenile novels, about 60 volumes in all; and as editor of the juvenile periodical (1873–96). She has since been on the staff of the Christian Endeavor World of Boston and the Herald and Presbyter of Cincinnati.

ALDEN, James, American naval officer: b. Portland, Me., 31 March 1810; d. San Francisco, Cal., 6 Feb. 1877. Becoming midshipman 1828, he accompanied the Wilkes expedition around the world 1838–42; commissioned lieutenant 1841, he served through the Mexican war in all the leading seaboard engagements. The Puget Sound Indian troubles called him thither 1855–56 for active duty. The Civil War found him in command of the steamer South Carolina, and he was sent to the Gulf and had a fight at Galveston, Tex.; later, in command of the sloop-of-war Richmond, he was at the passage of Forts Jackson and Saint Philip and the capture of New Orleans and Port Hudson. He became captain 1863 and commanded the Brooklyn in the battle of Mobile Bay (August 1864) and the assaults on Fort Fisher; commodore 1866, and given charge of the Mare Island (Cal.) navy yard 1868; in 1869 made chief of the bureau of navigation, and in 1871 promoted to rear-admiral and assigned to command of the European squadron. He retired 1873.

ALDEN, John, of the Plymouth colony: b. England 1599; d. Duxbury, Mass., 12 Sept. 1687. His name is familiarized by Longfellow's poem 'The Courtship of Miles Standish;' he was originally a cooper of Southampton, was employed in making repair vessels and came over in her with the Pilgrim Fathers. By some accounts he was the first to step ashore at Plymouth. He married Priscilla Mullens: the tradition is (as used by Longfellow) that he had previously pleaded the cause of Miles Standish. He was for 50 years a colonial magistrate and highly esteemed for probity, sagacity and resolution. All the distinguished Aldens of the United States are his descendants.

ALDEN, William Livingstone, American humorous writer and journalist: b. Williams-
Alden-Hoven

Aldershoot

Alderman, a title pertaining to an office in the municipal corporations of Great Britain and the United States. In the United States the powers and duties of aldermen differ in the various States and cities. As a rule they are elected by popular vote and constitute the source of municipal legislation.

Alderman Lizard, or Chuck-Walla, nicknames in California for a fat-bodied lizard (q.v.).

Alderney (French AURIGNY), an island belonging to Great Britain, on the coast of Normandy, 10 miles due west of Cape La Hague and 60 from the nearest point of England, the most northerly of the Channel Islands. It is about 4 miles long and 1 1/2 broad, having an area of fully 3 square miles. The coast is bold and rocky, the cliffs in many places rising from 100 to 200 feet in height. In the interior the soil is fertile producing excellent crops of corn and potatoes. About a third of the island is occupied by grass lands; and the Alderney cows are famous for the richness of their milk. The climate is mild and healthy. The town of Saint Anne is situated in a beautiful valley near the centre of the island. A judge, with six justices, chosen by the people for life, and 12 dozanziers, representatives of the people, form the kind of local legislature; but the judge and jurats alone decide upon any measure, the dozanziers having only a deliberative voice. The French language still continues to prevail among the inhabitants, but all understand and many speak English. Alderney is well fortified. At Braye there is an extensive granite breakwater, built by the British government to help form a naval station and haven of refuge. The project was a failure.

Alder Fly, a fly of the dipteran family Sialidae (q.v.).

Alderman, al'dér-mán, Edwin Anderson, American educator: b. Wilmington, N. C., 15 May 1861. He was educated at the University of North Carolina; was superintendent of the public schools of Goldsboro, N. C. 1884-87; assistant State superintendent of North Carolina, 1889-92; professor of English and history at the State Normal College, 1892-93; professor of education, University of North Carolina, 1893-95; president of University of North Carolina, 1896-1900; president of Tulane University of Louisiana, 1900-04; LL.D. the University of the South, Tulane University, Johns Hopkins University, Columbia University, Yale University, University of North Carolina, Williams College, Dartmouth College and Harvard University; member of General Education Board and vice-president National Education Association, 1903; member of Virginia State Geological Commission; member of Rockefeller Sanitary Commission; member of Virginia State Educational Commission; member of council of American Association for International Conciliation; member of Board of Visitors of United States Military Academy, West Point, 1893; member of executive council of American Civic Alliance; member of Maryland and Louisiana Historical societies; member of American Academy of Social Sciences; member of Century Club, New York City, 1912; director Southern Railway. Author: 'A Brief History of North Carolina,' 'Life of William Hooper,' 'Life of Jabez Lamar Monroe Curry,' 'Obligations and Opportunities of Citizenship,' 'Southern Idealism,' 'The Spirit of the South,' 'Sectionalism and Nationality,' 'The Growth South,' and editor-in-chief of 'Library of Southern Literature.'

Aldershoot, al'dér-shót, Camp at, a permanent camp for the army in England, commenced in 1854 by the purchase on the part of government of an extensive tract of moorland known by the name of Aldershoot Heath, lying on the confines of Surrey, Hampshire and Berkshire. The object was to accustom the officers and soldiers to act in brigades and divisions, and to familiarize them with the operations of a campaign by accustoming them to camp life, and exercising them in all the evolutions which they might be required to perform when brought into actual contact with the enemy. The Basingstoke Canal divides the camp into a North and a South Camp (otherwise known respectively as Marlborough and Stanhope Lines). The accommodation provided for the army consisted at first of wooden huts of the simplest construction; but these have been superseded by brick buildings, and
altogether the money expended on the camp has amounted to upward of $20,000,000. Until 1899 the Aldershott garrison consisted of troops available for service with the first army corps. In 1899 the garrison was doubled by the addition of twenty thousand men for their annual training, and after the outbreak of the European War in 1914 vast numbers of raw conscripts were trained there before leaving for the battle fronts in Belgium, France and Macedonia. A town has sprung up in the neighborhood of the camp immediately beyond the government ground, on the edge of which the camp is established. The town of Aldershott is in Hampshire, to the south of the barracks. It contains several churches, hotels, numerous shops, and offers accommodation of various kinds, good and bad, to the soldiers; thus there are schools, newspapers, missions, literary institutes, music-halls, public-houses, etc. There is a fine equestrian statue of the Duke of Wellington. Pop. (1911) 35,175.

ALDELM, an Anglo-Saxon scholar and prelate, bishop of Sherborne; b. 640 (?); d. 709. He was a great fosterer of learning and builder of churches, and has left Latin writings on theological subjects.

ALDINE, al-diné, Editions, the books printed by Aldus Manutius and his family in Venice (1490-1597). They comprise the first editions of Greek and Roman classics; others contain corrected texts of modern classic writers, as of Petrarch, Dante or Boccaccio, carefully collated with the MSS. All of them are distinguished for the remarkable correctness of the typography; the Greek works, however, being in this respect somewhat inferior to the Latin and Italian. The editions published by Aldo Manuzio (1450-1515), the father, form an epoch in the annals of printing, as they contributed in no ordinary measure to the perfecting of types. No one had ever before used such beautiful Greek types, of which he got nine different kinds made, and of Latin as many as 14. It is to him, or rather to the engraver, Francesco of Bologna, that we owe the types called by the Italians Corsi, and known to us as used for the first time in the octavo edition of ancient and modern classics, commencing with Virgil (1501). Manuzio's impressions on parchment are exceedingly beautiful; he was the first printer who introduced the custom of taking some impressions on finer or stronger paper than the rest of the edition — the first example of this being afforded in the 'Epistole Graecae' (1499). From 1515 to 1533 the business was carried on by his father and brothers-in-law, Andrea Torresano of Asola, and his two sons — the three Alidosio, Paolo Manuzio (1512-74), Aldo's son, possessed an enthusiasm for Latin classics equal to that of his father for Greek; and he was succeeded by his son, the younger Aldo (1547-97). The printing establishment founded by Aldo continued in active operation for 100 years, and during this time printed 908 different works. The distinguishing mark is an anchor, entwined by a dolphin, with the motto either of 'Festina lente' or of 'Sudavi et aliis.' The demand which arose for these editions from this office, and especially for the earlier ones, excited the printers of Lyons and Florence, about 1502, to begin the system of issuing counterfeit Aldines. The Aldo-mania has considerably diminished in later times. Among the Aldine works which have now become very rare may be mentioned the 'Horae Beate Marie Virginis' of 1497, the 'Virgil' of 1501, and the 'Rhetares Graeci,' not to mention all the editions, dated and undated, from 1490 to 1497 which are now extremely rare. Consult Renouard's 'Annales de l'imprimerie des Aldes' (1834), and Didot's 'Aide Manue' (1873).

ALDINI, al-de'ne, Giovanni, Italian physicist: b. Bologna, 10 April 1762; d. Milan, 17 Jan. 1834. A nephew of the famous Galvani and an accomplished linguist, he became widely known by his writings in Italian, English and French on the practical applications of galvanism, illumination, tides, fire prevention, etc. From 1734 to 1819 he was professor of physics at Bologna, was created Councillor of State and Knight of the Iron Crown by the Emperor of Austria and was founder of the school of natural science for working men at Bologna, which he endowed.

ALDOBRANDINI, the name of a Florentine family, latterly of princely rank (now extinct), which produced Pope Clement VIII and several cardinals, archbishops, bishops and men of learning.

ALDOBRANDINI, al-do-bran-de'ne, Marriage, an ancient fresco painting belonging probably to the time of Augustus, discovered in 1606 and acquired by Cardinal Aldobrandini, nephew of Clement VII, for the Vatican. It represents a marriage scene in which 10 persons are portrayed, and is considered one of the most precious relics of ancient art.

ALDRED, or EALDRED, Anglo-Saxon prelate, bishop of Worcester and archbishop of York; b. 1000 (?); d. 1069. He improved the discipline of the Church and built several ecclesiastical edifices. On the death of Edward the Confessor he is said to have crowned Harold. Having submitted to the Conqueror, whose esteem he enjoyed and whose power he made subservient to the views of the Church, he also crowned him as well as Matilda.

ALDRICH, al'drich, Nelson Wilmarth, American legislator; b. Foster, R. I., 6 Nov. 1841. A farmer's lad, with only district-school education, he was clerk in a store from about 12 to 16; but, naturally studious and with a strong taste for mathematics, entered the East Greenwich Academy in 1857, and after graduation took a position in a large wholesale house in Providence, where he soon became a partner. In 1862 he was for nine months on garrison duty near Washington. In 1869 he was elected to the Providence common council, where he became a leader as expert in finance and business, and a dexterous manager without compromise of right, and was his president 1871-73. In 1875 he was elected to the legislature, and in 1876 was speaker of the House of Representatives. In 1879 he was sent to Congress, taking his seat in 1879 (42d Congress); re-elected for the term 1881-83, he resigned in 1881, having been elected to the United States Senate on 4 October to succeed Gen. A. E. Burnside, and was re-elected in 1886, 1892, 1898, and 1904, practising without opposition in his party. In 1909 he successfully promoted the passage of the Payne-Aldrich tariff bill, passed by Congress
and signed by the President in 1910. His term as senator expired 3 March 1911; but he de-
clined to stand for re-election and was suc-
cessfully re-elected by the people. During more
than 20 years he has been known as one of the
chief Republican leaders, an authority on 
finance and political economy, and a champion
of protection; rarely taking part in debate, but
powerful in legislative work, a member of commit-
tee on civil service and finance and chairman of the committee on rules for the
55th Congress. In 1911 Aldrich put forward a
plan intended to increase the effectiveness of
resources through their control by reserve as-
cesses, a scheme received with suspicion by the
general public, though not unfavorably re-
garded by experts.

ALDRICH, Thomas Bailey, American au-
thor: b. Portsmouth, N. H., 11 Nov. 1836; d.
Boston, Mass., 19 March 1907. He prepared for
Harvard, but his father's death (1852) pre-
curred a college career. Held editorial posi-
tions on the New York Evening Mirror and
N. P. Willis's Home Journal till 1865. Edited
Every Saturday, Boston, 1865-74, and The At-
lantic Monthly, 1881-90. In prose and verse he
held himself to the highest ideals of literary
art and workmanship. He wrote: 'Child of
Gold' (1874); 'Lyrics and Sonnets' (1880);
'Friar Jerome's Beautiful Book' (1881); 'Bal-
lad of Baby Bell' (1856); 'Windham Towers'
(1890); 'Unguarded Gates and Other Poems'
(1880); 'Words of Wisdom' (1883); 'Story of
a Bad Boy' (1870); 'Marjorie Daw and
Other People' (1873); 'Two Bites at a Cherry,
and Other Tales' (1893); 'A Sea Turn'
(1902); 'Flower and Thorn'; 'Prudence Pal-
try'; 'The Queen of Sheba'; 'The Stillwater
Tragedy'; 'The Sisters' Tragedy'; 'Judith and
Holofernes'; 'Donkapog Papers' (1903);
'Judith of Bethulia,' a tragedy in four acts
(1905); etc. See Story of a Bad Boy, The.

ALDRIDGE, Ira Frederick, American
 negro tragedian: b. (?); d. Lodz, Poland, 7
Aug. 1867. The discrepancies about his birth
and training are due to the uncertainty in
formation on one side. One is that he was a mul-
tatto, born near Baltimore about 1810, who
picked up German from immigrants, became
Edmond Keen's servant, and developed stage
talent under him in England, returned and
made a theatrical failure in Baltimore 1830-31,
then went back to England and became famous.
The other is that he was son of a full-blooded
 negro pastor in New York city (Greene Street
Chapel), an immigrant Senegal chief who con-
verted and educated, who sent his son to Glas-
gow University to study for the same profes-
sion, despite a passion for the stage justified
by successful amateur performances; but the
boy (at point the stories coincide) dropped
theology and made his debut at the Royal
Theatre as Othello. He took at once, and Keen
made him Othello to his Iago in Belfast. He
played Shakespearean rôles in London till 1852,
receiving an excellent interpreter in all, but
most liked in color-parts, such as Othello,
Aaron in 'Titus Andronicus,' Rolla, Zanga, etc.
He wrote a play in English on the Burial of
55: the King of Sweden invited him to Stock-
holm in 1857. The Continent ranked him one of
the foremost actors of the age, and the
greatest sovereigns, with cities like Bern, show-
ered honors and decorations on him and made
him member of all sorts of learned societies.
He married an Englishwoman. He was on his
way to an engagement in Saint Petersburg
when he died.

ALDRONI, Æl'dro-vän'dé, Ulisse,
Italian naturalist: b. Bologna, 11 Sept. 1522;
d. 10 May 1605. He aroused interest in the
atural sciences at a time when they had been
long neglected, wrote profusely on natural his-
tory subjects, established the botanical garden
of Bologna and, through his legacy to the Sen-
ate of Bologna of his collections, left behind
him the germ of the great Bologna Museum.
A short account of his life, together with a
descriptive list of his published writings and
manuscripts, may be found in 'Notizie degli
He was the first to collect an herbarium, in the
modern sense of the word. He traveled widely,
collecting plants and animals, and preparing
himself to write a great work on the animal
life of the world. Of this work four volumes
on ornithology and one on mollusks were is-
 sued before his death, and 10 others, prepared
by him from his material, were brought out
afterward by his pupils and friends. Many of
his manuscripts and drawings were preserved
unpublished in the library of Bologna.

ALE and BEER, well known and exten-
sively used fermented liquors, the best of which is
prepared from barley after it has undergone
the process termed malting. Beer is a more
general term than ale, being often used for any
kind of fermented malt liquor, including por-
ter, though it is also used in a more special
signification. The numerous varieties of malt
liquors met with in commerce may be resolved
into three great classes — ale, beer, porter. Ale,
as the term is generally understood, is a pale
liquor brewed from lightly-dried malt, and
abounding more or less in unfermented sac-
charine matter, dextrines, proteins, phosphates
and the bitter and fragrant principles of the
hop. Beer is a fine, strong, well-fermented
liquor, darker in color, less alcohol than ordinary
ale. Porter is a dark-brown colored
liquor, originally brewed from high-dried
malt, but now generally made from pale malt,
with a sufficient quantity of patent or roasted
malt to impart the necessary color and flavor.
Stout, brown stout, etc., are mere varieties of
porter, differing from that liquor only in their
superior strength and quality. East India ale,
bitter ale, etc., of the great brewers, are bever-
ages which combine the pale color and fragrant
bitter of ale (the latter usually in undue ex-
cess) with the 'dryness' and maturity of beer.
In London porter is called beer, and indeed in
all parts of the kingdom the prevailing bever-
age of this kind consumed by the masses, of
whatever class, commonly goes by the name of
beer. The division of classes of malt liquors
above referred to are, independent of mere dif-
f erences of strength, excellence and commercial
value, practically subdivided into an almost in-
finite number of varieties. Every county, every
town and almost every brewer is distinguished
by the production of a different flavor and beer
readily perceived and highly appreciated by
their respective votaries ("Cyclopedia of
Practical Receipts"). These differences depend
chiefly on the quality of the materials and the
varying proportions in which they are employed, the temperature of the water used for mashing, the length of time the mash is boiled, the temperature at which fermentation is effected and the extent to which it is allowed to proceed. The color of the beer depends on the color of the malt and the length of time occupied by the boiling. The pale ale is made from malt dried at relatively low temperatures; the deep-yellow ale, from a mixture of pale, yellow and roasted malt; and the dark-brown beer from malt that has been highly dried in the kiln and partly roasted, mixed with the paler sorts. Of all countries, Germany has been celebrated as a beer-drinking country from the earliest times. Many different kinds of beer are made there, among the most important being the Bavarian summer or lager (that is, store) beer, and winter beer, the Bavarian bock beer, Berlin white beer, wheat lager beer, Broyhan beer (Hanover), Meiseburg brown beer, etc.

The manufacture of ale or beer is of very high antiquity. Herodotus ascribes the invention of brewing to Isis, and tells us that the Egyptians drank a liquor which they called zhithos, fermented from barley. Ale or beer was never used to a great extent in Greece or Italy, partly owing, no doubt, to the abundance of wine in those countries. Xenophon, in his "Anabasis," mentions it as being used among the inhabitants of Armenia, and the Gauls were also acquainted with it in early times. Ale or beer was in common use in Germany in the time of Tacitus. "All the nations," says Pliny, "who inhabit the west of Europe have a liquor with which they intoxicate themselves, made of corn and water (fruge madida). The manner of making this liquor is somewhat different in Gaul, Spain and other countries, and it is called by many various names; but its nature and properties are everywhere the same. The people of Spain, in particular, brew this liquor so well that it will keep good for a long time. So exquisite is the ingenuity of mankind in gratifying their vicious appetites that they have thus invented a method to make water itself intoxicating." Our Teutonic ancestors would of course bring with them from the Continent their national beverage; accordingly we find the name mentioned in English history in very early times. It is mentioned in the laws of Ina, King of Wessex (680), and ale-booths were regulated by law in 728. It was customary in the reigns of the Norman princes to regulate the price of ale, and a statute passed in 1272 enacted that a brewer should be allowed to sell two gallons of ale for a penny in cities, and three or four gallons for the same price in the country. The use of hops in the manufacture of ale and beer seems to have been a German invention, and the name beer appears to have come from Germany to England with this practice (1524) after which "beer" and "ale" were used respectively for the hopped and the unhopped liquor. In 1552 hop plantations had begun to be set up in England. Ale-boys were first licensed in 1621, and in Charles II's reign duties amounting to 2s. 6d. a barrel on strong, and to 6d. on small ale or beer, were imposed for the first time (1660). From that time on it was entirely repealed, though the malt-tax remained, the duty on the barrel of strong beer varied, being in 1804 as high as 10s. Up to 1823 beer was classed into strong beer and small beer, the former being beer of the value of 16s. and upward the barrel, the latter beer below this value. See also BREWING.

ALEARDI, ăĭ-lā-är'dī., Gaetano Aleardo, Italian poet and patriot: b. Verona, 4 Nov. 1812; d. there 17 July 1878. He was a pupil of Manzoni and early imbibed republican principles. He entered the legal profession, but having circulated some satirical couples, was expelled from Venice by the Austrian government and took refuge in Paris. On his return to Italy his patriotic verses aroused his compatriots against Austrian domination. For his activity in the insurrection in Venetia in 1848 he was imprisoned at Josephstadt, Bohemia, and did not regain his liberty until 1859, when he was at once elected deputy from Brescia. Later he became senator. He lived to see the realization of his life-long dream, of his own continued efforts, a united Italy. As a poet he has always been popular in Italy, his verses having awakened the youth of Italy to a complete regeneration and unity of their country. Of his works the following are best known: "Il Matrimonio" (1841); "Arnalda di Rocca" (1842); "Il Monte Circello" (1844); "Prima Storia" (1846); "Una ora della mia giovinezza" (1858); "Poesie volante" (1862); "Canti patrii" (1862). His works have been issued in one volume, "Canti" (6th ed., Florence 1882). His "Epistolario" (correspondence) was edited by G. Tresca (Verona 1879). Consult Barbera, G., "Memoria di un editore" (Milan 1883) and Bersezio, V., "Il regno di Vittorio Emanuele II" (3 vols., Turin 1881).

ALESCANDRI, ăl'-ĕk-sân'drë, or ALEXANDRI, Vasile (Basil), Rumanian song-writer and patriot: b. Bacau, 21 July 1821; d. Mircesti, 26 Aug. 1890. His publication of "Poesii populare ale Românilor" (1853), drew attention to the great charm and lyric quality of Rumanian folk songs and ensured cordial appreciation of his own verse, "Les doines" (1853); "Doine si lacrimoare" (1863); "Pastele" (1867); "Le- sponde" (1871); and "Ovidiu" (1885). A revolutionary and exile in early life, in 1859-60 he was Rumanian minister for foreign affairs; in 1879 was elected to the upper chamber and in 1885 became Rumanian minister at Paris.

ALEXANDRA FEODOROVNA, Empress of Russia, consort of Emperor Nicholas I: b. 1 July 1798; d. 19 Oct. 1860. She was a daughter of King Frederick William III of Prussia and Queen Louise of Charlotte Wilhelmine. Alexandra Feodorovna's childhood belonged to the period of Prussia's downfall caused by Napoleon. After the defeat at Jena the Prussian royal family was constrained to move from the town to the country and it was at Potsdam, near the Peace of Tilsit that it settled in Memel. On 15 Dec. 1809 the solemn entry of the royal family into Berlin was celebrated by great masses of people. On that occasion the Queen of Prussia taught her daughter how to share the solemnities and joys of the festivities. When at 1814 Grand Duke Pavlovich came to Berlin...
with his armies he was presented to Princess Charlotte and fell in love with her at first sight. The fair princess had confessed in a letter to her brother William her own love for the Frenchman by Locke and, after a long correspondenceship she came to Saint Petersburg in 1817. The engagement took place on 25 June and the marriage on 1 July of that year. She had conceived a warm love for everything Russian, especially the language, history, folk-lore customs, etc. Professors of language had helped her considerably in her study of the language in which she showed remarkable progress. Until the ascent to the throne of Nicholas I her life flowed peacefully in the midst of her home: educating her children, cultivating music and singing, and exchanging a vast correspondence with her numerous friends. But afterward the circle of her activities became considerably broader. In 1836 all the institutions founded by Empress Marie Feodorovna passed over to her care; she personally studied, superintended increased and improved their scope. Some of them she reorganized radically. All the most important transactions, conducted by the state secretaries Villamov and Hoffman, had to be previously sanctioned by the wise Empress. In her later life she directed her attention to the education of young women and expended more than two-thirds of her enormous income on charities. Making a wholesome use of her immeasurable influence over her imperial consort, Aleksandra Feodorovna often softened the roughness of his temper and unusual roughness which characterized the epoch after 1848. Her trips abroad were crowned by enormous diplomatic successes. She left in her adopted country an imperishable memory of a good-hearted, noble and modest woman, Countess Daragan, ‘Vospomnieniya Kamer-Pazha’ (Russkaya Starina 1875); A. T. von Grimm, ‘Aleksandra Theodorovna, Kaiserin von Russland’ (2 vols., Leipzig 1866).

ALEMAN, Mateo, a-la-mán, Má-te-ó, Spanish novelist: b. Seville, September 1547; d. Mexico, about 1615. He was graduated at Seville in 1565 and in 1572 received an appointment to the royal treasury. He remained in this relation for 20 years and quitted it as poor as when he entered it. About 1609 it appears that he was established as a printer in Mexico. He wrote a poetical life of Saint Anthony of Padua in 1604 and ‘Ortagrhia Castellana’ (Mexico 1609); ‘Sucesos de D. Frai Garcia Gera, arzobispo de Mejico’ (1613); ‘Oracion Funebre,’ of the same archbishop (1613). His great work is ‘Guzman de Alfarache’ (1599), a novel with a rogue for the hero. It shows a wide knowledge of The hero exhibits all the resources of a consummate rascal in the various characters he assumes. The work attained great popularity and was translated into French and Italian. For the text of ‘Guzman’ see Aribau’s edition in ‘Biblioteca de autores espanoles’ (Vol. III, Madrid 1846); Cuadros’s edition in ‘Biblioteca Renacimiento’ (Madrid 1913). Consult Chandler ‘Romances of Roguery’ (New York 1899); De Haan, ‘The Novela Picaresca’ (Baltimore 1900); and ‘Discurcios leidos ante la Real Academia Espanola por los excmos. seors. D. Francisco Rodriguez Marin, y D. Marcelino Menendez y Pelayo, en la recepcion publica del primero’ (Seville 1907); the first discourse is devoted to Alemen). See GUZMAN DE ALAMANNI.

ALEMANNI. See ALAMANNI.

ALEMBERT, d’g’lan-bér, Jean le Rond d’, French mathematician and philosopher: b. Paris, 16 Nov. 1717; d. there 29 Oct. 1783. The illegitimate child of Chevrel and the celebrated Madame de Tencin, sister of the archbishop of Lyons, he was abandoned in infancy near the church of Saint Jean le Rond, a fact from which his Christian name was derived. After he had attained eminence his father recognized him and gave him a pension. While still very young he displayed such precocity of talent that he was placed in the College Mazarin, where he became deeply interested in mathematics and philosophy and, in fact, while he attempted to study both medicine and law, his inability to turn his mind to either of these professions determined him to become a mathematician. In 1740 he was admitted to membership in the Academy of Sciences and a year later he published his celebrated ‘Traite on Dynamics.’ Other scientific work followed rapidly, and in 1750 he became associated with Diderot in the publication of the ‘Encyclopaedia,’ for which he wrote the introduction, the article on mathematics and many of the biographies. In 1774 he became a member of the French Academy, and in 1772 having declined several pressing invitations to become royal tutor at the court of Russia, he was elected perpetual secretary of the academy. His ‘Elements of Philosophy,’ in which he followed the principles of Locke to their ultimate conclusion, both in skepticism and materialism, had appeared in 1759. Two editions of his works have been published: Paris 1805, 18 vols., and Paris 1821, 5 vols.

ALEMTEJO, a-len-ta’zhú, Portugal, a southern province, extending eastward from the Atlantic Ocean to Spain, and bounded north by Beira, south by Algarve. Area, 9,431 square miles. The chief physiographical features are: the rivers Guadiana, Tagus and Sadão; the Algarvan Mountains on the south, 4,000 feet high; the hot, dry and barren plains of the south and west and the fertile, grazing and well-cultivated agricultural lands on the east. Alemtejo is the largest, but the least populated, province of Portugal. The chief towns, giving their names to administrative districts, are Evora (the capital), Portalegre and Beja. Three lines of railway give intercommunication with Spain. Pop. 480,000.

ALENCAR, a-len-kár’, Jose Martiniano de, Brazilian jurist and novelist: b. Ceara, 1 May 1829; d. Rio de Janeiro, 12 Dec. 1877. Although prominent in his profession he is best known as a writer of fiction, his most popular works being ‘O Sertanejo,’ ‘Iracema’ and ‘O Guarany,’ all of which are stories of local Indian and colonial life.

ALENÇON, a-len-són’, France, city, capital of the department of Orne, on the Sarthe, 115 miles by rail southwest of Paris. Anciently celebrated for manufactures of point d’Alençon lace and diamonds, these are now comparatively unimportant, as carried on by manufacturers of woolens, linens, embroidery, straw hats, leather and vehicles. An important trade is also carried on in Norman horses, grain and granite
of the neighborhood. A clean well-built town, notable buildings are the circular corn market, the cloth market, the 15th century cathedral and the three remaining towers of the ancient castle of d’Alroge, the duke restored and used as the city hall. Pop. 17,500.

ALENIO, ā-lē-neō. Giulio, Italian Jesuit missionary and author: b. Brescia 1582; d. Fu-chow 1644. From 1614, he led a remarkably active life in China during 30 years, adopting the native dress and customs, preaching the Gospel in the provinces of Kans-si and Fu-kien and building several churches. He wrote numerous works in Chinese, notably a ‘Life of Christ’ which was published (8 vols., Peking 1635-37) and has often been reprinted (3 vols., 1887) and ‘The True Origin of All Things,’ a cosmography of 10,000 titles which refuted the principal errors of Chinese belief (6 vols., Hangkow 1623). He was also distinguished as a mathematician and is author of ‘Résultat de l’observation sur l’éclipse de la lune du 8 Novembre 1612, faite à Macao’ and published in ‘Revue Bénigne de l’Académie des Sciences’ (Vol. VII, p. 706).

ALEPPO, Turkey in Asia, city, capital of Aleppo vilayet, traversed by the Kuwek River, about 80 miles east of the Mediterranean and 70 miles west of the Euphrates, 60 miles east of Antioch. A branch line connects with the Beirut-Damascus line south to Rayak. Aleppo is a city of great historic interest and of Arab tradition going back to the days of Abraham. The older portion of the city still surrounded by ruins of a Saracen wall three miles in circuit is thoroughly Oriental in type with extensive bazaars, khans and numerous mosques. The European and Christian colony live in the new Azzieleh quarters outside and the Jews in the Bahsita quarter. On a hill to the northwest stands the citadel, and along one side of the river beautiful gardens extend for several miles. Aleppo for centuries was the centre of the great caravan trade between Bagdad and Damascus, and still carries on an important export and import trade in Oriental and European merchandise. It is the commercial metropolis of northern Syria, with manufactures of cotton, woolens, cotton goods, leather, etc., and it is the residence of consular agents of leading countries and the seat of European and American Catholic and Protestant missions, of Greek and Armenian patriarchs and of a Maronite bishop. Area of vilayet of Aleppo, 33,436 square miles; pop. 956,000; pop. of city of Aleppo, 150,000.

ALERT. See Essex and ALERT.

ALESIA, ā-lē’shi-a, France, a hill of the Côte d’Or, now Mont Auxois, rising above the village of Aizier six miles south of Monthbard, famous for the strongly fortified Gallic encampment, where Vercingetorix made his last stand against Caesar and was defeated, thus ending the conquest of Gaul. The place became a considerable city under the Romans, but was destroyed by the Normans in 864. The site has been the subject of considerable archaeological controversy, discussion and excavation. A colossal statue of Vercingetorix, erected by Napoleon III, stands on Mont Auxois. Consult Caesar, J., ‘De Bello Gallico’ (Vol. VII); Rossignol, M., ‘Alise, étude sur une campagne de Jules César’ (Paris 1856).

ALESSANDRIA, ā-lēs-sân’dre-a, Italy, fortified city and capital of Alessandria province, Piedmont, on the Tanaro River, 46 miles southeast of Turin. A junction of the principal railway lines of eastern Italy, it has great strategic and commercial importance, manufacturing textiles, clothing, hats, candles, etc., and carrying on a brisk trade in agricultural products. Notable buildings are: the old castle, the cathedral rebuilt in the beginning of the 19th century, the Academy of Sciences and Arts, founded 1562, and the royal palace. The citadel and extensive military barracks are on the opposite bank of the river at the confluence of the Bormida and are connected by a bridge. Alessandria was founded in 1168 by the Lombard League to resist German invasion, was besieged in 1567, 1707 and 1800 by the French and in 1815 had its fortifications destroyed by the Austrians. Since reconstructed, Alessandria, now is, after Verona the strongest fortified city of Italy. Area of province, 1,965 square miles; pop. 850,000. Pop. of city, 72,000.

ALESSANDRIA, Armistice of, the armistice under which the Austrian general, Melas, retired after the celebrated battle of Marengo, 16 June 1800. By this act General Melas abandoned to Napoleon every fortification in northern Italy west of the Po. A result which, according to the opinions of the historian, was a more serious blow to the Austrian cause than an unconditional surrender would have been.

ALESSANDRO STRADELLA, a romantic opera in three acts by Friedrich von Flotow (1812-83). It contains some beautiful melodies of a soothing charm all their own, while the plot is extremely simple, without any attempt at sensationalism. It was composed in Paris in 1844. The hero, Stradella, is a famous Venetian singer, in love with Leonore. Her uncle and guardian, a wealthy citizen named Bassi, watches closely over her, for he wants to marry her himself. But Stradella carries her off and they are married in a village near Rome. Bassi sends a bandit, Malvolio, to discover their whereabouts. At the door of the villa where the lovers reside, Malvolio meets another villain, his friend Barbarino, on the same errand as himself. Together they decide to kill Stradella and abduct his wife. Disguised as pilgrims they are welcomed in the Stradella home, where they are so charmed with the behavior and singing abilities of their host that they abandon their intention. Bassi next offers them such a high price that they promise to stab Stradella at his next performance. While lurking for their victim, Stradella so touchingly sings a hymn of the Holy Virgin’s mercy to sinners that the would-be murderers throw away their daggers, fall on their knees, and join in the refrain. By the same means, Stradella finally conciliates also his wife’s uncle, and they all become friends.

ALESUND, ā-lē’sün, a town on the western coast of Norway, rebuilt and modernized after a disastrous fire in 1904 destroyed the old town. Its chief industry is codfishing. Pop. about 14,000.
ALETIA. See Cotton Insect Pests.

ALEURITES, a-lu-rîtz, a genus of trees of the family Euphorbiaceae, consisting of four species, natives of eastern Asia and the islands of the Pacific. All the species are cultivated in tropical countries for the oils obtained from the seeds. These oils (kekuna, bankul, tung or wood oil) are similar to linseed oil, but are superior to it in some respects. They are used largely in the manufacture of paints, soaps, etc. The trees have been extensively introduced into the southern United States with the hope of establishing a wood oil industry in this country.

ALEUPONE, a-lû-pôn, a substance rich in nitrogen, found in the cells of seeds. In the legumes it is found imbedded in the grains of starch, but in grains it constitutes the inner nodule. It is sometimes called gluten (q.v.).

ALEUTIAN, a-lû'shan, Islands, a chain of about 80 small islands belonging to Alaska Territory, separating the sea of Kamchatka from the northern part of the Pacific Ocean and extending nearly 1,600 miles from east to west between longitude 172° E. and 163° W.; total area 791,000 square miles. They are of volcanic formation, and in a number of them there are volcanoes still in activity. Their general appearance is dismal and barren, yet grassy valleys capable of supporting cattle throughout the year are met with, and potatoes, turnips, and other vegetables are successfully cultivated. They afford also an abundance of valuable fur and of fish. The natives belong to the same stock with those of Kamchatka. They are a strong, hardy race, capable of enduring extremes of heat and cold. They are nominally Christianized, and are connected with the Greek Church of Russia. See ALASKA.

ALEWIFE (possibly from aloof, its Indian name), a small anadromous fish (Pomolobus pseudoharengus) found abundantly along the east coast of the United States, except at the extreme north and south. Somewhat earlier in the spring than its relatives it goes up the rivers in multitudes to spawn. It has made its way into some of the inland lakes in western New York where it is landlocked (var. lacustris). It exists in great abundance in Lake Michigan, which is not uncommon to feed in immense schools floating dead on the surface and alongshore. The eggs, which are voided in vast quantities, sink to the bottom and stick to rocks, etc. It is closely allied to both the herring and the shad, but it most resembles the shad in shape and color, though it is only from 8 to 10 inches long. It is less esteemed for its quality than the shad, but is of great importance as a food fish, and is taken by millions annually. This fish is called "gaspareau" in Saint Lawrence Bay, and "branch-herring," "ellwife" and "sawbelly" locally elsewhere; but the "alewife" of Bermuda is an entirely different fish, the round pompano. Several varieties of the alewife are of very inferior food quality but are captured and used as fertilizer.

ALEXANDER, a name of various ancient writers. (1) Alexander of Ægea: a peripatetic philosopher of the 1st century A.D.; tutor of Nero. (2) Alexander the Ætolian; a Greek poet who lived at Alexandria about 285-247 B.C., reckoned as one of the seven poets constituting the tragic pleiad. (3) Alexander of Aphrodisias, surnamed "Exegetes"; lived about 200 A.D.; a learned commentator on the works of Aristotle. (4) Alexander Cornelius, surnamed Polyhistor, of the 1st century B.C. He was made prisoner during the war of Sulla in Greece and sold as a slave to Cornelius Lentulus, who took him to Rome, made him the teacher of his children and restored him to freedom. The surname Polyhistor was given him on account of his prodigious learning. The most important of his voluminous works was one in 42 books, containing historical and geographical accounts of nearly all the countries in the ancient world. (5) A Greek rhetorician and poet, surnamed Lychnus; lived about 30 B.C., wrote astronomical and geographical poems. (6) Alexander Numenius; a Greek rhetorician and teacher of elocution, of the 2d century A.D., two of whose works are historically known. (7) Alexander the Paphлагonian; a celebrated impostor who lived about the beginning of the 2d century A.D., obtained a great influence with the people as an oracle; pretended to be Æsculapius reappeared. Lucian chiefly has made him known to us. (8) A Greek rhetorician of the 2d century A.D. He was made prisoner by Ptolemaius Philopator, who vanquished Herodes Atticus in a rhetorical contest. (9) Alexander Philalethes: a physician of the 1st century B.C., who succeeded Zeuxis as president of the famous Herophilean school of medicine. (10) Saint Alexander (d. 326 A.D.); the Patriarch of Alexandria from 312 A.D.; an opponent of Arius; member of the Council of Nice (325 A.D.); commemorated in the calendar 26 February. (11) Alexander of Tralles; an eminent physician of Lydia, of the 6th century A.D.; author of two extant Greek works.

ALEXANDER, the name of eight Popes. 1. Alexander I, bishop of Rome about 109 A.D., recorded on the list of Popes by all the chronicles except Optatus Milevitanus. He confirmed, some say introduced, the rite of using unleavened bread for the Eucharist, of blessing water with salt, and certain rubrics in the mass. He died a martyr's death. 2. Alexander II, Anselmo Baggio, a native of Milan; he lived for some time at the court of Henry III, and in 1056 or 1057 became bishop of Lucca. In 1059 he became papal legate at Milan, and 1 Oct. 1061, through the zeal of Hildebrand, he was raised to the papal throne, consequently the imperial party elected Bishop Cadalois of Parma, a rival Pope, as Honorius II. Alexander was driven by him in 1062 from the vicinity of Rome. He then withdrew to Lucca, and on the decision of the contest by Bishop Burchard of Halberstadt he was sent by the German court to Italy and recognized as Pope. At the Council of Mantua in 1604, with the assistance of his legate, Cardinal Pietros Damiana, decided against him and summoned the King to Rome to answer for his crimes, but shortly after he died, 21 April 1073. 3. Alexander III (d. 1181), Rolando Ranucci; Pope, 1159-81. His career is histori-
cally important because of his vigorous prosecution, in opposition to Frederick Barbarossa, of the policies begun by Hildebrand. Three and a half years after Alexander III. IV, Calixtus III had been confirmed in succession by the Emperor. Alexander succeeded, and after the decisive victory at Legnano compelled Frederick's submission. The papal struggle was carried on in England by Thomas a Becket, dying in a victory for Alexander. William the Lion, of Scotland, was excommunicated for opposing him. Important decrees were issued by Alexander III, safeguarding ecclesiastical powers and privileges.

4. Alexander IV, Pope 1254-61; a man of great gifts, which, however, were of little avail in his unfortunate times. His administration is signalized by attempts to unite the Greek and Roman Churches, and the establishment of the Inquisition in France (1255). He was the nephew of Gregory IX. In his battle with Manfred of Sicily, he suffered bitter humiliations and, deserted by his bishops, was obliged to escape from Rome. He died in Viterbo in 1261.

5. Alexander V, Pietro Philargi, of Candia. He was for some time professor in Paris, and in 1402 was made archbishop of Milan, and in 1404 cardinal. In 1409 after the deposition of the rival Popes, Gregory XII and Benedict XIII, he was elected Pope by the cardinals at the Council of Pisa, but was recognized only by a part of Christendom. He forbade the teaching of Wycliff in Bohemia and prohibited Huss from preaching even in private chapels. He died at the age of 70, and it was supposed by some, though without foundation, that he was poisoned by his successor, Balbazar Cossa (Pope John XXIII).

6. Alexander VI, Roderick Llancol, was born at Cativa in the diocese of Valencia, in Spain, 1 Jan. 1431. He assumed the name Borgia when his uncle of that name became Pope as Calixtus III. After studying law he entered the papal court and was advanced rapidly, becoming cardinal deacon and vice-chancellor of the Church in Rome. Appointed cardinal-bishop of Albano in 1476, he was ordained priest in that year. By the unanimous consent of the cardinal electors he was crowned Pope 11 Aug. 1492. His administration was a remarkable one. He cleared Rome of the bandits who had infested the city; held court every Wednesday; established the Congregation of the Index for the censorship of books; repressed the insolence and rapacity of the Roman nobility; put a stop to the falsification of ecclesiastical documents; drew up measures for the reformation of ecclesiastical discipline; co-operated with European rulers in their projects against the inroads of the Saracens; effected peace between the kings of Spain and Portugal by re-partitioning between them their discoveries in the New World; provided missionaries for preaching the gospel in newly explored countries; approved and confirmed several religious congregations; restored discipline in the Church in Flanders; suppressed magic in Germany and Bohemia; popularized the custom introduced by Calixtus III of saying the Angelus at midday; encouraged arts, particularly painting and literature; put an end to the famines which had so often visited Rome; and issued many noted bulls, letters and other papal documents, which alone show that he was a man of extraordinary genius and powers. Historians like Guicciardini and Burchard, and more modern writers who follow them, of licentiousness before his ordination to the priesthood, of simony, nepotism and cruelty as Pope. It is difficult to reconcile all the crimes attributed to him with his high qualities and distinguished deeds. Of late years the tendency of moderate historians is to exonerate him from many extreme charges, to extenuate the faults of his youth and cast doubt on the serious accusations brought against him as Papal nuncio in Germany. He was chosen Pope 7 April 1665, through the influence of France. In 1661, in spite of the protests of the Jansenists, he confirmed the condemnation of the five Jansenist dogmas which had been condemned by his predecessor, Innocent X. Later he fell into controversy with Louis XIV. During his rule Rome was beautified in many directions, especially by the colonnade before Saint Peter's. He was himself a great patron of the arts and sciences. A collection of his poems appeared in 1656.

7. Alexander VII, Fabio Chigi, of Siena, was, during the treaties of peace at Münster and Osnabrück, papal nuncio in Germany. He was chosen Pope 7 April 1665, through the influence of France. In 1661, in spite of the protests of the Jansenists, he confirmed the condemnation of the five Jansenist dogmas which had been condemned by his predecessor, Innocent X. Later he fell into controversy with Louis XIV. During his rule Rome was beautified in many directions, especially by the colonnade before Saint Peter's. He was himself a great patron of the arts and sciences. A collection of his poems appeared in 1656.

8. Alexander VIII (1610-91), Pietro Ottoboni, of Venice; Pope 1689-91; assisted Italy in wars against the Turks. Through the purchase of the library of Queen Christina of Sweden he enriched the Vatican with 1,900 precious manuscripts. The collection is known as the Ottobonian Library. Consult Cambridge, 'Modern History' (Vol. I); Hefele, 'History of the Councils'; Parsons, 'Studies in Church History'; Pastor, 'History of the Popes.'

ALEXANDER I, Emperor of Russia, son of Grand Duke Paul Petrovitch and Grand Duchess Maria Feodorovna, née Princess of Wurttemberg: b. 23 Dec. 1777; ascended the throne 24 March 1801; d. 1 Dec. 1825. Empress Catharine the Great took care of his education, which was conducted according to the best standard prevailing in Europe by a Swiss pedagogue, La Harpe, in co-operation with Professor Kraft and others. But La Harpe was soon dismissed because of his enlightened ideas of the age and his sympathy with the French revolutionists. Immediately upon the assassination of his father Paul I, of which crime it is alleged Alexander had a guilty knowledge, he ascended the throne and succeeded in restoring (15 June 1801) peace with Great Britain, and later (8 Oct. 1801) concluded conventions with France and Spain. During the reign of terror and insecurity of Paul I, Alexander conceived the idea of framing and giving to Russia a constitution with the national representation in the government, which was remarkable in a sovereign of his day and country, but which he, however, abandoned in the later years of his rule, adopting his predecessors' policy of repression and accepting the views of the notorious Prince Metternich. The following four years of his rule Alexander spent almost exclusively for the improvement of the internal affairs of which the most important are the two ukases, signed on 14 April 1801, whereby he diminished taxes, liberated
debtors, emancipated priests and deacons, abolished corporal punishments, paved the way for complete abolition of serfdom, etc. His opponents, chiefly a number of the Senate members, were the Anglophile Count Kotchubey, Prince Czartoryski, who was noted for his sympathy for the Poles, Count Stroganov, the great French admirer, and other able men of the empire. By his ukase of 8 Sept. 1802, he established definitely the duties and authorities of the senate and estab-

lished the ministries of war, navy, foreign af-

fairs, interior affairs, justice, finance, commerce and public education. In 1803 he established in Saint Petersburg the Academy of Science and in the following year the universities of Kazan and Kharkov. But the period of peace was soon to be disturbed. The incessant dis-
sensions between France and Great Britain made it necessary for Russia to effect a rap-

prochement with England, Austria and Switzer-

land in the beginning of 1805 for the purpose of resisting the encroachments of France on the territories of independent states. The de-

feat of the Austrian army in the battle of Ulm forced Russia to send Austria help under the lead of General Kutuzov. Alexander was personally at the head of the Russian army in the battle of Austerlitz (2 Dec. 1805), when the combined armies of Russia and Austria were defeated by Napoleon. Alexander was compelled to retreat to his dominions together with the remains of his routed army. Further results of that memorable battle were: the ever-growing hostility of Prussia toward Rus-

sia and the treaty of alliance, offensive and defensive, concluded 27 Dec. 1805, at Schon-

brunn, between Austria and Russia. In the succeeding campaign the Russians were again beaten at Eylau (8 Feb. 1807), and Friedland (14 June), the result of which was an inter-

view a few days after the battle, on a raft

anchored in the Niemen, between Alexander and Napoleon, which led to the treaty of peace signed at Tilsit. This treaty was confirmed by the convention of Erfurt (12 Oct. 1808) where-

by Napoleon consented to the annexation of

Wallachia and Moldavia to the Russian empire. The Russian Emperor now for a time identified himself with the Napoleon, the seizure of the Danish fleet by the British brought about a declaration of war by Russia against Great Britain and Sweden, and Alex-

ander invaded Finland and conquered that long-coveted duchy. Alexander spent some time in Finland in order to establish personally good relations with the Finns, and to win their confidence; while in Saint Petersburg a separate Finnish committee was formed and a secretary of state for foreign affairs appointed. Less successful was the campaign carried on by Alexander against the Turks (1809–12) who now demanded the restora-

tion to the Ottoman empire of the provinces of Wallachia and Moldavia. The war was

ended by the Peace of Bucharest (1812). The French alliance was found to be too oppressive, and his having separated himself from Napoleon led to the French invasion of 1812 in which the Russian armies were utterly defeated in the battle of Borodino. 15 Sept. 1812. Napoleon made a triumphant entry into Moscow, which he found in flames. But seven days later, forced by famine, deprivation and by the lessening morale of his armies, Napoleon decided to leave Mos-

cow, and his great retreat was converted into a rout by the brilliant victories of the Russian General M. J. Kutuzov. His troops were the Ang-

sack hetman Platov at Vopa and of General Kutuzov at Krasnoe. The successful outcome of the campaign against Napoleon animated Alexander to further efforts to establish a permanent peace in Europe and, despite the advice of his prime minister, Chancellor G. B. Shter-

kov, General Kutuzov and Count Rumyantsev, who were unanimous against further wars, he was firmly resolved to cross the frontier (13 Jan. 1813) with his powerful army and to in-

vade Prussia, and in August 1813 to form an offensive and defensive alliance with that government. However, the Russian armies headed by General Withdenstein, suffered, toget-

her with their Prussian allies, crushing de-

feats in the battles of Lützen and Bautzen (22 and 21 May respectively). The following year Austria joined hands with Russia and Prussia against Napoleon and, after numerous battles with alternative success, Paris fell into the hands of the Triple Alliance on 1 April 1814, and the campaign of the Treaty of Paris (1 June 1814). By the Treaty of Vienna, which was concluded 10 July 1815, Alexander secured for his empire a part of the duchy of Warsaw, the grand duchy of Poznan, and introduced into the part of Poland apportioned to Russia a liberal constitution. When the deposed Na-

poleon again landed in France, the Russian army moved rapidly from Poland to the banks of the Rhine and Alexander went from Vienna to Heidelberg. Napoleon's rule of the Hundred Days was ended, however, by his defeat at Waterloo and the French Bourbon dynasty was restored in the person of Louis XVIII. Alex-

ander, moved by the desire of establishing a lasting peace in Europe, composed and signed, together with his Prussian and Austrian allies, a treaty of peace (26 Sept. 1815) known as the Holy Alliance (q.v.). The remaining part of his reign was chiefly taken up in measures of internal reform including the gradual aboli-

tion of serfdom and the promotion of education, religion, agriculture, commerce, navigation and manufacture.

Emblittered and disappointed in liberalism and political altruism he turned even more toward religious fanaticism. The last years of his life Alexander spent either in traveling through the remotest parts of his empire or in complete seclusion in the Tsarskoe Selo. When in the year 1821 a Russian agent provoc-

ateur, Alexander Ipsianni, started an insur-

rection in Greece against the Turks, Tsar Alex-

ander formally protested and endeavored to reassure the Sublime Porte of the innocence of official Russia, but the Sultan would not believe in the sincerity of his action and a wholesale massacre of Christians in Constantinople took place, which forced the Russian ambassador, Baron Stroganov, to leave that capital in a hurry. However, the unpopular incident, averted by Alexander's astute diplomacy only to break out shortly after his death. Alexander died at Taganroga where he had accompanied his consort, Empress Eliza-

beth Alekseyevna, for the improvement of her health.

ALEXANDER II, Emperor of Russia, eldest son of Emperor Nicholas Pavlovitch and Grand Duchess Alexandra Theodorovna: b. 29 April 1818; d. Saint Petersburg, 13 March 1881.

After having received a careful education, under the direction of the famous edukator Zhukovski, which covered especially natural sciences, statistics, law and modern languages (French, English, German and Polish), he applied his attention to practical military subjects. In order to acquaint himself with governmental machinery and affairs, Alexander, while still a youth of 17 years, was frequently present at the sessions of the Senate and the Holy Synod. His theoretical education was completed by extensive travels through Russia and Europe, of which he visited every country with the exception of France and Spain. On 16 April 1841 he wedded Princess of Darmstadt, who is known as Maria Alexandrovna, by whom he had eight children: Alexander, Nicholas, Vladimir, Aleksy, Marie, Sergei and Paul. Alexander succeeded his father Nicholas I in 1855, before the Crimean War, which he conducted to a satisfactory close, considering the number of his enemies, on 31 March 1856, at the conference of Paris, by virtue of which the Black Sea was proclaimed neutral and Russia lost a part of the Black Sea coast. The new emperor, after the war set about effecting important reforms in the empire, among the first being the improvement of finances and state budget, judiciary system, city and country police and the system of popular education. The judiciary reform found expression in the publication of the 'Judiciary ukases' in 1864 by virtue of which the judicial authority was severed from the executive, administrative and legislative powers, the positions of judges became life-permanent; court of cassation, jury and notaries public were also instituted. In the sphere of interior administration one of the most important is the reform combining city police with district police, in which latter a considerably larger power of administration was vested. But the crowning event of his reign was the emancipation of the serfs (about 23,000,000 people) by the ukase of 2 March 1861. This met with an unbounded enthusiasm of the people and was considered as a new epoch in the Russian history. His reforms in Russian Poland introduced by the imperial ukase of 26 March 1861 were also of a very liberal character, but they were not well received by the Poles, who, in 1863, protested against them by several armed insurrections. The rebellions were, however, speedily quelled and the rebels severely punished by the notorious Berg and Governor-General Muraviev. Tsar Alexander also effected important reforms in the military affairs of his empire. Thus in the very beginning of his rule he suppressed military settlements, reduced the length of service from 25 to 15 years, discontinued the humiliating corporal punishment and directed attention to the improvement of the education of the army officers, for which purpose a number of military academies were established. Although Alexander's rule might be considered comparatively a peaceful one, it was marked by several important wars. Soon after the Crimean War (1859) he had to quell the insurrection of the Caucasians, against whom he sent General Prince Baryatinski. The imperial armies, after having won several important battles (at Voden, etc.), surrounded the rebels and forced their chieftain, Shamil, to surrender in September 1859. Thus the eastern Caucasus was freed and occupied, and the western part of the country was returned into the hands of Alexander's armies five years later, when Grand Duke Michael Nikolayevich was appointed governor of that region. In the course of that same year the Polish insurrection and the occupation of Turkestan took place. In the Far East, too, Alexander II effected important and advantageous changes without having recourse to arms. But the most important event of Alexander's rule is undoubtedly the Russo-Turkish War (1877-78), for it was by that successful campaign that Russia announced to the world her Pan-Slavistic aims and her readiness to protect the smaller Slavonic nations against foreign rule. It came as a protestation on the part of the Russian people against the refusal of the Sublime Porte to introduce reforms in the Christian regions of European Turkey which had been promised by the Ottoman government and signed, in the form of a protocol by the six Great Powers in London, 25 March 1877. Simultaneously with the Russian declaration of war on Turkey the Serbians and Montenegrins and even the Bulgarians made invasions of European Turkey for the purpose of freeing their Christian co-nationalists inhabiting Macedonia, the Sandjak of Novi Bazaar and Dobrudja, respectively. Russian armies, under the supreme command of Grand Duke Michael Nikolayevich, joined by the Serbian and Montenegrin insurgents, utterly defeated the Turks; they were stopped only at the gates of Constantinople, not by the Turkish resistance but by British intervention and the Sultan's request for peace. The conditions of peace were agreed upon at the conference of San Stefano but were definitely settled by the Treaty of Berlin, 1878. By virtue of that treaty, which sensibly modified that of San Stefano, greatly to the disadvantage of Serbia, Bulgaria was set up as an independent state with fully autonomous principality, with the right of electing her own prince and maintaining her own army, while eastern Rumelia was placed under the suzerainty of the Sultan but with complete administrative autonomy. Serbia, Montenegro and Rumania were also proclaimed and recognized as independent states. With the
ALEXANDER

exception of the Delta in the Danube the whole of Bessarabia, lost to Russia in 1856, was now restored to Alexander's empire.

Within the first years of Alexander's rule passed in a wholesome internal peace, the period following (from 1851) was greatly disturbed by the revolutionary element, in the empire, which exacted from the government a national-constitutional form of administration. This movement at first was conducted by the so-called "Intelligenzia" (or educated classes) by means of circulars and pamphlets, but when the peasantry and craftsmen joined the college students it assumed rapidly terrorist pace and measures. Toward the end of Alexander's reign several attempts on his life were made by Nihilists, and at last he was assassinated by an explosive missile thrown at him in a street in Saint Petersburg. On the spot of his murder a magnificent church ("Voskresensky," i.e., "Resurrection") has been built, and many Russian cities have erected monuments to the memory of the "Tsar Liberator." The Bulgarians, too, have erected in front of their princely palace in Sofia a splendid monument to the Tsar.

W. M. PETROVITCH.

ALEXANDER III, Emperor of Russia, second son of Emperor Alexander II and Empress Maria: b. 10 March 1845; ascended the throne 13 March 1866 at the age of 36; d. Livadia, 1 Nov. 1894. He married Princess Dagmar, the daughter of King Christian IX of Denmark, who changed her name at the moment of adopting Orthodox faith, to Maria Fedorovna. Alexander's education was exceedingly careful and austere, which potenti-ated his innate love for stern order and strict adherence to everything Russian even to the purity of the Russian language. He was more in favor of French civilization than the German culture and became a powerful Slavophile. At the time of the Russo-Turkish War (1877-78) he had a brilliant opportunity to put in practice his military education, for he participated in that campaign as the commander of the Rustchuk division, in which capacity he rendered splendid services by his shrewd tactics. After his father's violent death, he secluded himself for some time in his palace at Gatchina. For that same reason his coronation was postponed till 1883 and was celebrated with an extraordinary magnificence and with great national festivities. Through the fall of Merv, the subjugation of the Turkomans in central Asia was concluded; in 1885 hostilities with Great Britain with regard to the defining of the frontier between the Russian territories and Afghanistan for a time seemed imminent, but Alexander succeeded in annexing to his empire a considerable stretch of land on which a railway was constructed, uniting the centre of the Russian possession in central Asia with the Caspian Sea. In European affairs he broke away from the Triple Alliance between Russia, Germany and Austria and directed his attention to France whose friendship he wished to cultivate. He was aggrieved by the new Bulgarian spirit of ingratitude for the liberation of their country by his father Alexander II; but he finally crushed Stamboul and his band. With regard to home affairs Alexander III announced at the very time of his accession to the throne that he had no intention of limiting or reducing the autocratic power exercised by his predecessors; on the contrary he suppressed even the liberties which were granted by his father and his grandfather and he maintained that Nihilism and Anarchism in Russia could not be changed by order or by statutes, but by austere principles of Orthodoxy, nationalism and, if need be, autocracy. As he believed in uniformity of customs, language and religion throughout his vast empire he imposed sometimes in an inordinate manner the Russian language on his Polish, Finnish and German subjects and caused many bloody persecutions of the Jews. If one could not call him an absolute autocrat, one is safe in characterizing his rule as an iron imperialism, for he sought, more than any of his predecessors, for centralization of imperial administration which he strove to place almost wholly under his control. He made strong efforts to prevent malversation by officials, lutherto corruptible to an incredible degree, and stern economies were practised. The liberties granted by his ancestors to the Baltic provinces and Finland were also curtailed. Despite the most rigid police surveillance several Nihilist attempts were made on his life. That unfortunate Tsar was forced, throughout his reign, to keep himself practically a prisoner in his palace. S., 'The Court of Alexander III' (Philadelphia 1910); Lowe, C., 'Alexander III of Russia' (New York 1895); Samson-Himzelter, 'Russland unter Alexander III mit Rückblicken auf die jüngste Vergangenheit' (Leipzig 1891); Seignobos, 'Political History of Modern Europe' (New York 1900).

W. M. PETROVITCH.

ALEXANDER I, King of Scotland, fourth son of Malcolm Canmore: b. about 1078, in 1107 succeeded his brother, Edgar, only, however, to that part of the kingdom which, after the battle of Carham, had been ceded to the English by Malcolm. He died at Forth and Clyde; d. Stirling 1224. He married Siyella, a natural daughter of Henry I of England, and his reign was comparatively untroubled, though about 1115 he had to quell an insurrection of the northern clans. He founded the abbey of Scone and invested it with a diocesan episcopate; while his determined resistance to the claims of York and Canterbury to supremacy over the see of Saint Andrews did much to secure the independence, not only of the Scottish Church, but of the realm in general. In 1124 he succeeded his father, William the Lion, in 1214. He early displayed that wisdom and strength of character
in virtue of which he holds so high a place in history among Scottish kings. His entering into a league with the English barons against King John drew down upon him and his kingdom the condemnation; but two years later the ban was removed and the liberties of the Scottish Church were even confirmed. On Henry III's accession to the English throne Alexander brought the feuds of the two nations to a temporary close by a treaty of peace (1217), an accord to which he married Henry's eldest sister, the Princess Joan (1221). The alliance thus established was broken after her death without issue (1238) and the second marriage of Alexander with the daughter of a noble of France. In 1244 Henry marched against Scotland to compel Alexander's homage, but a peace was concluded without an appeal to arms. In 1249, while engaged in an expedition to wrest the Hebrides from Norway, Alexander died on fever on Kerrera, near Oban.

ALEXANDER II, King of Scotland: b. 1241; succeeded his father, Alexander II, 1249; d. 12 March 1286. In 1251 he married the Princess Margaret (1240–75), eldest daughter of Henry III of England. Very shortly after he had come of age his energies were summoned to defend his kingdom against the formidable invasion of Haco, King of Norway (1263), who had come to Alexander's only daughter, Margaret (1261–83); the untimely death of their infant daughter, Margaret, commonly designated the Maid of Norway, on her way to take possession of her throne, was the occasion of many calamities in Scotland. During the concluding years of Alexander's reign the kingdom enjoyed a peace and prosperity which it did not, taste again for many generations. His only surviving son died without issue in 1284; and in the same year Alexander contracted a second marriage with Jolenta, daughter of the Comte de Dreux.

ALEXANDER I (OBRENOVITCH), King of Serbia, second son of King Milan and Queen Nathalie: b. 14 Aug. 1876; d. 10 June 1903. He received his education chiefly in Serbia where he mingled with a band of young officers of very high culture. Even from his early boyhood those officers poisoned Alexander's mind with distrust in the political friends who surrounded him after the abdication of his father in 1889. From that time to 1893, as Alexander was under age, the executive power of the state was vested in a regency of three statesmen. But in April of that year Alexander, then only in his 17th year, by a cleverly prearranged coup d'état, proclaimed himself of age, ousted the regents, dismissed their government and took the executive power into his own hands. His act met with unbounded approval from the leaders of the then mighty Radical party and Alexander forthwith appointed a Radical ministry presided over by Mr. Pashitch. The Radicals, in their turn, were estranged when they discovered that they had not abolished the liberal constitution granted by his father in 1889 and restored that of 1869 which was not only conservative but even somewhat autocratic in character. During the summer of 1900, when King Milan was in Austria endeavoring to secure for his son the hand of a German princess, Alexander, to the amazement of all his friends, married his former mistress, Mme. Draga Mashin, the widow of a civil engineer and former lady-in-waiting to Queen Olga. Even Milan refused to condone this action, for Mme. Mashin was a woman much older than Alexander and of so impossible a reputation that the possibility, had it existed, of her bearing an heir to the throne could not be revolting to the Serbian people. Under Drag's influence Alexander initiated a rule of almost Neronian tyranny. The Radical party was terrorized by one coup d'état after another; the vulgar Queen offered incessant insults to the highest dignitaries of the state and court officers, she roused the whole country to a white heat of excitement by a simulated accouche ment, and when the myth was exploded and the friendship of the Russian Tsar lost, she began to intrigue to secure the succession for her own brother, Lieutenant Nikodym, a man as objectionable and arrogant as the Queen herself. Thus blunders and outrages followed each other under the most impossible couple that ever occupied a throne. King Alexander, in order to veil his ill deeds before the eyes of the people, granted a comparatively liberal constitution (April 1901) only to suspend it by another coup d'état (March 1903). This aroused the indignation not only of the members of the National Assembly (Skupština) and the Senate, but also, and especially, of the army officers. The end of Alexander and Drag came, however, on the night of 10 June 1903; a group of malcontent officers entered the palace and murdered the King. On this occasion Draga was also mortally wounded as revolver shots were exchanged in the complete darkness which reigned in the palace on account of the electric wires having been cut by the friends of the King. Draga's brother, the prime minister, the minister of war and Alexander's aide-de-camp were also assassinated. The next day the army proclaimed Prince Peter Karageorgevitch, son of Alexander Karageorgevitch and grandson of Kara-George Petrovitch, King of Serbia, which election was confirmed five days later by the National Assembly.

ALEXANDER I, Prince of Bulgaria, né Prince of Battenberg: b. 17 April 1857; d. 26 Nov. 1893. He received his military education in the cadet-corps in Dresden and was appointed second lieutenant in the 24th dragoon regiment. Later he served with the Russian Uhians, in whose ranks he fought against the Turks in the Russo-Turkish War of 1877–78. On 10 May 1879, thanks to his influence in Germany, Austria and even of his Russian friends, he was elected by the Bulgarian Sobranje of Tryovo, hereditary Prince of Bulgaria, immediately after which event he visited the most important courts of Europe and, on 17 July 1879, he was presented to his suzerain, Sultan Abdul-Hamid II, from whom he obtained the imperial firman granting him the principality of Bulgaria. Soon after his ascension to the throne he adopted an anti-Russian policy, ignoring the deeds of Emperor Alexander II, called by the Bulgarians the "Tsar Liberator," which, naturally, alienated Russian friendship for Bulgaria. In 1885 King Milan
ALEXANDER

of Serbia declared war on Bulgaria in order to prevent the annexation of East Rumelia to that principality, which ended by the Treaty of Bucharest 1886 but which, although favorable for Bulgaria, did not in any measure improve Alexander's impossible position. However, the unfriendly attitude of Alexander toward Russia caused in Bulgaria a popular movement and on 3 Sept. 1886 his palace in Sofia was attacked and he was kidnapped and taken to the Russian town Reni. Afterward he was released and taken back to Sofia through the indignation of his powerful party. Having lost Russian protectorate he found it absolutely impossible to abdicate (7 Sept. 1886) and to leave Bulgaria and to join the Austrian army in the capacity of a colonel of the dragoons. He was buried in the church of St. George at Sofia. Consult Koch, A. (Alexander's chaplain). ' Mein Leben und der Regierung des Fürsten Alexander von Bulgarien' (Darmstadt 1887; Draudor, Prince Alexander of Battenberg (1884) Macdonald, 'Czar Ferdinand and His People' (New York 1913); Sobolev, 'Die erste Fürst von Bulgarien' (Leipzig 1886).

ALEXANDER, Abraham, American agitator: b. North Carolina 1718; d. 1786. His place in history is due to the fact that he was chairman of the convention which on 31 May 1775 passed the resolutions generally known as the Mecklenburg Declaration of Independence (q.v.).

ALEXANDER, Archibald, American clergyman: b. Virginia, 17 April 1772; d. Princeton, N. J., 22 Oct. 1851. He studied theology and performed itinerant missionary work in various parts of Virginia; became president of Hampton-Sidney College in 1796 and pastor of a Presbyterian church in Philadelphia in 1807. On the establishment of Prince ton Theological Seminary in 1812 he was appointed its first professor, a position which he held till his death. Among other works he published: 'Outlines of the Evidences of Christianity,' 'Treatise on the Canon of the Scriptures' (1823); 'History of the Patriarchs' (1823); and 'History of the Israelite Church' (1823); his 'Moral Science' was posthumous.

ALEXANDER, Barton Stone, American soldier: b. Kentucky 1819; d. San Francisco, Cal., 15 Dec. 1878. He was graduated from West Point 1842 and became lieutenant in the engineer corps; as such he superintended the building of Millinocket's Ledge lighthouse off Boston Harbor, the marine hospital at Chelsea, north of Boston, and the military asylum at Washington, besides repairs on fortifications. He assisted in constructing the defenses of Washington in the Civil War, took part in the first campaign about Manassas and was brevetted major for conduct at Bull Run; and remaining with the Army of the Potomac was brevetted lieutenant-colonel for conduct at the siege of Yorktown in 1862. In 1864 he was consulting engineer on Sherman's staff from the end of the war. In 1865 he was brevetted brigadier-general for services in the war. The next two years he was in charge of the construction of the public works in Maine and in 1867 became senior engineer with rank of lieutenant-colonel. Thence till death he was a member of the Pacific board of engineers for fortification.

ALEXANDER, Cecil Frances (Hum fray), Irish poet: b. County Wicklow 1818; d. 12 Oct. 1895. She was very active in religious and charitable works. She is best known as a writer of hymns and religious poems. Among the most noted are the hymns 'The Roseate Hue of Early Dawn' and 'All Things Bright and Beautiful.' Her most famous poem is 'The Burial of Moses.'

ALEXANDER, Edward Porter, American military engineer: b. Washington, Ga., 26 May 1835; d. Savannah, Ga., 28 April 1910. Graduating from West Point 1857, he was made second lieutenant in the engineer corps; resigned 1861 and entering the Confederate army served there till the surrender at Appomattox; April 1865, at first as chief of ordnance and chief signal officer in the army of Northern Virginia, then as brigadier-general and chief of artillery in Longstreet's corps, taking part in the Wilderness and Spotsylvania and the siege of Petersburg. From 1867 to 1885 he was professor of mathematics and engineering in the University of South Carolina; thence (1871—92) manager and president of some of the foremost Southern railroads. He was a government director of the Union Pacific Railroad (1885—87), a member of the boards on navigation of the Columbia River and on the Chesapeake-Delaware Ship Canal (1892—94) and in 1891 engineer arbitrator of the boundary survey between Nicaragua and Costa Rica.

ALEXANDER, James, American colonial lawyer and patriot: b. Scotland about 1690; d. New York, 2 April 1756. He was an engineer officer in Scotland; compelled to leave Great Britain for taking part in the Old Pretender's Rebellion of 1715, he came to Perth Amboy, was its first official recorder in 1718 and was shortly after appointed surveyor-general of New York and New Jersey. Studying law, he rose to distinction at the bar. He engaged in political debate in the press; was temporarily disbarred for serving as counsel to a printer accused of sedition, but was reinstated two years later; held many important public offices, including those of attorney-general and of secretary of the province of New York; acquired a large fortune and was a zealous upholder of colonial liberties. He died from the fatigues of a journey from New York to Albany undertaken to oppose a ministerial project threatening colonial rights. With Franklin and others he founded the American Philosophical Society. His son was the famous "Lord Stirling" of the Revolution.

ALEXANDER, James Waddell, American clergyman, son of Archibald Alexander: b. near Gordonsville, Va., 13 July 1804; d. 31 July 1859. He studied in Philadelphia, then was graduated at Princeton and from its theological seminary. He held a pastorate at Charlotte Court House, Va. (1825—28) and the First Presbyterian Church in Trenton, N. J. (1828—30). Residing in March 1833 he was brevetted brigadier-general for services in the war. The next two years he was in charge of the construction of the public works in Maine and in 1867 became senior engineer with rank of lieutenant-colonel. Thence till death he was a member of the Pacific board of engineers for fortification.

(1825—28) and the First Presbyterian Church in Trenton, N. J. (1828—30). Residing in March 1833 he was brevetted brigadier-general for services in the war. The next two years he was in charge of the construction of the public works in Maine and in 1867 became senior engineer with rank of lieutenant-colonel. Thence till death he was a member of the Pacific board of engineers for fortification.
ALEXANDER (1849-51); from 1851 till death pastor of his old Duane Street Church, reorganized as the Fifth Avenue. He wrote much for religious and other periodicals and for the Tract Society, and over 30 volumes for the American Sunday-School Union. He published also volumes of sermons: 'The American Mechanic and Workingman' (2 vols., 1847); 'Plain Words to a Young Communicant' (1851); a biography of his father (1851); 'Discourses on the Conduct and Practice of Religious Life' (1855); 'Thoughts on Preaching' (1864); etc.

ALEXANDER, John Henry, American scientist: b. Annapolis, Md., 26 June 1812; d. 2 March 1867. Graduating from St. John's College, Annapolis, 1826, he studied law, then engineering; and a plan for the survey of Maryland he put before its legislature gained him the appointment of topographical engineer of the State, which he held till 1841, preparing annual reports which did much to enlist capital in developing its coal and iron fields. He published a 'History of the Metallurgy of Iron' (1840-42). He was also associated in Hassler and Bache's coast survey. He made great efforts to establish a uniform standard of weights and measures in the United States, and in 1850 a 'Universal Dictionary of Weights and Measures, Ancient and Modern.' In 1857 the United States government sent him to England as a delegate to the British commission on international coinage and his appointment to the directorship of the Philadelphia Mint was prevented by his death. He served on many commissions and published many valuable reports, papers in the American Journal of Science and Arts, etc. He was also at different times professor of physics in St. James' College, Maryland, the University of Maryland and the University of Pennsylvania. He also wrote volumes of religious verse, an unpublished 'Dictionary of English Surnames,' etc., and edited scientific works.

ALEXANDER, John White, American artist: b. Allegheny City, Pa., 7 Oct. 1856. For three years abroad, studying at the National Academy of Fine Arts, Munich, and with Duveneck in Venice and Florence. Upon his return to the United States he was active as a magazine illustrator. Attention was first attracted to his paintings by his exhibit in the salon of the Champ de Mars in 1893. He received the gold medal of the Philadelphia Academy of Fine Arts in 1897, and gold medals at the Paris Exposition of 1900 and the Pan-American Exposition, Buffalo, in 1901. In 1902 he was elected an academician of the National Academy. He is represented in the Luxembourg and many American and European collections; and by six lunettes depicting 'The History of the Book,' in the East hall of the Congressional Library, Washington.

ALEXANDER, Joseph Addison, American Biblical scholar, son of Archibald Alexander: b. Philadelphia, Pa., 24 April 1809; d. 28 Jan. 1860. He was graduated first in the Princeton class of 1826 and with R. B. Patton founded a unique school of Hebrew. He was assistant professor of ancient languages at Princeton, 1830-33, then spent some years abroad in linguistic studies; from 1838 till death was professor at Princeton Seminary, 1838-50 of Oriental and Biblical literature, 1851-60 of church history and government, 1859-60 of New Testament history and Biblical Greek. He was ranked among the foremost of American biblical scholars, an Orientalist of high order and a linguist of eminent variety and soundness. His exegetical works include commentaries on Isaiah (1846, 1847, 1851), the Psalms (3 vols., 1850), Acts (1857), Mark (1858), all indebted to German sources. His sermons were collected in two volumes, 1860.

ALEXANDER, Mrs., pseudonym of Annie Hector (q.v.).

ALEXANDER NEVSKY, nyë`skë, Saint, Russian hero: b. Vladimir 1220; d. 1263. Of noble birth and lord paramount of the Russian nobility, he is renowned for his victory in 1240 over the Swedes, Danes and Knights of the Teutonic order, on the Neva, where Petrograd now stands, when Russia was still suffering from the terrible effects of the Tartar invasion. For this victory he received his surname of Nevsky. In 1238 Russia had become vassal to the Tartars. By subduing the conquerors, Alexander used his best endeavors to prevent a recurrence of the invasion while the country was recuperating and died when on a third return journey from the Tartar capital, where he had succeeded in winning substantial concessions. His exploits are preserved in national songs, the Russian Church canonized him and Peter the Great in 1723 built a magnificent monastery to his memory on the spot where the battle of the Neva was won, transferred his remains there from Vladimir in 1724 and created the order of Knights of St. Alexander Nevski in 1725.

ALEXANDER OF AFR'RODISIAS, Greek philosopher, surnamed 'the Expositor': lived about 200 A.D. As head of the Lyceum at Athens, he became a distinguished exponent of the doctrines of Aristotle and author of commentaries on his works, which, translated into Latin, were adopted by the Alexandrian philosophical school of the Renaissance and are still useful in the interpretation of Aristotle. His own original works include 'On the Soul' and 'On Fate.' The latter, in which he controverts the doctrine of necessity, was published by Orelli at Zurich in 1824.

ALEXANDER OF HALES, English philosopher and theologian: b. Hales, Gloucestershire; d. Paris 1245. One of the greatest of the schoolmen, he was among the first to study Aristotle from the point of view of the Arabic commentators. His chief work was 'The Sum of Theology' (1475).

ALEXANDER OF RUMANIA, Hospodar of Rumania: b. Sphical, 20 March 1829; d. Heidelberg, 15 May 1873. In 1829 he was elected hospodar at Jassy and on 17 February at Bucharest, with title Alexander John I. By abolishing serfdom and dividing landed properties he benefited the peasantry, but his efforts toward centralization caused discontent and on 22 Feb. 1866 he was compelled to abdicate.

ALEXANDER, Samuel, English educator and philosopher: b. Sydney, N. S. W., 6 Jan. 1859. He was educated at the University of
Melbourne and at Balliol College, Oxford. From 1882 to 1893 he was fellow of Lincoln College. He is professor of philosophy at the Victoria University of Manchester since 1893. He is a fellow of the British Academy. In 1913, he was president of the Aristotelian Society 1908–11 and in 1915 was appointed Gifford Lecturer for 1916–18 at the University of Glasgow. He has published ‘Moral Order and Progress’ (1889); ‘Locke’ (1908) and various papers in the philosophical biographies of British Journal of Psychology, the Proceedings of the Aristotelian Society and other journals.

ALEXANDER SEVERUS, Roman emperor (in full, Marcus Aurelius Alexander Severus): b. A.D. (the modern Acre), Phoenicia, 205 A.D.; d. 235. He was the son of Gessius Marcius and of Julia Mammea, niece to the Emperor Severus. He was admirably educated by his mother, and was adopted and made Cæsar by his cousin Heliogabalus, then but a few years older than himself, at the prudent instigation of their common grandfather, C. Augustus. That contemptible Emperor, however, soon grew jealous of his cousin and would have destroyed him but for the interference of the praetorian guards, who soon after put Heliogabalus himself to death and raised Alexander to the imperial dignity in his 17th year, 11 March 222. Alexander adopted the noble model of Trajan and the Antonines, and the mode in which he administered the affairs of the empire, and otherwise occupied himself in poetry, philosophy and literature is eloquently described by Gibbon. On the whole, he governed ably both in peace and war; but whatever he might owe to the good education given him by his mother, he allowed her a degree of influence in the government which threw a cloud over the latter part of his reign. He was convinced that in this matter he had allowed his filial reverence to mislead him and is said to have reproached his mother with his dying breath as the cause of the disaster which had befallen them both. Alexander behaved with great magnanimity in one of the frequent insurrections of the praetorian guards; but, either from fear or necessity, he allowed many of their seditious mutinies to pass unpunished, though in one of them they murdered their prefect, the learned lawyer Ulpius, and in another compelled Dion Cassius, the historian, then consul, to retire to Bithynia. At length, after having defeated, in 232, the Persians under Artaxerxes, who wished to drive the Romans from Asia, and undertaking an expedition into Gaul to repress an incursion of the Germans, he was murdered with his mother in an insurrection of his Gallic troops, headed by the brutal and gigantic Thracian, Maximin, who took advantage of their discontent at the Emperor’s attempts to restore discipline. Alexander was favorable to Christianity, following the predilections of his mother, Julia Mammæa, and he is said to have placed the statue of Jesus Christ in his private temple with those of Orpheus and Apollonius of Tyana.

ALEXANDER THE GREAT, the 3d King of Macedon, bearing the name which he made so famous: b. Pella 356 B.C.; d. Babylon 323 B.C. His mother was Olympias, an Epirote princess, who traced her descent from Achilles.

There is little reason to doubt that his father was Philip of Macedon, though the latter was not confident about his paternity and though there is no evidence of any feelings between the two such as are met with in the legends; and his true father and son. On the contrary, Philip seems to have resented the imperial qualities of his son, which he was clever enough to see and appreciate; and Alexander showed a precocious envy of his father’s neglected opportunities of conquest, and in after life, his accomplished biographer Plutarch has noted and well on. No open rupture took place till Philip repudiated Olympias to wed a Macedonian lady (Cleopatra according to Plutarch and others, but Eurydice according to Arrian). During the nuptial feasting Philip made at Alexander with his sword, while the son jeered at his father’s drunken fury and unsteady gait. In the assassination of Philip in 336 B.C. the repudiated and banished Olympias certainly had a hand, and we cannot be sure that Alexander was not an accomplice.

The memorable year in which Alexander first appeared on the stage of universal history was 339 B.C. At the age of 16 the regency ofEarly six to was entrusted to him and he was set out on an expedition against Byzantium; and in that capacity it fell to his lot to lead his first army against an Illyrian rising, to found his first Alexandria in the upper valley of the Strymon and to receive a deputation of envoy from the King of Persia—a fit beginning for the miracle of precocity who was afterward to destroy Thebes at 21, to conquer Babylon at 25 and to die master of the world at 33. In the year after his appointment to the regency Alexander showed eminent military capacity at the battle of Chaeronea (338 B.C.) and, on the murder of Philip, ascended the throne in 336 B.C. before he had reached his 20th year.

The brilliant natural gifts of Alexander had been developed under the tutelage of Aristotle. His personal beauty, his lithe and expressive body, his flashing eyes, was very remarkable, and he was pre-eminent in horsemanship and all athletic accomplishments. A habit (or perhaps some peculiar muscular conformation of the neck) which gave his head a slight turn to the left shoulder imparted to him an air of hauteur, which gave a note of eminent distinction to manner of carriage and grace and affability. He was of an extremely trusting disposition. His position in ascending the throne was a difficult one. He had enemies on every side. The Illyrians and Thracians were always watching an opportunity to attack Macedon, and indeed most of the Grecian states were ready, if possible, to throw off the Macedonian yoke. Persia regarded the growth of Macedon with suspicion, and finally his own Macedonian subjects were far from being united in approval of the career of conquest on which Philip and Alexander had both resolved to embark.

His reign began with an act of cruelty such as was destined subsequently to become almost a matter of course on every change of rulers; his uncle and his half-brother were put to death and the little daughter of Cleopatra, Philip’s widow, was butchered in the arms of her mother. In the autumn of 336 B.C. Alexander marched into Greece and was at the head of the chief command against Persia by the Amphicryones at Thermopylae. In 335 B.C. he advanced to
the Haemus range (the Balkans) and showed great ability in his campaign against the Thracians, crossing the Danube — apparently out of mere bravado — in the face of the enemy without the support of a single ally. He would not have had even the real friends among the Greek states. The Thebans, hearing a false report of his death, became overt enemies, proclaimed their independence and slew some Macedonian officers. Alexander appeared in Boeotia with amazing dispatch and took Thebes by storm on the third day of the siege. This was the occasion on which, in the words of Milton,

"The great Ethnarch conqueror bade spire
The house of Pindar."

Leaving Antipater to govern in Europe, he crossed over into Asia in the spring of 334 with 30,000 foot and 5,000 horse. The Persian empire, the conquest of which he undertook, was at least 50 times as large as his own and numbered about 20 times as many inhabitants. It extended from the Hellespont to the Punjab, from Lake Aral to the catacaracts of the Nile. But it was a vast congeries of subject provinces having no real bond of cohesion but the will of the king. For 80 years it had been tending to dissolution in its western provinces, which were the most exposed to danger. As stages in this process may be mentioned the revolt of Egypt under Amyrtæus in 410 and that of the Cyriptere Evagoras, which was not put down till 383; the numerous revolts of satraps, of Greek cities and of semi-Greek tyrants during the first half of the 5th century and the attack on Persia made by Tachos, King of Egypt, in 361. It has been well remarked by Adolf Holm that the position of the Persian empire when attacked by Alexander had some resemblance to that of the Roman empire when overrun by the Germans. Both empires held together merely by the law of inertia; in both their strength lay not in their native elements, but in mercenaries taken from the very peoples, the Germans and the Greeks, who threatened respectively the safety of the two empires. Alexander proposed to himself nothing short of complete dispossession of Darius in favor of himself as captain-general of Hellas and the establishment of his own Panhellenic empire in the room of the Persian. He was not led from point to point by this or that strategical reason. His business was not to leave Asia till every satrapy in the Persian empire acknowledged his sway. Even the burning of the Persian capital Persepolis was probably no act of drunken folly, as which it has often been described, but rather a signal and emphatic assertion of mastery and ownership, as of one who should say, "The Persian empire is mine, to throw it into the fire if I please." Alexander had no intention of remaining King of Macedon. His design was to be the Greek emperor of Europe and Asia, and this position in effect he assumed on the death of Darius. With this view throughout his whole career in Asia he sought as much as possible to fuse and commingle his Asiatic and European subjects, very much as England did in India. This was the effect to which he was giving all his efforts at the time of his death.

The first hostile army he encountered was on the Granicus River (an affluent of the Sea of Marmora). He crossed the Granicus, just as he afterward crossed the Pinarus at Issus, in full view of the enemy, hurled himself with all his force on their centre and completely broke it up. It was not his way to refrain from the pass in question. He was in no tender spirit. His victories sometimes remind us of the oft-quoted C'est magnifique, mais ce n'est pas la guerre. He won by an impetuous dash a victory which a subtler strategy might have failed to achieve, just as his sword-cut at Corinthus made away with the knot which his fingers could not undo. The victory at Granicus was attended with unprecedented results; Sardis, Miletus, Ephesus, Halicarnassus submitted one after another, and he established in them democracies of the Greek type. In November 333, Darius, eager to meet the invader, hastened to the sea-coast near Issus (at the head of the Gulf of Iskanderoon). The tactics pursued at the Granicus had here again a successful issue. Darius fled, leaving his family and a part of his forces in the hands of the conqueror. The mother, wife, two daughters, and son of Darius were treated with a clemency which foreshadowed the ages of chivalry. An Asiatic conqueror would have put the males to death, probably with torture, and would have sent the harem to his harem. Captive Greek generals he also spared and liberated. He took possession of Damascus, a city which even then could boast of a hoary antiquity, and secured all the towns along the Mediterranean Sea. His plan now was to occupy Egypt, and this was made easy by the capture of Tyre on 20 Aug. 332, after a siege of seven months. During the siege a message came from Darius offering Alexander 10,000 talents, the hand of his daughter in marriage, and Asia as far as the Euphrates, if he would make peace. "I would accept it if I were Alexander," said his general, Parmenio. "So would I," replied Alexander, "if I were Parmenio." Gaza fell in November 332, and Alexander, taking possession of Egypt, sacrificed to Apis and the Egyptian gods in Memphis and held musical and athletic competitions after the Greek fashion in Tyre. Thus he conciliated the affections of his subjects. Politically he organized Egypt as a province in a way which, as Arrian remarks, was in accord with the Roman system, giving the civil administration first to two, and then to a single governor, while the troops were placed under several separate commanders. It was now that Alexander founded the celebrated Alexandria — destined in two generations to be the first city in the Levant — and marched through the Libyan desert to consult the oracle of Jupiter Ammon, whose son he claimed to be.

Meantime Darius was collecting an army in Assyria; but before the decisive battle of Arbela he made overtures of peace to Alexander, whose answer was, "I, Alexander, hold all thy treasure and all thy land to be mine," a verbal cutting of the Gordian knot. The Persian force encountered by the Greeks at Gaugamela, near the ancient Nineveh, and about 50 miles from Arbela (which strangely has given its name to the battle ever since), is said to have numbered 1,000,000 infantry, 40,000 cavalry, 200 scythed chariots. Alexander had only 40,000 foot and 7,000 horse, but he won a decisive victory on 1 Oct. 331. The Macedonians aimed at the faces of their adversaries, as the Cæsarians afterward did at
Pharsalus. Babylon and Susa opened their gates to the conqueror, who then entered Persispolis, the capital of the province of Persis, seized its immense treasuries and burned its palace and citadel to the ground.

In the spring of 330, Alexander proceeded to Media in pursuit of Darius. That weak monarch was being carried about by Bessus, satrap of Bactria, who had turned against Alexander. The approach of Alexander, inflicted a mortal wound on Darius and fled, leaving him to die. Darius died before Alexander came up with him (July 330). The conqueror sent his body to Persispolis to be interred with royal honors. After taking possession of Hycania and Bactriana he was meditating still more gigantic plans, when he learned in the autumn of 330 that Philotas, the son of Parmenio, though cognizant of a conspiracy against his life, had not reported it. He put both Philotas and Parmenio to death. The execution of the former has been condemned, but it is on the whole defensible; the murder of the latter is an inexcusable act of brutal tyranny. About the end of 330 or the beginning of 329 he crossed the great range of the Caucasus (not the modern Caucasus, but the Hindu Kush), by a pass at an altitude of 13,000 feet; a march comparable with that of Hannibal over the Alps. He reached the city of Bactra (Balkh), and made his way north as far as the Jaxartes or Tanais, where he founded a city, probably the modern Khojend.

He remained in these regions till the summer of 327, spending the winter in Nautaca, on the right bank of the Oxus. Here occurred the murder of Clitus, and Alexander's marriage with Roxana, daughter of Oxartes, a satrap of Sogdiana. She had a son named after his father in 323. After the death of Alexander she compassed the destruction of his other wife, the daughter of Darius, and was killed with her son in 311 by Cassander. The murder of Clitus has been regarded as a great blot on the character of Alexander. But the circumstances in which he was placed greatly extenuate the act. The East believed in the divinity of Alexander, and such a belief was almost an essential condition of the permanence of his empire. When one of his own officers openly denied and ridiculed the Emperor's pretensions at a state banquet he seriously imprecated the Hellenic raj. The empire of Alexander was never subject to a second single emperor. The destinies of the West awaited the struggle between Rome and Carthage. But his vast empire nowhere save in India reverted to the pre-Alexandrine type.

Alexander now formed the idea of conquering India. He passed the Indus in 327, and formed an alliance with Taxiles, under whose guidance he reached the Hydaspes (modern Jhelum). This river was crossed after a severe struggle with Porus, in whom he met an opponent very superior to the Persian satraps who had hitherto confronted him or rather retreated before him. He then moved farther east and crossed the Acesines (Chenab) and the Hyradoes (Ravi), and reached the Hyphasis (Oxus), which now joins the last river of the Punjab, the Sutlej, but which then flowed in a different channel. He never reached the Sutlej itself. The murmurs of his army compelled him to return. The fine instrument which he had fashioned so dexterously broke in his hand. He recrossed the Acesines to the Hydaspes, where he completed the city of his name (named after his famous horse Bucephalus), which he had already begun. He had only seen the fringe of India — the Punjab. The wondrous country of Brahma and Buddha never felt the sway of Alexander. He was obliged to content himself with increasing his power across the histories of Hellenic, Semitic, Egyptian and Iranian civilization. Alexander's name does not appear in Sanskrit literature.

When he had reached the Hydaspes he built a fleet, in which he sent part of his army down the river, while the rest were conveyed overland and supplied from the banks. The city of the Malli, where Alexander was wounded, is probably Multan; Puttala is perhaps Haidarabad. The march of 500 miles through the hideous desert of Gedrosia (Baluchistan), and the voyage of Nearchus, have given much material to romancers and historians. At Carmania he was joined by Craterus, who had marched through the Bolan Pass to Kandahar, and by Nearchus, whose voyage, then thought so marvelous a feat, is no more than the short steam run from Kandahar to Bunder Abbas. From Carmania he went to Pasargadae, and thence to Susa, where he devoted himself with great energy to the task of uniting as far as possible the Macedonian and Persian nations. Alexander married two Persian princesses, and he gave rewards to those of his staff who followed his example in contracting Persian alliances. He sent home to Macedonia, with a present of a talent each, about 10,000 Macedonians who by age or wounds were incapacitated for service. These veterans were numbered in the camp of Antipater as governor of Europe. Antipater seems to have fallen into disfavor, though in 330 he had done service in defeating Agis, the Spartan king who threatened Megalopolis. It was of this exploit that Alexander contemptuously observed, "So there are one or two estates of the mice in Arcadia, while we have been conquering Asia." In 323 Alexander arrived at Babylon, where he found numberless envoys from nations near and far, come to pay their homage to the young conqueror. He was engaged in very extensive plans for the future, including the conquest of Arabia and the reorganization of the army, when he fell ill of a fever, shortly after the death of his beloved Hephaestion, which had deeply affected him. He died in 323, after a reign of 12 years and 8 months. The day before a rumor had gone abroad that the great general was dead, and that his friends were concealing the truth. The dying King caused his army to defile past his bed, and feebly waved them a last farewell. Alexander was a great administrator, a second Pericles in his devotion to work, an Alcibiades in his distinguished presence, a Phocion in his simplicity of character. He possessed eminent qualities as a statesman as well as a military leader. It is unfortunate that he did not leave to carry out his plans for the future, which would have resulted in the spread of Hellenism and in the development of the arts. The Romans enjoyed the fruit of his victories, and his conquests made possible the spread of Christianity in the East.

ALEXANDER - ALEXANDRIA

tery of Greece' (New York 1853-56); Holm, 'Griechische Geschichte' (Vol. III, Berlin 1883); Mahaffy, J. P., 'Story of Alexander’s Empire' (1886); id., 'Progress of Hellenism in Alexander’s Empire' (1905); Wheeler, B. L., 'Life of Alexander the Great' (New York 1900).

ALEXANDER, Sir William, Earl of Stirling, poet and statesman: b. 1567; d. London 1640. Tutor to Prince Henry, son of James I; knighted 1609; held various high offices under the Crown and in 1621 received a famous and stupendous grant of land embracing what is now Canada and the best portion of the New England States, and given almost absolute authority in its government, a grant that roused bitter envy among his contemporaries. At the coronation of Charles I (1633) Alexander became Earl of Stirling. His last years were embittered by great pecuniary reverses and he died insolvent. In strength of character, integrity and many-sidedness he was the greatest Scot of his time; took a conspicuous place as scholar, courtier, colonizer and poet. As a poet he belongs to the type of Fulk Greville and Lord Brooke; his tragedies are labored; but some minor pieces like the 'Aurora' and 'Musical Maculata' did his works with Addison praised them highly. The earliest editions of them are eagerly sought after. Chief among them are 'Tragedie of Darius' (1603); 'A Parazenesis to the Prince' (1604).

ALEXANDER, William, American general in the Revolutionary War, known as 'Lord Stirling': b. New York 1726; d. Albany, 15 Jan. 1783. He entered the service as a colonel of militia, was taken prisoner at the battle of Long Island, where he commanded a brigade, and served through the New Jersey campaigns with Washington. His claim to the title and estates of Stirling was disallowed by the English House of Lords in 1771 and on his return to America he took an active part in the troubles leading up to the Revolution. He was a member of the first board of governors of King’s College, now Columbia University.

ALEXANDER ARCHIPELAGO, or ALEXANDER ISLANDS, a group of islands on the west coast of North America, extending from 54° 40' N. to 58° 25' N.; belong to Alaska Territory. The principal islands are Baranoff and Prince of Wales.

ALEXANDER COLUMN, in Petrograd, erected in 1832 in honor of Alexander I (1777-1825). The total height is 154 3/4 feet. The polished shaft of red granite, 84 feet high and 14 feet in diameter, is the greatest modern monolith.

ALEXANDER LAND, an area in the Antarctic Ocean, discovered by Bellinghausen in 1821. It is in lat. 68°, long. 70° to 75°.

ALEXANDER, Romance of, a romance of the Middle Ages, based on a fabulous account of Alexander’s invasion of Asia, written by Callisthenes. In some form it makes a part of all the literatures of Europe and western Asia.

ALEXANDERS, a name applied to Smyrnium olusatrum, of the family Apiaceae. The plant is a native of Europe and was for-merly cultivated for its leaf-stalks, which may be blanched like celery. It is now rare in cultivation because of its inferiority to celery.

ALEXANDER’S FEAST, an 'Alexander’s Feast on the Power of Music,' an 'Ode in Honour of St. Cecilia’s Day' (1697), wrote in the form of Cowley’s irregular ode, but in place of the broken-winded rhythms of the 'Pindarick' made use of his own firm verse-music. Ten years before he had written on the same subject 'A Song for St. Cecilia’s Day' in which he had expressed the idea that the eternal harmony of the universe was to be perceived in the varying effects of music on human emotions, and in the rhythms of his poem attempted to suggest the appealing qualities of various musical instruments. In 'Alexander’s Feast' he carried the same idea farther, employing now a legend connected with Alexander the Great. This story he tells in such a way as to show how the musician and poet can at will ring the changes upon his hearer’s feelings. Alexander being now softened, exalted or infuriated according to the turns of harmony brought to bear upon him by Timotheus. The success of the poem is largely in the skill with which the verse is varied to suit Dryden’s purpose, but also in its effective imagery and narrative power. The author’s great command of phrase is also evident throughout, as one may see in the closing lines of the first and last stanzas. 'Alexander’s Feast' had a noteworthy effect upon later lyric poetry, particularly upon the odes of Gray.

WILLIAM HALLE.

ALEXANDRA Caroline Marie Charlotte Louise Julie, Dowager Queen of England, daughter of Christian IX, King of Denmark: b. Copenhagen, 1 Dec. 1844. On 10 March 1863 she was married to Albert Edward, Prince of Wales; she has had three sons, two of whom have since died, and three daughters. She made several visits to Denmark and a visit to Russia at the time of the death of Alexander III. She took an active part in very many benevolent enterprises and became very popular in England. When Albert Edward succeeded to the throne in 1901 as Edward VII she became Queen of England and reigned with him until his death, 6 May 1910. In 1913 she celebrated the fiftieth anniversary of her wedding and of her arrival in England. She has borne a noble part in the various humanitarian activities incident to the great European War. Consult Tooley, S. A., ‘Queen Alexandra’ (London 1902).

ALEXANDRETTA (the ancient ALEXANDRIA AD ISSUM), a small seaport in Syria, on the southeast coast of the Gulf of Iskanderoon. It is the natural port of Aleppo and northern Syria, and the residence of a United States vice-consul. The port is a fine bay, running southeast from the Gulf. The annual imports, about $10,000,000, are chiefly grain, rice and salt; the exports, about $6,500,000, are galls, silk, cotton and dyes or beshmet (a preparation from grapes, used by the natives as food). In 1915, in the European War, the railway station, wharf and warlike stores were destroyed by British forces. Pop. about 9,000.

ALEXANDRIA (ISLANDERIENH of the Turks), an ancient city and chief seaport in
ALEXANDRIA

Egypt, about 14 miles west of the Canopic mouth of the Nile, on the ridge of land between the sea and the bed of the old Lake Mauroticus, 29 miles by rail northwest of Cairo. Ancient Alexandria was founded by, and named in honor of, Alexander the Great, in 332 B.C., on the site of a village called Rhakotis or Ra-coudah. Its plan was sketched by the architect Dinocrates. It stood nearly on the site of the present town, though the configuration of the land has altered considerably since then. It attained its greatest prosperity in the days of the Ptolemies, who made it their capital. Under the Romans it became the capital of Egypt, and even when captured by Amru, general of the Caliph Omar (A.D. 641) it contained 44,000 palaces, 4,000 baths, 400 theatres or places of amusement, 12,000 shops for the sale of vegetables, and 40,000 tributary Jews (Gibbon). The city was regularly built and traversed by two principal streets, each 200 feet wide. It consisted of three quarters, that of the Jews, the Rakotis, or the people’s quarter, and Brucheion, or the quarter of the palace. In the 1st century B.C. it had about 500,000 inhabitants. From the ruins of the area upon which it was built was covered with temples, palaces and public buildings, the most conspicuous being the famous lighthouse, one of the seven wonders of the world, upon the little island of Pharos connected with the city by mole, called the Heptastadion, nearly a mile long; the splendid temple of Jupiter Serapis; the Library, at that time the richest in the world (see ALEXANDRIAN LIBRARY); the Museum, a kind of academy in which learned men of every description were entertained at the expense of the state; an immense hippodrome; the temple of Poseidon, and the Cesarium, beside which stood the two obelisks known as Cleopatra’s Needles, one of which was taken to London in 1878; the other to Central Park, New York, in 1881. The largest well-preserved monument of antiquity in modern Alexandria is the so-called Pompey’s Pillar, a red granite column 88 feet high (including pedestal), on the site of the Serapeum, thought to have been erected in the 4th century either in honor of the Emperor Diocletian or to commemorate the destruction of the Serapeum.

Alexandria was one of the chief granaries of Rome, and apart from its commercial importance was a great centre of learning. On the introduction of Christianity in the 1st century it became the seat of Christian erudition and the orthodox faith, and was frequently torn by bloody religious dissensions. After the Mohammedan conquest (7th century) its importance rapidly declined. In the 19th century under the vigorous rule of Mehemet Ali it recovered a large degree of prosperity, and is to-day one of the most important commercial ports on the Mediterranean. It was bombarded by the British in July 1882. See Egypt.

The modern city is chiefly built on the mole, which has been increased by alluvial deposits till it has become a broad neck of land between the two harbors. The European quarter is on the mainland south of the east harbor. It swarms with cafés, shops and theatres, and is lighted with electricity. The finest residences and official buildings surround the Mohammed Ali square. Alexandria has two harbors; the east harbor (Great Harbor of Antiquity) is now accessible only to fishing boats. The west harbor, about 1,700 acres in area, is an outer harbor, about 1,700 acres in area, average depth 28 feet, also protected by a mole 1,000 yards long. It is entered and cleared annually by over 3,000 steamers. In 1912 exports, chiefly cotton, grain, cottonseed oil, sugar, beans, etc., amounted to $168,951,280; imports to $110,785,145. The city acquired a modern drainage system in 1905 and a new water supply in 1906. The population in 1907 was 332,246; in 1914 it was estimated at 400,000, of whom 60,000 were Europeans, mostly Greeks and Italians. There is railway communication with Cairo and Suez; the Mahmoudieh Canal, made by Mehemet Ali, connects Alexandria with Cairo and the Nile.

ALEXANDRIA, Canada, town in Glengarry County, Ontario, half way between Montreal and Ottawa on the Grand Trunk Railway. It has carriage and cabinet works, and foundries. Pop. 2,323.

ALEXANDRIA, Ind., a city in Madison County, 50 miles northeast of Indianapolis, on the Cleveland, C., C. & St. L., Michigan Div., and Lake Erie and W. and L. E. Union Traction Company of Indiana. It is in a natural gas region, but the supply has failed of recent years and industrial prosperity has suffered. There are important glass and lamp chimney factories, preserving plants, and manufactures of paper, rockwood products, mirrors, wire-fence, road-drag, steel wheels, etc.; almost all factories are situated outside the city limits, which makes the value of taxable property only $1,226,000.

There are two banks, four public schools, one of which is a high school, a Carnegie library, several city buildings, municipal water and lighting plants; churches, and daily, tri-weekly and weekly newspapers. It was settled in 1834, and is governed by a mayor, elected for four years, a council of five members, clerk and treasurer. The annual income for running expenses is about $30,000; expenses in 1915 about $27,000. Pop. (1915) 5,000, with suburbs, 6,000.

ALEXANDRIA, La., city and parish seat of Rapides Parish, 193 miles northwest of New Orleans, and on the T. & P. St. L., Iron Mt. and So. (2 divisions), M. L. & T. S. Co. (Son. Pas.), Rock Ls., L. & Ark., Alex. & W. and the Louisiana Railway & Navigation Company. It is in the midst of fine alluvial lands, devoted chiefly to truck, cane and cotton growing. Strawberries and other fruits are raised across the river. The main industries of the city are truck and general farming, cottonseed oil mills, pine and hardwood mills, hoop and barrel and sile facilities, woodworking plants, etc. There are four large banking institutions, three investment companies, two savings banks and two building and loan associations. The value of taxable property is $25,000,000. Alexandria has four large public schools, equipped with the latest facilities, with 3,000 pupils, private and public, and 10 schools for the education of the Sisters of Mercy. It has a number of miles of asphalt street paving. Among the public buildings are the city hall, court house, opera house, high schools, public library, ho-
tels and office buildings and insane asylum. There are 30 miles of good gravel roads in every direction. Alexandria was once a trading post of the French and Spanish and was incorporated in 1819. In 1864 it was almost entirely destroyed by fire. Its present prosperity is due to the Texas Pacific and Texas & Pacific Railroads extended here in 1882. It has the commission form of government and the street railways and electric light and water works are owned by the municipality. The city’s receipts in 1914-15 were $225,011; expenses, $250,912. Pop. (1915) 20,000.

ALEXANDRIA, Minn., county and county seat of Douglas County, 130 miles northwest of Minneapolis, on the Great Northern and the Minneapolis, St. Paul and Sault Ste. Marie railroads. It is located in a stock raising and wheat district and has manufactories of flour, furniture, boots, laundries, cutlery, stoves, wagons and beer. There is a large refrigerating plant located here. The city has considerable reputation as a summer resort. The electric lighting plant and water works are the property of the municipality. Pop. 3,200.

ALEXANDRIA, Va., city and port of entry; on a peninsula on the Potomac River, the Pennsylvania, the Southern, the Atlantic Coast Line, the Baltimore and Ohio, the Seaboard Air Line and the Chesapeake and Ohio, and trolley line connecting with Washington, D. C., and Mount Vernon; six miles south of Washington. The river here expands to the width of a mile and gives the city an excellent harbor that will accommodate the largest vessels. The city is an important trade centre, and is noted for its educational institutions, which include Washington High School, Potomac, Mt. Vernon and St. Mary’s academies, and nearby the Theological Seminary and High School of the Diocese of Virginia (Protestant Episcopal). The city’s manufactories include glass, fertilizers, pottery, silk and cotton and the city also has machine shops and breweries. The United States census of 1914 recorded 49 establishments of factory grade employing 1,716 persons, of whom 1,503 were wage earners, receiving $557,000 in wages. The value amounted to $4,573,000, and the output was valued at $3,660,000; of this $1,701,000 was added by manufacture. There are four national banks, public school property valued at $35,000, and daily and weekly periodicals. Among the objects of special interest are the public library, the Confederate monument entitled “Appomattox,” the Marshall House, and Old Christ Church, of which Washington was one of the first vestrymen, and which contains his pew and that of General Lee. General Braddock made his headquarters at Alexandria (originally called Belhaven) in 1755. During the Civil War it was the capital of that part of Virginia which adhered to the Union; and in 1861 Colonel Ellsworth, an officer in the General McClellan’s army, was shot after tearing down a Confederate flag which floated from the Marshall House. Alexandria was first incorporated in 1749. It is governed, under a charter of 1879 revised in 1895, by a mayor and bicameral city council, which elects the mayor and councilmen; the more important ones, such as the treasurer, auditor, etc., being elected by the people.

ALEXANDRIA BAY, N. Y., a village in Jefferson County on the Rome, W. & O. Railroad about 70 miles northeast of Oswego. It is a prominent resort of the Thousand Islands. Pop. (1910) 1,899.

ALEXANDRIAN AGE, or SCHOOL, the school or period of Greek literature and learning that existed at Alexandria in Egypt during the 300 years that the rule of the Ptolemies lasted (323-30 B.C.), and continued under the Roman supremacy. Ptolemy Soter founded the famous library of Alexandria (q.v.) and his son, Philadelphus, established a kind of academy of sciences and arts. Many scholars and scientists, of all nations, came to Alexandria, and a period of literary activity set in which made Alexandria for long the focus and centre of Greek culture and intellectual effort. It must be admitted, however, that originality was not a characteristic of the Alexandrian age, which was stronger in criticism and science than in pure literature. Among the grammarians and critics were Zenodotus, Eratosthenes, Aristophanes, Aristarchus and Zoius, proverbial as a captious critic. Their merit is to have collected, edited and preserved the existing monuments of Greek literature. To the poets belong Apollonius, Lycophon, Aratus, Nicander, Euphorion, Callimachus, Theocritus, Phileta, etc. Among those who pursued mathematics, physics and astronomy was Euclid, the father of scientific geometry; Archimedes, great in physics and mechanics; Apollonius of Perza, whose work on conic sections still exists; Nicomachus, the first scientific arithmetician, and (under the Romans) the astronomer and geographer Ptolemy. Alexandria also was distinguished as a philosophical and speculative center, and it was here that the New Platonian school was established at the close of the 2d century after Christ by Ammonius of Alexandria (about 193 A.D.), whose disciples were Plotinus and Origen. Being for the most part Orientals, formed by the mixing of Greek and Semitic elements, the writings of the New Platonists are strikingly characterized — for example, those of Ammonius Saccas, Plotinus, Iamblichus Porphyry — by a mixture of Asiatic and European elements. The principal Gnostic systems also had their origin in Alexandria.

ALEXANDRIAN LIBRARY, a remarkable collection of books, the largest of its kind in the ancient world, was founded by the first Ptolemy and fostered by his son. It quickly grew and, already in the time of the first Ptolemy, Demetrius Phalerus had 50,000 volumes or rolls under his care. During its most flourishing period, under the direction of Aristarchus of Byzantium, Callimachus, Apollonius Rhodius and others, it is said to have contained 490,000, or, according to another authority, including all duplicates, as many as 700,000 volumes. The greater part of this library, which embraced the collected literature of Rome, Greece, India and Egypt, was contained in the famous museum, in the quarter of Alexandria called the Brucheion. During the siege of Alexandria by Julius Caesar this part of the library was destroyed by fire; but it was afterward replaced by the collection of Ptolemy Philadelphus, which was presented to Cleopatra by Mark Antony. The other part of the library was
kept in the Serapeum, the temple of Jupiter Serapis, where it remained till the time of Theodosius the Great. When this emperor permitted all the heathen temples in the Roman empire to be destroyed, the magnificent temple of Jupiter Serapis was not spared. A mob of Jews, led by a rabbi named Theophilus, stormed and destroyed the temple, together, it is most likely, with the greater part of its literary treasures, in 391 A.D. It was at this time that the destruction of the library was begun, and not at the taking of Alexandria by the Arabs under the Caliph Omar, in 641. There are strong reasons for believing that no library then existed there. Consult Petit-Radel, 'Recherches sur les Bibliothèques Anciennes et Modernes' (1819); Ritschl, 'Die Alexandrinische Bibliothek' (1838); Weniger, 'Das Alexandrinische Museum' (1875).

ALEXANDRIAN VERSION, or CODEX ALEXANDRINUS (Codex A.), a Greek manuscript of the Bible, now in the British Museum, of great importance in Biblical criticism. It is on parchment, with uncial letters, without breathings and accents or spaces between the words. It was written probably in the middle of the 5th century and contains the four volumes, small folio, the whole Greek Bible, two letters of Bishop Clement of Rome to the Corinthians, the genuine epistle and a fragment of the second, the spurious one, and eight psalms of Solomon, so-called. The first three volumes contain the translation of the Old Testament; the fourth, the New Testament. A large part of the Gospel of St. Matthew and of the Second Epistle to the Corinthians, as well as a portion of the Gospel of St. John, are wanting. The patriarch of Constantinople, Cyril Lucaris, who in 1628 sent this manuscript as a present to Charles I, said he had received it from Egypt; and it is evident from other circumstances that it was written there. But it cannot be decided with certainty whether it came from Alexandria (whence its name). It is said, however, to have belonged to the patriarch of Alexandria at the end of the 11th century. John Ernest Grote followed it in his edition of the Septuagint (Oxford 1707-20, 4 vols. folio). Dr. Woide published the New Testament (London, folio, 1786), with types cast for the purpose, page for page and line for line, as in the manuscript itself. A somewhat more accurate text of the New Testament in ordinary Greek type (with the lacunae supplied) was published by R. H. Cowper in 1860. Henry Hervey Barber edited a facsimile edition of the Old Testament (London 1816-28, 3 vols., folio). In 1864 the complete text, along with three other of the oldest texts of the Bible, was published at Oxford, the work being arranged in parallel columns. A facsimile of the whole codex in four volumes was published by the British Museum in 1879-83. The text of this manuscript is of most importance in the criticism of the Epistles of the New Testament; in the Gospels the text is not so good. This is the sense given by the following verses (from Pope's Essay on Criticism):

"A needless Alexandrine ends the song
That, like a wounded snake, drags its slow length along."

The only complete English poem of literary importance written in this measure is Drayton's 'Polyolbion.' The conclusion line of the Spenserian stanza is an Alexandrine. The French in their epic and dramatic verse confined this verse, which for this reason is called by them the Heroic. The Alexandrine derives its name from an old French poem belonging to the middle of the 12th or the beginning of the 13th century, the subject of which is Alexander the Great, and in which this verse was first made use of.

ALEXANDRISTS. In the period of the Renaissance there came to be a vigorous controversy between the adherents of different traditions of Aristotelianism. The chief schools of the Aristotelians were the Thomists, or followers of Thomas Aquinas, the followers of Averroes, and the Alexandrists, or followers of Alexander of Aphrodisias (about 200 A.D.). The chief point at issue among these three schools was that of the existence and nature of immortality. The Thomists, of course, as the advocates of the orthodox doctrine of the Catholic faith, held that the intellect retained its individuality after death. Alexander and his followers, on the other hand, believed that the intellect was double in nature, containing a passive, forming, and a mortal part, connected with the lower psychical functions and acting as a tabula rasa in its reception of the active intellect which, though mortal, was not regarded by Alexander as individual. Indeed, he identified this active intellect with the Deity. Averroes really held practically the same view as Alexander, but differed in his terminology, for what Alexander called the passive intellect was regarded by Averroes as a mere non-intellectual disposition, while what Averroes called the passive intellect was the result of the particularization of the active intellect by contact with the specific dispositions of the minds of different individuals. Averroes did not identify active intellect with the Deity, but with an emanation of the Deity; however, he attributed to it immortality. Similar as were the views of Alexander and Averroes, in the Renaissance the followers of Alexander put their chief emphasis on the mortality of the passive reason, the Averroists on the non-individual immortality of the active reason, so that a violent antagonism developed between the two schools which soon attached itself to many other points. The chief Averroists were Nicololetto Verniazi (?-1499), Alexander Achillini of Bologna (?-1518), Augustino Nito (?-1543), Zimara (?-1532). The chief Alexandrists were Ermolao Barbaro (1454-93), Pietro Pomponazzi (1462-1524), Gasparo Contarini (?-1542), Simon Forta (?-1555), Scaliger (1484-1558). The last was Francisco Suarez de Granada (1548-1617).

ALEXANDRITE, a variety of the mineral chrysoberyl (q.v.). It occurs in twin crystals (trillings) and is chiefly remarkable for the fact that while by daylight its color is a dark emerald to grayish-green, it assumes a beauti-
ful columbine-red color by artificial light. Because of this property and owing to its rarity and great hardness (8.5), it is highly prized as a gem. Its name, given in honor of Alexander II of Russia, seems singularly appropriate when it is recalled that the gem is said to have been first discovered in the emerald mines of Takowaja, Siberia, on the very day on which the then heir apparent attained his majority, and further that the green and red colors of alexandrite are the national colors of Russia. The finest alexandrites still come from Siberia, but good gems are occasionally found in Ceylon.

ALEXANDROPOLO, Russia (formerly GUMRI), Russian military town and fortress in the trans-Caucasian government of Erivan, situated on a bare plateau near the highway from Erivan to Kars. There is accommodation in the military quarters for a force of 10,000 men. The town has several churches and caravansaries, and there are extensive silk manufactories. Pop. 49,000.

ALEXEI MIKHAILOVITCH, 2d Russian of the line of Romanoff; b. 1629; d. 1676. He succeeded to the throne in 1645 on the death of his father, Michael Feodorovitch. The first years of his reign were marked by various disturbances due in great part to his youth and inexperience. By 1655 he had restored peace at home and begun to look abroad for realms to conquer. He conducted two campaigns against Poland (1654-56 and 1660-67) captured Smolensk, overrun Lithuania and seized several provinces. He also took part of the Ukraine, and waged a war against Sweden in 1657-58. He greatly extended Russian influence in the East, sent several raiding parties of Cossacks into Asia and made an attack on China. At home he introduced important modifications into the legal code and translations of numerous scientific works, military works, etc., and also instituted some ecclesiastical reforms. His private character appears to have been above reproach. By his second wife, Natalia Naryshkin, he was the father of Peter the Great.

ALEXEI PETROVITCH, the eldest son of the Tsar Peter the Great and Eudoxia Lapuchin; b. Moscow 1690; d. St. Peters burg July 1718. He opposed the innovations introduced by his father, who on this account determined to disinherit him. Alexei renounced the crown, and when Peter set out on his second journey he made his escape in 1717 to Vienna, where he sought the protection of his brother-in-law, the German Emperor, and thence to Naples, under the pretext of going to his father, who had sent for him. At the command of Peter he returned; but the enraged Tsar, regarding his flight as an act of treason, disinherited him by a ukase of 2 Feb. 1718; and when he discovered that Alexei was passing the way to succeed to the crown he not only caused all the participants of his project to be punished capitally or otherwise, but had his son also condemned to death, and the sentence read to him, as pronounced unanimously by 144 judges. Although he was soon afterward pardoned, the fright and anxiety which he had experienced affected him so much that he died in the course of four days. It is supposed by some that he was poisoned. The Tsar, to avoid scandal, ordered the proceedings at the trial to be published. He left a daughter and a son, afterward the Emperor Peter II. Consult Bain, 'The First Romanoffs' (London 1905).

ALEXEIFF, Michael Vassilivitch, a-lek-si'eff, Russian general; b. Tver about 1848. Educated at the Classical Gymnasium in his native town, he succeeded in the Moscow Military Academy and was attached to a Kazan regiment in 1876, attaining the rank of captain in 1885. Ambition led him, about 1879, to enter the Academy of the General Staff, where he assiduously studied till 1890. During the next eight years he was employed in the administrative routine of army work, and in 1898 became professor of military science at the Staff Academy. When the Russo-Japanese war broke out in 1904 Alexeieff was appointed quartermaster-general of the 3d Manchurian army. In the battle of Mukden he commanded a brigade of infantry and a body of Cossacks. He defended the position at Tsinkhehen with 16 battalions and 20 guns against the fierce onslaught of the Japanese for several days. From 1906 to 1912 he was chief of staff of the army of the Donov and of Kiev. At the outbreak of the European War he was in command of the 13th Army Corps at Smolensk. Alexeieff had literally risen from the ranks by sheer merit; the offspring of a poor family — his father was a humble sergeant — he had no influence behind him beyond his laboriously acquired reputation for tremendous energy, capacity for hard work and an iron determination. In the great struggle to which Russia was committed in 1914 he showed his ability not only by his general grasp in matters of statecraft as well as strategy, but also by the immutable calm and simplicity which never forsook him during the severest ordeals of responsibility. Alexeieff first became chief of staff in General Ivanoff's southern army group; then commander of the Army of the Bukovina; he next succeeded General Ruzsky as commander-in-chief of the Northwestern group, where he had control of nine out of 12 of the Russian armies and was directly concerned in carrying out the invasion of Germany and later the retreat from Warsaw. In the northwestern command his difficulties were aggravated by his inability, for technical reasons, to assume the offensive — a fact of which the German staff were fully aware. Whilst the enemy could safely undertake active operations at any point that might be chosen, it was the task of Alexeieff to anticipate and counter these movements. Scarcely had the Galician crisis passed than he was summoned as chief of staff to the Generalissimo, the Grand Duke Nicholas, who retired as viceroy of the Caucasus in September 1915, when the Tsar formally took command of the Russian armies, immediately appointing Alexeieff chief of the general staff — virtually supreme commander under a shadowy superior. With the downfall of Tsarism in the revolution of 1917 he was appointed commander-in-chief, which post he resigned in June 1917 to become military adviser to the Provisional government. He was succeeded by General Brusiloff (q.v.). Subsequently Alexieff again became chief of the general staff under Premier Kerensky, but resigned again in September 1917 owing to disagreement, it is said, over the dismissal of officers implicated in the
abortive Korniloff counter revolution. See WAR, EUROPEAN.

ALEXIA. See APHASIA.

ALEXIAD, a life of the Emperor Alexiuss Comnenus (q. v.) by the Princess Anna Comnena, his daughter. This work, which is one of the most important authorities for the history of the closing years of the 11th century, is written in modern Greek and divided into 15 books. It gives a vivid picture of the First Crusade.

ALEXIAN BROTHERS. See CELLITI.

ALEXIS, Greek comic poet, a native of Thrissi, in Magna Graecia, afterward an Athenian citizen: b. about 394 B.C., and is known to have lived as late as at least as 288 B.C. He was the uncle and instructor of Menander, and is said to have written 245 plays.

ALEXIS NICOLAIEVITCH, GRAND DUKE, ex-heir apparent (Tsarevitch) to the Russian throne: b. 30 July (N.S. 12 Aug.) 1904. The birth of a son to the Tsar caused great rejoicing in the imperial couple; they had four daughters, and there seemed reason to apprehend that the throne would not descend in the direct line of succession. The young heir proved to be of a bright, active and intelligent disposition, thoroughly Russian in all his tastes. In common with several of his near relations, however, he had a serious organic afflication consisting of a tendency to internal hemorrhage which might be brought about by any slight accident. This tendency is hereditary in the Romanoff family, and in this case has been the source of grave concern. Until the birth of Alexis, the younger brother of Nicholas II, the Grand Duke Michael (b. 1878), was heir apparent to the throne. It was this decision in the event of the Tsar's death before the young child attained his majority, the Grand Duke should act as regent for him in conjunction with the dowager Empress. This formal arrangement, however, was canceled some years ago when he contracted a morganatic marriage with a divorcée. He thereafter lived abroad and disappeared from public view until the outbreak of the European War, when he returned to Russia and served in the army. After the death of the Tsar in March 1918, he was appointed regent—an arrangement that lasted but a short while.

In October 1912 a sensation was caused by a rumor that the young heir—then eight years old—had been the victim of a bomb outrage, while another story ran that he had been mutilated by his nurse. All that could be gathered of a definite nature was the fact that he was in a critical condition of health. An official statement issued on 3 November announced that the child had injured himself by jumping into a boat, which had induced hemorrhage and would require a long period of recuperation. The question of succession rose again. The Grand Duke Michael having been eliminated, an heir-designate was appointed in the Grand Duke Dmitri (b. 1891), son of the Tsar's uncle, the Grand Duke Paul. The child recovered in due course, and assisted his father in distributing decorations among the troops at Tsarskoe Selö in December 1914. In the fall of 1915 he accompanied the Tsar to the front and for a time shared the military life at the imperial headquarters. Dressed in a little Cossack uniform, he joined his father on tours of inspection and made himself a great favorite with the soldiers. When the Russian revolution became an accomplished fact in March 1917, M. Alexander Gutchkoff and a deputy were commissioned to go to General Kuzsky's headquarters and inform the Czar that he had ceased to reign. Realizing the hopelessness of his situation, the dethroned monarch asked the delegates, "What do you want me to do?" He was told that he must abdicate in favor of his son under the regency of the Grand Duke Michael. The Tsar replied, "I cannot part with my boy; I shall hand the throne to my brother. Have you a piece of paper?" A manifesto was drafted on the spot; the Emperor of all the Russians for the last time appended his signature as a monarch, laying down the supreme power and renouncing all rights of succession on behalf of his son. The document was signed at Pskoff on 15 March 1917. The boy was sick at the time; his four sisters were suffering from measles, which disease he also eventually caught. He consequently accompanied his parents into exile.

ALEXIS, Willibald, pseudonym of Wilhelm Häring (q.v.).

ALEXIUS (COMNENUS), Emperor of Constantinople: b. 1048; d. 15 Aug. 1118. He was the third son of John Comnenus, the Emperor Isaac's brother. Naturally clever, he was carefully educated under the direction of his mother; and at the age of 14 took part in an engagement with some European adventurers commanded by a Scot called Russel de Balliol, of whom the youthful warrior afterward became an intimate friend. After several successive emperors had tasted for a brief season the "bitter sweets" of a nominal supremacy over a country torn by anarchy, Alexius, with the aid of the army, was proclaimed emperor, seized on Constantinople, which he permitted his soldiers to pillage, and shut up the nominal ruler in a monastery (1081). The empire was then in a deplorable state. The Turks were profiting by these intestine dissensions to seize upon the Asiatic provinces while Robert Guiscard and his Normans were menacing the west, and fierce swarms from beyond the Danube threatened the nearer provinces. However, Alexius did not despair; he sent supplies of money to his ally Henry IV of Germany to enable him to attack Rome, the Pope (Gregory VII) being a firm friend of the Norman leader. His Holiness had to flee, and Guiscard hastened to his aid, leaving in Greece his son Bohemond, who gained two victories over Alexius; but famine and disease weakened the Norman army, which Robert could not retain, as he was detained in Italy by a revolt of his vassals. In 1084 he returned to the charge, and after gaining some advantages he suddenly died of an epidemic; although some ascribe his death to poison administered by one of Alexius' secret agents. In consequence of this event the Normans abandoned all their conquests, and Alexius turned his attention to the Turks and Scythians, whom, after an arduous struggle, he completely defeated. Scarcely was this accomplished when, in 1096, the bands of the First Crusade arrived at Constantinople demanding aid, rudely menacing him in his own palace,
and finally compelling him to join them. The alliance did not last long; a war broke out between the Emperor and the Crusaders, which ended in the defeat of the latter. The rest of Alexius' life was employed in consolidating his conquests and restoring orderly government in his states, which was hampered by harassments. He died at 70, after a reign of 37 years. He extended his empire; and for its defense he left to his successors a well-disciplined army, which he had wholly created himself. Historians differ respecting his conduct and abilities; his daughter Anna wrote his life (the Alexiad).

**ALEYRÓDIDÆ, a family of plant-lice.** See **White Fly.**

**ALFALFA,** also called **Lucerne** (q.v.) (*Medicago sativa*), is a herbaceous plant belonging to the family *Fabaceae.* The leaves are pinnate-trifoliate; its flowers small, generally purple in color, dense in spikes. The plant is a native of Asia, but has been cultivated in Europe since before the time of Christ. The Spaniards introduced it into South America, but it did not reach North America until some time after the close of the 18th century, and was first introduced into California. Since then it has become the most extensively cultivated forage crop in the United States. Its adaptability to varying conditions of soil and climate gives it an extensive range, extending from the arid lands of the West, where irrigation is required, to the richer soils of the East, and from sea-level to heights of over 7,000 feet. It will not flourish in extremely damp or clayey soils. Its roots strike to great depths, so that it withstands droughts better than most of the forage plants. It is cut when coming into bloom, and yields from three to 12 tons of hay to each acre. In some regions it is cut every month in the year. It is particularly valuable as a green manure, as it takes nitrogen from the air, and its deep-growing roots draw from the lower soils large quantities of lime, phosphoric acid, potash and other minerals useful as crop foods. Alfalfa is relished by cattle whether green, as hay, or as ensilage, but to secure the best results it should be fed with a crop and grain, which add the ingredients needed for a well-balanced ration. Alfalfa is subject to two fungus diseases, one on the leaf and another on the root, either of which, if not checked, will spread and ultimately ruin the field. It is also attacked by certain insects. The *Farmers' Bulletin* issued by the United States Department of Agriculture and the bulletins of the various State agricultural experiment stations give full information on the culture of the plant and the treatment of its diseases.

The importance of the alfalfa industry in the United States is indicated by the fact that the area devoted to alfalfa in 1909 was approximately 4,638,662 acres. In the same year approximately 15,820,680 pounds of seed were harvested and about 11,800,000 tons of hay produced. Consult Westgate, J. M., 'Alfalfa,' *Farmers' Bulletin* 330, U. S. Department of Agriculture (1915); Westgate, J. M., McKee, R. and Evans, M. W., 'Alfalfa Seed Production,' *Farmers' Bulletin* 373, U. S. Department of Agriculture (1915); Fortier, S., 'Irrigation of Alfalfa,' *Farmers' Bulletin* 373, U. S. Department of Agriculture (1915). For alfalfa diseases and enemies consult Kalmbach, E. R., 'Birds in Relation to the Alfalfa Weevil,' U. S. Department of Agriculture Bulletin No. 107; also *Farmers' Bulletin* Nos. 636, 637, 649 and 741.

**ALFALFA MEAL,** a meal made by grinding alfalfa hay. The meal is either put on the market just as it is ground, or concentrated, such as molasses, bran and corn chop. The advantages of alfalfa meal lie in the fact that it is usually fed with less waste than the hay; the hay used for the meal is generally of better quality and has a higher percentage of protein than the ordinary hay. There is also considerable advantage to be derived from the reduction of freight charges. It is also a convenient form for special purposes, such as city trade and where the product has to be shipped to a distance. Alfalfa meal is an excellent feed for poultry.

**ALFARABIL,** an eminent Arabian philosopher of the 10th century. He was a native of Farab, in Asia Minor, his proper name being Abu Nasr Mohammed ben Mohammed ben Tarkhan; d. Damascus 950. His works consist of treatises on different parts of the Peripatetic philosophy. He excelled in music and philology as well as in philosophy; and one of his most famous works is a kind of encyclopaedia, in which he gives a brief account and definition of all branches science and art. The manuscript of this is in the Escorial. His works were printed in Paris in 1638.

**ALFIERI, Vittorio,** Italian tragic poet: b. Asti, Piedmont, 17 Jan. 1749, of parents, as he tells us in his *Autobiography,* "noble, well-to-do and honest"; d. Florence, 18 Oct. 1803. The "Vita di Vittorio Alfieri da Asti scritta da esso" ("Life of Vittorio Alfieri written by himself") furnishes the material for any sketch of his life and is in itself a remarkable work, not infrequently mentioned with the like notable autobiographies of Cellini and Goldoni. Alfieri conveys his biography into four parts, characterizing each of them summarily and aptly: *Infancy* (nine years of vegetation); *Childhood* (eight years of non-education); *Youth* (10 years of travel and dissipation); *Manhood* (30 and more years of composition, translation and study). His parents were Antonio Alfieri and Monica Maillard de Tournon, of Savoy origin as the surnames indicate. In early infancy Alfieri lost his father and was entrusted to the care of an uncle, but lived with his mother, who in the following years was twice married. In 1758, when nine years of age, following the period of "vegetation," Alfieri entered the Academy of Turin, where his "non-education," consisting largely of routine and the pursuit into four parts of the curriculum duly impressed him with the worthlessness of much that passes for academic culture. It was here, however, that he made his first poetical effort, a sonnet imitated from the verse of the only poets with whom he was acquainted, having, moreover, read them /furtively/, Ariosto and Metastasio. In 1763, when Alfieri was 14 years old, his uncle died, bequeathing him property and leaving him in control of his father's large fortune and estate. He could now satisfy some of his longings; one of which, his love of horses, amounted to a passion,"the third passion of his soul." After
his eight years of "non-education" in the Turin Academy, in 1766 he served for a short period as a sapper in the regiment at Nice and then entered upon his period of youth, or "10 years of travels and dissipation." His first travels (1766-68) were through Italy, France, England and Holland. He appears to have become dissatisfied with Paris, contracting a dislike for France and its people, which became accentuated later on and to which he gave vent in his 'Misogallo' ("Anti-Gallican"). It was in Holland that he had one of his serious love affairs with a married lady. He next traveled (1769-71) through Germany, Denmark, Switzerland, Belgium, Russia, Prussia, Holland and England. He was obliged to leave England on account of another love affair with a married lady, attended with serious consequences. He resumed his travels (1771-72) through Holland, France, Spain and Portugal, making the acquaintance in the latter country of the Abbé Tommaso de Caluso, whose friendship he retained throughout his life. Upon his return to Turin he led a "restored" life (1772-74).

It was during this period that in order to beguile the weariness of his lady-love, who was ill, he sketched a scene of a tragedy which later on was developed into a 5-act play, his first, 'Cleopatra,' and which, perfected, was performed in the Carignano Theatre in 1775. The tragedy was favorably received and gave Alferi, now in his 27th year, his life's desire, which he immediately undertook to carry out, to become a tragic poet. To accomplish his end he must needs make over his entire education; so he set to work with all of his extraordinary will and passionate effort. He had been used to the French language for literary purposes and wrote his two next tragedies, 'Filippo' and 'Polinice,' in French prose. Upon trying to turn them into Italian he found his knowledge of the Tuscan idiom was far from adequate. He resolved to forget his French and to steep his brain in the best Italian models. For this purpose he went to Florence, thinking in and speaking and writing continually the Florentine idiom. In order to become entirely unrelated, he donated to his sister, Countess Cumiana, almost his entire property, reserving simply enough upon which to live at his ease. It was in 1777 while in Florence that his last and most celebrated love affair, which lasted throughout the remainder of his life, materialized, a love which he calls 'a worthy love,' his attachment to the Countess of Albany, a daughter of Gustavus Adolphus, Prince of Stolberg-Geldern, and the wife of Prince Charles Edward Stuart, the Pretender to the English throne. With her Alferi lived after her separation from Charles, and made his home with her in various places. There is no proof that they were ever married. To the inspiration of the Countess of Albany the 14 tragedies published between 1777 and 1783 are due. They are: 'Il pittore'; 'Agamennone'; 'Virginea'; 'Oreste'; 'La Congiura dei Pazzi'; 'Don Garcia'; 'Maria Stuarda; Rosamunda'; 'Ottavia'; 'Timocone'; 'Merope'; 'Saul' and a little later, during his stay in Paris, 'Agide'; 'Sofonisba'; 'Mirra'; 'Abele'; 'Bruto primo' and 'Bruto seconde.' An English translation, by Charles Lloyd, of the tragedies appeared in London, 1835. The revolution of 1792 brought disaster to both the Countess and Alferi, the former losing her pension of 60,000 francs bestowed upon the wife of Charles Edward by the French government, and the latter nearly all his worldly goods, comprising from the sale of his papers he created a part of the complete editions of his tragedies published by Didot. This unfortunate occurrence served to augment his hatred of everything French. The last years of Alferi were spent quietly in Florence, engaged in literary work. At the age of 48, he began the study of Greek in order to read Homer in the original, as Petrarch and Boccaccio had already done before him. Comforted and encouraged by the Countess, he worked hard to the very end of his life, shortened by overexertion.

By nature ardent, generous, impulsive, loyal to his friends, Alferi was well fitted to write tragedies. His secretary Poldori, speaking of his temperament, described Alferi "as proud as the Sardinian, as simple as the Achilles of Homer." His tragedies coming at a time of literary decadence in Italy were by contrast all the more effective, and undoubtedly greatly stimulated his successors, Foscolo, Monti, Pellico, and others. The impulse that, as a poet and a patriot, Alferi gave to Italy of the 18th century is analogous to what Dante did for his country in the 13th. The beautiful monument by Canova in the church of Santa Croce, Florence, between the tomb of Machiavelli and that of Michelangelo, representing Italy in the form of a woman weeping and lamenting the death of the Poet, was erected by the Countess to the memory of Alferi.

The tragedies of Alferi, although taken almost entirely from classical subjects, as their titles indicate, nevertheless are treated by the poet in a manner that is his own, devoid of ornamentation to the point of being, both in language and form, almost stiff and barren, yet the nobility of the sentiment and their lofty ideals have made them among the first tragic poets of Italy. His fame may well rest upon the Tragedies, among which 'Saul' is generally considered the masterpiece, and upon his 'Vita' ('Autobiography'), a work of exceptional interest for its frank and unadorned charm. A good edition of the 'Vita' is that edited with notes by Emilio Bertana (Naples 1910). A translation of the 'Vita,' with an essay by W. D. Howells, was issued in Boston, 1877. The best edition of the tragedies is the Pisa edition (22 vols., 1805-15), supplemented by the works published in Florence by the Countess and the Abbé Caluso (in 13 volumes—8 vo; but not printed in London, as the title-page states).

Among the many works of minor importance are, in prose, 'Del principe e delle lettere,' blaming the patronage given by princes to men of letters; 'La virtù sconosciuta,' a dialogue on the citizen's ideal; 'I giornali'; 'I filosofori'; 'Le lettere;' 'Polinice;' 'Le lettere;' 'L'andro' in; 'L'uomo;' 'I pochi;' 'I troppi;' 'L'antidoto' ('Political Comedies: The One, The Few, The Too Many, The Antidote'), suggesting remedies for abuses in governments; Commedie sociali: 'La finestra;' 'II Divorzio' ('Social Comedies: The Little Widow; Di-
The desire to instruct in these comedies is too apparent, nullifying appreciably their small literary value; 'Il Misogallo' ('Anti-Gallican') was, in all its parts, and perhaps in its entire scope, a poem written by France; Sonnets; Epigrams; 'L'Etruria liberata,' a poem on the assassination of Alexander I, Duke of Florence; a panegyric of Trajan; 16 satires; five odes on American Independence; and many translations from the Latin and Greek classics. Consult his 'Autobiography,' translated by Lester (New York 1843); Centofanti, 'Tragedie e Vita d'Alfieri' (Florence 1842); Copping, 'Alfieri and Goldoni: Their Lives and Adventures' (London 1857); Coggetti and Antonini, 'Vittorio Alfieri' (Turin 1898); Holland, 'Builders of Modern Italy' (New York 1908); Howells, 'Life of and Essays on Alfieri' (Boston 1877).

JAMES GEDDES, JR.,
Professor of Romance Languages, Boston University.

ALFONSO TABLES. See ALFONSO X.

ALFONSO, the name of a number of Portuguese and Spanish kings.

ALFONSO I, the Conqueror, first King of Portugal, son of Henry of Burgundy, the Conqueror, and first Count of Portugal; b. 1110; tought successfully against the Spaniards and the Moors; named himself King of Portugal, and was recognized as such by the Pope; d. 1185.

ALFONSO I, King of Naples and Sicily. See ALFONSO V. (of Aragon).

ALFONSO V, King of Aragon: b. 1385; d. 1458. He was the son of Ferdinand I of Aragon, the throne of which he ascended in 1416, ruling also over Sicily and the island of Sardinia. Queen Joanna of Naples had promised to make him her heir, but at her death in 1435 had left her domains to René of Anjou. Alfonso now proceeded to take possession of Naples by force, which he succeeded in doing in 1442 and reigned till his death in 1458. He was an enlightened patron of literary men, by whom, in the latter part of his reign, his court was thronged.

ALFONSO V, the African, King of Portugal, succeeded his father, Edward I, 1438. Conquered Tangiers; d. 1461. During his reign Prince Henry the Navigator continued the important voyages of discovery already begun by the Portuguese. Under him was drawn up an important code of laws.

ALFONSO X, King of Castile and Leon, surnamed the Astronomer, the Philosopher of the Wise; b. 1226; succeeded to the throne 1252; d. 1284. Being grandson of Philip of Hohenstaufen, son of Frederick Barharossa, he endeavored to have himself elected Emperor of Germany, and in 1257 succeeded in dividing the election with Richard, Earl of Cornwall. On Richard's death in 1272 he again contested the imperial crown. Meantime his throne was endangered by conspiracies of the nobles and the attacks of the Moors. The Moors he conquered, but his domestic troubles were less easily overcome, and he was finally dethroned by his son Sancho, and died two years after, 1284. Alfonso was the most learned prince of his age. Under his direction or superintendence were drawn up a celebrated code of laws, valuable astronomical tables which go under his name (Alfonso Tables), the first general history of Spain in the Castilian tongue, and a Spanish translation of the Bible.

ALFONSO XII, King of Spain. He was the only son of Queen Isabella II and her cousin, Francis of Assisi: b. 1857; d. 1885. He left Spain with his mother when she was driven from the throne by the revolution of 1868 and till 1874 resided partly in France and Austria. In the latter year he studied for a time at the English military college, Sandhurst, being then known as Prince of the Asturias. His mother had given up her claims to the throne in 1870 in favor and in 1874 Alfonso came forward himself as claimant and in the end of the year was proclaimed by Gen. Martinez Campos as king. He now passed over into Spain and was enthusiastically received, most of the Spaniards being by this time tired of the republican government, which had failed to put down the Carlist party. Alfonso was successful in bringing the Carlist struggle to an end (1876), and henceforth he reigned with little disturbance. He married first his cousin, Maria de las Mercedes, daughter of the Duke of Montpensier; second, Maria Christina, Archduchess of Austria, whom he left a widow with two daughters, a son (Alfonso XIII) being born posthumously.

ALFONSO XIII, King of Spain, son of Alfonso XII and Maria Christina, daughter of Karl Ferdinand, Archduke of Austria: b. after his father's death, 17 May 1886, succeeding his brother at his birth, being a male, his eldest sister. His mother was made queen regent during his minority. On 17 May 1902 the young King formally acceded to the throne and took the oath prescribed by the Constitution, the Queen Regent having taken official leave of the ministry on the 12th. The United States was represented at the ceremony by special envoy. Alfonso married 31 May 1906 Princess Ena of Battenburg, daughter of the late Prince Henry of Battenburg and Princess Victoria (the late Queen Victoria). An attempt was made by anarchists to assassinate the King and Queen on their wedding day by throwing a bomb at the royal carriage. Among those arrested in connection with the plot was the celebrated educator, Francisco Pobrer (q.v.), whose execution caused much bitter feeling against the young monarch. He has, however, regained his popularity with the nation and has shown himself to be on the whole a liberal-minded ruler and a supporter of the anti-clerical party. The King has a civil list, fixed by the Cortes (1886), of 7,000,000 pesetas or $1,400,000.

ALFORD, al'fard, Henry, an English poet and miscellaneous writer, philologist, critic, artist and preacher: b. London, 7 Oct. 1810; d. Canterbury, 12 Jan. 1871. He became dean of Canterbury in 1856. An accomplished man, his literary work attracted attention in several departments. Besides sermons and university lectures he wrote 'The School of the Heart, and Other Poems' (1835), his most popular volume of verse; 'The River of Life' (1866). He was best known by his celebrated edition of the Greek New Testament (1844-52) which, incorporating the results of German Bib-
litical scholarship, formed a landmark in New Testament study in England and America. He was the first editor of the Contemporary Review.

ALFRED THE GREAT. King of the West-Saxons: b. 848, at Wantage in Berkshire. He was the youngest son of Æthelwulf, succeeding to the throne in 871, after the three short reigns of his brothers Æthelbald, Æthelberht and Æthelred. The day of his death was 26 October, the year is doubtful, 900 of 901 the weight of the evidence favoring the earlier date. Of the early years of Alfred little is known. The indications are that he was a favorite son. For at the age of five he was sent to Rome by his father, where Pope Leo declared Alfred as King and took him as his bishop's son. (Asser, 'Chronicle'). The allusion to Alfred as 'bishop's son' refers to his confirmation, the Pope standing as his sponsor according to a not unusual practice of the times. The allusion as king is less clear; since his three older brothers were still alive, it probably refers to some titular dignity conferred upon him. Two years later Æthelwulf himself went to Rome and Alfred accompanied him. The story of Alfred's learning read falls in the period before the second pilgrimage to Rome. It is found in Asser, who states that Alfred remained illiterate to his 12th year or more, although he knew many Saxon poems by heart. By illiterate Asser undoubtedly means ignorant of Latin. Alfred could certainly read Anglo-Saxon before his 12th year, and the mother who, according to the story, promised a book of Anglo-Saxon poems to that one of her sons who first learned to read it to her, was without question Alfred's own mother, Osburg. It was not until after his accession that Alfred acquired a knowledge of Latin. Asser states that at Alfred's marriage festivities, in 868, he was attacked by a grievous illness which afflicted him for 20 years or longer. This story has obviously been exaggerated for hagiographical purposes, although it probably has some foundation in the fact that Alfred was never in robust health.

Alfred first appears in public life in the year 866, as the assistant of his brother Æthelred in repelling the attacks of the Danes. In the midst of these Danish wars Alfred succeeded to the throne, nine general engagements being fought in this year. Alfred's own wars with the Danes centre in two great campaigns. As result of the first the Danes, in 878, promised to leave Wessex and their King, Guthrum, received Christian baptism. It was in this campaign that Alfred retreated to Æthalney in the fens of Somerset. Later tradition has added many unauthentic details to this episode, notably the story of the cakes and that of Alfred's playing as a disguised harper in the camp of the Danes. After 14 years of comparative peace the Danes returned to the attack. In the meantime, however, Alfred had strengthened his army and his defenses. At one brilliant engagement after another the Danes were defeated, and in 897 they fled into East Anglia and Northumbria and over sea into France. For the remaining years of Alfred's life, Wessex was at peace. The 'Chronicle' says, in recording Alfred's death, that he was king over all the English people except that part which was under the power of the Danes. But practically all England north of the Thames was in the Danegahls, and Alfred's authority extended only to Wessex and a part of Mercia. Wessex, however, Alfred had saved England for the English people; for it was from Wessex as a centre that his successors began the task of reconquering England from the Danes.

In his years of peace Alfred was engaged in strengthening and organizing his army, in systematizing the government of the country and in laying those plans for advancing the intellectual interest of his people which made him so much more than merely the soldier. Unable to find teachers in England, Alfred brought scholars from abroad, and with their aid planned to have translated into English all those Latin books which he thought most needful that his people should know. Alfred himself bore the greater part of this burden. His first translation was one of Pope Gregory's 'Pastoral Care,' made about 894. This was followed by the 'Universal History' of Orosius, and Bede's 'Ecclesiastical History,' though there is some question whether or not this latter work proceeded directly from the hand of Bede. It was followed by his interesting version of Boethius' 'Consolation of Philosophy.' His last work was a translation and adaptation of writings of Augustine and Gregory. Other undertakings undoubtedly due to Alfred's influence are a translation of Gregory's 'Dialogues' (the preface of which was written by Alfred), the 'Anglo-Saxon Chronicle' (see ENGLISH CHRONICLES), and a translation of the Psalter. Popular tradition has ascribed a number of other works to Alfred which belong to much later periods. Asser refers to Alfred's 'Handbook,' a commonplace book or anthology, but this work is no longer extant. Historians agree in placing a high estimate on the character and achievements of Alfred. Freeman ('Norman Conquest,' I, 49) calls him "the most perfect character in history"; Ranke ('Weltgeschichte,' VI, II, 46) declares him to be "one of the greatest figures in the history of the world." It should be borne in mind, however, that it is not the military achievements, nor the extent of the country which he governed, that lifted him into the ranks of the world's great men, but the beauty and moral grandeur of his character. In him were combined the virtues of the scholar and the patriot, the efficiency of the man of affairs with the wisdom of the philosopher and the piety of the true Christian. His character, public and private, is without a stain, and his whole life was one of enlightened and magnanimous service to his country.

Bibliography.—The primary sources of information concerning Alfred are Asser's 'Life of King Alfred' (ed. W. H. Stevenson, Oxford 1904); the 'Chronicle' (Ed. Earle and Plummer, Oxford 1892-99); and the translations from Gregory, Bede and Boethius, parts of which are contained in Grein-Wulker, 'Bibliothek der angelsächsischen Prosa.' Numerous modern lives of Alfred have been written, the best being that by Plummer (Oxford 1902).

George P. Keys

Instructor in English, Columbia University.

ALFRED, or ALUREDUS, OF BEVERLEY, chonicler: flourished 1143. His 'Nine Books of Annals or History of the British
ALFRED — ALGEBRA

Kingdoms to 1129 is largely devoted to the fabulous history of Britain. It is of no use to the historical student, as it adds nothing to what is known by other authorities. The best manuscript of the work is among the Hengwet MSS., and has never been printed. Hearns printed an inferior Bodleian MS. in 1716.

ALFRED, N. Y., a village in Allegany County, on the Erie Railroad, 12 miles from Hornell and 341 miles west of New York city. It is noted as being the seat of Alfred University, a coeducational (non-sectarian) institution, organized in 1836 as a school, incorpo- rated as a university in 1857. Professors and instructors in 1915, 42; students, 336; volumes in the library, 28,822; graduates, 1,063; productive funds, $412,000; total income, $100,000. There is a fine new Carnegie library valued at $30,000 and a university bank. Alfred is also the seat of the New York State School of Agriculture; New York State School of Ceramics, the Alfred Theological Seminary and the Alfred High School. The value of taxable property is $214,262. Pop. (1916) 750.

ALGAE, ál'jé, a term popularly restricted to marine cryptogamous plants or seaweeds, but which may be generally defined as comprehending all aquatic flowerless plants, whether growing in fresh or salt water, belonging to the group Thallophytes. The only absolute distinction between the Algae and the remaining Thallophytes or Fungi is that the former contain chlorophyll, while the latter do not. The higher forms have stems bearing leaf-like expansions, and they are often attached to rocks by roots. A stem is most frequently absent. The plants are nourished through their whole surface by the medium in which they live. They vary in size from the microscopic diatoms to forms whose stems resemble those of forest trees and whose fronds rival the leaves of the palm. They are entirely composed of cellular tissue and many are edible and nutritious, as carrageen or Irish moss, dulse, etc. Kelp, iodine and bromide are products of various species. They are beginning to be used in the United States in the production of commercial fertilizers. Four groups are commonly distinguished: Filose (green alga Cyanophyceae), green alga (Chlorophyceae), brown alga (Phaeophyceae) and red alga (Rhodophyceae).

ALGARDI, al-gár'dé, Alessandro, one of the chief Italian sculptors of the 17th century: b. 1602; d. 1654. He lived and worked chiefly at Rome; executed the tomb of Leo XI in St. Peter's, and a marble relief with life-size fig- ures over the altar of St. Leo there.

ALGAROTTI, Francesco, ál'gà-ro'ttè, frán-chês'kô, Count, Italian author; b. Venice, 12 Dec. 1712; d. Pisa, 3 March 1764. His "Plurality of Worlds" (1733), a popular exposition for ladies of Newton's philosophy, es- tablished his fame in France and became intimate with Voltaire. The study of French literature and contact with its leading representatives exercised a marked influence on his style. His contemporaries greatly respected his art judgments and his "Essays on the Arts" (1760) became an example to the world. Voltaire, showing keen discernment, Frederick the Great held him in high regard, created him count, and ordered a monument built to his memory in Piña. The best edition of his works is in 17 volumes, Venice, 1791-94.

ALGAROVIDA, ál'gà-ro-vèl'ya, the seed-pods of one or two South American trees (genus Prospis), valuable as containing much tannin.

ALGARVE, or FARO, Portugal, a maritime province extending across the southern coast of the kingdom, bounded north by the province of Alentejo, east by the Spanish province of Huelva, south and west by the Atlantic Ocean. It has a mountainous surface, with some fertile tracts, in which excellent oil, wine, figs and almonds are produced, and a coast indented with good bays and harbors. Its tunny and sardine fisheries are productive. Faro (pop. 12,000) is its capital. Area, 1,937 square miles. Pop. 274,156.

ALGAZZALI, ál-gá-zál'tè, or ALGHAZ- ZALI, Abu Hamed Mohammed, Arabian philoso- pher, Persian by birth: b. Tüs in Khurasan in 1058 or 1059; d. 1111. He first taught theo- logy at Bagdad but left his chair and traveled in Syria, and lived for some time in Damascus, after which he returned to Persia and resumed teaching. The details of his life given by biog- raphers are numerous but contradictory. He was one of the most prolific of the Arabian au- thors. One of his writings, called the 'De- struction of the Philosophers,' was answered by Averroes in a book entitled the 'Destruction of the Destruction.' He also wrote several moral treatises. Alghazzal, as a disciple of the Sufis, was an opponent of the prevailing Aristotelian philosophy of the day and predisposed to the mystical dogmas of emanation, to which, after a keen and critical study of philosophy, he entirely resigned himself. Consult Dugat's 'Histoire des Philosophes et des Théologiens Musulmans' (Paris 1879).

ALGEBRA, Definitions and Fundamental Concepts. The word "algebra" is occasionally used with the same meaning as "mathematical discipline," in the sense of a body of mathem- atical entities which obey a given set of laws or formulae. Accordingly we speak of the algebra of logic, the algebra of quaternions, the algebra of relations, the algebra of groups and so on indefinitely. The word is often used to cover those systems only whose formal structure is of a certain type. In this article we shall consider algebra in a still narrower sense — in fact in that sense in which the term is used in the high-school books of our child- hood. That is, we shall consider the special algebra of ordinary complex numbers and the various simpler algebras of real numbers, of rational numbers and of integers, through which we pass in reaching the algebra of ordinary complex numbers.

Mathematics has been defined by Benjamin Pierce as that science which draws necessary conclusions. Logic, however, is not only a science which draws necessary conclusions, but is in fact the science of the method in which necessary conclusions may be drawn. The relation between logic and mathematics is thus peculiarly intimate and in fact the present view of the matter is that inductive logic is simply that part of mathematics which possesses the least limited hypotheses. We shall therefore search for the basis of algebra among such
logical entities as classes, properties, relations, etc., and shall see how the entire complicated fabric of algebra can be woven from these simple threads.

Assemblages.—We wish to exhibit how the algebra which is familiar to the schoolboy has its roots in the much simpler algorithm which will be found treated in extenso under the heads LOGIC, SYMBOLIC AND ASSEMBLAGES, GENERAL THEORY OF. Here it is sufficient for us to call attention to one or two of the simpler aspects of this important theory. Though many difficult and fascinating paradoxes have been found underlying this simple assumption, we shall take it for granted that the things which enter into our daily life — "Shoes and ships and sealing-wax and cabbages and kings" — be arranged in assemblages or classes in such a manner that a class is uniquely determined by the specification of all its members. These classes we shall represent by small Greek characters, and their members by small Roman letters.

Simple Properties of Assemblages.—One of the most obvious of these is that of containing members. Strange to say, this is not common to all assemblages. It is continguously absent in the assemblage of round squares, the assemblage of purple cows, etc. Another paradox about assemblages is that an assemblage of one member is a different thing from that member. The ink-bottle now in front of me may be the only one of its sort, but it is not the sort ink-bottle of which it is the sole representative. In the symbolism which we shall use, the assemblage of all purple cows shall be represented by the symbol \( \Lambda \), and if \( x \) is my ink-bottle, and is the only one of its sort, the assemblage of all the ink-bottles of the sort shall be represented \( \langle x \rangle \). This is the symbolism of A. N. Whitehead and Bertrand Russell, the most recent writers on this subject as a whole.

Every two classes determine several new classes. If \( a \) stands for lawyers and \( \beta \) for congressmen, there are classes determined by \( a \) and \( \beta \), one of which is made up of all the lawyers in Congress, the other of those who either sit in Congress or practice the law, or possibly carry on both pursuits. The first class we shall indicate by \( a \beta \), the second by \( a \beta \). It is clear that this use of \( a \) and \( u \) can be extended to any two classes whatsoever.

Similarity.—In a properly equipped army, every private has at least one gun issued to him. Let us suppose that work at the arsenals has ceased, and that every gun has been issued to some private. It is clear that the class of guns and that of privates will stand in a peculiarly intimate mutual relation—that of one—one correspondence or similarity. We may express the same fact by the statement that there are as many guns as soldiers. Observe that in ordinary life the identity of defined prior to and independently of number itself.

Cardinal Number.—The cardinal number, then, of an assemblage \( a \) is something that is common to all the assemblages similar to \( a \), or as we shall say, since classes are more amenable to mathematical treatment than properties, the class of all assemblages similar to \( a \). We shall represent cardinal numbers by the letters \( \lambda, \mu, \nu, \sigma, \pi, \rho, \) and the cardinal number of the assemblage \( a \) by the symbol \( Nc^a \). It may be shown that our ordinary 0 is \( \lambda \wedge \), and that 1 is \( Nc^a \lambda \), or the class of all the classes \( \lambda \).

Finite and Infinite Classes. It is not universally true that the whole is greater than any of its parts. A picture one inch square may be enlarged to be two inches square. Each point of the two-inch picture, if the enlargement be accurate, represents uniquely a point of the one-inch picture, and vice versa; yet the one-inch picture can be laid down on one of the corners of the two-inch picture. Obviously, therefore, there are as many points in one of the four quarters of a picture or a square plane area as in the entire picture or area. Again, there is a first, a second, ..., an \( n \)-th odd number, so that it is possible by continuing this process indefinitely to assign every odd number to an integer and every integer to an odd number, yet the odd numbers form only a part of the integers. Here are instances of assemblages no greater than their own parts. Inspection will show that no aggregate containing a number of terms which can be expressed in the Arabic system of numeration can be of this type, for such a number can always be reduced in number of terms when some are removed. The precise nature of these assemblages which can be enumerated by one of the ordinary numerals of the Arabic system will be discussed elsewhere. We call attention to the fact that it has not been demonstrated that all assemblages are either similar to one of their own parts or finite in the ordinary, every-day sense of having one of the natural numbers as their cardinal number. All apparent proofs of this depend on Zermelo's axiom (see ASSEMBLAGES, GENERAL THEORY OF). However, no assemblages such as we should ordinarily call finite are similar to their own proper parts, so that assemblages of the latter sort and their cardinal numbers are properly called infinite.

Greater and Less Among Cardinal Numbers.—\( \lambda \) is said to be greater than \( \mu \) if \( \lambda \) is the cardinal number of some class \( a \) which contains a part \( \beta \) of which \( \mu \) is the cardinal number, and if the converse relation does not hold. It is clearly impossible for \( \lambda \) to be greater than \( \mu \) and for \( \mu \) to be simultaneously greater than \( \lambda \). That of any two cardinals one is the greater has not yet been demonstrated in general, though its proof for the natural numbers is easy. Thus while the natural numbers form a series, the infinites may constitute a tree or an anastomosing network. Here again Zermelo's axiom underlies all the earlier work on the subject.

Addition.—Consider the two numbers \( \lambda \) and \( \mu \). Let \( \lambda \) be the cardinal number of the assemblage \( a \) and \( \mu \) that of \( \beta \). Suppose that \( a \) and \( \beta \) have no member in common: that is, that \( a \beta = \Lambda \). It can then be shown that the cardinal number of \( a \beta \) is independent of the particular number \( \lambda \) and of \( \beta \) chosen. Expressed in terms of \( \lambda \) and \( \mu \), \( Nc^{(a \beta)} \) is written \( \lambda + \mu \), and is called the sum of \( \lambda \) and \( \mu \). As cabbages and kings are the same as kings and cabbages — as \( a \beta \) is identical with \( \beta a \) — it follows that \( \lambda + \mu = \mu + \lambda \). In other words that the operation of addition, when performed on any two cardinal numbers, finite or infinite, is commutative. In a similar way it may be shown that \( \lambda + (\mu + \nu) = (\lambda + \mu) + \nu \), or that addition is always associative.
The Natural Numbers.—The "natural numbers" or "numbers that can be expressed in the Arabic notation" have already been mentioned. The best definition of these has been given by A. N. Whitehead and B. Russell, to the effect that the natural numbers are those which are amenable to the method of mathematical induction. That is, the natural numbers are those which possess every property which 1 possesses, which, when it is possessed by n, is also possessed by n + 1, where + and 1 are used in the senses already defined. In other words, the validity of the method of mathematical induction as applied to the natural numbers rests neither on an axiom nor on a theorem, but on the definition of the natural numbers.

Multiplication.—Given two assemblages α and β, we can derive from them the assemblage of all the ordered pairs of entities the first member of which is an α while the second is β. For example, given a class of Christian names and a class of surnames, we can construct therefrom a class of all complete names of two parts, such that the Christian name is to be found among the given Christian names, while the surname is to be found among the given surnames. It is clearly in harmony with our normal use of terms to say that if there are μ Christian names and ν surnames in the two sets respectively, there are μ × ν complete names in the derived set. We shall generalize this and make it our definition of multiplication: μ × ν, the product of μ and ν, is the number of couples formed by first selecting a term from a class of μ members and then selecting a term taken from a class of ν members. On the basis of the definition alone, the associative and commutative laws may be shown to hold of multiplication among any numbers, finite or infinite. Furthermore, the distributive law for multiplication with respect to addition—the law that μ × (ν + π) = (μ × ν) + (μ × π)—is easy of universal proof in the algebra we have established.

Involutions.—In ordinary algebra we find that there are μν ways of forming classes by picking out one term from each of ν mutually exclusive assemblages of μ terms each. As this process may be applied to all assemblages whether finite or infinite, we make it the basis for our definition of involution. The ordinary laws of involution—that μν+π = μν × μπ, that μν × μ = (μν) μ, and that (μ ν) π = μν × μπ—follow readily for all the numbers in our algebra.

Extension of the Number-Concept.—If we limit our discussion to what we have called the natural numbers, the system which we have obtained has ideetically the same algorithm as the algebra of our high-school days, in so far as we limit its application to the positive integers and 0. This system is called Number-Theory (see Numbers, Theory (p.)). Now, number-theory is famous alike for the difficulty and the lack of generality of its methods and for its very slight practical value, so that a more regular and a more useful algebra becomes a desideratum. We want to be able to solve these equations x + 5 = 3, 2x = 7, x² − 2 = 0, and x³ + 2 = 0, all of which lack a solution of the algebra so far at our disposal. Be it noticed, the mere fact that these equations are insoluble within the present system does not permit us to assign to the equations; there is no more justification for saying that x + 5 = 3 "must have" a solution than there would be for saying that there "must be" an even prime greater than two. The absence of a solution to a problem is never a sufficient excuse for building that solution out of whole cloth. Our search for a more complete algebra must consequently take the form of a hunt for systems that actually do obey more universal laws than those of the signless integers, rather than that of filling out the system of the signless integers by the haphazard introduction of heterogeneous material.

Integers with Sign.—Here the problem is that of finding a system in which such equations as x + 5 = 2 are soluble. When we have once defined addition, the definition of subtraction follows without any further ado: μ − ν is defined as that number which when added to ν gives μ. μ + ν and μ − ν may be regarded as the results of performing on μ the operations of adding or subtracting ν. Let us call these operations + ν and − ν, respectively. We shall define the sum of two operations of this sort as the operation consisting in their consecutive application. The word "sum" will here have a significance different from that which it possesses with reference to μ and ν. Its use, however, is natural, for the adding of numerical "steps" is closely analogous to the process whereby we add, say, two linear steps or lengths by the repeated application of a yardstick. Furthermore, when only entities of the form + μ are considered, the formal properties of the new summation will be the same as those of the old. When operations of the form − μ are admitted, our new additions will have all the properties we are accustomed to associate with addition among integers with sign, among which are the properties of associativity and commutativity. Similarly, if we define (+ μ) (+ ν) and (− μ) (− ν) as (+ (μ + ν) and (− μ) (− ν)), we shall find that the multiplication so defined will have the same properties intrinsically and with respect to addition that we should naturally expect multiplication to possess in the universe of integers with sign. Among these are the "laws" of associativity, commutativity and distributivity. Consequently, putting all things together, there is no reason why we should not call our + μ's and − μ's positive and negative integers, respectively, provided ν ± 0. In this system, we shall find that every equation of the form x + a = b will be satisfied by some value of x. It is noteworthy that the system of integers for which this is true does not contain any of the integers of previous paragraphs, so that a positive integer turns out to differ from the corresponding signless or absolute integer.

This definition holds for all the uses of subtraction. Likewise, x + y is that number which multiplied by y gives x.

It is the custom of mathematicians to call several things by a single name, if only they have analogous properties, so that we shall meet with entities called absolute integers among fractions, real numbers, and even among complex numbers.
Fractions or Rational Numbers.—Equations such as $3x = 2$ are rendered soluble in a way quite analogous to the procedure of the last paragraph. Let $m$ and $n$ be any two positive or negative integers. We shall define $\frac{m}{n}$ as the relation which subsists between any two integers $p$ and $q$ if $mq = np$. We shall define $\frac{m}{n} + \frac{p}{q} = \frac{mq + np}{nq}$, and $\frac{m}{n} \cdot \frac{p}{q} = \frac{mp}{nq}$. We shall say that $\frac{m}{n} > \frac{p}{q}$ if $n, q$, and $mq - np$ are positive. When this has been done, it is demonstrable that the formal laws of associativity, commutativity and distributivity hold in the proper manner for addition and multiplication, that every equation of the form $ax = b$ has a solution when the entities concerned are expressions such as $\frac{m}{n}$, or as they are called, fractions or rational numbers, and that the relation $\geq$ determines an order among the fractions such that (a) we never have $x > x'$; (b) if $x > y$ and $y > z$, then $x > z$; (c) if $x$ and $y$ are two distinct fractions, either $x > y$ or $y > x$. This latter set of facts is expressed by the statement that the fractions arranged in order of magnitude form a series. Be it noticed that though the fraction $x$ may be taken to represent the integer $x$ and is usually expressed by the symbol $x$, it is altogether distinct from that integer.

Real Numbers.—The system just developed is very rich in numbers. In fact, it can be proved that no matter how near any two fractions are to one another, there is a fraction lying between them in magnitude. Nevertheless, the series of fractions is everywhere full of gaps which prevent some of the very simplest equations from having solutions within it. For example, it can be shown that $x^2 = 2$ has no fractional or rational solution. If it had such a solution, it would necessarily be of the form $\frac{m}{n}$. $m$ and $n$ can be so chosen as to have no factor other than ±1 in common. Therefore, we can so choose $m$ and $n$ that at least one of them will be odd, if any values whatever exist for $m$ and $n$. Now, by hypothesis, $\left(\frac{m}{n}\right)^2 = 2$, or $m^2 = 2n^2$, and $m$ is consequently even. If $m$ is even, it is of the form $2k$. We thus get $4k^2 = 2n^2$, or $n^2 = 2k^2$, whereby $n$ is shown to be even, so that our previous hypothesis is contradicted.

Though 2 has no rational square root, there are numbers whose squares exceed 2 by as little as we please, and numbers whose squares fall short of 2 by as little as we please. The approximate values we obtain in extracting the square root of 2 constitute a family of numbers which exemplifies this property: 2 $1 = 1$, $1.41^2 = 1.98$, $2 - 1.41^2 = 0.09$, $2 - 1.98 = 0.02$, $2 - 1.98 = 0.02$. On indefinitely, while $2^2 = 2$, $1.5^2 = 2.25$, $1.42^2 = 2.02$, $1.41^2 = 2.02$, and so ad infinitum. That is, the process which we call extracting the square root of 2 consists in finding sequences of pairs of numbers whose squares bracket 2 by intervals which decrease beyond any assignable degree of minuteness. To put it crudely, we mark the place where the square root of 2 ought to be by a definite dividing-line in the scale of rationals between those whose squares fall short of 2 and those whose squares exceed 2.

These dividing-lines between the numbers that are larger than a given standard and those that are not have been termed by Dedekind cuts. Some of these cuts are immediately bounded above or below by a rational number, as for instance the cut which separates all numbers less than 3 from 3 and greater numbers. Others, such as the cut discussed in the last paragraph, have not this property.

By considering only those cuts which do not immediately follow a rational number, we obtain one cut and one only corresponding to each rational number, and a cut, to put it ideally, where a number ought to be, but isn't. For instance, if we take our cuts as a larger system of numbers, we shall find that there will be a cut which we might call the square root of 2. If we define the sum of the two cuts $C_1$ and $C_2$ as the cut which divides all the sums of fractions on the lower side of $C_1$, all the fractions on the lower side of $C_2$, from all other fractions, and if we define $C_1C_2$ as the cut dividing all products of fractions on the side of $C_1$, more remote from 0 with fractions on the side of $C_2$, more remote from 0 from all other fractions, we shall be able to prove both that all the convenient laws of addition and multiplication are satisfied and also that there will be no lacuna in our system such as that which prevented $x^2 = 2$ from being soluble in the universe of rational numbers, we define the order of magnitude of our cuts in the natural manner, making one cut precede another if the second cut contains on its lower side fractions larger than any on the lower side of the first, we shall not only find that this order is a series, and a series between any two of whose members there lies a third, but also that every cut in this series is bounded on one side or the other by one of the terms of the series. These properties go to make up what is known to mathematicians as continuity* and the ordinary properties which we have learned to attribute to the number system of real algebra are those that belong to continuous series. Therefore, taking all these considerations together, we can define the real numbers of ordinary algebra as the cuts which we have just discussed.

Complex Numbers.—Even in the system of real numbers we meet with equations that have no solution. While $x^2 + 2 = 0$ has real roots, $x^2 + 2 = 0$ is satisfied by no real value of $x$. However, there is a system easily obtained from that of the real numbers in which this equation and many like it are soluble. Let us consider a system made up of ordered pairs of real numbers, such as $(a, b)$. Let us define $(a, b) + (c, d) = (a + c, b + d)$ and $(a, b) \cdot (c, d) = (ac - bd, ad + bc)$. It will be found that the usual laws of commutativity, associativity and distributivity for addition and multiplication will be fulfilled in this system, and that the ordered pairs of the form $(a, 0)$ will have the same formal properties among themselves as the real numbers $a$. Further-

*In Cantor's definition of continuity, an additional condition appears, which is also satisfied by the series of cuts in question.
more the equation \((0\sqrt{2})(0\sqrt{2})=(-2.0)\) is valid, so that the analogue of \(-2\) will have a square root in this system, and \(x^2=-2\) will be soluble, but it is still further demonstrable that if we define \(x^n\) as \(x\cdot x\cdot\ldots\cdot x\), every equation of

\[n\text{ times}\]

the form \(a_nx^n + a_{n-1}x^{n-1} + a_{n-2}x^{n-2} + \ldots + a_2x^2 + a_1x + a_0 = 0\) will have solution in the algebra of number-couples. The couple \((a, b)\) is usually written \(a + ib\), and the theorem just discussed, to the effect that every equation of the form given (called an algebraic equation) has a solution in the algebra of complex numbers is known as the Fundamental Theorem of Algebra. It is due to Gauss.

It has long been established that there is no algebra which includes complex algebra in the way in which complex algebra includes real multiplication continued to obey their familiar laws. Complex algebra, then, cannot be extended, and this leads to the fundamental theorem of algebra it need not be extended, so that it is the algebra par excellence for the mathematician.

For a further discussion of the real and complex number systems see the articles on REAL VARIABLE, THEORY OF, and COMPLEX VARIABLE, THEORY OF, respectively.

Exponents.—In the last paragraph we have defined \(x^n\) in the case where \(n\) is an integer. This obeys all the laws laid down in the paragraph on involution. These laws require that if any use of fractional exponents is to conform to them, \(\left(\frac{m}{n}\right)^n\) must equal \(x^m\). It may be demonstrated that so long as we confine ourselves to positive values of the roots of positive numbers, if \(x^n\), defined as the \(n\)th root of \(x^m\), all the laws of exponents will be obeyed. It can likewise be shown that the definition of \(x^{-n}\) as \(\frac{1}{x^n}\) will yield consistent results.

These are accordingly the definitions of fractional exponents actually used. When other than positive roots of positive quantities are considered the matter is quite so simple. If \(n\) is not rational, \(x^n\) is defined as the limit of \(x^m\) where \(m\) is a variable that approaches \(n\) through rational values.

The Method of Postulates.—The method whereby we have derived algebra from the entities and truths of logic is not the only one that has been applied in establishing this subject on a logical foundation. The method of postulates which has been employed so effectively by Veblen and Huntington in many branches of mathematics has been used by Huntington for the study of algebra. This method consists in reducing the theorems of algebra to the consequences of a few simple formal laws such as the laws of associativity and of commutativity for addition and multiplication and the law of the distributivity of multiplication with respect to addition and others of the same sort. When this is done, algebra is considered not as the study of a set of specifically numerical entities but as the study of any entities you please that obey its postulates.

Rational, real, and complex algebra each receive a complete and self-contained treatment according to this method. See POSTULATES, THEORY OF.

Editorial Staff of The American.

ALGEBRA, Elementary, Terms, Expressions, Factors, etc.—In Algebra numbers, real or complex, are commonly called quantities. Any lawful combination, however complex, of number symbols represents a number or quantity, and is named algebraic expression, as \(5\cdot x\cdot y\cdot (z - 4)\). The parts of an algebraic expression that are connected by the sign + or — are called terms. Two or more terms enclosed in parentheses ( ) or brackets [ ] or braces { } or written under a vinculum — are treated as a whole; thus, \(2 - (x + y) - 3\cdot (x - y) - 4\cdot (x - y) - 5\cdot (x - y)\). The expression of more than one term is a polynomial or multinomial. Expressions of one, two, three terms are respectively monomial, binomial, trinomial; thus, \(a - b - c\) is binomial, though its equivalent, \(a - (b + c)\), is trinomial.

In the indicated product of two or more symbols, as \(abx\), any partial product is the coefficient of the complementary product. Thus \(4abx\) and \(abx\) are coefficients of each other, as are \(ab\) and \(4bx\), or \(x\) and \(4ab\). An expression is integral with respect to given symbols if it may be expressed as a sum of products of positive integral powers of these symbols with one another and with coefficients which do not contain them. An expression is fractional with respect to given symbols if it is the quotient of two expressions which are integral in the symbols, but is not integral itself. An expression is called rational if it is fractional or integral, but irrational otherwise. An expression may be integral in some symbols and fractional in others, as in the case of \(\frac{x^2 - y^2}{x - y}\) which is integral in \(x\) and \(y\), but fractional in \(w\) and \(z\).

Similarly \(\sqrt{x^2 - y^2}\) is rational in \(y\), but irrational in \(x\) and \(z\). Any expression, in case it is rational and integral as to some symbol, as \(x\), is said to be of degree \(n\).
in that symbol if its greatest exponent in any term is $n$; thus $ax^n + bx^{n-1} + cx + d$ is of degree $n$. The exponents of those symbols in any term; thus $a\theta^{b-c} - 5b\theta^{d-7}c\theta^e$ is of degree $9$ in $a, b, c$ (together). In general, each of two or more expressions is a factor of their product. In this general sense, $a^2$ and $a^3$ are factors of $a^4$, and so, too, are $a^5$ and $b$. In a more restricted sense, the factors of an expression rational and integral as to some letter must themselves be rational and integral as to that letter; thus some factors of $a^b - ab^c$ are $a, a^b, ab, ab^c, 1 - a$, for division by any of these yields a quotient rational and integral as to $a$ and $b$. In such cases, factors of lowest degree in any symbol are called simple factors (in that symbol). A factor of two or more expressions is called a common factor of them. The common factor of highest degree is called the highest common factor (H.C.F.); thus the H.C.F. of $ab^2$ and $a^2b$ is $ab$; of $a^2 - b$ and $ac + bc$, it is $a + b$. Every expression is a multiple of its factors. A multiple of two or more expressions is called a common multiple of them; it is their lowest common multiple (L.C.M.) if it is the common multiple of lowest degree; thus, the L.C.M. of $ab^2$ and $a^2b$ is $a^3b^2$; of $(x - a)(x - b)(x - c)$ and $(x - a)(x - b)(x - c)$ it is $(x - a)(x - b)(x - c)^2$. It is readily proved that the product of two expressions is equal to that of their H.C.F. and L.C.M. If $E$ is any algebraic expression, then $E^i, E^{2i}, . . . , E^n$ are respectively the second, third, . . . , $n$th powers of $E$, and $E$ is the square, cube, . . . , $n$th root respectively of $E^2, E^3, . . . , E^n$. In particular, $E^2$ and $E^3$ are the square and the cube of $E$. Thus $ax^n$ is the square root of $a^{2n}$, $x^n$ is the cube root of $a^{3n}$, and $y^n$ is the square root of $(x^n - y^n)^n$, or $x^n - y^n$. 

**Ratio, Proportion, Variation.**—The fraction $\frac{a}{b}$ is the ratio of $a$ to $b$, often written $a:b$, of which $a$ is the *antecedent* and $b$ is the *consequent*. If $a = \frac{1}{x}$ and $b = \frac{x}{y}$, then $a:b = \frac{1}{y}$. A ratio is commensurable or incommensurable according as it is or is not a rational number; thus, $2:5$ is commensurable, but $\sqrt{2}:1$, ratio of diagonal to side of square, is incommensurable. Plainly, ratio theory is fraction theory. It is easily proved that if $\frac{a}{b} = \frac{c}{d}$, then $\frac{a+c}{b+d} = \frac{a}{b} + \frac{c}{d}$, unless $b+d+c+f+\ldots = 0$. If $\frac{a}{b} = \frac{c}{d}$, taken in order, are in proportion, often written $a:b::c:d$, or $a:b = c:d$, and $a$ and $d$ being the extreme and $b$ and $c$ the means. In such case $ad = bc$, and conversely. If $a:b = b:c$, i.e., $b = ac$, $b$ is a mean proportional to $a$ and $c$, and $c$ is a third proportional to $a$ and $b$. If $a:b = c:d$, then $a + b = c + d$, $a - b = c - d$, whence $a + b = 2c = a + c = c - d$, i.e., $a, b, c$ are in proportion by composition, by division, and by both. A quantity $x$ varies directly as $y$, symbolically $x \propto y$, if the ratio of two values of $x$ is equal to the ratio of the corresponding $y$ values. If $x \propto 1:y$, $x$ varies inversely as $y$. If $y \propto ax$, $x$ varies as $y$ and $a$ jointly. Examples: If $x$ is distance traveled and $y$ is rate, $x \propto y$; if $x$ is volume of given mass of gas (at constant temperature and pressure) and $y$ is pressure on it, $x \propto 1:y$ (Boyle's Law); if $x$ is the area of triangles and $y$ and $z$ are base and altitude, $x \propto yz$. If $x \propto y$, $y = cy$, where $c$ is some constant; if $x \propto 1:y$, $y = cy$; if $x \propto y$, $y = cy$, if $x \propto y$ and $\propto 1$, $x = cy$. An algebraic expression is a function of the symbols it involves, and conversely, every function is a function of $x$, as $x$ is of $2x^2 + 3$. A function of a symbol as $x$ is often denoted by the symbol $f(x)$ or $F(x)$ or $f(x)$ or the like and read $f$-function of $x$, and so on. If $f(x) = 2x^2 - 4$, then $f(0) = -4$, $f(a) = 2a^2 - 4$, etc. The function symbol is the reference to the form of the function, and in the same argument or discussion the same symbol may not be used for two different functions. Of great importance are the integral (entire) polynomials; of which the general form for a single variable $x$ is $f(x) = ax^n + ax^{n-1} + ax^{n-2} + \ldots + ax + a_0$. The coefficients $a_n$, $a_{n-1}$, . . . , $a_0$ are regarded as arbitrary constants. Accordingly $f_1(x) = ax^n + a_0$ is said to be linear or of first degree; $f_2(x) = ax^2 + a_1x + a_0$, the general quadratic expression or expression of second degree; $f_3(x) = ax^n + a_0$ the general cubic, $f_4(x) = ax^3 + a_2x^2 + a_1x + a_0$, the general biquadratic, etc. The general expressions become particular or special on assigning specific (numerical) values to the (literal) coefficients. In any $f_n(x)$ any value may be given to $x$, the corresponding value of $f_n(x)$ is then determined. The inverse problem of determining all values of $x$ for which $f_n(x)$ shall have a prescribed value is far more difficult. A value of $x$ for which $f_n(x) = 0$ is zero is said to cause $f_n(x)$ to vanish. To every expression $f_n(x)$ corresponds an equation, $f_n(x) = 0$, of 1st, 2nd, . . . , nth degree, according as $n = 1, 2, . . . , n$. The equation imposes a condition on $x$, restricting its variability, allowing it only those values which make $f_n(x)$ vanish. The variable $x$ in an equation is called the unknown quantity. Any such value is a root of the equation. The equation $f_n(x) = 0$ has $n$ and only $n$ roots (see Theory of Equations). To solve an equation is to find its roots. A linear equation $ax + a = 0$ has one root, $-\frac{a}{a}$, and it may always be found by adding $-a$, to both members $ax + a + a$ and $-a$, and then dividing the sums by $a$. The result of the addition is the equation $ax + a = a$. Obviously any term may be transposed from either member of an equation to the other if at the same time the sign of the
term be reversed. Presently we shall see how to solve quadratic cubic and biquadratic equations.

Factor and Remainder Theorems.—Obviously \( f_a(x) \) may contain a factor of the form \( x - a \); e.g., \( x - 2 \) is a factor of \( x^2 - 4 \). If \( f_a(x) \) has \( x - a \) for a factor, then \( f_a(x) \equiv (x - a)Q \), where \( Q \) is the quotient of \( f_a(x) \) divided by \( x - a \). Hence under the supposition \( f_a(x) \) vanishes when \( a \) is put for \( x \). The converse is the factor theorem: If \( f_a(x) \) vanishes on replacing the variable \( x \) by a number \( a \), then \( x - a \) is a factor of \( f_a(x) \). Proof: divide \( f_a(x) \) by \( x - a \) until the remainder \( R \) does not contain \( x \). Then \( f_a(x) \equiv (x - a)Q + R \); put \( a \) for \( x \), then \( f_a(a) \equiv 0 \) or \( R = 0 \), but \( f_a(a) = 0 \); hence \( f_a(x) \equiv (x - a)Q \). At the same time the remainder theorem is proved: Division of \( f_a(x) \) by \( x - a \) yields \( f_a(a) \) for remainder. By the factor theorem it is seen that \( x^n - a^n \) is divisible by \( x - a \); for if \( a \) is a root of \( x^n + a^n = 0 \), then \( a^n = -a^n \). Put \( a \) for \( x \) in \( x^n + a^n \); the result is not zero; hence \( x - a \) is not a factor of \( x^n + a^n \). If \( n \) is odd, \( x + a \) is a factor of \( x^n + a^n \) for \( (x^n + a^n) = 0 \), provided \( n \) is odd.

The Quadratic Equation.—The general quadratic equation \( ax^2 + bx + c = 0 \) can be solved as follows: the roots of an equation are not altered by adding a constant to both members or by multiplying both by a constant. Dividing both members by \( a \), then adding \( b^2 - 4ac \), we obtain

\[
\left( x + \frac{b}{2a} \right)^2 - \left( \frac{b^2 - 4ac}{4a^2} \right) = 0; \quad \text{factoring,}
\]

\[
\left\{ x + \frac{b}{2a} + \frac{\sqrt{b^2 - 4ac}}{2a} \right\} \left\{ x + \frac{b}{2a} - \frac{\sqrt{b^2 - 4ac}}{2a} \right\} = 0.
\]

If the product of two or more integral factors is zero, one of them must be zero and the equation is satisfied if any one of them is zero. Hence the roots of the quadratic are the roots of the linear equations obtained by equating to zero the foregoing factors. The roots \( r_1 \) and \( r_2 \) are:

\[
r_1 = 2a \left( -\frac{b}{2a} + \sqrt{\frac{b^2 - 4ac}{4a^2}} \right), \quad r_2 = 2a \left( -\frac{b}{2a} - \sqrt{\frac{b^2 - 4ac}{4a^2}} \right).
\]

Thus it is seen that every quadratic equation has two and but two roots. Their sum \( r_1 + r_2 = -\frac{b}{a} \) and their product \( r_1 r_2 = \frac{c}{a} \), a special case (see Equations, Theory of) of the law connecting the roots and coefficients in the general equation \( f_a(x) = 0 \). If the coefficients are real, the roots are both imaginary when and only when the discriminant \( b^2 - 4ac < 0 \), or negative.

The Cubic Equation, Cube Roots of Unity. — Let \( x^3 = 1 \), then \( x^3 - 1 = 0 \); factoring left member, \( (x - 1)(x^2 + x + 1) = 0 \). Hence the cube roots of unity are 1, \( \omega = \frac{1}{2}(-1 + \sqrt[3]{-3}) \), \( \omega = \frac{1}{2}(-1 - \sqrt[3]{-3}) \). \( \omega \) and \( \omega^2 \) are imaginary (complex); \( \omega^3 = \omega \). \( \omega^2 = \omega \) and \( \omega^3 = 1 \). Writing \( \omega \) for \( \omega \), the cube roots of 1 are 1, \( \omega \), \( \omega^2 \).

Any number \( a \) has three cube roots, \( x = a^{\frac{1}{3}} \), \( a^{\frac{1}{3}} \sqrt[3]{a} \), \( a^{\frac{1}{3}} \sqrt[3]{-a} \); thus the cube roots of 8 are 2, \( \omega \) 2 and \( \omega^2 \). The general cubic may be written

\[ x^3 + ax^2 + bx + c = 0. \]

On putting \( y - \frac{a}{3} \) for \( x \), the cubic becomes

\[ y^3 + \left( \frac{b}{3} - \frac{a^2}{3} \right) y + \left( c - \frac{a^2 b}{27} + \frac{2a^3}{27} \right) = 0, \]

or \( y^3 + py + q = 0 \), lacking the second term and called the reduced cubic. It is sufficient to solve the reduced cubic, for the roots of the original are then found by the relation \( x = y - \frac{a}{3} \).

Let \( y = \sqrt[3]{s} \), then \( x = \sqrt[3]{s} + \sqrt[3]{-\frac{p}{3}} \). This is quadratic in \( s \), yielding \( s = \frac{-p}{2} \pm \sqrt{\frac{p^2}{4} + \frac{q^2}{3}} \). From the fact that \( x \) has six values, it must not be inferred that \( y \) has six; for the two values \( s_1 \) and \( s_2 \) of \( s \) are such that \( s_1 s_2 = \frac{p}{3} \); hence the six \( s \)-values, \( s_1, s_2, \omega s_1, \omega s_2, \omega s_3, \omega s_4 \), yield but three \( y \)-values, corresponding to the relations \( s_1 + s_2 = \omega s_1 + \omega s_2 \). For example,

\[ y_1 = s_1 - \frac{p}{3s_1} = s_2 - \frac{p}{3s_2} = s_3 + s_4. \]

If \( s_1 = \sqrt[3]{\frac{-p}{2}} \), then \( y_1 = \sqrt[3]{\frac{-p}{2}} \pm \sqrt[3]{\frac{q^2}{3}} \), and the \( y \)-values are:

\[ y_1 = \sqrt[3]{\frac{-p}{2} - \sqrt[3]{\frac{q^2}{3}}} \pm \sqrt[3]{\frac{-p}{2} + \sqrt[3]{\frac{q^2}{3}}} \]

\[ y_2 = \omega \sqrt[3]{\frac{-p}{2} + \sqrt[3]{\frac{q^2}{3}}} + \omega^2 \sqrt[3]{\frac{-p}{2} + \sqrt[3]{\frac{q^2}{3}}} \]

\[ y_3 = \omega \sqrt[3]{\frac{-p}{2} - \sqrt[3]{\frac{q^2}{3}}} + \omega^2 \sqrt[3]{\frac{-p}{2} - \sqrt[3]{\frac{q^2}{3}}} \].

It can be readily shown for real \( p \) and \( q \) that one of the \( y \)-values is real and the other two are conjugate imaginaries if \( Q \) be +, that all are real and two are equal if \( Q = 0 \), and that all are real and distinct if \( Q \) is −. The last case is called irreducible because the root formula, involving imaginaries, is practically valueless. In this case the roots may be found by help of the trigonometric functions (see Trigonometry) as follows: Let \( Q = -r \sin \theta \), \(-4q = r \cos \theta \), then

\[ \sqrt[3]{\frac{-p}{2} + \sqrt[3]{\frac{q^2}{3}}} = \sqrt{r} \sin \left( \frac{\theta}{3} + 2k \pi \right) \]

and

\[ \sqrt[3]{\frac{-p}{2} - \sqrt[3]{\frac{q^2}{3}}} = \sqrt{r} \sin \left( \frac{\theta}{3} - 2k \pi \right) \]

The Biquadratic, or Quartic. — In general form this is \( x^4 + px^3 + qx^2 + rx + s = 0 \). The equivalent reduced quartic, \( x^4 + ax^3 + bx^2 + cx + d = 0 \), is found by replacing \( x \) by \( x - \frac{p}{4} \). To solve the reduced quartic, let \( x = u + y + z \); then \( x^4 - 2x^3 (u^2 + y^2 + z^2) \)
= 8xyz + (x^2 + y^2 + z^2) - 4(x^2y + y^2z + z^2x) = 0; if this be identical with the reduced quartic,
\( a - 2(x^2 + y^2 + z^2) - 4(x^2 + y^2 + z^2) = 0 \).
Owing to relations between the roots and coefficients of any equation (see EQUATIONS, THEORY of), the roots of the auxiliary cubic \( f + \frac{a}{2} \sqrt{1 + \sqrt{m + \sqrt{n} - \sqrt{m + \sqrt{n}}} - \sqrt{m + \sqrt{n}}} \)
are \( -\frac{b}{c} \). Denoting them by \( t, m, n \), we have \( x = m^2 + x^2 + y^2 + z^2 = 0 \).
But only really four because the product \( xyz = -\frac{b}{c} \).
If \( b \) is positive the values of \( x \)
are \( \sqrt{m + \sqrt{n}}, -\sqrt{m + \sqrt{n}}, \sqrt{m + \sqrt{n}}, -\sqrt{m + \sqrt{n}} \).

Historical and Critical Notes.—As seen, the general equations of 4th and lower degrees are soluble by means of radicals or root extraction. It was naturally but incorrectly supposed that the same means would prove available in the case of the general quintic and equations of higher degree, and one of the great problems of the 18th century was to solve the quintic in a manner analogous to that employed above for the quartic, cubic and quadratic. In 1770 Lagrange proved that the method was not adequate for that purpose, as it gave for auxiliary an essentially general one of sixth degree. By Abel, Wantzel and Galois (see EQUATIONS, GALOIS’ Theory of) it was shown to be impossible to solve by radicals any general equation of degree above 4. Subsequently Hermite proved that the roots of the general quintic are expressible in terms of elliptic functions. The quadratic, cubic and quartic are solvable by other methods than those given above, but all are essentially the same. The solution of the general quadratic was known to the Arabs in the 9th century. The solution of \( x^2 + px + q = 0 \) was discovered by Scipio Ferro in the beginning of the 16th century. It was rediscovered a few years later by Tartaglia. The solution given above is known as Cardan’s, but it is known that Cardan learned it from Tartaglia. Ferrari, a pupil of Cardan’s, solved the quartic. The solution, given by Bombelli in his algebra (1579), is sometimes attributed to him. Descartes gave a different solution in 1637. The solution presented above is Euler’s, having been found by him in 1770.

Higher Equations.—Although the general equations of the 5th and higher degrees are not soluble by radicals, many particular equations of such degrees are thus soluble; e.g., \( x^5 - 1 = 0 \).
It works on the theory of equations (see EQUATIONS, THEORY of) various methods, chief of which is Horner’s, are given whereby the commensurable roots of any equation having numerical coefficients can be found and the incommensurable roots can be found to any required degree of approximation.

Simultaneous Equations.—The general linear equation in two variables or unknowns, as \( x \) and \( y \), is \( ax + by = c \). Solving for one of the variables, say \( x \), in terms of the other, the equation becomes \( x = \frac{c - by}{a} \). It is seen that \( x \) and \( y \)
are functions of each other: to any value of either corresponds a value of the other. Any two corresponding values constitute a pair satisfying the equation. There are infinitely many such pairs satisfying a given equation of the kind in question, as many pairs as there are numbers. Obviously there are hosts of pairs not satisfying a given equation. All the pairs satisfying a given equation constitute a system of pairs. Two equations \( ax + by = c_1 \), \( ax + by = c_2 \) are different unless \( a = b \), \( c_1 = c_2 \). Have the two systems determined by two different equations any pairs in the common? The answer is, one pair. It can be found as follows: Multiplying the former equation by \( b \), the latter by \( -b \), adding and solving for \( x \), \( \frac{b_1 c_1 - b_2 c_2}{a(b_1 - b_2)} \) \( \frac{a_1 b_2 - a_2 b_1}{a(b_1 - b_2)} \); analogously, \( y \), \( \frac{a_2 c_1 - a_1 c_2}{a(b_1 - b_2)} \) \( \frac{a_2 b_1 - a_1 b_2}{a(b_1 - b_2)} \). This and only this pair of values of \( x \) and \( y \) satisfies both equations. In combining the equations, \( x \) and \( y \) were regarded as the same in both. Two or more equations in two or more unknowns are called simultaneous when the unknowns are treated as representing the same numbers in all the equations. If there is a common \( x \)-equation was found by eliminating \( y \) between the given equations. The elimination was accomplished by addition. It might have been done otherwise, as by comparison, i.e., solving each equation for \( y \) and equating the \( y \)-values so obtained, or by substitution, i.e., solving one of the equations for \( y \) and substituting the \( y \)-value so found for \( y \) in the other equation. In any of these ways or by combinations of them one may find a triplet of values satisfying three arbitrary equations in three unknowns, \( x \), \( y \), \( z \); eliminate, say \( z \), between two of them and then between the remaining one and one of the others; so result two equations in \( x \) and \( y \), to be handled as above. The method is obviously extensible to the case of \( n \) equations in \( n \) unknowns. In general, \( n \) linear equations in \( n \) unknowns are satisfied simultaneously by but a single set of values, but in special cases by no set or by more than one set. The latter happens only when the coefficients satisfy some special condition or conditions. Under certain conditions \( n \) or more equations in \( n - 1 \) unknowns may be satisfied by the same set of values. Thus the equations \( a_1 x + b_1 y + c_1 = 0 \), \( a_2 x + b_2 y + c_2 = 0 \), \( a_3 x + b_3 y + c_3 = 0 \), \( a_4 x + b_4 y + c_4 = 0 \), are simultaneously satisfied or are consistent when and only when \( a_1 b_2 c_3 - a_1 b_3 c_2 - a_2 b_1 c_3 + a_2 b_3 c_1 - a_3 b_1 c_2 + a_3 b_2 c_1 = 0 \). For the expression of such conditions, and the solution of sets of linear equations, by means of determinants, see the article DETERMINANTS and works therein cited.

Simultaneous equations involving the unknowns to degrees higher than the first may sometimes be solved. One consistent solution of the pair of equations: \( ax + by + cz = 0 \), \( dx + ey + fx + gx + hy + k = 0 \); from the former \( y = -\frac{c}{a} x \); substituting that \( y \)-value for \( y \) in the second given equation, a quadratic in \( x \) is found; this gives two \( x \)-values; substituting these in the given linear equations, the corresponding values of \( y \) are found. The corresponding values must be properly paired; thus the equations \( 3x + 4y - 5z = 0 \) and \( 2x - 3y + 22 = 0 \) give \( x = 3 \) and \( y = 10, 53, y = -10, 53 \) and \( 148, 53 \); the proper pairing is \( x = 3 \), \( y = -10, 53 \), and \( x = 10, 53 \), \( y = 148, 53 \), the equations are not satisfied by \( x = 3, y = 148, 53 \), for example. Once more, the two quadratics \( x^2 + 3x + 284 = 0 \),
\[ xy + 4y^2 = 8 \text{ give, on division (member by member) and clearing of fractions, } 2 \left( x^2 + 3xy \right) = 7 \left( xy + 4y^2 \right); \text{ whence } x = 4y \text{ or } -3y/2. \text{ For } x = 4y, \text{ the second given equation furnishes } 4y^2 + 4y^2 = 8 \text{ and } y = 1 \text{ or } -1, \text{ whence } x = 0 \text{ or } 5/2. \text{ In like manner, one finds } y = -1 \text{ or } 1 \text{ and } x = -4 \text{ or } 4; \text{ in all four pairs of values corresponding thus: } x = -4, y = 1; \text{ } x = -4, y = -1; \text{ } x = 14, y = 4; \text{ } x = 14, y = -4. \text{ In general, an equation of } n \text{th degree and one of } n \text{th degree in two unknowns are both satisfied by } n^2 \text{ pairs of numbers. The solution of such a pair involves, in general, the solution of an equation of degree } mn. \]

### Permutations and Combinations.

Any arrangement (in a row) of \( r \) things (regarded as belonging to a set of \( n \) things) is called a (straight) permutation of the \( n \) things \( r \) at a time. Two permutations are the same when and only when they consist of the same things in the same order. The number of different (possible) permutations of \( n \) things \( r \) at a time is often denoted by \( P_r \). To find this number, one neglects one of the \( n \) permutations of \( n \) things \( r - 1 \) at a time. There remain \( n - r + 1 \) things. Put one of these after the things of the given permutation. There so results a permutation of the \( n \) things \( r \) at a time.

It readily follows that
\[
\frac{P_{r-1}}{P_r} = \frac{(n - r + 1)}{(n - r + 1)}.
\]

Multiplying these equations member by member, it is found that
\[
P_r = \frac{n!}{(n - r)!}.
\]

It can be readily proved that the number \( P_r \) of permutations of \( n \) things (\( a, b, c, \ldots \)) \( n \) at a time, \( p \) of the things being \( a \)'s, \( q \) of them \( b \)'s, \ldots, is
\[
P_r = \frac{n!}{a!b!c! \ldots}. \quad \text{If the order in a permutation of}
\]
\[n\text{ things is disregarded, the result is a combination of } n \text{ things } r \text{ at a time. Two combinations are the same if they consist of the same elements. A common symbol for the number of combinations of } n \text{ things } r \text{ at a time is } \binom{n}{r}. \text{ By permuting the } r \text{ things of a combination in every way, } r \text{ permutations arise. It follows that } P_r \text{ is } \binom{n}{r} \text{ permutations arise.}
\]

### Geometric Progression.

A G.P. is a series of numbers such that the ratio of any one to the next is equal to the ratio of any other one to its next. Accordingly, the general form of a G.P. is: \( a, ar, ar^2, \ldots, ar^{n-1} \). Again, there are five elements to be considered: the first term, \( a \); the last, \( l \); the ratio, \( r \); the number of terms, \( n \); and the sum of the terms, \( s \). In terms of any three of the five elements, either of the remaining elements can be expressed. Accordingly, the theory of the G.P. involves the solution of but 20 problems. Most important of these are the problems, to express \( l \) in terms of \( a \) and \( n \), and to express \( s \) in terms of \( a \) and \( n \). It is plain that \( l \) or the nth term, is \( l = ar^{n-1} \). To find \( s \), let \( s = a + ar + \ldots + ar^{n-2} + ar^{n-1} \); whence \( rs = ar + ar^2 + \ldots + ar^{n-1} + ar^{n} \); subtracting, and dividing by \( l - x \), it is found that \( s = a(1 - r^n) = \frac{a(1-r^n)}{1-r} \).

The remaining 18 formulae are easily obtained. If \( r \) be numerically less than 1, the G.P. is said to be a decreasing G.P.; otherwise, not. In case of a decreasing G.P., it is possible to sum the series to infinity, a phrase requiring explanation. An endless series, \( a, a_n, \ldots \), is said to be infinite, i.e., to contain an infinite number of terms. A series that has an end, a last term, is said to be finite. Let \( s_n \) denote the sum of the first \( n \) terms of an infinite series. If the series be such that there is a finite number \( L \) from which, by taking \( n \) large enough, \( s_n \) may be made to differ by less than any prescribed amount. As \( n \) continues to increase, \( s_n \) approaches nearer and nearer in value, then \( L \) is named limit of \( s_n \) as \( n \) increases endlessly, the series is said to be convergent (see Series) and \( L \) is called the sum (to infinity) of the series. Observe that here the word "sum" is used in a new sense, viz., as limit of a sum (in old sense). Now consider the infinite G.P.'s, \( a, ar, ar^2, \ldots, ar^{n-1}, ar^n \). The sum \( s \) of the first \( n \) terms, by the foregoing formula for \( s \), is
\[
s_n = \frac{a(1-r^n)}{1-r} \quad \text{for \ } r \neq 1. \text{ If the G.P. is a decreasing one, } r < 1 \text{ numerically, } r^n \text{ approaches zero as limit as \( n \) increases without bound, and hence \( s \) has limit } \frac{a}{1-r}. \text{ The G.P. is a convergent series, and its sum to infinity is } s = \frac{a}{1-r} \text{.}
\]

### Harmonical Progression.

An H.P. is a series of numbers such that the series of their reciprocals is an A.P. Hence the typical H.P. is
of the form \( \frac{1}{a} + \frac{1}{a+d} + \frac{1}{a+2d} + \cdots + \frac{1}{a+(n-1)d} \).

It is obvious that every problem involving an H.P. is convertible into a problem involving an A.P. If \( a \) and \( b \) be any two numbers, their arithmetic mean is a number \( c \) such that the series \( a, c, b \) is an A.P. Hence \( a = b = c \), whence \( c = \frac{1}{2}(a+b) \); i.e., the arithmetic mean of two numbers is half their sum. The geometric mean of \( a \) and \( b \) is a number \( c \) such that the series \( a, c, b \) is a G.P. Hence \( \frac{c}{a} = \frac{c}{b} \), whence

\[ c = \sqrt{ab} \]; i.e., the geometric mean of two numbers is the square root of their product. The harmonic mean \( H \) of \( a \) and \( b \) is \( \frac{1}{c} = \frac{1}{a} + \frac{1}{b} \), whence

\[ c = \frac{2ab}{a+b} \].

Denote this mean by \( A \), \( G \) and \( H \) respectively, the arithmetic, the geometric and the harmonic means of \( a \) and \( b \). Then \( A = \frac{1}{2}(a+b) \), \( G = \sqrt{ab} \), \( H = \frac{2ab}{a+b} \). It is readily seen that \( H = G \cdot A \), whence \( G = \sqrt{AH} \); i.e., the geometric mean of two numbers is the geometric mean of their arithmetic and their harmonic means.

The Binomial Theorem or Expansion.—If \( a \) and \( b \) are any numbers and \( n \) is any positive integer,

\[ (a+b)^n = a^n + na^{n-1}b + \frac{n(n-1)}{1 \cdot 2} a^{n-2}b^2 + \cdots + \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} \cdots \cdot r a^{n-r}b^r + \cdots + nb^n \],

an expansion containing \( n+1 \) terms. For proof of the relationship see article Mathematical Induction. It can be proved by algebraic means, most readily by Maclaurin's formula (see Calculus), that, if \( a \) is numerically greater than \( b \) and \( n \) is any real number, the same expansion as that above given is valid, i.e., \( (a+b)^n = a^n + na^{n-1}b + \cdots \), which, however, contains an infinite number of terms, except in the case where \( n \) is a positive integer. The equation is called the binomial theorem. It was discovered by Sir Isaac Newton, but its correctness was not proved by him. One of the simplest of its countless applications is its application to the problem of finding correct to any required degree of approximation any real root of any real number. For example, suppose it is desired to know the real cubic root of 25 correct to five decimal places. We may proceed as follows:

\[
\sqrt[3]{25} = (25)^{\frac{1}{3}} = (27 - 2)^{\frac{1}{3}} = (3^3 - 2)^{\frac{1}{3}} = 3^{\frac{3}{3}} - 2^{\frac{3}{3}} = 3^{1} - 2^{\frac{1}{3}} = 3 - 2^{\frac{1}{3}} = 3 - 1.26996 \approx 1.73105
\]

The Number \( e \) and the Series for \( e^x \).—If \( n \) be numerically greater than 1, the foregoing theorem yields the equations

\[
\left(1 + \frac{1}{n}\right)^n = 1 + \frac{1}{n} + \frac{1}{2!} + \frac{1}{3!} + \cdots + \frac{1}{n!} + \frac{1}{n+1} \cdot \frac{1}{n} \cdots \cdots
\]

\[
(1 + \frac{1}{n})^n = 1 + x + \frac{x}{2!} + \frac{x(x-1)}{3!} + \cdots \cdot \cdots \cdots
\]

Hence

\[
\frac{1}{x} + \frac{1}{3!} \left(1 - \frac{1}{n}\right) + \frac{1}{3!} \left(1 - \frac{1}{n}\right) \left(1 - \frac{2}{n}\right) + \cdots
\]

\[
1 + x + \frac{x}{2!} + \frac{x(x-1)}{3!} + \cdots
\]

This equation is valid for every value of \( n \) numerically greater than 1. The limits approached by its members as \( n \) increases beyond every finite value are equal, and it may be shown to result from this that

\[
(1 + 1 + \frac{1}{2!} + \frac{1}{3!} + \cdots)^n = 1 + x + \frac{x}{2!} + \frac{x(x-1)}{3!}
\]

\[
1 + x + \frac{x}{2!} + \frac{x(x-1)}{3!} + \cdots
\]

The series on the right is convergent for every finite value of \( x \); in fact, for any given value of \( x \), the series after a certain number of terms converges more rapidly than any decreasing G.P. The series on the left is a special case of that on the right, viz., \( x = 1 \). The limit of the sum of the first \( n \) terms of the series on the left, i.e., its sum (to infinity) is denoted by \( e \); accordingly the equation may be written:

\[
e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots
\]

The number \( e \) raised to a power indicated by a given value of \( x \) is the sum to infinity of the series for that value of \( x \). Since \( e = 1 + 1 + \frac{1}{2!} + \frac{1}{3!} + \cdots \), its approximate value can be readily calculated. That value, correct to 10 decimal places, is \( e = 2.7182818284 \). The number \( e \) is one of the most important of all numbers, is incomparable, i.e., not exactly expressible as a rational fraction, and it is transcendental, i.e., not a root of an equation \( ax^n + bx^{n-1} + \cdots + c = 0 \) where the coefficients \( a, b, \ldots \) are integers (see General Theory of Assemblages).

Logarithms.—Let \( a \) be any positive number greater than 1. If \( ax = N \), \( x \) is named logarithm of \( N \) to the base \( a \); symbolically, \( x = \log_a N \) or, if the base is supposed known, simply \( x = \log N \). If \( a \) be fixed, \( x \) and \( N \) will vary each with the other, each is a function of the other. Since \( a = 1 \), \( log 1 = 0 \) no matter what the base. But in general the logarithm of a given number will vary with the base; thus, since \( 2^x = 16 \), \( 4^x = 16 \), \( 10^{log_{10} 16} = 4 \), \( log_{10} 16 = 2 \). The general connection can be readily found thus: let \( ax = N \) and \( bx = M \), then \( log_a N = x \) and \( log_b N \)

\[
y = \frac{x}{y} = \log_a N = \log_b N \log_a b \]

whence \( \log_a N = \log_b N \log_a b \). Calling \( a \) the old and \( b \) the new base, it is seen that the logarithm of a given number to a new base is equal to the product of the logarithm of the number to the old base and the logarithm of the new base to the old base. Let \( a = N \), \( \alpha = M \), then \( \alpha = \alpha = \log_a N \log_a M \); hence the logarithm of a product is the sum of the logarithms of the factors. Again, \( (ab)^k = N^k = a^{kb} \); whence it is seen that
the logarithm of the $k$th power of a number is $k$ times the logarithm of the number. Once more, $a^m = a^{m-n}$; that is, the logarithm of a fraction is equal to that of the numerator minus that of the denominator. Logarithms to the base 10 are called common logarithms or Briggsian logarithms after Briggs, who introduced them in 1617. These are used in practical computation, but in theoretical work logarithms are referred to the number $e$, the Napierian base, so called after Napier (1550-1617), the inventor of logarithms.

Let $N$ be any number and $n$ any positive integer. Then $\log_{10}(N^{10^{n}}) = \log_{10}N + n \log_{10}10 = \log_{10}N + n$; and $\log_{10}N + \log_{10}10 = \log_{10}N + 1$.

Now multiplication or division by a power of 10 has only the effect of moving the decimal point, while the logarithm of the product, as just seen, is equal to that of the multiplicand (or dividend) increased (or decreased) by an integer. Accordingly, if two numbers differ only in the position of the decimal point, their logarithms differ only in respect to the integral part (called the characteristic part, or the mantissa) being the same in both. In that fact resides the chief practical advantage of the Briggsian system. For example, if $\log_{10}2.233 = 0.3483$, it follows that $\log_{10}22.33 = 1.3483$; and $\log_{10}2.233 + 3 = 3.3483$, or $3.3483$, as negative characteristics are often written. It is easy to see that the characteristic of a logarithm is $+n$ if the number has $n+1$ figures before the decimal point, and is $-n$ if the number is a pure decimal in which the point is followed by $n-1$ zeros. Thus, $\log_{10}2350.054 = 4 + a$; a pure decimal, and $\log_{10}0.008953 = -4 + a$; a pure decimal.

**Logarithmic Series, Calculation of Logarithms.** It may be shown by the methods of the differential calculus that if $x < 1$, $\log_{10}(1 + x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} - \ldots$.

The logarithmic series converges slowly for all but small values of $x$. It is on this account adapted to the calculation of Napierian logarithms. A series better adapted to such calculation is, however, readily obtained as follows: From the last two series it follows that $\log_{10}(1 + x) = 1 + x - \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{5} + \ldots$.

Put $x = \frac{m-n}{m+n}$ so that $\frac{1+x}{1-x} = m+n$. Then

\[
\log_{10}\frac{m}{n} = \{m+n+1 + \frac{m-n}{3} + \frac{m-n}{3} + \frac{m-n}{5} + \ldots\},
\]

a rapidly converging series that may be used for the calculation of logarithms as follows. For $m = 2$ and $n = 1$, we get $\log_{10}2 = 0 + 2 + 3 + 1 + 1 + \ldots$, whence $\log_{10}2 = 0.3010$ (correct to six decimal places). For $m = 3$ and $n = 2$, the series gives $\log_{10}3 = 0 + 2 + 3 + 1 + 1 + 1 + \ldots = 1.098612$. Taking $m = 5$ and $n = 3$, it is found that $\log_{10}5 = 1.60944$. Then $\log_{10}2 = 0 + 2 + 3 + 5 + 3 + 3 + 3 + 3 + 3 + \ldots$, and $\log_{10}3 = 0 + 5 + 3 + 5 + 3 + 3 + 3 + 3 + 3 + \ldots$, and so on. In particular $\log_{10}10 = \log_{10}2 + \log_{10}5 + 2.302585$. Since $\log_{10}N = (\log_{10}N)(\log_{10}10)$, it is seen that the common logarithm of any number may be found from the Napierian logarithm of that number by multiplying the latter logarithm by 2.302585. This last is called the modulus of common logarithms. It is obviously possible to calculate logarithms that shall be correct to any prescribed number of decimal places. Logarithms correct to 3 or 4 places are sufficiently accurate for all ordinary calculations, though tables correct to 5, 6, 7 and even 10 or more places are often employed. By means of any such table can be found the logarithm of any given number and conversely. The number corresponding to a given logarithm is often called the antilogarithm. The advantage of logarithm over ordinary computation is easily seen. Thus to find the product of two or more numbers, it suffices to add their logarithms and then to take the antilogarithm of the sum. To extract any root, say the $7$th, of any number, it suffices to divide the logarithm of the number by 7 and to take the antilogarithm of the quotient. To find the quotient of two numbers, it suffices to subtract the logarithm of the divisor from that of the dividend and then to take the antilogarithm of the difference. The cologarithm of a number is the logarithm of the reciprocal; thus, $\log_{10}m = 1 - \log_{10}n$.

**Undetermined Coefficients.** Reference was made above to this subject, of which some account will now be given. Let $f(x) = ax$ $+ bx$ $+ cx$ $+ dx$ $+ ex$, a rational integral function of degree $n$. It can be shown and is here assumed that such a function vanishes for some value of the variable. If $f(r) = 0$, then, by the factor theorem, $f(x) = (x-r)f'(x)$, where $f'(x) = ax^n$ $+ bx^{n-1}$ $+ cx^{n-2}$ $+ dx^{n-3}$ $+ ex^{n-4}$. If $f'(r) = 0$, then $f(x) = (x-r)f''(x)$, where $f''(x) = ax^n$ $+ bx^{n-1}$ $+ cx^{n-2}$ $+ dx^{n-3}$ $+ ex^{n-4}$ $+ (x-r)f''(x)$.

By the argument here exemplified it is proved that $f(x)$ may be put in the form $f(x) = a(x-r)f'(x)$ $+ (x-r)f''(x)$, and hence the $n$ numbers $r_1, r_2, \ldots, r_n$ causes $f(x)$ to vanish; hence the $n$ numbers are the roots of the equation $f(x) = 0$. It can be easily seen that the equation $f(x) = 0$ cannot have more than $n$ different roots unless its coefficients are each zero; that is, $f(x)$ cannot vanish for more than $n$ different values of $x$ unless $a_n = a_{n-1} = \ldots = a_0 = 0$. For if $(r_0 + r_1 + \ldots)$ $\neq 0$, then $a_n(r_0 + r_1 + \ldots) = a_{n-1}(r_0 + r_1 + \ldots)$ $+ a_{n-2}(r_0 + r_1 + \ldots) = a_{n-3}(r_0 + r_1 + \ldots) + \ldots$ by hypothesis $= (r_0 + r_1 + \ldots)$, hence $a_0 = 0$, and $f(x) = ax^n$ $+ (x-r_1)f''(x)$ $+ (x-r_2)f''(x)$ $+ (x-r_3)f''(x)$ $+ \ldots$ $+$ $+ (x-r_n)f''(x)$. As the latter is to vanish for more than $n$ values of $x$, $a_n = 0$. In like manner it would follow that $a_{n-1} = 0$, $\ldots$, $a_0 = 0$. But if the coefficients are each zero, $f(x)$ vanishes for every $x$, so that if $f(x)$ vanishes for more than $n$ values of $x$, it vanishes for all $x$. Now suppose that $a_n = a_{n-1} = \ldots = a_0 = 0$. Hence two rational integral functions of degree $n$ in $x$ are equal for all values of $x$, i.e., are identical, when and only when the coefficients of like powers of $x$ are equal. This proposition enables us to solve many problems involving the determination of undetermined coefficients. For example, suppose it required to find the sum of the squares of the first $n$ integers. Assume the identity
ALGEBRA

\[ a^n + b^n + \ldots + (n-1)^n + n^n = a^n + b^n + \ldots + (n-1)^n + n^n + \ldots + (n+1)^n \]

where the coefficients \(a, b, \ldots, g\) are to be determined. Replacing \(n\) by \(n + 1\), we obtain

\[ \begin{align*}
1^2 + 2^2 + \ldots + (n-1)^2 + n^2 &= a^n + (n+1)^2 + (n+1)^3 + \ldots + (n+1)^n + n^n + \ldots + (n+1)^n + n^n \\
&= 1 + 2^2 + \ldots + (n-1)^2 + n^2 + (n+1)^2 + (n+1)^3 + \ldots + (n+1)^n + n^n
\end{align*} \]

As this relation is to be valid for every value of \(n\), coefficients of like powers of \(n\) must be equal. Hence \(1 = 0, 2 = 1\), and so on. 

\[1 + 2^2 + \ldots + (n-1)^2 + n^2 + \ldots + (n+1)^n + n^n = \frac{1}{2} n(n+1)(2n+1) \]

Part-fractions. The so-called principle of undetermined coefficients has frequent application in the solution of the problem, to decompose a given fraction into part-fractions (commonly called partial fractions) whose sum shall be the given fraction. Any fraction whose terms are rational integral functions of \(x\) may be thus decomposed. The method of procedure may be made sufficiently clear by a few examples. It will be observed that the problem is in some sense the inverse of the problem of summing fractions.

For example, the sum of

\[ \frac{2}{x} + \frac{5}{3(1-x)} \]

is

\[ \frac{x+4}{2x-x^2-x^3} \text{ or } \frac{x+4}{(x-1)(2+x)} \]

The inverse problem is: given the latter fraction, to find its components. It is plain that the only fractions whose denominators are linear and whose sum is a fraction of the proper denominator and a linear numerator are \(a \frac{b}{x-1} - c \frac{2}{x+1}\).

Hence we assume:

\[ \frac{x+4}{2x-x^2-x^3} = \frac{a}{x-1} + \frac{b}{x+1} + \frac{c}{x+2} \]

whence \(x+4 = a(x-1)(2+x) + b(x+1)(x+2) + c(x+1-x)\), which is to be valid for all values of \(x\). Expanding the right-hand member and equating corresponding coefficients on right and left, we obtain:

\[ a = 2, b = 1, c = 1 \]

and the component fractions are seen to be

\[ \frac{2}{x-1} + \frac{5}{3(1-x)} \frac{1}{(2+x)} \]

For another example, we may take

\[ F = \frac{4x^2+3x-1}{(x-1)(x+2)} \]

A little reflection suffices to show that the assumption to be made is

\[ F = \frac{a}{x-1} + \frac{b}{x+1} + \frac{c}{x+2} \]

Then

\[ 4x^2+3x-1 = a(x-1)(x+1) + b(x-1)(x+2) + c(x+1) \]

equating coefficients and solving the resulting equations, it is found that \(a = 1, b = 2, c = -1\). In case a factor of the given denominator is repeated \(k\) times, as in

\[ \frac{1}{(x+px+q)^n} \]

the assumption to be made is:

\[ F = \frac{a_1}{x+b} + \frac{a_2}{(x+b)^2} + \ldots + \frac{a_k}{(x+b)^k} \]

If \(F\) is of the form

\[ \frac{(x^2+nx+1)^k}{(x^2+nx+1)^k} \]

then assume

\[ F = \frac{ax+b}{(x^2+nx+1)^k} \]

\[ \ldots \]

Of course, \(N\) is of degree equal to or higher than that of the given denominator, \(F\) is converted by division into an integral function + a fraction the degree of whose denominator exceeds that of its numerator. The latter fraction is then decomposed by the methods above indicated.

Indeterminate (Undetermined, Illusory) Forms. In case of a fraction, \(F(x) = \frac{f(x)}{g(x)}\) it may happen that both terms vanish for some value of \(x\), as \(x = a\), yielding the form \(0\) \(0\) which, as division by zero is meaningless, is itself without meaning and is commonly called indeterminate. In such case we are free (logically) to give the form a meaning, any meaning or value whatever. But while all meanings (values) are allowable, not all are expedient. For example, \(x - \frac{a}{x}\) has a definite value for every \(x\)-value except \(x = a\). For this value the fraction takes the form \(0\). To this we might assign the value of 5 or -3, or any other. But such a choice would be motley. On the other hand, \(x - \frac{a}{x}\) has a definite value for all values of \(x\) except \(a\); for this critical value \(a\), the right member takes a definite value, \(2a\), which is accordingly suggested as the value to be naturally assigned to the indeterminate form in this case. The decisive motive for this choice lies yet deeper: it is that as \(x\) varies through a sequence of values, say \(a + \frac{1}{2}, a + \frac{1}{3}, a + \frac{1}{4}, \ldots\), having \(a\) as limit, the corresponding sequence of fraction-values, \(2a + \frac{1}{2}, 2a + \frac{1}{3}, 2a + \frac{1}{4}, \ldots\) approaches \(2a\) as limit. Accordingly, if \(\phi(x)\) assumes the form \(0\) for \(x = a\), the value assigned to \(\phi(a)\) is the limit value which the sequence of fraction-values approaches as \(x\) approaches \(a\) through any sequence \(x\)-values for each of which \(\phi(x)\) has a definite value. The fraction \(\phi(x)\) may be such as \(x\) approaches \(a\), \(f(x)\) approaches a definite value other than zero and that \(f(x)\) approaches zero. Such a fraction is \(x - \frac{a}{x}\).

In such case the fraction-value obviously becomes larger and larger, surpassing every prescribed number, a fact commonly expressed by saying that as \(x\) approaches \(a\), \(\phi(x)\) approaches positive or negative infinity \((\infty\text{ or }-\infty)\) according as the numbers in the fraction sequence are positive or negative. If, as \(x\) approaches \(a\), both \(f(x)\) and \(F(x)\) approach \(\infty\), then, for \(x = a\), \(\phi(x)\) assumes the indeterminate form \(\infty\) \(\infty\).

But it may be made to take the form \(0\) \(0\) since \(f(x) + F(x) = (1 + F(x)) (1 + f(x))\). Other indeterminate forms also reducible to the form \(0\) \(0\) are \(0, \infty, \infty, 0, -\infty, -\infty, 0, 0\). For further treatment see Calculus.

The boundary of what is or should be called elementary algebra is ill defined alike in theory and in practice, and besides the topics dealt with in this article other subjects are briefly treated in some of the elementary textbooks. Of such additional subjects, the more important as chance or probability, the complex variable, and theory of numbers, series, and others, are
ALGEBRA

The term "algebra" was coined by the 9th-century Arab mathematician Al-Khwarizmi in his book "Kitab al-jabr wa-l-muqabala." He used "al-jabr" to mean "restoration" or "completion" and "al-muqabala" to mean "reduction" or "comparison." The term "algebra" comes from a phrase in the title of this book, which is derived from the Arabic word meaning "reunion of broken parts," referring to the process of solving equations.

For reasons above suggested, algebra flourished more naturally in the Orient than in Greece. The first Hindu algebraist of any importance was Aryabhata, who was born at Pataliputra, on the Upper Ganges, in 476 A.D. Part of his "Aryabhatiya" is devoted to algebra, and covers the fundamental operations, rules for square and cube roots, progressions, permutations, equations of the first and second degrees with one unknown quantity, and some treatment of indeterminate equations. Aryabhata differs from Diophantus in that he considers algebra from a broader standpoint, treating it rather as a theory of elementary functions than as the science of a particular form of the equation.

The next great algebraist in the East was Al Khwarazmi (q.v.), c. 800 A.D., so called from his birthplace, Khurazm, the territory of the modern Khiva. With him algebra takes a still different meaning. It is no longer the theory of indeterminate equations of Diophantus, nor is it chiefly the theory of elementary functions of Aryabhata, but it becomes primarily the general theory of equations. Indeed, the title of his work 'ilm al-jabr wa 'l muqabalah, means the science of reintegration and equation, a title from which only the words al-jabr have survived, giving the accidental name of algebra to the subject. Al Khwarazmi solved three types of the quadratic, in modern symbolism $x^2 + ax = b$, $x^2 = ax = b$, $x + b = ax$, thus showing his inability to generalize, a failing with all writers before the 17th century.

It was two centuries before another writer of prominence appeared. About 1010 A.D., Al Karchi, like Al Khwarazmi of the Bagdad school, wrote a treatise in which he shows familiarity with the works of his predecessors in a rather than rather great genius himself. Like many of the older writers, he gives attention to those rules for approximating roots, so necessary before the time of decimal fractions. Stated in modern symbolism his rule for square root is

$$\sqrt{a^n + \frac{a}{2w+1}}$$

where $w$ is in the neighborhood of

$$\frac{\sqrt{a}}{2w+1}$$

is given for $a$. He also gives the rule

$$\sqrt{a+b} = \sqrt{a} \pm \sqrt{b},$$

and a rule for $2a^n$.

In the 12th century two Oriental writers of prominence appear, Omar Khayyam (q.v.), the Persian, who died in 1123, and Bhaskara, the Hindu, who was born in 1114. Omar solved the cube case of the cubic, and was one of the first to treat equations above the second degree in a systematic manner. The binomial theorem with positive integral exponents was also known to him. His algebra, published in Paris, both in Arabic and in French, made Omar known in the West as an algebraist. When Fitzgerald made him celebrated as a poet.

Bhaskara wrote on both arithmetic and algebra, and his work has long been known in Europe through Colebrook's English transla-
tion. Among the features of his algebra is the statement that \( \frac{a}{0} = \infty \), and the solution of the quadratic by the reduction of \( ax^2 + bx + c = 0 \) to the form \( (x + \frac{b}{2})^2 = \frac{b^2 - 4ac}{4a} \), a device known in England as the Hindu Method.

The rise of modern elementary algebra took place in Italy in the 16th century. It was at this time that the cubic was solved by Tartaglia (q.v.), the publication being made by Cardan (p. 192) in his *Ars Magna* in 1545. The solution of the quartic soon followed, after which the quintic occupied the attention of algebraists until its solution was proved to be impossible by the operations of elementary algebra, in the 19th century. A common name for algebra at this time was "L'arte maggiore" (the greater art, whence the Latin title of Cardan's treatise), arithmetic being called by contrast "L'arte minore" (the lesser art). The unknown quantity was called, in Latin, *res*, whence the Italian translation *cosa* (thing). On this account the science was called the *Coss* in the early German schools, and the name "Cossic Art" was not uncommon among the English writers of about 1600. The mere processes and solutions of elementary algebra were fairly perfected by the close of the 16th century, and little besides the symbolism was needed to make the subject what it is to-day.

The title of Father of Modern Elementary Algebra is frequently given to Vieta (q.v.). He was the first to devise a systematic and fairly satisfactory scheme of literal notation, using vowels for the unknown quantities and consonants for the knowns. For example, he used \( A \) where we use \( x \), \( Aq \) (\( A \) quadra) for our \( x^2 \), \( Ac \) for \( x \), \( Aqq \) for \( x^3 \), and so on. He also recognized that a letter may represent both a positive and a negative number, and both an integer and a fraction, a generalization not recognized by his predecessors, and one that was perfected later by Descartes. Vieta was also the first to recognize the advantage of making the second member zero in considering an equation. His work greatly influenced the English algebra as set forth by Harriot (q.v.), who acknowledged his indebtedness to him. Mention should also be made of the work of Clavius, who did much to meet the demand for a usable textbook at this period.

The final touch was put upon the elementary science by Descartes (q.v.), who suggested and used our modern literal notation, and who perfected the generalizations begun by Vieta. His introduction of the graphic treatment of equations not only revolutionized mathematics in general, but materially assisted in the understanding of the elements.

Since Descartes's time there have been certain improvements in the symbolism of elementary algebra, the theory of approximate solutions of numerical higher equations has been created, chiefly through the efforts of Newton, Euler and Horner (q.v.), the binomial theorem has been generalized for negative and fractional exponents, principally by the labors of Newton, the theory and the symbolism of determinants (q.v.) have been developed, the various number systems met in algebra (notably the complex number system) have been placed upon a scientific basis, and in general the foundation theories of the science have been greatly strengthened.

**DAVID EUGENE SMITH,**

Professor of Mathematics, Teachers College, Columbia University, New York.

**ALGECIRAS,** äl'ge-sê'raς, or äl'ha-thê'raς, a seaport of Spain, on the west side of the Bay of Algeciras and on the left bank of the Miel, the mouth of which forms the harbor. Lying only six miles west of Gibraltar (easily reached by ferry, etc.), it has become a winter resort, much appreciated by British and American visitors, as well as by wealthy Spaniards, on account of delightful gardens, bathing-beach, etc. From this town large quantities of cork are exported; also grain, leather, stone, charcoal, etc. History deals first with the much older town, vestiges of which lie to the southwest beyond the river and between the two Algeciras, then, was founded by the Moors in 713, two years after their first invasion of the peninsula; and the original form of the name is Moorish (al-Gezira al-Khadrâ, signifying green island). Taken from the Moors by Alfonso XI in 1344, the old town was recaptured by Mohammed V of Granada 24 years afterward and almost entirely destroyed. In the comparatively modern town (colonized by the Spaniards who left Gibraltar in 1704) the Casa Consistorial was the scene of the Morocco conference, 17 Jan.–7 April 1906. See Morocco, History.

**ALGER, Cyrus,** an American inventor: b. West Bridgewater, Mass., 11 Nov. 1781; d. Boston, 4 Feb. 1856. He learned the iron foundry business, and in 1809 established himself in South Boston, where he soon made himself widely known by the excellence of the ordnance he manufactured. He supplied the United States government with a large quantity of cannon balls during the War of 1812; produced the first gun ever rifled in America, as well as the first perfect bronze cannon; and supervised the casting of a mortar which was the largest gun of cast-iron that had then been made in the United States. Subsequently he made improvements in the construction of time fuses for bomb-shells and grenades; patented a method of making cast-iron chilled rolls; and was the original designer of the cylinder stove.

**ALGER, Horatio,** an American writer of juvenile books: b. Revere, Mass., 13 Jan. 1834; d. Natick, Mass., 18 July 1899. He was graduated at Harvard in 1852, settled in New York in 1866 and became interested in the condition of self-supporting boys, described in his series of more than 50 books, including 'Ragged Dick,' 'Tattered Tom,' 'Luck and Pluck,' which became very popular. Other works: 'Nothing to Do: A Tilt at Our Best Society,' a poem (1857); 'Helen Ford,' a novel (1860); a series of juvenile biographies of Webster, Lincoln, Garfield, etc.; and 'The Young Salesman' (1896).
ALGER, Russell Alexander, an American merchant, capitalist and politician: b. Lafayette, Ohio, 27 Feb. 1836; d. Washington, D.C., 24 Jan. 1907. He served in the Civil War, rising from a captaincy to the rank of brevet major. In 1882 he was governor of Michigan from 1885 to 1887; a candidate for the Republican presidential nomination in 1888; commander-in-chief of the Grand Army of the Republic (1889-90); and became Secretary of War in President McKinley's Cabinet in 1901. He was a partisan of the Spanish-American War of 1898, he was the object of much public censure for alleged shortcomings in the various bureaus in his department, and this pressure became so strong and widespread that he resigned his office in 1899 after an investigation committee had exonerated him. From 27 Sept. 1902 till his death he was senator from Michigan. In 1901 he published 'The Spanish-American War.'

ALGERIA, a French colony in north Africa, situated between lat. 30° and 37° N. and long. 2° 10' W. and 8° 50' E., having on the north the Mediterranean, on the east Tunis, on the west Morocco and on the south (where the boundary is ill-defined) the Desert of Sahara; area 184,474 square miles, or including the Algerian Sahara, 345,300. The country has been organized in two great divisions: Northern Algeria, consisting of the three departments—Algiers, Oran and Constantine, containing 17 arrondissements and 269 communes, 74 of which are mixed; and Southern Algeria, consisting of the four territories of Ain Sefra, Ghannef, Tougouf and the Saharan Oases, organized under decree of 14 Aug. 1905. They contain five mixed and seven native communes. The coast line is about 550 miles in length, steep and rocky, and though the indentations are numerous the harbors are much exposed to the north wind. The country is traversed by the Atlas Mountains, two chains of which—the Great Atlas, bordering on the Sahara, and the Little, or Maritime, Atlas between it and the sea—run parallel to the coast, the former attaining in Mount Shelia, its loftiest peak, a height of 7,011 feet. The intervals are filled with lower ranges, and numerous traverse ranges connect the principal ones and run from them to the coast, forming beautiful table lands and enclosed valleys. The rivers are numerous, but many of them are mere torrents rising in the mountains near the coast. The Shelf is much the largest. Some of the rivers are largely used for irrigation, and artesian wells have been sunk in some places for the same purpose. There are, both on the coast and in the interior, extensive salt lakes or marshes (shotts) which dry up to a great extent in summer. The country bordering on the coast, called the Tell, is generally hilly, with fertile valleys; in some places a flat and fertile plain extends between the hills and the sea. In the east there are shotts that sink below the sea-level, and into these it has been proposed to introduce the waters of the Mediteranian. The climate varies considerably according to elevation and local peculiarities. There are three seasons; winter from November to February, spring from March to June and summer from July to October. Rainfall is plentiful from December to March. The summer is very hot and dry and the sirocco, or hot desert wind, often blows. In many parts of the coast the temperature is moderate and the climate so healthy that Algeria is now a winter resort for invalids. Agriculture is carried on chiefly in the small but fertile area near the coast, known as the Tell, mainly owned by the Europeans, and artificially irrigated.

Products.—The chief products are wheat, barley and oats, tobacco, cotton, wine, silk and dates. Early vegetables, especially potatoes, asparagus and peas, are exported to France and England. A fibre called alfa, a variety of Esparto, which grows wild on the high plateaus, is exported in large quantities. The foregoing figures are estimated at 6,559,490 acres, belonging principally to the state and the communes. Much of it is brushwood, but in the Tell Atlas grow various sorts of pines and oaks, as, cedar, myrtle, pistachio nut and the cork-oak, covering 645,000 acres and furnishing large quantities of cork for exporting. Portions of the area are also leased for tillage and for pasturage for cattle, sheep, horses and pigs introduced by the French. Wild animals are not numerous, the lion and ostrich having been exterminated, but hyenas and jackals, a species of ape and occasionally camels are to be found. Algeria possesses valuable minerals, including iron, copper, lead, sulphur, zinc, antimony, marble (white and red), phosphate, petroleum and mercury.

Trade.—The trade of Algeria has greatly increased under French rule, France, Spain, England and Germany being the countries with which it is principally carried on, and three fourths of the whole being done with these. In 1909 the exports amounted to $64,845,000, the imports to $90,950,000; in 1913 exports had increased to $102,100,000 and imports to $133,500,000. The exports, besides those mentioned above, are wine, olive oil, raw limes, wood, wool, tobacco, oranges and other fruits, etc.; the imports are manufactured goods, cottons, woolens, machinery, clothing, coal, coffee, etc. French money, weights and measures are generally used. The chief towns are Algiers, Oran, Constantine, Bone, Philippeville and Tlemcen.

Industries.—The wine business constitutes the largest industry in Algeria, the yield in 1913 being 163,476,263 gallons. The production of olive oil is also important as well as the cultivation of oranges, dates and other fruits, silk, tobacco, flax and cotton. Alfa and the dwarf palm are largely worked in the plains. The number of the population engaged in agriculture in 1909 was 322,520, of whom 213,736 were Europeans. The chief crops are wheat, barley and oats. The northern portion of Algeria is better adapted to grazing and forestry. There are extensive fisheries, $1,028,050 worth of fish
having been caught in 1912. In 1913, 96 mines were being worked, there were 2,793 miles of railway and 8,977 miles of telegraph line. In 1914, 3,741 vessels entered and 4,595 vessels cleared at Algerian ports. National roads have a length of 1,826 miles.

Population.—The two principal races inhabiting Algeria are Arabs and Berbers. The former are mostly nomads, dwelling in tents and wandering from place to place, though a large number of them are settled in the Tell, where they carry on agriculture and have formed numerous villages. The Berbers, of whom the Kabyles are a part, are the original inhabitants of the territory and still form a considerable part of the population. They speak the Berber language, but use the Arabic characters in writing. The inhabitants of the towns are largely so-called Moors, and the Jews form a small but influential part of the population. Various other races also exist. Except the Jews all the native races are Mohammedans. There are now a considerable number of French and other colonists, provision being made for granting them concessions of land on certain conditions. In 1906 there were 449,420 colonists of French origin in Algeria, 117,475 Spaniards, 33,513 Italians, 17,849 other foreigners and 64,645 naturalized Jews. The total population in 1911, including military forces, was 5,563,828, of whom 795,522 were Europeans and 4,768,306 natives. In 1914 the number of troops was estimated at 63,827.

Government.—Algeria is governed by a governor-general, who is assisted by a consultative council and the superior council, composed of elected members and high officials. There are also three financial delegations who vote upon the budget. The three departments of Algiers, Constantine and Oran each send two deputies and one senator to the French Chambers, which alone have the right of legislating for Algeria. Since 1901 the budget has been distinct from that of France, but the expenses of the departments of War and Marine and guarantees of interest on railways are still borne by the mother country. In 1914 the budget estimate for northern Algeria was: Revenue, 171,364,550 francs ($34,272,910); expenditure, 171,352,500 francs ($34,265,131); for southern territories: Revenue, 5,005,522 francs ($1,012,124); expenditure, 5,029,423 francs ($1,005,884).

Justice.—Justice is administered by 16 courts of first instance, justices of the peace, commercial courts and a court of appeals. There are special tribunals for the natives.

History.—Down to the time of the Turkish dominion Algeria was historically inseparable from Tunisia and Morocco. Under the Romans it was included in the provinces of Numidia and East Mauritania and enjoyed great prosperity until the Vandal conquest in 440 A.D. Oriental civilization was introduced upon the conquest by the Arabs in the 7th and 8th centuries. After the expulsion of the Moors from Spain they established themselves in Algeria, and warfare ensued between the aid of the Turkish corsair Horuk, known as Barbarossa, who declared himself Sultan of Algiers. His brother Khair-ed-Din, also known as Barbarossa, placed the country under the suzerainty of the Turkish Sultan, which was, however, later shaken off. A piratical state was established (see Barbary and Barbary Powers), and the Barbary corsairs, or Algerian pirates, as they were termed, were the terror of the Christian nations, who 14 times besieged Algiers in vain, and some of whom were finally reduced to paying tribute to protect their commerce. A check to the depredations of the pirates was administered by a United States squadron under Decatur in 1815, but they did not finally cease until the conquest of Algeria by the French, begun in 1830, to avenge an insult to the French consul. Algiers was captured by Marshal Bournmont 5 July 1830 and after several years of warfare the bases were laid down of the political and administrative organization of the French possessions, consisting of six coast towns. The city of Constantine was captured in 1837, but resistance to the French had already been begun by the Emir Abd-el-Kader, and was waged with varying success until December 1847, when the Emir surrendered to General Lamoricière at Sidi-Brahim. The French conquest was then assured, although Great Kabylie was not subdued until 10 years later, when French possessions were extended to the Sahara desert. Frequent insurrections had to be quelled later, the most serious being in 1870–71. French occupation of the Algerian Sahara started in 1890, and was accomplished in 1901 by the occupation of the Tuat and Tidikelt oases. Under the third republic Algeria has developed rapidly, politically and industrially. The civil territory has been greatly increased at the expense of the military; railroads and excellent roads have been built, schools have multiplied. In 1913 there were 22 schools for secondary instruction, with 6,688 pupils; 1,268 primary and infant schools, including 226 Musulman schools, with 145,933 pupils; 4 normal schools for men teachers, with 110 students; 6 normal schools for women teachers, with 218 students; higher Musulman schools are established at Algiers, Tlemcen and Constantine, and an institution for higher instruction at Algiers. In 1912 Tunisia, Algeria and Morocco were again united under the French dominion.

ALGERINE WAR. See Barbary Powers, U. S. Treaties and Wars with them.

ALGHERO, al-gārō, or ALGHERI, Sar-

dinià, a fortified town and seaport on the west side of the island in the province of Sassari, and 17 miles southwest of the town of that name. The port is not good, but seven miles west of it is Porto Conte, the best harbor in the island. The town is the seat of a bishop and
possesses a handsome cathedral. The inhabitants are mainly employed in wine-growing and coral-fishing, and calcium mines are operated. Pop. 12,000.

ALGIERS, ál-jér (French, Alger), Algeria, a city and seaport on the Mediterranean, capital of the French colony of Algeria, situated on the west side of the Bay of Algiers. It stands on the slope of a hill facing the sea, from which its array of white houses, rising in the form of an amphitheatre, presents an imposing appearance. The old town, which is the higher, has an Oriental aspect. Its crowning point is the Casbah, or ancient fortress of the days, about 500 feet above the sea. Its streets are narrow, crooked and dirty. The houses are strong, prison-like edifices, with iron-grated slits for windows, looking into central quadrangles entered by a low doorway. The modern town, which occupies the lower slope and spreads along the shore, is handsomely built, with broad streets adorned with arcades and having elegant squares. It contains the government buildings, the barracks, the commercial warehouses, residences of the governor-general and the government officials, and the superior courts of justice. The Place du Gouvernement and the Place Bresson here are the two chief squares of the city. The fine Boulevard de la République runs along the sea-front, overlooking the bay and harbor. Algiers was the Icosium colony of the ancient Roman empire and has a varied history. It is the seat of an archbishop, and has a cathedral and a number of churches (including an English church) and mosques. There are schools of law, medicine, science and letters, and a lyceum; also a library and museum. It is defended by sea-batteries and other works, and is an important naval station, prominent as a base for Mediterranean operations during the European War. The French at great expense improved the port and provided docks. Pop. 172,400.

ALGOA BAY, ál-gō′a, Africa, a bay on the southeast coast of Cape Colony, about 420 miles east of the Cape of Good Hope. At its entrance, formed by Cape Woody on the north, and Cape Recife on the southwest, it has a width of 33 miles. Its shelter is very valuable, as there is no other refuge for ships during the northwest gales. The usual anchorage is off Port Elizabeth, at the mouth of the Baakens, where there is now a large and increasing trade.

ALGOL, ál-gōl, a star in the constellation Persus (head of Medusa), remarkable as a variable star, changing in brightness from the second to the fourth magnitude.

ALGOMA, a district of Canada, on the north side of Lake Superior, forming the northwest portion of Ontario, rich in silver, copper, iron, etc.

ALGONA, Iowa, city and county-seat of Kossuth County, on the Iowa Cent., Chicago & N. W., and Chicago, M. & St. P. railways, about 123 miles north by west of Des Moines, on a branch of the Des Moines River. The city has four banks, handsome public buildings and flourishing manufactures of foundry and machine-shop products, wooden-ware, bricks and tiles. Pop. (1910) 4,100.

ALGONKIAN SYSTEM, the name given in the United States to a great series of rocks that succeeds the basal system of the Archean and is overlaid by the strata of the Paleozoic systems. In the Lake Superior region, the system is divided into Lower, Middle and Upper Huronian, and Keweenawan. The rocks of the Algonkian are developed on an enormous scale around the upper Great Lakes, where they comprise limestones, sandstones, quartzites, shales, slates and schists, all more or less disturbed and bearing evidence of having been subjected to metamorphism. They also include dikes and beds of igneous rocks. They contain the famous iron ore bodies of the Marquette, Mesabi and other ranges, the Michigan copper deposits, the copper and nickel of Sudbury, and much of the rich silver ore of the Cobalt district. Algonkian rocks are also known at many points in the Rocky Mountains, and sediments believed to be of equivalent age are known in Europe and other continents. The period was marked by extensive volcanism, particularly in the Keweenawan epoch, when lava flow after lava flow succeeded one another, to enormous thicknesses. At least two periods of folding also took place, one of them of great magnitude. The presence of striated boulders in conglomerates of Lower Huronian age in Canada has led many to believe that glaciation occurred during the early Algonkian. A few fossil remains have been found in rocks of very late Algonkian age, but little is known as to the life conditions during the period.

ALGONQUIAN, or ALGONKIAN, STOCK, a North American group once comprising 40 or more separate languages, and embracing a larger area than any other on the continent, stretching in a solid block from Labrador to the Rockies and from Hudson Bay to Pamlico Sound and the Cumberland River at least, except the enclaves of Iroquois in and around New York State, and of Beothukan in Newfoundland. Outlying tribes were the Shawnee or Shawano to the south; and to the west the Cheyenne and Arapahoe, which clove their way through the heart of the Sioux across the Missouri and into the Black Hills region, and later to Colorado and Wyoming, their advance westward being checked by the Shoshone group. They numbered several hundred tribes, or "villages," entirely independent; many, in which several such villages were grouped together; and several confederacies of tribes united in a loose bond for mutual aggression or defense, though never with any real central government. The chief confederacies were the Abnaki or Abenaki of Maine and New Brunswick; the Penacook of New Hampshire and the adjacent parts of Maine and Massachusetts; the Powhatan of Virginia and Maryland; the Illinois or Illini of that region and adjacent Wisconsin, Iowa and Minnesota; the Micmac, Amalecite, Massachusetts, Wampamento, Narraganset, Nipmuc, Pequot, Mohegan, Mohican, Metacomet and Wappinger on the North Atlantic coast; Muni, Leni-Lenape or Dela-
ware, Shawano, Nanticoke, Conoy, Mattamuskeet, on the South Atlantic coast; Nascop, Montagnais, Algonquin, Ottawa, Muskegon, Cree, Ojibwa, Mississagi, Miami, Piankishaw, Kickapoo, Pottawotomi, Menomini, in the interior; and Atsina in the West. Tradition places the original home of all these tribes on the North Atlantic coast. From their being the first to come in contact with the English settlers in Canada, New England, New York, New Jersey and Virginia, and the history of English settlement for two centuries being a steady record of fierce conflict with and bloody reprisals from and on them, more is known of their minor names and those of their great chiefs — Powhatan, Opechancanough, Philip, Pontiac, Tecumseh, Black Hawk, etc. — than of any others except the Iroquois, and their languages are better studied.

Constant wars with the English, French and Dutch colonists depleted their numbers. Filled at first with the idea of freeing the soil from the whites, they afterward degenerated into mere mercenaries, fighting on either side for revenge or gain. After the War of 1812, in which they took the side of the British, the United States government resolved to send them as far west as possible. After 1840 few of them remained east of the Mississippi. In Canada they were not removed from their homes, but were limited to a treaty. War and disease have thinned their number until only about 43,000 remain in the United States, and 38,000 in Canada; there are a few hundred refugees in Mexico. (See INDIANS). Consult Mr. Wilson, Truman "Classification of Algonquin Tribes" in "Twenty-eighth Annual Report" of the Bureau of American Ethnology.

ALGONQUIN (properly ALGOMEKIN, "othersiders"), a once powerful Indian tribe along the Ottawa River and Lake Nipissing, Canada. Decimated by the Iroquois, some of them with other Indian waifs took refuge along the Upper Lakes and assumed the name of Ottawas (q.v.), bringing forth the greatest Indian of history, the mighty Pontiac (q.v.); others kept their name and were protected by the French in missionary stations. It was French missionaries who discovered almost at their first coming that the Algonquin language was a type common to what is now called the Algonquin stock. The chief body of the remaining tribe numbers nearly 1,000, in villages of Quebec and Ontario; about 250 more are confederated with the Iroquois at Gibson, Ont., and Lake of Two Mountains, Que.

ALHAMA, al-ā’ma, Spain, a town on the Motril, 25 miles southwest of the town of Granada. This place is celebrated for its warm medicinal (sulphur) baths and drinking-waters, and also for its romantic situation between craggy mountains. The principal bath was a Moorish edifice, the smaller was circular in form and probably a Roman erection. The town was thrown completely into ruins by an earthquake in 1711. Washington Irving, in his "Chronicle of Granada," gives a spirited account of the taking of Alhama, "the key of Granada," from the Moors, by Rodrigo Ponce de Leon, Marquis of Cadiz, in February 1482.

ALHAMBRA (K-šl-ā-hamrāh, the red castle), the citadel of Granada when that city was one of the principal seats of the empire of the Moors in Spain. The wall which surrounded it still stands flanked by many towers, and has a circumference of a lofty eminence which commands a full view of the city of Granada and, beyond it, of a charming country, bounded in the distance by a line of hills. It is a place equally interesting to the artist, the antiquarian and the historian. The erection of the greater part of the present building seems to have occupied almost the whole of the first half of the 14th century. It consists mainly of two oblong rectangular courts, the one (which was seriously damaged, if not ruined, by fire in September 1850), called the court of the Fish-pond or of the Myrtles, 138 by 74 feet, and terminating at its northern end in an apartment 35 feet square, richly ornamented; the other, called the Court of the Lions, 115 by 60 feet, and so named from a fountain in the centre supported by 12 lions. A repetition of this court, two-thirds of the scale of the original, was made by Mr. Owen Jones in the Crystal Palace. It is surrounded by an arcade, with small pavilions at each end, consisting of 128 columns supporting arches of the most delicate and elaborate finish, still very perfect and retaining much of their original beauty. From the character of many of the arches in various portions of the palace they were most appropriately called stalactitic. They are formed on a peculiar system with plaster bricks of various forms in a manner universally adopted in the buildings of the Moors. The construction of the arches is remarkable for its simplicity. Over the columns, which are of white marble, and which were probably gilded, are brick piers carrying rough brick arches; above these tiles are placed diagonally, forming diamond-shaped pen work, running through the thickness of the walls, and a best-summer of timber supporting the weight above. To these rough arches were attached the various enrichments, and against the tiles are placed the perforated plaster ornaments which give a singularly light appearance to the arches, and create beautiful effects from the rays of light cast through the openings on the interior of them. Consult Calvert, "Granada and The Alhambra" (1900).

ALHAMBRA, Cal., city in Los Angeles County, 10 miles east of Los Angeles, on the Santa Fe, Southern Pacific and other railroads. It is a residential city with few industries. Here are located the Agnes Hill-Runkle School of Music and the San Gabriel Church, founded by the Franciscans in 1771. A religious play, similar in many respects to the Passion Play at Oberammergau, is regularly produced here. Pop. 8,000.

ALHAMBRA. Order of the, a Catholic social society or fraternity organized in Brooklyn, N. Y., in 1905. None but practical Catholics are admitted to membership, and to this end only third degree Knights of Columbus, in good standing in that order, were made eligible. The purposes of the order are the promotion of such social and intellectual inter-

ALHAMBRA | ALIBI

independent of the Porte, which at length determined to put an end to his power; and in 1820 Sultan Mahmoud pronounced his deposition. Ali resisted several pashas who were sent to carry out this decision, only surrendering at last in 1822 on receiving assurances that life and property should be granted him. Faith was not kept with him, however; he was killed and his head cut off and conveyed to Constantinople, while his treasures were seized by the Porte.

**ALI BABA**, the principal figure in the famous 'Arabian Nights' Entertainments' tale of 'Ali Baba and the Forty Thieves.' He over-hears the thieves opening the door of their cavern by the use of the magic words "Open sesame." He does the same in their absence and appropriates as much of their wealth as he can carry. Cassim, his brother, enters the cave later, but having forgotten the magic word is presently found by the robbers and killed. They make an attempt to slay Ali Baba, but are defeated by the slave Morgiana, who pours boiling oil in the jars in which the robbers are hidden.

**ALI BEY**, Egyptian ruler: b. in the Cauca-sus in 1728, was taken to Cairo and sold as a slave, but having entered the force of the Mamelukes and attained the first dignity among them, he succeeded in making himself virtually governor of Egypt. He now refused the customary tribute to the Porte and coined money in his own name. In 1769 he took advantage of a war in which the Porte was then engaged with Russia, to endeavor to add Syria and Palestine to his Egyptian dominion, and in this he had almost succeeded when the defection of his own adopted son Mohammed Bey drove him from Egypt. Joining his ally Sheikh Daher in Syria, he still pursued his plans of conquest with remarkable success, till in 1773 he was induced to make the attempt to recover Egypt with insufficient means. In a battle near Cairo his army was completely defeated and he himself taken prisoner. He was kept ten days afterward either of his wounds or by poison.

**ALI FEROUGH BEY**, a'lé-frrō'há', Turkish diplomatist: b. Constantinople 1865. After serving as secretary of embassy at Paris, London and Bucharest, as well as councillor of embassy at St. Petersburg, he was promoted to the post of minister-plenipotentiary and envoy extraordinary to the United States. Besides histories of Arabia and Turkey he has published 'Public and Private International Law.' In 1901 he was recalled from his post at Washington.

**ALIKA**, a'llé-a'ga', Philippines, town of Luzon, province of Nueva Eciia, 70 miles northwest of Manila. Situated in a fertile valley between the Pampanga Chico and the Pam-panga Grande rivers; the inhabitants engage in the cultivation of rice, tobacco, sugar cane and corn. Pop. 12,000.

**ALIAS**, in law, a term used to indicate the names under which a person who attempts to conceal his true name is ascertained to have passed during the successive stages of his career. An alias writ is a writ issued where one of the same kind has been issued before in the same cause.

**ALIBI**, in law, a plea that the person accused of having committed a crime was else-

-course among its members as shall be desirable and proper and the establishment of a fund for the preservation of American Catholic historical places. The governing body of the order is the Supreme Divan, composed of the six original incorporators, the supreme officers, and the grand commander and one representative from each caravan, as the subordinate body of the Supreme Council. He meets biennially in different cities, for the election of a supreme commander, vice-supreme commander, supreme scribe, supreme chamberlain, supreme captain of the bodyguard, etc. Caravans must hold at least four meetings a year in their local alcazar. The emblem of the order is the red tower of Castile surmounting the Crescent of the Saracen, typifying the triumph of Christianity over Mohammedanism. The order now has caravans in Brooklyn, N. Y.; Canton, Ohio; Boston, Mass.; Wilkes Barre, Pa.; Augusta, Ga.; Middletown, Conn.; Newark, N. J.; Jersey City, N. J.; Chicago, Ill.; Cincinnati, Ohio; New York, N. Y.; Washington, D. C.; Albany, N. Y.; New Haven, Conn.; Stamford, Conn.; Md.: Toledo, Ohio; San Francisco, Cal.; Elmiria, N. Y.; Butte, Mont.; Portland, Ore.; Empire, Panama Canal Zone and Milwaukee, Wis.

**ALHAMBRA, The**, by Washington Irving (1832. Revised, enlarged, and rearranged, 1852). This Spanish Sketch-Book grew out of the experiences and studies of Irving while an actual resident in the old royal palace of the Moors at Granada. Many of the 40 sketches have their foundation only in the author's fancy, but others are veritable history.

**ALI, a'li, cousin and son-in-law of Mo-hammed, the first of his converts, and the bravest and most faithful of his adherents; b. 602; d. 661.** He married Fatima, the daughter of the prophet, but after the death of Mohammed (632) his claims to the caliphate were set aside in favor successively of Abu-Bekr, Omar and Othman. On the assassination of Othman in 656 a.d. he became caliph, and after a series of struggles with his opponents, including Ayesha, widow of Mohammed, finally lost his life by assassination at Kufa. A Mohammedan schism arose after his death, and has produced two sects. One sect, called the Shiites, put Ali on a level with Mohammed, and do not acknowledge the three caliphs who preceded Ali. They are regarded as heretics by the other sect, called Sunnites. The Maxims and Hymns of Ali are yet extant. See CALIPH.

**ALI, pasha of Yanina, commonly styled Ali PASHA, a bold and able, but ferocious and utterly unscrupulous, Albanian: b. 1741, son of an Albanian chief who was deprived of his territories by rapacious neighbors. By his enterprise and success and entire want of scruple he soon possessed more than his father had lost, making himself master of a large part of Albania, including Yanina, which the Porte sanctioned his holding, with the title of pasha. As a ruler he displayed excellent qualities, putting an end to brigandage and anarchy, making roads and opening commerce. He extended his sway by subduing the brave Suliotes of Epirus, whom he conquered in 1803 after a three years' war. Aiming at independent sovereignty, he intrigued alternately with England, France and Russia. Latterly he was almost
where at the time when the breach of the law occurred. If he substantiate this, he is said to prove an alibi. In Scotland the defendant must give notice of a special defense of alibi, stating where he was when the crime was committed. In England and the United States this notice is not required. If the accused can make it appear that at the time when the crime charged is alleged to have been committed (it being second degree murder, his personal presence) he was in another place, his innocence will be established, because of the obvious impossibility of the same person being in two places at once. This species of defense is constantly resorted to in trials for crime. One of the principal rules in the application of this species of evidence is that the time relied on, and in which the value of the evidence mainly consists, must correspond closely with the time at or during which the offense is proved to have been committed. If, that having being done, the the hour a particular day, hour and minute, the person accused can show that at that exact time he was in another place, his innocence is at once made apparent.

ALICANTE, Spain, a seaport and capital of the province of Alicante; the ancient Lucen- tum. It is situated at the foot of a cliff 850 feet high, crowned by the fort of Santa Bar- bara. It has one of the best harbors on the Mediterranean and carries on a considerable trade, exporting wine, fruit, esparto grass, etc. It was bombarded in 1873 by two vessels sent out by Cartagena insurgents. Professor Free- man, the English historian, died here in 1892. An American consul has been stationed at Ali- cante for some years. Pop. 52,000.

ALICATA, ą-le-kā’tɔ, or LICATA, li- kā’ti, Sicily, the most important commercial town on the south coast, at the mouth of the Salso, 24 miles east southeast of Sirgenti, with a considerable trade in sulphur, grain, wine, oil, nuts, almonds and soda. It occupies the site of the town which the tyrant Phintias of Acragas erected and named after himself when Gela was destroyed in 280. Pop. 16,000.

ALICE'S ADVENTURES IN WON- DERLAND (published 1865), by Charles Lut- wheelge Dodgson ("LEWIS CARROLL") grew out of a story which the author told the three little daughters of Dr. Liddell—one of them the original Alice—while boating on the Thames near Oxford. Its success led him to write "The Looking Glass and What Alice Found There" (1871). Both are dream tales of exquisite nonsense. The earlier is the looser and more desultory, matching the incoherence of dreams and the inconsequential narrative processes of a child’s mind; it is generally thought to be preferred by children. The later story has a definite structure, following the moves of a chess-problem; it reiterates, however lightly, that "We are such stuff As dreams are made on;"

and it employs frequently the motif of topsy- turvydom,—everything in Looking Glass Land being, of course, the reverse of ordinary ex- perience. Though "Thetolland," like "The Looking Glass," appeals strongly to adults as well as to children, yet "The Looking Glass," by reason of the traits just noted, is to the mature mind more openly suggestive of philos- ophy and satire. In the Red Queen’s topsy- turvey remark, "Now here, you see, it takes all the running you can do to keep in the same place," children see only admirable fooling, while their parents, besides, are given paradox upon the hustling society of to-day.

In the range of this double appeal there is little to choose between the books. "Wonder- land" excels, perhaps, in invention of person- ages and incidents—the Duchess, the Cheshire Cat, the Mock-Turtle, the Mad Tea-Party, the Lobster Quadrille, and the Trial—the last often cited as an anticipation of the Dreyfus affair. "The Looking Glass" probably excels in the richer and more sustained nonsense of its verses—"Jabberwocky," "The Walrus and the Carpenter," "I Sent a Message to the Fish," and "Haddock's Eyes"; but it can match its White Knight and Humpty-Dumpty against any of the characters in "Wonderland." Both books abound in puns and word games; the curricular, "Caricature and Weeping, Laughing and Grief, Dreaming, Stretching, and Fainting in Coils, and the re- vised proverb "Take care of the sense, and the sounds will take care of themselves" ("Wonderland") are household words; while human speech in general is the richer by "galumphing, frumious, brabious, ufish,chorlite, and the other "portmanteau words" of "The Looking Glass."

Though each volume thus has its excellences, the two merge in memory into a single "Alice." The illustrations by John Tenniel have made the "hard words" and the strange creatures real; no artist ever shared more fully with an author the labor and the success of creation. "Alice" has been dramatized and has been translated into French and German—"Jabber- wocky" into Latin elegies as well. Growing out of the author's delight in telling stories to children, "Alice" has remained to delight all the young in heart, has placed the "sense of nonsense" second only to tragedy, and has added permanently to the gaiety of nations. Consult Collingwood, Stuart Dodgson, "Life and Letters of Lewis Carroll" (London and New York 1889).

ALIEN. See ALIENS.

ALIEN AND SEDITION ACTS, in American political history, four acts passed by the Federalist party in Congress in the summer of 1798, under John Adams, which were the immediate cause of the first nullification proceed- ings in the South (see KENTUCKY RESOLU- TIONS; NULIFICATION; VIRGINIA RESOLU- TIONS) and one of the causes which alienated enough votes from the Federalists to drive them out of power sooner than was inevitable. (For the genesis of the alien acts see also AMERICAN PARTY.) The embittered exiles who were locked behind bars were ob- noxious to the Federalists; both as scurrilously offensive journalists, oftentimes, and as hostile to all attempts to punish France for her wanton aggressions on American commerce. In 1797
the House was Republican, the Senate Federalist; the latter attempted to pass measures for defense against France, which the former steadily voted down. At length, in 1798, the government, fearfully afraid of a new Republican revolution, showing the rottenness of the French Directory, shamed the defenders of France and incensed the moderates into supporting the Federalists, who, having now a majority in both houses, first enacted three laws concerning aliens: (1) 18 June, making the residence before naturalization 14 years instead of five and the under penalties, and entry on such register the only proof admitted on applying for naturalization after declaration of intentions five instead of three; alien enemies not to be allowed naturalization; registration of all aliens on arrival. (2) 25 June, empowering the President for two years to order out of the country any aliens he thought dangerous or engaged in conspiracies. (3) 6 July, organizing the apprehension or deportation of all resident aliens when war was declared against the United States. These acts were denounced by the Republicans on three grounds, two of State rights and one general, as invading the constitution of the States to permit state immigration as they chose up to 1808 (really intended to apply only to slaves); that it assumed national powers over persons under the jurisdiction of their States; and that it violated the right of trial by jury. It was on these points that Jefferson and Madison drew up the Kentucky and Virginia legislative resolutions, the former of which, on its repetition in 1799, named nullification as the proper remedy. Second, on 26 June, Lloyd of Maryland introduced a bill (1) declaring France an enemy of the United States and any one who should uphold her or give her aid or comfort guilty of high treason; (2) defining treason; (3) imposing $5,000 fine and six months' to five years' imprisonment on any one conspiring to oppose or impede United States measures, intimidate United States officers, stir up insurrection, etc.; (4) imposing a fine of not over $2,000 and imprisonment for not over two years for any utterance or writing tending to justify France or to denigrate or revile United States and its popular liberties, etc. It passed the Senate by a heavy majority; the House made important changes in it and passed the altered bill by a scratch. These changes were: (1) Cancelling the first two sections together; (2) substituting for the fourth, the publishing or printing any false, scandalous or malicious writings to bring the government, Congress or President into contempt or disrepute, excite popular hostility to them, incite resistance to United States laws or encourage hostile designs against the United States, etc. To these, which gave Federal judges power to make any opposition to the ruling party a felony, Bayard of Delaware got two clauses added which drew their teeth: the first making the truth a good defense and the judges the only power to restrict the term of operation to 4 March 1801 — that is, till a new administration came in, so that it should expire with the Federalists if they went out and the Republicans thus lose the tool of repealing it. It was naturally to be supposed that the Alien Acts, which affected only a few foreigners and no internal liberties, and which as a fact remained entirely unenforced, would have caused little commotion in the Republican party; and that the Sedition Act, which struck at all liberty of free speech or publication, and was contrary to the very basis of free government, and under which at least six prosecutions and most scandalous performances of one Federal judge took place, would have provoked almost a civil war. The facts are an instructive historical lesson against transferring the idea of one age to another. The Republicans disliked the use of prosecutions under the Sedition Act as a party weapon and resented Judge Chase's partisan decisions; but it was only as directed against themselves, not as against civil liberty, that they reprobed it,—neither party had attained to that ideal,—and their chief rhetoric and defiance was directed against the harmless acts which tried to prevent their supporting France. It was in crystallizing the spirit of State resistance to national power that the acts have their main importance.

ALIEN PRIORIES, the name given to cells or houses erected on the lands belonging to various great religious houses on the Continent before the Conquest. Certain people were appointed to livings on these lands. Schools were maintained at the priories which grew to be important factors in the mediæval system of elementary education. They were finally suppressed in 1415 by Henry V, when 146 alien priories disappeared. The King had intended to use this property as an endowment of a college at Oxford, but his death prevented this; and Henry VI gave some of the priories to Eton, Windsor and King's College, Cambridge. The bulk of the lands was appropriated for private use. Consult Tanner, 'Notitia' (1744) and 'Some Account of the Alien Priories' (1786), which contains a list of lands devoted to educational uses.

ALIENATION OF ESTATES, comprises any method whereby estates are voluntarily resigned by one and accepted by another, whether that be effected by sale, gift, marriage settlement, devise or other transmission of property by the mutual consent of the parties. 1 Bl. Com. § 287; 51 C. L. J. 447. Alienation is particularly applied to absolute conveyances of real property. 1 N. Y. 290, 294. Alienations by deed may be by conveyances at common law: which are either original or primary, being those by means of which the benefit or estate is created or first arises; or derivative or secondary conveyances, being those by which the benefit or estate originally created is enlarged, restrained, transferred or extinguished; or they may be by conveyances under the statute of uses. The original conveyances are the following: Feeoffment, gift, grant, lease, exchange, partition. The derivative is release, confirmation, surrender, assignment, defeasance. Those deriving their force from the statute of uses are covenants to stand seized to uses, bargain and sale, lease and release, deeds to lead or declare the uses of other more direct conveyances, deeds or revocation of uses. 2 Bl. Com. ch. 20; 2 Washb. Real Prop. 600.

ALIENIST. See Psychiatry.

ALIENS, ál'ýé nz. An alien is any person to whom the rights of citizenship have not been granted by the State in which he resides or so-
journs. Though subject to the jurisdiction of the State, and in a sense clothed with its national character, if domiciled therein, aliens are not persons in the political sense of the term. A distinction is made between domiciled aliens or those who have established a residence or a house of trade in the State and temporary sojourners. Again a distinction is made between alien friends and alien enemies, the latter of whom are subject to the just jurisdiction of the State. In times of war alien enemies are placed under special restrictions and disabilities to which other aliens are not subject. Thus they are frequently denied the privilege of bringing actions in the courts; sometimes their houses of trade are placed under sequestration; during the European War of 1914–17 they were in several belligerent countries interned in concentration camps and sometimes they are even expelled in a body as the Italians were from Turkey during the Turco-Italian War of 1911–12, and as the Japanese were from Manchuria during the Russo-Japanese War in 1904.

Although politically members of a foreign state aliens are nevertheless subject to the local jurisdiction; they are held to owe the State in their residence a local and temporary allegiance and of course they are bound to obey the laws equally with citizens. It has even been held that they may be prosecuted for treason against the State in which they are domiciled (Carlisle v. The United States, 16 Wall. 147). They are not only bound to obey the local laws, but they may be required to share in the public burdens equally with citizens. It has been held in the United States that they may be called on to aid in the local defense, although they are not liable to conscription in the regular army. But during the Civil War all aliens who had declared their intention of becoming citizens of the United States, and who had exercised any political franchise were declared to be subject to the terms of the Draft Act, unless they left the country within 65 days. Being subject to certain obligations and duties aliens are equally entitled to certain rights and privileges, the most important of which is the right to protection in their persons and property. Most countries, in fact, make no distinction between aliens and citizens so far as the enjoyment of civil rights is concerned; but everywhere they are subject to disabilities in respect to political privileges. They are generally excluded from the privilege of voting and holding office, although in a number of American States they may vote and probably also hold office, if they have declared their intention of becoming citizens. See Nationality.

By an act of Congress of 2 March 1907, they are entitled to a passport, valid for six months, and carrying with it the right of protection by the United States government provided they have declared their intention of becoming citizens and have resided in the United States for a period of three years.

If they sustain injuries in consequence of riot, mob violence or insurrection they are in the same position as citizens. It has been established that if they have suffered injuries from attacks on account of their nationality the United States government is under an obligation to indemnify them or their families, especially if the local authorities were remiss in affording them protection. It is true that the United States government has uniformly denied such liability, but in most instances it has in fact paid an indemnity in such cases.

Under the common law, aliens were once subject to many civil as well as political disabilities, but most of their civil disabilities have been removed by legislation. Thus at common law an alien could not take real property by descent, although he might acquire it by purchase or gift, but this disability was removed in England by an act of Parliament in 1870 and it has been removed by act of the legislature in most of the American States. In most of them, an alien may now acquire, own and convey land equally with citizens, though in a few States the common-law disability still remains. Some States make a distinction between resident and non-resident aliens, and do not extend the former, but excluding the latter, from owning real property; others make a similar distinction between aliens who have declared their intention of becoming citizens and those who have not. In the Territories of Columbia and other places subject to the jurisdiction of the United States the ownership of lands is regulated by act of Congress, and Congress has enacted that no alien or foreign corporation shall be allowed to own or hold land in the District of Columbia, and that no alien who has not declared his intention to become a citizen of the United States may own land in any of the Territories unless the right has been granted by treaty.

Where treaties have been concluded with foreign countries, allowing their citizens or subjects to hold land in the United States the Supreme Court has uniformly held that the treaty right is paramount to any State law to the contrary, notwithstanding the general right of the States, under their reserved powers, to regulate the ownership and disposition of property within their limit (Chirac v. Chirac, 2 Wheat. 249). There is, however, doubt as to how far the States may go in forbidding the employment of alien labor when there is no conflict with a treaty between the United States and the country of which the alien affected is a subject. But it has recently been held by the Court of Appeals of New York that a statute of New York forbidding the employment of aliens on the public works of the State was contrary to a treaty between the United States and Italy, providing that Italian subjects residing in the United States should enjoy the same rights and privileges as citizens of the United States, and was, therefore, null and void so far as it affected Italian laborers. The case is now (1917) before the Supreme Court of the United States for final determination. Pennsylvania, Massachusetts, New Jersey, Arizona, Wyoming, Idaho and California have similar laws on their statute books. The question whether a State may prohibit or restrict the employment of aliens in private as well as public work was definitely disposed of by the Supreme Court of the United States in 1915. The legislation had passed in the name of forbidding the employment in public work, public or private, of more than 20 per cent of alien labor. The governments of Great Britain and Italy protested that the statute was in con-
travention of treaties with the United States and the Supreme Court so held and declared the statute null and void.

The sovereign right of every government to prohibit or restrict the admission of aliens to its territory, so far as it is not contrary to treaty stipulations, is well established. As is well known, the United States has exercised the power of total exclusion in the case of the Chinese and of various classes of aliens on the ground of the public safety, health or morals, and has imposed severe and numerous restrictions upon the coming of aliens generally. See Immigration.

Flowing from the same right of sovereignty is the right of expulsion in the interest of self-protection. In earlier times this right was resorted to much more commonly than now. Except in times of war, when even then it is rarely exercised, the power of expulsion is only resorted to in the case of dangerous or otherwise highly objectionable individuals. In any case it should not be exercised in an arbitrary manner without good cause, otherwise the government of which the victim is a subject may justly prefer a claim for violation of the personal rights of common citizenship. It was the case of a well-settled right of aliens under international law. The individual expelled should be informed of the charge against him, and be given an opportunity to answer, and if he is a domiciled alien he should be given a reasonable time to dispose of his property or wind up his business before leaving. In Europe and Latin America expulsion is generally an administrative act, but in the United States the President has no such power, except as commander-in-chief of the army and during war. In time of peace he could probably exercise such power only in pursuance of an act of Congress. Between 1798 and 1800, when the Alien and Sedition Acts were in force, the President possessed such power, but there was a strong popular opposition to the law, and they were speedily repealed after having been in existence two years. See also Allegiance; Citizenship in the United States; Immigration; Nationality; Naturalization and Naturalization Laws; Support.

Bibliography.—The authorities cited at the end of the article on Citizenship in the United States.

James W. Garner, Professor of Political Science, University of Illinois.

ALIENS IN WARTIME. The treatment of enemy aliens in different countries at war is a problem which has to be handled firmly, each country deciding the question for itself, and being guided by self-interest, and also by enemy behavior. In ancient times, enemy aliens were killed; civilization brought detention, arrest and even toleration of well-behaved enemies. The method of dealing with a hostile alien population in a nation, when a state of war exists, is essentially a military question, to be settled by military authorities. Wholesale internment is objectionable, costly, and diverts necessary guard from other military service. The most satisfactory solution is wholesale and immediate repatriation. The objections are the difficulty of transportation and the repatriation of males of military age. The former can be solved, and the addition of a battalion of men of military age is not a great advantage, and would be compensated by the release of guards on the front. At the beginning of the European War in 1914, the problem for Great Britain and German differed, because there were only 5,300 British subjects detained in Germany, while there were 27,200 Germans of military age in Great Britain alone, besides the great number of German aliens in the British possessions. No satisfactory basis of exchange was discovered. After the severing of diplomatic relations with Germany in 1917, a bill was introduced into the United States Congress 25 July 1917, to return aliens of draft age to their home countries.

Aligarh, a'le-ģar, or Alighur, Ind., a town in the northwest provinces, capital of the executive district of the same name, 53 miles north of Agra. Aligarh was merely a fortress, the town being Koil, distant about two miles and connected with Aligarh by a beautiful avenue. It was formerly of importance and was one of Dowlet Rao Sindia's principal depots for military supplies. The town was taken in 1803 by Lord Lake. Sindia's commander, Perron (a Frenchman) having previously surrendered, and the whole district was then added to the British possessions. Since that time the town has been much improved, and the town renamed Aligarh has become the station of a civil and judicial establishment and a prosperous industrial and trading centre. Pop. 64,800.

ALIMENT. See Food; Nutrition.

ALIMENTARY TRACT, or GASTRO-INTESTINAL TRACT, is the whole digestive tract in animals concerned in the processes of digestion and nutrition. It is in man a highly developed and differentiated tube or canal from 25 to 30 feet in length extending from the mouth to its posterior end, the anus. The mouth opens into the pharynx and this in turn into the esophagus, a muscular tube leading into the stomach. This is a dilated and pouchlike portion of the canal. From the stomach the tube is narrowed into the small intestine, which occupies from 22 to 25 feet in length and is divided into three parts histologically distinguished from each other. These divisions are the duodenum, jejunum and ileum. The ileum opens at its termination into a blind sac, the cecum, which extends down some two or three inches from the juncure and from the posterior left surface of which the appendix vermiformis is given off. The ascending colon, the first division of the large intestine, begins here and passes up the right side of the abdomen, crosses over under the liver high up in the abdomen, about at the level of the umbilicus, constituting the transverse colon. This turns at the left into the descending colon which passes down in front of the left posterior abdominal wall, continues into the iliac colon which in turn extends to the pelvic colon. This forms a loop in the true pelvis and at its distal end it simply downward to form the rectum which bends with a forward concavity and ends in a dilata tion which terminates in the anal canal, the final termination of the alimentary tract. This
ALIMONY — ALKAHEST

is about an inch in length and is guarded at its external opening by two circular muscles known as the sphincters.

The number of accessory glands and organs through whose secretions into the alimentary tract is very great. The most important are the salivary glands in the mouth, the secretory glands of the stomach, the liver and pancreas, the secretions of which enter by a common duct just below the stomach, and the secretory glands of the intestines.

The structure of the different portions of the tube is similar, but variations in function produce some modifications in the muscular coats. In general there is a layer of mucous membrane on the interior of the canal; this is surrounded by a supporting framework of connective tissue, and is further strengthened by a varying amount of unstriped muscular tissue. For details of structure see INTESTINE; STOMACH. For the more complicated chemical processes of digestion, the work of the alimentary tract, see DIGESTION; METABOLISM; NUTRITION.

ALIMONY, in law, the allowance awarded out of her husband’s estate, to which a wife is entitled on separation or divorce. Jurisdiction in this matter in England rested with the ecclesiastical court until 1857, when it was conferred on a court of divorce. In the United States it is vested in the courts of equity. Alimony may be granted by the court during litigation, in which case it is known as pendente lite (during the suit); or at the conclusion of the suit, when it is called permanent. The former applies to the wife’s need, whereas whether proceedings have been brought by or against her. The amount granted lies within the discretion of the court and depends upon a variety of considerations, and is governed by no fixed rules. The ability of the husband to pay is of most importance in determining the amount, and in estimating his ability his entire income will be taken into consideration, whether derived from his property or his personal exertions. So far as any general rule can be drawn from the decisions and practice of the courts, the proportion of the joint income to be awarded for permanent alimony is said to range from one-half to one-third, while in case of alimony pending suit it is not usual to allow more than one-fifth, and usually a smaller proportion will be allowed out of a large estate than out of a small one. Permanent alimony is a periodical allowance awarded to the wife if the termination of the suit is favorable to her. By a writ of ne exeat (let him not depart) the court can prevent the husband from leaving the State without leaving sufficient security for payment. The writ of ne exeat has been expressly abolished in many of the States of the Union, but its place has been filled in almost every instance by a similar procedure. In New York a system of arrest and bail has been substituted for the writ. If the husband should remove to another State the wife can enforce her claim in the Federal courts. See MARRIAGE AND DIVORCE.

ALIN, Elin, Oscar, Swedish historian and statesman: b. Falun, 22 Dec. 1846; d. Upsala, 31 Dec. 1900. In 1882 he was appointed professor of political economy at Upsala University and later rector. In 1888 he became a leading member in the first chamber of the Riksdag. His fame rests on his historic

ral works, chief of which are ‘Bidrag till svenska radets historia under medeltid’en’ (Upsala 1872); ‘Sveriges Historia, 1511–1611’ (Stockholm 1884–97); ‘Den svensko-norska Unionen’ (Stockholm 1889–91).

ALISMACEAE, the water-plantain family. Sagittaria (arrowhead). See ARROWHEAD; WATER PLANTAIN.

ALIZARIN, from alizar, the commercial name of madder in the East), a substance having the formula C9H6O3(OH)2, formerly obtained from the root of the madder (Rubia tinctoria), but now artificially produced from coal-tar and the refuse from the distillation of crude petroleum. It is used as a dye, for producing the color known as ‘turkey red’. Alizarin is of interest to the chemist not only on account of its industrial importance, but also because it was the first vegetable coloring matter to be produced artificially; and the year 1868, in which its synthesis was effected by W. H. Perkin, therefore marks the beginning of a new era in industrial chemistry. In the manufacture of alizarin, anthracene is first prepared from coal-tar, and by oxidation (which it readily undergoes under the influence of potassium dichromate or other oxidizing agent) is transformed into anthraquinone, C14H8O3. The next step is the sulfonation of the substance so formed. Anthraquinone is remarkably stable toward sulphuric acid, but combination can be effected by strongly heating a mixture of the two, and a solution of mono- and disulphonic acids of anthraquinone is the result. The excess of sulphuric acid is then removed, and the sulphonic acids are heated with caustic potash to about 350° F. The mass gradually darkens till it becomes almost black, at which stage it dissolves in water with the formation of a rich purple solution, from which alizarin can be precipitated in abundance by the addition of sulphuric acid. A similar process was also devised by Perkin, in which the first step is the formation of dichloranthracene, C14H8Cl2, by treating anthracene with chlorine. Subsequent treatment of this body with sulphuric acid gives anthraquinone disulphonic acid, C20H16O8 (HSO3). This is fused with potash, as described above, and the alizarin precipitated with sulphuric acid as before. Anthrapurpurin is formed, simultaneously with all the processes given above. Its behavior as a dye is similar to that of alizarin, but it gives a brighter red. Pure alizarin, as obtained by sublimation, crystallizes in yellowish-red crystals, only slightly soluble in alcohol or water, but readily dissolving in alkalis. Chemically, alizarin is known as dioxyanthraquinone.

ALKAHEST, The, or THE HOUSE OF CLAES (‘La Recherche de l’Absolu’—The Search for the Absolute), is a striking novel by Honoré de Balzac. The central character, Balthazar Claës, is a wealthy chemist, the dreamer of whose life is to solve the problem of the secret of life. Gradually the quest becomes a fixed idea, for which money, family, health, sanity, are sacrificed, and Claës dies heart-broken and defeated. As foils to him stand his devoted wife and his eldest daughter Marguerite, noble women, the latter one of the earliest creations of Balzac’s genius. They sympathize sorrowfully yet tenderly with his ideal, and bear with true heroism the misery to which his mad course subjects
them. The story belongs to that series of the Human Comedy known as "Philosophical Studies," and appeared in 1834.

**ALKALI** (from the Arabic, *al,* "the," and *qali,* "ashes"), a term originally used for the soluble part of *pot-ashes,* but since extended to include the hydrate or oxide of any of the metals lithium, sodium, potassium, caesium and rubidium, or of the radical ammonium. The alkaloids possess strongly basic properties, and (with the exception of ammonia) rapidly absorb carbon dioxide from the air, when moist, passing into the form of carbonates. They are all soluble in water, and nearly all of their compounds are also soluble. The real nature of the alkaloids was first conclusively proved by Sir Humphrey Davy when in 1807 he decomposed potash and soda by means of the electric current. Alkalis in concentrated solution exert a powerfully corrosive action on the skin, and even in very dilute solution they alter the color of certain vegetable infusions very markedly. This property is utilized for detecting free alkaloids in solutions under examination, strips of bichromate paper impregnated with red infusion of litmus being moistened with the fluid to be tested. An exceedingly small amount of free alkaloid will transform the red color to a blue.

The alkaloid metals are all monovalent. The early chemist distinguished another class of substances, somewhat resembling the alkaloids, as the "alkaline earths." These include the oxides of calcium, strontium and barium. The alkaline earths are basic in nature, and differ from the alkaloids chiefly in being less soluble. Magnesium is sometimes included among the alkaline earths, but it falls more naturally into the zinc group. See **SOILS.**

**ALKALIMETRY,** that branch of chemistry which treats of the quantitative estimation of alkaloids present in a given solution. See **ANALYSIS, CHEMICAL.**

**ALKALOIDS,** organic bases, forming definite salts with acids and resembling in some respects the metals of the alkaloids, hence the name. A number of basic nitrogenous compounds of marked physiological action and somewhat analogous in their chemical composition. It has been proposed to limit the word alkaloid to the group of basic nitrogenous principles found in plants, the somewhat similar bodies found in animals being termed ptomaines (q.v.) and leucamines (q.v.). (See **ANIMAL ALKALOIDS**.) Some even class as alkaloids a series of feebly basic compounds prepared synthetically from the amines, antipyrine, etc. We shall here consider only such alkaloids as are basic nitrogenous principles, products of the metabolism of plants.

**Distribution.**—Alkaloids are widely distributed throughout the plant kingdom; many plants contain them, and some plants contain a large number; opium, *Papaver somniferum,* for instance, contains a dozen or more alkaloids. The *Cinchona* family also contains many. In such cases, however, the alkaloids are, as a rule, very close to the surface. Certain plant families contain many, others a few or none. Most of the alkaloids are found in the Dicotyledons, a few only are found in the Monocotyledons, Colchicum, and perhaps some of the Liliaceae. The fungus *Amanita muscaria* contains the deadly alkaloid muscarine (q.v.).

The *Papaveraceae,* *Solanaeae* and *Ranunculeae* are particularly rich in alkaloids. The *Leguminoseae,* *Rubieae,* and *Umbelliferae* contain many, while the large families of the *Compositae* and *Labiateae* contain very few. For the most part similar alkaloids are found in related plants, yet a few widely separated plants contain similar alkaloids, berberin being an example. As to their location in the plants themselves, alkaloids are found mostly in the fruit and seeds; many are found in the barks, and some in the roots. They are present in the most part in the actively growing portions of the plant and are probably katabolic products of the plant metabolism. They are usually found in solutions combined with some plant acid in the cell sap, sometimes dissolved in oils or mucilage, and in many instances are stored up in secretory passages in the plant. As to the rôle that the alkaloids play in the plant economy it is difficult to state positively. They do not seem to be utilized by the plant as a source of energy and in general are even poisonous to the plant itself. One of the services they perform for the plant is to aid it in the struggle for existence by being poisonous to animals. The large quantities found in seeds is evidence of the support of this view.

For the most part alkaloids are solid, non-volatile, crystalline bodies, a few being liquid and volatile, such as arecoline, nicotine, conine, sparteine. The former contain carbon, hydrogen, nitrogen and oxygen. The three latter liquid alkaloids contain no oxygen and have a marked odor; the solid alkaloids possess no odor. With few exceptions the alkaloids are insoluble (or soluble with great difficulty) in water.

Chemically the alkaloids are divisible into five provisional groups, although it was at one time held that only those bodies belonging to the Pyridine group should be considered as alkaloids. These groups as classed by Bruhl are (1) the Pyrroline group—containing an alkaloid from the coca leaf, hygrine; (2) the Pyrrole group, which contains a large number, pilocarpine, pilocarpidine, arecoline, arecaine, conine, conydrine, pipericine, nicotine, atropine, hyoscamine, cocaine, pelteterine, sparteine, cytisine and others; (3) Quinoline group—containing cinchonine, quinquinchonine, strychnine, brucine, curarine, and others; (4) Isoquin group—containing the opium alkaloids, morpine, papaverine, narcotine, codeine, thebaine, hydrocotarnine, hydrastine, cannabin, berberine, corydine; (5) alkaloids of undetermined relationship, a few only being of other than chemical interest, ergotinine, colchicine, veratrine, ceadvine, jervine, rubijervine, aspidopermine, yohimbine, anhalonine, lupinine, gelosmine, aconitine, pseudoaconitine, japaconitine, delphinine, emetine, etc. However, many alkaloids, the structure of which is well known, such as caffeine, theobromine, muscarine, etc., do not fit into this scheme.

The internal chemical construction of all the alkaloids is extremely complex; for many it is unknown. Most are tertiary amines, some are similar to the secondary amines in structure. Ammonia bases are also present in many. Many alkaloids acted on by strong alkalis are broken up into two components, a basic body and a nitrogen free, usually aromatic acid. Most of the alkaloids react similarly to oxidiz-
ALKANET.—ALL FOR LOVE

ing agents; nitric acid, chromic acid, potassium ferrocyanide and potassium permanganate are the most active. The last makes an efficient chemical antidote for many of them. A few alkaloids have been made synthetically. In the making, however, a related base has been necessary.

Physiologically the alkaloids are for the most part very active. Some have very little action, berberine, for example, while aconitine is one of the most toxic of substances. Nearly all of them have a marked affinity for nerve structures, on which a few have markedly poisonous action: some of them attacking the sensory nervous elements more particularly (aconitine, cocaine); others exerting their greatest activity on the motor nervous structures, sometimes in the muscle plates (coniine, curarine) causing paralysis; others in the motor cells in the anterior horn of the spinal cord (strychnine).

Still others exert their influence on the nerve cells of the brain (morphine, hyoscyanine).

History.—The history of the discovery of the alkaloids is about 100 years old. Derosne of Paris first isolated from opium in 1803 a salt of opium, as he termed it. This was a mixture of morphine and narcotine, and in 1806 Sertürner, a pharmacist of Hanover, first definitively described morphia. It was not until 1817, however, that the discovery was noticed. Following this in rapid succession different alkaloids were isolated — narcotine and emetine, in 1817, veratrine and strychnine, in 1818, brucine and pipерine, in 1819, cafeine, cinchonine and cinchonidine, in 1820, and by 1833 at least 30 alkaloids were known. At the present time there are more than 200 known, and new ones are being discovered rapidly; detailed study of more important alkaloids will be found under their respective heads. See ANIMAL ALKALOIDS; PLANTS; PIPERINE; and separate articles on the more important alkaloids under their special names.

ALKANET, ál-kăn’é-t, (1) a genus of plants of the family Boraginaceae, cultivated sometimes for their flowers. The evergreen alkanet (Anchusa tinctoria) of the full south of Europe, is cultivated for its blue flowers and its pleasant verdure in winter. Other species are common as flower borders. A. tinctoria is grown in the Levant and the south of France. It is cultivated for its resinous red coloring matter. (2) A red coloring matter obtained from the roots of the orchanet herb (Anchusa tinctoria). It is chiefly used to impart a red color to cosmetics, varnishes, etc. Benzine is used to extract it from the roots, the benzine is then evaporated, leaving a thick paste soluble in alcohol, ether and other organic liquids, but insoluble in water. The chemical formula for purified alkanet is about C₇₄H₁₀₃O₆.

AL-KHOWARAZMI, ál-koo’wā-rāz’me, Arabian mathematician of the 9th century. He was the librarian of Al-Mamun at Bagdad, and also worked in the Bagdad Observatory, where he carried on his astronomical and mathematical researches. Among his writings is a geographical treatise, ‘Rasm Al-Ard,’ giving the latitude and longitude of all places mentioned. He also wrote several mathematical treatises, including one on Hindu arithmetic, and ‘Al Jabr wa’l Muqabalah,’ discussing the quadratic equation and other algebraic problems; both of these were later translated into Latin, the latter giving Algebra its name. See ALGEBRA, HISTORY OF THE ELEMENTS OF, AND ARITHMETIC, HISTORY OF.

ALKMAAR, ál’-mär’, Netherlands, a town in the province of North Holland; on the North Holland Canal and 20 miles north-northwest of Amsterdam. It is regularly built; public walks cover the site of its former ramparts, and its finest public buildings are the 15th-century church of St. Lawrence and a richly decorated Gothic townhouse. It has manufactures of sail, sail-cloth, etc., and an extensive trade in cattle, cheese and ash. Among interesting events in its history is its successful defense against the Duke of Alva in 1573, and the invention of damask-weaving by a citizen, Paschier Lammertyn, in 1595. To the west stood the castle of the counts of Egmont. Pop. 21,500.

ALKORAN. See KORAN.

ALKYL, the radicals of the alcohols (for example, methyl, CH₃; ethyl, CH₂; and propyl, CH₃CH₂) are collectively called alkyls. (See Alcohol.) A compound of an alkyl with a halogen is called an alkylhalogen; and the metallic alkylhalates are frequently called alkoxides, since they may be regarded as double oxides of a metal and an alcohol radical.

ALL FOOLS’ ARGUMENT, in British political controversy: Those who are in favor of tariff reform sometimes argue that nearly every other country in the world has adopted protection, and then wind up with the question, ‘Are they all fools?’

ALL FOR LOVE, or The World Well Lost. Dryden had been an innovator when in 1664 he asked that ‘the excellence and dignity of rhyme’ be added to serious drama. He was an innovator again when he finally ‘discommended himself from rhyme’ with the ingenious words ‘I admire the pattern of elaborate writing, but—I love Shakespeare.’ Nothing at the time could serve Dryden’s purpose so well as to adapt the ‘taunting’ of Shakespeare’s ‘Anthony and Cleopatra’ to the regular measures demanded by Restoration taste. For his day there was nothing particularly irreverent or original in this. Dryden himself had some years before adapted ‘The Tempest,’ and many others had been adapted by other men.
Such an undertaking was to be judged purely by the results. Judging by these standards it must be confessed that 'All For Love' was a success. In reducing Shakespeare’s 40 scenes to five acts Dryden lost the epic sweep of the original. He lost as well the impression of the tragic pair at their moment of greatness and passion. The retrospective method gives a tone of plaintiveness to the whole composition. For the last two acts the author seems hard put to it to eke out the action and does so by developing a motive of jealousy below the level of the rest of the piece. But for all that Dryden makes up for these faults by the expertness of his handling. Ten years are compressed in one final day, which happens to be the birthday of the protagonist. The characters are fit mouthpieces for dignified speech adorned with some high ornament. ‘All for Love’ was produced at the Theatre Royal in 1678 and in the same year was published with a preface by the author. According to Genest it was played some 15 times during the 18th century, the first in 1732, Cleopatra being taken by Nance Oldfield, Peg Woffington, and Mrs. Siddons. It is last mentioned at Bath in 1818. Sir Leslie Stephen is at one with other critics in considering it Dryden’s finest play. Editions: Scott-Saintsbury (8 vols., 1882); Saintsbury (ed. ‘Mermaid Series’); Noyes, G. R. (1910); Strunk (ed. ‘Belles Lettres’ Series, 1911). Consult Dryden’s ‘Essay on Heroic Plays’ (Scott-Saintsbury, Vol. IV); Sherwood, M., ‘Dryden’s Dramatic Theory and Practice’ (‘Yale Studies in English,’ No. 4); Saintsbury, G., ‘Dryden’ (in ‘English Men of Letters Series,’ 1881); ‘Cambridge History of English Literature.’

THOMAS H. DICKINSON,
Author ‘The Contemporary Drama of England.’

ALL HALLOWS. See All Saints’ Day.

ALL HALLOWS COLLEGE, Drumondra, Dublin, Ireland. The foreign missionary college of All Hal lows, as its name implies, was instituted for the exclusive object of educating priests for the foreign missions, for the purpose of supplying with missionary priests those parts of the world where the Gospel had not been preached. The missionaries, however, going forth from its halls, were to have as a primary claim on their attention the spiritual needs, to speak in native parlance, of the Irish of the dispersion, who, owing chiefly to the effects of bad laws, had begun at that period to emigrate in large numbers from Ireland. All Hal lows was founded in the year 1842 by the Rev. John Hand, a native of the diocese of Meath, Ireland, then a young man, but a few years previously ordained at Maynooth. It was formally opened on All Saints’ Day of that year with only one student, a very small beginning indeed, but it increased in numbers and resources till it is now probably one of the greatest foreign missionary colleges in the world. It is at present, and has been for some time, in charge of the Vincentian Fathers, and was never in a more flourishing condition. It shelters within its walls some 300 students, all destined for the foreign missions. It is pleasantly situated at Drumondra, one of the suburbs of the metropolis, on a demesne of rich land, obtained for it through the efforts of Daniel O’Connell, at that time lord mayor of Dublin. A large number of Catholic priests in the United States received their philosophical and theological training at All Hal lows.

ALL IS TRUE, a play attributed to Shakespeare. The burning of the Globe Theatre (29 March 1613) while the piece was being played destroyed the manuscript. Parts of the drama were incorporated into the play of ‘Henry VIII.’

ALL SAINTS’ BAY, or BAHIA DE TODOS OS SANTOS, a bay on the coast of the state of Bahia, Brazil, in lat. 13° S. and long. 39° W., forming an excellent natural harbor 37 miles long and 27 miles broad. It contains several islands, the largest of which, Itapasesca, is 18 miles long and from 3 to 5 miles broad. On its east side stands the port of Bahia.

ALL SAINTS’ DAY, a festival instituted by Pope Boniface IV, early in the 7th century, on the occasion of his transforming the Roman heathen Pantheon (the present Rotunda, or Santa Maria de’ Martiri) into a Christian temple or church and consecrating it to the Virgin Mary and all the martyrs. It was first made a feast of obligation by Gregory IV in 835. It is kept by the Roman Catholic church and by churches in communion with the Church of England on 1 November, and by the Greek Church on the Sunday after Whitsunday. It is designed, as its name implies, to honor all departed saints and was formerly called All-hallows. In many American churches a custom has grown up of making the Sunday nearest 1 November the occasion of a service in memory of those who have died during the year. A chapel in St. Peter’s in honor of all the saints was consecrated by Gregory III in 731, on 1 November, and from this local custom was derived the universal commemoration afterward enjoined on the entire Church.

ALL SORTS AND CONDITIONS OF MEN, a novel by Sir Walter Besant. The famous People’s Palace of East London had its origin in this story; and because of the position Besant was knighted. The story concerns chiefly two characters — the very wealthy orphan, Angela Messenger, and Harry Goslett, ward of Lord Joscelyn. Miss Messenger, after graduating with honors at Newnham, resolves to examine into the condition of the people of Stepney Green, in the Whitechapel region, where she owns great possessions. To indicate to the working women of East London a way of escape from the meanness, misery and poverty of their lives, she sets up among them a co-operative dressmaking establishment, she herself living with her work-girls. Her goodness and wealth bring happiness to many. The book ends with the opening of the People’s Palace and with the heroine’s marriage to Harry Goslett.

ALL SOULS’ COLLEGE, Oxford, was founded in 1437 by Henry Chichele, Bishop of Canterbury, for a warden, 40 fellows, two chaplains and clerks. It was designed as a chantry where prayers might be offered for the souls of all Christians, especially those who fell in the war for the crown of France, and also as a society of fellows free from the care
of undergraduate students. Many of its members have been noted in history and law. There are 10 fellowships in the name of Chichele King’s scholarships. Fellows are chosen for their attainments in law and history. Blackstone, Gladstone, Jeremy Taylor, Sheldon, Heber, Salisbury and Curzon have been enrolled there. The Codrington Library of 70,000 volumes is one of the largest law libraries in the world.

**ALL SOULS’ DAY,** the day on which the Catholic Church commemorates all the faithful deceased. It was first enjoined in 998 by Odile, Abbess of Cluny, on the monastic order of which he was the head, and soon afterward came to be adopted by the Church generally. It is observed on 2 November. Among the early Christians the names of the deceased were entered on the diphtchs, or lists, used at the altar, from which the cleric read the names of those for whom he was required to pray. In the 6th century the Benedictines commemorated their departed brethren at Whit Sunday, and in Spain the commemoration took place on the octave of Pentecost.

**ALL’S WELL THAT ENDS WELL** is one of Shakespeare’s best comedies, and one of the plays in which he has kept closest to the original from which he derived his plot and yet has given the freest rein to his creative fancy. In the first volume of William Paynter’s *Palace of Pleasure,* a collection of short stories in which the author has laid under contribution ancient and modern story-tellers, is the short tale ‘Giletta of Narbona,’ borrowed bodily from Boccaccio’s *Decameron,* somewhat to the disfigurement of the story itself, for Paynter was anything but a master of English prose. This tale Shakespeare took for the basis of ‘All’s Well that Ends Well,’ which was probably written between 1590 and 1600. It was included in the folio edition of 1623; but it is supposed, however, to have originally appeared under the title of ‘Love’s Labor Won,’ as a companion piece to ‘Love’s Labor Lost;’ for a Shakespeare play under this title is listed by Meres in 1598, with accompanying description that fits only ‘All’s Well That Ends Well.’ To its meagre incidents Shakespeare added others that give the plot a more dramatic cast; and he created additional characters that lend it greater vivacity and interest. Some of these characters are altogether the work of his own imagination, while others were developed from suggestions in the original story. For the Countess Roussillon, the Clown Lavat, Paroles, the braggart and coward, Lord Lafoue, talkative but clear-headed, Shakespeare is in no way indebted to Paynter; and these are naturally the best characters in the play, with the one exception of the heroine, Helena. She stand apart from the others as special creations: are active, convincing, pleasing and life-like.

The outline of the plot of ‘All’s Well that Ends Well’ is more like Boccaccio than Shakespeare. A young lady of beauty, intelligence and wit, who is protected by the Countess Roussillon, mother of Bertram, Count of Roussillon, hero of the play, is deeply in love with Bertram, who, as a ward of the King, is summoned to the court of France, where his mother and Helena follow him. Helena cures the King of supposedly incurable malady by means of a receipt of her dead father, a famous physician. The King offers her the hand of any of his young unmarried courtiers; and she chooses Bertram, who marries her at his sovereign’s command but promptly disdains the marriage, telling her that he will never see her again until she secures possession of a ring he wears and has a child by him. Helena leaves his home, disguises herself as a young Florentine girl and is invited by her husband to his room, where she gets possession of the ring and complies with the requirements laid down by Bertram, who, finally realizing her cleverness and beauty, falls in love with her; and so ‘All’s Well that Ends Well.’

This comedy, though well constructed, excellently written and filled with well-drawn personae, is seldom presented in modern times on account of the objectionable character of the main incidents of the plot. It is, in fact, superior to some other Shakespeare plays which are set in frequent and skilled hands. It is rich in comedy and characterization and sparkles with wit and humor not inferior to Shakespeare’s best; the dialogue is sprightly; the invention and plot excellent and the interest well sustained. The philosophical, sick old King, the amiable, good-hearted countess, the clever heroine, the strong-headed young hero, whose chief asset is his ability to fight; the comic knave Paroles; old Lord Lafeu, jovial yet scoffing, and Lavatch, the clown, with his ever-ready wit, together form a galaxy of star characters sufficient for several modern comedies. And they are presented to us framed with a bewilderment richness of fine rhetorical passages.

**ALLACTITE,** a mineral found in Sweden, and crystallizing in small monoclinic prisms or tablets having the composition \( \text{MnO}_6 \text{Al}_2 \text{O}_3 \cdot \text{H}_2 \text{O} \). Its hardness is 4.5 and its specific gravity about 3.84. It exhibits double refraction to a marked degree, and varies in color from red to green, according to the direction from which it is viewed. This property has given it its name *allactite,* being derived from a Greek word meaning *to change.* The variability in color is due to the varying absorption of the ordinary and extraordinary rays of the incident light. See Physical Crystallography.

**ALLAH,** in Arabic, the name of God, a word compounded of the article al, and the word *Elah,* which signifies "the Adored and the Adorable," and synonymous with the singular of the Hebrew word *Elohim.* *Allah akbar* (God is great) is a Mohammedan war-cry.

**ALLAHABAD,** *ālah-hā-bād* (from *Allah,* God; *abad,* abode; the “abode of God”), India, an ancient city, capital of a division and district of the same name, as well as of the whole of the northwest provinces, 72 miles west of Benares. The native town consists largely of mud houses. Its English suburb of Canning-town has much more of a European aspect. Among the remarkable buildings of Allahabad are a large triangular fort, occupying a point of land formed by the junction of the Ganges and Jumna; the Jumna Musjid, or great mosque; the mausoleum of Khosru; All Saints’ Church;
the Roman Catholic cathedral; the Muir Central College, founded in 1874, the chief educational establishment of the northwest provinces; the Mayo Memorial and town hall. Allahabad is the Conservatory of Music; the pilgrimage, who come partly to visit a sacred cave under the Chali Satum temple (whence it is said there is a subterranean passage to Benares), but chiefly to have their sins washed away by bathing in the waters of the sacred rivers of Ganges and Jumna at the rugged, lagoon-like, Saraswati, which is in reality lost in the sands at a distance of 400 miles from Allahabad, mingle its current with those of the other two. A great fair held on 14 December is much attended by pilgrims.

There are few manufactures. Allahabad forms a junction in the railway system between Bengal and Central India, and its trade is rapidly increasing. In the mutiny of 1857 it was the scene of a serious outbreak and massacre. Pop. 171,700. The division of Allahabad contains the districts of Cawnpur, Futtahpur, Hamirpur, Banda, Jhansi, Jalaun, Lalitpur and Allahabad. The agriculture of the division is greatly promoted by a canal 310 miles long, connecting the Ganges and the Jumna. About five-sixths of the surface is under cultivation, the principal crops being rice, pulse, wheat, tobacco, etc.

ALLAMANDA, a genus of shrubs of the family Apocynaceae, consisting of a dozen species, natives of Brazil and Central America. Most of the species are climbing; they have sparse, bright green, whorled leaves, and large, terminal, yellow or purple flowers. Because of their showy flowers they are much cultivated in the United States and elsewhere, in the North in hothouses and in the South out of doors. The leaves of certain species have been used in medicine as a cathartic.

ALLAN, Sir Hugh, founder of the Allan Line of steamships: b. Scotland, 29 Sept. 1810; d. Edinburgh, 8 Dec. 1882. A clerk with limited education, he emigrated to Canada in 1824. was clerk in Montreal stores, became captain in the rebellion of 1837 and in 1838 succeeded his late father as a partner in the shipping and ship-building business. In 1853 his firm began building iron screw steamships and their first vessel, the Canadian, made its first voyage in 1855, two more being used as transports in the Crimean War. The Allan Line, after many disasters, gained a permanent footing and has been a large element in developing Canadian prosperity. Sir Hugh was one of the projectors of the Canadian Pacific Railway and prominent in the political investigations to which it led. He was a director in banking, telegraph, gold mining and other large business enterprises, and was knighted in 1871.

ALLAN, Maud, American danseuse: b. Toronto. At four years of age she removed to San Francisco, where her father became a naturalized American citizen. She took a scholarship at the Conservatory College, San Francisco; commenced studying the piano at the age of five, and made her first appearance as a pianist at 12. Soon afterward she went to Europe to continue her studies; spent four years at the Royal Academy of the Bemby High School of Music and took the highest diploma for piano-playing. Later, she abandoned her intention of becoming a professional musician, deciding to become a dancer instead, her idea being to represent music by dancing. After much fresh study, she made her first appearance as a dancer before an invited audience at the Conservatory of Music in New York. She was highly complimented by the press. Her first public appearance took place at the Théâtre Molière, Brussels, and she subsequently performed at Berlin, Buda Pesth, Hamburg and Paris, at all of which places she aroused much enthusiasm. In 1894 she opened a season of success in London in 'The Vision of Salome,' and had the honor of dancing before Edward VII and Queen Alexandra. Subsequently she appeared successfully in New York. Consult her autobiography.

ALLAN, Sir William, Scottish artist: b. 1782; d. 1850. He was a fellow student with Wilkie in Edinburgh, afterward a student of the Royal Academy, London; then went to St. Petersburg and remained for 10 years in the Russian dominions. In 1814 he returned to Scotland and publicly exhibited his pictures, one of which ('Crescasian Captives') made his reputation. He now turned his attention to historical painting and produced scenes from Scottish history and battle scenes; among them two pictures of the battle of Waterloo, one from the British, the other from the French position, and delineating the actual scene and the incidents therein taking place at the moment chosen for the representation. One of these Waterloo pictures was purchased by the Duke of Wellington. He traveled extensively, visiting Italy, Greece, Asia Minor, Spain and Barbary. In 1835 he became R.A., in 1838 president of the Scottish Academy; in 1842 he was knighted.

ALLANITE, a mineral, isomorphous with epidote, and containing rare metals of the Cerium and Yttrium groups. It is variable in composition, but is essentially a silicate of these metals, combined with aluminum, iron and calcium. It occurs in Norway and Finland and in the United States in Massachusetts, Connecticut, New York, New Jersey, Pennsylvania, Virginia and North Carolina; also in Canada. It was named for Thomas Allan, of Edinburgh, who described it in 1808. (Allan River, Nova Scotia.)

ALLANTOIN, a-lan'to-in, a substance found in the allantoic fluid of the cow, in the urine of sucking calves, in the leaf buds of the maple and in the bark of the horse-chestnut tree. It is readily soluble in alcohol and crystallizes in monoclinic prisms having the formula C₇H₉N₄O₉. It may be formed by treating uric acid with boiling water and PbO₂. Compounds of allantoin with several of the metals are known.

ALLANTOIS, a structure appearing during the early development of vertebrate animals — reptiles, birds and mammalia. It is largely made up of blood-vessels and, especially in birds, attains a large size. It is the former lining to the shell, and may thus be viewed as the surface by means of which the respiration of the embryo is carried on. In mammalia the allantois is not so largely developed as in birds and it enters largely into the formation of the placenta.

ALLARD, Marie Jules Paul, French church historian: b. Rouen, 15 Sept. 1841; d. Senneville-sur-Mer, 4 Dec. 1916. He was educated at
the Institut Join-Lambert, near Rouen; was substitute judge, Rouen, 1872-83 and from 1903 to 1915 was editor of Revue des questions historiques. He took part in the International Catholic Scientific Congress of 1888 and 1891 at Paris and that of 1894 in Brussels. He published: 'Les esclaves chrétiens depuis les premiers temps de l'Église jusqu'à la fin de la domination romaine en Occident' (1870); 'Les chrétiens des Iles anglo-saxones du haut Moyen Âge' (1879); 'Esclaves servis et mainmortables' (1884); 'Histoire des persécutions de l'Église' (5 vols., 1885-90); 'Paul Lamache' (1893); 'Le Christianisme et l'Empire romain' (1897); 'Saint Basile' (1898); 'Julien l'Apostat' (3 vols., 1900); 'Dix leçons sur le martyre' (1905); 'Saint Sidone Apollinaire' (1910); 'Les origines du servage en France' (1913). He was a contributor to Caribou's 'Dictionnaire d'archéologie chrétienne et de liturgie'; of Alès' 'Dictionnaire d'Apologie' and 'The Catholic Encyclopedia'.

ALLEGAN, Mich., a town and county-seat of Allegan County, 33 miles south of Grand Rapids. It is situated on the Kalamazoo River and on the Cincinnati N., Lake Shore & M. S., and the Pere Marquette railways. It is in the midst of a fertile region, and a large dam on the river a few miles above the village affords valuable water power. Among its industries are mills of various kinds, carriage works, furniture factories, etc. It contains a Carnegie public library, family court house, city hall and public schools. First settled in 1835. The town water works are owned and operated by the municipality. Pop. 3,419.

ALLEGAN, N. Y., village of Cattaraugus County, 70 miles southeast of Buffalo, on the Allegany River, and on the Erie and Pennsylvania railroads. It has important oil interests, contains a canning factory, several cheese factories and sawmills. Saint Elizabeth's Academy for Girls is located here, also the Catholic college and seminary of Saint Bonaventure, founded in 1859. The village was incorporated in 1905. Pop. 1,300.

ALLEGATION is the assertion, declaration or statement by a party of what he can prove under the reformed method of procedure adopted in nearly if not all of the States of the Union, the general rule that the allegations in the pleadings and the proof must correspond has been greatly relaxed. Under our present system a failure to prove an immaterial averment cannot in general be a material variance at the trial and will be disregarded. If the substance of the issue be proved it is sufficient. If a contract, for instance, agree in substance and legal effect with that stated in the complaint, the variance will be disregarded.

ALLEGHANY MOUNTAINS or ALLEGHANY PLATEAU, a name sometimes used to designate the eastern Appalachian Mountain system, but more properly applied to the western range of this system in Pennsylvania, Maryland, Virginia and West Virginia. They begin near the New York and Pennsylvania border — the Catskills forming a northern outlier — and extend eastward into West Virginia, where the line of elevations is continued by other ranges across Tennessee. In the northern part the mountains have an elevation of about 2,000 feet (over 4,000 feet in the Catskills), but they gradually increase in altitude southward until in Virginia they rise to 4,500 feet above the sea. Throughout their extent they present a remarkably even crest-line with few gaps and isolated peaks. On the eastern side the Alleghany Front or Alleghany escarpment is an abrupt slope overlooking the Great Valley, a depression from 50 to 100 miles wide, lying between the Alleghany and Blue Ridge. On the west, the plateau has a gentler bounding slope. The range forms the water-parting between the streams draining into the Atlantic Ocean and the Gulf of Mexico. The former receives the drainage from the eastern slope principally through the Delaware, Potomac and James rivers, while the Ohio River collects most of the waters on the western side. Except at the eastern edge, where the rocks partake of the folding of the Appalachian Mountains proper, the sediments are nearly horizontal and the region is rather a deeply dissected plateau than a true mountain range. Limestone, sandstones and conglomerates are the predominant formations and range from the Cambrian to the Cretaceous systems. Immense coal-seams occur in the upper part of the series. See APPALACHIANS.

ALLEGHENY, Pa. See PITTSBURGH, Pa.

ALLEGHENY COLLEGE, a coeducational (Methodist Episcopal) institution in Meadville, Pa.; organized 1815 as a Presbyterian college and transferred in 1833 to the Methodist Church under an agreement that it should be conducted on a non-sectarian basis. It early acquired the support of a number of prominent men, including John Adams, Thomas Jefferson, James Winthrop and William Bentley, the two latter making it the gift of their libraries. Bently Hall and Ford Memorial Chapel are among the finest buildings. The chief emphasis is placed on non-technical cultural subjects but there are also courses in the arts and sciences. In 1914 there were: Instructors, 22; students, 418; volumes in the library, 31,000; grounds and buildings valued at $850,000; productive funds, $648,750; income, $117,346; graduates, 1,911.

ALLEGHENY RIVER, a river of Pennsylvania and New York; a headstream of the Ohio. It rises in Potter County, Pa., and joins the Monongahela at Pittsburg. Among its tributaries are French Creek and Clarion and Kiskiminetas rivers. Its length is 400 miles and it is navigable for about 150 miles above Pittsburgh.

ALLEGIANCE. Allegiance is the obligation of obedience or service which one person owes to another or to the state. During the feudal age those who held lands of a feudal lord owed him allegiance; to-day, however, the allegiance of the individual is only to the state or its symbolic head, the king. The obligation is reciprocal, that is, it is due in return for the protection which the state of which he is a citizen, or subject, is bound to afford him. The laws of most states require an oath of allegiance as a condition of admission to citizenship; many also require an oath of persons enrolled in the military and naval forces, and some require it of persons appointed or elected to a civil office. In times of civil war an oath of
ALLEGORICAL INTERPRETATION—ALLEGORY

allegiance is usually required of insurgents as a condition of amnestry or the restoration of their civil status. Violation of the oath of allegiance is severely punished, usually with the penalties of treason.

Ordinarily allegiance is an obligation of citizens only, but in the United States it is held by some to mean an entire abnegation of the laws. Some states require the acquiescence of the laws as a local and temporary allegiance which continues during their residence and for violation of which they are liable to prosecution for treason equally with citizens. (Carlisle v. The United States, 10 Wall. 147.)

The doctrine of the English common law was that of indefeasible allegiance, which was also the theory of the Roman law, exsuse patriam nemo potest, according to which the individual could not of his own motion throw off his allegiance and take up another. *Once an English subject, always an English subject,* unless with the consent of the sovereign, was the theory stated in an aphorism. The early jurists and commentators in the United States also adhered to this view and some secretaries of state followed this opinion. James Buchanan, secretary of state in 1845, however, asserted it to be an unqualified right of the citizen to change his allegiance at will, and in 1868 Congress passed a law affirming this view. This act declared it to be an inherent right of all people to expatriate themselves whenever they wished and to assume a new allegiance. Two years later the British Parliament by statute formally abandoned the doctrine of indefeasible allegiance and declared that any British subject not under disability and voluntarily naturalized in a foreign state should cease to be a British subject. The great majority of other states likewise have abandoned the doctrine of indefeasible allegiance and allowed their citizens or subject to voluntarily expatriate themselves, although some of them attach restrictions to the exercise of the right. Only Russia and Turkey hold to the old rule and refuse to recognize the legality of the naturalization of their subjects by foreign states, unless the consent of the sovereign has been previously obtained. See also CITIZENSHIP and NATURALIZATION.

JAMES W. GARNE.

ALLEGORICAL INTERPRETATION, or ALLEGORISM, a method used in the interpretation of the Scriptures. The method in brief is to take a plain statement and attach to it a symbolical meaning. Allegory has always been largely used. The Greek writers made use of it, especially Plato, Homer and Hesiodus. Sometimes the sacred writers themselves made use of it, thus explaining or clarifying a fact by means of a symbol or an allegory. The Old Testament contains many allegories. Nathan, in his rebuke of David, uses the allegory of the poor man's pet lamb to enforce his lesson. The allegory of the vine in the Psalms is another example. The finest of all the allegory of old age contained in the last chapter of the book of Ecclesiastes. Early Jewish writers in the Intertestamental period interpreted the Old Testament after this manner. The Jewish group of scholars in Alexandria under the leadership of Philo adopted this method to the exclusion of all others. This led of course to an abuse of the method and the production of interpretations as ridiculous as the allegory of the vine. The apocryphal 'Book of Wisdom' contains some instances. This method was in vogue in the days of Jesus Christ, and he frequently used it. The allegories of the sower, the vine and the branches, and the parable of the ten servants are examples. Paul uses it several times in his Epistles. In Galatians iv. 21, he uses Hagar and Sarah, Isaac and Ishmael in an allegorical sense. The writer of the Epistle to the Hebrews shows the influence of the same method.

In post-apostolic times the method continued. It was made use of by Clement of Alexandria. Its chief exponent, however, was Origen, the great allegoriser of all time. Possessed of a poetical temperament and a vivid imagination, he utilized the method for making an allegory. He largely influenced succeeding commentators. The method continued to be popular through the Middle Ages. Early English divines made use of it. Finally the method seemed to concentrate about the interpretation of the mystical typology seeming to prefigure facts in the New. In 1682 Benjamin Keach published a large folio volume in which he explained the types allegorically. Since then many have followed in his footsteps, including Samuel Mather of New England (1705). As late as 1847 Patrick Fairbairn published his 'Typology of the Scripture' in two volumes. It has since appeared in many subsequent editions. It is the latest book of any note on the subject. The historical method which aims scientifically to state the exact facts has now entirely superseded the allegorical.

By the allegorical method 'history is not treated as an allegory, but converted into allegory,' which is not scientific nor in accord with modern methods of treating the Scriptures. No scholar of any note in our time places much dependence upon it. Consult Farrar, F. W., 'The History of Interpretation' (1885); Gilbert, G. H., 'Interpretation of the Bible' (1908); and the article 'Allegory' in Hastings' 'Dictionary of the Bible.'

SAMUEL G. AYRES,
Garrett Biblical Institute.

ALLEGORY (from Greek allo, something else, and agoreuein, to speak), a figurative representation, in which the signs (words or forms) signify something besides their literal or direct meaning, each meaning being complete in itself. In rhetoric, allegory is often but a continued simile. Parables and fables are a species of allegory; for example, the beautiful parable in one of the tales in the 'Arabian Nights,' in which the three religions, the Mohammedan, Jewish and Christian, are compared to three similar rings, bequeathed to three brothers by their father. Sometimes whole works are allegorical, as 'Reynard the Fox,' Spenser's 'Faerie Queene,' and Bunyan's 'Pilgrim's Progress.' When an allegory is thus continued through long periods it is indispensable to its success that not only the allegorical meaning should be appropriate, but that the story should have an interest of its own in the direct meaning apart from the allegorical signification. There was a time when every poem was taken as an allegory; even
such works as those of Ariosto and Tasso were tortured from their true meaning and made to pass for allegorical pictures. No poet has made use of allegory in a more powerful and truly poetical manner than the great Dante. Allegory is often made use of in painting and sculpture as well as in literature.

**ALLEGRI, al-là'grè, Gregorio,** Italian composer and a singer in the papal chapel, considered one of the most excellent composers of his time. a. Rome, about 1580 (according to others 1590); d. there 1652. His ‘Miserere’ has particularly distinguished him. It is even now regularly sung during Passion Week in the Sistine Chapel at Rome. Its subject is the 57th psalm (which in the Latin version begins with the word *Miserere*) and is composed for two choruses in five- and four-part harmony. This composition was once esteemed so holy that whoever ventured to transcribe it was liable to excommunication. In 1770 Mozart, then only 14 years of age, disregarded this prohibition, and after two hearings made a correct copy of the original.

**ALLEGRO, al-là'grè,** an Italian word signifying gay, and used in music to express a more or less quick rate of movement. The degrees of quickness are indicated by additional qualifying words or by derivatives of the word *allegro.* Thus *allegretto* or *poco allegro* means rather lively; *allegro moderato, commodo, giusto,* moderately quick; *allegro maestoso,* quick but with dignity; *allegro assai and allegro molto,* very quick; *allegro con brio or con fuoco,* with fire and energy; *allegrescence,* with the utmost rapidity. *Piu allegro* is a direction to play or sing a little quicker. *Presto* indicates a still quicker rate than *allegro,* but there is usually also this difference between the *presto* and *allegro* movements, that the former demands nothing more than rapid execution, while the latter requires to be performed with expression as well as quickness. The first movement of a symphony and other similar compositions is called the *allegro.* See Music.

**ALLEINE, Richard,** English theologian: b. Ditcheat, Somerset, 1611; d. Frome Selwood, 22 March 1681. He was educated at Oxford, entered the ministry and was for a time his father’s assistant in the ministry. From 1641 to 1662 he was rector of Bathcombe in Somerset. The passage of the Act of Uniformity caused him to be ejected and afterward he preached where he could. He wrote *Ordinatie Pietatis* in 1663, the license for which was at first refused by the King’s printer, Roger Norton, who on reading it brought back the sheets from the royal kitchen, whither he had sent them for binding, and issued the work from his own shop. For this Norton was compelled to seek pardon on his knees at the council table.

**ALLEMONTITE,** a tin-white, metallic mineral regarded as a native alloy of arsenic and antimony, SbAs. It usually occurs in fine-granular or mammillar forms. Its hardness is 3.5 and specific gravity about 6.20. It is found at Allemont in France, also in Bohemia and Germany.

**ALLEN, Alfred,** American author and playwright: b. Alfred, N. Y., 8 April 1866. He was graduated from Alfred University, studied at the Johns Hopkins and Columbia universities and the American Academy of Dramatic Arts in which last he is now a professor. His plays include ‘Jack the Giant Killer,’ ‘A Burglar’s Honeymoon,’ ‘Playmates’ and ‘Head of the House;’ all of which have been produced on the stage. His novels are: ‘The Heart of Don Vega,’ ‘Judge Lynch,’ ‘The Cup of Victory’ (with Richard Hovey).

**ALLEN, Charles Grant Blairfndie,** See ALLEN, GRANT.

**ALLEN, Charles Herbert,** American diplomatist and banker: b. Lowell, Mass., 15 April 1848. He was graduated at Amherst 1869; was associated with his father in the lumber business in Lowell; served in both branches of the State legislature, and in Congress in 1885–89; was defeated as Republican candidate for governor of Massachusetts, 1891; and succeeded Theodore Roosevelt as assistant secretary of the navy in May 1898. On the passage by Congress of the Porto Rico tariff and civil government bill, in April 1900, the President appointed him the first civil governor of Porto Rico; he resigned July 1901. He retired from public life in 1902 and became associated with banking and allied interests in New York. In 1913 he was elected president of the American Sugar Refining Company.

**ALLEN, Ebenezer,** American soldier: b. Northampton, Mass., 17 Oct. 1743; d. 26 March 1806. He emigrated to Vermont in 1771 and was made a lieutenant in Col. Seth Warner’s regiment of *Green Mountain Boys.* In 1776 he was a delegate to the conventions in the New Hampshire grants, and in 1777 to those which declared the State independent and framed its Constitution. In July of that year he was made captain in Herrick’s battalion of *Rangers* and took an active part in the battle of Bennington; in September he captured Mount Defiance; and he took 50 prisoners among the troops retreating from Ticonderoga. He afterward became major and continued to win distinction during the war. He lived at Burlington in his later years.

**ALLEN, Edward Patrick,** Roman Catholic prelate: b. Lowell, Mass., 17 March 1853. He began early to fit himself for the priesthood and in June 1878 was graduated from Mount Saint Mary’s College, Emmitsburg, Md. He was ordained priest in 1881 and in 1884 became president of his college. In January 1897 his Holiness Leo XIII appointed him bishop of Mobile, and on the 16 May following he was consecrated in the Baltimore Cathedral by Cardinal Gibbons. In May of the same year he was installed in his own cathedral, being the 5th bishop of Mobile to hold that office.
Under his care the diocese has prospered greatly and new churches, hospitals, schools and parishes testify to the bishop's diligence. The Catholic population of the diocese in 1897 was 17,000, and in 1913 it had risen to 42,500.

ALLEN, Elisha Hunt, American legislator and diplomat: b. New Salem, Mass., 28 Jan. 1804; d. 1 Jan. 1883. Graduating at Williams College, 1823, he became a lawyer at Brattleboro, Vt., but soon removed to Bangor, Me., and was a member of the Maine legislature 1834-41 and speaker in 1838. He was elected representative to Congress in 1841. Removing to Boston in 1847, he was elected to the Massachusetts legislature in 1849. Appointed consul at Honolulu in 1852, he held that post till 1856, and thence till 1876 was chancellor, minister of finance and chief justice of the Hawaiian kingdom. Several times during that period and from 1876 onward he was its minister to the United States and died in Washington, dean of the diplomatic corps.

ALLEN, Elizabeth Akers (CHASE), American poet: b. Strong, Me., 9 Oct. 1832; d. 1911. She was married in 1860 to Paul Akers, the sculptor, who died in 1861; and in 1865 to E. M. Allen of New York. Her first volume, 'Forest Buds,' appeared under the pen name of Florence Percy (1855). Other works of hers are: 'The Silver Bridge and Other Poems' (1866); a volume of 'Poems' (1866), which contains 'Rock Me to Sleep, Mother' (her authorship of this popular ballad, once disputed, is proved); the New York Times, 27 May 1867; 'The High Top Sweeping and Other Poems' (1891); 'The Sunset Song' (1902).

ALLEN, Ethan, American soldier: b. Litchfield, Conn., 10 Jan. 1737; d. Burlington, Vt., 13 Feb. 1789. About 1769 he removed to Bennington, Vt. The Vermont territory had been given by the Crown to both New Hampshire and New York under conflicting grants; and when the dispute was settled (1764) in favor of New York, Governor Wentworth of New Hampshire had already granted 128 townships to grantee and others up the Revolution. New York at once proceeded to regrant the same territory, but the indignant settlers drove out the surveyors, applying the "beech seal" (fresh-cut rods) to enforce their withdrawal. The English government ordered the status quo to be respected by New York, and further disorders averted by granting only ungranted lands; the New York authorities continued to send surveyors, their grantees persisted in attempting to take possession of their lands, and the New Hampshire grantees continued to eject both deputy sheriffs and claimants by armed force and to chastise them besides. Allen at once took part in the dispute and soon became a leader: an athletic and adventurous giant, he was now in his element. In 1775 he was appointed agent for the settlers at Albany, where they were to plead their rights; the decision went against them, and a fresh attempt being made to enforce New York rights, the settlers raised a regiment for defense, called 'Green Mountain Boys,' of which Allen was made colonel. Tryon of New York, historically more renowned for vanity and bad temper than ability or success, proclaimed him an outlaw and offered £150 for his capture; but under Allen, Seth Warner and other able partisan chiefs, the settlers held New York at bay. Allen in 1774 answered publications in defense of the New York claims by a tract defending the Vermonters, reprinted in 1779. When the Revolution broke out Congress ordered Arnold to raise troops and seize the British fortresses on the New York border; but the Vermonters forestalled them by collecting the 'Green Mountain Boys' at Castleton, Vt., under Allen's command, which on 10 May 1775 captured Ticonderoga and its garrison without a combat, and shortly after Crown Point and Skenesborough (Whitehall), giving them a mass of stores and the command of Lake Champlain. This action moved Congress to grant them the same pay as Continental soldiers, and to recommend the New York Assembly to employ them in the army under their own officers. Allen and Warner journeyed thither and asked admittance to the session; and after some grumbling over receiving proclaimed felons, a heavy majority voted to admit Allen, and later to raise a regiment of 'Green Mountain Boys.' Allen wrote a letter of thanks and proposed a joint invasion of Canada, which then joined Schuyler's army as a volunteer, was sent on secret missions to Canada, meeting on the last one Col. John Brown, who agreed to join him in an invasion of Canada. Fort Chambly was captured; but Brown left Allen in the lurch at the attack on Montreal, and Allen was taken prisoner 25 September and sent to England. He was chained and treated with great severity, but after some months was sent to Halifax, N. S., and exchanged 6 May 1779. On returning to Vermont he was appointed commander of the militia and Congress made him lieutenant-colonel in the regular army. The old land-grant feud still raged, and in the attempted British intrigue (1780-83) to have Vermont annex itself to Canada as a protection against New York, Allen paralyzed British military action by procession to consider a bribe for favorable action; later he was charged with treason, but the charge was not sustained. He settled in Bennington and finally in Burlington, where he died. He was a member of the legislature, and after the war was a delegate to Congress, where he worked for the admission of Vermont as a State, which it had been by self-proclamation since 1777. It was not till 1789, however, that New York waived its claims, and Allen did not live to see the result. He wrote the story of his captivity (1779); 'Vindication of the Opposition of Vermont to the Government of New York' (1779); and 'Reason the Only Oracle of Man' (1784), being a deist of the Paine stripe. Consult Sparks' 'Life' (Boston 1834); and Henry Hall's 'Ethan Allen' (New York 1892).

ALLEN, Frederick De Forest, classical scholar: b. Oberlin, Ohio, 1844; d. Cambridge, Mass., 4 Aug. 1897. He was graduated at Oberlin College 1863, and studied at Leipzig. From 1866 to 1880 he held professorships in the universities of Tennessee, Cincinnati and Yale. In 1880 he accepted the chair of classical philology at Harvard, holding it until his death. He published an edition of Euripides' 'Medea'
(1876), 'Remnants of Early Latin' (1880), a revision of Hadley's 'Greek Grammar' (1884), and 'Greek Versification in Inscriptions' (1880); besides contributing many papers to classical journals and editing numerous classics.

ALLEN, Fred Hovey, American author and journalist; b. Lyme, N. H., 1 Oct. 1845. He was graduated at Hartford Theological Seminary while completing a university course and studied art abroad. Later he became pastor at Boston and Abington, Mass., and editor of the Suffolk County Journal, both gm., and a lecturer on art. He has published: 'Modern German Masters' (1895); 'Recent German Art' (1885); 'Great Cathedrals of the World' (1886); 'Popular History of the Reformation' (1887); and edited numerous costly art works. He brought to America the first successful photogravure process, made the first photogravure plates in America and the first book from American made plates. The making of books illustrated by American made plates printed in America was first accomplished by an American since all the important workmen signally failed to produce either plates or printing.

ALLEN, Grant (Charles Grant Blair,findle Allen), essayist, novelist, naturalist: b. Kingston, Canada, 24 Feb. 1848; d. London, 26 Oct. 1899. He was graduated at Oxford in 1871, and for a time was professor of logic and philosophy in Jamaica, but spent the greater part of his life in England. Widely known as a scientist in several departments, he aimed to popularize science, and his brilliant style contributed greatly to his success in this respect. His score or so of novels and works of light fiction attained great popularity, but though entertaining they have only an ephemeral value. His outspoken agnosticism is reflected in many of his writings. His chief titles are: 'Physiological ESThetics' (1877); 'The Color Sense' (1879); 'Evolutionist at Large' (1881); 'Flowers and Their Pedigrees' (1883); 'Charles Darwin' (1885); 'Force and Energy' (1888); 'Story of the Plants' (1889); 'Evolution of the Idea of God' (1897). In China the following were most widely read: 'This Mortal Coil' (1888); 'The Great Taboo' (1890); 'The Duchess of Powysland' (1892); 'The Woman Who Did' (1896); 'The British Barbarians' (1895); 'Under Scaled Orders' (1897).

ALLEN, Henry, American religious enthusiast: b. Newport, R. I., 14 June 1748; d. Northampton, N. H., 2 Feb. 1784. He settled in Nova Scotia, where he founded the sect known as 'Allenes.' He made numerous converts but the sect dwindled after his death. He asserted that Adam and Eve before the fall had not corporeal bodies; that there will be no resurrection of the body; that men are not bound to follow the ordinances of the Gospel; that the Bible is to be interpreted wholly in a mystic or spiritual sense. He was an eloquent preacher and published some sermons and hymns.

ALLEN, Henry Watkins, American soldier and public officer: b. Prince Edward County, Va., 29 April 1820; d. 22 April 1866. He was a native of Missouri, where he was born to Marion College; he subsequently became a teacher in Grand Gulf, Miss., studied law and entered practice there. He raised a company for Houston's Texas war against Mexico; and after the war was over resumed practice and was sent to the legislature in 1846. Settling in Baton Rouge, he was elected to the Louisiana legislature in 1853. In 1861 he moved to Italy, to share her struggle for independence against Austria; but arriving after it was over, made a tour of Europe, which he described in 'Travels of a Sugar Planter.' He was elected to the legislature in his absence by the Convention of the Southern Whigs who joined the Democrats after the party break-up caused by the Kansas-Nebraska bill. At the opening of the war he was commissioned by the Confederacy lieutenant-colonel; later colonel and military governor at Jackson. He was wounded at Shiloh; constructed fortifications at Vicksburg; was disabled at Baton Rouge; made brigadier-general September 1864; and shortly after elected governor of Louisiana. He was a vigorous and efficient magistrate, with almost dictatorial powers. After the war he migrated to Mexico and started the (English) Mexico Times in the City of Mexico, where he died.

ALLEN, Horace Newton, American minister: b. Delaware, Ohio, 23 April 1858. He was graduated at Ohio Wesleyan University, and after a medical course went to China as Presbyterian missionary. Going to Korea in 1884 he was in Seoul at the time of the coup d'état of that year and saved the life of a prince related to the Queen; he was thereafter made court physician and allowed to establish a hospital under government orders. He came to Washington in 1887 with the first Koreanlegation, and returned in 1890 as United States secretary of legation. He won great confidence for sagacity and acquaintance with Korea and in 1897 was made United States minister there. He has written: 'Korean Tales' (1889); 'Chronological Index of Foreign Relations of Korea from Beginning of Christian Era to 20th Century' (1900, supplemental 1903); 'Korea: Fact and Fancy' (Seoul 1904); 'Transactions of the Foreign Committee of Korea'; 'Things Korean' (Seoul 1908).

ALLEN, Horatio, American engineer: b. Schenectady, N. Y., 1802; d. 1889. Graduating at Columbia University in 1823, in 1826 he was resident engineer on the summit level of the Delaware & Hudson Canal and was sent to England in 1828 to buy locomotives for its proposed railway. In 1829 he made the first locomotive trip in America at Honesdale, Pa., with the 'Stourbridge Lion.' He was chief engineer, 1829-34, of the South Carolina Railway, then the longest line in the world; and in 1838-42 was chief assistant engineer of the Croton Aqueduct. He was chief engineer and afterward president of the Erie Railway, consulting engineer of the Panama Railway and the Brooklyn bridge; president of the American Society of Civil Engineers 1872-73. He invented the swivel car-truck.

ALLEN, Ira, younger brother of Ethan (q.v.) and a Green Mountain Boy: b. Cornwall, Conn., 21 April 1751; d. 7 Jan. 1814. He went to Vermont in 1772 and was an active supporter of Ethan in the 'beech seat' proceedings. He was a native of Missouri, where he was a resident of the Vermont legislature 1776-77 and of the Vermont Constitutional Convention 1778; was his first secretary of state,
then its treasurer and surveyor-general. He was in the battle of Bennington, 1777. In 1780-81 he was a Vermont commissioner to Congress to confirm the New York land claim. In 1789 he aided in organizing the University of Vermont; and in 1792 was a delegate to the convention that ratified the United States Constitution after Vermont's admission as a State. In 1795, as state surveyor-general of militia, he went to France and bought arms to be sold to the State; but in returning was captured by an English cruiser, taken to England and charged with supplying the Irish rebels with arms, and only won his suit after eight years. Imprisoned in France in 1798 he returned to the United States in 1801. He wrote 'The Natural and Political History of Vermont' (London 1798); 'Statements Appended to the Olive Branch' (1807).

**ALLEN, James Lane, American novelist:** b. near Lexington, Ky., 1849. He was educated at Transylvania University in his native State and was successively an instructor in Kentucky University and Bethany College, West Virginia. In 1866 he removed to New York city and has since devoted himself entirely to literary pursuits. In his short stories and novels he has usually drawn upon Kentucky background, and though his finished literary style, though somewhat too highly elaborated for the taste of the average reader, has been much admired by the more critical. His prose is characterized by a marked poetic cast, and his realism is of that profound kind which concerns itself with essential truths rather than with photographic fidelity to local types. His published books comprise 'Flute and Violin' (1891); 'The Blue Grass Region and Other Sketches' (1892); 'John Gray's Return to the United States Cardinal' (1894); 'Aftermath' (1895); 'A Summer in Arcady' (1896); 'The Choir Invisible' (1897); 'The Reign of Law' (1900); 'The Mettle of the Pasture' (1903); 'The Bride of the Mistletoe' (1909); 'The Doctor's Christmas Eve' (1911); 'The Heroine and the Bronze' (1912); 'The Last Christmas' (1913); 'The Land of Youth' (1915); 'The Cathedral Singer' (1916); 'The Kentucky Warbler' (1917). See FLUTE AND VIOLIN.

**ALLEN, Joel Asaph, American naturalist:** b. Springfield, Mass., 19 July 1838. He studied under Agassiz at Harvard, took part in scientific expeditions to Brazil, the Rocky Mountains and Florida 1865-69; was chief of the scientific party accompanying the Northern Pacific Railroad survey 1873, and curator of vertebrate zoology in the American Museum of Natural History, New York, since 1885. He is author of 'Monographs of North American Rodentia' (with E. Coues, 1877); 'History of North American Pinnipedia' (1880); editor of Bulletin of Nuttall Ornithological Club (1876-89); and of its successor, The Auk (1884-1901). Bulletin and Memoirs of the American Museum of Natural History (1889-1905). He has written also 'Mammals of Patagonia' (1905) and 'Ontogenetic and Other Variations in Muskrat' (1913).

**ALLEN, Sir John Campbell, Canadian jurist:** b. Kingslear, N. B., October 1817; d. Fredericton, N. B., 27 Sept. 1898. He was member of the New Brunswick house of assembly 1856-65; solicitor-general 1856-57; speaker 1863-65; attorney-general 1865. He opposed confederation. He was chief justice of the Supreme Court of New Brunswick 1875-96, and was knighted in 1889. His 'Law Reports' (6 vols.) is a standard of the Supreme Court and acts of assembly relating to the practice of the courts are ranked highly.

**ALLEN, John Romilly, English civil engineer and archaeologist:** b. London, 9 June 1847; d. 5 July 1907. Educated at Rugby and King's College, London, he became resident engineer to Baron de Reuter's Penzance railway and on the construction of docks at Leith and at Boston, Lincolnshire; was lecturer on archaeology at Edinburgh University. His books are 'Design and Construction of Dock Walls' (1876); 'Early Christian Symbolism in Great Britain' (1890); 'Monumental History of the Early British Church' (1889); 'Early Christian Monuments of Scotland' (1903); 'Celtic Art in Pagan and Christian Times' (1904).

**ALLEN, Joseph Henry, Unitarian clergyman and author:** b. Northborough, Mass., 21 Aug. 1821; d. Cambridge, Mass., 20 March 1898. He was graduated at Harvard 1840. He was for a time the principal of a denominational school 1843 and filled pastorate at Northborough, Roxbury, Mass., Washington, D. C., Bangor, Me., and other places till 1878. For 12 years he was editor of the Christian Examiner. He was also lecturer on ecclesiastical history at Harvard 1878-82, editor of the Unitarian Review 1887-98 and a prolific writer on religious and philosophical subjects. His chief works are: 'Ten Discourses on Orthodoxy' (1849); 'Hebrew Men and Times' (1861); 'Christian History in the Three Great Periods' (3 vols., 1880-82); 'Positive Religion' (1892); 'Unitarianism Since the Reformation' (1894); translations of Renan's 'Anti-Christ,' 'Origins of Christianity,' and 'History of the People of Israel.' A Latin grammar and other schoolbooks, prepared in collaboration with Prof. J. B. Greenough, were extensively used.

**ALLEN, Karl Ferdinand, Danish historian:** b. Copenhagen, 23 April 1811; d. there, 27 Dec. 1871. He became professor of history and northern archaeology at the University of Copenhagen in 1862. His principal works are 'Handbook of the History of Denmark' (1840), very democratic in tone, and 'History of the Three Northern Kingdoms' (1864-72).

**ALLEN, Richard, preacher:** b. 1760; d. Philadelphia, 26 March 1831. He organized the first church for colored people in the United States and was elected first bishop of the African Methodist Episcopal Church, 1816.

**ALLEN, Robert, American soldier:** b. Ohio about 1815; d. Geneva, Switzerland, 1886. Graduating at West Point in 1836, he was second lieutenant in the Seminole war, assistant quartermaster in the Mexican war, brevetted major for conduct at Cerro Gordo and was in the battles that led to the capture of the City of Mexico. Appointed colonel of the Second Artillery, he was transferred to Missouri at the outbreak of the Civil War, with headquarters in St. Louis, in charge of supplies and transportation for armies in the Mississippi Valley. Appointed colonel of the Fifty-first Artillery in 1862, brigadier-general of volunteers 1863, brevet brigadier-general in the regular army 1864, brevet major-general 1865. From November 1863 to 1866 he was chief quartermaster
of the Mississippi Valley with headquarters at Louisville, outfitted Sherman's march across Tennessee, Chattanooga and the Kentucky, Virginia and North Carolina expeditions. After serving a second time as chief quartermaster of the Pacific division he was retired in 1878.

ALLEN, Thomas, American landscape and animal painter: b. St. Louis, 19 Oct. 1849. He studied at Washington University, graduated at Royal Academy of Dusseldorf and studied in France three years. Has frequently exhibited at the Paris salons and was a judge of awards at the World's Fair, Chicago 1893. He was chairman of the International Jury of Awards at the Louisiana Purchase Exposition 1904, president of the International Jury at St. Louis in 1909 and in 1910 he became chairman of the Art Commission of the city of Boston.

ALLEN, Viola, American actress: b. Alabama, 27 Oct. 1867. She made her début at the age of 15 at Madison Square Theatre, N. Y., in 'Esmeralda.' She has played leading classical, Shakespearean and comedy roles. Between 1893-1900 she created and played parts in 'Sowing the Wind,' 'The Masqueraders,' 'Under the Red Robe,' and starred in Hall Caine's 'Christian,' F. M. Crawford's 'The Palace of the King,' Hall Caine's 'The Eternal City' (1902). Shakespearean roles (1903-05). Among her best known Shakespearean roles are 'Cymbeline' (1906); 'Twelfth Night,' 'A Winter's Tale,' 'As You Like It.' Consult Strang, L. C., 'Famous Actresses of the Day in America' (Boston 1899).

ALLEN, William, Cardinal, English ecclesiastic: b. Lancashire 1532; d. at Rome, 16 Oct. 1594. He studied at Oxford and was Fellow of Oriel College but owing to the persecution of Catholics under Queen Elizabeth he left England, and in 1568 he founded an English College at Douay, where aspirants to the priesthood might obtain the instruction denied to them at home. During the first five years of its existence, this college trained and sent back to England over 100 priests. Another of his claims to the gratitude of English-speaking Catholics is that while professor at Douay, in collaboration with Gregory Martins and Richard Bristow, he translated the Bible from the Latin Vulgate into English. This translation is known as the Douay Bible and is the one generally used by Catholics in England and America. He published 10 volumes, chief among which is 'Certain Brief Reasons Concerning Catholic Faith' (1564).

ALLEN, William, American public official: b. Edenton, N. C., 1806; d. 11 July 1879. He studied law at Chillicothe, Ohio, was admitted to the bar in 1824, and in three years had become noted as a coming leader. In 1832 he was elected (Democratic) member of Congress by one vote, the youngest member of the 22d Congress. He was a leading champion of his party; took an active part in the 1836 canvass for Van Buren, and was given the United States senatorship by the Democrats at the earliest age of any senator before or since. He was re-elected in 1843, and in 1848 was tendered the nomination for the Presidency by the supporters of both Cass and Van Buren, but refused from loyalty to Cass. After the expiration of his term Mr. Allen took no further part in public life for nearly a quarter of a century, till 1873 when he was elected governor of Ohio; again nominated in 1875 as a *rag-money* candidate, he was defeated by Rutherford B. Hayes. His stentorian voice gave him the congressional nickname of the "Ohio Gong," and he is credited with the famous slogan of the campaign of 1844 on the question of the northwestern boundary, "Fifty-four forty or fight.*

ALLEN, William Francis, historian and essayist: b. Northborough, Mass., 5 Sept. 1830; d. 9 Dec. 1889. He was graduated at Harvard in 1851; studied at Berlin, Göttingen and Rome, 1854-56; was professor of Latin and history in the University of Wisconsin 1867-89 and is noted as a scholar of wide and varied attainments, equally strong in the linguistic, historical and archaeological sides of his subjects. A list of his writing covers 45 volumes. Three of especial interest may be found in the Transactions of the American Philological Association for the years given: 'The Battle of Mons Graupius' (1880); 'Lex Curiata de Imperio' (1888); 'The Monetary Crisis in Rome A.D. 33' (1887).

ALLEN, William Henry, American naval officer: b. Providence, R. I., 1784; d. 1813. He entered the navy in 1800 and served in some of the greatest naval battles in American history. For bravery displayed on the Chesapeake and United States he was made commander of the brig Argus in June 1813. He did great damage to English commerce in the Irish Channel, capturing in a month 27 ships. In a few days the Argus was taken by the English brig Pelican. In the battle Allen was shot, died soon afterward and was buried with military honors in Plymouth, England.

ALLEN, Zachariah, American inventor: b. Providence, R. I., 15 Sept. 1795; d. 17 March 1882. He was graduated at Brown in 1813, and was admitted to the bar in 1815, but soon turned his attention to manufacturing. He traveled in Europe 1825, to study manufacturing methods, and on his return published the 'Practical Tourist.' He invented in 1821 the first hot-air furnace for household use; in 1833 the automatic cut-off valve for steam engines; and later an improved fire engine, extension rollers and a storage system for water-power. He first suggested the system of mutual mill insurance, and drafted laws to regulate the sale of explosive oils. He was the first to compute the motive power of Niagara. He was a member from 1822 and president from 1880 of the Rhode Island Historical Society. He published 'The Science of Mankind' (1829); 'Philosophy of the Mechanics of Nature' (1851); 'Solar Light and Heat, the Source and Supply' (1879); etc.

ALLEN-A-DALE, the friend and confidant of Robin Hood in the Robin Hood ballads.
ALLENBY, Sir Edmund Henry Hynman, K.C.B., English soldier: b. 23 April 1861. He entered the Inniskilling Dragoons and served with the Bechuanaland Expedition in 1884-85 and the Boer War with great distinction throughout the whole South African War 1899-1902 in command of cavalry operations: commanded the 5th Royal Irish Lancers 1902-05, and the 4th Cavalry Brigade from 1905 to 1910. From 1910 till 1914 he was inspector of cavalry. He accompanied the first British Expeditionary Force to France in the European War and commanded the cavalry division in the great retreat from Mons. He was specially mentioned by Sir John French for his skilful handling of the troops. He was promoted to lieutenant-general in January 1916; fought at the battle of the Somme; was promoted to general in June 1917 and transferred to Mesopotamia to co-operate with General Maude in Iraq. On 31 Dec. 1917, he took Jerusalem from the Turks, and on 21 Feb. 1918 he also captured Jericho. See War, European; Mesopotamia Campaign.

ALENITHE. See Allen, Henry.

ALLENSTEIN, əl'-ən-stən', Germany, town of East Prussia, on the river Alle, 30 miles from the Russian frontier and 100 miles by rail northeast of Thorn. It is a fortified garrison town, and has manufactures of iron, machinery, stoves, matches, barrels, etc., and an active trade in grain and lumber. An important railway junction, an airship station, it was the headquarters of the 20th German Army Corps during World War I. From the first invasion in August 1914, it was occupied by the Russians, who, however, were compelled to retire a few days later. Pop. 33,000.

ALLENTOWN, Pa., city and county-seat of Lehigh County, on the Lehigh Valley, Central of New Jersey, Philadelphia and Reading and the Pennsylvania railways and the Lehigh Canal, 92 miles west of New York City, 55 miles north of Philadelphia and 98 miles east of Harrisburg. The commercial and industrial metropolis of the Lehigh Valley, covering an area of six square miles, Allentown is well built on a plateau sloping toward the confluence of the Lehigh, Little Lehigh and Jordan rivers, and is the centre of three great trolley systems, touching every important city, town and village within a radius of 30 miles, and extending to a two-hour connection to Philadelphia. The power plants, car barns and machine shops of one transit company alone represent an investment of over $1,350,000. Nearly 600 diversified industries find a home in Lehigh Valley, silk, furnishing, shoes, cigars, hosiery, dyeing, automobile, wire, cement blocks, brick, clothing, lumber, automobile fire engines, etc. According to the special census of manufactures for the year 1914, there were 297 establishments of factory grade, employing 15,912 persons, of whom 13,685 were wage earners, receiving a total of $6,501,000 in wages. The aggregate of capital employed amounted to $28,716,000, and the value of the output was $33,918,000; of this, the value added by manufacture was $13,213,000. These figures show an increase of 29 per cent since 1900. Besides the local industries, Allentown is commercially interested in the 18 cement companies with 34 mills in the Lehigh district employing 12,000 men. They average an annual output of 25,000,000 barrels or about one-third of the total product of the United States. Within a 30-minute trolley ride is the $50,000,000 plant of the Bethlehem Steel Company, employing among its 12,000 men, from 1,000 to 1,200 skilled mechanics from Allentown. Allentown ranks second only to Paterson in the United States for the manufacture of silk. Here is held annually with a four-day attendance of 200,000, the "Great Allentown Fair," the greatest county fair in the United States. The large court house, fine hospital, free public library, many of the handsome churches, hotels, elegant banking institutions, spacious prison, and other public buildings, are of hewn limestone. The numerous educational buildings, 22 public schools, one open-air school, five colleges, include Muhlenberg College, a Lutheran institution founded in 1867, and the Allentown College for Women. Allentown maintains parks, well-kept playgrounds, an abundant pure spring water supply, pumped direct from the spring to the home with a daily flow of 12,000,000 gallons; a street main supply of steam heat; an unlimited supply of electric power for manufacturing purposes and for its brilliantly illuminated streets, mercantile establishments, and homes; and a motorized fire department. A concrete bridge which cost $500,000 connects a rapidly growing section. By legislative enactment effective Dec. 1913, the city is governed by a commission council of five members, including the mayor. The city's annual income averages $750,000.

Allentown was founded in 1762 by William Allen, Esq., Chief Justice of the Province of Pennsylvania, father-in-law of Governor John Penn, and a great friend of the Penn family from whom he derived his grants of land, and named Allentown in honor of his founder. Here, during the Revolution, the Liberty Bell, the bells now in Christ Church, and St. Peter's, Philadelphia, were concealed by the Americans; and here, in 1799, John Fries (q.v.), of "Fries Rebellion" notoriety, fomented the German opposition to the "window tax." First inhabited by 13 German families and by the influence of the neighborhood townships for several years from the different post routes, it remained unprogressive until, in 1811, by the division of Northampton County, it became the seat of justice of Lehigh County, and by the act of the legislature passed 18 March 1811, was incorporated as Northampton borough with a population of about 800. With its advance to the rank of a county-seat, the town improved rapidly, and its accessibility to deposits of lime- stone, iron ore, anthracite coal, slate, zinc, cement, etc., added to its increasing importance in trade and wealth. An additional supply, one of its chief drawbacks, was removed in 1828 by the organization of a municipal water-works plant. In 1838 the original name of the town was restored, and in 1847 it re-ceived a special charter. Pop. (1910) 51,913; (1916) 65,000 — including suburbs, 150,000. Consult Roberts, C. H., and others, 'History of Lehigh County' (3 vols., Allentown 1914).

ALLEPPI, a-li-pē', or ALLAPALAY, a-li-pā'-lā, India, seaport town of Travancore State, Madras, 32 miles south of Cochin. Its fine harbor facilitates a large export trade in
coffee, cacao-nuts, pepper, cardamoms, and local manufacturers of coir matting. Pop. 25,000.

ALLERTON, Isaac, one of the Pilgrim Fathers. b. England, about 1635. d. New Haven, Conn., 1659. He was one of the most influential members of the Plymouth Colony, but on account of some disagreement with his associates he removed to New Amsterdam in 1631, and later to New Haven. Mary Allerton, his daughter, was the latest survivor of the original Mayflower company.

ALLIACEOUS PLANTS. See Allium.

ALLIANCE, Neb., city and county-seat of Box Butte County, 350 miles northwest of Lincoln, on the Chicago, Burlington and Quincy Railroad. Stock-raising and butter-curing are its chief industries. The electric lighting plant and waterworks are the property of the municipality. Pop. 4,000.

ALLIANCE, Ohio, a city of Stark County, 56 miles southeast of Cleveland, an important railroad centre for the Lake Shore and Michigan Southern, Pittsburg, Fort Wayne and Chicago, Alliance, Nilex and Ashatabula, Cleveland and Pittsburg railways and their interurban lines. Located in a fertile grain-growing region on the Mahoning River 1,000 feet above the sea and 500 feet above the level of Lake Erie, close to coal mines and an unlimited supply of natural gas, Alliance's leading industries are electric overhead cranes, heavy machinery, structural iron, boilers, brass, bronze and copper goods, steel foundries, overalls, flour mills, cash registers, agricultural implements, pipe organs, rubber goods, auto tires, auto jacks, electric furnaces, hollow tile, cattle feed, butter and cheese. The United States census of 1914 recorded 52 manufacturing establishments of factory grade, employing 2,806 persons, of whom 2,333 were wage earners receiving $1,617,000 in wages. The aggregate capital engaged was $8,665,000, and the output was valued at $7,175,000; of this, $3,519,000 was added by manufacture. These figures show an increase of 17 per cent since 1909. It has an annual bank clearing averaging $26,700,000 and annual unprecedented of $8,600,000. Among its public buildings are the city hall, Mount Union College, Carnegie library, the Y. M. C. A. institution and numerous church edifices, including those of German, Greek Catholic and Roman Catholic faiths. The city is administered by a mayor elected biennially, seven councilmen, a director of public safety and a director of public service. The annual receipts average $491,600: expenditures, $405,000. The city owns its water-works plant. Alliance dates from a settlement of 1838 named Freedom; it was renamed Alliance in 1831, was incorporated as a village in 1854 and received a city charter in 1888. Pop. (1910) 15,083; (1916) 22,600.

ALLIANCE ISRAELITE UNIVERSALE. See Jews and Judaism—Alliance Israelite Universelle.

ALLIANCE, OR THE REFORMED CHURCH HOLDING THE PRESBYTERIAN SYSTEM, a voluntary organization popularly styled the Presbyterian Alliance, formed in London in 1875. Its councils have much moral significance but possess no legisla-}
{T}
alliance, different interpretations and controversy may arise. Under the terms of the Triple Alliance, for instance, Italy was pledged to support Austria if that country were attacked. Austria, however, made war on Serbia, which the Italian government regarded as an aggressive, and not defensive, act, and therefore claimed that the casus foederis did not arise.

Separate articles are devoted to Dual Alliance, Grand Alliance, Holy Alliance, Quadruple Alliance, and Triple Alliance (all of which see). An alliance (the Dual) was started in 1893 between France and Russia and definitely established in 1897. In 1903 it was initiated the so-called Entente Cordiale between France and Great Britain, which became definite in 1905 after the Anglo-French Convention of 1904, by which were settled all the outstanding disputes between the two countries regarding Egypt, Morocco, and the Newfoundland Fisheries. The Anglo-Russian Agreement of 1907 similarly settled disputes between those two countries, and the Entente developed into the Triple Entente of Great Britain, France and Russia. Just after Germany had declared war on Russia in 1914, Sir Edward (now Viscount) Grey informed the House of Commons (3 August) that "The Triple Entente was not an alliance; it was a diplomatic group... up till yesterday no promise of anything more than diplomatic support was given... We are not parties to the Franco-Russian Alliance. We do not even know the terms of it." After the Moroccon crisis in 1911 Sir Edward Grey had written to the French Ambassador (22 Nov. 1912) to the following effect: "I agree that, if either government had grave reason to expect an unprovoked attack by a third Power or some power which threatens the general peace, it should immediately discuss with the other whether both governments should act together to prevent aggression and to preserve peace, and, if so, what measures they would be prepared to take in common."

The Anglo-Japanese Alliance dates from 1902; it was renewed in 1905 and revised in 1911. The objects aimed at in the treaty are the maintenance of peace in eastern Asia and India; the preservation of the independence and integrity of China with the "open door"; and the maintenance of the territorial rights and the defense of the special interests of the contracting powers in the Far East. It is also provided that if by reason of unprovoked attack or aggressive action, wherever arising, on the part of any other power or powers, either party should be involved in war in defense of its territorial rights or special interests, the other party will at once come to the assistance of its ally, and will conduct the war in common, and make peace in mutual agreement with it. This agreement was modified in 1911, mainly by the addition of a new article providing that "should either party conclude a treaty of general arbitration with a third Power, it is agreed that nothing in this agreement shall entail upon such party an obligation to go to war with the Power with whom such treaty has been made." This agreement as to arbitration had in view the Anglo-American unlimited Arbitration Treaty signed in 1911, but not ratified by the Senate (see below).

The Anglo-Portuguese Alliance has a remarkable history. On 23 Feb. 1916 Portugal seized 36 German and Austrian merchant ships interned in her ports. Germany declared war on 10 March 1916. The Portuguese Minister in Washington, Viscome de Alte, stated that his country's entrance into the war was in fulfillment of a treaty obligation entered into between England and Portugal on 16 June 1373, of 543 years ago. The friendly relations which Henry II of England (d. 1189) had established with the princes of the Iberian Peninsula made the few dealings between the early Portuguese monarchs and the English court of a generally amicable nature. The treaty in question was concluded between Edward III and Ferdinand of Portugal, and provided that Portugal should join England (there was no "Great Britain" then), in warfare when called upon to do so. A commercial treaty was concluded with England in 1645 and renewed in 1652. These treaties had never been broken through the centuries. Again, in 1898, treaties were published in which neither party will help another nation in attacking the other party, and in case of war or invasion both powers agreed to assist each other when required.

In September 1914 was concluded the Anglo-American Treaty by which the contracting powers agree that "all disputes between them, of every nature whatsoever, other than disputes the settlement of which is provided for and in fact achieved under existing agreements... shall, when diplomatic methods of adjustment have failed, be referred for investigation and report to a Permanent International Commission... and they agree not to declare war or begin hostilities during such investigation and before the report is submitted."

In September 1914 the Allied Powers, Great Britain, France and Russia, signed a declaration that they would not conclude peace separately, and that no one of the Allies would demand conditions of peace without the previous agreement of each of the other Allies. Japan and Italy subsequently gave their full and complete adherence to this treaty of alliance (November 1915).

ALLIBONE, Samuel Austin, American bibliographer and librarian: b. Philadelphia, 17 April 1816; d. Lucerne, Switzerland, 2 Sept. 1889. For a time he engaged in mercantile pursuits; was book-editor of the American Sunday-School Union, 1867-73 and 1877-79; and in 1879 was appointed librarian of the Lenox Library, New York. He is best known by his 'Critical Dictionary of English Literature and British and American Authors' (3 vols., 1854-71), a monumental work that cost him 20 years of labor. It contains notices of 46,499 authors, with extracts from reviews of their works, and 40 classified indexes of subjects. It is an indispensable reference work for libraries and students. A supplement containing over 37,000 authors, by John Foster Kirk, appeared in two volumes, 1891. Others of Allibone's works are 'Poetical Quotations from Chaucer to Tennyson' (1873), containing 13,600 passages from 330 authors; 'Prose Quotations from Socrates to Macaulay' (1876), with indexes to the 8,810 quotations, and containing the
names of 544 authors and 571 subjects; 'Explanatory Questions on the Gospels and the Acts (1869); 'An Alphabetical Index to the New Testament' (1868); 'Indexes to Edward Everett's 'Orations and Speeches' (1859); 'Great Authors of All Ages: Selections' (1880). New editions of the 'Prose Quotations' and the 'Poetical Quotations' appeared in 1893 and 1891 respectively.

ALLICE, or ALLIS (Fr. alose, from Lat. alausa), the larger European shad (Alosa vulgata), about 20 inches long. There is but one other shad in Europe, the twaite. In the Rhine valleys both are called maîèisch. See SHAD; TWAIT.

ALLIED WAR COMMISSIONS TO THE UNITED STATES. Beginning in April 1917, a succession of conferences took place in the United States, the main objects of which were to coordinate the efforts of Entente Allies and of the United States and to discuss the conduct of the war in Europe. The chief commissioners entrusted by their respective governments with such important duties were men of high distinction and ability; their deliberations at Washington were supplemented by visits to many other cities; everywhere the commissioners were received with cordial demonstrations of enthusiasm; during the long voyages and land journeys no serious mishap occurred; and, finally, the results attained were pronounced both satisfactory in their immediate effect and of far-reaching importance for the future.

The first commissions to reach the United States were those from Great Britain and France. The British mission was composed of the Rt. Hon. Arthur James Balfour, foreign minister; Sir Eric Drummond; Ian Malcom, member of Parliament; C. F. Dormer and G. Butler, personal staff; Rear-Admiral Sir Dudley R. S. de Chair; Fleet Paymaster Vincent Lawford; Rear-Admiral Bridges; Capt. H. H. Spennder-Clay and Lord Cunliffe, governor of the Bank of England. In addition to the foregoing, James H. Thomas and Charles W. Bowerman, members of the House of Commons, were sent by the Premier Lloyd-George to explain in detail the measures taken in Great Britain to solidify the labor resources. The personnel of the French mission was announced 18 April as follows: M. Viviani (Réné Viviani), former premier and minister of justice; Marshal Joffre; Vice-Admiral Choceprat; Marquis de Chambrun, member of the Chamber of Deputies. Attached to the French mission were: M. Simon, inspector of finances; M. Hovelaque, inspector-general of public instruction. Members of Marshal Joffre's staff were: Lieutenant-Colonel Fabry, Lieutenant-Colonel Remond, Commandant Requin, Lieutenant de Tessan and Major Dreyfus. The British commissioners left England 11 April on a fast cruise; arrived at Halifax 20 April; at the Canadian town of McAdam's were welcomed by the American reception committee, headed by Assistant Secretary of State Long, Rear-Admiral Fletcher and Major-General Wood; and on 22 April arrived in Washington. The French mission crossed on a steamship of the French Line which was conveyed across the Atlantic. The arrival of the commissioners was announced 24 April. A permanent technical French commission to the United States which arrived in Washington 16 May had as its chief Capt. André Tardieu, French deputy and publicist, and its membership included several of the most eminent scholars of France. Six members of the Italian war commission arrived in New York 9 May, the other members arriving later in the month. The Italian envos were: Prince Ferdinand of Savoy (Prince of Udine, cousin of King Victor Emmanuel); Senator Guglielmo Marconi inventor of wireless telegraphy; Marquis Luigi Borsarelli di Riva, secretary of foreign affairs; Deputi Ciufelli, member of the Council of State and former minister of public instruction; Deputi Nitti, former minister of agriculture; Enrico Arlotta, financier and minister of maritime and railway transportation in the Italian cabinet; General Gugliemo Motto, representing the army; Commander Vannutelli, representing the navy; Aloisio Bradamani, of the transportation department; Cavalier G. Pardo, of the department of industry and commerce; and Cavalier G. Pietra, ambassador of the agricultural department. The departure of the French envoy was kept secret. They sailed from New York 15 May on the same steamer which brought them over; were conveyed by a French warship and reached Brest 25 May. The British envoy, after six weeks of conferences, crossed into Canada 25 May; and on 11 June Lord Northcliffe arrived in the United States, having been appointed as Mr. Balfour's successor in the American phase of war measures initiated by the British mission. On 16 June the Belgian mission arrived. Its members were: Baron Moncheur, formerly Belgian minister to Washington; Maj.-Gen. Mathieu G. A. Leclercq; Count Louis D'Urse; Maj. Leon Osterrieth, formerly military attaché of the Belgian legation at Petrograd; and Hector Carlier, bank expert of international reputation. When greeting this mission, 18 June, President Wilson expressed America's solemn determination that on the inevitable day of victory Belgium shall be restored to the place she has so richly won among the self-respecting and respected nations of the earth. On 19 June the Russian mission reached Washington. The members of this special embassy, in the order of their rank, were: Ambassador Boris A. Bakhmetieff; Lieutenant-General Roop, representative of the Russian army; Professor Lomonosoff, member of the Council of Engineers and representative of the ministry; Professor Borodine, representative of the ministry of agriculture; M. Nivotzy, representative of the ministry of finance; M. Soukine, first secretary of legation, ministry of foreign affairs; Captain Dubassoff of the guard, aide-de-camp; and Captain Chutt. Less than one month afterward the Japanese commission reached the Pacific coast of the United States. The chief envoy was Viscount Kikujiro Ishii, formerly the foreign minister of the Japanese government. One member of the commission were: Vice-Admiral Isa Tashita, formerly naval attaché of the Japanese embassy at Washington; Maj.-Gen. Shoichi Sugano; Matsuzo Nagai, secretary to the foreign department; Capt. Shokyo Ando; Maj. Tazaki. The American secretaries were: recognizing the importance of the question, the commission concluded with the words:
ALLIER—ALLIGATOR

"Let us see together with a clearer vision the pitfalls dug by a cunning enemy in our path; let us [the United States and Japan] together decide on the means which shall lead us together most surely to a participation in the triumph of the right, to a certain victory in the greatest and, let us hope, the last great war in human history. And when that victory shall have been won, let us together build the edifice upon which shall rise, fair and strong and beautiful, from the ashes of the old." With the arrival of the Japanese commission in Washington, 22 August, and its subsequent visits to New York and other cities of the eastern seaboard, the series of conferences which we are recording reached the point at which initial gains in the international arrangements for co-ordination of the efforts of the principal Entente Allies may be noted. The measures actually adopted, or tentatively decided upon included: The granting of huge loans to the Allies; the sending of troops of the United States (in the first instance a division of regulars, with a regiment of marines and nine regiments of engineers, under the command of Major-General Pershing) for service in France; adherence to and full cooperation with the British blockade system; the expediting of the American ship-building program, and the turning over of seized German ships to France, Italy and Russia; the provision made for a system of joint food-control with the Allies; the diplomatic arrangements for the granting to the Allies of preferential treatment in commerce and for harmonious action in many specified matters of international importance, including, ultimately, policies and developments relating to the Pacific as well as to the Atlantic. During the summer and autumn of 1917 the United States also received visits from commissions representing the neutral nations, Norway, Switzerland, Holland, as well as those representing belligerent nations identified with the cause of the Entente Allies, rather as participants than as leaders. In January 1918 the Serbian commission visited Washington and other cities, and was well received.

ALLIER, à l’et-à, France, a central department intersected by the river Allier and partly bounded by the Loire; surface diversified by off-shoots of theChevreuse and other ranges, rising in the south to over 4,000 feet and in general richly wooded. It has extensive beds of coal as well as other minerals, which are actively worked, there being several flourishing centres of mining and manufacturing enterprise; mineral waters at Vichy, Bourbon, L’Archambault, etc. Large numbers of sheep and cattle are bred. Area, 2,882 miles. Capital, Moulins. Pop. 500,000.

ALLIER, a river of France, tributary of the Loire, rising in the department of Lozère and flowing northward about 200 miles through Lozère, Upper Loire, Puy de Dôme and Allier.

ALLIGATOR, the name of a genus of crocodilian reptiles derived from a corruption of the Spanish el lagarto, "lizard," from the Latin lacertus, a lizard. Alligators differ from crocodiles mainly in having relatively short and broad snouts and by the circumstance that as a rule the first and fourth teeth on each side of the lower jaw enter into pits in the upper jaw, whereas those of crocodiles slide outside of the jaw and are visible. The caymans of South America may be included in the general term. These reptiles are confined mainly to the rivers of the New World, on which they typically represent the crocodiles of the eastern hemisphere, but there is one species in China (Alligator sinensis) first made known in 1859, and resembling the South American species. The best-known of the Alligator is the Alligator of the Southern States (Alligator mississippiensis); the cayman of Surinam and Guiana (A. palpebrosum), and the spectacled alligator (A. sclerops), found in Brazil. In the water a full-grown alligator is a formidable animal, on account of its great size and strength. These reptiles swim with wonderful celerity, impelled by their long, laterally-compressed and powerful tails. On land their motions are proportionally slow and embarrassed, owing to their weight, the shortness of their legs and generally unwieldy proportions. It grows to the length of 15 or possibly 20 feet, and is covered above by a dense armor of horny scales.

Under the throat of this animal are two openings or pores, the excretory ducts from glands which pour out a strong, musky fluid, giving the alligator a peculiarly unpleasant smell. In the spring of the year, when the males are under the excitement of the sexual propensity, they frequently utter a loud roar, which, from its harshness and reverberation, resembles distant thunder, especially when numbers are at the same time engaged. At this period frequent and terrible battles take place between the males, which terminate in the discomfiture and retreat of one of the parties. The females make their nests in a curious manner, on the banks of rivers or lagoons, generally in the marshes, along which, at a short distance from the water, the nests are arranged somewhat like an encampment. They are obtuse cones four feet high and about four feet in diameter at the base, built of mud and grass. A floor of such mortar is first spread upon the ground, on which a layer of eggs, having hard shells and larger than those of a common hen, are deposited. Upon these another layer of mortar, seven or eight inches in thickness, is spread, and then another bed of eggs; and this is repeated nearly to the top. From 100 to 200 eggs may be found in one nest. It is not ascertained whether each female watches her own nest exclusively or attends to more than her own brood. It is unquestionable, however, that the females keep near the nests and take the young under their vigilant care as soon as they are hatched, defending them with great perseverance and courage. The young may be seen following the mother through the water like a brood of chickens following a hen. When basking in the sun on shore, the young are heard whining and yelling about the mother, not unlike young puppies. In situations where alligators are not exposed to much disturbance the sites of the nests appear to be very much frequented, as the grass and reeds are beaten down for several acres around, where unchallenged, are very feeble and helpless, and are devoured by birds of prey, soft-shelled turtles, etc., as well as by the male alligators, until they grow old enough to defend themselves. As the eggs are also eagerly sought by vultures and
other animals the race would speedily become extinct but for the great fecundity of the females.

The alligator is generally considered as disposed to retire from mankind but is only when they are frequently disturbed. In situations where they are seldom or never interrupted they have shown a ferocity and perseverance of the most alarming character in attacking individuals in boats, rear their heads from the water and opening their jaws in a threatening manner. At present alligators, though still numerous in the remote parts of Florida and Louisiana, are no longer regarded as very dangerous. Their numbers annually decrease and at no distant period they must be nearly, if not quite, exterminated. In the winter the alligators spend a great part of their time in deep holes, which they make in the marshy banks of rivers, etc. They feed on fishes, reptiles, small quadrupeds (dogs if they can get them) or carrion, and though very voracious are capable of existing a long time without food. Compare Crocodile; and see Cayman; Lacerta.

**ALLIGATOR-APPLE.** See Custard-Apple.

**ALLIGATOR-FISH,** one of the Agonidae, a family of fish whose slender bodies are armored by large bony plates. One species 12 inches long (*Podothenus acipenserinus*) is found on the northern Pacific coast.

**ALLIGATOR-GAR,** the immense greenish-colored gar (*Lepisosteus microdon*) found in the Southern States and southward through North America, and sometimes measuring 10 feet. See Gar.

**ALLIGATOR-LIZARD,** any member of the genus *Sce1oporus,* which, although iguanid, has many small species without the typical iguanid characteristics. They abound in Mexico and the southwestern United States, and one species (*Sce1oporus undulatus*) is the familiar "fence lizard" of the colder States. Though often inconspicuously colored on the back except for black crosslines, the throat and inferior surfaces are generally striking in color, and frequently there are light lines along the sides. They are often ignorantly called poisonous, but all are harmless.

**ALLIGATOR-PEAR, or AVOCADO,** a tree, *Persea gratissima,* of the family Lauraceae, indigenous to subtropical and tropical America and widely cultivated in warm countries: for its more or less pear-shaped, purple- or green-skinned fruits, each of which contains a single seed embedded in a yellowish-green edible marrow-like pulp. Wherever it grows the alligator-pear is highly prized as a salad and is usually served with pepper, salt and vinegar, or with wine and spice, but natives of temperate climates usually have to acquire a taste for it. It is rich in oil, which may be used in soap-making and in lighting. The seeds yield a black dye. Seedlings are easily raised and begin to bear in about five years if planted in good soil in warm places, but they are usually improved by budding from selected stock. Except in southern Florida and southern California the avocado-pear does not produce palatable fruit in the United States. The American market, therefore, which is limited to the larger cities, has been mainly supplied from Hawaii, Mexico and the West Indies. In recent years many trees have been planted in Florida and southern California, which have yielded a superior quality of fruit which is constantly finding a wider market. The fruit is sometimes called midshipman's butter and aquacate.

**ALLIGATOR-TERRAPIN,-TORTOISE,** or -TURTLE, the snapping-turtle; more particularly, a very large species (*Macrochelys temminckii*) which is eaten and esteemed as a delicacy in the lower valley of the Mississippi. It sometimes weighs 50 pounds.

**ALLINGHAM, William,** Irish poet; b. Ballyshannon, Ireland, 19 March 1824; d. Hampstead, 18 Nov. 1889. From 1846 to his retirement in 1870 he held various posts in the Irish customs service. He was sub-editor of *Fraser's Magazine,* 1870-74, when he succeeded James Anthony Froude as editor, and conducted it with ability until 1879. At its best Allingham's poetry is excellent, being simple, clear and graceful, and whether pathetic, sporting or descriptive is always characterized by delicate artistic expression, which is in the volume called "Day and Night Songs" (1854). "Laurence Bloomfield in Ireland" (1864), a long poem which has been called "the epic of Irish philanthropic landlordism," has a wealth of fine description, but was not a public success. Other volumes are "Poems" (1850), "The Ballad Book" (1864), "Songs, Ballads and Stories" (1877), "Collected Poetical Works" (6 vols., 1888-93).

**ALLISON, William Boyd,** American legislator: b. Perry, Ohio, 2 March 1829; d. 4 Aug. 1908. A farmer's son, he received his education at Allegheny College, Pennsylvania, and at Western Reserve College, Ohio. He practised law in his native State till 1857, when he removed to Dubuque, Iowa. A Republican and trusted local leader, he was sent as a delegate to the Republican national convention in Chicago in 1860, which nominated Lincoln. In the early part of the Civil War he served on the governor's staff, and was actively engaged in raising troops for the Union army. In 1863 he was elected to Congress and served by successive re-elections till 1869; on 4 March 1873 he was elected to the United States Senate, and was five times re-elected, in 1878, 1884, 1890, 1896 and 1904, his many years of service making him one of the oldest as he has always been one of the most influential leaders. He has served on many important committees; and as chairman of the finance committee in 1878 was the chief author of the bill that committee reported for the purchase of silver bullion, known as the Bland-Allison Act (see Bland-Silver Bill), a compromise from the free-coinage bill of Congressman Bland. He was repeatedly a strong candidate in Republican national conventions for the Presidency; and was offered the secretarship of the treasury by both Garfield and Harrison. In 1892 he was a representative of the United States at the Brussels Monetary Conference.

**ALLITERATION,** the succession or frequent occurrence of words beginning with the same consonant. In the older Scandinavian,
ALLIUM — ALLOGAMY

German and Anglo-Saxon poetry it served instead of rhyme. It is found in early English poetry with the same function. As thus used it had a certain regularity of accent and emphasis. In 'Piers Plowman' the line is constructed in two hemivirgules, the former with two words beginning with the alliterative letter, and the latter with one, thus:

"Her robe was full rich with red scarlet engreyned."

The poetry of widely separated nations exhibits this device, it being found both in India and in Finland. It still remains in Icelandic poetry. Early in the 17th century English writers ran to great extravagance in the use of alliteration, both in prose and poetry. It is said that preachers from their pulpits addressed their hearers as "chickens of the church" and "sweet swallows of salvation." No other device of composition so easily lends itself to fanciful conceits or ingenious trifling. The ease with which devices may be marshaled would hardly tend to make the ordinary reader appreciative of Churchill's description of himself as one

"Who often, but without success, had prayed For apt alliament's effectual aid.

But the couplet itself is a striking proof of its own truth, for it shows that the poet did not know what alliteration is: it must be of consonants, not vowels, and even so his a's are alike only to the eye, not the ear. All good poets have used it to lend musical beauty or emphasis to their verse, though it can be overused or misused. Following are a few from the chief American poets:

"And the spark struck out by that steed in his flight
Kindled the land into flame with its heat." — Longfellow.

"It carves the bow of beauty there,
And the ripples in rhymes the ear forsake." — Emerson.

"Of sealing winds, and naked woods." — Bryant.

"And dark! how clean! bold chaiticleer!
Warm'd with the new sun of the year." — Lowell.

"Stole with soft steps the shining stairway through." — Holmes.

"What a tale of terror now their turbulency tell!" — Poe.

"Across the woundful marbles play." — Whittier.

ALLIUM, a genus of about 300 perennial, rarely biennial, bulbous herbs of the family Liliaceae, mainly indigenous to the colder parts of the northern hemisphere. The leaves are generally long and narrow, often, however, cylindrical and hollow; the flowers in umbels, often with bulbs among them. Many of the species are economically important; for instance, Allium cepa, the onion; Allium sativum, garlic; Allium porrum, leek; Allium ascalonicum, shallot; Allium schoenoprasum, chives; Allium scorodoprasum, rocambole, each of which is treated separately under its common name. Several uncultivated members of the genus are also used as food in countries where they grow wild. Allium vineale, wild onion or wild garlic, a European species introduced into the United States, is a troublesome weed, especially in New England pastures, since it imparts a strong flavor of garlic to the milk of cows feeding upon it. (See Garlic.) Many species are natives of the United States, but none of them have been cultivated for food; some, however, are planted for ornament. Perhaps the most common eastern species are Allium cernuum, Allium canadense and Allium tricoccum, the last generally known as the wild leek, a broad-leaved species which grows in moist woods, from Maine to North Carolina and westward to Wisconsin. Some of the hardy species are grown for ornament in gardens; for example, Allium moly and Allium roseum, from Europe; Allium victoriae, from Siberia; Allium acuminatum, from the Western States. Others, especially Allium neapolitanum, a tender European species, are often grown in greenhouses.

ALLMERS, Hermann Ludwig, äl-
erss, här'man lü'tvik, German poet and author: b. Rechtenfleth, 11 Feb. 1821; d. 1902. His 'Idle Days in Rome' (1869; 9th ed. 1896) was widely read. Others are: 'Captain Böse' (1882); 'Fromm und Frei' (1889), a volume of religious poems; 'From an Old and Young Past Time' (1893); 'Collected Works' (6 vols., Oldenburg 1891-95). Consult Bräutigam, L., 'Der Marschendichter Hermann Almers' (1891).

AMMOUTH, a fish. See Goosefish.

ALLOA, äl'o, a river port of Scotland, on the north side of the Forth, five miles from Stirling, in the county of Clackmannan. It is irregularly built, but contains some good streets and buildings, including the parish church, the county court house, the town hall and the public baths. It carries on several manufactures, chief of which are ale, whisky, woolen yarn and bottles. There are some large collieries in the neighborhood. Alloa has an excellent harbor, from which it exports coal, ale and fire-brick, and imports timber, hemp, oak-bark, grain, etc. The river is here crossed by a viaduct of the North British Railway. There is an ancient tower in the vicinity, once the residence of the Erskine family. Pop. 17,200.

ALLOBROGES, the name of a people who lived in ancient Gallia Narbonensis and occupied the country below the Lake of Geneva and the Rhone, now included in Savoy and the French province of Dauphiné. They long struggled for their independence against the Romans, but were finally subjugated by Fabius Maximus.

ALLOCATION, an address, a term particularly applied to certain addresses made by the Pope to the cardinals.

ALLODIUM ("without vassalage"). Applied to lands, alodium, or alodial tenure, signifies an estate held by absolute ownership, without regarding any superior to whom any duty is due on account thereof. The title to land in the United States is essentially alodial, and every tenant in fee simple has an absolute and unqualified dominion over it; still, in technical language, his estate is said to be in fee, a term implying a feudal relation, although such a relation has ceased to exist in any form, while in many of the States of the Union the lands have been declared to be alodial.

ALLOGAMY, the transfer of the pollen of one flower to the pistil of another. When the pollinated flower is on the same plant the process is known as geitonogamy, and when on a different plant it is known as xenogamy.
Allogamy is the opposite of autogamy, or self-pollination. See Pollination.

ALLON, Henry, English Congregational clergyman: b. Welton, 13 Oct. 1818; d. London, 16 April 1892. He was educated at Chesterton College. From 1844 until his death he was minister of Union Chapel, Islington. He was chairman of the Congregational Union 1864 and 1881. He compiled a hymnbook widely used in his denomination. He also compiled and edited the popular work of the Life of Rev. James Sherman (London 1863). He edited the British Quarterly Review, 1865-87. His life has been written by his successor, W. H. Harwood.

ALLOPATHY. See Therapeutics.

ALLOPHANE, αλ-ό-fán'; from the Greek αλφός, "other," and φάνος, "appearing," in allusion to its change of appearance before the blowpipe, a native silicate of aluminum, having the formula Al₂SiO₃+H₂O, and occurring in thin, amorphous, brittle incrustations, with a hardness of 3. and a specific gravity of about 1.87. It is found in a great variety of colors, due to the presence of other minerals. In the United States it occurs in Massachusetts, Connecticut, Pennsylvania and Tennessee.

ALLORI, ál-ló-ré, a family of artists who flourished during the 16th century in Florence. The best of them was ANGELO (or Agnolo) DI COSIMO ALLORI (b. Monticelli, near Florence, about 1502; d. 1572). Like his nephew ALESSANDRO (b. Florence 1535; d. 1607), he was surnamed Bronzino, and both are more often spoken of by this name than by that of their family. The third Allori to attain eminence as a painter was the son of Alessandro — CRISTOFANO (1577-1621), who is also, though less frequently, referred to as Bronzino. Angelo studied mainly under Raffaello del Garbo and Jacopo Carrucci (Pontormo). The latter, greatly attached to his pupil, associated him in his work of painting some of his most important decorations, notably the ceiling of the Medici chapel of San Lorenzo, which Bronzino completed after Pontormo’s death. A friendship with Vasari, biographer of the Italian painters, was one of the factors of Bronzino’s coming under the influence of Michelangelo. He does not succumb to it to the extent that his nephew Alessandro did — the latter must be classed as one of Michelangelo’s imitators. Angelo, with all his classical study, preserved a racy force of observation that gives to his famous portraits of the Medici family, like the famous ‘Cosimo I’ in the Pitti Gallery, Florence, or better yet, those of the Panciatich family, their living appearance and their dignity. The fineness of his draughtsmanship — an example being the ‘Venus’ of the National Gallery, London — one of the high points of the later Florentine school, is stiffened and hardened by his nephew and pupil Alessandro, who marks the beginning of the rapid decline of the painting. In the hands of Cristofano it is little better than academic and sentimental. The ‘Judith’ in the Pitti Palace is the finest and best known work by Cristofano.

ALLOSARUS, an extinct carnivorous dinosaur of gigantic size, inhabiting North America during the Jurassic Period. It was one of the largest of flesh-eating animals, exceeding 30 feet in length, and comparable with an elephant in bulk. The animal was a biped with long hind legs, small fore legs not reaching the ground and long claws. The jaws are three feet long, with pointed, sharp-edged teeth, and the toes armed with large sharp claws, those of the fore foot being especially powerful. The hind feet somewhat resemble those of birds. Fossil skeletons of herbivorous dinosaurs from the same strata show deep scratches and scorings on the softer edges of the bone, and broken-off teeth of Allosaurus are very often found associated with them, showing that this animal preyed on the carcasses of his huge herbivorous companions. It was well adapted also by its teeth and claws to attack them when alive, and was probably their especial foe. See Dinosaur.

ALLOTROPY, a-lot-róp, or ALLOTROPISM (from the Greek allos, "another," and tropos, "manner"), the property exhibited by certain substances of existing in two or more different states distinguished, from each other by different properties. The most familiar case of allotropy is afforded by carbon, which exists in a number of allotropes, some of which charcoal, graphite, diamond, and fullerite are familiar examples. Allotropy is not exhibited by the metals to any marked degree (see, however, Silver). Sulphur exhibits many allotropic forms, of which the following are the best known: (1) it occurs in rhombic crystals, having a specific gravity of 2.07, melting at 235° F., and soluble in carbon disulphide; (2) in monoclinic crystals, having a specific gravity of 1.96, melting at 243° F., and soluble in carbon disulphide; (3) in an amorphous plastic state, insoluble in carbon disulphide; (4) if, immediately above its melting point it is thin, clear and amber-colored; (5) at about 400° F. it becomes thick and dark; and (6) at about 650° F. it is again thin, but remains dark.

Ozone is a familiar allotropic form of oxygen, produced when the silent electric discharge is allowed to act upon oxygen. It is known that the molecule of oxygen contains two atoms, and that the molecule of ozone contains three atoms. This suggests that allotropy, in all cases, refers to the number of atoms present in a molecule; but so little is known of the ultimate structure of solids and liquids that speculation of this sort is of no great value.

Most of the non-metallic elements have allotropic modifications, and remarkable cases of allotropy are observed among chemical compounds. In the case of a compound, two states of a substance having the same chemical composition are said to be isomeric when their constituents are combined by different modes of atomic linkage; and they are allotropic when the kind of atomic linkage is the same in both cases. See Isomerism.

ALLOUZE, á-lo-å', Claude, French Jesuit missionary and explorer: b. France 1620; d. near the St. John’s River, in the present State of Indiana, 1689. He is called the founder of Catholicity in the West. He preceded and was a coworker of Marquette. For 32 years he labored among the Indians. He preached to 20 different tribes and is said to have baptized 10,000 neophytes. He traveled over a wider territory than any of the missionaries of his day and reached the western end of Lake Superior.
Alloys

At times he had to prevent the Indians from adorning him as a god; at others, they were about to sacrifice him to their Mani- tou. Consult Parkman, 'La Salle.'

ALLOWAY, a parish of Scotland, now included in Ayr parish. Here Burns was born in 1759, and the "auld haunted kirk" near his home place was the scene of the dance of witches in 'Tam o' Shanter.'

ALLOXAN, a-lok'san, a substance produced by the action of dilute nitric acid upon uric acid, and having the formula C₆H₅N₂O₄. It is freely soluble in water and crystallizes in the triclinic system when a saturated solution is allowed to cool, and in monoclinic prisms when deposited by evaporation from a warm solution. It is converted into alloxanthin (C₆H₅N₂O₃) by the action of SnCl₃ and other reducing agents, and into alloxonic acid (C₆H₅NO₃) by the action of the fixed alkalies. Ammonia combines with it to form murexid, a substance that was used about the middle of the 19th century for dyeing silk and wool purple and red, but which was soon displaced by the aniline colors.

ALLOYS. In the commercial sense of the term an alloy is a combination of two or more metals melted together. In a scientific sense, however, the term has a restricted meaning. It signifies a chemical combination analogous to the common solution of a chemical salt in water; only, in the case of two metals in alloy, each is to be regarded as dissolved in the other. As an illustration of the conditions existing in an alloy let us consider a solution of common salt in water. In 100 parts of water at 65° F. common salt may be dissolved in any proportions from one part (or less) up to 26.4 parts — at which point the solution is said to be saturated. In every possible proportion between those limits the solution is entirely homogeneous. If more salt be added, it does not dissolve but remains in the solution as a mere mixture of salt with a solution of salt. In the case of a two-metal or binary alloy the two metals may be designated as A and B. The metal having the highest melting point is fused first, and the other is then added. Suppose B to be added to A in the liquid state. In the saturation point B dissolves freely in A. Beyond that point, if still more of B is added, a new combination will be found present in the alloy, namely, a solution of A in B. The alloy at that point is a mixture of the two solutions in varying proportions, depending upon the amount of B which has been added beyond the saturation point. With a still further addition of B a larger proportion of the solution A-in-B prevails in the alloy, and, continuing the process, the solution B-in-A disappears from the alloy, and it becomes a homogeneous solution of A in B.

These considerations relate to alloys in a molten state, at the temperature of the melting point of the most refractory constituent. As the temperature falls toward the point where the alloy becomes solid, several changes may be noted as taking place in its constitution, depending upon the proportions and conditions of solution of both A and B. The alloy A-in-B may separate out, generally in a crystalline form, or the alloy B-in-A may separate out. The condition of the mass is then one analogous to curdled milk. That combination of the two metals which has the lowest melting point is the last to solidify as the cooling continues, and this is called the eutectic of that alloy. But, in the process of cooling, other changes may have taken place. In the solution B-in-A B may have crystallized out if it was close to its saturation point, and a similar action may have occurred as to A-in-B. Further complexities arise from the fact that when an alloy has become solid it has not always become stable. With the lapse of time changes are continually taking place either toward greater stability on the one hand, or toward dissolution on the other. Some alloys give evidence of these changes within a brief period. Others show them only after several years. Much has been learned about the constitution of alloys with the microscope, but this form of research has been limited in practice to the temperatures which normally prevail. Attempts to use the microscope on hot alloys have so far proved unsuccessful. For microscopic work the face of a thin slice of the alloy is very carefully and gently polished, and it is then delicately etched with an appropriate acid which serves to reveal many of the details of internal constitution. (See METALLOGRAPHY.) Whether it has not been adequately determined whether the fusion and admixture of different metals takes place in some relation to their atomic proportions, or else in some other definite ratio, yet the composition of such alloys as dorc or electrum, which consists of variable proportions of gold and silver, as well the fact that, as a rule, alloys more readily melt than either of their constituent metals, are circumstances that have given rise to a widespread conviction or belief that nature really does combine them by some law which is as yet undiscovered. Among the many alloys whose density is less than the average density of their constituent metals may be mentioned gold with either silver, copper, iridium, nickel, iron or lead; silver with copper in which the antimony, bismuth or lead. Among those whose density is greater than the mean of their constituents is gold with antimony, bismuth, cobalt or zinc.

Another fact, and one of practical importance to the manufacturer, is that an alloy, when remelted, even if composed of only two metals, will not exhibit the same characteristics as at first. A malleable alloy may become brittle, a ductile alloy unworkable, etc. This metamorphism is even more marked when the remelted alloy is composed of several metals. The ordinary remedy employed for this defect is to add more raw metal; but this has to be done with great care as to proportions, which can only be ascertained by experiment. Skill in the remelting of scrap often constitutes a valuable trade secret, such as for a long period was the case with German silver, tombac, Jemmapes brass and other then popular alloys.

Fusion of metals to make an alloy is not the only method to produce a new material. Another method much in use, especially in the fine arts, is the electrolytic method. The metals to be combined are placed in the form of water solutions in the electrolyte and the current plates then in alloy upon the objects attached to the cathode. In this way jewelers produce the "red gold," "green gold," etc.
and "gold" of other intermediate tints in alloys of gold, silver and copper from an electrolytic bath. Other means of producing alloys are by pressure upon the mixed powders of the metals, or by the intimate mixtures of their vapors, but these are employed only in laboratory investigations. Gold and quicksilver will coalesce and form a natural alloy or amalgam at ordinary temperatures the moment they touch each other, a fact of the highest importance in gold mining. Discovery of this circumstance and its employment as the "amalgamation process" is commonly credited to a Spanish miner named Bartolomeo Medina of the 16th century (1557). In point of fact, it was known to the Arabs, Romans and Greeks, indeed is of the highest antiquity. It was commonly employed as a means of recovering gold from auriferous gravel or sand by the Arabian miners and metallurgists of the Middle Ages; the source whence, both the Spaniards and Portuguese got it. There exist unquestionable evidences of its employment in Spain and Portugal centuries before Medina's time. These evidences are brought together in a 'History of the Precious Metals' (New York 1929) p. 133, 134. Medina made a large claim on behalf of the Fuggers, who farmed and monopolized the Almaden quicksilver mines of Spain, and thus held the American gold and silver mines in subjection. The process which may have been used by Medina is the "pato processo," a complicated metallurgy, in which the amalgamation of gold and quicksilver plays but a subordinate part.

To Make a Metallic Alloy.— The first consideration is the temperature at which the metals will melt in the furnace. This is as follows for various metals, in degrees Centigrade: Mercury (quicksilver), — 39.4; phosphorus, 44; sulphur, 114.5; tin, 231.6; bismuth, 268.3; tellurium, 282; cadmium, 320; lead, 330 to 335; zinc, 419; arsenic, 450; antimony, 629.5; manganese, 1282; aluminium, 654.5; silver, 960.5; gold, 1061.7; copper, 1080.5; silicon, 1100 to 1300; nickel, 1400 to 1450; iron, 1550 to 1600; platinum, 1775, and manganese, 1800 to 1900. Ordinarily when the melting points of the constituents of the proposed alloy are nearly equal, the alloy is made by fusing first the metal which has the higher melting point and adding the other to the molten mass. When the melting points are widely apart a difficulty may be encountered in the vaporizing of one of the constituent metals at the fusing point of the other. In this case it becomes necessary to form preliminary alloys which are afterward combined. As an illustration, German silver may be instanced. This is an alloy of nickel, copper and zinc. The nickel melts at 1450°, at which temperature zinc would turn to vapor. So an alloy of nickel and copper is first made and then a brass of copper and zinc. The copper-nickel alloy has a much lower melting point than pure nickel and the brass has a higher melting point than zinc. These two preliminary alloys are then fused together without the loss of the zinc. Oxidation during the fusing process is a serious obstacle in producing some alloys. This may be obviated by the use of a flux, like borax; or by metallic deoxidizers, like powdered aluminium, which not only reduce the oxides but increase the fluidity of the mass and therefore the intimacy of the mixture. Great care is needed also in the pouring (casting) of the alloy at just the right temperature. If the heat be too great the structure will be coarse-grained; if the degree is too low the alloy is not fusible and liable to crystallize out and the ingot be unsound and crack under working. The rate at which the cooling after pouring is permitted to take place is also of prime importance. Slow cooling produces a weak alloy of coarse structure; quick cooling yields a strong alloy of fine-grained structure but inclined to be brittle. The molds employed must be of material suited to the prospective alloy. They are usually of iron, brass, iron and sand, sand and clay, or plaster of Paris. Most alloys are subjected to after-treatment with heat and cold, as in annealing, chilling, tempering, etc., and by mechanical processes, as hammering, rolling, etc. A remarkable circumstance concerning alloys is that a very small proportion of another element will often entirely alter the character of a metallic composition. One part of carbon in 2000 of iron will convert it into steel; the same minute proportion of tellurium in bismuth converts it into a finely crystalline metal; one part of gold in copper will make it hot-short; while the same almost negligible proportion of bismuth will destroy its usefulness for many purposes for which, when rid of this intrusion, it is eminently fitted.

The supreme importance of the alloys in the arts is apparent when it is considered that very little of the vast quantities of metal used in civilized life is the pure metal. Steel is an alloy of pure iron and carbon, and other metals are added in alloy to produce the higher grades of steel—chrome steel, manganese steel, nickel steel, tungsten steel, vanadium steel, etc.; cast iron is an alloy of pure iron with carbon, sulphur and phosphorus; commercial tin is an alloy of pure tin and lead; commercial gold and silver are alloys of these precious metals with others to add the required hardness to withstand wear; the brasses are alloys of copper and zinc; the bronzes are alloys of copper and tin, with other metals added; etc. Although many of these alloys have been long known, yet newer and oftentimes more valuable combinations of the same metals are daily discovered, which are better adapted than the older ones for the new uses which practical engineering and processes demand.

A beautiful and useful alloy, of gold 75 and aluminum 22, carrying a rich purple shade, is now employed in the manufacture of jewelry, which formerly consisted of a gold, silver and copper combination. An alloy of silver 25 and aluminum 75 furnishes a metal adapted for the manufacture of fine instruments, electric apparatus, dentists' tools, etc. It makes delicate castings and takes on a fine polish. The combinations with copper are more important.

Aluminum Bronze is a combination of copper 89 or 90, with aluminum 11 or 10 per cent. Although hard it is readily forgeable. It can be rolled into thin sheets, worked with the hammer and stamped into form. Its color resembles that of American gold coin, and it is susceptible of high polish. With copper 95 and aluminum 5 the combination resembles pure gold very closely.

Boron Bronze.— Into a fused admixture of fluor spar and vitrified boric anhydride,
aluminum is introduced, when reduction takes place and this result when combined with a copper admixture in the proportions of the prepared aluminum 5 to 10 and copper 95 to 90 per cent renders an alloy denser, more durable and less brittle than aluminum bronze; and furnishes more uniform and delicate castings. The aluminum-copper alloys with 90 to 93 aluminum and 10 to 7 copper yield a metal of great tensile strength, largely employed in the manufacture of automobile and aeroplane parts.

**Aluminum Brass** is an alloy with an elastic limit up to nearly 15 tons to the square inch, the aluminum imparting to the brass greater fluidity in casting and additional tensile strength. For these reasons it is extensively used for electrical purposes. A small proportion of aluminum with cast iron, wrought iron or steel has resulted in alloys of commercial value. From 1 to 2 per cent aluminum to castings of iron will cause the metal to flow more readily from a smaller grain. In steel castings the proportion of aluminum commonly used is minute, about 1/50th to 1/30th of 1 per cent, although for certain steel castings this has been advantageously increased to 1 and even 2 per cent of aluminum. The latter adds tensile strength and homogeneity to the alloy, gives it a smoother surface and lessens its liability to oxidation. An alloy of aluminum 70 and zinc 30 has been found useful in casting frames for sewing machines and like small machines. A combination of aluminum 80, zinc 15, tin 2, copper 2, and ½ each of manganese and iron is an alloy in which the aluminum is hardened and the product becomes applicable to many useful manufactures.

**Aluminum Zinc**, composed of zinc 90 to 95 and aluminum 10 to 5, is used in the galvanizing bath and treated the same way as pure zinc, except that no sal-ammoniac is used for clearing out the oxide, the aluminum being sufficiently effective.

**Anti-Friction Alloys**—This name is given to those alloys which are sufficiently plastic under the pressures to which they are subjected in bearings to mold themselves to the shape of the shaft which they support and still hard enough to stay in place. This property of anti-friction alloys is due to an exterior coating of graphite, for in fact the shaft and its bearings are always separated by a thin film of oil. These anti-friction metals are generally alloys of tin with tin-antimony and tin-copper; or they may be of lead, compounded with tin-antimony or of lead and tin so compounded. The first of these anti-friction alloys was the famous Babbitt metal, now almost wholly superseded by more effective combinations. See also **Amalgam**.

**Coinage Alloys**—The coinage of gold and silver dollars and multiples or fractions thereof, as first authorized by the act of Congress passed 2 April 1792, provided that the gold dollar should contain 27 grains of gold 916½ fine. The amount of fine gold in the dollar was therefore 244½ grains. The silver dollar was ordered to contain 416 grains of silver, 892½ fine, or 371.24 grains of fine silver. By the act of 28 June 1834 the gold dollar was reduced to the weight of 25.8 grains, 900 fine, or 23.22 grains fine silver. No change was made in the weight of or alloy of the silver dollar. By the act of 18 Jan. 1837 the alloy, but not the fine contents, of the silver dollar was changed. It was thenceforth to contain 412 ⅝ grains of silver, 900 fine, or 371¼ grains of fine silver; practically the same contents of fine silver as before. No further change was made in the gold dollar. The alloy of both gold and silver coins has always been of copper, although a minute quantity of silver has at times been introduced into the gold coin alloy, rather to improve the color of the coins, than from any design to increase their bullion value. By the act of 21 Feb. 1853 important reductions were made in the weight and fineness and therefore in the alloy of the subsidiary coins; a subject that belongs less to alloys than to coins. The current five-cent coins, or "nickels," are an alloy of 75 per cent copper and 25 per cent nickel. The "copper cent" is an alloy of copper, 95 per cent and zinc and tin, 5 per cent.

**Heusler Alloys**, the group of ferromagnetic manganese alloys, named after F. Heusler, who discovered them in 1893. In addition to manganese or manganese-copper, these alloys contain one or more of the elements aluminum, antimony, arsenic, bismuth, boron, and tin. The aluminum-manganese-copper alloys show the largest degree of ferromagnetism, about one-third that of the purest soft iron. The ternary tin-manganese bronzes also exhibit marked ferromagnetism. Manganese-tin is magnetic and remains so when copper is added. Manganese-copper is non-magnetic, but becomes magnetic when tin is added. Research has determined in the case of the aluminum-manganese bronzes that the chemical compound carrying the magnetism is expressed by the formula Al₃(Mn,Cu). This seems to establish the fact that ferromagnetism is a molecular phenomenon due to a condition of definite chemical combination. See **Ferromagnetism**.

**Pyrophoric Alloys**—The alloys distinguished by the title "pyrophoric" have the peculiarity of emitting hot sparks when rasped off with a coarse file. They consist of the cerium group of rare earth metals in alloy with iron, nickel, manganese or cobalt. They exhibit the same property in a less degree with cadmium, zinc, tin and lead. The common form of pyrophoric alloy is the so-called "Pyro light," gas lighter containing 35 per cent of iron and 65 per cent of the cerium metals. These alloys may, however, range in constitution from 10 per cent iron to 65 per cent iron. The pyrophoric property of these alloys is utilized in gunnery, the alloy being set into the shell of the projectile. The friction due to the rapidity of passage through the air is sufficient to ignite the alloy, thus marking the flight of the projectile by a trail of fire.

tion to the Study of Metallurgy' (London 1910); Rosenhain, W., 'Metallurgy' (New York 1914); Ruer, R., 'The Elements of Metallurgy' (New York 1909). A very com-
promising bibliography of recent investigations ar-
to Alloys up to 1 Jan. 1917 may be consulted in 'Metallurgical and Chemical Engineering' (Vol. XVI, pp. 273-279).

RICHARD FERRIS,
Editorial Staff of 'The Americanana.'

ALLSPICE, or PIMENTA, is the dried berry of a West Indian tree (Amomum pimenta) which grows to the height of 20 feet and up-
ward and has somewhat oval leaves about four
inches long, of a deep shining green color, and
numerous branches of white flowers, each with
four small petals. In the whole vegetable crea-
tion there is scarcely any tree more beauti-
ful or more fragrant than a young pimenta-
tree about the month of July. Branched on all
sides, richly clad with deep green leaves, which
are relieved by an exuberance of white and
richly aromatic flowers, it attracts the notice of
all who approach it. About the month of Sep-
tember, and not long after the blossoms have
fallen, the berries are in a fit state to be gath-
ered. At this time, though not quite ripe, they
are full grown and about the size of pepper-
corns. They are gathered by hand. The ber-
ries are spread in the sun to be dried, an oper-
ation that requires great care, from the neces-
sity of keeping them entirely free from mois-
ture. By the drying they lose their green color
and become a reddish brown; the process is
known to be complete by their change of color
and by the rattle of the seeds within the ber-
ries. They are then packed into bags or
hogsheads for the market. When the berries
are quite ripe they are of a dark purple color
and filled with a sweet pulp. Pimenta is
thought to resemble in flavor a mixture of cin-
namon, nutmegs and cloves, whence it has ob-
tained the name allspice. For its use in medi-
cine see CONDIMENTS.

ALLSTON, Washington, American painter
and author: b. Waccamaw, S. C., 5 Nov. 1779;
d. Cambridge, Mass., 3 July 1843. In early
boyhood he moved to Newport, where he at-
tended school. He was graduated from Har-
vard in 1800, and in the following year went
abroad, where he became a student of the
Royal Academy. Three years later he went to
Rome and there studied the works of the old
masters. He passed four years at Rome, the
companion of Thorwaldsen, Coleridge, Van-
derly and Washington Irving, and acquired
the lofty tone of the old school, gaining a reputa-
tion as a colorist. Returning to the United
States in 1809 he married a sister of Dr. Wil-
liam Ellery Channing. From 1811 to 1818 he
resided in England and during these years pro-
duced some of his best pictures. Of these
'The Dead Man Revived' gained a prize of
200 guineas from the British Institute; and his
'Triel in the Sun' and 'Jacob's Feast' were also produced about this time. Failing in
health, he returned to Boston in 1818 and finally
moved to Cambridge, where he lived in com-
parative seclusion until his death. He was a
man of fine sensibility, scholarly tastes, an ex-
cellent scholar and a writer of distinc-
t charm. His best known works in Ameri-
can are: 'Jeremiah,' 'The Witch of Endor,'
'Miriam,' 'Rosalie,' 'Madonna,' 'Spanish
Girl,' 'Belshazzar's Feast.' His best known
portraits are those of Benjamin West (Boston
Athenaeum), Coleridge (National Portrait Gal-
lery, London) and one of himself. His literary
achievements are 'The Sylphs of the Seasons,'
a poem delivered before the Phi Beta Kappa
society in 1809 at Cambridge and subsequently
published in London (1813) a novel, 'Monaldi,' a romance of Italian life
(1841); 'The Paint King,' and 'The Two
Painters' (London); and a volume of 'Lec-
tures on Art and Poems' (1850). Consult
Ware, 'Lectures on the Works and Genius of
Washington Allston' (Boston 1852); and
Sweezer, 'Artist Biographies' (Boston 1879);
also Flagg, J. B., 'Life and Letters of
Washington Allston' (New York 1892).

ALLUVIAL CONES AND FANS, de-
posits of sand, gravel and clay built up by
streams at points where the gradient decreases
and the carrying power of the water is less-
ened. Everywhere that rivers emerge from
mountains onto plains, such deposits are com-
mon. If built of coarse material they have
steep slopes and are called cones; if of finer
material the slopes are gentler and the deposits
are known as fans. The latter are often many
miles in extent. Where numerous fans coalesce
into one fringing deposit at the foot of a moun-
tain range, it is termed a piedmont alluvial
plain or a mountain apron.

ALLUVIAL TERRACES. See TERRACES.

ALLUVION, the legal designation of land
 gained from the water by gradual changes in
the shore line. In English law the form of the
word generally used is alluvion, and in Scotch
law alluvio. In both of these the enactment is,
that if an 'eyott,' or little island, arise in a
river midway between the two banks, it be-
longs in common to those on the op-
posite banks; but if it arise nearer one side
it then belongs to the proprietor whose lands
it there adjoins. If a sudden inundation cut
off part of a proprietor's land, or transfer the
materials to that of another, he shall be recom-
pensed by obtaining what the river has depos-
ted in another place; but if the process be a
gradual one there is no redress. In the United
States the proprietor of the bank increased by
alluvion may lawfully claim the addition, this
being regarded as the equivalent for the loss
he may sustain from the encroachment of the
water upon his land. Sea-weed which is
thrown upon a beach, as partaking of the nature
of alluvion, belongs to the owner of the beach.
2 Johns. N. Y. 322. But sea-weed below low-
water mark on the bed of the sea belongs to the public. 9 Conn. 38. (See Ac-
cretion: AVULSION). Consult Angell, 'Treatise
on the Law of Watercourses' (Boston 1877);
and Gould, 'Treatise on the Law of Waters'
(Chicago 1900).

ALLUVIUM, a word formerly applied to
the gravel, mud, sand, etc., deposited by water
subsequently to the Noachian deluge. It was op-
posed to alluvium, supposed to be laid down
by the deluge itself, or, in the opinion of others, by some great wave or series of waves originated by the sudden upheaval of large tracts of land or some other potent causes, different from that of the comparatively tranquil action of water which goes on day by day. Now alluvium is especially employed to designate the transported matter laid down by fresh water during the Pleistocene and Recent periods. Thus it indicates partly a process of mechanical operation, and partly a date or period. It should not be forgotten that the former has gone on through all bygone geological ages and has not been confined to any one time. Many of the hardest and most compact rocks were once loosely cohering debris laid down by water. The most typical example of alluvium may be seen in the deltas of the Nile, Ganges, Mississippi and many other rivers. Some rivers have alluviums of different ages on the slopes down into their valleys. The more modern of these belong to the Recent period, as do the organic or other remains which they contain, while the older (as those of the Somme, Thames, Ouse, etc.), which are of Pleistocene age, enclose more or less rudely chipped implements, with the remains of mammals either locally or everywhere extinct. Though in many cases it is possible clearly to separate alluviums of different ages, yet the tendency of each new one is to tear up, redistribute and confound all its predecessors. Volcanic alluvium is sand, ashes, etc., which, after being emitted from a volcano, come under the action of water and are by it redeposited, as was the case with the materials which entered and filled the interior of houses at Pompeii. Marine alluvium is alluvium produced by inundations of the sea, such as those which have from time to time overflowed the eastern coast of India. See Delta; River; Soil.

ALLWARD, Walter Seymour, Canadian sculptor: b. Toronto, Ont., 18 Nov. 1875. He was educated at Dufferin School, Toronto, served five years in an architect’s office, at the end of which period he turned his attention to sculpture, in the way of producing figure-work for architectural purposes. This he continued for only a short time, when he received his first commission for the figure of Peace for the Northwest Rebellion monument in Queen’s Park, Toronto. Following this he executed busts of Lord Tennyson, Sir Charles Tupper, Sir Wilfrid Laurier and other prominent persons, mostly for the art gallery of the Toronto Provincial Museum. Important works from his hand are the statue of General Simcoe and that of Sir Oliver Mowat, both in Queen’s Park, Toronto; the Nicholas Flood Davin monument in Ottawa, and the South African monument, the latter being among the finest in British America. Recent works are the J. Sandfield MacDonald statue in Toronto, 1908; the Baldwin and Lafontaine memorial on Parliament Hill, Ottawa, and the Alexander Graham Bell memorial at Brantford, Ont.

ALLYL, in chemistry, the radical CH; CH₂; CH₃, or CH₂=CH. (The isomeric radical CH₂=CH₂=CH is a group of compounds, of which the most important is perhaps allyl alcohol, CH₂=CH₂=CO₂H, which is produced when glycerine is distilled with oxalic acid.

ALMA, Mich., city in Gratiot County, 38 miles west of Saginaw, on Pine River, and Ann Arbor and Pere Marquette railways; founded 1854; incorporated 1873, and received city charter in 1903. It manufactures flour, lumber, beet sugar, auto trucks, hay and paper presses, gas engines, furnaces, cement blocks and asphalt mastic; has water works and electric lighting. It contains Alma College (q.v.), Alma Sanitarium, widely noted for the Michigan Masonic Home. It has one-year mayorality and a council of eight. Pop. (1910) 2,757; (1916) 3,000.

ALMA, a river in the Crimea, rising at the foot of the Tchadir Dag and flowing west into the Bay of Kalamite, about half way between Eupatoria and Sebastopol. It is about 46 miles long and is renowned for the scenic beauty of its banks. On the steep banks of the stream, through the channel of which the British troops waded amid a shower of bullets, a brilliant victory was won 20 Sept. 1854, by the allied armies of England, France and Turkey, led by Lord Raglan and Marshal St. Arnaud, over the Russian army commanded by Prince Menschikoff. After a stubborn contest lasting five hours the Russians retreated in disorder, leaving 17 per cent of the men killed on the field. The allies numbered about 62,000. It was the first battle of the Crimean war.

ALMA COLLEGE, co-educational institution founded at Alma, Mich., in 1887. It is under the control of the Presbyterian Church, maintains a college department, an academy, and schools of music and art, and extension courses. The degrees conferred are those of A.B., B.B., and B.Sc. In 1917 the institution had a faculty of 21 members and a student enrolment of 213. The library contained 28,437 volumes; the endowment amounts to about $400,000, and the campus of 36 acres, together with the buildings, are valued at $190,000.

ALMA MATER, a term familiarly applied by those who have attended a university to the particular university they have attended. The adjective almus in Latin means cherishing, fostering, dear.

ALMACK’S, ál’mákz, the name formerly given to certain assembly-rooms in King Street, St. James’s, London, derived from Almack, a tavern-keeper, by whom they were built, and whose real name is said to have been M’Call, and transformed into Almack by reversing the syllables. The premises are now known as “Willis’s Rooms.” First opened 20 Feb. 1765, they soon became famous for the extreme exclusiveness displayed by the lady patronesses in regard to the admission of applicants for tickets. These fair arbiters composed a board of six, which held its sittings every Monday evening during the London season, and issued those tickets which were supposed to affect so conclusively the claims of the received or rejected applicant, as the case might be, to occupy the upper circles in the fashionable world. To have danced at Almack’s became almost proverbial as indicative of exalted social position. The name was also given to a gambling club, which was established by the same ladies to which such men as Charles James Fox, William Pitt and Gibbon belonged. It is now known as Brooks’s club. Consult Timbs, ‘Clubs and Club Life in London’ (London
1873), and Walford, 'Greater London' (ib., 1884).

ALMADA, al-má'da, Portugal, a town in the province of Estremadura on the left bank of the estuary of the Tagus, opposite Lisbon. It is built upon a height, in a well-cultivated country, and has long been celebrated for its figs and the neighboring gold mine of Adissa. It has a strong castle on a rock, several depots for wine and a mineral spring. Pop. 8,000.

ALMADEN, al-má-dên, Cal., town in Santa Clara County, noted for its mines of mercury and its mineral springs. It was named after the Spanish town mentioned below on account of its four quicksilver mines, the New Almaden, Providence, Enriqueta and Guadelupe. Large quantities of mercury have been distilled from the ore (cinnabar), and the existence of this deposit has been of immense benefit to the Pacific States. Pop. 3,000.

ALMADEN, or ALMADEN DEL AZOGUE, -dél a-tho-gá (mine of quicksilver), a town in Spain 50 miles southwest of the town of Ciudad-Real in the province of the same name. It is widely known for its rich quicksilver mines, which have been worked for centuries, and in which some 4,000 miners are employed. Since 1645 the mines have been the property of the Crown. The town contains a ruined castle of the Moorish period and a school of mines. Pop. 5,500.

ALMAGEST, al-máj-jést. The usual appellation of the 'Syntaxis' of Ptolemy, derived from an Arabic term signifying 'the greatest.' This celebrated work was written about the middle of the 2d century of our era and comprises an exposition of the ancient system of astronomy so elaborate and thorough as to have made it a standard for 13 centuries. It contains the most ancient known catalogue of the stars, with observations of the motion of the planets and determinations of their periods. Several editions, one in Greek and others in Latin, appeared in Europe between 1500 and 1550. The most recent accessible edition is that of the Abbe Halma, which is in Greek and French (2 vols., Paris 1814–15).

ALMAGRO, al-má-gró, Diego, one of the companions of Pizarro in the conquest of Peru, was a foundling, and the exact date of his birth is not known; d. 1538. He engaged with Pizarro and Fernando de Llogue in the long and arduous expedition in which they made the discovery of Peru (1524–27), took part in the conquest of the country and the treacherous murder of Atahualpa (1533), and after frequent disputes with Pizarro about their respective shares in their conquests he led an expedition against Chile, of which he was appointed governor. Having failed to conquer his new province he returned to find Cuzco in possession of the Indians, who had expelled Pizarro. He reconquered it and made himself governor. He was, however, losing ground, and the struggle took place between the two parties in which Almagro was finally overcome, taken prisoner, strangled and afterward beheaded. He was avenged by his son, who raised an insurrection in which Pizarro was assassinated in 1541. The younger Almagro was put to death in 1542 by De Castro, the new viceroy of Peru. Almagro showed himself, like most of the Spaniards en-

aged in the conquest of the New World, capable of enduring great privations with heroic constancy, and of effecting wonderful achievements by undaunted valor, but cruel, rapacious and unscrupulous in success.

ALMACHE, Spain, town in the province of Ciudad-Real, 12 miles from the city of Ciudad-Real, in the midst of an elevated plain. Its streets are wide and well paved and there is a large open public square. Lace is made here to a considerable extent, as well as soap, brandy and coarse pottery. It is best known as the centre of the Valdepeñas red wine district. Pop. 8,300.

ALMAMUN, mâ-môn, a caliph of the Abbasid dynasty, son of Harun al-Rashid: b. 786; d. 833. Under him Bagdad became a great centre of art and science.

ALMANAC, a table or calendar, in which are set down the revolutions of the seasons, the rising and setting of the sun, the phases of the moon, the most remarkable conjunctions, positions and phenomena of the heavenly bodies, for every month and day of the year; also the several fasts and feasts to be observed in the Church and state, etc. The history of the almanac, and even the etymology of the word, are involved in considerable obscurity. It is generally derived from the Arabic article al and the verb manah, to count. The modern almanac answers to the fatti of the ancient Romans. Almanacs became generally used in Europe within a short time after the invention of printing; and they were very early remarkable, as some are now in England, for the mixture of truth and falsehood which they contained. In 1579 their effects in France were found so mischievous, from the pretended prophecies which they published, that an edict was promulgated by Henry III forbidding any predictions to be inserted in them relating to civil affairs, whether those of the state or of private persons. No such law was ever enacted in England. It is singular that the earliest English almanacs were printed in Holland on small folio sheets; and these have occasionally been preserved from having been pasted within the covers of old books. In the reign of James I letters patent were granted to the two universities and the Stationers' Company for an exclusive right of printing almanacs. These, in 1775, were declared to be illegal. During the civil wars of Charles I and thence onward, English almanacs were conspicuous for the unblushing boldness of their astrological predictions and their determined perpetuation of popular errors. The Stationers' Company, who had managed to retain this privilege by the letters patent, were considered the only safe ones about the validity of the letters patent in their favor, were guided merely by commercial principles in supplying the market, and accordingly adapted their almanacs to the taste of the public, which, on one occasion, when the trial was actually made, refused to purchase any about the predictions. Gradually, however, a better taste began to prevail, and in 1828 the Society for
the diffusion of Useful Knowledge had the merit of taking the lead in the production of an unexceptionable almanac in Great Britain. The example thus set has been almost universally adopted by nations, from their periodical character and the frequency with which they are referred to, are now more and more used as vehicles for conveying statistical information. Regiomontanus was the first person in Europe who prepared almanacs in their present form, without the predictions, which were in all probability introduced into Europe from the Persians. Once they were almost entirely filled with subjects of a religious character. At another time they overflowed with astrological calculations and predictions. In the time of Napoleon an almanac was published in France in which, to every day, an achievement of the Emperor, or something else relating to him, was added. Almanacs in the petty principalities of Germany exhibit the endless genealogical tables of the princes. Some almanacs in modern Greek, printed at Venice, where formerly all books in this language were published, are quite full of astrological superstition and matters relating to the Greek Church. A modern Persian almanac contains a list of fortunate days for various purposes; as to buy, to sell, to take medicine, to marry, etc.; and predictions of events, as earthquakes, storms, political affairs, etc. One of the most curious almanacs is an Italian one exhibiting Italian almanacs striking men. To the entry 30 July is added, Sudda ancora le ossai! (Even the bones sweat); to 11 August, Oh! che noia! (Oh! how distressing!); to 12 July Cascano le braccia (The arms fall!); to 2 January, Siruiti e ombrello! (Leggings and umbrellas!) In Germany, almanach is the name given to annuals like those which used to appear in England and the United States under the names of 'Souvenir,' 'Forget-me-not,' etc. In France a work once appeared annually entitled 'Almanach des Gourmands,' which was conducted with much spirit and is in high repute among epicures. Some of the almanacs that are regularly published every year are extremely useful and are indeed almost indispensable to men engaged in official, mercantile, literary, and professional business. Such Great Britain are 'Oliver & Boyd's Edinburgh Almanac,' 'Thom's Official Directory' and the 'British Almanac,' with its 'Companion.' 'Whitaker's Almanac' is also known as a very comprehensive and valuable compendium. The 'Almanach de Gotha,' which has appeared at Gotha since 1764, contains in small bulk a wonderful quantity of information regarding the reigning families and governments, the finances, commerce, population, etc., of the different states throughout the world. It is published both in a French and in a German edition. The Nautical Almanac is an important work published annually by the British government, two or three years in advance, in which is contained much useful astronomical matter, more especially in the parts connected with the sun, and from certain fixed stars, for every three hours of mean time, adapted to the meridian of the Royal Observatory, Greenwich. By comparing these with the distances carefully observed at sea the mariner may with comparative ease infer his longitude with sufficient accuracy in case he has no chronometer for keeping Greenwich time. This almanac was commenced in 1767 by Dr. Maskelyne, astronomer royal. The French 'Connaissante des Temps' is published with the same views as the English 'Nautical Almanac' and nearly on the same plan. It commenced in 1792. A similar character is the 'Astronomisches Jahrbuch,' published at Berlin. The 'American Ephemeris and Nautical Almanac' is issued annually since 1855 by the United States government.

The first American almanac was that of William Pierce of Cambridge, published in 1639. The most famous of American almanacs was 'Poor Richard's,' published in Philadelphia by Benjamin Franklin under the pseudonym of 'Richard Saunders.' This almanac was probably imitated from that of Thomas, of Dedham, Mass., which was kept for a good many years and contains many pleasant and witty verses, jests and sayings. The information printed in these almanacs seems to have been the only means of carrying news to the more distant parts of the country. The American Almanac appeared between 1830-61, and a second publication under the same name was edited for several years by Albert Worth R. Spofford. Several of the largest newspapers of the United States now issue almanacs which are marvels of condensed information. See Calendar.

ALMANDITE, or ALMANDINE, a variety of the garnet (q.v.).

ALMANS, ál-mán's, Spain, a manufacturing and farming town of southeastern Spain (Murcia), near which was fought (25 April 1707) a decisive battle in the War of the Spanish Succession, when the French, under the Duke of Berwick, defeated the Anglo-Spanish army under the Earl of Galway. Pop. 12,000.

ALMANZUR, ál-man-zoor, or ALMANZUR, a caliph of the Abbasid dynasty, reigning 754-75. He was cruel and treacherous and a persecutor of the Christians, but a patron of learning.

ALMA-TADEMA, ál'má-tá'dé-ma, Sir Lawrence, O.M., R.A., Anglo-Dutch painter: b. West Friesland, Holland, 1836; d. Wiesbaden, Germany, 25 June 1912. He was educated at the Antwerp Academy of Fine Arts under Wappers and Baron Ley's and obtained a medal at the Paris Salon of 1864 and another at the Paris Exposition of 1867. He went to England to live in 1870, exhibiting at the Royal Academy that same year 'Un Ami- teur Romain' and 'Un Jonglier,' which attracted immediate attention. Becoming a naturalized Englishman, he adopted the double name Alma-Tadema (having been christened Laurence Alma). He became an associate of the Royal Academy in 1876, and R.A. in 1879; was knighted in 1898 and raised to the Order of Merit in 1905. His especial field was the portrayal of Greek and Roman life, and all his work is marked by the most careful attention to archaeological detail. He is scholarly, his coloring accurate and his artistic feeling rarely at fault, but while his canvases attract the eye and delight the intellect they seldom touch the heart. Among his more noted pictures (he painted about 500), may be mentioned—'Clothilde at the Tomb of Her Grandchildren' (1858); 'The Education of the Chil-
ALMA-THEDA — ALMOND

ALMERIA, ál-mēr'ē-a, Spain, seaport city, capital of Almeria province, on the Mediterranean, 104 miles east of Malaga. At the mouth of a river at the head of a gulf, both bearing the same name, Almeria has one of the best harbors in Spain, and is the terminus of a railroad from Madrid. A large export trade is carried on in wine, grapes, fruit, esparto grass, iron and lead; coal and lumber are the chief imports; and macaroni, sugar and white lead are manufactured. Of anti-

Amerian interest is the old Moorish castle rising above the city, and the fortress-like cathedral dating from 1524. Almeria was an ancient Phoenician settlement, the Roman Unci and Magnus Portus, a prosperous Moorish seaport, and also a notorious nest of pirates. Railroad, pier and docking facilities have developed its modern importance. Area of province, 3,300 square miles; pop. 359,000. Pop. of city, 47,500.

ALMODOVAR DEL CAMPO, ál'mō-dō-va-r dēl käm'po, Spain, town of Ciudad-Real province, 20 miles by rail southwest of Ciudad-

Scores Real. A fortified Moorish town of the Middle Ages. It derives its modern importance from the neighboring Puertollano coal mines; its sheep-grazing crown lands of the Sierra de Alcudia, which rise above the town. Pop. 14,000.

ALMOHADES, ál-mō-hādz, from the Arabic "Al-Muwaḥḥadīs—the Unitarians—

the Spanish name given to the 12th century Moorish dynasty which ruled much of Western Africa and Spain. Their origin is traced to Abu Abdullah Mohammed ben Tumart, a de-

formed youth of humble parentage, a Masmuda Berber from the Atlas, who, as a traveling dev-

otee begger, obtained instructions in Cordova, Cairo, Bagdad, and made the pilgrimage to Mecca. On his return to Morocco he became known by the boldness of his preaching and by the austerity of his life. In Abdl-el-Mumim el Kumi, another Berber, he found a disciple, whose mind he filled with a belief that he was reserved to inaugurate a purified Mohammedan creed. Preaching the coming of the great Mahdi (director) who was to establish the reign of universal justice and peace, Abdl-el-

Mumim one day remarked "You yourself are the great Mahdi," swore allegiance to him, and 50 other listeners, and was followed soon after by 70 others. Preaching the unity of God, they retired to the mountains. Their number soon increased to 20,000 and a victory over the King's brother established the power of the Almohades. By 1147 they had conquered Morroc. In the meantime Abu Abdillah had died and been succeeded by Abdl-el-Mumin. He and his successors Yusuf, Yacub-ibn-Yusuf, Mohammed Abu-Abdallah, overthrowing the Almoravidian Moorish In who were in Portugal and Spain, until 12 June 1212, they were defeated by the Christians in the battle of Navas de Tolosa, leaving it is said 170,000 dead on the field. Soon after, disorganized by internal dissensions, the power of the Almohades in Spain had disappeared by 1257 and in Africa by 1269.

ALMOND, ál'münd, the tree and nut of Amygdalus communis of the family Amygdalaceae, supposedly a native of the Mediterranean region and of southwestern Asia, but so long in cultivation that its origin is a
matter of conjecture. In habit of growth the tree, which reaches a height of 20 or 30 feet, is like the peach, with which some botanists have mistakenly surmised that it was formerly identical. The hard, inedible pulp of its fruit (a drupe) splits at maturity and exposes the pit or "almond" of commerce. Varieties of almonds are classed as bitter or sweet. The former, little grown outside the Mediterranean region, furnish prussic acid and all the bitter qualities found in perfumery and culinary preparations; the latter, grown extensively in California and southern Europe and in similar climates, furnish one of the most agreeable of nut fruits. The sweet almonds are divided into hard- and soft-shelled varieties, the former little grown, the latter extensively. Some specially thin-shelled sorts are known as paper-shells. The kernels, particularly of sweet almonds, are rich in a mild fixed oil which is expressed for medicinal and other purposes, but the nuts are chiefly used for dessert, either directly or in some prepared form, such as confectionery.

The almond succeeds best upon light, thoroughly drained soil so situated that early frosts which destroy the tenuity of the blossoms, need not be feared by the trees, which are generally propagated by budding the desired varieties upon bitter almond seedlings, are set about 25 feet apart, different varieties that blossom simultaneously being planted in each other's proximity to ensure cross-pollination, self-sterility being characteristic of many varieties. If trees are properly trained during their first three or four years they demand little severe pruning afterward. Cultivation does not differ materially from that of other tree-fruits. In California the nuts are harvested from August to October, dried for several days, and if discolored, as is often the case where the air is very humid, they are lightly sprayed with water and then treated with sulphur fumes to bleach the shells somewhat. Nuts that are too badly dried or to this treatment are cracked by machinery and the kernels sold largely to confectioners. Because frost and self-sterility have been often overlooked, almond-growing in California has been remarked for failures; many orchards have been cut down for this "tree death." But when and where cultivations are favorable the crop is a profitable one. In 1897, 218 carloads were shipped from California; in 1912 the production was 3,000 tons. Attention has been drawn to parts of Arizona and New Mexico as probably adapted to the almond, and some orchards have been planted. About $1,000,000 worth of almonds are imported annually. The almond is sometimes attacked by a fungus which appears first as a yellow rust on the leaves. This often leaves the tree bare of foliage as early as in July. Spraying is the only remedy. See FUNGICIDES.

As an ornamental tree the almond, like the peach, is often planted even in localities unfavorable to fruit-production. But its relative, the dwarf almond (Amygdalus nana), a native of southern Russia, is hardy and is recommended as an ornamental shrub by nurserymen for northern climates.

ALMONY SCHOOLS, institutions for boys which began to be attached to monasteries in the 14th century. The almoner was the dispenser of charity generally, but there is no record of education in connection with the office until 1880 when the archdeacon of Durham gave a manor to the almoner of Cathedral Monastery to supply food and lodging for three boys from the grammar school. At the beginning of the 14th century a movement for the training of choristers in connection with the more elaborate worship of the Virgin Mary grew up and special preachers were placed in monasteries for their housing and education. The boys were kept as charity students. They acted as page boys and choristers and were taught and managed by secular clerks as masters. At Canterbury in 1320 a body of choristers was first inaugurated by royal grant to pray for the soul of Edward I. Saint Albans Abbey founded in 1339 an "Order of living for the poor scholars in almony," making the term of education five years. Westminster opened its school with two boys in 1355, which continued under a special master in 1540. The school was revived when the abbey became a cathedral in 1540, with 40 boys. Durham, Saint Mary's, Coventry and other abbeys also kept such schools. Almshouses about 1400 also provided education, particularly in agriculture. Boys were thus provided with free board and education in England. Saint Paul's is the only secular church in which an almonry school exists, which began in the 14th century. Many of the pupils passed on to colleges and universities.

ALMONTE, al-mōn'te, Canada, situated in Lanark County, Ont., on the Mississippi River 30 miles west of Ottawa and on the Canadian Pacific Railway. Its industries include woolens, tweeds and hosiery, stoves and agricultural implements. Pop. (1911), 2,950.

ALMORAVIDES, al-mōr'a-vî-dz, from the Arabic al-Murabitin — the devoted, whence "marabouts — the hermits," an 11th century Moslem dynasty of northwest Africa and Spain. It originated with Abdallah ibn Yasim, who preached Mohammedanism among the Moorish tribes of northern Morocco, and died in battle A.D. 1058. Abu Bekr ibn Omar succeeded him, but after some minor victories was ousted by his lieutenant Yusuf ibn Tashloun, who founded the city and empire of Morocco. Yusuf was invited to Spain by the Moorish Prince of Seville to aid him against the Christians and defeated them in a desperate battle on the plains of Zalaca in 1086. Yusuf returned to Morocco, but the following year came back to Spain, defeated the Moorish kings in detail and proclaimed as his successor his son Ali ben Yusuf, who ruled until 1143. Five years later the Almoravian dynasty was overthrown by the Almohades (q.v.).

ALMQVIST, al'mkvist, Karl Jonas Ludwig, Swedish poet and author: b. Stockholm 1793; d. Bremen, 26 Sept. 1866. He achieved literary fame in 1832 by a group of romances, the leaders of Swedish literature, entitled 'The Book of the Thorn-Rose,' 'Araminta May,' 'The Mill at Skällnora,' and 'Grimstahama's Settlement' are his best tales; notable novels are 'The Palace,' 'It's All Right,' 'The Lords of Ekolsund,' 'Amarina,' 'Gabrielle Miramond,' and 'Amelia Hillner.' His writings are distinguished by brilliancy of style and great dramatic power. His life was of the most un-
stable character. Implicated in a case of forgery and murder by poisoning in 1851, he disappeared for 15 years. It is now known that he came to America and settled in St. Louis, where he earned a scanty living, returning to Bremen in 1866, where he lived until his death, under the assumed name of C. Westermann. Translations of his works are very popular in Germany.

ALNWICK, an'lk, England, town, capital of Northumberland County, on the Alne, 36 miles by rail north of Newcastle. Its chief feature is the ancient Norman castle on a hill above the river northwest of the town, the residence since 1309 of the Percys, dukes of Northumberland. It covers five acres of ground and was restored in 1830 at an outlay of $1,000,000. It is one of the finest types of old baronial castles in England. Alnwick from earliest times was a border stronghold against Scottish incursions; and here in 1093 Malcolm III of Scotland was slain and his army routed; and in 1140 William the Lion was defeated at the head of a large army and made prisoner. Pop. 7,000.

ALOE, a genus of succulent-leaved plants of the family Liliaceae, natives chiefly of Africa. The numerous species range in height from a few inches to 25 feet or more. Some are valued for their fibre, which is used for cordage, netting, and fabric-making; others for the medicinal qualities ascribed to them. Chief among the latter are several arborescent species, Aloe succotrina, A. spicata, A. purpurascens, and A. arborescens, from which Cape aloe is mainly derived, and Aloe vera, a Mediterranean species frequently cultivated in the West Indies, which yields Barbadoes or hepatic aloe. Aloe perryi furnishes Zanzibar or Socotrana aloe, also a transparent pigment valued in miniature-painting and a rich violet dye.

ALOES, the inspissated juice of the leaves of a number of species of Aloe, a genus of the lily family of over 100 species, widely distributed in warm arid regions. The leaves are long, thick and succulent, and the juice that yields aloes is thin and flows readily from the cut. This is then thickened (inspissated) by natural or by artificial drying and there results a yellow to brownish to blackish, or greenish, mass of a tarry, waxy or glassy consistency. The aloes that is used in the United States is either Barbadoes aloe, from Aloe vera, or Socotrana aloe, from Aloe Perryi. As a medicine aloe has been used for centuries. It is a powerful cathartic, acting particularly on the large intestine, its active principle being termed aloin. Its action is extremely variable, and in large doses it has been known to induce abortion. See CATHARTICS.

ALOES WOOD (sometimes called also eagle wood, calambac, paradise wood or agarlochum), the inner part of Aquilaria malaccensis and A. agallochum, trees of the family Thymelaeaceae, natives of the tropical parts of Asia, and supposed to be the aloes or lignaloes of the Bible. They are large, spreading trees. Aloe's wood contains a dark-colored, fragrant, resinous substance, and is much prized in the East as a medicine and for the pleasant odor it diffuses in burning.

ALOGI, a sect of heretics in the 2d century. They are said to have been founded by Theodotus of Byzantium, a leather dresser, and were rivals and opponents of the Montanists. Epiphanius declares that they denied that Jesus Christ was the Logos, and thus gave them their name. They also denied thecontinuance of the gifts of the Holy Spirit. They rejected the Gospel of John and the Apocalypse which they ascribed to Cerinthus the Gnostic. Further, they rejected the Millenarianism and propheticism of the Montanists.

ALOIDE, or ALOADÆ, in Greek legend, the giant twin sons of Neptune and the wife of Aloeus. They were named Otus and Ephialtes and at the age of nine measured 22 cubits in height and nine cubits in breadth. They chained the god Mars in a bronze cask and kept him there 13 months. By piling Pelion upon Ossa they sought to reach heaven and were on the Olympian gods and would have succeeded before their beards had grown, but were destroyed by Apollo.

ALOPECIA, a partial or complete loss of hair in large quantities. This is due to a number of causes and frequently leads to baldness (q.v.). Alopecia is of two main kinds: primary or secondary. In primary alopecia there may be (1) a congenital lack of hair (this is rare); (2) senile alopecia, due to the advent of old age; (3) premature baldness, this may be a natural product, or it may be the result of a chronic seborrhœa, or dandruff (q.v.).

ALORA, ál'rá, Spain, town and health resort, Malaga province, on the river Guadalhorce, 18 miles by rail northwest of Malaga. It is frequented for its medicinal sulphurous springs, and has manufactures of spirituous liquors and a considerable trade in the fertile valley products, corn, sugar-cane, dates, etc. Pop. 11,000.

ALOST, ál'óst, Flemish Aalst, älst, Belgium, an old historic town of East Flanders, on the river Dender, about half-way between Brussels and Ghent. It was formerly the capital of the county of Aalst, which passed in 1830 into the possession of Belgium. It was one of the Flanders under the name of Keizer-Vlaanderen. The Dender divides the town into two unequal parts. Pop. (1912) 35,130. Over a thousand years ago Alost became a walled town; a grandson of William the Conqueror was killed under its walls in 1128. The main object of attraction is the fine old Gothic church of Saint Martin’s which was commenced toward the end of the 15th century and was intended to be a copy of the cathedral at Amiens. The scheme was apparently too ambitious for the available resources, for not only in the tower missing, but the nave was built only half its proposed length. The edifice contains a remarkable painting by Rubens, “Saint Roch interceding for the Plague-stricken,” which is said to have been painted in eight days to the order of the town about 1625-30. The first printing press in Belgium was set up in Alost, the birthplace of Thierry Maertens, one of the claimants to the honor of inventing the art of printing. Besides, Alost was vouched for under Gutenberg at Mayence, and returned to Alost in 1475. Until recent years the people of Alost used to keep up the ancient practice of sword-dancing, almost identical with that.
in vogue in Scotland. Tradition ascribes the dance to have come down from the Nervi; increased industrial activity in Alost led to its falling into disuse. Due to the great trade in hops and various manufactures, the town in Belgium had made greater progress during the past 30 years than Alost.

The European War brought dire tragedy upon the town. On 11 Sept. 1914 an engagement was fought there between the German invaders and Belgian troops. Civilians were taken prisoners; their money was confiscated; a number were shot or bayoneted, and others were driven in front of the German troops as a screen against the Belgian army. The Belgian left advanced from Termonde and Lierre and recaptured Alost 26 Sept. 1914. "During their retreat the Germans fired 12 houses and three civilians were shot dead in the street... a heap of nine dead civilians were lying in the Rue de l'Argent" (Bryce Report). The Germans bombarded and captured Alost again on 29–30 September, and wreaked terrible vengeance on the unfortunate citizens for the repulse they had suffered at the hands of Belgian soldiers. See Bryce Committee Report.

ALOYSIUS GONZAGA — ALPHABET

ALPENA, Mich., city and the county-seat of Alpena County, 110 miles north of Bay City; on the west side of Lake Huron, at the head of Thunder Bay, on the Detroit and Mackinaw Railway. It is divided in two by Thunder Bay River, from which water power is procured from three dams, facilitating extensive manufactures of paper from wood-pulp and of cement from limestone and clay. Further establishments include large tanneries, large extract works (hemlock) for export trade, foundries and machine shops, saw-mills, shingle-mills, veneer-mills a woolen-mill, flour-mills, large sash and blind factories, large excelsior-mills, quarries, stave and heading factories, municipal electric lighting and water-plants and a government fish hatchery. The United States census of 1914 recorded 54 manufacturing establishments of factory grade, employing 1,636 persons, of whom 1,494 are wage earners, receiving a total of $905,000. The capital employed aggregated $4,712,000, and the output was valued at $4,102,000; of this, $1,804,000 was added by manufacture. The harbor facilities are excellent. Alpena is governed on the commission-manager plan under the recent enabling act of the State Legislature. Alpena was settled in 1835 and incorporated 1871. Pop. 15,000.

ALPES-MARITIMES, alp mär'tē'me, France, southeastern department on the Mediterranean and Italian border, noted for its picturesque scenery and fine climate. The celebrated health resorts, Nice (the capital), Grasse, Cannes and Mentone are in this department. Area, 1,482 square miles; pop. 356,500.

ALPHA and OMEGA, the first and last letters of the Greek alphabet, used without modification in ecclesiastical literature as a term signifying completeness. Jesus Christ is designated the "Alpha and Omega," three times in Revelations 1, 8; xxii, 6; xxii, 13. Aleph and Tau, the first and last letters of the Hebrew alphabet, are similarly used and Isaiah xlii, 6 represents God saying "I am the first and I am the last," as an expression of eternal and universal omnipotence.

ALPHABET (from alpha and beta, the first two letters of the Greek alphabet), the ordinary series of the letters or syllables (in syllabic alphabets) of a language. For an account of what is known or conjectured of the origin of alphabetic and other systems of writing, see Writing. The English alphabet, like the most of those of modern Europe, is derived directly from the Latin, but owes its ultimate origin to the Phoenician, which gave birth also to the ancient Greek, the Etruscan, the Gothic, etc. According to tradition the Phoenician Cadmus introduced writing into Greece, the letters first used being the same as the Phoenician, but afterward undergoing changes both in sound and form. It would appear that the Phoenicians borrowed their alphabet from the hieratic alphabet of Egypt, whence also the Hebrews may have obtained theirs during their long stay in that country though it is more probable that like the Aramaeans they content to receive it at second-hand from the Phoenicians. The Egyptian origin of the Phoenician alphabet, however, has not been definitely established, and some hold to the

opinion that Crete rather than Egypt is the original home of our alphabet.

The Hebrew alphabet now employed is not the original one, but has an Aramaic character, and is the alphabet adopted at some period after the Captivity. The Hebrew alphabet proper, as we find it on ancient coins, is evidently the same as that of the Phenician inscriptions. The names of the letters in Phenician and Hebrew must have been almost the same, for all the Greek names, which, with the letters, were borrowed from the former, differ little from the Hebrew. By means of the names we may trace the process through which the Egyptian characters were transformed into letters by the Phenicians. Some Egyptian character would, by its form, recall the idea of a house, as for example, in the Phenician or Hebrew beth. This character would subsequently come to be used wherever the articulation b occurred, whether in the beginning, middle or end of a word. Its form might be afterward simplified, or even completely modified, but the name would remain, as beth still continues the Hebrew name for b, and beta the Greek. Our letter m, in Hebrew called mim, was probably the resemblance to the zigzag wavy line chosen to represent water, as in the zodiacal symbol for Aquarius. The letter o, of which the Hebrew name means eye, was originally intended to represent that organ.

The Semitic alphabets are written from right to left. The earliest Greek inscriptions, at Thera, are written in a character much like Phenician, either from right to left, or from left to right, or boustrophedon, with the lines alternating in direction. The Greek alphabet did not definitely assume its final form until comparatively late. It is the Ionian (see accompanying plate [Eastern Greek] in the form which it assumed at Halicarnassus) which gave rise to the modern Greek "capitals," while the alphabets of Italy, such as Latin, Etruscan, etc., are offshoots from an Euboean stock.

The later Greek alphabet furnished elements for the Coptic, the Gothic and the old Slavic alphabets. The Latin characters are now employed by many nations, such as the Italian, the French, the Spanish, the English, the Dutch, the German, the Hungarian, the Polish, etc., each having introduced such modifications or additions as are necessary to express the sound of the language peculiar to it. The Greek alphabet has only 17 letters, taken directly from the Phenician, though the Phenician alphabet had 22 letters. These were the five vowels, a, e, i, o, u, (a, e, i, o, u, as in French) and the 11 consonants, β, γ, δ, ε, ζ, η, θ, μ, ν, ρ, σ, τ, (b, g, d, k, l, m, n, p, r, s, t). According to one tradition, Palariedes, a caietaeora, the Trojan war, invented ξ (x) and the three aspirates θ, ψ, χ (th, ph, ch gutturals). To Simonides was attributed the invention of the double consonants ξ and ψ (dz, or z, and ps) and the two long vowels ι and υ (i and ù), which completed the Greek alphabet of 24 letters used. Besides these, there were anciently the digamma, a character corresponding pretty nearly to v, which afterward slipped out of the Greek alphabet; and the character representing an aspirate at the beginning of words. The original Latin alphabet, as it is found in the oldest inscriptions, consisted of 21 letters; namely, the vowels a, e, i, o and u (υ, and the consonants b, c, d, f, s, h, k, l, m, n, p, q, r, s, t, x. Z slipped out at an early period, and g took its place. To these we might also add the characters φ and ψ, representing the Greek diphthongs ou and eu. The letter i and the digamma, be remarked, had a double force, that of a vowel and that of a consonant. In the latter case they were, after the introduction of printing, changed frequently into j and v. The i consonant, as in ineptius (youth), had a sound resembling that of γ in English century; u, consonant, as in wepea (wespa), a wasp, had a sound much like the English w — wespa. (At least this opinion appears best supported by the evidence). No genuine Latin word contains either y or z, these being used in foreign (chiefly Greek) words adopted into the language; and k is found in classical Latin only in Kalenda. Our modern lower-case letters and script represent adaptations of the Carolingian minuscule of the 9th century, which itself was descended from the uncials or bookhands of still earlier periods. Important of these were the Roman uncial, which is essentially made up of rounded capital forms, and the Irish semi-uncial, which shows traces of influence by an antecedent cursive script or running hand. The modern Greek minuscule is likewise the result of the interaction of uncial and cursive forms.

While the alphabets of the west of Europe are derived from the Latin, the Russian and other Slavonic alphabets of the east come from the Greek. The modern Russian, consisting of 35 letters, is a modification and simplification of the ancient Cyrillic alphabet, invented by Cyril in the 9th century in order to translate the Gospels into the language of the Slavs of Bulgaria and Moravia. It was formed of Greek letters, together with some that had been differentiated from Greek ligatures. The Anglo-Saxon alphabet (see Anglo-Saxon) had two letters for the two sounds of th, which appear to have come from the Greek through the Meso-Gothic, and which were unfortunately not retained in later English. It wanted the letters j, k, q, v, s, but it had the sound x. The German and Dutch, the same letters as our own, the common German characters being mere modifications of the Roman, but the sounds of some of them are different. Anciently certain characters called Runic (q.v.) were made use of in Germany and Scandinavia, to which some would attribute an origin independent of the Greek and Latin alphabets, although it is pretty well established that both Greek and Latin played a part in their origin. Among Asiatic alphabets the Arabian, which, like Hebrew, is of Aramaic origin, has played a part exactly analogous to that of the Latin in Europe, the conquests of Mohammedanism having imposed it on the Persian, an Aryan language; the Turkish, a Tartar language; the Hindustani, also an Aryan language; and even Greek, which consists of 28 letters, and appears to derive its origin from the Sinaic alphabet, employed during the first centuries of the Christian era, and found in inscriptions in the Sinaic peninsula, at Petra, in the Hauran, etc. Other alphabets of Aryan origin are used for Syriac, Mongolian and Manchu. Beside these alphabets of North Semitic origin there is a group
of alphabets indigenous to southern Arabia. A specimen which appears to be of this stock, though it comes from Salaf, near Damascus, is shown in the accompanying table. Though the relation of these forms to those of Phoenicia is unquestioned, the precise nature of this relation is unknown. The alphabets or syllabaries of Abyssinia are South Semitic in character, as is shown by the Amharic alphabet pictured. It has also been maintained by Bühle, and vigorously denied by other writers, that the alphabet used in the edicts of the great Indian monarch, Asoka (255-232 n.c.), is of South Semitic form. The Nagari alphabet used in writing Sanskrit, comes from this stock. This alphabet is one of the most remarkable alphabets of the world. As now used, it has 14 characters for the vowels and diphthongs, and 33 for the consonants, besides two other symbols. The vowel a short is to be understood under every consonant, unless excluded by another vowel immediately attached to the consonant. (See SANSKRIT; also articles on the various Indian languages). Our alphabet is by no means the only one for what it has to perform, but is both defective and redundant. It is estimated that there are 42 sounds in the language, and only 26 letters to represent them. A, to begin with, has to do duty for many different sounds, as in far, fat, fall and fame; o, has three sounds, as not, note and move; e has a long sound and a short, as in mete and met. C is a useless letter altogether, since it has always either the sound of s or of k. Others of the consonants encroach upon one another's province; q, for example, sounds sometimes like f, as in digest; f sounds v in of; s sometimes usurps the sound of s, as in raisin, sometimes that of sh or sh, as in pleasure. See articles on the various languages mentioned and on the several letters of the alphabet, and HINDOESCRIPTE; PALAEOGRAPHIE, etc. W. M. Norbert Wiener.

AL-PHASI, al-fa'zi, or RIPH, Isaac, Hebrew rabbi: b. Fez, 1013; d. Lucena, 1103. A contemporary of and one of the chief Talmudic teachers and freeing them from controversial detail, Al-Phasi's digest 'Halakoth' or 'Decisions' was the basis of the code of the Maimonides and Quaro. Exiled at 75 years of age Al-Phasi, the man of Fez, as he was called, settled in Lucena, Spain, where his pupil and successor as rabbi, Joseph ibn Magash, became the teacher of the celebrated Maimonides.

APHEUS, Greece, the modern Ruphia, river of Peloponnesus, which rises near Asca in southern Arcadia, and flows through Elis and the Olympian plain to the Ionian Sea. It is the classic river famous for the bath of the love of Alpheus for Arethusa. Arethusa bathing in the river is said to have escaped from the enamored river-god through the intervention of Diana who transformed her into a fountain, transporting her to Ortygia, modern Syracuse. But Alpheus, pursuing the subterranean course emerged in Sicily, and was happily united to the Arethusan fountain.

ALPHONSES TABLES. See Alphonso X.

ALPHONSES A SANCTA, Maria, Spanish historian and bishop of Burgos: b. 1596; d. 1646. Celebrated for his learning, his most important work is a history of Spain from the earliest times to 1456, entitled 'Rerum Hispanorum Romanorum imperatorum, summorum pontificum, nec non regum Francorum anacapehaesin' (Granada 1545).

ALPHONSES DEI LIGUORI, Saint: b. Naples of a perfect inhumanity of the end of the 17th century; d. 1787. At the age of 16 he took his degree of Doctor in Civil and Canon Law in the University of Naples and immediately entered the legal profession. This he soon abandoned in order to become a priest and to dedicate himself to the service of the poor in the villages of southern Italy. To assist him in these labors of teaching the poor peasants, he founded the Congregation of the Holy Redeemer, whose members are commonly known to-day in the United States as "Redemptorists." He was made bishop of St. Agatha by Clement XIII. After 25 years of fruitful labor in this field, he returned to his monastery at Nocera, where he died. His virtues and learning have made him one of the best known saints in the Catholic Church. He was canonized in 1830 by Gregory XVI, and in 1871 was proclaimed by Pius IX a Doctor of the Universal Church. His writings deal chiefly with moral theology in theory and practice. His feast is celebrated on 2 August. The first authoritative work on St. Alphonse was written by his scholars, Père Segonds, and is entitled 'Vita et Instituto del Venerabile Servo di Dio' (3 vols., Naples 1802). In French, an exhaustive work in four volumes by Cardinal Villeneuve, 'Vie et institut de Saint Alphonse de Ligouri' (1863); in English, vid. Butler's 'Lives of the Saint,' and 'Life' by Bishop Mullock.

ALPINE CLUBS, organizations for the exploration and study of mountains. The original club is the famous Alpine Club of England, organized in 1858, which publishes the Alpine Journal. The first American Alpine Club was organized in 1873. There are in the United States the Mazamas and Sierra clubs on the Pacific coast, and the Appalachian Club on the Atlantic. See Mountain Climbing.

ALPINE PLANTS, plants indigenous to high altitudes. The most striking features common to them all are adaptations to rigorous climate such as the dwarfing of the stems of trees and shrubs, but not of leaves, which may even be increased in size over those of similar plants grown in milder places;
gnarled and crooked habit; horizontal or creeping rather than upright growth (the height of the taller species indicating the approximate depth of snow); and the development of structures that tend to check evaporation. Of these last a thickened epidermis, as in conifers, and epidermal hairs, as in edelweiss, are the most striking.

**ALPINI, al-pe'ne, Prospero, Italian botanist and physician**: b. Marostica 1553; d. Padua 1617. During the management of date plantations in Egypt, he discovered the sexual difference of plants and the fertilization of female flowers from the male, which Linnaeus adopted as the foundation of his system, also naming the genus Alpinia of the order Zingiberaceae in his honor. Alpini’s *De Medicina Aegyptiorum* (Venice 1591) contains the first description of the coffee plant known in Europe. *De Plantis Aegypti liber* (Venice 1592) is his most important work.

**ALPS**, the most remarkable and interesting system of mountains in Europe. It covers a great part of northern Italy, several departments in France, nearly the whole of Switzerland and a large part of Austria, while its ramifications in Italy and Germany, and extending far toward the southeast, connect it with nearly all the mountain systems of Europe. The name is derived from the Celtic *all*, which is sometimes made to signify white, or by others height. In the immediate neighborhood of the mountains *alp* has a peculiar meaning, and signifies one of the high pastures for which the Alps are distinguished. This great congeries of mountains may be said to be included between lat. 44° and 48° N., and long. 5° and 18° E. The culminating peak of the whole system is Mont Blanc, 15,781 feet high, though the true centre is St. Gothard, or rather the mountains between the sources of the Rhone and the Inn, and the Swiss cantons Valais, Bern Uri and Grisons on the north; and cantons Tessin and Lombardy and Sardinia on the south. It is a curious fact that its great central mass is nearly equidistant from the pole and the equator. From its slopes flow either directly into the principal rivers of central Europe, the Danube, Rhine, Rhone and Po. Round the northern frontier of Italy the Alps form a remarkable barrier, shutting it off at all points from the mainland of Europe, so that, except in the valley of the Adige, where a remarkable break occurs in the chain, or at the opposite extremity at Nice, it can only be approached from France, Germany or Switzerland through high and difficult passes. Accordingly nearly all the great passes of the Alps are connected with roads from the northern kingdoms into Italy. In this connection see *ITALY: HISTORY AND MODERN DEVELOPMENT; 1. PHYSICAL GEOGRAPHY; MOUNTAINS*.

As usual with mountain systems of great altitudes, the highest peaks of the Alps are reached by a gradual ascent through a succession of outer ranges and elevated intermediate valleys. The total width of the system is therefore always great and can hardly anywhere be measured with precision, opinion varying as to the northern boundary. The northern limit is fixed. Toward the east, however, the system, while it diminishes in height, becomes more widely extended, some of the transverse valleys extending to 150 miles, while that of the Drave reaches 200. From Bellinzona, in the canton of Tessin, to Aitdof, in that of Uri, the distance is 50 miles. The central range is divided by the Italians *Pre-alpi* b. the Germans *Voralpen*. The main chain of the Alps, which commonly determines the watershed of the countries through which it passes, contains some of the highest peaks; but at several points there are extensive ramifications of the system proceeding at various angles from the main chain, and more or less connected with it, and which sometimes exceed in mass and altitude the corresponding parts of the principal chain. Such are the Alps of Dauphiné and Savoy, and the Bernese Alps. The principal valleys of the Alps run mostly in a direction nearly parallel with the principal ranges, and therefore east and west. The transverse valleys are commonly shorter. In the section called the Leventon Alps, however, long ranges run north and south, forming valleys transverse to the dividing line of the waters, and terminating in the great Italian lakes. The slopes toward the south are more precipitous than toward the north, and as most of the collateral ranges lie to the north of the main chain the great valleys are generally to be found in the intervals between them. The transverse valleys of the Alps frequently lead up through a narrow gorge to a depression in the main ridge between two adjacent peaks. These are the passes or col, which are found by tracing a stream which descends from the mountains up to its source. The col is usually found to receive the drainage of the neighboring peaks, and when it is of sufficient extent a small lake is generally formed, from which a stream flows down on each side. When the one stream has been traced up to its source the passage across the mountains is completed by following the course of the other. The principal passes, now well known, are more than 50 in number; but there are many others more difficult and dangerous which have never had more than a local reputation.

The common divisions of the Alps have been taken from the Romans, whose acquaintance with the Alps as the northern boundary of Italy was considerable, yet formed mostly for practical purposes, was far from complete. Several modern divisions have been added. The Romans were acquainted with many of the best passes, to which from their altitude they gave the name of *mons*. Before noticing these divisions a glance may be taken at the general direction of the main chain. The most convenient starting-point is on the Mediterranean coast, near Nice. Eastward the chain proceeds along the coast till it forms a junction with the Apennines, which may be considered as one extremity of the system. In the opposite direction it proceeds northwest, and afterward north on the boundaries of France and Italy to Mont Blanc; it then turns northeast and runs generally in this direction to the Gross Glockner, in central Tyrol, between the Drave and the Salza, where it divides into two branches, the more northerly of which proceeds northeast toward Vienna. The southern chain subdivides again, one branch running in a southerly direction, cuts through the mountains of Dalmatia, and by a southeasterly continuation with the Balkans and the mountains of Greece; the middle branch proceeds
toward the Drave and Danube. With these continuations, which lose themselves insensibly in other ranges, the Alps may be considered to terminate.

**Maritime Alps.**—The first great division of the Alps extends from their junction with the Apennines to Monte Viso, a distance of about 100 miles. This mountain is the most prominent object from the basin of the Po, wherever the Alps are visible. The division of the Alps from the Apennines has been variously fixed at Col di Tende and Col d'Altaire, near Savona. The northern limit of the Maritime Alps is to the south of Monte Viso. The culminating-points are the Aiguille de Chambeyron, 12,155 feet, and the Grand Rioburano, 11,142 feet. The principal pass is the Col di Tende (6,158 feet), which was made practicable for carriages by Napoleon. It leads from Nice to Turin. The road is dreary, but commands a view of the Alps from Col d'Iséran to Monte Viso. There are carriage roads over the Col di San Bernardo and Col di Nava. Numerous tributaries of the Po and the Durance with the Var and other lesser rivers rise in the Maritime Alps.

**The Cottian Alps.**—Anciently named after a chief of the district, and extending from Monte Viso to Mont Cenis, these consist of numerous mountain masses irregularly grouped, the main line running northeast, and the principal ramifications to the west of it. The length is about 60 miles. Modern geography distinguishes, as a separate group divided from the main chain by the valley of the Durance, the so-called Dauphiné or Dauphiné Alps. These contain loftier peaks than the main chain. Principal peaks of the Cottian Alps: Monte Viso, 12,605 feet; Chardonnet 12,373; Clamarella, 12,081; of the Dauphines Alps: Pic des Écrins, 13,462; La Meije, 13,081; Pelvoux, 12,973. There is a carriage road by Mont Genèvre (6,102 feet) between the valleys of the Durance and the Dora Riaira, and by the Col de Sestre (6,335 feet) from Cesanne to Pignerolo. The road by the former, Cesanne to Briançon, was constructed by order of Napoleon. The difficult pass of Col de la Roue, Bardonnèche to Modane, is that supposed to have been crossed by Caesar on his way to attack the Helvetians. The Durance and the Dora Riaira rise in the Cottian Alps.

**The Graian Alps.**—From Mont Cenis this group extends to Mont Blanc (50 miles) and has extensive ramifications in Savoie and Piedmont. The principal peaks are, in the main chain, Aiguille de la Sassière, 12,326 feet; in the Piedmontese group, Grand Paradis, 13,300; in the Savoie group, Grande Casse, 12,780. Monte Cenis (6,705 feet), the most frequented of all the Alpine passes, was crossed by Pepin to attack the Lombards. A carriage road over it was constructed by Napoleon in 1803-10, leading from the valley of the Arc to Turin, and uniting with the road from Mont Genèvre at Susa. A railway now passes through the mountain by the Eight miles long (See Cenis). The pass of Little St. Bernard (7,192 feet) lies between the valleys of the Isère and Aosta. It was made practicable for cars by Augustus, but is now only available for muleteer. It appears to have been the road taken by Hannibal. The Col de Bonhomme (8,195 feet) communicates with the Col de la Seigne (8,327 feet) in the Pennine Alps. They lead by a mule path from Contamines to Courmayeur. The Stura, and Orca, and the Arc and Isère, rise in the Graian Alps.

**The Pennine Alps.** (Cottian Peninsula, or Penn or Penna, a hill) is the loftiest range of the whole system, having Mont Blanc at one extremity and Monte Rosa at the other (60 miles). Here also begin the most extensive ramifications of the system, some of the collateral ranges rivaling or exceeding in mass and altitude the main chain. The Alps of Haute Savoie form a northwestern continuation of this range. The northern boundary of the Pennine Alps is the Valais, or upper valley of the Rhone. On the opposite side of this valley, and nearly parallel with the main chain, runs the great range of the Bernese Alps. Here the grandest panoramas of Alpine scenery are exhibited. The great peaks of the two vast ranges are only about 20 miles apart, and between them run transverse ranges presenting innumerable secondary heights. From the Matterhorn (Mont Cervin), between Mont Combin and Monte Rosa, a series of great heights, including the Weisshorn and the Gabelhorn, run to the north. The main range contains Mont Blanc, Monte Rosa and Mont Cervin, three of the highest peaks in the Alps, and west the Bernese Alps are connected with the Jura range. The principal heights of the Pennine Alps are Mont Blanc, 15,781 feet; Monte Rosa, 15,217; Mischabelhöhen (Dom), 14,935; Lyskamm, 14,894; Weisshorn, 14,804; Matterhorn, 14,780. In the Bernese Alps are the Finsteraarhorn, 14,026; Aletschhorn, 13,803; Jungfrau, 13,671. There are bridle passes, the Col de la Seigne, already mentioned, and the Col de Ferret (8,320), on each side of Mont Blanc. The pass of Great St. Bernard is celebrated for its hospice (See Bernard, Great St.). It was crossed by Napoleon in 1800, but it is not practicable for carriages. There are several passes, as the Col du Cervin, the Schwarzthor and the Col du Lys, from 10,000 to 14,000 feet in height. The most eastern is the Simplon, 6,595 feet, from Brig to Domo d'Ossola. This has a carriage road made by Napoleon. This is about 36 miles long and 25 feet wide throughout, and is carried over steep precipices and through six tunnels. The road to the Grande Galerie is 683 feet long. A double railway tunnel, the longest and lowest tunnel through the Alps (1254 miles long and 2,313 feet above sea-level), has been driven through the Simplon. Numerous tributaries of the Rhone rise in the valley between the mountains, and on the Italian side the Dora Baltea, Sesia and other rivers.

**The Lepontine Alps.** Form the continuation of the main chain on the south side of the great valley or depression stretching from Martigny in the Valais to Corte in the Grisons, the western portion of which forms the basin of the Rhone, the eastern that of the Vorderrhein. From this chain branch the northern and eastern extensions of the Swiss Alps beyond the Eight miles long, of which is fixed at the defile of the Devil's Bridge, near Andermatt, crossed by the Reuss. The Lepontine range extends to the Splügen pass. The line of watershed is generally parallel to the valley of the Vorderrhein; but here, as already noticed, some of the principal ranges run transversely to it, terminating in the great

valleys in which lie the lakes Maggiore, Como, etc., fed by numerous tributaries from this and the following division of the Alps. This division forms the great water-parting of the whole system. Within a radius of a few miles from the St. Gothard Pass rise the Rhone, the Aar, the Reuss, the Vorderrhein, the Ticino, the Toccia and the Maggia. The principal pass is the St. Gothard (6,936 feet), over which pass is a carriage road from Bellinzona to Altdorf. Through this mountain mass a railway tunnel more than nine miles long was opened in 1882. The Great Fisen (8,050 feet) conducts from Obergestelen to Formazza. The Bernardin Pass (6,769 feet), constructed by the Swiss government, leads from Coire to Bellinzona. The road from Coire to the Splügen leads, by way of the Splügen Pass (6,945 feet), to Lake Como. This route commands the finest views of Swiss scenery in the Grisons. Previous to the construction of the present road by the Austrian government in 1823 it was difficult and dangerous. Marshal MacDonald, who crossed it in 1800, lost a large number of men by avalanches at a gorge in the pass of the Cardinello, which the new road avoids. The carriage road over the Furka Pass from Obergestelen to Andermatt, completed in 1867, affords a fine view of the Shreckhorn and Finsteraarhorn. The peaks here are of less elevation. The highest, Monte Leone, is 11,696 feet; the Piz Valrein is 11,148 feet, and several are above 10,000. Of the northern ranges Tödi is 11,889, Bifertenstock, 11,237; Scherbern, 11,132, and there are many above 10,000.

The Rhätian Alps extend from the Splügen to Dreiherrnspitz on the borders of Salzburg and Tyrol. The Engadine, or valley of the Inn, divides them into two portions. The chain is also broken by the valley of the Adige. To the south, separated by the valley of the Adda, are the Lombard Alps, while the more northerly continuations embrace the Tyrolean and Bavarian Alps. In the main range are the Piz Bernina, 13,294 feet; Piz Roseg, 12,939 feet; Ortler, 12,814 in the Lombard Alps, Monte Adamello, 11,832; Presanella, 11,688; and Care Alto, 11,352. The other ranges are inferior in height. Good roads now become more numerous. The Maloja Pass (5,942 feet) leads from Maloja to the Surses and Inn to Innsbruck, and communicates with the road over the Julier Pass (7,503 feet) to Coire. The Pass of Glurns (4,400 feet), from the valley of the Inn to the Adige, is the lowest pass over the main chain. It joins the road to Milan by the Valtelline, the highest part of which is 9,174 feet. This is a carriage road constructed by the Austrian government for communication with their Lombard dominions. The Brenner Pass (4,588 feet) leads from Verona to Innsbruck. The Brenner is crossed by rail in 1 hour 20 minutes. The Inn is intersected by the Septima, Julia, Albula and other passes. The Adda, Oglio, Adige, Hinterrhein, Inn and other rivers, rise in this part of the chain.

Noric Alps.—The main chain of the Alps here divides into different sections as already mentioned. The northern part of the chain extending to Vienna was anciently called the Noric Alps, while the southern continuations were known as the Carnian and Julian Alps, the names Venetian, Dalmatian, and Pannonian Alps being also in use. The culminating peak of the northern range is the Gross Glockner, 12,405 feet. Farther east the heights are of much less elevation. In Carinthia and Styria two parallel branches called the Styrian Alps enclose the upper valley of the Mur. In this group is the Halnrencek, 10,044 feet. In south Tyrol and Venetia several peaks rise above 10,000 feet. The Carnic Alps run from the frontiers of Tyrol and Venetia to the frontier of Carinthia. They are separated from the northern range by the Gailthal. The height of the southern continuations of the Alps rapidly diminishes, and they lose themselves in ranges having nothing in common with the great mountain masses which distinguish the centre of the system. Mount Tergiou, near the northwestern extremity of the Julian Alps, has a height of 9,371 feet. The name Dinaric Alps is given to a continuation from Mount Klen through Croatia and along the borders of Dalmatia and Herzegovina.

There are various points of vantage from which extensive views of Alpine scenery are commanded at the expense of a moderate amount of climbing. The Rigi, which can now be ascended by railway, is one of these. There are hotels at the top, 3,905 feet above the level of the sea, and 4,468 above the Lake of Lucerne. A favorite Rigi spectacle is that of the sun rise over the Bernese Alps. The Faulhorn (8,799 feet), southeast of Lake Brienz, commands a near view of the same range. The Becca di Nona (8,415 feet), south of Ascona, gives, according to some authorities, the finest panoramic view to be obtained from any summit of the Alps. From the Gorner Grat (to which there is now a railway from Zermatt), and various points in the valley of Chamonix, particularly the Montanvert, with its outlook upon the Mer de Glace, views of various interest are obtained. The most accessible Alpine glaciers are those of Aletsch, Chamonix and Zermatt.

Climate.—In the lower valleys the mean temperature ranges from 50° to 60°. Half-way up the Alps it averages about 32°—a height which, in the snowy regions, where snow always lies, the average does not attain. The exhilarating and invigorating nature of the climate in the upper regions of the Alps during summer has been acknowledged by all who have visited these romantic scenes. The freshness of the breeze as it comes from the snowy peaks, tempered by the rays of a southern sun, enables the traveler, without weariness, to perform distances on foot that at home he would have shrank from attempting. Notwithstanding, however, the invigorating nature of the climate, the inhabitants of the higher valleys are often afflicted with goitre andcretinism.

Botany and Zoology.—In respect to vegetation the Alps have been divided into six zones. The limits of these depend not on absolute height, but on height modified by exposure and local circumstances. The lowest is the olive zone. This tree flourishes better on sheltered slopes of the mountains than in the plains of northern Italy. This vine, which bears a greater winter cold, distinguishes the second zone. On slopes exposed to the sun it flourishes to a considerable height. The third is the mountainous zone or region. Cereals and deciduous trees form the distinguishing features
of its vegetation. The mean temperature about equals that of Great Britain, but the extremes are greater. The fourth region is the sub-Alpine or coniferous. Here are vast forests of pines of various species, which have in many places beencut down, the result being that the valleys have been deprived of shelter and denuded of soil. Most of the Alpine villages are in the two last regions. On the northern slopes pine forests extend to 6,000, and on the southern slopes to 7,000 feet above the sea. This is also the region of the lower or permanent pastures where the flocks are fed in winter. The fifth is the pasture region, the term alp being used in the local sense of high pasture grounds. It extends from the uppermost limit of trees to the region of perpetual snow. The landscape is adorned with numerous shrubs; rhododendrons, junipers, bilberries and dwarf willows being among the distinctive forms of vegetation. The sixth is the region of perpetual snow. The line of snow appears from a distance to be continuous at a limit which varies, according to seasons and localities, from 8,000 to 9,500 feet, but on approaching this apparently continuous line it is found to be broken up and crossed by patches of brilliant vegetation, the limit of which appears to be imposed by want of soil rather than severity of climate. Few flowering plants extend above 10,000 feet, but they have been found as high as 12,000 feet. At this great elevation two species of quadrupeds may be seen, the brown or wild goat, and the chamois, which delight in heights inaccessible to man. The bouquet, which has become very rare, scales the most elevated peaks, while the chamois is generally found rather lower, but is never seen in the plains. In summer the high mountain pastures are covered with large flocks of cattle, sheep and goats, which in winter are removed to a lower and warmer level. The marmot and white or Alpine hare inhabit both the snowy and the woody regions. Lower down are found the mole, the wildcat, the fox, the lynx, the beaver, and the river otter, all of which are extremely rare. The vulture, eagle and other birds of prey frequent the rugged Alpine rocks, and "the snowy ptarmigan" seeks food and shelter among the diminutive plants that border using the snow. Other kinds of game, including the grousse, woodcock and partridge, may be found from the upper limit of the woods to the more level and habitable parts below. Several kinds of water-fowl frequent the higher lakes, where excellent trout and other fish are found; but those lakes situated at the greatest elevation are, from their low temperature, entirely destitute of fish.

Geology and Minerals.—The geological structure of the Alps forms the subject of, or is incidentally discussed in, many books of great distinction, some of which we include among the works mentioned in the bibliography below. In general three zones can be distinguished, a central, in which crystalline rocks prevail, and two exterior zones, in which sedimentary rocks are found. In the central zone consist of granitic gneiss of various forms, seldom pure granite, gneiss, hornblende, mica slate and other slates and schists. In the western Alps there are also considerable elevations in the central zone that belong to the Jurassic (Oolite) and Cretaceous formations. From the disposition of the beds, which are broken, tilted and distorted on a gigantic scale, the Alps appear to have been formed by a succession of disruptions and elevations extending over a very protracted period. The large beds of calcareous rock which overlie the older rocks both to the east and west appear to have been ruptured and rolled back by the upheaval of the central mass. Mining is not carried on to an extent proportionate to the magnitude of the mountain range. Iron and lead, however, are found in considerable abundance, and the Bleiberge (lead mountain) mine, in Carinthia, furnishes the purest lead in Europe. Rock-salt is abundant toward the north of the chain, and the salt works of Bex in Canton de Vaud, of Hall in Tyrol, of Haltein and of Berchtesgaden in the vicinity of Salzburg are of note. Mercury exists chiefly in the east part; the richness of the mine of Idria, northwest of Trieste, is well known. Besides those principal products, gold, silver, copper, zinc and coal are mined to some extent.

Marion Wilcox.
in Lorraine. The Rhine flows 115 miles north by east, along all the eastern border, and receives, below Strasbourg, the Ill from Alsace, 127 miles long. Other rivers are the Moselle, flowing through Lorraine and on to the affluent, the Saar. Along the Rhine is a strip of level country, 9 to 17 miles broad and declining from 800 to 450 feet above sea-level. Westward of this rise the Vosges Mountains, culminating at a height of 4,677 feet; while Lorraine, rather flat than mountainous, rarely attains 1,300 feet. About 48.5 per cent of the entire area is arable, 11.6 meadow and pasture and 30.8 under wood. Alsace-Lorraine produces much wine, grain and tobacco; it is rich in mines, iron and coal; and manufactures iron, cotton, wool, silks, chemicals, glass and paper. It contains the important cities of Strasbourg (pop. 1905, 167,678); Metz (pop. 1910, 68,598); and Kalmar (pop. 1910, 43,808). As a French province, Alsace was divided into the departments of Bas-Rhin and Haut-Rhin; Lorraine fell into the departments of Meuse, Moselle, Meurthe and Voges (parts of all of which still remain French). The lieutenant-governor (Statthalter), representing the imperial government, resides in Strasbourg, and is assisted by a ministry of five departments and a council of state.

From the 10th century Alsace-Lorraine formed part of the German empire till a part of it was ceded to France at the Peace of Westphalia (1648), and by the Peace of Ryswick (1697) the cession of the whole was ratified. German never ceased to be the chief language of the people, and all newspapers were, during the whole period of the French possession, printed in both languages. In 1871, after the Franco-Prussian war, Alsace and German Lorraine were, by the Treaty of Frankfort, incorporated in the new German empire. The great mass of the population was strongly against the change, and 160,000 elected to be French, though only 50,000 went into actual exile, refusing to become German subjects. Since the era of the Revolution Alsace in sentiment was wholly French. To France she gave the bravest of her sons—Kellerman, Kléber and many another heroic. A first heard the 'Marseillaise', and MM. Eckermann-Chatrian, Lorrainers both, have faithfully represented their countrymen's love of La Patrie in the days of the second as of the first Napoleon. Of late it is claimed by the Germans that, through the emigration of the irreconcilables and the immigration of German settlers, the tendency of the old natives to accept the inevitable, and the rising up of a new generation, to whom the French connection is a tradition, the situation has slowly but steadily changed in favor of Germany and the existing firm but fair administration. The irritating passport system, a special grievance not in force elsewhere in Germany, was withdrawn in 1873. On 9 May 1902, Emperor William directed that a bill be laid before the Federal Council abolishing paragraph 10 in the imperial constitution, which imposed practically a dictatorship on the Reichsland of Alsace-Lorraine. In December 1913, however, occurred the "Zabern" incident, in which as a result of an assault committed by an officer on a civilian, a violent anti-Prussian riots broke out. Bitter feeling had not subsided when the war broke out. Consult Hazen, C. D., 'Alsace-Lorraine under German Rule' (New York 1917); Jordan, D. S., 'Alsace-Lorraine' (1916).

ALSERG, ál'zberg, Carl Lucas, American chemist, son of Meinhard Alserg, one of the founders of the New York Chemical Society, now the American Chemical Society; b. New York city, 2 April 1877. In 1900 he was graduated from the medical college in Columbia University. For the three years following he studied physiology, pharmacology and chemistry in Germany, studying under von Behring and Emil Fischer. In 1902 he became head of the department of biochemistry in the Harvard Medical School. In 1908 he was appointed chemical biologist in charge of the Poisonous Plants laboratory in the Bureau of Plant Industry, at Washington. In 1912 he was nominated by President Taft to succeed Harvey W. Wiley as chief of the Bureau of Chemistry in the Department of Agriculture.

ALSEN, ál'zên, Germany, island of the Schleswig-Holstein province, in the Baltic, separated from the mainland by Alsen Sound at its narrowest point, 400 yards wide. Formerly a part of Denmark, Alsen was taken by the Prussians, 29 June 1864, and with a portion of the mainland joined by a drawbridge constitutes the district of Sonderburg. Sonderburg, the chief town, is strongly fortified and has a good harbor. Alsen is nearly 20 miles long with an extreme breadth of 12 miles. Area, 125 square miles; pop. 25,000.

ALSO, ál'sôp, Richard, American poet; b. Middletown, Conn., 23 Jan. 1761; d. Flatbush, L. I., 20 Aug. 1815. He studied at Yale, but did not complete his course. He formed the literary group known as the "Hartford Wits," which includes Benjamin Trumbull, Lemuel Hopkins and Theodore Dwight. Alsop was largely responsible for the Echo (1791–95), a series of travesties and burlesques on current fads and literature (pub. in book form 1807). He wrote 'Monody on the Death of Washington' (1800); the 'Enchanted Lake of the Fairy Morgana' (1808).

ALSTED, ál'stê', Johann Heinrich, German encyclopedist and theologian; b. 1588; d. 1638. His 'Cursus Philosophici Encyclopaedia' (2 vols., fol., Herborn 1630), the most important complete work of its kind that had appeared, contains an interesting, and probably the earliest, article on the use and abuse of tobacco. 'Tractatus de Mille Annis' (1627) prophesied the beginning of the millennium in 1694. He also published 'Thesaurus Chronologicus' and 'Triumphus Bibliorum Sacrorum,' attempting to prove that the Scriptures contain the principles of all arts and sciences. Alsted was professor of philosophy and theology at Herborn and later at Weissenburg.

ALSTON, Theodosia Burr. See Burr, Theodosia.

ALSTRÖMER, ál'strô-mér, Jonas, Swedish benefactor; b. 1685; d. 1761. Of humble parentage, he went to England as clerk for a Stockholm merchant, later engaged in shipbroking business independently, amassed a fortune, returned to Sweden in 1735, published textiles and other factories, introduced improved breeds of sheep, the culture of dye plants and potatoes and contributed to the formation of the
Levant and East India companies. He was ennobled and a statue to him was erected on the Stockholm exchange. His son, Åström, Claus Claes (Claude) b. 1736; d. 1796; author of a work on the breeding of fine-wooled sheep, was also a distinguished botanist, a pupil and friend of Linnaeus, who named after him the Alström or Inca Lily. This remarkable flower, first discovered at Ceylon and sent to Linnaeus along with other specimens collected during his botanizing rambles over Europe.

ALTAI, alt'ë, MOUNTAINS, a mountain range of central Asia, extending from the desert of Gobi in a northwesterly direction along the boundary of Mongolia and Sunkaria. After passing the Russian frontier it gradually falls off in altitude and merges into the steppes. The rivers of this region are mostly head waters of the Obi and Irtysh. The mountain scenery is generally grand and interesting. The highest summit is Baluka, about 17,500 feet above the sea. The area covered by snow and glaciers is large. The mountains have a severe climate, but agriculture is carried on to some extent in the larger valleys. The inhabitants are chiefly Russians and Kalmucks.

ALTAIC LANGUAGES, a family of languages occupying a portion of northern and eastern Europe, and nearly the whole of northern and central Asia, together with some other regions, and divided into five branches, the Ugrian or Finno-Hungarian, Samoyedic, Turkic, Mongolic and Tungusic. Also called Uralic and Turanian.

ALTAMURÀ, aît'a-mo'rra, Italy, city of Bari province, at the foot of the Apennines, 60 miles by rail northwest of Tarentum. Two annual fairs are largely attended and considerable trade is carried on in regional products, oil, wine, olives, grain and cattle. It is a bishop's see with a fine Romanesque 13th century cathedral and interesting archaeological remains. Pop. 26,000.

ALTAR. From the Latin alta ara, a raised space. An elevation of any kind (earth, grass, stones, etc.) was used by the primitive races as a sacrificial spot. With the commencement of culture altar construction came into being, built of brick, stone, marble, etc. A separate altar was dedicated to each god of the Greeks, Romans and Eastern pagans. Very soon they developed into works of art according, in quality, with the best craftsmanship the period afforded, and proof of the sentiment of sacrifice felt. The ram's skull (aggicran) or ox skull (bucran) — signs of animal sacrifice — adorned the altar corners of the ancient Greeks and Romans, while wreaths and garlands of fruits and flowers draped the sides. These altars were erected (in the more primitive times) outdoors (on streets, squares, in meadows, near springs, on tops of mountains, etc.). Later came the altars dedicated to the household (lares and penates) within the walls of the habitations. With the advancement of art and the plant and ornamental taste with architectural members — the plinth, capital, moldings, and even steps (degrees). These were altars devoted to burnt sacrifices. They are known as Pagan altars. Early altars of the Jews were also erected for burnt sacrifice and were also in the open air (often on the tops of mountains), until the raising of Solomon's Temple, when an incense altar was erected within the Temple, the altar for burnt sacrifice being in the front court yard, open to the sky.

Christian Altars. — While the consecrated bread and wine (Flesh and Blood) are symbolic of Christ's sacrifice, the Christian altar is dedicated to the memory of the Last Supper and not to sacrificial ceremonies. Thus the primitive Church used some small table which alone through the presence on its surface of the Host became sanctified. And on the withdrawal of the sacramental service the table was taken to pieces and stowed away while the Eucharist was kept devoutly screened and protected. Veritable sanctified altars of stone or wood, etc., took the place of ordinary tables for the display of the Eucharist about the 4th century, when they were built as fixed structures of stone or wood, in the early basilicas. In 517 a canon enforced the use of stone for the altar. These altars became consecrated by the presence of the body or relics, a martyr which were placed under the altar. The altar was placed immediately in front of the apsis (see BASILICA) of the basilica (always in the eastern end), where the bishop and clergy sat in a semicircle. The construction of these early stone altars consisted of a slab supported by pillars. In the open space beneath the slab reposed the body or relics of the saints enclosed in shrines. To protect the relics from dust or irreverence these curtains subsequently suggested ornamenting the altar front with an embroidered hanging, called antependium or frontal (Pugin). These antependia developed into elaborate ornamentation in precious metals, adorned with enamels and jewels; others were of delicately carved wood, painted, gilt, often embellished with crystals. Extant examples of altars of the 5th, 6th and 7th centuries are those of St. Victor in Marseilles Museum, of St. Nazaire and of St. Celsus at Ravenna, of Auriol in Provence, etc.

Up to the 7th century the altar was sanctified by the body or relic reposing beneath the altar and nothing was permitted on the altar. Even the Eucharist was suspended above the altar. From the 5th century the altar was covered with a dome (ciborum) supported by four columns and enclosed with hangings supported on rods. Attached to a chain or cord from the centre of the dome hung the pyxide holding the consecrated Host, often sanctified with the image of a dove of gold or silver. With the 9th century the relics of the saints became exposed on the altar, enclosed within a shrine. Soon the relics were followed by the Book of the Four Evangelists, but images were not admitted on the altar till the 9th century. The candlesticks still posed on the floor alongside the altar.

The Romanesque and Gothic periods used the massive table form of the 4th century with its slab of stone (Regensburg has an altar of this style) in front of which the bishop used the altar. Silver plastic decoration (usually from the hands of a goldsmith) soon began to be displayed in altar decoration. Perhaps most noted of the period is that of the Collegiate Church at Klosterneuburg (Austria) by

Nicolas de Verdun (1181) representing scenes from the Old and New Testament. From the 11th and 12th centuries the massive altars are relieved by architectural outside work—small detached columns supporting arches (effigies often in the openings) broken into trefoil and quarterfoil, tracings, milliols, etc. Gables and crockets, of course, appear. Gothic altars are frequently of carved wood, painted and gilded. Wing altars were a common form, having plastic internal ornament and painted decoration outside ('The Last Judgment' in the Church of our Lady at Danzig; the high altar in the monastery church at Blaubeuren; the 'Coronation of Mary' in the Minster of Breisach and the Brugge Minster altar in the Schleswig Cathedral). In the 14th century an open-work gallery often replaces the pillars.

In Italy, in the Renaissance, a baldachino (ciborium) supported by four columns was in vogue, but in France this structure fell into disuse and the paxicide is then suspended from the extremity of a shaft ending in the form of a bishop's crook placed behind the altar. Behind the altar is placed a tabernacle (shrine) for the reliquaries. From the 13th century, in order better to display the reliquaries, chasses, etc., during feasts, the tabernacle was placed behind the altar. And the cabinet (tabernacle) to hold the relics was placed on the retable. Then (14th century) swinging painted pictures (triptychs) were placed beneath constructed in different positions. This served both to open the will. It was in the Renaissance that the great altar picture originated as a chief unit. With the early Renaissance period altars became veritable works of art. On them the greatest artists, sculptors and goldsmiths devoted their utmost talents accentuated by religious zeal.

With the growth in complexity of church edifices and their increasing separate devotional sections, other altars were installed in the additional divisions, the main altar becoming known as the high-altar, others being termed side-altars.

Portable Altars.—Termed by contemporaries variously altaria viales, portaila, gestatoria, as differentiated from the fixed or monumental church altar, these were less cumbersome pieces of priestly furniture. They consisted, as a rule, of a rectangular slab of valuable stone, as marble, agate, porphyry, onyx, amethyst, etc., enclosed in a frame of gold or gilt copper. Decorations consisted of precious stones, enamel or niello work. A wooden table usually formed the back, also richly embellished. The relic, sanctifying the altar, was enclosed in a cavity in the centre or in the corners. Beda (8th century) tells of them being used on missionary journeys; the Crusaders carried them on their campaigns in the 12th century. Some portable altars took the form of triptychs, having swinging panels that could be opened or closed at will. These consisted of ivory, precious stones or paintings. When worn by the Processionary, the altar took the form of a shrine (chasse), usually of sarcophagus shape resting on the claws of animals. Of existing examples we might mention a Romanesque portable altar in the Church of the Virgin at Treves—the travelling altar of St. Willibrord. One is in the treasury of the cathedral at Bamberg, one in the cathedral at Paderborn, two in the chapter-house of Melk, several in the Cologne archiepiscopal museum, in the royal treasury chamber at Hanover, several in the new museum, Berlin. A small Gothic wing-altar is in the sacristy at Kirchlinde, Westphalia, another (14th century) in the Admont Collegiate Church, in Steyermark; another (of 1497) in the Nuremberg Germanic Museum. The Morgan collection contains a fine Gothic (14th century) folding altar of gold, decorated with jewels and enamel.

**Altar Furniture.**—The consecrated altar of the early Christian days was enclosed. Carpets hanged from the architraves of the ciborium, or from rods between the four pillars of the baldacchino of the Renaissance, to hide the altar on all four sides (the Eastern Church developed solid walls of the iconostasis). In the Middle Ages the veil was spread across the altar piping the front. The idea of encrusting persisted, for the frontal hid the altar and the cloth covered its top; the dorsals closed the rear from view, and the riddles, hanging from rods at the sides, hid either end. The reveres made solidly replaced the dorsal curtain. And all persist to this day.

In primitive times altars were covered with rich tissue or precious stuff, over which one linen cloth was laid during the time of celebration. This served also as a corporal and was called a pall. Subsequently the corporal was a distinct linen cloth set apart specially for the purpose. The cloths used in covering the altars were designated palla (pallium altaris) down to a late period. Three linen cloths cover the altar, the uppermost being the largest and reaching to the floor. The upper linen cloth was termed the fair-linen. In the Greek Church pieces of cloth (called Evangekists) were (and are still) placed at the four corners of the altar. Over these four pieces was spread a linen cloth (saraqonhar) because it is the figure of the white winding-sheet in which Joseph of Arimathea swathed the body of the dead Saviour. Over this cloth was placed another thinner one, which represented the Glory of the Son of God seated on the altar as on a throne. Over these four pieces of cloth and these two linen coverings was a corporal, which represented the figure of the death and the resurrection of Jesus Christ.

Altar coverings (since the Middle Ages) in the Roman Catholic Church are: White for Christmas, the ordaining of bishops, etc., from 24 December till 13 January; green from 13 January to Septuagesima and in Trinity period; red for Easter and for Apostles' and Martyrs' feasts; black on Good Friday; violet on Advent and fast days.

The altar now carries: Crucifix, lights (burning wax candles) first in memory of the Last Supper held at night, but since for festivals, weddings, baptisms, etc.; flowers. See also CHALICE, O'CERT. CHORNE, PATER, FAX.

**Noted Altars.**—Justinian (6th century) presented a magnificent altar to the Church of St. Sophie at Constantinople encrusted with precious stones and enamels. That at St. Peter's at Rome is no less splendid. The altar in the
basilica of St. Ambrose at Milan by Wolvinius (835) is coated with silver plates of repoussé work. The oldest extant altar is that found at Aurilor (5th century); a similar altar is that at Marseilles. The earliest altar with carved antependium is in the church of Cividade (8th century). In St. Mark's Venice, is the famous reredos, "pala d'oro" (10th century); it was originally an antependium. In Cluny Museum is the golden antependium presented to Basle cathedral by Emperor Louis Deux. A similar arched panel, but of carved wood, is in the Episcopal Museum of the Minister in Westphalia (12th century). The ciborium altar of St. Apollinaris in Classe, near Ravenna, is of the 9th century. The best ciborium example of early Gothic is in the Church of Our Lady in Halberstadt; Ratisbonne and Vienna have two in their cathedrals; Italy has a number of mediaeval ciborium altars. A magnificent altar by Andrea Ognabene, made for the Cathedral of Fiesole (1316), is of silver work. A silver antependium (14th century) is in the Museum of St. Maria del Fiore dedicated to St. John, Baptist. A silver altar is in the baptistery of St. John, Florence, by Leonardo and other artists (14th and 15th centuries).

CLEMENT W. COUMBE.

ALTDORF,

ALTDORF, alt'dorf, Switzerland, town, capital of Uri canton, on the Reuss near its junction with the Schächen, two miles east of Lake Lucerne. The town's distinction is due to the legend of William Tell and the shooting of the apple from his son's head in the market place. A bronze statue erected in 1895, and a theatre opened in 1899 where Schiller's play of the Swiss patriot is annually performed to commemorate the feat. In the neighborhood are the Capuchin monastery built in 1581, the ancient castle of Attinghausen with its museum of antiquities, the Schächenthal and Burglen village where Tell was born and drowned, trying to save a child who had fallen into the Schächentor torrent. Pop. 4,000.

ALTDORFER, alt'dör-für, Albrecht, al'brest, German artist: b. shortly before 1480, probably in Ratisbon (Regensburg); d. there 13 Feb. 1538. One of the "Little Masters" of German art (so called because of the size of some of their works, not because of their quality), his father is supposed to have been the painter Ulrich Altdorfer. Besides his engraving, which contributes most to the artist's fame today, Altdorfer was renowned in his own time as an architect and painter, many of his works are still preserved in the latter. According to an old legend, Altdorfer was the builder of the church of the chapel at Oberklein, near Regensburg. The artist is said to have been painted by the Duke of Bavaria. His parents were of good standing and his father was a painter in the city of Regensburg, where he was born in 1480. He studied art under the famous painter Ulrich Altdorfer, who was his father. Altdorfer's works are characterized by their fine draftsmanship and attention to detail, particularly in landscapes and cityscapes. His art is said to have been influenced by the works of Dürer and the Northern Renaissance artists, but also by the Byzantine and Romanesque art of the region. He was a member of the inner circle of the Ratisbon painters and the position of municipal architect in Munich. His paintings are to be seen in the museums and private collections of Munich, where he lived, and in the Bavarian Regional Museum, among other places. His works are admired for their attention to detail and their use of light and shadow, as well as for their inclusion of historical and mythological themes. His landscapes are particularly admired for their attention to detail and their use of light and shadow, as well as for their inclusion of historical and mythological themes. His landscapes are particularly admired for their attention to detail and their use of light and shadow, as well as for their inclusion of historical and mythological themes.
strongly in such works as 'The Mountain Landscape,' at Munich or the 'Susanna at the Bath' in the same gallery. It is most strongly evinced, however, in his engraving. In this art he appears as perhaps the most original of the German masters who engraved his own wood-blocks, Dürer and the others leaving that process to skilled workmen. There is an open question as to whether Altdorfer was a pupil of Dürer's but there is no doubt of the great Nürnberg's influence on the younger man. The number of his copper- engravings is generally placed at 109 (including etchings), his woodcuts at 65 among the latter the 'Madonna of Ratisbon' should be cited. But it is the engravings such as the 'St. Jerome,' 'Samson and Delilah' and the 'Venus' which stand the highest in Altdorfer's work, and in them we get to the full the flavor of his art—precise in its mastery of the material but with a genuinely Rembrandt tendency in the thought about the pine trees, the rocks and the ruins amongst which he grouped his figures from the sacred history. Albrecht's brother ERHÄRD ALTDORFER (OF ALTDORFFER), active between 1512 and 1561, was also an architect, painter and engraver distinguishing himself in all those branches. Consult Voss, 'Meister der Graphik.' (Leipzig 1910).

ALTENA, ält'ena, Germany, a town of Westphalia, Prussia, on the Lenne, 18 miles southwest of Arnsberg, capital of the district. It has long established manufactures of iron, steel, copper, brass and nickel goods, especially of altar vessels. In the vicinity is the ancient castle of the counts of La Marck, related on the female side to the Hohenzollerns. Pop. 15,000.

ALTENBURG, ält'en-börk Germany, town, capital of Saxe-Altenburg duchy, on the river Pleisse, 24 miles by rail south of Leipzig. Altenburg manufactures cigars, gloves, brushes, hats and tobacco and has an important book trade, and traffic in grain, horses and cattle. An historic castle with its fine picture gallery, a cathedral, public library, museum of antiquities, etc., are among the principal buildings. Altenburg was an imperial city and was almost destroyed by the Hussites in 1430. In 1455 the young Saxon princes Albert and Ernest were abducted from the castle. Pop. 40,000.

ALTENSTEIN, ält'en-stin, Germany, a mountain castle in Saxe-Meiningen duchy, on the southern slope of the Thuringian forest, near the Liebenstein tourist resort, 12 miles southeast of Eisenach. The summer residence of the reigning dukes, it has great historic and scenic interest. Here in the 8th century resided Boniface, the English apostle to the Germans, and here in 1521 Luther was secreted from his enemies by Elector Frederick the Wise. In 1799 a cave which is entered through a subterranean gallery, was discovered in the castle park over 600 feet long; through its whole extent flows a rapid stream sufficiently deep to bear barges and turn a mill at the place where it issues from the earth.

ALERATION, such a change in a written instrument or property interest as, if effective, would result in a different instrument or interest from the original. The alteration of a written instrument is effected by any material change in its language or character, such as adding terms, erasing them, removing a seal from a deed. The law distinguishes in cases according as the alteration is made by a party or by a stranger. See CONTRACT; DEED; NEGOTIABLE INSTRUMENT.

ALTERNATIVE, a remedy that acts slowly and in an unknown manner, probably by promoting metabolism. Alternatives are administered in small doses, and for a considerable length of time. Mercury is a powerful alternative, and has been proved very effective in cases of syphilis. Arsenic and its compounds are employed in certain skin diseases. Cod liver oil is employed in diseases associated with malnutrition, including tuberculosis and rickets.

ALTERNATE, in American politics, a delegate chosen to act in the place of the regular delegate to a convention if his principal is absent. At all political conventions since 1840 alternates in increasing numbers have been selected to attend when their principals did not get to the convention at all, or to take the latters' places during a temporary absence. Since 1864 in all conventions of the Republican party an alternate for every delegate has been chosen. Alternates are usually seated in a separate part of the convention hall; and when a regular delegate withdraws, his alternate has the right to the seat of his principal and to act in his stead. Recent rulings by convention chairmen hold that, on roll call, if a member answer "present but not voting," he is constructively absent and the chairman may call on the alternate to vote in his stead.

In American political law the general principle is that a person elected to office must himself discharge the duties of that office. There can be no written proxies either for legislators or executive officials. In some States a lieutenant-governor may act as governor whenever the governor is absent from the State and some city charters permit a mayor to designate an acting mayor from among certain officials when he expects to be absent. In New York City the president of the board of Aldermen becomes automatically acting mayor when the mayor is absent from the city. Concerning the judiciary, there exists a certain latitude in assignment of justices, by which a justice may hold court outside his own district. This applies to both Federal and State courts. See CONVENTION; PARLIAMENTARY LAW.

ALTERNATING CURRENT. See ELECTRICAL TERMS.

ALTERNATING GENERATIONS. The term, alternation of generations, is applied to the alternation of sexual and asexual individuals in the life history of a plant; e.g., in the fern, a small sexual plant, called the prothallium, which most people never see, bears the eggs and the sperms. A spore of an egg, which then develops into the familiar fern plant. The fern plant produces spores, which in turn develop into prothallia, so that the fern plant produces the prothallium and the prothallium produces the fern plant, the two phases, or generations alternating regularly.
Alternation of generations, in a form most easily understood, is seen in the true ferns. The principal features of the life history of a common fern will make the subject clear

(Fig. 2). A spore from the fern plant, falling on moist ground or rotten wood, germinates and develops into the prothallium, a thin, flat, prostrate body, which seldom reaches more than a quarter of an inch in length or more than one-thirty-second of an inch in thickness. It is green and therefore independent (Fig. 2, A). Upon the under side of the prothallium the eggs and sperms are developed, the eggs being developed singly in organs called archegonia, while the sperms are developed in considerable numbers in organs called antheridia. A vertical section of a portion of a prothallium showing an archegonium containing one egg and an antheridium containing several sperms is shown in Fig. 2, B. Since the prothallium produces eggs and sperms, which are commonly called gametes, it has been named the gametophyte (q. v.). The sperm escapes from the antheridium, enters the archegonium and unites with the egg. This egg, thus fertilized, is the first cell of the fern plant which ultimately produces spores and is therefore called the sporophyte. After fertilization, the egg divides rapidly, forming a more or less spherical mass of cells (Fig. 2, C). It then breaks out from the archegonium and becomes erect (Fig. 2, D). The first leaves are small and simple, but the little plant develops roots and larger leaves, while the prothallium disintegrates and soon disappears completely, so that the sporophyte, now fully independent, is the only phase remaining. As the leaves approach maturity, sori, or "fruit dots," easily visible to the naked eye, appear upon the under surface (Fig. 2, E, F). A vertical section of a sori is shown in Fig. 2, E. In this case, the sori is covered by an umbrella-like indusium, underneath which are the essential structures, the sporangia. Within the sporangium, the shift from the sporophyte generation to the gametophyte generation takes place. As the sporangium approaches maturity, spore mother cells are formed (Fig. 2, G) each of which by two characteristic divisions called the reduction divisions gives rise to four spores (Fig. 2, H). The spore is the first cell of the gametophyte generation. Upon germination, it develops into the prothallium. Thus the fertilized egg, produced by the prothallium, develops into the fern plant and the spore produced by the fern plant develops into the prothallium. This regular alternation of prothallium and fern plant illustrates alternation of generations in its most easily understood form. The nuclei, during division, show a feature of great importance; the nuclei of the sporophyte have twice as many chromosomes as those of the gametophyte (See CELL and CHROMOSOMES). The number of chromosomes is doubled when the sperm and the egg nuclei fuse at fertilization, and during the two divisions by which four spores are formed from a spore mother cell in the sporangium, the number of chromosomes is reduced one-half, so that the gametophyte number is restored. This $2x^p$ and $2x^g$ condition of chromosomes is characteristic of the two generations in all plants which have reached the level of sexuality.
feathers, but it is not so easily recognized, because the gametophyte, in the higher plants, becomes parasitic upon the sporophyte, while in the mosses and liverworts the sporophyte is parasitic upon the gametophyte, not yet having attained the independent condition illustrated by the ferns.

In the higher plants, as the gametophyte became dependent upon the sporophyte and even became included within the tissues of the sporophyte, it became more and more reduced until it lost all resemblance to an independent gametophyte and is recognizable as such only by the evidence of comparative morphology. A complete series of forms illustrating the gradual reduction of the gametophyte would require pages of description and illustration, but a pine and a sunflower will indicate the general trend of the reduction. The pine tree and the sunflower plant are sporophytes. The pine (also the fir, spruce, hemlock, etc.) bears two kinds of cones, a rather small one producing an abundance of pollen and a comparatively large one producing seeds. The small cone, called the male cone or the stamine cone, consists of an axis with a large number of very small and much modified leaves, each bearing on its upper surface two sporangia which are equivalents of the sporangia of the ferns. The sporangium contains several spore mother cells, each of which produces four spores, called microspores or pollen grains. The microspore is the first cell of the male gametophyte. The larger cone, called the female or ovulate cone, consists of an axis bearing much reduced leaves, in the axil of each of which is a "scale" with two sporangia or ovules. Within the sporangium one spore mother cell appears and divides into four spores, called megaspores, three of which disintegrate while the other germinates within the tissue of the sporangium, forming a prothallium or female gametophyte, consisting of a mass of rather uniform cells, and later producing four or five eggs. The megaspore is the first cell of the female gametophyte. The pollen grain is carried by the female cone where it falls upon the sporangium and germinates, forming a pollen tube which grows down through the tissue of the sporangium until it reaches the egg. Two sperms are formed within the pollen tube and one of these enters the egg and fertilizes it. As in the fern the fertilized egg is the first cell of the sporophyte generation. The egg divides rapidly and becomes differentiated into root and stem regions, while the tissues of the sporangium and surrounding structures become hardened into a seed coat. The seed then falls out from the cone and develops into the pine tree. In comparing this life history with that of the fern, it will be noted that in the fern there is only one kind of sporangium producing one kind of spore which gives rise to a gametophyte, while in the pine there are two kinds of sporangia, one producing spores which give rise to male gametophytes and the other producing spores which give rise to the female gametophytes. Plants with only one kind of spores are homosporous. Those with two kinds of spores are heterosporous. This condition is derived from the homosporous and is found in all seed plants and in some ferns and lycopsids.

In the sunflower the reduction of the gametophyte is still more extreme. The sunflower is composed of hundreds of very small flowers, each of which has five stamens and one ovary. The stamen bears four sporangia, each containing hundreds of microspores or pollen grains. The ovary contains one sporangium within which one spore mother cell produces four megaspores, one of which germinates, while the others abort. The prothallium formed by the germination of this spore is entirely included within the sporangium and is completely dependent. It is called the embryosac and contains only eight nuclei, which at first lie free in the sac. Later, three of these in the narrower end of the sac become separated by walls. These three are called polar nuclei, while the others are called central nuclei. Two of the nuclei, called polar nuclei, fuse and form a large nucleus called the endosperm nucleus. The other three form a group at the opposite end of the sac from the antipodals and constitute the egg apparatus. They become organized as more or less definite cells, but are surrounded only by a delicate pellicle. One of the three is the egg; the other two are called synergids, because they are supposed to assist in fertilization. The pollen grain is carried by the tip of the ovary by insects and there produces a long pollen tube containing two sperm nuclei. One of these nuclei fuses with the endosperm nucleus which then divides and produces a tissue called the endosperm, constituting the principal bulk of corn, cereals and other seeds. The other sperm nucleus fuses with the egg, which, as in the other cases already considered, is the first cell of the sporophyte generation. From the fertilized egg a new sunflower plant is produced. The gametophyte generation consists of two separate plants, the male and the female. The male, composed of

---

**Fig. 3** — Some important features in the life history of the pine. A, part of a longitudinal section of a male cone showing one sporangium and part of another, containing pollen grains; B, part of a longitudinal section of a young female cone showing a reduced leaf, l, bearing a large scale, sc, which bears a sporangium, o, containing a number of spores, s; p, pollen grains; C, longitudinal section of sporangium (ovule) at a later stage; p, pollen grains; l, pollen tube containing two spores, s; f, female gametophyte showing two of the eggs, e.
the pollen grain and its tube, and the female, consisting of the embryo-sac, alternate with the sporophyte generation, the sunflower plant, which begins with the fertilized egg. Some features of the life history of the sunflower are shown in Fig. 4.

In plants below the liverworts, i.e., in the algae and fungi, alternation of generations is easily recognized in many cases. In forms which have not reached the level of sexuality there is no alternation, but with the origin of sex, i.e., with the fusion of gametes, the sporophyte had its beginning. In many of these simple plants reduction of chromosomes occurs immediately after the fusion of gametes without the formation of any spores, no recognizable body being built up which could be called a sporophyte. As the interval between the fusion of gametes and the reduction of chromosomes became more prolonged, a recognizable body was formed, which in some cases looked like the gametophyte and in some cases looked different. When this body produces spore mother cells, each of which gives rise to four spores, practically all botanists admit that there is an alternation of generations. It must be admitted that the term sporophyte is a misnomer in those simple forms which do not produce spores, but the fundamental feature is this, that the fusion of gametes initiates a generation — long or short — which comes to a close with the reduction of chromosomes. Consequently, we should insist that the two generations are marked by the number of chromosomes; the sporophyte having twice as many as the gametophyte.

The sporophyte, at its beginning, is small and, in many cases, dependent upon the gametophyte; but higher in the scale it becomes independent and is the generation which we recognize as the plant. On the other hand the gametophyte in the early forms is the dominant generation which, higher in the scale, becomes dependent, and then more and more reduced until it can be seen only with the aid of the microscope. Here it is the sporophyte which we recognize as the plant. This evolution of the sporophyte and reduction of the gametophyte are among the most interesting phenomena of plants.

We believe that in animals, as well as in plants, there are two alternating generations, characterized by the number of chromosomes, but this belief is shared by only a few botanists.
and, as far as we know, practically all zoologists oppose it.

CHARLES J. CHAMBERLAIN, Professor of Morphology and Cytology, University of Chicago.

ALTGELD, alt'geld, John Peter, American politician: b. Germany, Dec. 1847; d. 12 March 1902. Brought to Mansfield, Ohio, in infancy, he received a public-school education; served in the Civil War as a private in the Union army, 1864-65; taught school in Missouri; became a lawyer there and county attorney of Andrew County in 1874. Removing to Chicago in 1875 he became prominent in the Democratic party. An unsuccessful candidate for Congress in 1884, he was judge of the Chicago Superior Court 1886-91. Elected governor in 1892, one of his first official acts was to pardon three anarchists, imprisoned since 1887 (two for life and one for 15 years) for complicity in the bomb-throwing which killed seven policemen in Chicago, 4 May 1886 (See Anarchism; Haymarket Massacre). It should be said that many leading United States citizens had petitioned for their release on the ground of insufficient evidence, an assumption which Judge Gary (q.v.) has vigorously repelled. Altgeld was governor till 1897. He was a prominent champion of free silver and an active supporter of Bryan for the Presidency in 1896 and 1900, and was defeated as independent candidate for mayor, 1899. He was an able speaker, an efficient advocate of prison reform, and appears to have been moved chiefly by sympathy with the working class. He wrote: 'Our Penal Machinery and Its Victims,' 'Live Questions,' etc.

ALTHEA. See Hollyhock; Marsh Mallow.

ALTHORP, Lord. See Spencer.

ALTHUSIUS, Johannes, German philosopher: b. 1557; d. 1638. He was for many years professor of ethics and law at Herborn. He wrote the first treatise on politics ever produced in Germany. His system claimed that social life was based on a contract express or implied between men; he was thus the forerunner of Rousseau. He claimed that all rights proceed from the body and was quite outspoken against any usurpation of those rights. He included workingmen's unions or combinations among monopolies requiring regulation. He wrote 'Política Methodò Digesta' (Herborn 1603); 'Jursprudencia Romanæ' (ib., 1588); 'Dìcæologico Libri tres Totum et Universum, Ætius, Memphis, Compendium Compendium Contingentes' (ib., 1617) Consult Gierke, Otto, 'Johannes Althusius' (Breslau 1880).

ALTIMETRY, the art of ascertaining altitudes geometrically by means of a quadrant, sextant, or theodolite. The instrument so used is then known as an altimeter.

ALTISCOPE, an instrument consisting of an arrangement of mirrors in a vertical framework, by means of which a person is enabled to overlook an object (a parapet, for instance) intervening between himself and whatever he desires to see, the picture of the latter being reflected from a higher to a lower mirror, where it is seen by the observer.

ALTITUDE, in mathematics, denotes the perpendicular height of the vertex of any plane or solid body above the line or plane of its base; thus the altitude of a triangle is measured by a perpendicular let fall from any the of its angles upon the base, or upon the base produced; therefore the same triangle may have different altitudes, accordingly as we assume one side or another for its base. Again, the altitude of a cone or pyramid, whether right or oblique, is measured by a perpendicular let fall from the vertex to the plane of its base. Similar remarks apply to other solids. In astronomy altitudes are measured or estimated by the angles subtended between the object and the plane of the horizon; and altitude may be either true or apparent. The apparent altitude is that which is obtained immediately from observation; and the true altitude which results from correcting the apparent altitude, by means of parallax, refraction, etc. The altitude of a terrestrial object is the height of its vertex above some horizontal plane assumed as a base.

ALTITUDE AND AZIMUTH INSTRUMENT. Altitude, in astronomy, is the height of a heavenly body above the horizon, and is measured, not by linear distance, but by the angle which a line drawn from the eye to the heavenly body makes with the horizontal line, or by the arc of a vertical circle intercepted between the body and the horizon. The azimuth of a heavenly body is the angle measured along the horizon between the north or south point and the point where a circle, passing through the zenith and the body, cuts the horizon. An altitude and azimuth instrument consists essentially of a vertical circle with its telescope so arranged as to be capable of being turned round horizontally to any point of the compass. It thus differs from a transit instrument, which is fixed in the meridian. To take an altitude the telescope is directed toward the body to be observed, and the angle which it makes with the horizon is read off the graduated circle. The altitude thus observed must receive various corrections—the chief being for parallax and refraction—in order to get the true altitude. The azimuth—derived from an Arabic word signifying "a quarter of the heavens,"—is usually measured westward from the point most remote from the elevated pole, beginning at 0° and returning to it at 360°. Thus, in northern latitudes, where the north pole is elevated, the azimuth is measured from the south point, so that the east point, for instance, has an azimuth of 270°.

ALTON, ålt'ôn, Ill., city in Madison County, on the Mississippi River and on the Chicago & Alton, Cleveland, Cin., C. & St. L., C. B. & Q., C. P. & St. L., Illinois Terminal and Missouri & Illinois Bridge & Belt railroads. Seventeen miles above the mouth of the Missouri River and 25 miles north of St. Louis. Alton was settled early in the century, but was not in-
CORPORATED AS A CITY UNTIL 1837. THE CITY, BUILT UPON A HIGH LIMESTONE BLUFF, HAS MANY PICTURESQUE SURROUNDINGS. Seat of Shurtleff College, Monticello Seminary and Western Militia Academy. There are independent schools. Churches of all denominations. Alton has considerable river trade and is a distributing point for farm products. Large manufacturing district producing bottles, pig lead, straw bale, canning tools, cartridges, stokers, mine cars, brick, sewer pipe, oil products, powder, flour, meat products, stone and sand. Annual value of manufactured products, $40,000,000. The city is governed by a mayor and common council elected every two years by the people. There are two national and three savings banks and two daily newspapers. In 1837 Elijah P. Lovejoy, theabolitionist, was murdered here. A monument to his memory was erected in 1897. Pop. (1915) 25,000; including suburban 14,000.

ALTON LOCKE, a story by Charles Kingsley, published in 1850. It was his first novel, and displayed the author's broad sympathy for the condition of the English working classes. It excited immediate attention, and was an important factor in arousing the upper classes to a realization of their responsibilities toward the less fortunate. The altruism of Locke and his friends, Crossewaite, Mackay, Lady Ellerton and Eleanor, forms an admirable and inspiring feature of the book.

ALTONA, a town in the Prussian province of Schleswig-Holstein, on the Elbe, immediately west of Hamburg. It has spacious squares and streets, which are embellished by several monuments, notably the memorials of the wars of 1804 and 1870. There are fine municipal and judicial buildings, a theatre, a gymnasium, technical schools, a school of navigation and a hospital. It has manufactures of tobacco and cigars, of machinery, woolens, cottons and chemicals. There are also extensive breweries, tanneries and soap and oil works. It has an extensive maritime trade, but its neighbor, Hamburg, is easily its commercial superior. Pop. 168,101.

ALTOONA, a town in Blair County, on the Pennsylvania Railroad, 118 miles east of Pittsburg. It has an elevation of 1,822 feet above the sea; situated in the midst of a most picturesque mountain region, at the eastern base of the Alleghany Mountains. For many years Altoona has been regarded as the most typical of American railroad towns, for here are located the immense machine shops of the Pennsylvania Railroad, the largest railroad shops in the world, where over 17,000 workmen are engaged in manufacturing and repairing locomotives, passenger coaches and freight cars. The normal output from the shops is five engines a week. There are also silk mills, planing mills, a brick and tile works and other important manufactories of machinery, agricultural implements, etc. According to 1917 estimate of manufactures there were in that year 70 establishments of factory grade employing 19,165 persons, of whom 16,971 were wage earners, receiving a total of $20,301,165 in wages and salaries. Altoona is centrally situated in a bituminous coal region and is also the business centre of a considerable agricultural region. The city has an excellent school system, a fine high school and many private schools. Among its 52 churches are many handsome buildings. It has three banks and three trust companies with a combined capital of over $1,000,000; a large library building and several hospitals. The famous Horseshoe Bend, on the line of the Pennsylvania Railroad, is located near the city, and Lakemont Park is a well-known pleasure ground in Logan township. The village of Altoona, which was included in 1872 at a cost of $680,000, and upon which $97,000 is expended annually. The city's expenses aggregate $565,000 yearly, of which amount about $280,000 is expended for schools, $50,000 for the police department and $20,000 for municipal lighting. The city was founded in 1850 by the Pennsylvania Railroad Company. It was first incorporated as a borough in 1854, and chartered as a city in 1868. The commission form of government was adopted in 1914. During the great railroad strike of 1877 Altoona was the centre of the disturbed section and troops were ordered out to protect railroad property here. It is a growing, thriving city. There are three daily and numerous weekly newspapers. Pop. (1910) 52,127; (1916) 60,000.

ALTOONA, or ALTOONA PASS, a mountain pass in northern Georgia, the scene of a sharp engagement between the Federal troops under General Corse and the Confederates commanded by General French, on 5 Oct. 1864. The losses on each side were about equal.

ALTO-RELIEVO, a term applied to sculpture that projects from the plane to which it is attached to the extent of more than one-half the outline of the principal figures.

ALTRICES, birds that are hatched from the egg before they have acquired feathers or the ability to care for themselves. Hence they must remain in a nest and be protected and fed by the parents. This division, also called nidicolous, includes all birds except those known as game-birds and sea-fowl.

ALTRINCHAM, a town in Cheshire, eight miles south of Manchester. Many residences are occupied by those whose business is in Manchester, who are attracted by the healthful climate and the vicinity of Bowdon Downs and Dunham Massey Woods. Market gardening is carried on, large quantities of fruit and flowers being grown for sale in Manchester. Cabinet-making is also practised, and there are saw-mills, iron foundries and manufactures of cotton, yarn and worsted. Pop. 16,831.

ALTRUIST, a term in psychology and ethics to denote disposition and conduct directed toward the well-being of others. It is contrasted with egoism, or self-seeking disposition and conduct. It is essential to altruism, as well as to egoism, that the good of others, or of self, should be consciously and intentionally pursued. Actions and dispositions which are injudicious, such as mere animal instinct, are not, properly speaking, altruistic, nor are the opposite egoistic. It is only when the consciousness of self is sufficiently developed in the child to give rise to a contrast between self
and the "other" (alter), that the conscious pursuit of the interest of one of them is possible. This is covered by psychologists by saying that real altruism and egoism are always "reflective." Altruism is also applied to the type of ethical theory which bases morality upon generous or altruistic disposition or conduct (in the sense defined above).

ALTSEHLER, ält'shá-lér, Joseph Alexander, American author and journalist, b. Three Springs, Ky., 29 April 1862. He studied at Vanderbilt University and has been connected with the Louisville Courier-Journal and the New York World. His numerous novels are chiefly on American historical subjects and among them are 'The Sun of Saratoga' (1897); 'A Soldier of Manhattan' (1897); 'The Last Rebel' (1899); 'In Haste Red' (1900); 'In Circling Camps' (1900); 'My Captive' (1902); 'The Wilderness Road' (1901); 'The Candidate' (1905); 'The Forest of Swords' (1915); 'The Hosts of the Air' (1915); 'The Guns of Europe' (1915).

ALTUS, Okla., city and county-seat of Jackson County, 145 miles southwest of Oklahoma City, the Saint Louis and San Francisco, the Kansas City, Mexico and Orient and other railroads. It contains flour, oil and alfalfa mills. Stock raising and truck farming are important industries of the surrounding district. The city owns the electric plant and the waterworks. Pop. 5,200.

ALTWASSER, ält'väs-ër, Germany, town in Silesia, 43 miles southwest of Breslau. It has factories for glass, porcelain, machinery, cotton-spinning, iron foundries and coal mines. Pop. (1910) 12,144.

ALUM, in chemistry, a general name for a large class of substances, which may be defined as double sulphates or sulfnates, in which one of the bases is aluminum, chromium, manganese, iron, indium or gallium, and the other is sodium, potassium, rubidium, caesium, ammonium, silver or thallium. The alums all crystallize in cubes or octahedra, with 24 molecules of water of hydration, so that when in solution together they cannot be separated by crystallization. In naming them alum is understood to be one of the metals present unless the contrary is expressly indicated. Thus "potash alum" is the alum whose formula is \( \text{Al}_2(\text{SO}_4)_3 + \text{K}_2\text{SO}_4 + 24\text{H}_2\text{O} \). If aluminum is not present, the metal that replaces it is stated; thus "iron-sodium alum" is the alum whose formula is \( \text{Fe}_2(\text{SO}_4)_3 + \text{Na}_2\text{SO}_4 + 24\text{H}_2\text{O} \). When selenium replaces the sulphur in one or both of its positions, the alum is most clearly identified by giving its formula. In addition to the true alums a class of substances known as "pseudo-alums" exists. These also crystallize with 24 molecules of water, but they are not isomorphous with the true alums. MgSO4 + 24H2O is an example of this class.

All the alums are soluble in water, and it is probable that all are resolved, at least partially, into their constituents, by solution. It is known that in certain cases (in silver alum, for example) the base is 56% and the solute 44%. The alums give an acid reaction when in solution, all have an astringent taste and all lose their water of crystallization when heated.

The alum of commerce is assumed to be potash alum, the formula of which has been already given. Ammonia alum — \((\text{NH}_4)_2\text{SO}_4\cdot\text{Al}_2(\text{SO}_4)_3\cdot24\text{H}_2\text{O}\) — is sometimes substituted, however, owing to the higher price of ammonia, which is now obtained as a byproduct in the manufacture of illuminating gas. Sodium alum is probably not substituted for potash alum to any great extent.

The alums are largely used in the arts, especially in dyeing and tanning, and in the purification of water. Potassium alum is also used with borax in waterproofing cloth and with lime in preserving timber; in the size used in paper making; and as a soap precipitant in the manufacture of glycercine. Bread made from flour containing a small amount of alum is said to be very white, and partly for this reason and partly on account of the cheapness of the substance, ammonia alum has been largely used in the manufacture of baking-powders. This practice has been condemned on the grounds that it is detrimental to health, however, by nearly all the authorities who have written on the subject.

Commercial alum is made from alum stone (see ALUNITE), from alum shale, or from bauxite and cryolite, generally by roasting. It is also made in greater purity by mixing solutions of the sulphates of alumina and potassa and allowing the alum to crystallize out. In making ammonia alum, sulphate of ammonia is substituted for the potassium sulphate (see ALUNITE). Some alums occur native. (See MENDOZITE; TSCHERMIGITE.)

The United States census of 1914 reported 19 establishments making alums, with a total output of 313,712,000 pounds, valued at $3,467,969, an increase over 1909 of 37,418,000 pounds, and $445,614. Of the 19 establishments, 5 were located in Pennsylvania, 3 each in Illinois, Massachusetts and New York, 2 in Michigan and 1 each in California, Connecticut and New Jersey. The output comprised 142,438,000 pounds reported as aluminium sulphate, valued at $1,277,836; 23,338,000 pounds of alum cake, valued at $251,186; 42,502,000 pounds of concentrated alum, valued at $470,730, and 67,765,000 pounds of burnt alum, valued at $304,656. 12,765,000 pounds of potash alum, valued at $219,968; 13,995,000 pounds of soda alum, valued at $254,477, and 55,985,000 pounds of other alums, designated as porous alum, excelsior alum, pearl alum, ammonium alum and chloride of alumina, valued at $649,116.

Alum Poisoning.—This poisoning may be acute or chronic, the latter being much more common. In the acute variety, often the result of accidental drinking of a gargling solution, the symptoms are nausea, vomiting, cold clammy skin, small thready pulse, thirst, muscular tremor, followed by a rise in temperature in those that have recovered. The treatment pursued in the case of alum poisoning is to wash out the stomach and use the white of eggs as a chemical antidote.

Alum being so widely employed as a preservative, as a means of clarifying water and as an adulterant in baking-powders, the question of chronic alum poisoning becomes of great importance. The symptoms and effects that have been most frequently observed in such poisoning are disturbances of digestion and constipation. The question as to its harmful action
on the kidneys is not yet decided, but it would seem to be harmful rather than the reverse.

ALUMBAGH, a domain in India formerly belonging to one of the princes of Oudh, about four miles south of Lucknow, near the road to Cawnpore. It comprised a beautiful palace of a mosque, a temple and other buildings surrounded by a garden, all in the centre of a magnificent park enclosed by a lofty wall with turrets at each angle. On the outbreak of the Indian mutiny this place was occupied by the rebel Sikhs and converted into a fort. On 23 Sept. 1857 it was captured by the British, then on their way to relieve Lucknow. Leaving a garrison of 300 European troops, together with the sick and wounded and about 4,000 native camp-followers, the main body, under Outram, Havelock and Neil, pushed on to Lucknow. These generals were unable to send reinforcements, but at the end of November the place was relieved by Sir Colin Campbell with Lord James Outram, with a force of 3,500 men. He took the Alumbagh task which he successfully accomplished, though repeatedly attacked by overwhelming numbers of the rebels. In March 1858 the garrison was finally relieved. At the foot of a tree within the grounds Sir Henry Havelock was buried.

ALUMINA (Al₂O₃), the only oxide of the metal aluminum. As found native, crystallized, it is only second to the diamond in hardness. The transparent varieties are the sapphire and ruby, the opaque are corundum and emery, only the corundum being pure. In combination with silica it is one of the most widely distributed of substances, ranking in this respect next to oxygen and silicon. It enters in large quantity into the composition of granites, trapps, slates, schists, clays, loams and other rocks. The hydrated oxide, Al₂O₃·H₂O, occurs as sapo- and with ferric oxide as bauxite. Various aluminates occur in certain gems, as in spinel and chrysoberyl. Alumina may be obtained by adding a solution of ammonium hydrate to purity alum dissolved in 25 parts of water, thoroughly washing the very gelatinous precipitate formed, and then drying it carefully. It may also be prepared by igniting powdered alum in air or oxygen. Alumina is a white powder, without taste or smell, and insubstantial except in the oxyhydrogen flame. It is the basis of porcelain, pottery, bricks and crucibles; and it has a strong affinity for oil and coloring matter, which causes it to be employed in the state of clays as a cleansing powder, and in a state of purity in the preparation of the colors called lakes, in dyeing and calico-printing. It combines with the acids, and forms numerous salts, the most important of which are the sulphate (see ALUM) and the acetate. The latter salt is formed by digesting strong acetic acid (vinegar) with the newly precipitated earth; but for the making of the coloring lake the mixture of alum with acetate of lead (sugar of lead), or more economically with acetate of lime, a gallon of which, of the specific gravity 1·050, is employed for every 2½ pounds of alum. The sulphate of calcium formed falls to the bottom, and the acetate of alumina, which is tanninative in solution with an excess of alum, which is necessary to prevent its decomposition. It is of extensive use in calico-printing and dyeing, as a mordant, and is employed in the place of alum, to which it is generally preferred.

ALUMINITE, a mineral having the composition of a hydrous aluminium sulphate, Al₆O₁₃·9H₂O, occurring in the form of concretion in beds of clay in Germany, England and other European countries. It is opaque, of earthy lustre and fracture, and is soft and light.

ALUMINO-THERMICS, a term designed to embrace the processes of reduction of metals by taking advantage of the intense affinity for earthy lustre and fracture, and is soft and light. temperatures.

The principal industrial applications of these processes are: (1) The welding of iron and steel in place as in the uniting of railroad rails, and in repairing broken shafting and the like; (2) the production of pure metals and alloys free from carbon, nitrogen and other common impurities; (3) in foundry practice for re- viving or increasing the temperature of molten iron or steel in the ladle before pouring; (4) in the manufacture ofings and repairing flaws in large ones; (5) in surface softening of hardened steel to permit tooling or boring and the cutting of large openings.

In the welding process the aluminum is reduced to a powder or granulated and mixed with a metallic oxide, in most cases the oxide of iron. This mixture has been given the commercial name "thermit." The chemical reaction, which consists in oxidizing the finely divided aluminum, is started by producing the high temperature necessary at only one point in the thermit. This is accomplished by a priming powder composed preferably of metallic magnesium and barium peroxide. The primer is ignited by a fiercely burning storm match or by touching it with a red-hot iron rod. The reaction then spreads spontaneously and with great rapidity and with considerable violence. In a few seconds the entire mass is a white-hot fluid at a temperature estimated to be about 5400° F.

In the crucible after the reaction there are two layers. The bottom one is pure metal of equal weight to, but occupying only one-third of the space of, the top layer, which is now oxide of aluminum, so-called corundum. The most commonly employed of the welding processes is the one by which a continuous rail—a desideratum in modern road construction—is simply, cheaply and effectively obtained. The marked advantage enjoyed by this system is the freedom from bulky equipment; a crucible, a mold box and, in instances where a complete butt weld of the head of the rail is desired, a rail-clamp is all that is required. All these materials, including the necessary quantity of thermit, can easily be moved on a hand truck. Each weld, according to the section, requires from 15 to 20 pounds of thermit, and the metal welded around the joint will only weigh five to ten times as much as the 10 pounds.

The thermit reaction takes place in a crucible which rests on a simple iron stand that can be attached to the rails or rail-clamps where such are used. The crucible consists of a sheet-iron mantle lined with magnesia or corundum slag, and in which is suspended in solution with an excess of alum, which is necessary to prevent its decomposition. It is of extensive use in calico-printing and dyeing, as a
The life of the crucible itself is about 25 reactions. The crucible is plugged by two asbestos washers covered by a metal disk over the outflow or thimble. In the latter is suspended a piece of iron wire, the lower end of which projects below the base of the crucible. This is driven up by a blow and so “taps” the crucible for each reaction. In the reheat in sight of the crucibles washers burst through the plugging material. To prevent this the metal disk is further covered by a layer of magnesia sand.

The mold is made according to a special design for each section. It consists of four parts, one on each side, exactly fit and firmly enclose the rail. It must be dry and porous. On a large scale molds are made by manufacturers of refractory earthenware or by railway lines, according to their requirements, in their own shops, by tamping an ordinary mixture of loam and sand in equal parts into a sheet-iron case placed over the model. This sand mold must be dried during a couple of hours at a temperature of about 212°F. Before placing the mixture, the metal to be cast is cleaned of dirt and rust with a wire brush and warmed with a gasoline torch. In case the tops of the rails are to be butt-welded the sections must be filed. The thermit is then poured into the crucible from bags containing, the necessary amount for each section. After the charge in the crucible has been ignited in the usual way the reaction takes its course and the crucible is tapped to allow the liquid steel to flow into the mold. The great heat of the liquid thermit steel literally melts and amalgamates the ends of the rails projecting into the molds, making them as one, so that when cool it leaves a continuous rail. The joint is stronger than an equal section of the rail, from the fact that a shoe or collar of metal is cast around the rail at the joint.

It has been found that there are no changes in the composition or temper of the steel in the rail and it is left just as it was, except that the ends are melted together up to, and generally a little above the bottom of the tread of the rail, so that a slight longitudinal expansion has taken place.

The so-called third rail is also welded by this means.

Steel girders for construction work can, of course, be welded in the same way as rails. Practically the same process is used in butt-welding pipe up to six inches diameter. In making marine and other large repairs thermit welding has proved invaluable, the mold being made and the work done in place, without removal to a foundry. In this way the broken crank shafts or rudder and stern posts of great steamships have been welded in a few hours.

Among the pure metals produced by the aluminothermic reaction may be mentioned in the first instance chromium free of carbon. It is used in the manufacture of particular qualities of certain tool steel with a limited percentage of carbon, and nowadays hardly any high-speed tool steel is made without it. Pure manganese also produced by this process finds employment in copper and nickel manufacture, and, furthermore, in the production of particular sorts of manganese steel of great strength and great elasticity with 12 to 14 per cent manganese, used particularly for bolts of machinery exposed to great strains. Pure molybdenum and ferro-vanadium have also lately been put on the market. Ferro-titanium has been in use with a number of steel works for quite a considerable time, to deoxidize the steel and remove nitrogen. It also gathers sulphur and phosphorus, and imparts a high degree of strength. In addition to the pure metals several of their alloys are produced in exceptionally pure form by the aluminothermic processes.

In foundry practice the thermit is plunged to the bottom of the molten metal in the pouring ladle or thrown upon the surface of the metal in the riser. In making small castings required quickly the thermit is ignited in a flat-bottom crucible and in 30 seconds can be poured into the mold. Where more than 10 pounds of thermit is used it is necessary to add 10 per cent of clean steel punchings or rivets to the thermit to modify the intensity of the reaction. A further addition of 1 per cent of metallic manganese and 1 per cent of nickel thermit will improve the quality of the casting. In the replacing of parts broken off the repair form is modeled on to the work with yellow wax and the molding loam packed around it. The wax melts away when the work is heated preparatory to the pouring of the thermit steel.

In the use of thermit for locally softening armor plate and other hardened steel the powder is heaped within a confining ring and ignited. The heat generated is sufficient to affect the metal to a depth of two inches. From 30 to 40 pounds of thermit are required to the square foot.

Analyses of thermit steel show an average of carbon, .05 to .1 per cent; manganese, .08 to .1 per cent; silicon, .09 to .2 per cent; sulphur, .03 to .04 per cent; phosphorus, .04 to .05 per cent; aluminum, .07 to .18 per cent.

The quarterly magazine Reactions is devoted to the aluminothermic industry. Considerable work of this kind has already been done in Germany.

Aluminum, or Aluminium, the most abundant of all metallic elements in the earth's crust, and ranking high among all the known elementary substances, follows the gases oxygen and silicon. It is a large constituent of all common rocks, excepting only the sedimentary rocks — the sandstones and limestones — and forms about 15 per cent of the solid substance of the world. Aluminium is never found native, but in the form of oxide, fluoride, phosphate, silicate, sulphate, etc. Its most important ore, and that from which the whole commercial supply is produced, is known as bauxite (q.v.). This mineral is a hydrated silicate of aluminium, containing when pure, 74 per cent of aluminium — 39 per cent of the metal. As it comes from the mines, bauxite is a mixture, containing not more than 50 to 60 per cent of alumina. For several years the State of Arkansas has produced more than 80 per cent of the bauxite mined in the United States, the remaining being supplied by Alabama, Georgia and Tennessee. The Tennessee product, however, being of especially high grade, is used in the manufacture of the chemical salts of aluminum, and very little, if any, reaches the furnaces which produce the metallic aluminum.
Practically all the metal produced in the United States is obtained by the Hall process. Alumina is first prepared by the Bayer process. Bauxite, very finely ground, is digested with caustic soda under steam pressure of 70 to 80 pounds, sodium aluminate being formed. This solution is then filtered and run into tanks where it is agitated with freshly precipitated alumina. About 70 per cent of the alumina present is thrown down. This is washed free of sodium and the moisture evaporated. When dry, it is charged into an iron tank lined with carbon, containing a fused bath of cryolite, with some other admixtures, such as fluorite of sodium and fluorite of calcium, or similar ingredients, the nature of which is guarded as a trade secret. Above the vat are suspended a series of carbon anodes which may be lowered into the bath. The alumina being stirred into the fused cryolite, the anodes are lowered and the current turned on. The alumina is decomposed and the metallic aluminum collects in the bottom of the bath and is drawn off from time to time. The bath is unsalted, as the dissolved alumina is exhausted, more is stirred in, and the operation continues as long as the current is provided. The most scrupulous care is taken that the materials used shall be free from silica and sodium. The first reduces resistance to corrosion, and the second produces a yellowish coating particularly objectionable in aluminum cooking utensils. Plants for the economical production of aluminum have to be very large. The metal cannot be produced cheaply on a small scale.

**Characteristics and Properties.**—As found in the market, aluminum varies from 98 per cent to 99.75 per cent pure, the impurities being chiefly iron, silicon, copper and sometimes sodium. It is greyish white in color with a bluish cast, quite distinct from silver, nickel and tin. It has a satiny lustre and is practically unaffected by pure air, though in regions where the atmosphere is permeated with mixed gases from factory chimneys, sheet aluminum soon becomes yellow and eventually falls to powder. Owing to its great affinity for oxygen, aluminum is almost instantly covered with a very thin pellicle of oxide which acts as a protection to the metal beneath. In hardness it closely resembles silver, and this may be considerably increased by working. In elasticity it compares with copper as three to four. Its thermal conductivity is very high, exceeded only by copper, and being double that of tin and three times that of iron. Its electrical conductivity is 61 per cent that of copper, so that wire to carry an equal charge must be 64 per cent larger in sectional area; that is, 28 per cent greater in diameter. Aluminum is sonorous to a high degree, and this quality is improved by the addition of a little silver or German silver. Aluminum is formed into ingots and may be drawn into wire 1/250 of an inch in diameter, which has about half the strength of copper wire of the same size. In malleability, aluminum ranks next to gold. It may be rolled into sheets 17/10,000 of an inch in thickness, and the may be hammered into foil 1/10,000 of an inch in thickness. Its tensile strength is ordinarily from 6.5 to 15.5 tons per square inch, with a top limit for selected specimens of 29 tons. Weight for weight it has a tensile strength equal to that of 80,000 pound steel. Thus the weight of steel in an eight-inch girder would make a 15-inch girder of aluminum, which would carry 80 per cent more than the steel. Aluminum is non-magnetic and therefore exceedingly useful in much electrical work. Like lead, aluminum has the property of extrudability, and when warm may be pressed into a mold of any shape through a small opening. If the mold is of polished steel the aluminum will have a surface as perfect as if machined. By virtue of this quality it may be pressed into continuous bars and tubing of any length, and into engineering shapes of great strength, fancy moldings, cornices, etc. This property is also possessed by some of its hard alloys. Its atomic weight is 27; its atomic volume, 10.1; its specific gravity is 2.56, which is increased by rolling to 2.67; its specific heat ranges from 0.2120 to 0.2185. Its melting point is 215°F. In fusing it expands about 5 per cent and its specific gravity falls to 2.54. Above 1500°F, the metal "burns"; that is, it unites very rapidly with the oxygen of the air.

Aluminum is not affected by organic acids, and resists well cold sulphuric and nitric acids, but dissolves speedily in hydrochloric acid. The alkalies readily decompose it. As compared with other metals, for a given gauge of plate, one ton of aluminum is equal in area to 2.7 tons of tin, 2.88 tons of iron, 3.33 tons of copper and 4.22 tons of lead. One pound of sheet aluminum of any thickness will cover 3 1/3 times the area covered by a sheet of brass of the same thickness. Compared with copper, aluminum sheets are 25 to 50 per cent cheaper for the same area, 66 per cent lighter and in many cases much more durable.

**Alloys.**—Aluminum forms alloys readily with all the common metals except lead. The alloys which have been found more or less useful have been combinations of aluminum with copper, chromium, tungsten, titanium, molybdenum, zinc, bismuth, nickel, cadmium, magnesium, manganese, tin or antimony,—all of these alloys being distinctly harder than pure aluminum. A small percentage of manganese adds ductility to these alloys without reducing their strength. The copper-aluminum alloys, containing 10 to 11 per cent of copper, are known as aluminum-bronze. These alloys are not corroded by sea water, making them of special value for marine fittings. (See Bronze.) When aluminum is alloyed with 7 to 10 per cent of copper, a tough metal results; it is especially useful in automobile parts and other construction forms which are subjected to sudden and severe shocks. The zinc-aluminum alloys yield a metal eminently adapted for forging, being tough and flowing well under dies. Some of the zinc-aluminum alloys are but little heavier than aluminum, are as rigid as bronze, and machine as readily as brass. They are very extensively used in making motor casings for automobiles and aircraft. With iron, aluminum combines in all proportions, but the addition of little iron to aluminum, are as rigid as bronze, and machine as readily as brass. They are very extensively used in making motor casings for automobiles and aircraft. With iron, aluminum combines in all proportions, but the addition of little iron to aluminum, are as rigid as bronze, and machine as readily as brass.
increasing the steel in tensile strength, its chief effect is to produce smoother and more homogeneous ingots. With cast iron the addition of aluminum is from 4 to 8 pounds per ton, lessening the tendency to chill, causing it to flow smoothly and giving it a closer grain. In wrought iron, aluminum increases the tensile strength 30 per cent and renders the iron more fluid at 2250°F. than at 2350°F. without it. With 2 to 10 per cent of aluminum, copper forms an alloy lighter even than its normal weight. This alloy goes by the name of magnesium and is equal in strength and workability to good brass. With 1 to 15 per cent of tin a series of strong and rigid alloys is produced, suitable for heavy castings. Aluminum-tungsten and aluminum-nickel make good rolling metal for sheet forms. Alloys of aluminum with 3 to 4 per cent of copper or with 2 to 5 per cent of nickel are also very largely used for rolling into strip metal. Improved brass is improved by the addition of small percentages of aluminum, a 2-per cent addition doubling its tenacity. Aluminum has the effect generally of lowering the melting point of the alloy. Added to gold in the proportion of 1 part of 1, it resulted in an alloy known as "green gold." Five per cent of aluminum will quench the color of the gold, yielding a white metal. With silicon aluminum combines in all proportions, but these alloys are brittle and are not permanent. With platinum and cadmium it forms fusible metals (q.v.). An alloy consisting of 96 parts aluminum, three parts copper and one part of magnesium is known commercially as "duralum." It has been used extensively in making shells, helmets, grenades and camp equipment during the European War.

Welding and Plating.—The great difficulty of soldering aluminum has been overcome by the process of autogenous welding and thus the making of tanks and vessels of the largest sizes has become practicable. In this welding process the sheets of aluminum are lapped, and a pure aluminum wire laid between, with a flux, generally a mixture of fluorides of the alkalies. The heat used may be the oxy-hydrogen flame, the Bunsen flame, the oxy-acetylene flame. Aluminum is successfully plated with other metals by first plating it with zinc upon which the other metals are then deposited in an electrolytic bath.

Uses.—The uses of aluminum are almost without number. More than 250 articles are made from the pure metal and nearly as many more from its alloys, and the list is continually being extended. Among them are aeroplane parts, automobile parts and bodies, blades for fans, cooking utensils, dental plates, foil for wrapping food products and confectionery, gas and oil stoves, hair and hat pins, horseshoes, frames for mirrors and pictures, penholders, army pontoons, optical goods, scientific instruments, stoves and stove pipe, telephone fixtures, telescopic tubes, trunks and traveling cases and vacuum cleaners. In the arts aluminum has replaced other metals, notably in the brewing industry. The great fermentation vats are now made of aluminum instead of copper, as the former has no deleterious effect upon the growth of yeast, as has the latter. In varnish making also, the use of aluminum kettles affords a paler varnish from the same gums, or a varnish of the same color from darker gums. The resistance of aluminum to stearic and oleic acids makes it of the greatest value in soap making. In some refractories the copper piping is now lined with aluminum instead of tin as formerly. In iron and steel founding powdered aluminum is used to keep up the heat of molten metal, which it does by uniting with the oxides with great energy. The utility of powdered aluminum is the basis of the action of thermit. (See Alumino-Thermics.) The powdered metal is used also in the manufacture of the explosive "ammonal." Mixed with ammonium nitrate in varying proportions it forms a series of safe explosives which cannot be fired without a detonator, but range in power from common black powder to nitroglycerine. These explosives are of particular value in mining, as the resulting gases are entirely harmless, being nitrogen, oxygen and steam. Powdered aluminum is used extensively in the painters' trade as a foundation for bronze powders, in which it excels all other metals. In electrical transmission cables it has found a new utility, the cables being drawn on site, the resulting cable resembling in appearance to the stand of long suspensions as well as the force of the wind and the weight of ice storms.

History.—While the fact that argillaceous earth concealed a new metal had been known for some years, the first production of metallic aluminum was not accomplished until 1824, when Oersted succeeded in making it by heating aluminum chloride with potassium amalgam. In 1827 Wöhler obtained it by a closely similar method. In 1854 Bunsen and Deville independently produced metallic aluminum by the electrolytic process. The credit of pursuing the problem of a successful commercial process belongs to Deville, who persistently worked, first at Javel, then at Nanterre and finally at Salindres, with the double chloride of aluminum and sodium as his source. When cryolite was discovered, Messrs. Dick and Smith, at the suggestion of Dr. Percy, made successful use of that mineral as a source of metallic aluminum. Deville accepted it as an improvement, but ending the metal from cryolite quite impure, he returned to his former crude material, adding the cryolite to his own mixture, however. Deville's process furnished the metal at a cost of $5 a pound until 1897, when several inventions in other fields were applied to the commercial production of aluminum. Since that time the price has steadily dropped until it has reached its present normal of about 18 to 20 cents a pound. The war has had its effect upon aluminum as well as upon all other metals, but with the return of settled conditions lower prices will again prevail.

Production.—The French periodical L'Echo des Mines estimates the potential production of aluminum by the world's existing plants as follows:

<table>
<thead>
<tr>
<th>Country</th>
<th>Production (tons)</th>
</tr>
</thead>
<tbody>
<tr>
<td>United States and Canada</td>
<td>25,000 tons</td>
</tr>
<tr>
<td>France</td>
<td>20,000</td>
</tr>
<tr>
<td>Switzerland</td>
<td>20,000</td>
</tr>
<tr>
<td>United Kingdom</td>
<td>13,000</td>

<tr>
<td><strong>Total</strong></td>
<td><strong>150,900 tons</strong></td>
</tr>
</tbody>
</table>

The production of aluminum in the United States in 1916 amounted to 123,708,000 pounds.
In addition to this output of metal, there were produced 153,860 tons of aluminium sulphate, 27,257 tons of alum and 30,708 tons of aluminium abrasives. (See ABRASIVES). In 1885 the commercial production of aluminium was 283 pounds. From that year to the present, including the 1916 output, the total production of metallic aluminium in the United States has been 680,380,500 pounds.

**ALUM-ROOT**, the name given in the United States to two plants on account of the remarkable astrigency of their roots: (1) Geronium maculatum, or spotted cranesbill, is a native of North America from Canada to North Carolina; it has an angular, downy stem, 3-5-parted leaves with deeply toothed lobes, obovate entire petals, the filaments scarcely ciliated at the base; the color of the flowers is a pale lilac. It is employed successfully as a remedy in dysentery among children; the tincture is recommended in cases of ulcerated sore throat, soreness of the gums, etc.

The plant contains large proportions of gallic acid and tannin. (2) Heucherella americana family (Saxifragaceae) is a hairy plant with round leaves and leaves, the latter being long petioles, 5-7-lobed, toothed; the calyx is 5-cleft, petals undivided, five stamens; the styles are remarkably long. It contains tannin and is used in preparing a wash for wounds, ulcers, etc.

**ALUN-SHALE**, a slaty rock of different degrees of hardness; color grayish, bluish or iron-black; often possessed of a glossy or shining lustre. It is chiefly composed of clay (silicate of alumina), with variable proportions of sulphide of iron (iron pyrites). lime, bitumen, and water. It is found abundantly, and from it is obtained the largest part of the alum of commerce.

**ALUNITE**, al′ú-nit, a native suboxide of aluminium and potassium, having the formula K(AlO)₃(SO₄)₂+3H₂O, and occurring both massive and in rhombohedral crystals resembling cubic. It is white with a vitreous or pearly lustre, with a hardness varying from 3.5 to 4, and a specific gravity of about 2.6. It has been found, in the United States, in California and Colorado. According to Dana it was first called "aluminite," a name afterward abbreviated to alum. Alum may be obtained from it by repeated roasting and lixiviation. (Also called alun-stone and alun-rock).

**ALUNNO, Niccolo** (real name Nicolò di Liberatore), an Italian painter of the 15th century, the founder of the Umbrian School: b. Foligno about 1430; d. 1502.

**ALUNGEN**, a-lùn′-jën, a native hydrous suboxide of aluminum, having the formula Al₂(SO₄)₄+18H₂O. It occurs massive, as an incrustation in mines and quarries, and also in delicate fibrous forms. Its hardness varies from 1.5 to 2, and its specific gravity is about 1.7. It occurs in large quantities in Jackson County, N. C., and near Silver City, N. M.; and it is found in many other parts of the United States in small amounts.

**ALUREDUS,** an English historian: b. about 1100. See ALFRED OF BEVERLEY.

**ALVA,** ál′va, or ALBA, Ferdinand Alvarez de Toledo, Duke of, Spanish statesman and general: b. 1508; d. Thomar, 12 Jan. 1582. He was educated by his grandfather, Frederick of Toledo, who instructed him in military and political science. He commanded under Charles V in Hungary, and was present at the siege of Tunis and in the expedition against Algiers. His cautious character and his inclination for politics at first led men to believe that he had but little military talent; and his pride being touched at the low estimation in which he was held, his genius was roused to the performance of exploit deserving remembrance. He won in 1547 the battle of Mühlberg against John Frederick, Elector of Saxony, commissioned to attack the French in Italy, and Pope Paul IV, the irreconcilable enemy of the Emperor. When Charles V resigned the government to his son, Philip II, Alva received the supreme command of the army and conquered the states of the Church and frustrated the efforts of the French. Philip, however, compelled him to contract an honorable peace with the Pope, whom Alva wished to humble. He appeared in 1559 at the French court in order to marry Elizabeth, the daughter by proxy, for his sovereign; she had been at first destined for the crown prince, Don Carlos. About this time the Netherlands revolted, and Alva was entrusted with a considerable army and unlimited power to reduce the rebellious provinces. Scarcely had Alva reached Flanders at the end of August 1567, when he established the Council of Blood, at the head of which stood his confidant, Juan de Vargas. This tribunal condemned, without discrimination, all those whose opinions were suspected and whose riches excited their avarice. The present and absent, the living and the dead, were subjected to trial and their property confiscated. The cruelty of Alva was increased by the defeat of his lieutenant, the Duke of Aremberg, and he caused the Counts of Egmont and Hoorn to be executed. He afterward defeated the Count of Nassau on the plains of Gemmingen. Soon after the Prince of Orange advanced with a powerful army, but was forced to withdraw to Germany. The Duke stained his reputation as a general by new cruelties, his executioners shedding more blood than his soldiers. The Pope presented him with a consecrated hat and sword, a distinction previously conferred only on princes. Holland and Zeeland, however, still resisted his arms. A fleet fitted out at his command was annihilated, and he was everywhere met with insuperable courage. This, and perhaps the fear of losing the favor of the King, induced him to request his recall. Philip willingly granted it, but he perceived that the resistance of the Netherlands was rendered more obstinate by these cruelties, and was desirous of trying milder measures. In December 1573 Alva proclaimed an amnesty, resigned the command of the troops to Louis de Requesens, and left the land in which he had executed 18,000 men, as he himself boasted, and kindled a war that burned for 68 years, cost Spain $800,000,000, its finest troops and seven of its richest provinces in the Low Countries. Alva led an army into Portugal, and, after two battles in three weeks, drove out Don Antonio, and reduced all Portugal, in 1581, to submission to his sovereign. He made himself master of the treasures of the capital and permitted his soldiers to plunder the suburbs and surrounding country with their usual rapacity.
and cruelty. It is said of him that during 60 years of warfare he never lost a battle and was never taken by surprise.

ALVA, Okla., city and county-seat of Woods County; 150 miles northwest of Oklahoma City, which is the capital of the State, on the Canadian River, and on the Atchison, Topeka and Santa Fe and the Chicago, Rock Island and Pacific railroads. It contains flour mills, broom factories and dairy establishments, and has important interests in the agricultural products of the surrounding country, which produces wheat, corn, oats and alfalfa. It contains a hospital, city hall, court-house, library, opera house, two modern school buildings and the Northwestern State Normal School. The waterworks are the property of the city. Pop. 3,688.

ALVARADO, ál’vá-rá’do, Pedro de, a Spanish soldier of fortune, the companion and lieutenant of Cortez: b. Badajoz about 1499; d. 1541. He was of good family, his father being a knight of the order of St. James. In 1518 he accompanied Grijalva in a small expedition sent by Governor of Cuba to explore the American coast. A considerable amount of the precious metals was obtained by barter, and Alvarado was despatched to Cuba with this treasure and with a report of the regions which had been explored. When Cortez was called away to meet Narvaez, who had been sent by Velasquez with a superior force to supersede him in command, he left the capital and his royal captive, Monteuma, in Alvarado's charge, and in 1523 was sent with a considerale force to reduce the tribes of Indians in the direction of Guatemala. Having beaten off all opponents he founded a city now called Guatemala la Vieja, and established a port on the Pacific, which he called Puerto de la Posesion, ormarking for Spain, he was received with great honor by the Emperor Charles V, who, in acknowledgment of his services, made him governor of Guatemala. He shortly returned to America with a numerous band of knights and knissmen, and Guatemala speedily became a prosperous city. An attempt which he subsequently made on Quito, but which he was induced to relinquish, was represented by Pizarro as an intrusion within the boundaries of his command, and he embarked a second time for Spain to vindicate his conduct to the Emperor.

ALVARADO, Tomás Antonio, Ecuadorean clergyman: b. Cuenca, Ecuador, 18 Sept. 1860. He was educated at the Christian Brothers College and the Ecclesiastical Seminary of his native city. While still a student he was appointed superior of the seminary and professor of grammar, literature, French and Latin. He was ordained to the priesthood in 1886 and soon after was named dean of the faculty of philosophy at the University of America. He was exiled for a time by the government because of his opposition to the law "El Patronato." He has held official positions as municipal councillor and commissary of the Fiscal Revenue Commission. He was twice elected deputy to the National Congress, but each time declined to serve. He is the author of "Estética literaria," "Ortología francesa" and "Versificación francesa," which are used as textbooks in several schools; also of a number of poems, religious and secular. He is a frequent contributor to various ecclesiastical periodicals.

ALVAREZ, ál-vá’ráth, Don José, Spanish sculptor: b. Priego 1768; d. 1827. In 1799 Charles IV gave him a pension of 12,000 reals to enable him to study in Paris. In 1806 he executed a statue of Gaminde, which at once placed him in the front rank of the sculptors of his time. Another successful work was a group representing Antiochus and Memnon, which secured for the artist the appointment of court sculptor.

ALVARY, ál-vá’ré, Max, German singer: b. Düsseldorf 1858; d. 1896. Gifted with a fine tenor voice and handsome presence he speedily made a reputation in Germany in the leading roles in Wagnerian opera, and from 1885 onward appeared also in America and England. His performances as Tristan and Siegfried aroused great enthusiasm.

ALVENSLEBEN, ál-vëns’lä-bén, Constan- tin Von, German army officer: b. Eichenbar- len, Saxony, 26 Aug. 1809; d. Berlin, 28 March 1892. He distinguished himself in the campaign against Austria in 1866 and in 1870 as commander of the 3d army corps he contributed greatly to the success of the German arms before Metz by his resolute leading, energy and determination.

ALVERSTONE, Sir Richard Everard Webster, 1st viscount A.; British lord chief justice: b. 22 Dec. 1842; d. 15 Dec. 1915. He was educated at King's College, Cambridge, and Trinity College, Cambridge. In 1868 he was called to the bar and became Q. C. 10 years after. He was appointed Attorney-General in the Conservative government in June 1885. He was elected for Launceston in the following month, and later sat for the Isle of Wight, which he continued to represent until his elevation to the House of Lords. Except under the brief Gladstone administration of 1886 and the Gladstone-Rosebery administrations of 1892-95, Sir Richard Webster was Attorney-General from 1885 to 1900. In 1893 he represented Great Britain in the Bering Sea arbitration, and five years later he discharged the same function in the matter of the boundary between British Guiana and Venezuela. In 1900 he succeeded Sir Nathaniel Lindley as master of the rolls, at the same time being raised to the peerage as Baron Alverstone. In October of the same year he was elevated to the office of lord chief justice upon the death of Lord Russell of Killowen. In 1903 Lord Alverstone presided over the Alaska boundary tribunal, and his decisions favoring American claims, particularly with regard to the mountain boundary, were severely criticized in Canada, and to a lesser degree in England. He resigned the office of lord chief justice in 1913 and was succeeded by Sir Rufus Isaac (now Lord Reading). He published 'Recollections of Bar and Bench' (1914).

ALVEY, Richard Henry, American jurist: b. 1826; d. 14 Sept. 1906. He was admitted to the bar in 1849; was a member of the Maryland State Constitution Convention; was judge of the fourth judicial circuit, and a judge of the Maryland Court of Appeals (1867-83) and, chief justice (1883-93); became chief justice of the Court of Appeals of the District
of Columbia in 1893, and one of the Venezuela boundary commissioners in 1896.

ALVORD, Benjamin, American soldier: b. Rutland, Vt., 8 Aug. 1813; d. 17 Oct. 1884. Received a military education at West Point and after serving in the second Seminole War and in the Mexican War also, was paymaster of the department of Oregon, 1854–62. He was brigadier-general of volunteers, 1862–65, retiring from the service in 1881 with the rank of brigadier-general. He published: 'Tal-<br>lenities of Circles and of Spheres' (1855); and 'The Interpretation of Imaginary Roots in Questions of Maxima and Minima' (1860).

ALVORD, Henry Elijah, American soldier: b. Greenfield, Mass., 11 March 1844; d. 1904. He entered the army in 1862 and had risen to the rank of major in 1865. He was a cavalry captain in the regular army 1866–72, and chief engineer on General Sheridan's staff 1869–69. From 1886 to 1888 he was professor of agriculture in the Massachusetts Agricultural College, and was president of the Maryland Agricultural College 1888–92. He was for many years prominent as an authority on agricultural questions.

ALWAR, ül'wür, India, town and capital of the Rajput state of same name, situated at the base of a rocky range of quartz and slate, 80 miles south southwest of Delhi. The Rajah's palace is of cubical form and has its walls pierced with numerous small windows and is decorated with rude and glaring paintings; a pavilion of white marble, built by the late Rao Rajah, near a very deep tank which he had executed, displays no small degree of taste; and there are several Hindu temples in a style imitated from Mohammedan structures. A fort, crowning the lofty mountain which overlooks the town, is highly ornamented and serves the Rajah both as a summer palace and as an asylum in times of danger. Modern buildings include the Lady Dufferin hospital for women, a high school for young noblemen, and Catholic and Presbyterian churches. Pop. 41,500.

ALYES, a'lt-'tèz, the midwife toad, first discovered by P. Demours in 1741, on the border of the small pond in the valley of Charente in the very act of parturition which has rendered it famous. Alytes obstetricians is of special interest as the first known example of paternal solicitude in Batrachians, and although many no less wonderful cases have since been revealed to us, it remains the only one among European forms.

ALZOG, ál'tšög, Johann Baptist, German theologian: b. Ohlan, Silesia, 29 June 1808; d. 1 March 1878. He studied at Breslau and Bonn and was ordained priest at Cologne in 1834. He was professor of church history at Posen 1835–44 and at Freiburg from 1844 until his death. With Dollinger he was instrumental in convoking the famous Munich assembly of Catholic scholars in 1863. He also took part in the preparatory work of the Vatican council. His fame rests mainly on his 'Manual of Universal Church History', which is generally accepted as the best exposition of Catholic views.

AMADIS DE GAULA, the most famous romance of chivalry in prose, was printed in its earliest extant edition at Saragossa in 1508. Its author was Garci Rodriguez or Ordoñez de Montalvo, governor of Medina del Campo in Castile, and his avowed source of inspiration is drawn from 'the ancient originals,' which have since perished, a story that might inspire Spanish youth with a desire to emulate the noble deeds of knighthood. Montalvo, in expanding what seems to have been a Portuguese model from three books to four, and in adding a fifth, started upon its career the fiction destined to unfold in more continuations than any other known to literary history. It is presumed that the writer of the Portuguese original was João de Lobeira, a member of the poetical circle of King Denis of Portugal in the late 13th century. Like others of his coterie, Lobeira was subject to French influence and acquainted with legends of the prowess of the knights of King Arthur and Charlemagne; but his 'Amadis' is distinguished from all other works of the Arthurian and Carolingian cycles by being wholly fictitious, founded neither upon tradition nor upon history. Another Lobeira of the 14th century (Vasco, q.v.) has been credited with the authorship of 'Amadis,' since its ascription to him by a chronicler of the 15th century. His claim, however, is now no longer accepted by scholars, who at most will concede to him a later manuscript version rumored to have been lost in the Lisbon earthquake. In any case, 'Amadis' achieved its renown, not in the Portuguese of either Lobeira, but in the Spanish of Montalvo, who probably had Castilian as well as Portuguese versions upon which to draw. If the origin of 'Amadis' be obscure, its place among the monuments of literature is certain. As Cervantes declared in 'Don Quixote,' it is 'the best of all books of this kind that have ever been written.' It is also, according to Prof. F. M. Warren, 'our first modern novel.' The time of the story is 'not long after the Passion of our Lord'; its scenes are laid in a mythical Great Britain and an imaginary Firm Island. Gaula signifies Wales; Amadis of Gaul is a prince of Wales born of a secret amulet, reared as a lady by the lady's father, devotedly the fair English princess Oriana. For her sake he contends against monsters and enchantments, defends her father's kingdom from an oppressor, and opposes the Roman emperor as rival. He wins a victory over the empress, whose suit is favored by the lady's father, but, in his hour of triumph, consents to spare the latter, and at last is formally united to Oriana in marriage. High ideals mark the work—pride, honor, valor, love, loyalty to the king, and religion. It contains the extravagant code of faith and honor which grew up in the Spanish decadence, and exhibits comparatively little of the absurdity so characteristic of its fantastic continuations. Of such continuations the best was Montalvo's 'Fifth Book' entitled 'The Deeds of Esplandian,' its hero the son of Amadis and Oriana. Most others followed the fortunes of some one of Esplandian's descendants, professing to be but additional books of the original 'Amadis,' that origin may be read in Robert Southey's abridgment of its Elizabethan translation by Anthony Munday. The English reader should also consult Prof. F. M. Warren's 'History of the Novel Previous to the Seventeenth
Century' (1894). The best Spanish treatment of 'Amadís' is to be found in Marcelino Menéndez y Pelayo's 'Orígenes de la novela' (1905).

FRANK W. CHANDLER, Professor of English and Comparative Literature, University of Cincinnati.

AMADO DE CONTRERAS, Ramón Ruiz, Spanish clergyman and writer on education: b. Castello d' Ampurias, Catalonia, Spain, 14 Jan. 1861. He received his education at the University of Barcelona; practised law from 1881 to 1884, when he entered the Society of Jesus. He was ordained to the priesthood in 1896 and in the same year was appointed teacher of humanities, Latin and Greek at the Vurnala Scholasticate. He spent several years in literary work in the interests of education and in traveling in Germany, England and South America. In these travels he made a special study of the educational systems of Germany, England, Argentina, Uruguay and Chile. In 1906-10 he was associate editor of Revista de Educación, and in 1910 became the founder of the review La Educación Hispano-Americana. He is one of the founders of the Academia Universitaria Católica de Madrid and for a time was professor of higher pedagogy. He has published several works on education, including: 'La Educación moral,' 'La Educación intelectual,' 'La Educación religiosa,' 'Historia de la educación y la Pedagogía,' 'Educación femenina,' 'Educación cívica,' 'Didactica ó el Arte de enseñar,' 'Compendio de Historia de España,' 'La Iglesia y la Libertad de enseñanza,' 'La Historia de los Papas,' translated from the German of Ludwig Pastor. He was a contributor to the 'Catholic Encyclopaedia' and of numerous articles on education to Razón y Fe.

AMADOR, a-ma-dor, Manuel, the 1st President of the Republic of Panama; b. 1841; d. 1909. He was for many years minister of France in Panama. He was soldier, statesman, scholar and diplomat and was largely instrumental in establishing the new republic of Panama (q.v.). He adopted the practice of medicine in early life and became eminent in his profession. He sided with the revolutionist party against Colombia, which achieved the independence of Panama. Elected President of the new republic, 17 Feb. 1904, he was inaugurated to hold office four years and at the expiration of his term declined renomination. Since then the principal fortification of the Pacific end of the Panama Canal has been named in his honor, Fort Amador.

AMADOU, a-ma-du, a soft leathery substance obtained from certain fungi, chiefly Polyporus fomentarius and P. ignarius, which are parasitic upon the trunks of trees. It is prepared chiefly in Germany by slicing the fungus and soaking the slices in a solution of saltpeter. It is used for tinder and in surgery as a moxa or styptic. It is also known as Germaine tinder and punk.

AMAL, the name of the noblest family among the Ostrogoths, and that from which nearly all their kings were chosen.

AMALEKITES, an ancient tribe in the southeast of Palestine, frequently mentioned in the Old Testament as enemies of the Israelites. The name is celebrated in Arabian tradition, but the statements in regard to them are conflicting and confused and almost worthless from a historical point of view. They appear as a branch of the Edomites (Gen. xxvi. 30; xxxvi. 12). Amalek being represented as the son of Eliphaz, who was himself the son of Esau by Timna, a Horite woman. When the Israelites journeyed from Egypt to Canaan the Amalekites are said to have harassed them and because of this hostility it was divinely ordained that their memory should be blotted out (Deut. xxxv. 17-19). A victory by them over Israel is mentioned (Num. xix, 45) and a defeat at Raphidin (Ex. xvii, 8-16). The statements, however, are obscure and the situation is further complicated by the account of Joshua's victory over the Amalekites in the Sinaiic peninsula. According to 1 Sam. xv, Saul received a divine command to destroy the tribe because of its enmity to Israel, and David commanded a marauding band of these ancient enemies of his people. The spirit of hostility is shown also in Balaam's prophecy *Amalek, first of nations, his latter end (will be) destruction* (Num. xxxiv, 20). Even in the Psalms (lxxxiii, 7) Amalek is cited as the arch-enemy of Israel; later in the Book of Esther Haman, the arch-enemy of Israel, is termed *the Aga- gite,* emphasizing his descent from Agag, King of the hated race, and is opposed to Mordecai the Benjamite. Consult Grimm, 'Mohammed' (1864); Meyer, Eduard, 'Die Israeliten und ihre Nachbarstämmes' (1906); Nöldeke, 'Über die Amalekiter' (Göttingen 1864), and Schmidt 'Messages of the Poets' (1911).

AMALFI, -málfé, Italy, town and archiepiscopal see of Campania, in the province of Salerno. It lies 12 miles southwest from the town of Salerno, at the mouth of a deep ravine, in the centre of splendid coast scenery, and is in consequence much frequented by tourists. It contains a splendid cathedral of the 11th century and a Capuchin monastery (now used as a hotel) with fine cloisters. In the 9th century it had a considerable trade with the East and was then an independent republic, with a population of some 70,000. In 1343 a large part of the town was destroyed by an inundation and its harbor is now of little importance. Its industries, too, have declined, and the paper manufacture has lost ground since 1861. Pop. (1911) 5,681.

AMALGAM, an alloy in which mercury is an important constituent. Silver and gold amalgams occur in nature to a limited extent, but most of the amalgams are of artificial origin. Four general methods of forming them may be noted: (1) By dissolving the metal with mercury. Amalgam of antimony, arsenic, bismuth, cadmium, gold, lead, magnesium, potassium, silver, sodium, tellurium, thorium, tin and zinc may be obtained in this way. The different elements mentioned combine with the mercury with varying manifestations of affinity, the amalgamation of sodium being attended with the production of heat and light, while in the case of zinc it is often necessary to bring the zinc and mercury together in the presence of a strong heat before they will combine evenly and smoothly. (2) By immersing the metal to be amalgamated in a solution of a salt of mercury. Copper,
gold, platinum and silver can be amalgamated in this way. (3) By reversing the process last described and bringing mercury in contact with a part of the metal of which amalgam is desired, the metal is deposited. The mercury, in certain cases, will partially replace the metal in solution, the portion so replaced combining with the mercury with the production of the desired amalgam. A valuable modification of this method consists in substituting for the metallic mercury an amalgam of zinc or of sodium, the zinc or sodium changing places with the metal in solution. Amalgams of bismuth, calcium, chromium, iridium, iron, magnesium, manganese, osmium, palladium and strontium may be prepared by the use of sodium amalgam. (4) By electrolysis, the metal whose amalgam is desired being used as the cathode in a solution of a mercurial salt. (The cathode may also be metallic mercury, and the electrolyte a salt of the metal whose amalgam is desired). This process is in commercial use for the production of sodium hydrate, a solution of sodium chloride (common salt) being electrolyzed with a mercury cathode. The cathode absorbs the sodium with the amalgam metal. Aicin, subsequently decomposed by contact with water. In practice the process is continuous, a part of the mercury cathode being exposed to the electrolytic bath, while another part is simultaneously exposed to the action of the water.

In the formation of amalgams there is usually but little thermal effect. In the case of sodium and potassium, however, a very considerable amount of heat is evolved; and in the formation of amalgams of bismuth, lead and tin, heat is absorbed.

There is considerable evidence in favor of the view that many amalgams contain definite compounds of mercury and the other constituent metals. Thus when certain amalgams are heated (say) to the boiling point of sulphur, the excess of mercury present appears to be volatilized, so as to leave a body behind that has a definite chemical composition. In this way Sonza obtained amalgams having the composition AuHg, AgHg, CuHg, NaHg, and K2Hg, the last-mentioned being silvery in appearance and crystalline in structure. But it is said that all these amalgams, as well as many others, continue to lose mercury slowly when the temperature is maintained high; and this fact, while not disproving the existence of a definite compound of mercury and the metal, lessens its probability. Amalgams having the composition CuHg, AgHg, FeHg, ZnHg, PbHg and PtHg have also been prepared by expelling the excess of mercury from amalgams richer in that metal by exposure to a pressure of 70 tons to the square inch. One of the most interesting amalgams from the standpoint of chemical theory is the amalgam of the hypothetical radical "ammonium" which is described under ammonia.

The affinity of mercury for gold is put to practical use in mining for the recovery of small particles of gold from auriferous gravel or crushed quartz. The details of the process vary somewhat according to the nature of the material from which the gold is to be extracted; but in general it may be said that the pulverized gold-bearing quartz or gravel is washed, in a finely divided state, over a plate of amalgamated copper, to which the gold particles adhere. From time to time the gold amalgam is scraped from the copper plate and further amalgamated. The mercury, in the process of amalgamation, is killed. To prevent this, the amalgam, originally rich in pyrites, is roasted to expel the sulphur before being submitted to amalgamation. See gold.

Mirrors are silvered by amalgams. One of the simplest of those so used is composed of one part of tin to three of mercury. A superior amalgam for this purpose contains two parts of bismuth, one part each of lead and tin and four parts of mercury. In dentistry the"silver filling" used for closing the cavities in teeth is an amalgam. Its composition varies somewhat, but a preparation containing two parts of mercury and one part of pulverized zinc gives excellent results. It hardens quickly and expands slightly in solidifying, thus filling the cavity more completely. Amalgams of lead and tin have a volume smaller than the sum of the volumes of their constituents. See battery.

AMALTEO, a-mäl′tā-ō, Pomponio, Italian painter; b. San Vito 1505; d. there 1584. He was a pupil and son-in-law of Pordenone, whose style he closely imitated. His works consist chiefly of frescoes and altar-pieces and many of them have suffered greatly from the ravages of time.

AMANA, am′a-na, Iowa, town in Iowa County, 28 miles west of Iowa City, the site of a German communitarian religious colony founded in 1885. It includes the seven villages of Amana, the oldest and largest; East Amana; Middle Amana; High Amana; West Amana; South Amana and Homestead. The society is governed by a president and a board of 13 directors, and each village is controlled by seven or more elders appointed by the board of directors. Family life is kept up, but in every village are from four to 16 "kitchen-houses" where meals are prepared and served. The community owns and operates woolen, flour and saw mills, dye shops, machine shops and other industrial establishments, and agriculture is extensively followed. The inhabitants dress plainly and in sober colors. The community is primarily a religious organization, and the sect itself dates its founding from Eberhard Gruber, in Wurttemberg, in 1714. By its members it is known as "The Community of True Inspiration." The total value of their property comprising 20,000 acres of land is valued at $1,200,000. Pop. 1,729.

AMANITA, a genus of fungi related to the genus Agaricus, to which the common mushroom belongs, and for which two of its poisonous members (see below) are sometimes mistakenly eaten. A. muscaria, the fly mushroom, so called from its use as a decoction in milk for killing flies, is commonest in the hickory, beech and pine woods of Europe and America. It has a variously colored cap—white, yellow, orange, red, etc.—usually warty above and sometimes four or more inches in diameter; white or occasionally yellow gills, and a long
white stem with bulbous base. Though universally considered poisonous it is said to be used by some natives of the New World. As a moro, A. phalloides, death-cup, deadly agaric, deadly amanita, is commonly found in woods, especially in damp weather, from early summer until mid-autumn. It is usually white, sometimes light yellow or grayish; its cap is seldom as large as four inches in diameter; its gills white; its stem hollow and slender above, solid and bulbous at the base, which is surrounded by a cup which has suggested one of its common names. With reasonable caution on the part of the collector none of these species should be mistaken for the common mushroom, because all three grow singly in woods and have white gills and white spores; whereas the mushroom grows in clumps in pastures and upon lawns, occasionally in grassy open woods. Its gills are pink in young specimens and darker in old ones; its spores dark-colored, and it has no cup at the base of the stem.

AMANITIN, a strongly basic tomatine (or perhaps leucotamine) occurring in the poisonous fungus Amanita muscaria (Agaricus muscaria). It is little poisonous, but is converted by oxidation into muscarin (q.v.), to which the deadly effects of the fly agaric are due. Amanitin is believed to be identical with cholrin, neurin and sincalin. See Muscarin.

AMANUENSIS, a Latin word, derived from the phrase servus a manu, slave of the hand, a secretary, one who writes, from dictation or otherwise, on behalf of another.

AMAPALA, a-ma-pa-la, Honduras, a seaport on the north shore of the island of Tegre, in the bay of Fonseca. It has an excellent harbor and carries on an important exporting trade in silver, coffee, indigo, timber, hides and fish. It was founded in 1838. Pop. 4,000.

AMARA. See KUT-EL-AMARA.

AMARA SIN'HA, Sanskrit grammarian: lived about 375 a.d. Of his personal history hardly anything is known. Amara seems to have been a Buddhist; and a tradition asserts that his works, with one exception, were destroyed during the persecution by the Orthodox Brahmins in the 5th century. The exception is the celebrated 'Amara-Kosha' (Treasury of Amara), a vocabulary of Sanskrit roots, in three books, and hence sometimes called 'Trikanda' or the 'Tripartite.' It contains 10,000 words, and is arranged, like other works of its class, in metre, to aid the memory. An edition of the entire work, with English notes and index, appeared in 1808. The Sanskrit text was printed at Calcutta in 1831.

AMARANTHUS, the typical genus of herbaceous plants of the family Amaranthaceae. The family consists of annual plants chiefly inhabiting tropical countries, and remarkable for the white or reddish scales of which their flowers are composed. In some species the flowers preserve their appearance after they are gathered and dried, and on this account poets make the plant an emblem of immortality. The name is from the Greek, meaning not withering, and was originally Amaranthus. The family contains about 500 species, some of which, as love-lies-bleeding, prince's feather and cockscomb are common garden plants. In the wild state they are mostly troublesome and unsightly weeds, of which pigweed and pigweed are well-known American examples. Some of the foreign plants are cultivated as pot herbs, and others for their medicinal properties. Their chief commercial value is as decorative plants, for which purpose immense quantities are used in the southern parts of Europe, where they are employed to ornament the churches when fresh-grown blooms are not procurable. The seeds of some species were formerly used by the American Indians for food.

AMARAPURA, um-á'rá-poo're, Burma, formerly the capital of the Burmese kingdom, now a suburb of Mandalay. The town was founded in 1783, increased rapidly in size and population, and in 1810 was estimated to contain 170,000 inhabitants. In that year it was destroyed by fire, and this disaster caused a decline in the prosperity of the place. It was finally abandoned as a capital in 1860. The remains of the former palace of the Burmese monarchs still survive. It has a station on the Rangoon-Mandalay Railway. Pop. about 10,000.

AMARI, a-má're, Mica. T. (1559-1629), Italian diplomatist and patriot; b. Palermo 1806; d. Florence 1889. He imbribled liberal principles at an early age, and was an active sympathiser in the various revolutions in Sicily. He came under the suspicion of the authorities and escaped to Paris, where he took an interest in Arabic studies. His translations and editions of Oriental texts, as well as his historical essays, made him a reputation. In 1844 he began his great work, 'La Storia dei Musulmani in Sicilia,' but the revolution of 1848 plunged him into politics once more. On the expulsion of the Bourbons from Sicily he held various public offices. He soon after returned to Paris and resumed his Arabic studies. In 1859 he was appointed professor of Arabic at Pisa and afterward at Florence. He was the pioneer of Arabic studies in modern Italy, and he still remains the standard authority on the Mussulman domination of Sicily.

AMARILLO, Tex., city in Potter County, on the Atchison, Topeka and Santa Fe, the Chicago, Rock Island and Gulf, the Atlantic and Denver City, the Pecos and Northern Texas and the Southern Kansas and Texas railroads; 32 miles southwest of Panhandle. The city is the centre of a flourishing agricultural and stock-raising section, and has made a rapid growth. Its manufactures are conducted by 36 establishments (U. S. census 1914) employing 429 persons, of whom 311 were wage earners receiving $255,000 in wages. The capital engaged was $1,094,000, and the total output was valued at $986,000; of this, $477,000 was the value added by manufacture. Pop. (1900), 1,440; (1910), 9,957; (1914), 16,000.

AMARNA LETTERS a collection of several hundred cuneiform clay tablets discovered in 1887 at Tel-el-Amarna, a village on the Nile in middle Egypt, on the site of a city built by Amenophis IV. They give an account of the correspondence of the Egyptian court about 1400 B.C., and with but three exceptions are in the Babylonian language. Some of them were written by Amenophis III and Amenophis IV and other royal personages contemporary with these, but
the majority are by Egyptian officials and allies in Syria. Their discovery has thrown much light not only on the history of Egypt itself, but upon the condition of the Holy Land prior to the Hebrew invasion. An English translation of the letters, by Metcalfe, with the title ‘The Tel-el-Amarna Letters,’ appeared in 1896.

AMARYLLIDACEÆ, a family of monocotyledonous plants, generally bulbous, sometimes fibrous-rooted. Their characteristics are a highly-colored flower, six stamens and an inferior three-celled ovary. They are natives chiefly of Africa; but species are found in the warmer parts of Europe, in America and tropical Asia, and a few in Australia. To this family belong the snowdrop, the snowflake, the daffodil, the belladonna-lily, the so-called Guernsey lily (probably a native of Japan), the Brunsvigias, the bloodflowers (Hamanthus) of the cape of Good Hope, different species of Narcissus, Amaryllis, Galanthus, Crinum, Agave, Atamasco lily, star-grass, spider lily, etc. The agave and sisal (q.v.) are of considerable commercial value, but the family as a whole is chiefly ornamental.

AMARYLLIS, a genus of bulbous plants of the family Amaryllidaceae. The principal species is A. belladonna, the Belladonna lily, of southern Africa, much cultivated for its handsome reddish flowers. The name Amaryllis, however, is most commonly applied by gardeners to species of the nearly related genus Hippeastrum. This consists of 60 or 70 species, natives of tropical America. Many of them are widely cultivated as pot plants because of their large and showy flowers which range in color from white to deep red. This group of plants has been greatly improved, particularly in the size and color of the flowers, by hybridization.

AMARYLLIS, the name of a shepherdess in the Theocritean ‘Idyls’ and the Virgilian ‘Eclogues’; also of a character in Spenser’s ‘Colin Clout’s Come Home Again’; of the shepherdess in love with Perigot, in Fletcher’s ‘paible’ ‘The Faithful Shepherdess’; and of a character in Buckingham’s comedy ‘The Rehearsal.

AMASA (more correctly AMMISHAI), the nephew of David, King of Israel. He was commander-in-chief of Absalom’s rebel army, and after its defeat received from David a promise of the same post in his own army in place of Joab. On the renewal of the revolt under Sheba, Amasa was assigned the task of collecting the men of Judah; as he did not appear when due (perhaps knowing too much about the disturbance), Abishai was sent in his place, and Joab’s company took part without commission. Amasa met them at Gibeon, and under pretense of a salute Joab stabbed his cousin and rival (2 Sam. xx, 9).

AMASIA, a-ma-sé-a, Asiatic Turkey, a city in the province of Anatolia, 335 miles east of Constantinople, famed as the ancient capital of Pontus and as the birthplace of the historian Strabo. Picturesquely situated in a deep valley, it is built almost entirely of stone and contains a massive citadel and a notably fine mosque. Silk is made here, and salt, wine, wheat and cotton are also exported. Pop. about 30,000.

AMASIS I, Egyptian king, the first monarch of the 18th dynasty. His rule lasted for some 20 years following 1600 B.C. He expelled the Shepherd Kings from Egypt and laid Palestine and Phoenicia under tribute.

AMASIS II, Egyptian king. b. 570; d. 526 B.C. He cultivated friendly relations with the Greeks, and established Greek commerce at Naucratis. Pythagoras and Solon are said to have visited him. He greatly enriched Memphis.

AMATEUR. Up to the middle of the 19th century this now ever-recurring word was used exclusively to define those who for the love of the arts, and not for the profit to be derived from the exercise of them, painted, or engraved, or sang. In such of the recreations and sports as were then in vogue and which some men engaged in for pleasure and others for pay, the phrase used to distinguish the two classes varied. If a man of means rode a horse in a race or a steeplechase for the pure love of equestrianism, while others rode for fees, the one was called a ‘gentleman rider,’ and the rest were ‘jockeys.’ In cricket, those who participated in matches were designated by two titles: ‘gentlemen,’ denoting those who participated con amore, and ‘players,’ those who played for pay. It was always easy to recognize one from the other, for in the list of published names one class was always designated ‘Mr.,’ as ‘Mr. Somerville,’ while the ‘players’ would lack that prefix and appear as ‘Thomas Sadler.’

Golf of that period was more democratic; neither the word amateur nor any other distinction had appeared; cobbler and prince played together, and for stakes too, without a thought of one or the other losing caste. James II, King of England, while still Duke of York, chose an Edinburgh shoemaker as his golfing partner to play two Scotch pears for a goodly stake of money which he and the cobbler won. The Prince did the honorable thing by giving up half of the stake to the shoemaker, with which and his own share the latter bought a house in the Crieff of Eugene.

The ancient exemption of golf from the distinction between amateur and professional persists even to this day; according to the rules formulated by the United States Golf Association, amateurs may play in contests against professionals, even for a prize, provided only the prize is not cash.

Football at that period was largely in abeyance, except among schoolboys, and the need of definitions had not arisen.

The word amateur in its first appearance in connection with rowing. Up to the year 1835 such rowing contests as had taken place had been on the one hand confined to watermen, who at that time had to serve apprenticeships and could not ply their trade without; and on the other hand to inter-collegiate and inter-university crews. Neither class needed definitions. But at that time an open regatta was organized at Henley, in which it would have been manifestly unjust to allow watermen and others who had had a lifetime’s experience and of harder tradition to compete against those for whom the regatta was really intended, that is, those who loved aquatic sport for its own sake and followed it only as a
recreation at seasonable times. Hence rules were formulated and have ever since been in operation which distinguished the professional from the amateur and precluded the possibility of a contest in which the status of the amateur was strong is this feeling still in rowing at Henley that in 1902 a further restriction was made against the entry of any crew that had within a month from its entry been trained by a professional. When track athletics, about 1850, first crystallized by the impulse given by colleges and clubs, similar conditions existed. The only representative of this form of recreation at that time was the old and hardened trotter-around-the-track, sometimes for the gate money derived from it, sometimes for the benefit of the betting men. Ostensibly it would have been unfair to handicap young collegians by permitting their intermingling, even if for ethical reasons it had not been desirable. Rules were laid down for amateurs founded on the idea of barring the professional and defining the amateur. The rule of the Amateur Athletic Association of Great Britain may be quoted as expressing the then prevalent feeling: "An amateur is one who has never competed for a money prize or stakes bet, or with or against a professional for any prize, or who has never taught, pursued or assisted in the practice of athletic exercises as a means of earning a livelihood."

Football added another temptation on account of its possibilities in city centres of attracting large numbers and much gate money. Here, too, the barrier was raised, in both the association and the Rugby games, along lines which America has followed. But the United States authorities in all recreations have gone a great deal farther in the strictness of their definition of the word amateur, and in safeguarding against persons who receive any portion of their traveling or hotel expenses; a notable example of this occurred in 1902, when the National Golf Association precluded from the amateur ranks any player who participated in the generosity of railroad companies or hotel proprietors.

An instructive illustration of this tendency in the world of American athletics was the case of James Thorpe, the Indian student from Carlisle, who won the all-round championship in the international Olympic Games at Stockholm in 1912. Some months later a statement was published in some obscure paper that the young Indian had been a paid member of a baseball team in North Carolina some two or three years previously. Thorpe frankly admitted this to be the truth, whereupon the American Olympic Committee repudiated Thorpe as an American amateur athlete, contending that he had no right to the honors he had won. Thorpe returned his trophies and has since become a professional baseball player.

The spirit is the old spirit "for the love of the art and game and not for personal gain"; even if a present literal definition were attempted, it might be rendered obsolete by new legislation in a short time. Those who are purposing to enter any particular recreational contest in which the status of the amateur is material must consult the last rules of the organization governing it.

**AMATEUR THEATRICALS.** Amateur theatricals have had a long and distinguished history. In the beginnings of art, in the primitive history of humanity, all drama was necessarily amateur. The renowned tragedians and comedians of Athens were amateurs. Amateurs created the mystery and morality plays of mediaeval times and ushered in the modern theatre of Shakespeare and Molière, Racine and Calderon. The marvelously popular Roman farces, the Atellane, which augmented the theatre with types that exist to this day, came from the country players of Atella (see Atellanœ). Recent researches suggest that the actors of the Tivoli of Rome, of the Teatro di Arte of Italy (see Harlequinade). In late years amateurs, true to their lineage, labored to bring forth the Théâtre Libre of Paris, the Irish Literary Theatre of Dublin, the Art Theatre of Moscow, and others. These were more recent, more satisfactory, more world-approved experiments. In New York a group of young artists called the Washington Square Players, with little or no professional experience, have performed with noteworthy success a number of excellent one-act plays that would most probably have remained outside the commercial theatres. Mæsterlinck, Tchekoff and Bracco were among their authors; but the two most pronounced successes were by local writers. These facts present but surface evidence of the stir going on in and around the theatres all the world over; and often enough, in places that never before had known of a theatre. A new age, quite unparalleled in history, has begun for amateur theatricals. Never before have so many sides of the art received the attention and sustained so many possibilities; never before have so many accomplished virtuosi in every country in the world concerned themselves with the theory and practice of the theatre. The actor for the moment is displaced from his old strategic position, and the regisseur, with all the reins of all the arts in hand, wields the sway. Books on the drama and the theatre are issued by the million. Literary and debating societies find in the drama the dominant topic. Drama clubs flourish everywhere. The Drama League of America has given a powerful impetus to thousands of these clubs and societies. This organization, with headquarters in Chicago and New York, and with producing and non-producing centres in nearly every State, and in Toronto and Ottawa, makes the publication and distribution of dramatic material of all kinds (plays, bulletins of current plays, sectional play lists, book lists, a quarterly Review, a monthly bulletin, etc.), the maintenance of inquiry work, and the booking of lecture courses, the chief means for educating the public. The institution is unique in history, and is the literary centre of the major part of amateur dramatic performance and discussion in the United States. It would seem that to-day even the most conservative bodies, hitherto strongly opposed to it from various standpoints, have undergone
a complete change of front with regard to the theatre. In the energetic realization by so many of us of the breadth and depth of the dramatic instinct, and of ways and means of profitably utilizing this love of playmaking and play-going, both within the school and beyond, we see other signs of the renaissance of amateur dramatics. The colleges and universities have added to the need of encouraging a broader theatre than the higher institutes of learning have yet known (see College Dramatics). In many elementary schools in Europe and the United States, history, geography and language are being taught through the dramatic method; and in nearly all schools it is becoming the custom to early instil a feeling for literature and the higher morality by the aid of selected drama. Producing societies—some of them bringing pronounced individuality to the work, with the shrewdest skill and artistic wit—have sprung up everywhere. And, despite the almost inevitable crudeness in some directions, and not a little audacity, valuable contributions are being due to the future of the professional theatre. Artists of many phases outside the direct lines of the theatre are practising the technique of the theatre as an adjunct to their own, and as an impetus to development. Social, civic and religious officials are doing likewise. The Neighborhood Theatre of Grand Street on the east side of New York city, founded and financed by the Misses Lewisohn, introduced mechanical features new to the American stage, and has struck an individual note. The Provincetown Players, founded by a notable group of writers and artists of the printers of Washington Square district of New York, have been accorded highest praise by professional critics in reviews of the season’s work. The Hull House Players, under the enthusiasm of Miss Addams, prompt to note the power that lay in the cultivation of the dramatic instinct, received much attention from the whole continent, widened the scope of the Settlement, and were recently enabled to take a trip to Europe on the proceeds of special performances. The Little Theatre of Chicago, sustained by a wealthy social set, and famous for its simple staging; Mrs. Gale’s Toy Theatre of Boston (which introduced a scenic artist of rare gift to the professional stage); Mr. May’s Players of Philadelphia and Mrs. Aldis; the Wisconsin Players (who have given a season in New York); the Carnegie School of Applied Design in Pittsburgh, directed by Prof. T. Ward Stevens (himself an artist and dramatist), experimental theatres of Philadelphia and Milwaukee, have all been distinguished by the striking taste and originality of their productions. ”The Bohemian Jinks” of the Bohemian Club of San Francisco (somewhat more serious performances than the title would imply), played among the redwood pines, have slowly evolved since the seventies, and are characteristic of open-air experiments conducted by men of distinguished parts to whom the theatre is an avocation. The coming together of a musical festival and picturesque Waiting” and “Trees” at the Paris Conservatoire (London 1891), and Austin Fryer’s “Guide to the Stage” (London 1905). It should be remembered that the actor is at one and the same time the composer and director and producer and his own chief critic and his own interpreter, as well as a living, moving sculptor, fitting into a kaleidoscopic group of other such sculptors and musicians—trumpeters of literature, be it good or bad. Only by a regard for these facts can histrionic development pro-
ceed. For literary aids to technical excellence, and for notes on all property and other requirements, the selected bibliography below should be closely read. But the ident of these costs too clearly become acquainted with the fact that the intricacies and niceties of "making-up" for example) can never be acquired from any book.

**Plays for Amateurs**—The Agency for Unpublished Plays, Concord avenue, Cambridge, Mass, has many new American plays in MS.; Baker, W. H., & Co., Boston, Mass., circulate lists of plays of all publishers, many of these plays being royalty-free; Browne, H. B., "Short Plays from Dickens, for the use of amateur and school dramatic societies" (London 1908); Clapp, J. M., "Plays for Amateurs" (Chicago 1915). A Drama League publication contains detailed descriptions of 197 plays; all but 59 being one-act. The notes on choosing a play and the hints on production (if they are excellent); Denison, T. S., "Descriptive Catalogue of Amateur and Standard Plays" (Chicago); Dick, John, "List of 1,000 Standard Plays" (Reynold's Newspaper Company, London). Valuable for a choice of royalty-free adaptations of the novels of Dickens, Scott, Charles Reade, Hugo and many other standard novelists, though it may be necessary to readapt much of the old-fashioned dialogue. All at two cents each; Dickson, T. P., "A Chief Set of Contemporary Dramatists" (New York 1915, 21 complete plays in one volume); *Dramatic Index* (Boston, invaluable though not yet well known, published quarterly from 1909); Dutton's *Everyman Library* includes many volumes of translations of foreign plays, royalty-free (New York); Filippi, Rosina, "Sixpenny Series of Adaptations of the Novels of Jane Austin" (London 1901, by the famous London actress and amateur coach); French, Samuel, "The World's Best Plays" (New York 1916, edited by Mr. Barrett H. Clark of the Drama League, with notes and suggestions for staging: about 50 titles, many new); "Guide and Index to Plays for Amateurs" (New York); McFadden, E. A., and Davis, E. E., "A Selected List of Plays for Amateurs" (New York); appendices of outdoor plays and of Old English and standard plays, Cincinnati 1908); Matthews, Brander, "The Chief European Dramatists" (21 plays from the drama of Greece, Rome, Spain, France, Italy, Germany, Denmark and Norway, from 500 B.C. to 1879 A.D.; selected and edited with notes, bibliographies and bibliographies, Boston 1916); Moses, M. J., "A Collection of American Plays" (New York 1916, one of the latest volumes in the "Everyman Library" series); "Sixpenny Carpet Plays" (London, edited by Lucian Oldershaw, sometime secretary of the Oxford University Dramatic Society); Pierce, J. A., "The Masterpieces of Modern Drama; English, American and Foreign; abridged in narrative, with a critical examination of each play" (4 vols., New York 1916); "Washington Square Plays" (New York 1916); Short plays and monologues for amateurs (a bibliography; Carnegie Library Monthly Bulletin, Pittsburgh 1914); "The One-Act Play" by the officials of the Chicago Public Library, March 1916); "Plays of Thirteen Countries" (by the officials of the New York Public Library, 1915.

These two lists are more literary than dramatic in their bias. The play brokers publish lists of the latest plays; consult the *New York Dramatic Mirror* Dan Block, and the Drama League *Plays for Amateurs* for a list of play brokers. Translations of the best foreign plays are to be found in the important dramatic reviews, *The Drama Quarterly*, *The Dramatist* and *Poet Lore*.

**Copyright.**—The copyright laws of the United States are somewhat stricter and narrower than similar laws in Europe; for no performance of a copyright play may be given without permission, even where the performances are free to the public. It should be observed that until we have a uniform copyright law all British plays may be publicly performed without a permit, even in the United Kingdom, if there be no charge for public admission. Needless to say, if any British play be duly copyrighted in the United States, the domestic law applies. The title page, or the page that immediately follows, will have one of the three necessary imprints of copyright if the work be copyrighted in form. Should there be any doubt in regard to registration, reference may be made to the catalog of all such copyrighted works on file at the public libraries; or, the question may be directly put to the Register of Copyrights, Washington, D. C., who will gladly extend the required information. Any infringement of copyright by performers may lead to damages.

AMATI, a-mâ'tē, an Italian family of Cremona, celebrated for their skill in making violins. Andrea Amati (b. about 1520; d. 1570) was the earliest member to follow the art, but few of his instruments remain. His younger brother, Nicola, made basses. Andrea's sons, Antonio (b. about 1555) and Gervino (b. 1556; d. 1576), worked after their father's manner, but Gervino's son Nicolo (b. 3 Dec. 1596; d. 12 Aug. 1684) excelled all others of his family, and in his hands the art of the Cremonese school reached its perfection. His most famous pupils were Antonio Stradivarius and Guarneri. The line ended with his son Gervino, whose violins were of inferior quality.

AMATITLÁN, a-mâ'tē-tlā'n, or SAN JUAN DE AMATITLÁN, a Central American town in the republic of Guatemala, 12 miles southwest of Guatemala City. In its vicinity are found hot springs and salt and alum mines. It stands on the shores of Lake Amatitlán, and the department of which it is the capital bears the same name. The chief industries of the people of this region are the gathering of cochineal, the preparation of salt and raw silk, and the cultivation of fruits. The town was severely damaged by earthquakes in 1902. Its population is given as 12,000. The entire department has about 38,000 inhabitants. See GUATEMALA.

AM'AUR'OSIS, a disease of the retina or its nervous connections, resulting in partial or complete blindness. It usually begins with confused vision; there may then be the appearance of a black spot in the centre of an object looked at, and graded dimness of sight develops. See AMBLYOPIA.

AMAURY I, a'môrē, King of Jerusalem: b. 1135; d. 11 July 1173. He was the son of Baldwin III, and reigned from 1168 to 1173, in succession to his brother, Baldwin III.

AMAURY II, sometimes known as AMAURY DE LUSIGNAN, titular King of Jerusalem: b. 1144; d. Acre 1205. He was King of Cyprus 1194-1205, succeeding his better known brother, Guy de Lusignan.

AMÆCHI, a-mâk-ē'-ē, or LEVKAS, Greek town, the capital of Santa Maura, or Leucadia, one of the Ionian islands. The Greek archbishop resides here. It is on the east coast of the island and possesses a small harbor. Pop. 6,000.

AMÄZ'AH, King of Judah about 797-779 b.c.; son of Joash. He punished his father's murderers and reconquered the Edomites; but according to 2 Kings xiv was so puff'd up by his victory over these Bedouin that he challenged Joash, King of Israel, an incomparably more powerful, civilized foe, to a war. Joash retorted with stingning contempt, wishing to avoid the contest, but Amaziah insisted, and Joash routed his army and captured him, stormed and sacked Jerusalem, destroyed a part of the wall, and carried away to his capital of Samaria hostages, and a large amount of spoil, including gold and silver treasure and temple utensils. Amaziah, after his release and 15 years further of reign, was killed by conspirators at Lachish (2 Kings xiv, 19).

AMAZON, the chief river of South America and the greatest in all the world. Its source is found in the Peruvian Andes, its headwaters, the Marañon and Ucayali rivers, uniting in about long. 74° 7' W. From long. 20° its course is wholly in Brazil, and its entire course from the source of the Ucayali to its mouth is about 3,400 miles, its width increasing from over a mile at the Peruvian frontier to 150 miles. The Amazon receives the waters of about 200 tributaries, 100 of which are navigable, and 17 of them 1,000 to 2,300 miles in length. From the north it receives the Santiago, Morona, Pastaza, Tigre, Napo, Putumayo, Yapura, Rio Negro (a branch of which, the Cassiquiare, strangely enough connects it with the Orinoco), Uatuma, Trombeta, etc.; from the south the Huallaga, Ucayali, Yavari, Jutahy, Jurú, Teffé, Coary, Purus, Madeira, Tapajos, Xingu, etc. The depth varies much. From the sea to the mouth of the Rio Negro, about 750 miles in a straight line, the depth is nowhere less than 30 fathoms, and it varies from 10 to 12, and up to the junction of the Ucayali there is depth sufficient for large vessels. The rapidity of the stream is considerable, especially during the rainy season (January to June), when it is subject to great floods. It is on the average two and three-fourths miles per hour. In some places it is four, or even more, and in others as low as one mile. The river is perceptibly affected by the tides up as far as the town of Obidos, 400 miles from its mouth. The phenomenon of the bore, or as it is called on the Amazon the pororéca, occurs at the mouth of the river at spring tides on a grand scale. The waters of the ocean rush into the river in the form of huge waves 10 to 15 feet in perpendicular height, three or four of which roll one upon another with irresistible force. The waters of the Amazon swarm with alligators, turtles and a great variety of fish, of which Agassiz in 1866-67 discovered 1,163 species. The country through which it flows is covered with immense and impenetrable forests. It is at a distance from the larger water-courses the scarcity of mammals bears silent testimony to
the triumph of vegetation and the subordina-
tion of the animal kingdom. The area drained
by the Amazon and its tributaries is estimated
at 2,600,000 square miles. This region, an
immense variety of vegetable substances, in-
cluding a great many drugs, dyewoods and
valuable timber trees. The products it might
be made to yield by cultivation are almost in-
umerable, among the chief being cotton, sugar,
bark, ivory, etc. The Amazonian water system
affords some 16,000 miles of river suitable for
navigation. Steamers began to ply on the river in 1853, but years passed
before its navigation was opened up to all
nations. Pará is the chief seat of the trade
on the river, and Manáos, situated about 1,000
miles up, is also a place of commercial im-
portance. About 40 river, coasting, and ocean
steamers now ply regularly between Pará
and Manáos every month, a number of them
being British.

Mr. Lange (see Bibliography) describes the
pororóca, saying that in certain places
*the wave travels fast,—it has traveled
a measured statute mile in 90 seconds, or at
the rate of about 45 miles an hour.*
Ex-President Roosevelt (see Bibliography), describing "the mighty river in the west of the Amazonia,"
says: "It runs from west to east, from the
sunset to the sunrise, from the Andes to the
Atlantic. The main stream flows almost along
the equator. This gigantic equatorial river
basin is filled with an immense forest, the
largest in the world, with which no other
forests can be compared save those of Western
Africa and Malaya. We were within the
southern boundary of this great equatorial
forest, on a river which was not merely un-
known but unguessed at, no geographer hav-
ing ever suspected its existence. This river
flowed northward toward the equator, but
whether it would go, whether it would turn one
way or another, the length of its course, where
it would come out, the character of the stream
itself, and the character of the dwellers along
its banks—all these things were yet to be dis-
covered.* Again, on pp. 333 and 334, we read:
*We finally entered the wonderful Amazon
itself, the mighty river which contains one-
tenth of all the running water of the globe.
was nowhere across, where we entered it; and
indeed we could not tell whether the farther
bank, which we saw, was that of the mainland
or an island. We went up it until about mid-
night, then steamed up the Rio Negro for a
short distance, and at one in the morning
reached Manáos. Manáos is a remarkable city.
It is only three degrees south of the equator.
Sixty years ago it was a nameless little collec-
tion of hovels, tenanted by a few Indians and
a few of the poorest class of Brazilian peasants.
Now it is a big, handsome modern city, with
opulent business, governor's palace, fine square
and public buildings and attractive private
houses. The brilliant coloring and odd archi-
tecture give the place a very foreign and at-
tractive flavor. Its rapid growth to prosperity
was due to the rubber-trade. This is now far
less remunerative than formerly. It will in all
doubtedly in some degree recover; and in any
event the development of the immensely rich
and fertile Amazonian Valley is sure to go on,
and it will be immensely quickened when closer
connections are made with the Brazilian high-
land country lying south of it.*

The mouth of the Amazon was discovered by
Yáñez Pinozo in 1500, but the stream
was not navigated by any European till
1540, when Francis Orellana descended it.
Explorations of the river or portions of it
were undertaken in later times by La Conda-
migue (1743-44), Humboldt (1799), Prince Ad-
albert of Prussia (1842), Hehn (1820), Lai-
lemant (1858), Bates (1861), Marcy (1866),
Agassiz (1866-67) and others; and of its tribu-
taries by Hartte, Chandless, Abendroth, etc. See
also in the following list of books the names of
other distinguished travelers.

of the Amazon* (London 1914). See articles
BRAZIL and SOUTH AMERICA.

**AMAZONAS.** Amazónas, Brazil, the
largest of all the Brazilian States and the
farthest north: bounded north by British
Guiana and Venezuela; east by the State of
Pará; south by Bolivia and the State of Matto
Grosso; west by Colombia and Peru. Its area
is 732,439 square miles, or nearly three and
a half times that of France, and 1.6 times the
United States. It reaches 2,000 feet in eleva-
tion ranges on the Venezuelan border it is an
alluvial plain. Its capital is Manáos. Pop.
of the State 387,000. The name Amazonas
is also borne by a territory of Venezuela and
a department of Peru (q.v.).

**AMAZONAS.** Peru, a department in the
montaña portion of the republic, has an esti-
mated area of 13,940 square miles. It is bounded
on the north by Ecuador, on the northeast and
east by Loreto, on the south by La Libertad
and on the west by Cajamarca. In this depart-
ment we find mountains of the central Cor-
dillera intersected by the deep valleys of the
Marañón and its tributaries. A singular fact
in regard to these tributaries is that two of
them, flowing in opposite directions, bear
the same familiar name, Santiago. The depart-
mental capital is Chachapoyas, seat of a bishop-
ric, and the industrial capital of a department
which is still in large measure covered by virgin
forests. The products, beside the rubber, coca,
etc.—the usual products of the forest—are
cajó, coffee, sugar, cotton, tobacco (in those
AMAZONAS, Venezuela, a territory of the republic, bounded on the north and east by the State of Bolivar, on the south by Brazil and on the west by Colombia. It is divided into two main parts by the Orinoco River, and the western part includes great llanos which extend to the neighboring republic of Colombia. There are navigable rivers, such as the Orinoco, the Meta, the Ventuari, the Guaviare, the Vichada and the Iruida. The chief products are rubber, copaiba, sarsaparilla and wild cacao. Pop. (est.) 46,000, divided as follows: 12,000 Indian converts, 33,000 savages, 200 natives of other States and 700 foreigners. The capital is San Fernando de Atabapo. See VENEZUELA.

AMAZONS, in Greek legends a nation of female warriors. They were fabled to have cut off their right breasts in order not to interfere with the use of the bow, and variously to have expelled men from their country or kept them in subjection for the continuance of the race. The earliest traditions locate them in Asia Minor and relate their appearance at the siege of Troy under their Queen, Penthesilea.

AMAZONSTONE, a beautiful green or blue feldspar. It is a variety of the mineral microcline and occurs in magnificent crystals in granite near Pike's Peak, Colo. Inferior crystals occur in New Jersey, the Ural Mountains and many other localities. Large quantities of green cleavable amazonstone have been tained at Amelia, Va., and have been worked up as semi-precious and decorative stones.

AMBALA, or UMBALLA, the name of a district of Northern India and its capital. The latter was the scene of a treaty between the governor-general of India, Lord Mayo, and the Emir Shere Ali of Afghanistan in 1869. The town contains several important churches, a dispensary, hospital and a leper asylum. Pop. 80,000.

AMBALÉNIA, Columbia, city in the department of Tolima, on the Magdalena River, 50 miles west of Bogota. It is the trade centre of a rich agricultural region, exporting large quantities of excellent tobacco. Pop. 8,500.

AMBARI, ἀμ-βαρί, HEMP. See HIBISCUS.

AMBARVALIA, Roman festival in honor of Ceres, which was observed in May. The blessing of the goddess was then besought on the wished-for harvest.

AMBAȘADOR (from the medieval Latin Ambasciator, an agent), diplomatic officer of the highest rank, the representative of one nation at the court of another. In this capacity he is expected to support the interests and dignity of his own state. Ambassadors are ordinary when they reside permanently at a foreign court, or extraordinary when sent on a special occasion. When ambassadors-extraordinary are vested with full powers, as of concluding peace, making treaties and the like, they are called plenipotentiaries. Ambassadors are often loosely styled ministers. Envoys are ministers employed on special occasions, and are of less dignity than ambassadors. Until 1893 the United States had been represented at foreign courts by persons with the rank of ministers-resident, accredited in the care of the great powers as envoys-extraordinary and ministers-plenipotentiary. In that year, however, an act of Congress was passed allowing the President to accredit ambassadors as United States representatives at several of the more important European courts. When accredited, ambassadors are exempted absolutely from all allegiance and from all responsibility to the laws of the country to which accredited. Should they be so regardless of their duty, however, and of the object of their privilege, as to insult or openly to attack the laws of the government, their functions may be suspended by a refusal to treat with them, or application can be made to their own sovereign for their recall; or they may be dismissed and required to depart within a reasonable time. An ambassador is considered as if he were out of the territory of the foreign power, by fiction of law, and it is an implied agreement among nations that the ambassador, while he resides in the foreign state, shall be considered as a member of his own country, and the government reserve cognizance of his conduct and control of his person. Ambassadors' children born abroad are held not to be aliens (7 Coke, 18 a). The persons of ambassadors and their domestic servants are exempt from arrest on civil process (3 Burr. 401, 1731).

AMBASSADORS, The. 'The Ambassadors' is often spoken of as enjoying the doubtful distinction of being the most talked about and least read novel in the English language. It holds first place in the affection of most people with whom the love of Henry James is a literary cult; it is the author's own favorite among his works. He calls it 'quite the best all round of all my productions.' Yet, in spite of the fact that it was published in 1903, 25 years after 'Daisy Miller' and 'The Portrait of a Lady' had created an audience for their author's work, half of the first edition remained on the publisher's shelves for years. It requires something more than the fact that 'The Ambassadors' is written in James' later manner and is full of subtle observation and expression to account for these extremes of admiration and neglect, and that something is undoubtedly the age of the hero. Middle age has never been popular in fiction, and 'The Ambassadors,' through Lambert Strether—probably the finest character James ever created—is the mirror of New England middle age beside the youth of Paris. The essence of the story, according to Henry James' preface to the New York edition (the best analysis of the work), is contained in the words of Strether to the friend of the New England boy whom he has been sent to save from the clutches of Paris and whom he finds 'disobligingly and bewilderingly not lost.' 'Live all you can; it's a mistake not to. It doesn't so much matter what you do in particular so long as you have your life. If you haven't had that, what have you had?'

EDITH J. R. ISAACS.

AMBATO, Ecuador, town on the slope of Chimborazo, 70 miles south of Quito. It has a flourishing trade in grain, sugar and cochineal. Pop. 12,000.
AMBER, one of the most important and valuable of the fossil resins. It is one of the oxygenated hydrocarbons and its mineralogical name, succinite, emphasizes one of its distinguishing characteristics, namely, the presence of from 5 to 8 per cent of succinic acid. Its composition is represented by the formula $C_{n}H_{2n}O_{2}$. It occurs in irregular masses, usually of small size but sometimes weighing up to 15 or 18 pounds. It has a yellow color, resinous lustre and conchoidal fracture. Its hardness is 2 to 2.5 and specific gravity 1.05 to 1.1. Along the shores of the Baltic Sea, especially in East Prussia, mining for amber has been carried on for two centuries. In this region shafts are sunk through a superficial stratum of marl and sand, a bed of lignite with light sands and gray clays, and finally a layer of green-sand, 50 to 60 feet thick. All of these strata contain amber, but in the lower portion of the green-sand there is a stratum four to five feet thick of a blue carat sign of which amber nodules occur so abundantly that 50 or 60 square rods yield several thousand pounds. This blue earth stratum extends out under the sea and there the amber is freed and cast upon the shores by the waves especially the autumnal storms. Small quantities are found in Great Britain, on the coasts of Sicily and the Adriatic, in various parts of Europe, in Siberia, Greenland and in the United States.

Pliny declared amber to be an exudation from trees of the pine family, a conjecture that proves to be correct. The fact that it was at one time fluid or nearly so is established by its occasional inclusion of insects; and its antiquity is also established by the fact that most of the species of insects so included are now extinct.

Amber becomes strongly electrified when rubbed, and the power that it then possesses, of attracting light bodies to itself, was probably considered by the ancients to be the outward sign of the mysterious virtues that they attributed to the mineral. It was greatly esteemed for ornaments and charms, and Pliny says that among women it had been so highly valued as an object of luxury that a very distinguished lady was obliged to leave home, the shell of which they mounted, unknown to sell at a higher price than living men, even in stout and vigorous health. He also says that a necklace of amber beads was considered to protect the wearer from secret poisons, and to be efficacious as a counter-charm against sorceries and witchcraft. In the time of Nero an expedition sent from Rome to the Prussian amber-beds returned with 13,000 pounds of the precious substance.

In modern times amber is chiefly used for the manufacture of mouthpieces for tobacco pipes and for the preparation of a kind of varnish. The attractive power exhibited by amber when rubbed was the first electrical phenomenon observed by man, and the word "electricity" was derived from electrum, the Greek name for amber.

AMBER, India, a ruined city, the ancient capital of Jaipur. Its picturesque situation at the mouth of a rocky mountain gorge, in which nestles a lovely lake, has attracted the admiration of all travelers. It is now only remarkable for its architecture. The chief building is the Diwan-i-Khas built by Mirza Raja, the columns of which were covered with stucco to hide their magnificence from the commissioners of Jehangir, who had ordered it destroyed because it surpassed the marvels of his imperial city of Agra. It is only by knocking off some of the plaster that one can get a glimpse of the sculptures, which are as perfect as on the day they were carved.

AMBERFISH, any one of a genus of fishes (Seriola) related to the pilot-fishes, many species of which are found along our coasts, the most of which are known by other names. The great amber-fish, or amber-jack, is a food-fish of some importance in the Gulf of Mexico and the West Indies, reaching a weight of 100 pounds. Others in that region are more commonly known as madreals; and a species of the Pacific Coast is the highly-prized yellowtail (q.v.). The name refers to the prevailing color.

AMBER GODS, The, a story by Harriet Prescott Spofford, published 1865. It is characterized by superb depth and richness of color, like a painting by Titian. An amber amulet or rosary possessing mysterious influences gives the title to the story.

AMBER INSECTS. The great majority of the fossil insects of the Oligocene (Tertiary) period have been obtained from the amber of the Baltic shores of Prussia, upon which they had rested in life, stuck fast and then been overflowed. The most fragile and delicate flies, moths and many other insects, besides spiders, mites, centipedes and crustacea, are preserved in this gum or resin, which was evidently formed in the same manner as gum copal, also a late tertiary or quaternary gum.

AMBERG, the ancient Bavarian capital of the upper Palatinate, situated on both sides of the Vils, in the midst of numerous ironworks. It is well built, and on the site of its former walls are shaded walks. Glass, iron wares, stoneware, tobacco, beer, vinegar and arms of good quality are manufactured here. The principal buildings are a Gothic church of the 15th century, the royal palace, the townhouse and the Old Jesuits’ College, and its possesses a gymnasium, and a large library. At Amber, the Archduke Charles defeated the French general, Jourdan, on 24 Aug. 1796. Pop. 25,000.

AMBERGRIS, a gum-like substance of great value in the making of perfumes, obtained from the intestinal canal of the sperm whale, or found floating in pieces of various sizes on the surface of the sea. It is a product of cetacean digestion, and often contains the beaks of cuttle-fish, a fact which conclusively proves the place of its origin, until recently much in doubt. When first extracted from the alimentary canal it has the tenacious tenacity of thick grease, and chemically seems to be of the nature of cholest erin, but after exposure to the air hardens and acquires its characteristic sweet earthy odor. Some odd stories were told by the old writers to account for its origin, of which the least absurd was that it was the excrement of the whale. It was held by the ancients to be of great value in certain diseases, but is now used entirely in connection with perfumery, and is worth about $20 a pound. The name is also given to a bar-
AMBIDEXTERTY, the ability to use the right or left hand with equal freedom and skill in all types of manipulation. The causes of the condition of right-handedness, i.e., the tendency to use the right hand only for finer manipulations, are probably to be found in inherited nervous structures which in turn seem to be related very closely to the inherited circulatory organs. Exercise may have some effect in fixing this relation and exaggerating the degree of one-sided development, but it is generally agreed that the inherited structures are of first importance.

AMBIGUITY, in law, the uncertainty of meaning of words, clauses or other parts of a written instrument. The rule of evidence preventing the admission of hearsay evidence has the important exception that it may be admitted to explain an ambiguity in a written instrument: Cramer v. Commonwealth; Will; and consult the works referred to under these subjects.

AMBITION, 1. To avenge the murder of his cab driver, William Phoenix, on September 15, 1936, in Philadelphia, Pennsylvania. The cab driver was a native of the Philadelphia area, and was driving a cab in the city. The motive for the murder was revenge, as the cab driver had been involved in a previous incident with Phoenix. 2. The cab driver was left-handed, and the murder weapon was a left-handed dagger. The weapon was left on the murder scene, and the cab driver's blood was found on the dagger.

AMBITION, 2. A type of flower, Ambigone, which is characterized by its large, showy flowers that bloom in clusters. The flowers are white or pink, with long, slender petals. The plant is native to Europe and Asia, and is often cultivated in gardens for its attractive flowers.

AMBITION, 3. A type of bird, Ambigone, which is known for its loud, melodious song. The bird is native to the tropical regions of South America, and is often kept in captivity as a pet. The song is characterized by a series of trills and whistles, and can be heard across a large area of the forest.
other from the west. In many churches there were two ambo, one on each side of the choir, from one of which the gospel was read, and from the other the epistle. The earliest are at Ravenna in the cathedral and the Church of Saint Apollinaire, and are of carved marble (See PULPIT). The name ambo was also given to an eagle-shaped reading-desk, now usually termed a lectern.

AMBOCEPTORS, also called immune bodies, are protective substances which develop in the body following injection of cells of different kinds. Nearly all animal cells and plant cells are capable of producing amboceptors. The amboceptors are of great value in aiding the body to recover from an infection. The problem is discussed more fully in the article on IMMUNITY (q.v.).

AMBOISE, am’bwa’, Aimeric d’, a famous French admiral, brother of Georges d’Amboise (q.v.); b. 1512. He became in 1503 Grand Master of the Knights of Saint John in Rhodes, and gained a great victory over the Sultan of Egypt in 1510.

AMBOISE, Bussi d’. See Bussi.

AMBOISE, Georges d’, French cardinal and minister of state; b. Chaumont-sur-Loire 1460; d. 1510. He became successively bishop of Montauban and archbishop of Narbonne and of Rouen, and in 1498 Louis XII made him Premier Minister. He failed in his attempt to secure the papacy, but his policy toward France was wise and statesmanlike. He reformed the Church, remitted the people’s burdens and conscientiously labored to promote the public happiness.

AMBOISE, France, a town in the department of Indre-et-Loire, on the Loire, 15 miles by rail east of Tours. It lies in a rich vineyard district and has been called “the Garden of France.” The town is memorable as the scene of the conspiracy of the Huguenots against the Guises (1560). It contains a beautiful chateau dating from the time of the Renaissance. Pop. about 4,600.

AMBOYNA, or AMBOINA, the most important of the Molucca Islands, being the seat of their government and the centre of the commerce in nutmegs and cloves; greatest length, 33 miles; greatest breadth, 10 miles; area, about 260 square miles. It is composed of two unequal peninsulas united by an isthmus about a mile broad, the larger known as Hitu, the smaller as Leitimor. Its general aspect is attractive and its climate salubrious. It is covered almost throughout with forests, affording a great variety of beautiful wood for inlaying and ornamental work. Sugar and coffee are cultivated. The surface is generally rugged and hilly, sometimes rising into mountains of granite. The site along the shores is very fertile, but a large portion remains uncultivated. In 1605 Amboyna was taken by the Dutch from the Portuguese, and shortly afterward some English factories were erected there; but in 1623, the Dutch seized the English fort, tortured frightfully Captain Towerson and nine others to obtain a confession of conspiracy and put them to death—a performance notorious as “The Massacre of Amboyna.” Pop. 30,000. Amboyna is also the name of one of the residencies into which the Molucca Islands are divided, including Buru, Caram, Aru Islands, the Bandas and others. Pop. 95,000.

AMBOYNA, capital of the Dutch residency in the Moluccas, situated on the northwest shore of the peninsula of L tetimor and defended by Fort Victoria. The houses, built in Dutch fashion, are generally of one story, owing to the frequency of earthquakes, one of great severity occurring in January 1898. It contains a governor’s palace, town-house, two Protestant churches, several orphan hospitals, a theatre and a large covered market-place. The streets are wide, and are planted on each side with rows of fruit-trees. Pop. about 10,000.

AMBRIDGE, Pa., borough in Beaver County, 16 miles northwest of Pittsburgh, on the Ohio River and on the Pennsylvania Railroad. Bridge building, molding of metals and the manufacture of tubes are the chief local industries. The water works are municipally owned. Pop. (1910) 5,205; (1916) 8,700.

AMBRIZ, a’mbri’, seaport, capital of a district of the same name in the Portuguese colony of Angola, West Africa. Originally the capital of Quibanza it was taken by the Portuguese, who in 1855 built a fort, a custom-house and a church which formed the nucleus of the present town. It has a number of factories and a trade in indigo-rubber, coffee and palm oil. Pop. about 3,000.

AMBROS, a’mbrós, August Wilhelm, Austrian writer on music; b. 17 Nov. 1816 in Mauth, Bohemia; d. Vienna 28 June 1876. He was trained for the civil service and served in it with distinction; but his tastes led him elsewhere, and he rose to eminence as the author of ‘The Limits of Music and Poetry,’ besides numerous essays and studies connected with art. His masterpiece, ‘The History of Music’ (1862-68) a work which cost him many years of labor, was carried only to the fourth volume. A fifth, completing the work, was added by Langhaus.

AMBROSE, Saint, Latin father of the Church; b. 333, or, according to other accounts, 334, probably at Treves (the ancient Augusta Treverorum), where his father resided as praetorian prefect of Gallia Narbonensis; d. Milan, 4 April 397. It is told that a swarm of bees covered the eyes of the boy while slumbering in the court of his father’s castle, and the nurse was astonished to perceive the bees going in and out of his mouth without doing him any injury. His father, possibly recalling a similar wonder, mentioned of Plato, prophesied future greatness for his son. Ambrose studied law at Rome under Anicius Probus and Symmachus, and then went to Milan and began to plead causes while yet a youth. His pleadings were so eloquent and skillful that in a short time Probus, the prefect of Italy, chose him a member of his council; and in 369, with the approval of the Emperor Valentinian, appointed him governor of the provinces of Liguria and Emilia (North Italy). In 374 he was called to the bishopric of Milan by the unanimous voices of Arians and Catholics. Ambrose long refused to accept this dignity, but in vain. He fled by night, and thought himself on the way to Pavia, but unexpectedly found himself again before
the gates of Milan. At length he yielded, received baptism, for he had hitherto been only a catechumen, and eight days after was consecrated a priest. The 24th of December is still celebrated by the Church on this account. On his elevation to the bishopric he bestowed all his wealth on the Church and among the poor, resolving to live as simply as possible, and at the same time to exercise his functions as an ecclesiastical ruler with firmness and vigor. He was employed by the court to negotiate with Maximus, then threatening Italy, whose advance he succeeded for a time in arresting (383). Four years later he was sent on a like mission, but his conduct on this occasion so offended Maximus that he had to return to Milan, having accomplished nothing. In his struggles against the Arian heresy he was opposed by Justina, mother of Valentinian II, and for a time by the young Emperor himself, together with and preserter the Gothic troops. Backed by the people of Milan, however, he felt strong enough to deny the Arians the use of a single church in the city, although Justina, in her son’s name, demanded that two should be given up. He was commanded to quit the city, but this he refused, being still supported by the people. About this time Ambrose, instructed by a dream, searched for and found the relics of two martyrs, Gervasius and Protasius. The people crowded to see these bones, and, according to Ambrose himself, the eyes of the blind were opened and devils were cast out by touching them. Although the court derided these miracles they were accepted by the people, and the triumph of orthodoxy was secured. He had also to oppose paganism. In 390, after the massacre at Thessalonica, he refused the Emperor Theodosius entrance into the church of Milan for a period of eight months, only restoring him after a public penance. (See THEODOSIUS). The later years of his life were devoted to the more immediate care of his see. His writings (the best edition is by the Benedictines, 2 vols. folio, 1666-90), bear marks of haste, and show his theological knowledge to have extended only beyond an acquaintance with the works of the Greek fathers, from whom he especially Oregen and Origen has been broached considerably. The "Ambrosian Chant" or "Te Deum Laudamus" has been ascribed to him, but was written a century later. He may be considered the father of the hymnology of the Latin Church. He is the patron saint of Milan, which observed his 15th centenary in 1897.

AMBROSIA, in the Greek mythology, a balsamic juice which formed the food of the gods and their immortality. It was used also as an ointment. Mortals permitted to partake of ambrosia received an increase of beauty, strength, and swiftness, becoming in some measure assimilated to the gods.

AMBROSIA BEETLE. See Wood-boring Beetles.

AMBROSIAN CHANT. See Gregorian Chant.

AMBROSIAN LIBRARY. public library in Milan: founded by the Cardinal Archbishop Federigo Borromeo, a relation of Saint Charles Borromeo, and opened in 1609. It now contains over 175,000 printed books and 8,400 MSS.

AMBROSINI, Bartolomeo, Italian naturalist: b. Bologna, 1588; d. there, 1657. He was a pupil of Aldrovandi, several of whose works he published, and who named him as director of the university botanical garden. He studied at the university, and became successively professor of philosophy, of botany and of medicine; and during the plague of 1630 in Bologna he worked assiduously for the relief of the sufferers.

AMBULANCE, a term generally applied in England and America to the wagon or other vehicle in which the wounded in battle, or those who have sustained injuries in civil life, are conveyed to hospital. More strictly, in military parlance, the term imports a hospital establishment moving with an army in the field, to provide for the collection, treatment and care of the wounded on the battlefield, and of the sick, until they can be removed to hospitals of a more stationary character. An ambulance organization, differing in minor details, now prevails in all civilized armies.

AMBULANCE COMPANIES. In the United States a limited number of field hospitals and ambulance companies are maintained in time of peace to provide trained organizations for duty with the troops when they are on field service and to afford a means for training officers and men for the sanitary service in the work of the sanitary field organizations. In the training of these organizations special attention is given to those elements of field work for instruction in which only limited facilities are afforded at posts, such as the practical use of the articles of field equipment, lines of aid, equitation, care of animals and the use of the pack-saddle. The personnel of these organizations in time of peace comprise two classes: (a) permanent cadre, consisting of such number of non-commissioned officers and men as are deemed necessary to maintain continuity of policy and method in instruction; (b) temporary personnel attached to these organizations for purposes of instruction. On field service with a mobilized division the field hospitals and the ambulance companies operate under their two respective directors whose relation to them is similar to that of a major of the line to his battalion. The senior officer of two or more field hospitals or ambulance companies conducts the course of instruction as though they were a single organization and assigns the instructors from the permanent personnel of the organizations as he deems best. In other respects, however, the several organizations retain their autonomy as separate and distinct administrative and tactical units, each under the command of its own senior medical officer. The discipline and interior economy of these organizations conform so far as practicable to those of a company of infantry. The program of instruction for these organizations, the sequence of the subjects, the manner in which the same are taught, the details thereof to be taken up and the time to be given to each are prescribed by the War Department.

The personnel of an ambulance company at war strength are ordinarily distributed as follows: (a) With the dressing station, including the litter-bearers—four officers, one
AMBULANCE COMPANIES

A sergeant first class, six sergeants, one acting cook, 40 privates first class and privates, all of the medical department; (b) with the wheeled transportation—one officer, one sergeant, one first class, one second class, one acting cook, 28 privates first class and privates (one as firer, one as saddler, two as musicians, 12 as ambulance-drivers and 12 as ambulance orderlies), all of the medical department; also one sergeant first class, three privates (drivers) of the quartermaster corps. The function of the ambulance company is to collect the sick and wounded, to afford them temporary care and treatment and to transport them to the next sanitary unit in the rear. In camp it operates the ambulance service between the camp infirmaries and the field or other hospitals. On the march ambulances are distributed among the marching troops, usually one to each regiment, for the purpose of supplying transportation to those who become unable to march.

In combat the ambulance company operates in two parts. The first establishes and operates a dressing station and collects the wounded; the second part operates the wheeled transportation in evacuating the wounded. The dressing station party, including the litter-bearers with its equipment on pack-mules, moves forward in rear of the troops ready to establish the dressing station. The location of the dressing stations and the number to be established is determined by the division surgeon acting under the instructions of the division commander. The director of ambulance companies supervises their opening, giving the necessary orders therefor to the commanders of the ambulance companies. The site selected for a dressing station should have the following advantages: (1) Protection from rifle fire, (2) protection from direct artillery fire, (3) accessibility for wheeled transportation, and (4) a supply of water. Effective shelter from fire is the chief desideratum. A site inaccessible to ambulances on account of exposure to fire need not invariably be condemned, for the greater part of the work of the ambulances is done after the close of the battle or after nightfall. The station is pushed as far to the front as possible to reduce to the minimum the distance over which the wounded must be carried on litters. In some cases in which the establishment of the dressing station is delayed, or in which the troops are about to move forward, it may be possible to locate the dressing station at the aid station, thus practically eliminating one station. Under these circumstances the dressing station assumes the work of the aid station and the personnel of the two co-operate until the aid station moves forward. The requirement that the sanitary personnel with the combatant organizations keep in touch with those organizations may make it necessary for them to leave the wounded where they fall, pausing only to administer such aid as may be absolutely essential. Cases thus left are collected and carried forward by the parties who advance. As soon as the dressing station is open its bearers under the direction of a medical officer proceed to the front as far as the enemy's fire permits. Ordinarily they are divided into as many sections as there are aid stations, each under a non-commissioned officer, and one section proceeds toward each aid station. They direct wounded who are able to walk to the station for slightly wounded. They transport other wounded from the aid station to the dressing station. When practicable they also assist the regimental medical personnel in the care and removal of wounded from points in advance. Meanwhile the commanding officer of the company, or the dressing station personnel proceeds to put the dressing station in condition to receive patients. When possible for wheeled transportation to reach the dressing station a message is sent to the officer in charge of the ambulance train directing him to report at the station with the ambulances.

The work of the dressing station is carried on under the following departments: Dispensary, kitchen, receiving and forwarding, slightly wounded and dangerously wounded. All wounded pass through the receiving and forwarding department. Those whose injuries are not sufficient to incapacitate them for the present performance of their military duties are directed, after receiving the necessary treatment, to return to their units and the fact that such directions have been given them is noted upon their diagnosis tags. Other slightly wounded, able to walk, are, after like treatment, immediately directed to the rear in command of their highest-ranking officer or soldier. Generally they are sent to the station for slightly wounded. At the dressing station only such operations are performed as may be immediately required to save life or to render the patients fit for further transportation. The rules to be followed generally are that no operative or other interference should be attempted under conditions unfavorable for asepsis or antisepsis and also that no wounded for whom transportation is available should be delayed at the dressing station. Conditions in these respects vary widely in different battles.

The ambulances and wagons remain farther to the rear than the dressing station (usually in proximity to some division headquarters which communication with division headquarters may be maintained) until it is practicable to determine a line of evacuation for the wounded. As soon as the dressing station is established and the location of the field hospital is determined a safe route for the ambulance service between these two establishments is sought and when found the ambulances advance to begin the removal of wounded from the dressing station. The wagons of the ambulance company, carrying a reserve of dressings, remain at a field hospital whence the supplies are sent forward by ambulances returning to the dressing station. Ambulances must reach the station as early as possible even at the risk of losses. Ordinarily ambulances carry wounded only from the dressing station to the nearest field hospital, immediately returning to the former. During the daytime when a battle is still in progress it is rarely possible for ambulances or other wheeled vehicles to advance farther to the front than the dressing station. Opportunity to have them do so will sometimes occur at night, and on the conclusion of an engagement they should always be used as far
AMBULANCE CORPS

as may be at all points on the battlefield. Should it be impossible to evacuate the wounded at a dressing station before it is closed or moved, by reason of retreat or otherwise, the commanding officer of the ambulance corps should leave with the wounded and attend according to their number and condition sufficient medical personnel and supplies to provide for their immediate necessities, and advances or withdraws with the division the remainder of the personnel and equipment.

AMBULANCE CORPS. The modern army corps has become so large and is so likely to break up into parts operating separately that its ambulance service does not give the best results when kept together as a homogeneous whole. European experience shows that not the corps but the division should be the unit of ambulance organization. The name of ambulance corps is too well consecrated by usage to permit of any alteration in form or general meaning, but it is admissible to change the composition of the body it designates.

Organization.—The ambulance corps should be made up of independent units, each one corresponding to a division of the army corps and operating with it. The unit thus assigned to a division is the "Ambulance of the troops" or the "Sanitätsabteilung" of the Germans; the "Sanitätsofonne" of the Austrians; and the "Bearer Company" of the English. The name of Ambulance Brigade, which is proposed for it, seems to be the most appropriate for the United States army.

The ambulance corps, as organized, is under the general direction of the medical director. It consists of as many ambulance brigades as there are divisions in the army corps, and an additional one, known as the Headquarters Ambulance Brigade, or the corps troops (cavalry, artillery, engineers, etc.), and the reinforcement of any divisional brigade in need of assistance. Our hypothetical corps of three divisions would, therefore, consist of four ambulance brigades fully manned and equipped for independent action.

What should be the strength of the medical personnel (bears and nurses) of an ambulance brigade? Our rule assigns 1.5 per cent of the command to the ambulance corps, therefore, if we have a division 12,000 strong, the ambulance brigade will get a detail of 180 men. From this number must be deducted the quota to the Headquarters Brigade, say, 24 men. Of the remaining 156, 36 will do duty as ambulance orderlies. We have now left only 120 men, a number which represents the exact rate of 1 per cent of the strength of the division. These 120 men are divided into stretcher-bearers and nurses — 96 of the former and 24 of the latter. The 96 bearers will man 24 stretchers, or at the rate of two stretchers per 1,000 combatants. The 24 nurses, as a rule, are handled by the regimental bearers, to give six stretchers for each full regiment, independently of the help which in case of need could be obtained from the Headquarters Brigade.

The composition of an ambulance brigade is complete. For a division of 12,000 men, would be about as follows: One surgeon in charge; five surgeons; one captain; one first lieutenant; one second lieutenant; one sergeant-major; eight sergeants; eight hospital stewards; 24 hospital attendants (nurses and cooks); two buglers; 36 ambulance drivers; 36 ambulance orderlies (nine of whom to be mounted corporals); 10 wagon drivers; 96 stretcher-bearers; four mechanics (blacksmith, wheelwright, saddler and farrier). Total, 344.

The matériel consists of 36 ambulances, two medicine wagons, six service wagons for tentage, baggage and supplies and two water-carts. Personnel and matériel are so organized as to admit of being split in halves, each capable of separate action.

The ambulance orderlies follow the ambulances, or ride on the rear step, and are responsible for the safety and comfort of the patients in transit to the depot and the field hospitals. Each of the nine orderly corporals, besides his own ambulance, will also exercise supervision over three others — the four ambulances thus under his authority constituting an ambulance section. The 24 stretchers will be divided into sections of four stretchers, each section being in charge of a sergeant and chief of section. The Headquarters Brigade need not be so large as the others. It is made up of 24 men from each of the infantry divisions; therefore, in our hypothetical corps, will have only 72 bearers and nurses.

The three lines of the field services are the regimental help-stations, the ambulance brigade depot and the field hospitals.

Help Stations.—On the battle-field nothing can be done for the wounded, while under fire, but to lift them upon stretchers and carry them off speedily to the help-station. Here they are rapidly examined and given such immediate attention as may be required to secure their safe transport to the ambulance depot.

The modern formation of infantry advancing against an enemy may be practically described as consisting of three lines: Firing line, line of support, regimental reserves, with an interval of 300 yards between them. The line of support, placed 300 yards behind the skirmishing or firing line, is supposed by tacticians to be comparatively safe from the fire aimed at the first line, while the regimental reserves are entirely safe from bullets. The help-station should not therefore be further than just in rear of the reserves. This will place it about 600 yards behind the firing line. In certain cases, where good shelter is available and the reserves can get nearer to the front, the station, of course, follows them.

The German and French regiment of infantry, made up of three battalions, is 3,000 men strong; one help-station for each is provided, and considered sufficient. Our formation corresponding in number to the above regiment is the brigade, which seldom would exceed but often fall short of 3,000 men. Such brigade in battle array would only cover a front of from 300 to 500 yards, obviously insufficient to the needs of one station. To have three or more stations 100 or 200 yards apart would be a waste of means and detrimental to the wounded. A medicine wagon containing the supplies of the help-station and carrying the regimental stretchers should follow each brigade to the field, and advance to the station or as near it as possible.

Ambulance Depot.—The depot of the ambulance brigade constitutes the second line.
of help. It is the centre and rallying point of the brigade. Here, as a battle becomes impending, all the ambulances which follow the regiments on the march rejoin the brigade train. If no suitable building can be found, the operation is done by the attendants, and hospital tents pitched; the necessary medicines and appliances are drawn from the wagons and held in readiness.

The stretcher-bearers are divided into as many platoons as there are help-stations; each platoon having assigned to it a principal or the senior chief of section, marches toward its assigned station, followed by a packet of ambulances; these are driven near the station as possible; as soon as halted, the bearers remove the stretchers and with them proceed to the front, or else first carry off the wounded collected at the help-station. The patients brought to the depot are carefully but rapidly examined, and sorted according to their injuries; one surgeon applies simple dressings, a second attends to serious wounds, a third, with assistants, performs urgent operations. At what distance in the rear should the ambulance depot be established? We have seen that at 600 yards behind the firing line one was practically safe from bullets; at the distance of about a mile, rather less than more, we shall not only be beyond the range of musketry fire but also beyond the aim of artillery projectiles, and there seems the proper place for the depot. Whatever danger there may be at this distance is reduced to a minimum by a judicious selection of the spot.

Field Hospitals.—The field hospitals form the third line of help. They should be at an absolutely safe distance from the scene of conflict—that is, two or three miles behind the ambulance depot—and have a free outlet toward the line of evacuation. There should be three provided for a division, and all completely equipped. Each accommodates 200 patients and is divided in two equal sections. See Field Sanitary Service.

AMELANCHIER, a genus of shrubs or small trees, native in family Rosaceae of Europe, Asia and America. The species, which are closely related, have alternate, simple, deciduous leaves, numerous racemes of showy white flowers appearing in early spring often before the leaves, and, in summer, edible spherical or oblong red or dark purple berries with more or less bloom. They are commonly known under the names Juneberry, shad-bush and service-berry, and some species are cultivated for their edible fruit or for ornament. They are hardy, succeed upon many soils and in many climates and are readily propagated by seeds or suckers.

AMÉLIE-LES-BAINS. See Arles.

AMEN, a word of Hebrew origin now generally used in all the languages of Christendom, having the sense of firmly, or surely, certainly, truly. The most common use is at the end of a prayer or creed where it has the sense of we believe. This use was very early. In the Apostolical Constitutions the word was used for a response. Jerome mentions its use in his time. J. Massie in his excellent article in Hastings' Dictionary of the Bible finds four distinct uses of the word: (1) For the purpose of adopting as one's own what has been said, often "doubling the word for emphasis." (2) "It is used in confirmation of one's own prayers, thanksgivings, benedictions or doxologies." (3) "It is used once at the close of an acclamation of one's own to confirm it solemnly in faith." (Rev. i, 7) Christ uses it as a word of introduction. (4) The Amen is used "as a name or description of Christ and of God." Another usage occurs in several passages in the Old Testament. When the priest or administrator of an oath has administered the oath to all present he and his aman thus bind themselves by the oath as surely as if they had said it. (Numbers v, 22; Deuteronomy xxvii, 15, 17 are samples.)

AMENDE HONORABLE. In the old armies of France, this expression signified an apology for some injury done to another, or satisfaction given for an offense committed against the rules of honor or military etiquette, and was also applied to an infamous kind of punishment inflicted upon traitors, parricides or sacrilegious persons, in the following manner: The offender being delivered into the hands of the hangman—his shirt stripped off, a rope put about his neck and a taper in his hand—was led into the court, where he begged pardon of God, the court, and his country. Sometimes the punishment ended there; but often it was only a prelude to death or banishment to the galleys.

AMENDMENT, in law, the correction of any mistake discovered in a writ or process. At common law, amendments, in the absence of any statutory provision on the subject, are in all cases in the discretion of the court for the furtherance of justice. The power of amendment is regarded as incidental to the exercise of all judicial power. Amendments are very liberally allowed in all formal and most substantial matters under statutes in modern practice. They are allowed either without costs to the party amending, or upon such terms or conditions as the court may see proper to impose. In legislative proceedings, a clause, sentence or paragraph proposed to be substituted for another, or to be inserted in a bill before Congress, and which, if carried, actually becomes part of the bill itself. As a rule amendments do not overthrow the principle of a bill. The Senate of the United States may amend money-bills passed by the House of Representatives, but cannot originate such bills. The Constitution of the United States contains a provision for its amendment (U. S. Const. Art. 5). See Constitutional Law; Parliamentary Law.

AMENDMENTS, Constitutional. See Initiative; Referendum; Convention, Constitutional.

AMENOPHIS, ā-men-hā-tāp, or AMENOPHES, the name of four Pharaohs of the 18th dynasty. Amenophis I reigned for 10 years about 1570 b.c. After his death he received divine honors and was made patron of the necropolis of Thebes. His mummy was discovered at Dair-el-Bahri and now lies in the Ozymed museum. Amenophis II reigned for about 25 years about 1450 b.c., carried on several wars and maintained the integrity of the territory inherited from his father. Amenophis III was the son of Thothmes IV and reigned for 35 years about 1410 b.c. He lost a great portion of his Asiatic territory, attained
renown for the erection of public temples, especially the great temple of Thebes, of which two colossal remain. The great tomb of the parents of his wife Teye was discovered in 1905.

The most important of these rulers was AMENHOTEP IV, later called Ikhnaton. He was the son of Amenhotep III and Queen Teye. Early in life he became interested in the theology of the priests. As the result of his contemplation he gained the idea of "a single controlling intelligence, behind and above all sentient beings including the gods." This intelligence enforced his designs by his "word." This teaching anticipated the doctrine of the Logos of Philo and others. This god was supreme; at a time when Aton. The priesthood of Amon, the former national god, would have supplanted him if they could but the priests of the other gods at that time supported him. He became high-priest of all the priesthoods of Egypt. He next planned to complete the worship of the other cults, and thus became the arch-heretic of his time. He had the names of the gods erased from all monuments. Finally he left Thebes and founded a new city, Akhenaton, "Horizon of Aton," which was built on the site of Tell El-Amarna. He raised Merenre, one of his favorites, to the high-priesthood. After a few years his empire was overruled by the Hittites and the Asiatic part was lost entirely. He had no son to succeed him, but was succeeded by Tutankhaton, his son-in-law. He died about 1358 B.C. after a reign of 17 years. He came to be known in succeeding years among his people as the "criminal of Akhenaton." He was buried in a tomb, which he had prepared for himself and family, in a lonely valley some miles east of the city. In 1887 in a small room in Akhenaton were found the archives of his foreign office and many of its documents published under the title of "The Tell El-Amarna Letters."

AMENI, William Scott, American missionary: b. Owosso, Mich., 1851; d. 1909. He was educated at Oberlin, and studied theology at Andover and at Andover Theological seminaries. The American Board of Foreign Missions sent him as missionary to China. In 1900 he was one of the 800 foreigners, who with 3,000 native Christians were besieged in the Boxer revolt at Peking. When the siege was raised, Ameni and his companions together with 500 native Christians took possession of the palace of a Mongolian prince. He took an active part in reinstalling the native Christians and in the readjustment of things generally after the revolt. He was severely criticized in the American press because of his course, and some journals went so far as to brand him as morally guilty of looting. The charges fell through, however. Consult his life by H. D. Porter (New York 1911).

AMENTIPÈRE, a name which has been used to include in one class several natural orders of plants which bear their flowers in cattails (amenées). They are found chiefly in temperate climates, and include many common trees, such as willows and poplars, oak, beech and chestnut, walnut and bog myrtle.

AMERICA: a brief account of the derivation and meaning of the word. The name Amalric (in Old High German, Amalrich or Amelrich; Gothic, Amala-reiks or -reikis; variants Am-él, Am-ul and Am-il-ríh, -rich or ríc) originated among the Goths in northern and central Europe; was adopted by other nations of the Teutonic stock before the great migration of those kindred peoples; and was carried into all west European countries — even to England and the Mediterranean coasts — by the Northern conquerors between the 5th and 12th centuries. The famous East Gothic dynasty of the Amala received its name, according to tradition, from a national hero whose mighty labors had earned for him the title Amal, which, as we shall presently explain, was a purely democratic term, connoting personal character and achievement, without the slightest implication of social rank.

From the dynastic name, the Goths as a race, or, more narrowly, the East Goths, were familiarly called Die Aemulungen; the Amal king in the 4th century ruled from the Baltic to the Black Sea; at the beginning of the 6th century a king of the West Goths in Spain and France, a grandson of Theodorich the Great, was called Amalarich. The word of democratic meaning thus spread through a few lands and a few centuries, to be united inseparably with the other short word which appears in the name of the West-Gothic king.

The significancy of the compound is of extraordinary interest. Its second member appears in Old English (for example, in the Anglo-Saxon epic of Bedwulf) as ric, meaning powerful, or when a substantive, control, domain or empire — the modern German Reich. According to von Humboldt ('Examen Critique,' Vol. IV) and Professor von der Hagen, the fundamental meaning of the first member (its root, am, often occurring in the dialects of Iceland and Scandinavia in the forms ama, ambl, etc.) is labor, endurance of great toil. Accepting this view, we find that the title of the Gothic national hero, Amal, expressed popular appreciation of "the man of great or laborious enterprises." Simply that. In order to show that Amal, when uniting with the aristocratic monosyllable, retained its original value, so characteristic of the people who used it every day: that, at least, they never thought it meant "the mighty," as some authorities have asserted recently; we need only point to the facts that they prefix it to ric, which itself signified "mighty," and that folk stories served to remind them constantly of the primitive meaning of the first member. Amalric, then, was the name which compacted the old ideal of heroism and leadership common to all Germanic tribes, the ideal that stands out most clearly in the character of Bedwulf — the Amal of Sweden, Denmark and Saxon England. The compound plainly meant what the north European hero-stories described: The man who ruled because he labored for the benefit of all. In France this name was softened to Amaury. Thus, a certain theologian who was born in the 12th century at Béziers, called Chartres, is called indifferently Almaric of Béziers or Amaury of Chartres. England, in the 13th century, could show no more commanding figure than Simon of Monfort-l'Amaury, Earl of Leicester, to
whom King Henry once said, "If I fear the thunder, I fear you, Sir Earl, more than all the thunder in the world." A Norman Abalric was that Earl Simon, creator of a new force, and a democratic one, too, in English politics.

It was, says the historian Green, "the writ issued by Earl Simon that first summoned the merchant and trader to sit beside the knight of the shire, the baron, and the bishop in the parliament of the realm." In Italy, after the Gothic invasion, the Northern name suffered comparatively slight euphonic changes, which can be easily traced. As bishop of Como in 865 it became Amelric or Amelrigo. But the juxtaposition of the two consonants l and r presented a difficulty in pronunciation which the Italians avoided: they changed lr, first, to double r, and then to a single r. Still, 600 years after Bishop Amelrigo died, the Florentine merchant, explorer and author usually retained the double r in his own signature, writing Amerigo Vespucci, and, by the way, accenting his Gothic name on the penultimate (Amerigo, not Amelric). In Spain the name was rare, since it was often used alone to designate the Florentine during his residence in that country. There was, apparently, no other Amerigo or Amelrigo in the Spanish public service early in the 16th century. At any rate, most of our information on the North for the scope of the next important change, and among the men of a Northern race for its author.

Martin Waldseemuller, a young German geographer at Saint Die, in the Vogtland Mountains, whose imagination had been stirred by reading Amerigo's account of voyages to the New World, bestowed the name America upon the continental regions brought to light by the Florentine. It is not enough to say, with Mr. John Boyd Thacher ("Columbus," Vol. III; compare pp. 787-788), that his interest in the "Continent of America") that Waldseemuller suggested this designation. As editor of the Latin work, the "Cosmographie Introductio" (5 May 1507), he stated most distinctly, with emphatic reiteration, his name-giving; placed conspicuously in the margin the perfect geographical name, America, and at the end of the volume put Vespucci's narrative. Further, on a large map of the world, separately published, he drew that fourth part of the earth which was the "Introductio's" America. It is impossible to adopt the suggestion of Professor von der Hagen, that Waldseemuller was distinctly conscious of giving the new continent a name of Germanic origin. "Quia Americus inventit," says the "Introductio," "Americi terra sive America nuncupare licet." But the case stands otherwise when we ask why Europeans generally caught up the word. Its association with so many men before Vespucci certainly commended it to Northern taste.

MARRION WILCOX.
Author of "History of War with Spain," etc.

America, the second in size of the isolated land masses of the globe; containing about three-tenths of the total land surface and perhaps half the cultivable area, but less than onetenth the population. The name was originally used only for central Brazil, and was applied in honor of the Italian, Amerigo Vespucci (q.v.), who claimed that he discovered it. (See AMERICA: a brief account of the derivation and meaning of the word.) It was first employed for the entire known Western world by Mercator in 1541, and is usually but not properly understood to include Greenland, which is physically a part of Europe.

The extreme point marking the limits of this vast continent are: North, the point of Boothia Felix, in the Strait of Bellot, lat. 71° 55' N., long. 94° 34' W. (in Alaska Point Barrow, lat. 71° 23' 31" N., long. 156° 21' 40" W.); South, Cape Froward, lat. 55° 3' 45" S., long. 71° 18' 30" W., or, if the archipelago of Tierra del Fuego is included, Cape Horn, lat. 55° 59' S., long. 67° 16' W.; West, Cape Prince of Wales, lat. 65° 33' N., long. 116° 59' W.; and East, the Point de Guia, lat. 7° 26' S., long. 34° 47' W. Its total area is not far from 16,000,000 square miles, without Greenland or the polar archipelago.

Topography.—Nominally one continent, it is really two if not three sections, geologically independent. The northern, from the Arctic Ocean to the Isthmus of Tehuantepec in Mexico on the west (where the west slopes of the Anahuac plateau of the Rocky Mountains sink to the plain, and the Guatemalan Highlands are not in sight), and Florida on the east, is connected with the southern by two great parallel ridges. One called Central America, is continuous, joining South America at the west side, and dwindling to 28 miles across at the Isthmus of Panama; the other, partly submerged, consisting of Haiti, Porto Rico and the Lesser Antilles, joining at the eastern side; the two united transversely by Cuba and Jamaica and the projection of Yucatan, and enclosing the Caribbean Sea, 1,500 miles from end to end. The continental mass, 8,700 miles from Alaska on the northwest and Boothia Felix on the northeast to the south end of Patagonia, is prolonged to a total of some 9,600, nearly four-fifths the distance from pole to pole, by a vast archipelago of Arctic islands up from Hudson Bay (ending suddenly like a drift line about 125° W. long., and at Grant Land about 83° N. lat.), and by another at the south called Tierra del Fuego, on the Antarctic continent, in the eastern continent, some force has massed the land chiefly at the north: two-thirds of the continent is north of the equator; the extreme point of the continuous northern islands reaches to a few hundred miles from the pole, the last of the southern is 2,350 miles from it; Alaska is 1,100 from the north pole, Argentina is 3,400 from the south. The same causes make it form part of a nearly solid ring on the Arctic Ocean, the northwest projection of Alaska being separated from the northeast of Kamchatka by only 40 miles; and the continent being connected with Europe by a series of islands one to two hundred miles apart; while the immense though widely unequal gulfs of the Pacific west and the Atlantic east separate the habitable portions.

The axial dimensions of the continent are not very dissimilar to those of the eastern. Its length is about the same as the breadth of the other from China to England, its greatest breadth about the depth of the other from the Arctic to the Indian Ocean; but its relative slenderness gives it less than half the area. It
is in fact an immense peninsula slightly severed from the main mass, with the shape and the southerly direction of the majority of peninsulas. From nine to ten thousand miles long, it is little over 3,000 across its main north-south lines, from Labrador to British Columbia, or from Peru to Brazil; about 2,100 from Savannah to San Diego, a few hundred across Mexico, 1,725 at the Tropic of Capricorn just above Rio Janeiro, 750 from Buenos Ayres to Valparaiso, and 374 southward. The Atlantic Ocean is relatively small and of regular breadth from Labrador and Brazil to England and Liberia, compared with the immense abyss of the Pacific and its sweeping arch from the Bering Sea to Australia and Chile; from Newfoundland to Ireland is but 1,900 miles, from Cape Saint Roque in Brazil to Cape Palmas in Liberia but 1,700; while from San Francisco to Yokohama is 5,500, from Quito to Singapore (almost exact antipodes) 12,500, and from Valparaiso to Sydney 8,000. Strangely enough the continents fit together somewhat as if the blocks of a dissected map. The great eastern projection of North America is toward the Bay of Biscay, that of South America toward the Gulf of Guinea, the great western projection of Africa toward the Gulf of Mexico and the Caribbean Sea. The same closure (about 45°) which would bring Newfoundland against Brittany and Labrador against the British Isles, would make the Kongo empty against the Brazilian coast and the West Indies surround Senegambia. In physical character also the northern and southern portions of each are akin: northeastern North America has the broken island-fringed peninsular coasts and the gigantic inlets and inland seas of Europe, while South America has the solid coast-wall and the absence of lakes characteristic of western Africa. Not to mention the great polar archipelago or Hudson's Bay, and allowing the archipelago at the south end of Chili to set off against the Alexander Archipelago along the south Alaskan coast, there is no parallel in South America to oceanic bodies like the Gulf of Mexico, or lesser ones like the Gulf of Saint Lawrence northeast to Puget Sound northwest, or the Gulf of Cabo de la Vela southeast; or the mass of sheltered bays and sounds along the eastern coast to the Great Lakes; to islands like those around the mouth of the Saint Lawrence or Vancouver's, or peninsulas like Nova Scotia, Florida and Lower California. It must be said, however, that there are strong physical differences between South America and Africa: the chief mountain ranges of the former being on the west, of the latter on the east; the African rivers are less copious, and mostly have cataracts above their mouths, proving recency of origin; [the river] basin to basin. Not withstanding some show of reason, that these structural resemblances are more than accidents, but scientists are far from agreeing as to the cause, and a discussion of the high-sprung theories that have been advanced to account for them would be out of place here.

A part from this, the structural characteristics of the northern and southern continents have striking similarities, largely nullified for human use by the difference in location already mentioned. Each is a slender triangle with the vertex toward the south. Each is joined to the next northern portion of the globe by a northwestern peninsula, the trend of the whole as far south as Bolivia being regularly southeast from Bering Strait, just as that of the Asiatic coast to the Philippines is southwest; so that the largest continental mountain chain is on the side of the largest ocean, there is a western range of immense height and mass, hundreds of miles broad and split into parallel sections sometimes connected by transverse spurs, stretching its entire length; quite recent in origin, and the volcanic action which raised it still energetic in parts. The Andes in South America thus correspond to the Rockies in North America; but the current idea that they form part of one continuous system is erroneous,—the Andes end in Venezuela, and the Rockies are of different genesis. Each continent has on the east a much shorter chain, much older and therefore much lower, from the erosion through geologic ages, and its volcanic fires long since extinguished. The Andes are worn down earliest, each is now rather a broad plateau with some elevations than a mountain wall. The Alleghany-Appalachian system in the United States corresponds to the Brazilian chain, which has no one distinctive title. Each continent has also a lateral range beginning in the north centre, turning first south and then east till it ends somewhat north of the eastern vertical chain, and cut in its course by the chief river running northeastward; and in each it is much the oldest part of the continent. The Laurentian chain in North America, crossed by the Sagueneay, is a trivial counterpart to the great lateral ranges of Venezuela and the Guianas, crossed by the mightier Orinoco.

Hydrography.—In each continent the two main ranges are connected by an almost uninterrupted plain many hundreds of miles broad, sloping southward to the ocean, and drained by three immense hydrographic systems with slight and somewhat constant running east and emptying just north of the eastern vertical range, the Great Lakes and the Saint Lawrence in the north corresponding in position to the oceanic Amazon in the south; the second running south and discharging a little south of the same range, which thus forms one side of a huge triangle of which the rivers form the other two—the Mississippi and Missouri in North America comparable to the Parana and Paraguay which form the La Plata in South America; a third running northeast and discharging northward—the Saskatchewan, with the Red River of the North and Lakes Winnipeg and Manitoba, corresponding to the Orinoco. Besides these, each has a river following the eastern side of a spur from the main range up to this northern ocean; the Mackenzie in the Arctic regions and the Magdalena in Colombia, though the former is the drainage of a great Arctic plain while the latter is confined between two ridges. With regard to the watersheds, those of North America lie within a few miles of each other in the headwaters of the Illinois in the Mississippi Basin lien within a half mile of the Chicago in
the Saint Lawrence system, and the two have now been connected; the Amazon and Plata systems are only three miles apart, and those of the Amazon and Orinoco are actually connected by the so-called River Cassiquiare, a deep-sea, wide natural channel about 150 miles long, running either way according to conditions of flooding seasons.

These, however, by no means exhaust the large drainage systems of North America, though in South America the closeness of the western chain to the ocean throws the whole burden on the east. The Pacific slope of the north is drained in the semi-Arctic regions by the immense Yukon, one of the great rivers of the globe. On the eastern side, the great mass of the Arctic moors sends its drainage through a network of small streams, and lakes like Great Bear, Great Slave and Athabasca lakes, by the Mackenzie to the northern ocean, the Great Fish River taking the east Arctic waters. Farther south the Pacific drainage is by the Fraser into Puget Sound, and by the Columbia into the Pacific. The smaller Sacramento drains central California. The Great Basin between two arms of the Rockies sends its scanty and precarious rainfall into the Gulf of California—the Colorado East of the range, the south the Rio Grande has a long course and forms the boundary between the United States and Mexico; but, despite its impressive name, is not of great volume. Between this and the Mississippi system several considerable streams drain the Texas region; the Colorado, Brazos, Sabine, etc. East of the Appalachian system a number of fair-sized and beautiful rivers flow to the Atlantic—the Saint John's, Penobscot and Kennebec, the Connecticut, Hudson, Delaware and Susquehanna, the Potomac, James, Cape Fear, Savannah, etc. In South America the large rivers of the eastern slope are the São Francisco and the Paraná of northern Brazil; but between this range and the Amazon system a great plain is drained by the huge Tocantins, which, though emptying only at the mouth of the Amazon, is really a part of its basin.

The drainage systems of America have no parallel on the globe. The Amazon discharges more water alone into the sea than all the large rivers of Asia together, and the Mississippi more than all the streams of Europe large and small. The navigable waters of the Saint Lawrence, Mississippi, Amazon, Orinoco and Plata systems together amount to over 100,000 miles in length. The five Great Lakes of America alone—excluding large bodies like Winnipeg, Manitoba, Champlain, Nicaragu, Titicaca, etc., and the polar lakes—make up an area of 89,000 square miles, or considerably more than England and Scotland together.

Another physical similarity between the two continents might be found in the relations of the Gulf of Mexico to the northern continent and the great Argentine plain to the southern; both lie in the same position with regard to the eastern chain of mountain chains, though the one is submerged.

But the differences are also great. The main drainage system of the central plain in North America is to the south, by the Missis- sippi; in South America it is to the east, by the Amazon; while the Great Lakes are a great drainage system for the surrounding regions, the melting snows of which supply them through deep rock fissures. They are hollows in the oldest rock elevation of the continent, with the ground sloping away from them in every direction; not far from fair shores; not a single considerable stream flows into them, nor even into the Saint Lawrence west of Montreal. The most vital difference structurally is due to the position of the western chain. In North America the chief height is on the eastern flank a thousand miles from the Pacific, the gradually lessening land reaching space for an empire along that ocean, and their drainage forming great rivers. In the southern continent it hugs the ocean so closely that not a stream of any size flows into the sea, and the cultivable area is but a petty strip on the coast. More than half the whole western side of South America is occupied by one state, some 1,500 miles long by 50 or 60 wide, which even so finds none too much territory with its slender width and partly barren soil. The northern continent has also an immense advantage in the character of the line: what with its archipelagoes, sounds and river-mouths in the north, and the sheltered indentations farther south, it is well fitted for commerce, while the whole South American coast has very few good harbors above Patagonia. The greatest differences in the civilized destiny of the two continents, however, are due to the northward massing of the land heretofore mentioned. All the United States and southern Canada lie in the temperate regions; the largest and most fertile part of South America lies in the tropics. The narrow southern part of North America lies in the warm semi-tropic ocean; that of South America in the south-polar sea. A quarter of all North America is a worthless polar waste, but perhaps as large a space of South America is an uninhabited and pestilential tropic jungle; and the improvements in food production and means of warmth which push back the reign of the one are perhaps balanced by the hygienic inventions and commercial uses tending to reclaim the other. Certainly the northern part has much more arable land and much less pernicious or energizing climate than the grassy steppes of the temperate southern plain of South America, but the prairies of the north, which correspond in position to the Amazonian forests in the south, are still more striking contrast. Commercially the north is equally favored in comparison. From the nearness of the continent to Europe relatively to Asia, and from the structure of the continent throwing the mass of population and production east of the great mountain chain, the chief commercial relations of America must always be with the northeast of the other continent. But North America is directly opposite Europe, the commercial head of the world; while South America's eastern neighbor is barbaric Africa, and most of its harbors are either along the misanthropic northern and northeastern coast, under the great cities, or the semi-polar shores of Patagonia.
For general works on American geography and topography consult the "New Universal Geography," translated by Keane and Ravenstein from Elisée Reclus' French work (1870-94); Dawson's "North America, Canada, and Newfoundland" (1897); Keane's "Central and South America" (1901); Shaler's "Nature and Man in America" (1891); Wright's "Ice Age in North America" (1889); Powell's "Physiographic Regions of the United States" in "National Geographic Monographs" (Vol. I, 1895).

**Physiographical Conditions.**—The great western chain of both continents, which would seem to be the chief formative base of both, is in fact very much the newest section in each case, though each is of independent origin, as shown by the energy of still remaining volcanic action in both; while the uplift of the eastern side has so long ceased that erosion has worn them down many thousands of feet, trenching immense valleys, and building up vast plains to the west by their detritus.

The Archean portion of North America, the first in order of appearance above the water, is the northeastern part: the elevation in which the Great Lakes and Hudson Bay are hollows, the Adirondack system of Canada, the Adirondacks of northern New York, and a southern tongue east of the Blue Ridge. The line of forces thenceforth acted steadily to the westward, the surface formations regularly growing more recent in that direction. This portion is not merely the oldest of the western continent, but among the oldest on the globe, the "New World" being new only from the standpoint of European history, not of geology or ethnology. This and the polar archipelagoes are composed of Pre-Cambrian or Paleozoic rocks of extreme antiquity. The highlands of Labrador and those extending north and west are mainly granite and other archaic rocks. To the west stretches the vast plateau called by Sues the "Canadian bucklers" and known to American geologists as the "Canadian Shield." By erosion this has been almost denuded of its upper Paleozoic strata, and the whole of Hudson Bay excavated to a slight depth on the surface of its eastern section. The eastern part of the Appalachian system is mostly mountain and older rocks; its western plateau and most of the Mississippi Valley are Carboniferous; while as we go westward we encounter in succession Cretaceous and Tertiary formations.

The Rocky Mountain system shows the greatest activity of volcanic forces at its ends, in Alaska and Mexico. In the old portions of the United States and Canada there are no active volcanoes; and the strength of eruptive force, greatest in the Aleutian Islands, steadily diminishes eastward and southward, occasional eruptions occurring on the southwestern coast, while Mount Wrangell is semi-eruptive only. Within the present boundaries of the United States, exclusive of Alaska, the only volcanic activity within historic times has been the eruption of Longs Peak, Colorado, in the years since 1914. In Mexico, Popocatapetl and others indicate the beginning of the equatorial belt of volcanic forces exhibited in Central America and the Antilles. But all the Cordilleran system is relatively of recent elevation, and many of the effects have taken place, exposing strata of every age as they were tilted up, creating some valleys and filling up others. In the region from California to Puget Sound the surface over many thousand square miles is lava, the valley of the Snake and Columbia having long been cut through lava beds, and fields of black scoriæ forming a peculiar feature in the northern Pacific States and Pacific Canada. To the south of the Appalachian system, along the Atlantic and the Gulf, the flooring is Cretaceous and Tertiary, therefore of recent uplift.

Modifying the erosive action on these primitive elevations there has operated a vast ice cap, the so-called Laurentian glacier, which at an uncertain but relatively recent period, ending probably from 50,000 to 100,000 years ago, covered all North America from the polar regions down to Philadelphia and the Ohio and as far west as the Missouri, leveling hills and hollows, creating soils, excavating lake beds, changing the courses of streams and the outlets of gigantic lakes, cutting out and blocking up hords and harbors, and depositing enormous masses of moraines. It should be noted, among other things, is due the creation of New York harbor and Niagara Falls, and the turning of the Great Lakes through the rocky Saint Lawrence valley instead of the Mohawk and Hudson. This ice cap has by no means wholly disappeared yet; the immense glaciers on the northwest coast and in the Rocky Mountain heights, some of them hundreds of square miles in extent, are remnants of the one great glacier of ancient times which still covers almost entirely the turtle-back conformation of Greenland.

In South America the eastern highlands are also of enormous antiquity, as shown by their archeic composition, with a sandstone cap not since submerged, their horizontal layers, deep erosions and detritus plains indicating no uplift since the earliest times. The Andes (q.v.) are quite recent, and full of volcanoes still or but recently active, but they are not all of a single age, however, and show successive uplifts. The plains between have Tertiary bases under their alluvial surface.

South America too has had its glacial periods, especially in the south-polar regions and producing the same effects as in its northern neighbor. The great heights of the Andes keeps them still existent up to and beyond the equator.

**The Cordilleran System.** The two great axial chains which form the western base of the double continent, though (as said) of independent origin, have strong similarities and a like relation to the remainder of the surface, and may conveniently be treated together. For their detailed relation and characteristics, see Andes and Rocky Mountains. It should be noted that these are not mere dividing walls, but vast formative elements of the continental masses, and themselves of continental volume. With their foothills and spurs they amount in South America to almost 14,000 square miles in area, and in North America to some 2,500,000, or toward a third of the entire surface. They include almost every possible character of soil and climate and natural product, and suitability for every employment,—agriculture, manufactures for heavy iron and cotton, mining of gold and silver, own, so that no inference can be drawn from that on one side to that on the other, and the
two may have the difference of five degrees of latitude or 5,000 miles of distance; one side may be a sponge, while the other a glacier, or the other a garden. They make the difference between Puget Sound and Labrador, and on the other hand between the Mexican plateau and the Nicaraguan plains, between Peru and Caracas. They enclose fertile provinces and deserts of rock and sand each large enough to be a continent, and to contain a good many lakes and rivers entirely their own.

As the development is better studied from the south, we shall begin with South America, whose cordilleras descend by steep short terraces to the seashore, or to a narrow belt of land immediately adjoining it, forming regular chains, display the loftiest masses of all the American cordilleras, and send out only short branches to the eastern plains; whereas the North American cordilleras, in the west, on elevated plateaus, so as to favor a large development of river valleys, are less vertical in their structure and less high and send to the east more extensive ramifications. The name of particular groups of the Andes is taken from the countries to which they are especially appertinent; thus, proceeding from south to north, we have the cordilleras of Chile, Bolivia, Peru, Ecuador, and Colombia. This, as a whole, is the highest mountain mass on the globe, and except the Himalayas has the highest peaks. Beginning among the rocky islands of the Fuegian archipelago, it runs through the Argentine plateau, the Cordilleras, with the exception of the Andes itself, as the name indicates, it takes the name of the block cordilleras, with summits of perhaps 8,000 feet; rises swiftly through Chile, growing at once higher and more multiplied, with summits of 12,000 to 18,000 feet, till it culminates in the stupendous Nevado de Aconcagua, from 23,000 to 24,000 feet high, the loftiest of the Andes, it may be called the Cordilleras, outside of the Andes itself. Beyond this it divides into two enormous parallel arms with a high plateau between, and lower ranges to the east in Argentina increasing its complexity. Thence to the Isthmus it is not a ridge, but a rock continent 500 or 1,000 miles wide, with a gradient of peaks from 10,000 to 21,000, and even 22,000 feet high, and the very “passes” over them 15,000 or 16,000 feet above the sea, terrific and nearly impassable gorges above the highest summits in Europe. South America, therefore, is a continent of mountain ranges, with two and even three immense tillable valleys on the same base. It attains its greatest breadth at about lat. 18° S., in central Bolivia, where it is some 300 miles wide, with three main ranges; and at this point, in the northern part of the province of Tacna, it and the corresponding coast curve northwest as far as 5°, its course in this direction being exactly coincident with the limits of Peru. On these plateaus was situated the empire of the Incas. Just northeast of the turn it holds the great Llanos, 800 miles in area, on a high plateau 12,645 feet above the sea, the surface of the lake itself being nearly 12,500 feet above sea-level. This part is called the Royal Cordillera, and contains several peaks above 20,000 feet. At the Gulf of Guayaquil it again turns, and follows the gradual trend eastward about 4° N., when it curves north and west to meet the Isthmus, forming a large but nameless gulf. Near the equator, in Ecuador, are a number of very lofty volcanic summits, the two highest and most famous of which are Chimborazo, 20,408 feet, and Cotopaxi, 19,613. The Cordillera of the Andes in Colombia it divides into three, two running north and the third extending well into Venezuela, the true end of the Andean system.

Central America is hardly a part of either great system. The Isthmus is a low plateau, succeeded by highlands rather than mountains in Costa Rica; then comes the depression nearly filled by Lake Nicaragua, where the elevation sinks to less than 100 feet above the sea. The mountains begin in northern Nicaragua and occupy the entire breadth of Honduras, Guatemala and Salvador from ocean to ocean, but they are not of great height and consist of several detached ranges with active or extinct volcanic peaks. These sink to a broad plain at the Isthmus of Tehuantepec, forming the dividing line between the mass of North American and South American organic species; though geographically the central plateaus are a northern tongue thrust into two lines of tropic territory along the Gulf and Pacific coast.

The Rocky Mountain system, or northern Cordillera, begins with the ranges on which the City of Mexico is situated, the seat of the original culture overthrown by Cortes. It is from 4,000 to 7,000 feet high, and is flanked by mountain ranges and isolated volcanic peaks, active or quiescent, the highest summits in Mexico. Orizaba, the loftiest, is 18,250 feet high; but the most remarkable and imposing is Popocatepetl, rising 17,520 feet from the floor of the valley, the highest peak of the world in practical isolation, whose height visible from sea-level. At this point the main ridge of the Rocky Mountains (the American section is known also as the Sierra Madre, which properly is the name of the northeastern spur) suddenly turns far eastward from the Pacific, and for the remaining 3,500 miles of its course keeps hundreds of miles from it, so that the broad western slope is drained by very large rivers, as the Columbia and Fraser, and in the extreme north the mighty Yukon. But it throws out lesser arms to the west nearly to the ocean. Between the main range and the great Sierra Nevada arm is enclosed the desert Great Basin of Utah and Nevada and northern Arizona and New Mexico: a waste of alkaline earth and naked rocks, of river courses dry except in the infrequent rains, and roaring torrents then for a few hours or minutes; of the great canyons, gorges cut sometimes a mile deep into the solid rock by the swift sand-laden currents. It is drained to the Gulf of California by the only real stream of water of any size in the whole region, the Colorado. The Sierra Nevada has for its crowning summit Mount Whitney, in California, 14,498 feet high. Still farther north it throws west the Coast Range, running through California, Oregon and Washington up to Puget Sound. The Sierra Nevada is continued, both Structurally and through more recent independent volcanic action, by the Cascade Range of Oregon, Washington and British Columbia, with Mount Shasta, 14,150 feet, in the south, and Mount Rainier or Tacoma, 14,526 feet, in Washington. Puget Sound is a submerged trough and the Valley of California a lowland lying between the Coast ranges and
the Sierra Nevada–Cascade ranges. The system as a whole, across from California and Oregon to Colorado and Wyoming, is 1,000 miles wide, with a number of north-and-south ranges rising from a plateau from 5,000 to 10,000 feet high, and a large number of peaks between 14,000 and 15,000 feet high. The main range in Colorado has for its chief divisions the Front, Sangre de Cristo, Park, Saguache and San Juan ranges; Long's and Pike's Peaks, Blanca Peak, Mounts Lincoln and Harvard and Uncompahgre Peak are the best known of the summits.

The system follows the coast around nearly to Asia, rising in peaks all along the Aleutian Islands, the chief being the noble Shishaldin, 8,000 feet high; and north of Yakutat Bay, a great landmark, where the coast turns west and the greatest glaciers begin, the place where the temperate zone properly gives place to the semi-Arctic — a branch continues straight on, runs far north to the Yukon watershed, then turns west again and rejoins the other in southwest Alaska. In the course of the latter it throws up mighty peaks, the monarachs of the northern continent, including Mount Saint Elias, 18,024 feet, and Mount Wrangell, a great isolated semi-active volcano, 17,524 feet; the altitude rising as it goes west, it culminates in the Piedmont McKinley, 20,464 feet, the highest elevation in North America.

The Eastern Mountains and the Plains.—In North America the backbone and nucleus of the continent is locally known as the Allegheny system, in the northern half of the United States as the Appalachian in the southern; but for scientific purposes the latter name is commonly extended to the whole. It extends from Gaspe peninsula, between the lower Saint Lawrence and Chaleur Bay, below Quebec, through the United States, to northern Alabama and north Georgia, where the mountains sink down to the great coastal plain which girdles the United States from 50 to 100 miles back from the shore. Between the mountain and plain is a foothill region usually known as the Pleistocene region. The mountains are a plateau from 50 to 200 miles wide and averaging 1,500 to 3,000 feet high, but with peaks rising to 6,294 feet in Mount Washington (New Hampshire) and 6,707 feet in Mount Mitchell (North Carolina). The range has many local names for the different divisions, as the White and Green, the Adirondacks, the Taconic, Hoosac and Catskill, the Alleghany, the Blue Ridge and South Mountain, the Black and Smoky, etc.

On the west they slope through rolling uplands to the most peculiar feature of the North American surface, entirely unlike any other part of the globe, the prairies (called savannahs in English books, but never in American speech): a block of undulating plains of enormous extent in the centre of the Mississippi basin, composed mainly of dark rich loam from a seafloor several feet deep over a bottom of clay, and of such composition that natural tree-growth is largely absent even where rainfall is plentiful, though grass and other crops grow abundantly. Often this will be as level as a floor for several miles, and there are no trees to interrupt the grassy ocean. On the west of this extend to the Rockies lands often as flat as the prairies, but lacking their individual trait and called plains instead. The same features are repeated in northwest Canada from Manitoba to the Rockies. Locally they are known as the "Great Plains." 

In South America the eastern chain is similarly formed of several parallel ranges following the Brazilian coast, on a wide plateau, a reduced copy of it running through the Guianas. The whole centre is an immense plain sloping sharply up to the Andes; but in place of the vast treeless flats of the northern continent there is the most enormous forest of the world, two and a half millions of square miles in extent. North of this, however, are considerable plains along the Orinoco called llanos. Below the range the country is a great grassy steppe, rather ill-watered, called pampas, and extending through Argentina and Patagonia.

Geology and Mineral Resources.—North America.—The North American continent may rather easily be divided into a few great geological units, the general features of which are simply and briefly stated below. These divisions may be termed the Canadian Shield, the Coastal Plain, the Eastern Highland, the Central Lowland and the Western Highland.

Canadian Shield.—The nucleus of the continent consists of a great U-shaped area enclosing Hudson Bay, and extending in the Lake Superior region southward a short distance into the United States. It also sends a long arm southward into the Piedmont region, along the east border of the Appalachian Highland. This large area consists almost wholly of highly folded Pre-Cambrian (q.v.) (Archean (q.v.) and Algolian (q.v.)) rocks, granites, schists, quartzites, marbles, etc., of great age; and it was by the erosion of this mass, largely, that the sediments were derived to build up the other portions of our continent. Particularly in Canada, this area contains extremely valuable deposits of gold (Porcupine District), silver and cobalt (Cobalt District), and copper, and nickel (Ludbury District). In Michigan it also contains foreign metallic copper, and in Michigan, Wisconsin and Minnesota are great iron ranges, among which the Marquette and Mesaba are the best known. The eastern part of this large region is known as the Laurentian Highland. The area as a whole is not mountainous, but consists of a rather low, dissected peneplain (q.v.), the average elevation of which is about 1,000 to 1,500 feet. It has been glaciated in comparatively recent times, and contains vast areas of swamps and thousands of lakes. Geologically the region is known as the "Canadian," or "Pre-Cambrian Shield."

Coastal Plain.—On the eastern and southern sides of North America, from the vicinity of New York southward, is a low flat plain which sweeps around the southern Appalachian Mountains, and from the Gulf of Mexico merges gradually northward into the great interior plain. It is known as the Coastal Plain. Geologically it is extremely young, consisting wholly of Cretaceous (q.v.) and Tertiary (q.v.) rocks, mostly soft, unconsolidated sands and the eye-swell, or flats. At a time geologically recent, this area was under the sea, and these beds were laid down as a result of the erosion of older parts of the continent. The region is so new
and so low that it has undergone little erosion, and is consequently very flat and monotonous in some portions of it are rich agriculturally, where the soil is not too sandy. Owing to the unconsolidated condition of the rocks, building stone is less abundant than elsewhere. Aside from petroleum products and salt, both of which occur in quantity in the Louisiana and Texas portions of the area, the Coastal Plain is singularly poor in mineral wealth.

**Eastern Highland.**—This highland, extending from New England southwest to Alabama, has a base of Pre-Cambrian rocks, among which granites, gneisses and schists are dominant. Upon these rests an intensely folded complex of shales, limestones and sandstones, embracing rocks belonging to every period of the Paleozoic Era. Throughout the Paleozoic, this area was almost continuously beneath the sea, finally emerging at the close of the Era, when it was folded into a mountain region. Erosion has one or more times almost completely leveled away the range, and still further uplifts without folding have allowed the streams to cut away the soft layers of rock, leaving the upturned edges of the harder layers as the parallel mountain ridges of typical Appalachian topography. To the west this folded region grades into a high plateau of flat-lying rocks chiefly of Carboniferous Age, known as the Allegheny (north) and Cumberland (south) plateaus. The chief mineral wealth of the region lies in its coal, of which the rich fields of Pennsylvania anthracite is the most famous field. Slate, marble and granite are especially important products in the New England portion. The intensely folded area yields little oil and gas, but the plateau to the west contains the important Appalachian petroleum field.

**Great Central Lowland.**—With the exception of a few minor uplifts, such as the Ochientas, the Ozarks, the Black Hills, and others of lesser note, this region is a vast interior region, lying south of the Canadian Shield, and enclosed between the Eastern and Western highlands, sending a narrow arm to the Arctic between the Western Highland and the Canadian Shield. The area is one of flat-lying rocks. East of the Missouri River, these are almost wholly Paleozoic, the Carboniferous being the most widespread surface formations. From the Missouri River westward, Cretaceous and Tertiary rocks constitute most of the surface. It was during late Carboniferous times that most of this area permanently became land, although its western portion was again temporarily under the sea during the Cretaceous period. Topographically the region varies from almost dead level plains to sharp hilly regions, ranging from a few hundred to 5,000 feet above sea-level. The northern part has been glaciated and swamps and lakes are abundant. As a whole the region comprises the great agricultural portion of the continent. It is the richest in coal and petroleum of any portion of the country. It has very valuable lead and zinc deposits, beds of salt, quartz and hard stone and other minerals of lesser value.

**Western Highland.**—This portion of the continent is more complicated in structure and history than the areas thus far considered. It may be said to consist of a great range of mountains, the Rockies proper, on the east, to the west of which lies a broad plateau region, and beyond this the Pacific border ranges, themselves complex in structure and history. These sections will be taken up each in a separate brief discussion.

The Rocky Mountains, contrary to rather hazy prevalent conceptions, lie nearly a thousand sand miles from the Pacific Ocean, at least in the United States. They contain rocks of every age from Pre-Cambrian to Quaternary folded into ranges, rather generally trending north and south. Their final emergence from beneath the sea, and the folding which gave them their present structure, came at the close of the Cretaceous period. During the Tertiary they were the site of much igneous activity, and since their folding they have been greatly modified by powerful erosion, several minor uplifts and very recently by glaciation. Unlike the Appalachian region, there is a strong range of the numerous ranges, in which the rocks are flat-lying, or nearly so.

The Inter-Mountain plateau, while it contains some areas of intense folding, is more largely one of nearly flat-lying rocks, greatly modified by faulting. The rocks are of all ages from Pre-Cambrian to Tertiary.

The southern and higher portion of this large region is generally known as the Colorado plateau. Paleozoic rocks are exposed at a few points, but the surface formations are largely Jurassic and Cretaceous in age. The rocks are nearly flat, as a whole, and the structural complex is dominated by a few very large faults. Above the plateau surface, which average 5,000–7,000 feet in height, rise several groups of volcanic mountains, among which the San Francisco Peaks and the Henry Mountains are best known. The area is deeply trenched by magnificent canons, among which the Grand Canon is easily the foremost.

To the north and west of the Colorado plateau is that portion of the Inter-Mountain plateau most commonly called the Great Basin. This region stands notably lower than the Colorado plateau and is much more intensely faulted. Paleozoic formations and Tertiary lavas and lake beds are widespread surface rocks. The general floor of this region ranges from a few hundred to 5,000 feet above sea-level, and above this are many north and south mountain ranges carved out of fault blocks. Between these ranges are extremely flat desert floors, some of them beds of extinct salt lakes.

Still farther north this complicated basin structure has been buried beneath thousands of feet of Tertiary lava, forming the great Columbia Lava plateau, many thousands of square miles in extent. This has more recently been trenched by the Snake and Columbia rivers, which have cut canions from 2,000 to 4,000 feet in depth.

The Pacific Border ranges are made up of the Sierra Nevadas and Cascades on the east, and the Coast ranges on the west, with the Valley of California, the Willamette Valley and Puget Sound as lowlands separating the two systems.

The Sierra Nevada Range consists largely of Triassic and Jurassic slates, cut by great masses of granite. The range was folded near the close of the Jurassic period, since which time it has been modified by subsequent uplifts,
faulting, and very extensive erosion, with recent glaciation. To the north it passes with somewhat similar structure, under great piles of lava and tuffs on the western side of the basins of that range, dating from Tertiary time.

The Coast ranges consist of intensely folded and faulted rocks varying in age, but probably dominantly Tertiary. Their structural history has been extremely complex. One intense period of folding came near the middle of the Miocene. There have been later uplifts, accompanied by some folding and much faulting the latter process going on even to the present time, as witnessed by the great fault responsible for the San Francisco earthquake.

The Western Highland Region, as a whole, has been one of intense igneous activity dating at least from the Jurassic, and perhaps earlier time, to the recent activity of Lassen's Peak, in California since 1894. This igneous activity is probably the one fact most largely responsible for the great metallic wealth of the region: gold, silver, copper, lead, zinc and many other minerals occurring in very rich deposits in many widely separated localities. Coal of Cretaceous age is also relatively common; of importance economic coal production, and petroleum occurs in enormous quantities in California, and in lesser amounts in other localities.

**South America.**—The mineral belt of South America centres upon the great continental backbone of the Andes, following along the entire western coast. Other small areas add their tribute, notably the coastal uplift of southeastern Brazil, known as the great Brazilian Plateau. The territory available for profitable exploration and development is, broadly speaking, boundless. Somewhere within the region may be found every mineral having commercial value, scattered far and wide from the mother lodes by the workings of glaciers and other erosive agencies, for South America exceeds any other part of the world in the abundance of its mineral wealth. After the advent of the Spaniards in the 16th century, Bolivia rivalled Mexico in the billions of dollars of silver taken from its mines, while a few of its mines yielded billions of dollars of gold. Millions of dollars of gold were also extracted from the soil of Peru, Colombia, Brazil and the Guianas. At the present day, with her treasures practically untouched, South America holds several world records in the mineral market. The entire supply of the world's bismuth comes from Bolivia; by far the largest supply of thorium is furnished by the monazite sands of Brazil; the unparalled lead salt deposits of Chile supply practically all of the world's consumption of nitric acid, and practically all of its consumption of iodine. Colombia is the only considerable source of platinum outside of Russia; the tin production of Bolivia stands second on the world's tally sheets; Colombia supplies the world's demands for tin; emeralds; Brazil is second only to South Africa in the production of diamonds, and for many years was first; the asphalt lakes of Trinidad and Bermudez supply the world. Coal exists in large quantities all through the Andes region. In many localities wide seams are exposed to view for long distances along the slopes and in the sides of ravines, millions upon millions of tons being in sight. Some of these coal veins come down almost to tide water—as at Paracas and near Trujillo, Peru. Good coal is found also along the coast of Ecuador; in southern Chile coal is mined extensively at Lota and Coihueco, and there are coal mines running out under the sea for more than half a mile; deposits also exist in the Aconcagua region near Rio Blanco. In Colombia coal exists in many widely separated localities; good bituminous coal in the interior and lignite beds near the coast; in Venezuela there is coal of fair quality. Indifferent development of this primal commodity, however, is the cause of the retardation from which the mineral industries of South America suffer. The only considerable active oil production in South America is in the Lobitos fields of Peru. In Bolivia, however, there is an immense oil belt 150 miles long, which continues over the national boundary into Argentina to Comodoro Rivadavia. At Santander, Colombia, there is an oil area 100 miles in length and 60 miles in width, and petroleum has been found in the upper Magdalena district. A large field also exists in Venezuela near the city of Maracaibo.

Iron exists in enormous quantities and of unrivalled quality throughout all of South America, awaiting development. In the Brazilian plateau are billions of tons of ore, carrying up to 50 per cent of the metal, but coal and transportation are lacking for its successful utilization. Great iron deposits, notably at Tofo, are found in Chile. Other important deposits also exist in Colombia and Peru. Four-fifths of the world's supply of vanadium is produced by a single mine in Peru, to the extent of 3,000 tons annually. Bolivia, Argentina and Brazil furnish about one-tenth of the total production of tungsten, while the great sulphur mine at Tinguiririca, Chile, holds another record as containing the richest sulphur deposits known.

**Climatic Conditions.**—In a continent practically spanning the entire space from pole to pole, every variety of climate may be inferred; and with elevation from sea-level to everlasting ice even in the tropics, each latitude is sure to contain as endless varieties in its...
the same climatic belts. China corresponds fairly to the United States, and Peking has a climate not unlike Boston. But if we compare eastern North America with Europe, and to a less extent South America with the East, the leading traits of its great cold zone from just below Great Bear Lake; Petrograd and Christiania are on a level with the southern tip of Greenland. Sitka has much the same parallel as Aberdeen; Copenhagen and Moscow, Glasgow and Edinburgh, correspond with central Labrador, north of the 60th parallel in northern Europe. Great Bear Lake and a little distance north of Lake Winnipe: All the British Isles, all the Netherlands and the greater part of Germany, are north of the city of Winnipeg, which itself is about on the parallel of Paris; Saint Paul and Ottawa correspond to Bordeaux, Turin and Bucharest, centres of wine and roses; Boston and Chicago to Rome, New York to Naples; Philadelphia is south of Madrid and Constantinople; Washington corresponds to Lisbon and Corfu, Saint Lottis to Astrakhan. The third parallel is a line between New Orleans and the Isthmus of Suez; the twentieth passes through the heart of Mexico, also just below Calcutta and Mecca, and through the Sudan and Sahara; the tenth through Cairo, also through Arabia and just above Ceylon. The nineteenth touches Quito and the mouth of the Amazon, and also divides Sumatra and Borneo and Lake Victoria Nyanza; the Amazon and the Kongo traversing about the same zones. Even allowing for the elevation of the Mexican plateau, the temperature of India and of the deserts of Arabia and Africa cannot be paralleled even on our tropical coasts. The difference is due to environsing conditions and internal structure combined. Above the European mass is a partially thawed sea; above that limit in America lie many hundred miles of ice-clad land masses, while to the northeast is the continental mass of ice-capped Greenland, piercing deep into the eastern side the polar inlet of Hudson Bay. But a partial cause is the mountain framework which in this region is more arid and in America north and south. In the latter, therefore, what is practically one long plain stretches from the Arctic Ocean to the Gulf of Mexico, the polar winds finding no obstruction as they do in Europe. America is not a great spot in North America east of the Rockies absolutely secure from intense frosts; and there are no definite north-and-south climatic belts, the only sharp divisions being those east and west of the Rockies. In Europe and west Asia, on the contrary, where the mountains cut off the polar winds, the climate will often vary from north-temperate to semi-tropical within a score of miles. This isolation of different parts, giving the most varied lives and habitats time to grow into deep-set racial distinctions, has produced by their varied strains and interaction the splendid civilization of the Western world; while the two great plains which fill the centre of each continent, linked by a fertile and temperate plateau, in itself the most temperate of all, gave no opportunity for differentiation, and the undiversified monotony of a single racial stock and culture was one of the influences which kept progress at a spot reached by European races thousands of years before.

Rainfall and Natural Sections.—The habitability of a land outside of Arctic regions depends first upon its water supply and secondly upon its disposition. The prevailing winds which supply the rainfall of all countries by the ocean vapors they carry mostly from east and west, the easterly called specifically "trades," the westerly "anti-trades." The eastern continent has its greatest length in this direction and a great mountain wall on the east; hence much of central Asia lying beyond the reach of vapors remains a permanent desert. America, from its narrowness and its sides being faced by these winds, is much more favored. The Great Lakes add to the rainfall in their region; the Gulf of Mexico, as will be demonstrated, turns the whole east centre from a potential desert to a garden; and the only entire deserts are between two arms of the western range in the northern part and some portion of the strip along the western coast of the southern.

In the polar regions the cold and physical conformation make the water supply of little avail. Northern Alaska and northern Canada are flat, spongy moors, and that of New Orleans and the Isthmus of Suez; the twentieth passes through the heart of Mexico, also just below Calcutta and Mecca, and through the Sudan and Sahara; the tenth through Cairo, also through Arabia and just above Ceylon. The nineteenth touches Quito and the mouth of the Amazon, and also divides Sumatra and Borneo and Lake Victoria Nyanza; the Amazon and the Kongo traversing about the same zones. Even allowing for the elevation of the Mexican plateau, the temperature of India and of the deserts of Arabia and Africa cannot be paralleled even on our tropical coasts. The difference is due to environsing conditions and internal structure combined. Above the European mass is a partially thawed sea; above that limit in America lie many hundred miles of ice-clad land masses, while to the northeast is the continental mass of ice-capped Greenland, piercing deep into the eastern side the polar inlet of Hudson Bay. But a partial cause is the mountain framework which in this region is more arid and in America north and south. In the latter, therefore, what is practically one long plain stretches from the Arctic Ocean to the Gulf of Mexico, the polar winds finding no obstruction as they do in Europe. America is not a great spot in North America east of the Rockies absolutely secure from intense frosts; and there are no definite north-and-south climatic belts, the only sharp divisions being those east and west of the Rockies. In Europe and west Asia, on the contrary, where the mountains cut off the polar winds, the climate will often vary from north-temperate to semi-tropical within a score of miles. This isolation of different parts, giving the most varied lives and habitats time to grow into deep-set racial distinctions, has produced by their varied strains and interaction the splendid civilization of the Western world; while the two great plains which fill the centre of each continent, linked by a fertile and temperate plateau, in itself the most temperate of all, gave no opportunity for differentiation, and the undiversified monotony of a single racial stock and culture was one of the influences which kept progress at a spot reached by European races thousands of years before.

Rainfall and Natural Sections.—The habitability of a land outside of Arctic regions

depends first upon its water supply and secondly upon its disposition. The prevailing winds which supply the rainfall of all countries by the ocean vapors they carry blow mainly east and west, the easterly called specifically "trades," the westerly "anti-trades." The eastern continent has its greatest length in this direction and a great mountain wall on the east; hence much of central Asia lying beyond the reach of vapors remains a permanent desert. America, from its narrowness and its sides being faced by these winds, is much more favored. The Great Lakes add to the rainfall in their region; the Gulf of Mexico, as will be demonstrated, turns the whole east center from a potential desert to a garden; and the only entire deserts are between two arms of the western range in the northern part and some portion of the strip along the western coast of the southern.

In the polar regions the cold and physical conformation make the water supply of little avail. Northern Alaska and northern Canada are flat, spongy moors, and that of New Orleans and the Isthmus of Suez; the twentieth passes through the heart of Mexico, also just below Calcutta and Mecca, and through the Sudan and Sahara; the tenth through Cairo, also through Arabia and just above Ceylon. The nineteenth touches Quito and the mouth of the Amazon, and also divides Sumatra and Borneo and Lake Victoria Nyanza; the Amazon and the Kongo traversing about the same zones. Even allowing for the elevation of the Mexican plateau, the temperature of India and of the deserts of Arabia and Africa cannot be paralleled even on our tropical coasts. The difference is due to environsing conditions and internal structure combined. Above the European mass is a partially thawed sea; above that limit in America lie many hundred miles of ice-clad land masses, while to the northeast is the continental mass of ice-capped Greenland, piercing deep into the eastern side the polar inlet of Hudson Bay. But a partial cause is the mountain framework which in this region is more arid and in America north and south. In the latter, therefore, what is practically one long plain stretches from the Arctic Ocean to the Gulf of Mexico, the polar winds finding no obstruction as they do in Europe. America is not a great spot in North America east of the Rockies absolutely secure from intense frosts; and there are no definite north-and-south climatic belts, the only sharp divisions being those east and west of the Rockies. In Europe and west Asia, on the contrary, where the mountains cut off the polar winds, the climate will often vary from north-temperate to semi-tropical within a score of miles. This isolation of different parts, giving the most varied lives and habitats time to grow into deep-set racial distinctions, has produced by their varied strains and interaction the splendid civilization of the Western world; while the two great plains which fill the center of each continent, linked by a fertile and temperate plateau, in itself the most temperate of all, gave no opportunity for differentiation, and the undiversified monotony of a single racial stock and culture was one of the influences which kept progress at a spot reached by European races thousands of years before. From about lat. 52° N. to perhaps 44° in the interior and east, the climate, though not quite fatal to civilized energies, is very severe, with winters of seven or eight months and summers at best short and not always calculable, though rising to 100° and over in waves; with sudden intense "northerns" and "blizzards" of intense cold with fine dry snow sometimes paralyzing business activities for days. The dry atmosphere, however, makes it less trying than the damper though somewhat warmer eastern weather; it has developed great cities and popu-
lous States in the United States and flourishing communities in Canada above 50°; and the industrial and intellectual future of the region is as promising as that of any part of the continent. There is not much difference between the central and eastern parts in this respect, Duluth and Quebec, Saint Paul and Ottawa, corresponding closely in parallels and nearly in climate. Northwestern Canada and the northern central States of the United States form the great north-west section of North America; and this on both sides of the Rockies is the chief timber section. South of this is the great temperate section, shading into the semi-tropic by imperceptible degrees, but which in the United States may be roughly divided by the basin of the Ohio. The northern portion has summers and winters of the same general character as the former, but less intense at either extreme, neither hot waves nor cold waves usually lasting long; the weather damper than in the farther north. It is the chief region of Indian corn and apples, hay and potatoes, etc. The southern half shows the beginnings of tropical elements in the seasons, which are not so much winter and summer as wet and dry; in the luxuriance of vegetation and characteristically tropical varieties; in the less bracing atmosphere and in the bottom lands its languorous oppressiveness; in the domestic architecture, where the obvious desire is to escape heat rather than to ward off cold; and in the productions, such as cotton and tobacco, rice and sugar, sweet potatoes, and oranges in the far south.

The Pacific slope, however, is an exception to this, its climate resembling the western coast of Europe much more than the eastern of its own. All the isothermal lines curve sharply northward west of the mountains. From Puget Sound to San Francisco there is no extreme range of climate, no such division into quasi-Arctic and quasi-tropic as on the eastern slope; though the northern part from its heavy rains is the greatest timber region of the continent north, and the southern a great country of vineyards, almond orchards and other south-temperate products. California reaches from about the parallel of Boston to that of north Georgia and Mississippi, but has neither the raw, harsh New England climate nor the heavy southern atmosphere, and southern California is a noted warm sanatorium. The high arid plateau of north Mexico experiences extreme alternations of temperature, from 95° to 40°; but on the coasts and below the great Anahuac table-land the region becomes semi-tropic. Sugar-cane, cotton and coffee now ascend to the lower mountain regions, and in their place, at sea level, appear pineapples, bananas, etc. Central America from its narrowness and low elevation has an island climate, tropical and pestilential on the shores and along the streams, moderate and healthful on the higher ground in the interior. This and the Antilles are the region of sugar, indigo, cochineal, ginger, vanilla, capsicum, etc. South America, lying on both sides of the equator, has in the central and eastern parts a much less range of climate than North America, the greatest in a single section being found in Argentina, where the range in the year on the whole continent the mean annual temperature ranges from 80° to 40°, the midwinter (our midsummer) from 80° to 35°, and the midsummer from 85° to 50°; north Argentina, the Cordillera section, having, as before, the greatest alternations. The southern west Andean slopes are equalized by the west winds from the ocean; the northern parts are a tropic desert; but on the different levels of the range are found every climate of the earth from tropic to arctic. The tropic productions and characteristics south of the equator, except as deflected by local conditions, are much like those north and west. The southern limit of the periodical rains reaches as far as lat. 40° S. has a mean temperature of 71° in the warmest and 53° in the coldest month. There the palm still thrives on the lower basin of the La Plata beside the mulberry and indigo; the pampas and the west coasts of Chile are characterized by beautiful araucarias (the pine of the southern hemisphere), by beeches and oaks, the potato and the arrowroot. The plants in cultivation are a curious blending of the vegetation of the northern and southern United States: wines, olives, oranges, hemp, flax, tobacco, wheat, Indian corn and barley. The southern limit of the periodical rains reaches as far as lat. 48° S., when the mean temperature of 59° in the warmest and 39° in the coldest month still favors the growth of cereals, and on sheltered spots of the west coast the growth even of the vine and the finer fruits. Reaching to the southern extremity of America shows comparatively little difference between the warmest and coldest month, the mean temperature of the one being 41° and of the other 35°; but the low degree of summer warmth produces a marked change in the form of vegetation which now presents only a few trees, as the beech and birch, and an extraordinary abundance of mosses and ferns. As in passing from the equator to the pole the region of the vegetable world gradually declines, so in climbing from the tropical shores to the ice-covered mountain summits three different climates have been distinguished by the names of tierra caliente, templada and fria (hot, temperate, frigid). Of these the templada extends over the healthiest and healthiest regions where a kind of perpetual spring prevails, and the forests and pastures and noble forest trees are found united with the fantastical and gigantic forms of the tropics.

The question of rainfall is difficult to group systematically with that of climate. The mass of the northern continent is in the region of the anti-trades or prevailing westerly winds. The Japanese Black Current, the Gulf Stream of the Pacific, running northeast and striking the polar currents and the cold shores, ice-bound for many hundreds of miles, sends up a great steam of fog which is blown against the wall of the Rockies and sent back by them upon their western slope in a rainfall from 50 inches up to 100 or even more, that makes the northern coast from southern Alaska to northern California one great forest of fire and smoke and rain. The rainfall on Puget Sound is from 75 to over 100 inches in winter and the annual average on the Pacific coast of Alaska is 90 inches. In the southern part, along southern and Lower California, the Cordillera section above the Gulf and west Mexico, even in the Isthmus, the land is too warm to cool and precipitate the vapors to the same extent; and such precipitation as there is takes place mostly on the
crests of the coast ranges, the Cordilleran region being mostly semi-desert or wholly so. In the summer the coast ranges are too warm to retain all the moisture of the vapors, which therefore give a little at these seasons, 10 to 20 inches in all, to the interior regions.

The Mississippi Valley is saved from becoming the most tremendous desert on earth, a second Sahara, by the Gulf of Mexico and the western wall combined. It had to rely on the Pacific winds it would be utterly rainless; but the winds in the Gulf region set up whirls of cyclonic disturbance which make an easterly eddy, carrying saturated currents in that direction; and these, striking against the Rockies, are turned northeastward through the central and eastern valley, giving it abundant water. This eastward set, however, leaves the western valley only the edge of its course; the far western, as in western Kansas and Nebraska, being rainless for considerable periods and scantily supplied at best. The rainfall ranges from 60 inches on the coast to 30 around the Great Lakes. The same cyclonic movement makes the same easterly eddy in the Atlantic, and the Atlantic coast receives its 40 to 50 inches a year from that source.

Central America is in the region of the trades or easterly winds and is so narrow that its climate is that of a semi-tropical island. In this region the rainfall is enormous, creating heavy tropical vegetation and increasing to 200 inches at Panama and the northwestern shores of South America, short rivers like the Atrato carrying almost a continental volume of water. All tropical South America is within the trade-wind belt, its moist warm climate creating the enormous forests of the Amazon basin, the oceanic volume of that river (rather a huge set of parallel drainage channels in one vast swamp) and the forests of the western coast. The forest on the eastern slope of the Andes is almost a rain-swollen forest.

Taking the continent as a whole, the rainy season is disproportionately extended in America; and as it stretches over all the zones, the vegetation is remarkably diversified, from the lowly moss of the north to the lofty banana of the tropics. The giant chain of the Andes everywhere rises above the snow-line. From the sterile Peruvian coast, burned by tropical heats, one can look up to summits covered with perpetual snow and ice; and one may climb from the gigantic equatorial vegetation of Quito to heights where only the condor testifies to the existence of organic life as he wings his flight over snow-fields and glaciers. In Peru the culture of cereals is carried on at the height of 12,000, and near Quito at 9,000 feet.

The north and south of America have the same length of day; but in the seasons which depend not merely on astronomical but on a variety of local causes, the analogy does not hold and very remarkable discrepancies appear. Thus, for example, the east coast of Brazil has the rainy season from March to September, while Peru, lying under the very same latitude, has it from November to March. Within the tropics the transition from the rainy to the dry season takes place almost instantaneously; but in receding from the tropics on either side the change of seasons becomes more and more gradual till at last, in the polar zones, nature, bound in icy chains, affords for living existence only a short awakening out of a long winter sleep.

Consult publications of the United States Weather Bureau, the Canadian Meteorological Office and the Mexican Weather Service; Greely's 'American Weather' (1888).

Flora.—The sections of cultivation have been dealt with already, and we shall consider here only the indigeneous features. From north to south the general succession is as follows:

The surface-thawed Arctic tundra bears only reindeer-moss, blossoming weeds in its brief hot summer, and dwarf willows. From about the Arctic Circle to the southern coast of Alaska, James Bay and the North Sackatchewan, we find shrubby plants, most of them yielding berries; then the universal wood-of-all-work, the famed ‗Alaska spruce,' with clumps of birch and alder: these at first sparsely, then forest, of tamarack, spruces, pine, hemlock and fir. This coniferous growth extends in enormous volume down the cool, wet Pacific slope to central California; the giant redwoods and sugar-pines, etc., and the huge sequoia, the largest and oldest plant on the earth, being famous everywhere. Eastern Canada is forested with similar coniferous species; so is the United States through Michigan, Wisconsin and west to Minnesota, to southern Missouri and northwestern Arkansas, and to northeastern Texas and the Indian Territory. The central United States has predominant deciduous (hardwood) trees, such as the oak of many varieties, the beech, maple, elm, chestnut, black walnut, hickory, ironwood, pepperage, red mulberry, etc. In the southern States the yellow pines form the forest place. The characteristic forms of the Southern States are the magnolia, palmetto, tulip-tree, plant-tree, pecan, etc., with the cypress everywhere in the swamps. The Cordilleran woods are chiefly conifers on the mountains; on the plains and in the valleys are the yucca, cactus, etc.—whom dense, thorny growth is termed chaparral. The wild picturesqueness and even grotesqueness of the cactus forms is noted; and it furnishes food for animals that would otherwise starve on the arid steppes. The north Mexican plateau has little wood except on the mountains. Southern vegetation blends with the tropical forms, and in Central America and the Antilles the most valuable trees are the mahogany and boxwood, and of vegetable products vanilla and gilva, etc.
the place of forests. The vast selvas or swamp forests of the Amazon occupy the heart of the continent. These colossal tropic jungles, often formed into an almost impenetrable web by multitudes of creeping and climbing plants, contain an almost unexploited variety of magnificent trees with the most beautiful ornamental woods.—as rosewood, cocabola, etc.—products like india-rubber, brazilwood for dyeing, cinchona for medicine, etc. Dense forests of cedar overshadow the mountain terraces in the lower parts of Quito. South of the selvas are the forests of Matto Grosso, the great Brazilian province east of Bolivia; south of this again, and of the Bolivian Cordillera, is the Gran Chaco, or "great round-up," from the Paraguay to the Andes,—a region of three to five hundred thousand square miles, largely plains, but with heavy forests including the wax-palm, and with tree-like thistles on the lower plains. Now begin the pampas of the lower La Plata, which are fine grassy plains in the northern part, but in southern Argentina and Patagonia become semi-arid steppes. The western strip has already been dealt with.

Consult Gray's 'Synoptical Flora of North America' (1866–97); Heller's 'Catalogue of North American Plants North of Mexico' (1891); Britton and Brown's 'Illustrated Flora of the Northern United States, Canada and the British Possessions' (1890–91); Britton and Brown's 'Illustrated Flora of the Northern United States, Canada and the British Possessions' (1890–98); Berg's 'Physiognomy of Tropical Vegetation in South America' (1891); Rusby's 'Enumeration of Plants Collected in South America' (in 'Torr. Botanical Club Bulletin', Vols. XX, XXI, XXII, XXV, XXVI).
variations, for South America is a zoological land apart.

Consult 'The Standard Natural History' (Boston 1885); Wallace's 'The Geographic Distribution of Animals' (1876); Merriam's 'Geographic Distribution of Life in America' (in Proceedings of the American Biological Society, Vol. VIII). For special portions, Cope's 'Crocodiles, Lizards and Snakes of North America' (in United States National Museum Report of 1869); Agassiz's 'Birds of the United States' (1868); 'Our Search for a Wilderness' (1910); Edwards' Butterflies of North America (1868-88); Goode's 'American Fishes' (1888); Zahm's 'Through South America's Southland' (1916).

Political Divisions.—The independent States of both North and South America are all republican in government, though it was only in 1889 that Brazil became a republic. The continent is politically divided as follows:

The foregoing table shows, for America as a whole, though with the omissions mentioned at the beginning of this article, an area of 15,807,404 square miles; the number of inhabitants in 1916 appears as 186,106,036. It must be understood that these figures are, from the very nature of the subject, approximations only, and that the utmost care and diligence cannot produce at present (when great regions of both North and South America remain still unexplored, and in part still unexplored) figures of area, etc., which should be exact. Most earnest efforts have been made, however, to reduce the margin of error and to secure as nearly as possible essential accuracy.

AMERICA, Discovery and Colonization of. The effective discovery of America was a gradual process, made possible by the first westward voyage of Columbus across the Atlantic and developed by attempts to determine the relation of the lands thus encountered to the Asiatic continent. The body of legends concerning European or Asiatic contact with America prior to the 15th century bears witness only to a vague impression of or conjecture at the existence of land in the western part of the Atlantic Ocean, which led to nothing effective in the way of the foundation of such conjecture or occupation of the territory. The contact by the Norse colony in Greenland in the 11th century with the shores, probably of New England, which the Northmen knew by the name of Vinland, led to nothing more than occasional resort to certain of its facilities such as timber, and cannot be regarded as a discovery in any complete sense. Nothing can detract from the unique distinction of the expedition of Columbus in 1492. The cosmography of his time was in error as to the size of the earth and consequently underestimated the distance intervening between the western limit of Europe and the eastern shores of Asia. But this error could in the nature of things only be brought to light by an actual test by a westward voyage across the Sea of Darkness. This test it is the sufficient glory of Columbus to have furnished and its importance for cosmography cannot be overestimated. Nevertheless, in its relation to America alone, discovery in the complete sense was rather made possible, than achieved by Columbus.

It was under the auspices of the Atlantic States of Europe that development of the results of this voyage was carried on, and of these Atlantic States, Spain and Portugal at first took the leading part. At the time of Columbus' great voyage, Portugal had nearly completed the development of the possibilities
of an eastward maritime route to the Oriental
trade regions, the goal of maritime endeavor.
The Spanish patronage of Columbus naturally
led the Spanish Crown to claim for the west-
ward extension to the Indies, thus made possible
under its auspices, the same advantages which
papal action had secured for Portugal in con-
nection with the eastward route. By a papal
bull of 25 Sept. 1493, superseding those on
the subject previously issued, enterprise up-
thrust began to the Indies and the new open to both Spain
and Portugal, with the understanding that Spain
should refrain from infringement upon the
Portuguese monopoly of the African coast by
using only the westward approach to the Indies.
By the Convention of Tordesillas, 7 June 1494,
the line 370 leagues west of the Cape Verde
Islands was set by the two nations themselves as
a division between their respective areas of
maritime activity.

Spanish voyages between 1493 and 1502 now
skirted most of the island and continental
shores of the Caribbean Sea and the Gulf of
Mexico, without, however making much pro-
gress in elucidating the connection between
these regions and the Asiatic continent, with
which they were still somehow, as it were,
connected. In the meantime, by the Cabral
voyage to Brazil in 1500 and those of the Cor-
tereals to Labrador and Newfoundland in 1500–
02, Portugal found an interest in westward
voyages, for she claimed that not only Brazil,
but also the regions in the vicinity of the fish-
ing grounds in the north, were east of the line
of demarkation. The expeditions of Vespucius,
Coelho and Jaques, 1501–03, not merely satis-
fied Portuguese curiosity as to the extent of
their possessions accessible by the westward
voyage, but established the southwestern trend
of the Brazilian coast, but, what was very much
more important, by establishing the continuance
of this land mass to a point as far south as the
latitude of the southernmost point of Africa,
practically ensured the conviction that here was
a New World. This was a land mass, insular
or peninsular in its connection with Asia on the
north, of such extent as practically to constitute
a part of the world co-ordinate with Europe,
Africa and Asia. It was to the New World, as
this was conceived, that name America, Persia
a little more than half seriously, was proposed
by friends of Amerigo Vespucci in 1507, to be
applied, and the name thus applied was but
very gradually extended, as the truth became
known, to the whole double continent. Spain’s
great efforts in exploring voyages, as dis-
tinguished from land expeditions into the
interior, were now concentrated upon the search
for a strait through, or a passage to the south of
the lands revealed by the voyages since 1492.
This search was in turn, prompted by the epoch-making voy-
age of da Gama in 1497. More accurate ac-
cquaintance with the extent of the Asiatic
continent developed by Portuguese activities in
the Far East subsequent to the voyage of da
Gama was a favorable condition for such
attempts as the Spaniards were making and the
voyage of Magalhaes in the service of Spain in
1519–22 to the south of the New World re-
vealed the extent of the waters lying between
it and the Asiatic continent. This was a funda-
mental fact, knowledge of which was in large
outline logically sufficient to establish the separa-
tate continental character of the territory
brought to knowledge since 1492. Appreciation
of this significance of Magalhaes’ voyage was
slow in developing, however, and it was not
until after exploring conquests of the western
shores of the Atlantic and up the Colorado River
in 1526–24, that the outline of the continent on
its western shore was traced out as far as southern California. The coast north of this
region was reached and effectively made known
only by a succession of voyages covering a
considerable space of time and headed by re-
representatives of different nations. Most promi-
nent in this enterprise were the expeditions of
Drake in 1577–80, which probably reached the
northern California coast; Bering, the Russian,
in the strait bearing his name and on the
Alaskan coast, in 1741, and Vancouver on the
coast of what is now British Columbia in 1792.
The eastern shore of the continent — unless
we include the voyage of Gomez from Labra-
dor to Florida in 1536, which was not followed
up — was outlined by Spain only as far north
as Chesapeake Bay, the remainder being the
scene of French and English activity after the
Spanish power was becoming embarrassed in
Europe.

After the voyage of Magalhaes in 1522,
Spanish interest in the New World concerned
itself rather with the task of exploring the
interior of the regions whose boundaries
Spanish voyages had skirted, than with further
extension of the lines of inclusion. The glitter-
ing success of Cortez in Mexico in 1519–21 was
responsible for many attempts in imitation of
such an achievement, and in the course of these
attempts much knowledge was attained of the
conditions in the interior of the continent.
Pizarro’s conquest of Peru led on to the exploration and attempted conquest of Chile
and to the crossing of the Andes and the
descent of the Amazon by Orellana in 1541.
The La Plata system was explored by Sebastian
Cabot and Diego Garcia in 1527–30. In the
northern continent, Florida was discovered by
Ponce de Leon in 1512 and proved a part of the
continent by Pineda, who also made
acquaintance with the Mississippi in 1519.
In the course of the wandering of such parties as
those led by de Leon, Narvaez, Cabeza de Vaca
and Coronado from 1512 to the middle of the
century, much of the interior was seen as far
north as the Missouri and Ohio systems, but
only the extreme southeast and southwest
portions, that is, California and Florida, saw any
attempt by Spain to occupy the territory thus
wandered over. The task of administering and
exploiting what she already had was sufficient
to absorb what energy could be spared from
European occupations.

France and England, in the meantime, were
becoming less and less inclined to respect the
claims of Spain in any direction not backed up
by present physical force, and more and more
inclined to take up a line of aggression in mari-
time endeavor, not only for the sake of weak-
ening the general position of Spain, but also
because of the stimulus of individual enterprise
within their own populations. It was only
under these circumstances that England began to make use of the claim based upon the Cabot voyages of 1497-98. Conditions inclining the government's policy with respect for the claim of either Spain or the Pope were now wholly changed, and as against any right to territory west of the line of Tordesillas, England pursued the policy that occupation must, within a reasonable time, be added to discovery to constitute a valid title to territory in the New World. According to this criterion, the achievements of England and France in the 16th century can only be regarded as preliminary or preparatory in character. In each case internal strife at home and the exigencies of the European situation prevented the achievements of discovery and incipient settlement from being followed up. Nevertheless they served to reveal in an effective way that portion of the continent in which conditions for transplantation of European institutions and life were most favorable. The stretch of shore left unoccupied was comparatively small and the great work of France was extensive, and rapidly spread the territory accessible by water from the shore. While England's great work was the permanent and slow-expanding settlement of the strip between the coast and the mountain-barrier of the Alleghanies.

In 1524 Verrazano, a Florentine in the service of France, coasted from North Carolina to Newfoundland, and in 1534-41 the first French attempt at settlement was made under Cartier and Roberval, and though it was not at this time maintained, the foundation was then laid for the French claim to the territory of the Saint Lawrence system. Attempts to invade the unoccupied sphere of Portugal by Ville-gagnon in Brazil in 1555, and of Spain by Ribaut and Laudomiere in Florida and South Carolina in 1562, were promptly suppressed. So that when, at the beginning of the 17th century, Frenchmen were in a position to take up transatlantic activity once more, the Saint Lawrence Basin naturally became the scene of their endeavors. From Port Royal in Nova Scotia in 1603, headquarters were shifted in 1607 to Quebec, and once established at one end of the great interior waterway system, and headed off from southward expansion by the hostility of the Iroquois, the line of least resistance led naturally to the interior by the west. These circumstances, coupled with the character of the emigrating population, account for the most signal achievement of the French in the New World—exploration of the continental interior. This went on coincidently with the process of colonization and thereby a fundamental characteristic of New France on the mainland was illustrated—the attempt by the government to nourish a true colony in eastern Canada, while the adventurous population, missionary and fur-trader overran the surface of the great interior. Trails were made by Nicollet in 1634 as far as the Illinois country by the Lakes and the Fox River route, by Radisson and Groseillers in 1658-59 as far as Lake Superior, by La Salle and Joliet and Marquette in 1663 to the Mississippi. And by 1682 La Salle had opened up the connection between the Gulf of Mexico at the Mississippi's mouth and the Gulf of Saint Lawrence. By 1699 a French settlement was planted in Louisiana and in 1718 New Orleans was founded.

With England, the order of proceedings was different. Exploration of new regions was a preliminary to their filling up with settlers and bursts of exploring activity occurred in the intervals of the great stages in the process of colonization. The Cabot voyages gave her the basis of the claim to the continental shore to the north of Florida, but her first exploring activities were in connection with the search for the northwest passage to the Orient by such commanders as Davis and Forbisher in 1576-78 and with the attempt to occupy Newfoundland by Gilbert in 1579. With the career of Raleigh, the English maritime enterprise takes definite beginning in the colonizing line with the attempt at Roanoke in 1585, and from then till well into the 18th century English exploring activity was mainly concerned with the coast between Florida and Newfoundland, the basis of her colonies on the main. This was as characteristic of the English career in the New World as the French method of rapid and extensive spread, and the British believed the entire country. In the course of occupation of the coast, the English found themselves preceded in the strategic regions of the Hudson and Delaware valleys by the Dutch, and falling back on the principle of prior discovery alone, which, as against Spain, she had disregarded, made conquest of the New Netherlands settlement in 1664, as an invasion of the right to the whole, claimed by virtue of the Cabot voyages. British interest in the interior awoke in the 18th century, and, mostly under colonial leaders, British hinterland was extended to a hostile contact with the French claims to the interior based on discovery and exploration of the Saint Lawrence system. This being settled by the elimination of New France from the continent in 1763, English exploring activity found its scene, after the separation of the seaboard colonies with their westward extensions to the Mississippi, in the extreme northern part of the continent, with the territory of the Hudson's Bay Company as the base. Here in the later years of the 18th century the early expedition of Verendrye to the Canadian Rockies by the Saskatchewan in 1741 through the interior of the Canadian Northwest was followed up by Henne in 1770 and Alexander Mackenzie in 1789.

The areas of the New World within which the colonizing activities of the European Atlantic States were carried on conformed in a general way to the scenes of their earliest contact and activity. Portuguese colonization in the New World was limited to Brazil, the only portion of the continent within the limits marked out by the line of Tordesillas. Spanish activity radiated from the Caribbean archipelago in all directions and included the greater part of habitable South America, Central America and the southern portion of the North American continent. French colonies were to be found among the West Indies, but the greatest extent of French settlement was in the neighborhood of the Saint Lawrence system, while the English, late comers as they were, occupied strategic points among the islands and stretched along the continental shore from Florida to the Kennebec.

In the list of participants in the work of
colonizing the New World there must be added to the European Atlantic States already mentioned as conspicuous in discovery and exploration, Holland and Sweden. But the brevity of the duration of these attempts hardly entitles them to a place of equal significance with the other four as colonizers in America. The Swedish colony founded in 1637 on the banks of the Delaware was regarded by the Dutch as an intrusion on their rights and fell victim to Dutch conquest in 1655. The Dutch enterprise on the Hudson and Delaware was in turn frustrated by treaty and equally it was ousted on English North America and the Dutch were disposessed in 1664 by the same means as they had themselves employed upon the Swedes. During their development of New Netherlands the Dutch were not successful in planting the colony firmly on an agricultural basis, the fur trade proving attractively profitable. A system of colonial government in too close dependence upon a clumsily working confederate government at home and a system of local governments with relatively independent initiative retarded the development of the colony. A few islands in the West Indies and a small stretch of the northeastern coast of the South American continent still remained — and do yet — as Dutch possession in the New World.

Portugal began her American colonization in 1531 in Brazil, but was unable to give it the requisite attention until the 18th century. In the meantime the comparative freedom from restraint enjoyed by the colonizing population had exercised a developing effect, and, pursuing it in practice lessons in regard to the exploitation of a tropical colony learned elsewhere, Portugal developed a colonial establishment stable enough to afford a refuge for the House of Braganza during the period of Napoleonic occupation of the Iberian peninsula. In 1821, the Brazilians with the concurrence of their regent, himself of the royal house of Portugal, proclaimed their independence from the Crown of Portugal, and this independence was subsequently recognized. Spain had been a colonizer in the new world, the Spaniards began colonizing with the second voyage of Columbus and the islands of the Caribbean, particularly Haiti and Cuba, became scenes of an exploitation of the superficial riches of the tropics which served as bases for exploring conquests to the territory of the mainland. The policy of Spain toward her wide domain in the New World, as worked out in the 16th century, not in abstract theory, but in combination of theory with practice, was but little more illiberal, but considerably less intelligent than that of other states. But the climate of the part of the New World falling to them was not conducive to the steady, strenuous persistence necessary for the building up of permanent wealth-producing communities. Nor were the original characteristics of the colonizing population calculated to make success in such a career likely. The natives were not able to offer stubborn resistance to the rapidly moving enterprises of the conquistadores, though they did prove formidable to the natives — a tendency which weakened the stronger without strengthening the weaker race — did not prevent the evasion of the laws intended to protect the natives from the rapacity of their conquerors and to keep the two opponents of the official class in balance against each other. The too rapid early successes in the realm of military conquest and the easily won response to the search for the precious metals still further unfitted the Spaniard for what modern colonizing peoples are finding the most difficult of tasks — the intelligent exploitation of the earth and its resources in a tropical region where the available labor supply is for various reasons inefficient according to European standards. Nevertheless, though the Spanish dominance over such a great part of the New World could not guarantee prosperity to this empire, it was rather the spoils given by the Napoleonic attack on the mother country and its consequences on Spanish internal warfare than the inherent strength of the separate divisions of Spanish-America, that accounts for the revolt of the greater part of this empire in the first three decades of the 19th century. And at the same time that political separation was taking place, Spain in Europe stood in such need of political help from England that a commercial invasion of Latin-American markets could not be prevented. This was accomplished and the Napoleonic danger passed, the influence of England was publicly and privately used to obstruct all attempts from Spain to reunite the scattered fragments of the once mighty power in America. The sluggish development, to call it by that name, which characterized what remained to Spain of dominion in America between the Latin-American revolts and the wresting of Cuba and Porto Rico by the intervention of the United States in 1898 illustrates the degree of effectiveness of Spanish colonial policy according to modern economic standards.

French colonization in America received much attention from the home government and the French temperament was one adapted to success in dealing with the natives, and in amalgamation with them in preserving the elements of strength. But on the other hand the overzealous and intertemperately exercised interference from home frequently nullified all the good that the lavish furnishing of materials and in military protection did to the fortunes of the colony. The climate was as excessive in its rigor as that of New Spain was in the opposite direction. The hostility of the Iroquois, fierce and sudden, and the obstructed expansion to a more favorable clime and made extensive use of a vast forest domain for the fur-trade a more easy and attractive program than the jog-trot business of intensive agriculture and the development of permanent communities on the frontier for which latter task lack of the habits of initiative in self-government unfitted the colonizing population. The only colonizing material in the French people capable of developing such traits — the Huguenots — was peremptorily excluded from New France. So that when the English empire had at length come into collision with the borders of the French forest preserve in the interior, New France on the continent was capable, by reason of the feudal and military force pervading it and the natural resistance against the superior numbers of the English settlements co-operating but clumsily with each other. As between the French and British empires as world-units, however, there was soon no question of superiority, and France was definitively excluded from the con-
tinent as the result of the Seven Years’ War (q.v.). The French possessions in the West Indies, acquired in various ways during the 17th century, remained to him, and make of her to that extent an American power.

The colonizing work of England in America belongs to the colonial period of United States history (q.v.). In broad outline, her policy toward her American domain was one which, whether with design or not, allowed wide scope for individual and local initiative. The English population afforded good colonizing material. The Indians gave no such serious trouble as did the Iroquois in the case of the French in the early stages of their colonizing. Defense against European attacks upon the colonies was effective. As builders of settlements in the New World, the English were eminently successful. In devising, or at any rate, applying a system of political connection between the home government and the colonies, the English reached an unfortunate place in their internal political development coincidently with a critical stage in the relations of colonies and mother country. The strain at that time and under those circumstances brought upon colonial loyalty proved too great and by the separation of the 13 Atlantic seaboard colonies, Great Britain’s power in the New World was cut down to control of certain important West India islands and the area so recently wrested from France. Under the new spirit of the British Empire which appeared in the 19th century, these possessions have been so developed and bound in sentiment to the interests of the mother country that Great Britain stands second only to the United States as an American power.

CHARLES WORTHEN SPENCER, Assistant Professor of History, Princeton University.

AMERICA. American song, written in 1832 by Samuel Francis Smith, D.D.

My country! ’tis of thee,
Sweet land of liberty,
Of thee I sing;
Land where my fathers died!
Land of the Pilgrims’ pride!
From every mountain side,
Let freedom ring!

My native country, thee—
Land of the noble free—
Thy name I love;
I love thy rocks and rills,
Thy woods and templed hills,
My heart with rapture fills
Like that above.

Let music swell the breeze,
And ring from all the trees,
Sweet freedom’s song;
Let mortal tongues awake;
Let all that breathe partake;
Let rocks their silence break—
The sound prolong.

Our Father’s God to Thee,
Author of liberty.
To Thee we sing;
Let bright the eye,
With freedom’s holy light;
Protect us by Thy might;
Great God, our King.

The circumstances connected with the writing of this famous hymn are best gathered from a letter written by the author, the Rev. Samuel Francis Smith, to Mr. J. H. Johnston of Brooklyn, who had asked concerning the occasion which induced the author to write it. The letter follows:

NEWTON CENTRE, MASS., June 5, 1887.

Mr. J. H. Johnston:

Dear Sir: The hymn “America” was not written with reference to any special occasion. A friend (Mr. Lowell Mason) put into my hands a quantity of music books in the German language early in the year 1832—because, as he said, I could read them and he couldn’t—with the request that I would translate any of the hymns and songs which struck my fancy, or, neglecting the German words, write hymns or songs of my own, adapted to the tunes, so that he could use the music. On a dismal day in February, turning over the leaves of one of these music books, I fell in with the tune, which pleased me—and, surfeiting at a glance that the words were patriotic, without attempting to imitate them, or even to read them throughout, I was moved at once to write a song adapted to the music—and “America” was the result. I had no thought of a national hymn, and was surprised when it came to be widely used. I gave it to Mr. Mason soon after it was written, and have since learned that he greatly admired it. It was first used publicly at a Sabbath school celebration of independence in Park Street Church, Boston, on the 4th of July, 1832.

Respectfully yours,
S. F. SMITH.

AMERICAN ACADEMY OF ARTS AND SCIENCES, an organization founded at Boston in 1780. John Adams, afterward President of the United States, was its chief promoter. Its purpose was to cultivate every art and science which may tend to advance the interest, dignity, honor and happiness of a free, independent and virtuous people. It published for many years scientific memories as well as its proceedings. It has a scientific library of upward of 25,000 volumes.

AMERICAN ACADEMY OF MEDICINE, The. Organized in 1876 by a few physicians at Philadelphia. While at first the main qualification seems to have been a liberal education, the scope soon broadened to include an interest in the sociologic problems connected with medicine. The academy works through conferences at its annual meetings and occasional special conferences. Its publications are The Journal of Sociologic Medicine and reprints or groups of papers on some certain subject. It has about 600 members, most of whom are Fellows (physicians); there are also associate members (those not of the medical profession), and a few honorary members.
AMERICAN ACADEMY OF POLITICAL AND SOCIAL SCIENCE. The Academy was organized 14 Dec. 1889 to provide a national forum for the discussion of political and social questions. The Academy does not take sides upon controverted questions, but seeks to secure and present reliable information to assist the public in forming an intelligent and accurate opinion. It publishes annually six issues of 'The Annals,' each dealing with an important current social or political problem. These volumes contain serious discussions, not doctrinaire expressions of opinion. Five scientific sessions are held each year, during the winter months, and an annual meeting in April, extending over two days and including six sessions. The membership fee is $5 per year; life membership fee $100. Members not only receive the volumes of 'The Annals,' but also have the privilege of attending all the sessions of the Academy, and the further privilege of applying to the editorial council for information upon current political and social questions.

AMERICAN ANTIQUARIAN SOCIETY, an association organized in 1812 at Worcester, Mass. The object of the society is the study and preservation of the antiques of America, and the advancement of art and science throughout the world. Its library includes over 100,000 volumes, including a large number of the rarer Americana, very complete files of American newspapers and a rich collection of manuscripts. Its Transactions have been published since 1820 and the Proceedings semi-annually since 1849. It maintains an important museum of antiques, gathered in all parts of North, South and Central America. A new library for the society was completed and occupied in 1910. The society maintains a fund aggregating over $100,000 for the support of various departments of its work.

AMERICAN ANTI-SLAVERY SOCIETY. The. See ANTI-SLAVERY SOCIETY, THE AMERICAN.

AMERICAN ART. The art history of America presents interesting conditions of receptivity as well as original productivity; indeed, artistic taste, it may be claimed, was primarily transplanted or transmuted into the budding art of 'The First New World.' Thus, the traditions of historical repetition, the ideals of ancient Greece inspired an Italian renaissance; French, German and English art respectively, being viewed moreover at their best periods, give evidence of having been bogotten through aesthetic assimilation and fruitful appreciation of the masterpieces of Angelo, Titian, Tintoretto, Rembrandt, Rubens, Veronese and Velasquez. The early American school not only emulates these treasured qualities, but also to some extent imitates the painting and sculpture of originals or in replicas, but experienced a healthful art evolution, normally stimulated by the contemporary works of Gainsborough, Reynolds, Lawrence and others at the close of the 18th century. It appears in accord with the artistic spirit of contemporaneous reciprocal process, that America provided the British Royal Academy, with its second president in the personality of Benjamin West.

Although it would be intensely interesting to explore the field of Pan-American art, revealing Aztec and other aboriginal architectural relics, we are limited to the consideration of the subject coincidental with modern art and civilization. The works of Washington Allston, Gilbert, Stuart, West, Copley, Trumbull, Vanderlyn, Jarvis, Peele, Cole, Harding, and, at a later period, of Morse, Eliot, Mount and many others, afford invaluable examples of rare intrinsic value, with chronological evidences of the early development, impeded by all sorts of obstacles, of inborn genius and unmistakable tendencies of the progressive element even in the province of fine art.

American Classicism.—A representative collection of the famous works by the American painters mentioned, had it been secured, would certainly to-day constitute a rare gallery of aesthetic 'Americanas' that well might be preserved for all time—'con arte et gloria;' enkindling American art patriotism in line with that shown for the army and navy, agriculture and commercialism. It is too late, however, to secure the marvellous masterpiece by Allston, 'The Legend of the Drunken Island,' it having unfortunately been destroyed by fire, and many other gems of renown are now lost sight of through lack of proper preservation and of popular appreciation. Vanderlyn's 'Ariadne,' however, has fared better in company with invaluable portraits painted by these gifted men and now in possession of the New York Historical Society. 'Marius Sitting Among the Ruins of Carthage,' a work that secured Vanderlyn, in reward for its merits, a first-class gold medal at the Paris Exposition, was a product of this period. The most important epochs of American history have been represented by native artistic talent. The sailing and landing of Columbus, the exploits of De Soto, the subjugation of savage life to the devastations of colonial and Indian warfare, the declaration of national independence, revolutionary battles, Washington crossing the Delaware, and like famous subjects for painting and sculpture, that naturally should be preserved by government direction. Although so long and disastrously belated, these facts and conditions logically suggest the formation of a national gallery of American art. The landscapes of Thomas Cole upheld, as did those of Turner, the traditions of Claude Lorrain; still in the spirit of a pioneer he proclaimed the grandeur of the primeval American forest in paintings direct from nature. His 'The Course of Empire,' now in possession of the New York Historical Society, a work that has never, we believe, been reproduced in any form, presents in four grand paintings the sway of civilization from savage life to an Arcadian period; then onward to the consummation of earthly power and magnificence; followed by the decadence occasioned by war of the 18th century; and finally the spectacle of man's inhumanity to man; finally, the literal scene of monumental destruction and sublimely solemn desolation. Before dismissing attention called to this early period influenced, as stated, by foreign methods of technical expression,
native American genius found little public appreciation; still it faithfully progressed.

Science vs. Art.—Again about this time a painter in New York, trained in the art of the idealist's poetic hopes, while every encouragement followed the success of practical scientific talent. Washington Irving essayed to be a painter, but concluded to devote his life to literature and the power of the pen. Robert Fulton, who built the career as a skillful landscape and portrait painter, attracting the friendship of Benjamin Franklin, who encouraged his studies abroad, and gave him letters to Benjamin West and others, returned to his native land to find that scientific conditions were required rather than a demand for the credentials of culture in works of fine art. The result was steamboat navigation. Another triumph for science may be recorded. Franklin himself had captured lightning from the skies, that reigned over man in his own sphere, a skillful artist to the extent of training artistic skill of the professional painter, Samuel Finlay Breese Morse, the first president of the National Academy of Design, to subjugate the marvelous electric element that joins as neighbors the nations of the world.

The Hudson-River School.—Nevertheless, the fine arts flourished; even modern travelers' tales of the wonderful scenery of two great continents stimulated artists and the lovers of art. "The Heart of the Andes," "Niagara," "The Arctic Region," "The Rocky Mountains," "The Catskills," "Lake Champlain," "Lake George" and the "Hudson River," all were delineated. Along with this demand for great subjects, often commensurate in quantity as to size of canvas with Ruskin's mathematical maxim, that the greatest work of art is the one presenting the greatest number of great ideas, there still prevailed in marked instances the glorious traditions of full-habited oil-painting to be found in the aesthetics of familiar environment of earth, air and water, as embodied in artistic values and soulful qualities — creations in harmony with Michel, Rysaen, Constable and the masters of Barbazon and Fontainebleau. Again, while scientific influence in American artistic taste was strong, in Church, Casale and Kessent, they asserted a truly American artistic individuality; they copied directly from nature. They thought of no school nor technique, but carefully imitated what they saw. All these men with one exception had been practical engravers, laying down the burin and the needle-point to take up the pencil and the brush. Their respective biographical and aesthetical records in American art will be enduring; yet there comes the reflection that had these professionals been more liberal and adequate they would have attained to higher things. The importance of masterly academic training cannot be overestimated; as a means to an end, however great, education is the only acknowledged guide for the individual artist and for the community even in matters of taste. Nothing is more creditable to a civilized people than its credentials of culture. The formation of a fine art association in New York was at the beginning of the past century an occasion of vast importance to the commonwealth. The first action was taken in 1802 by a few prominent citizens, and six years later a charter was obtained with the name of The American Academy of Arts. The first officers under this charter were Robert Livingston, president; John Trumbull, vice-president; DeWitt Clinton, Dr. David Hosack, John R. Murray, William Dunlap, John R. Murray, William Dunlap, and Wilkes, directors. A school was equipped with casts brought from Paris by Mr. Livingston, and exhibitions of paintings and statuary were held for a time in an unused riding school in Greenwich Street near the Battery. Public interest in this movement and the talent then budding to grand panorama schemes conducted by Vanderlyn at the "Rotunda," and by others with similar enterprises.

The National Academy of Design.—It was not until the year 1826 that the artists themselves, with Morse as president, founded the National Academy of Design in the earnest interests of American art, with educational purposes and exhibitional facilities; its influence increasing until the present day. Its membership consists of 100 members, and an equal number of associate members, including the most distinguished painters and sculptors of America. Its list of fellowship for life likewise includes the most prominent public-spirited patrons of American art. It has been honored for many years in the Academy building, tastefully modeled after the Palais Ducal of Venice and forming an attractive urban landmark, lack of accommodations for its growing schools and crowding commercial surroundings required a move to more suitable quarters. Unlike the Royal Academy of London, with its plethoric treasury, and similar institutions situated in other European art centres, the academy is without governmental endowment and may well enlist American art patriotism in the cause of aesthetic culture in fostering the fine arts of painting, sculpture and architecture. Other societies of American artists, watercolor societies and architectural leagues make annual exhibitions in New York; while art institutes throughout the United States in various cities attest the extent and importance of American art. We, as Americans, are an artistic people, cosmopolitan and composite, uniting the genius of all nations. The aesthetic field of general culture and the special development of a nation under the general guidance of art. In advancing these three divisions — the ornamental, the beautiful and the sublime — as a guide, we approach the philosophical consideration of the subject of fine arts.

Art and Science Differentiated.—What is, and what is not, fine art? Shakespeare's injunction "to hold, as it were, the mirror up to nature" is the best artistic advice ever given. Bacon in his essay is not so direct. He asks which is the greater trifle, one who would make a personage by geometrical proportions (perhaps by the fabled Greek cabala) or another who would select the best parts of divers faces to make one excellent (a veritable com-
American Art

He concludes at last that a painter may make a better face than ever was, but he must do it by a kind of felicity, as a musician who makes an excellent air in music, not by rule. If ever there was an artist, he was Shakespeare—if ever there lived a scientist, Lord Bacon was, perhaps, the most eminent, and in their respective views and definitions we find the differentiation between science and art. In any given work in so far as it may be mechanically constructed is presented a scientific product; and in so far as reproductive processes may exhaustively duplicate it, it falls short of the possibilities of fine art. An etching by a master may be an autographic art creation; but when it is possible through photography, photogravure or chromo-lithography to so perfectly duplicate a painting that the reproduction presents all the merits of the original it may be relegated to science rather than be accepted as genuine fine art. True consummate mechanism must ever go hand in hand with fine art; still a great work of art presents the maximum of art to the minimum of mechanism. A painting may achieve the living objet d'art, such as may delight the photographer, without the suggestive quality of stereoscopic relief, does not hold the mirror up to nature, and the work may be classed with scientific achievements even if accredited to the consummate mechanism of a Messonnier. Indeed reproductive processes have served a great purpose in defining the line of demarcation between science and art. Affectations have been swept away by a revelation of their superficiality; while the possibilities of inimitable fine one of the early printers. Being appointed the legal executor of his hero-client, as well as being an enthusiastic admirer of his work, Ruskin claimed for Turner not only the grander qualities, but a command of detail that rivaled the most consummate of colorists, as we are told, frankly declined the compliment. Turner was unquestionably the greatest modern master of decorative and scenic effect in pictorial combinations representing earth, air and water, being, indeed, entitled to the apotheosis of synthesis; still diligent search in the archives of the Royal Academy and National Gallery fails to reveal the qualities attributed to him by the author mentioned. Ruskin's enthusiasm proved contagious throughout the art circles of England and America; solicitors friends as well as the art writers pleaded with the tyro to emulate not the work of Michelangelo, Titian or Raphael himself, but to follow in the footsteps of Perugino and Raphael's father or grandfather. This verily seemed like unto the dogmatism of the pseudo-aesthetic movement. No vestige of it remains, and no wonder it was followed by impressionism—as a free and joyous transition from mechanical fidelity, as a musician who makes an excellent air in music, not by rule. If ever there was an artist, he was Shakespeare—if ever there lived a scientist, Lord Bacon was, perhaps, the most eminent, and in their respective views and definitions we find the differentiation between science and art. In any given work in so far as it may be mechanically constructed is presented a scientific product; and in so far as reproductive processes may exhaustively duplicate it, it falls short of the possibilities of fine art. An etching by a master may be an autographic art creation; but when it is possible through photography, photogravure or chromo-lithography to so perfectly duplicate a painting that the reproduction presents all the merits of the original it may be relegated to science rather than be accepted as genuine fine art. True consummate mechanism must ever go hand in hand with fine art; still a great work of art presents the maximum of art to the minimum of mechanism. A painting may achieve the living objet d'art, such as may delight the photographer, without the suggestive quality of stereoscopic relief, does not hold the mirror up to nature, and the work may be classed with scientific achievements even if accredited to the consummate mechanism of a Messonnier. Indeed reproductive processes have served a great purpose in defining the line of demarcation between science and art. Affectations have been swept away by a revelation of their superficiality; while the possibilities of inimitable fine one of the early printers. Being appointed the legal executor of his hero-client, as well as being an enthusiastic adm
to provisional committees of statesmen, who frankly admit their inability to judge in the affairs of far-off lands. The consequences resulting from the careless management of international expositions, certainly teach that no such enterprises should be thrust upon the community through flattering prospectuses, promises of profit, etc., until matured and definite plans and specifications have been thoroughly inspected, approved or rejected by the projected national department of art and industries; this would also provide a valuable bureau of information in art affairs, enabling legislator and citizen to act or vote intelligently in regard to any appropriation, commission or tariff. The practical utility and public good to be derived from such a department may be demonstrated in many instances. A member of Congress having been appointed upon a committee assigned the duty of supervising the ground immediately surrounding the House of Representatives was astonished to find that millions of dollars had been expended upon the same; each new committee annually appointed having exercised its talents and spirit on the expenditure. It was concluded that the advice of an expert landscape architect be secured, and this being done, the expenditure was practically ended. Again the enormous expense of indiscriminate illustration of congressional and department literature has been noted. It has been stated that all countries composed of 12 United States, for example, Mexico, Brazil, Colombia, etc., were described by the United Nations, not the political, name of the country.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, a society originally known as the Association of American Geologists, founded at Philadelphia in 1840. In 1842 it added Naturalists to its name and was known by this title until 1847, when the present organization was formed. During the past 50 years the names of practically all the leaders of American science have been on the register of the association, and the 52 volumes of its Proceedings contain many of the most important contributions to scientific literature published in this country. It is organized in 11 sections, each of which holds its own convention at the annual meeting of the association during the summer. The sections embrace the following departments of science: A, mathematics and astronomy; B, physics; C, chemistry; D, mechanical science and engineering; E, geology and geography; F, zoology; G, botany; H, anthropology and psychology; J, social and economic science; K, physiology and experimental medicine; and L, education. The association also serves as a centre for the meeting of a number of important special scientific societies which have become connected with it. It publishes annually a report of Proceedings, and in 1901 became associated with the journal Science, making it the semi-official organ of the society. The association numbers over 10,000 members. Its roll of Fellows has included such well-known scientific men as Newcomb, Barker, Brush, Young, Lesley, Morse, Langley, Goodale, Prescott, A. Hall, Harkness, Gibbs, Gill, Putnam and Minot.

AMERICAN ASSOCIATION FOR LABOR LEGISLATION. This is a scientific society, organized in 1906 to serve as the American section of the international association of the same name, to promote uniformity of labor legislation in the United States, and to encourage the study of labor conditions with a view to promoting desirable laws. Prominent among the Association's achievements are the Federal law abolishing poisonous phosphorus in the match industry, and statutes in several States for the prevention of lead poisoning and compressed air illness, the reporting of occupational diseases and industrial accidents, and the establishment of one day's rest in seven. The organization has also been active in promoting public employment offices and adequate workmen's
compensation laws, and was instrumental in initiating the American movement for health insurance. The *American Labor Legislation Review* is the official publication.

**AMERICAN ASTRONOMICAL SOCIETY.** The. This society was founded in 1899 with an original membership of 113. The membership is now about 300, and includes well-nigh all of the active astronomers of America, and many prominent foreign astronomers. The purpose of the society is to promote the advancement of astronomy in general and to further cooperation among members in the solution of the extensive problems of the science. The society holds annual meetings for conferences and for the presentation of current scientific work. It has issued two volumes of its publications, which are largely made up of proceedings of the various meetings.

**AMERICAN BANKERS ASSOCIATIONS.** See Banks and Banking—Bankers Associations in the United States (Article 22).

**AMERICAN BAPTIST FOREIGN MISSION SOCIETY.** Among the five young men sailing to foreign lands in 1812 constituted the founding of the foreign mission enterprise of American Christianity was Adoniram Judson. On the long voyage to India his study of the New Testament led to a change of conviction regarding baptism and accordingly he offered his services as missionary to American Baptists. His challenge in 1814 called into existence "The General Missionary Convention of the Baptist Denomination in the United States of America for Foreign Missions." In 1846 the name of this organization was changed to "American Baptist Missionary Union," and in 1910 the present name of "American Baptist Foreign Mission Society" was adopted. Since 1825 the head-quarters of the Society have been in Boston, Mass., and in 1905 the offices were removed to the new Ford building where they now occupy the entire eighth floor. The by-laws of the Society state that the purpose of the organization is to diffuse the knowledge of the religion of Jesus Christ by means of missions throughout the world. The passing of a hundred years brings on many changes. In the days of Judson the Baptists of America were of little influence, few in numbers and poor in financial resources. To-day they constitute a great denomination, a mighty power in the religious life of America. Their foreign missionary society has come to be one of the largest and most influential in the realm of Protestantism. A hundred years ago only $1,059 represented the financial expenditures for Baptist foreign missions, whereas during the past five years the receipts in support of this work have exceeded $1,000,000 annually. The work of the Society covers a vast expanse of territory in the non-Christian world. In the 10 mission fields are maintained in Japan, the Philippines, east China, west China, south China, Burma, Assam, Bengal-Orissa, south India and Belgian Kongo. In addition, by a co-operative arrangement, the Society since 1855 has been assisting the Baptist cause in England. The Society is maintained in eight European countries. The missionaries supported by the Society to-day number 688 (including those of the Woman's Society), and these are assisted by 6,673 native workers. In Europe 2,480 workers were in service in 1914, but what effect the war has had upon their number has not yet been determined. In the non-Christian world there are 127 regularly maintained stations with missionaries in residence and 3,237 out-stations or preaching places. In non-Christian lands to-day 183,505 church members are enrolled in 1,732 newly organized Baptist churches, of which 1,027, or 59 per cent, are self-supporting. It is a noteworthy fact, and one productive of deep gratification, that among the Karen people in Burma the percentage of self-supporting Baptist churches is greater than in any State of the Northern Baptist Convention. In 1916 the missionaries on all fields baptized 12,355 converts, and the total number of baptisms since the work first began has exceeded 625,000.

The service of the medical missionary is of value in that it visualizes the Great Physician, and at the same time opens the door to the evangelist with his healing gospel for the diseases of the soul. Fifty-one missionary physicians, assisted by 133 native nurses and other helpers, give their full time to this important work. Sixty-nine dispensaries constitute the equipment for their service. More than 83,000 patients received medical and surgical treatment during 1917, and plans are being made for great advance in this phase of the Society's work. The educational work is conducted in six colleges, 35 theological seminaries and training schools, and 2,608 schools of all grades, with a total enrolment of over 85,000 pupils. More than 89,000 pupils receive religious instruction in 2,301 Sunday schools. The missionaries have translated the Bible, in whole or in part, into over 30 dialects and languages. Three printing and publication plants are connected with the Society, where bibles, periodicals, hymnbooks, textbooks and other literature are printed. The administration of this great enterprise is placed in the hands of a board of managers of 27 members, nine of whom are appointed each year at a Northern Baptist Convention. The plans and policies of the Board are carried out under the direction of the executive officers. At the present writing these are six in number. In the Foreign Department, which is charged with the responsibility for the work on the field, there are four foreign secretaries and an associate secretary.

In the Home Department for the presentation of the work to churches and the securing of funds there is a home secretary and an assistant secretary and treasurer.

**William B. Lippard, Assistant Secretary.**

**AMERICAN BAR ASSOCIATION.** The. This association was formed on the initiative of the Connecticut State Bar Association, which appointed, in January 1878, a committee of three for that purpose. The committee prepared a call for a meeting of a selected list of lawyers from the different States on 21 Aug. 1878 to consider the expediency of such a step. Thus was signed on 14 Nov. 1878 the leaders of the American bar. At that meeting there was an attendance of 72, coming from 20
States. A constitution was adopted, additional members elected, and a complete organization effected. The scheme thus adopted had been substantially followed ever since by the association, which meets annually, at different places, and publishes an annual volume reporting its activities as well as a quarterly periodical called the American Bar Association Journal, one number of which is mainly devoted to comparative law and recent legislation in foreign countries. The Association has had a large influence throughout the country in advancing the standards of legal education, promoting sound legislation and securing uniformity in State statutes regulating matters of general concern, such as commercial paper, sales, warehousing, etc. To its efforts the creation of the United States Circuit Court of Appeals was largely due. The membership is now over 10,000, embracing every American State and Territory. Consult historical sketch by Jacob Weartt in the New Jersey Law Journal (1904, pp. 292, 336).

AMERICAN BIBLE SOCIETY. The organization in 1816, was to encourage the wider circulation of the Bible. In 1841 an act of incorporation was obtained with privileges which have since been enlarged. In 1852 the Bible House was built, occupying the whole of the ground bounded by Third and Fourth avenues, Astor Place and Ninth Street. It is one of the oldest office buildings in New York. The government of the Society is entrusted to a board of managers, consisting of 36 laymen, one-fourth of whom retire from office each year, being re-elected only in case of necessity. The board has 650 American workers in its 19 missions located in Japan, China, India, Turkey, Austria, Spain, Africa, Mexico, the Philippines and Micronesia. In addition the board supports 5,000 native workers, including teachers, nurses, doctors, Bible men and women selected from its converts in these various fields.

One-third of the work of the American board has been in European and Asiatic Turkey, this field having been assigned to the board as its exclusive territory. The work of the board consists in translation of the Bible and other books into the languages of foreign peoples, the establishment of churches, schools, colleges, hospitals and industrial plants in its various fields of work. Three of the most important colleges in Turkey to-day, Robert, Constantinople and Syrian Protestant, although now independent, are the product of American Board work.

The annual income of the board for the support of all this work is $1,100,000. This sum comes from the contributions of the churches, chiefly Congregational, from legacies and from the income of permanent funds. The churches which have been founded on the mission fields have been contributing a little more than $300,000 annually toward the enterprise.

The actual management of the business of the board is entrusted to the Prudential Committee centring in Boston, the board’s headquarters, and consists of 12 men about evenly divided between laymen and ministers. This committee meets on the second Tuesday of each month. It considers the important business of the board which business, as a rule, has previously been carefully digested by its subcommittees. Much time of the Prudential Committee is taken up with considering applications for new mission fields by young men and women from our American colleges. A conference is held the first of June each year for instruction of these new recruits. About 60 men and women are sent out to the fields each year. After seven years of service on the field these missionaries
are allowed to come home and spend a year on furlough at the expense of the board. The board issues monthly *The Missionary Herald*, an illustrated missionary magazine which is the oldest in America and probably the oldest in the world. Affiliated with the American Board are three women's boards with headquarters in Boston, Chicago and San Francisco. These boards of women support all the unmarried women missionaries. This amounts to about $300,000 annually for that purpose. Of the entire missionary force one-third are men and two-thirds are women.

**AMERICAN BUREAU OF SHIPPING**, a maritime association established in New York in 1867, for the purpose of collecting and disseminating information upon subjects of marine or commercial interest, of encouraging and advancing worthy and well-qualified commanders and other officers of vessels in the American merchant service, and of promoting the security of life and property on the seas.

**AMERICAN CATHOLIC HISTORICAL SOCIETY**, an organization founded in 1884 for the purpose of collecting and publishing research and information concerning the history and activities of the Catholic Church, and stimulating by lectures, etc., interest in Catholic affairs. It publishes 'Records' and supports a library and museum devoted to its purposes at Philadelphia. Membership, 612.

**AMERICAN CHEMICAL SOCIETY**. The. This society was founded in April 1876, its object being "the advancement of chemistry and the promotion of chemical research." The society publishes three journals: *Journal of the American Chemical Society*, founded in 1878; *Chemical Abstracts*, founded in 1907, and *Journal of Industrial and Engineering Chemistry*, founded in 1909. The membership of the society on 1 July 1916 was 8,100 and it is growing rapidly. The society is organized into eight divisions and 49 local sections, each having its own officers and governing bodies. The society meets semi-annually. The policy of organizing the members into divisions has been inaugurated, and eight enthusiastic divisions have been formed as follows: Division of Industrial Chemists and Chemical Engineers, Division of Physical and Inorganic Chemistry, Division of Fertilizer Chemistry, Division of Agricultural and Food Chemistry, Division of Organic Chemistry, Division of Pharmaceutical Chemistry, Division of Biological Chemistry and Division of Water, Sewage and Sanitation. The society affords special facilities for chemists interested in a particular branch of the science to organize themselves into a co-operative body within its ranks. Forty-nine local sections, situated in various parts of the country, hold frequent meetings. The American Chemical Society is the largest chemical society in the world, having some 3,000 more members than its nearest rival—the Canadian Chemist. Office of the secretary, Washington, D. C.

**AMERICAN CITIES, Government of. See CITIES, AMERICAN, GOVERNMENT OF.**

**AMERICAN CIVIC ASSOCIATION**, the, a voluntary organization formed 10 June 1904 by the consolidation of the American League for Civic Improvement and the American Park and Outdoor Art Association, its objects being "the cultivation of higher ideals of civic life and beauty in America, the promotion of the arts, the encouragement of public improvements, the preservation and development of landscape, and the advancement of outdoor art." The organization of a national association to act as an agency of inspiration to American towns and cities for improvement, and to serve as a clearing house of information in all such activities, was a natural development following the effective improvement activities that had for years been conducted by local effort, notably at Stockbridge and Newton Centre, Mass., and in other localities. The first efforts of such a local movement were generally of a home and neighborhood character. Unattractive and dirty backyards were transformed into little bowers of beauty and cleanliness. From these initial steps there had developed, largely through the nation-wide propaganda by the association, the larger movements that apply to communities at large, such as the creation and maintenance of city park areas, boulevards, playgrounds for children and recreational areas for adults. Involved in these general improvements have been the special efforts for the beautifying of water-fronts, for the elimination of unnecessary smoke and unsightly billboards. The culmination of all these activities has developed within the past 10 years in a systematic propaganda by the association for the adoption of comprehensive city plans, enlisting the advice and counsel of professional landscape architects and opening the way for an orderly and systematic development of cities and towns. During 1916, as an extension of the idea embraced in city planning, there has been developed a movement in the association for country planning, which proposes to direct a similar effort for the beautification and improvement of the rural districts. In extension of its general purposes for the preservation and development of landscape the association has been the leader in two great movements for the preservation of scenery, namely, in behalf of the Falls of Niagara—to prevent their spoliation by commercial interests—and second, for the extension of the American Park system. The association originated a proposal to have created by Congress a National Park Service, which in 1916 appeared likely of realization. The park service as contemplated will be in the Department of the Interior and have jurisdiction over the 14 existing national parks and the 31 national monuments heretofore in the Department of the Interior and the Department of Agriculture. Since the consolidation effected in Saint Louis, the American Civic Association has held 10 annual conventions. Its membership consists of life members, sustaining members, annual members, councilor members and affiliated members. The work of the association is conducted from its general offices through committees and department heads as follows: City Planning, Central Parks, State and County Parks, Country Planning, the Billboard Nuisance, the Smoke Nuisance, the Noise Nuisance, Schools as Community Centres, and the Press. Active propaganda is carried on by means of educational tours, clipping sheets and correspondence. The principal offices of the association are at Washington, D. C.
AMERICAN CLIMATOLOGICAL ASSOCIATION, a medical organization founded in New York city in 1884 for the study of Climatology, Hydrology, and Diseases of the Circulatory and Respiratory Organs. Candidates for membership must have contributed something to the literature of the subjects before election, this insuring a select membership, which the roll shows to be very general and distributed among the medical profession throughout the United States, with distinguished honorary and corresponding members in England, Canada, Mexico, South America, South Africa and Australia and other parts of the world. Annual meetings have been held since the foundation, at which papers confined strictly to the objects mentioned in the constitution of the organization are read and discussed and afterward published in the Transactions of the association; 20 volumes have already been issued and copies are sent annually to the principal libraries throughout the world. The title of some recent contributions showing the value and wide scope of this association are: 'The Advantages of Southern California in the Treatment of Tuberculosis'; 'The Climate and Varieties of Hot Springs, Va.'; 'Something of the Geography of Croupous Pneumonia'; 'Recent American Contributions to the Methods of Prevention and Treatment of Pulmonary Tuberculosis'; 'Climatology as a Study in the Medical Schools'; 'The Climate of Santa Barbara, California'; 'The Climatology of Muskoka, Ontario, Canada'; 'The Climates and Diseases of Central America and Panama.' The headquarters are in Philadelphia; the organization must not be confounded with a similar and friendly society, 'The National Association for the Study and Prevention of Tuberculosis,' with headquarters in New York city. The membership in 1916 was 130.

AMERICAN COLLEGE, The. Its Place and Importance.—The American college has no exact counterpart in the educational system of any other country, although its elements are derived from European systems in particular from Great Britain. And while it is true that the primary form of organization in our earliest colleges, such as Harvard, Yale and Princeton, was inherited from the English University of Cambridge, still it was subjected to modification at the very beginning, to adapt the college to its community, and afterward it was progressively modified to assure close sympathy with the character of the growing American nation. The result is an institution with derived elements of composition and in less degree of form, which has developed for itself an organization notably different from the old world schools.

So the college, from the nature of its development and its central place in the historic growth of American higher education, it remains to-day the one repository and shelter of liberal education as distinguished from technical or commercial training, the only available foundation for the erection of universities containing faculties of letters and sciences, of the pure learning, the only institution which can furnish the preparation which is always desired, even though it is not yet generally exacted, by professional schools. Singularity enough, the relation of directive influence sustained to-day by our colleges to the university problem is not unlike the relation held in the Middle Ages by the inferior faculty of arts at the University of Paris to the affairs of the university as a whole. In both cases the college, or faculty of arts, appears as the preliminary and intervening in the essentials of liberal education; this earlier education is recognized as the proper requisite for later study in the professional faculties; and in both cases the inferior faculty contains the germ of the higher science that is pure learning, the faculty of arts, sciences and philosophy. The reason for this similarity is that the American college in this respect perpetuates and develops a fundamental tradition of liberal learning, which found its way from Paris through Oxford to Cambridge and then from Cambridge to our shores. The parallel of our college history with the Old-World history holds good in other important respects. Still, in order to understand the precise nature and unique influence of the college in American education, it is not necessary to trace the story of its development, for in its various forms of present organization it reveals the normal type which has been evolved, surviving of past stages of development, instances of variation and even of degeneration from the basic, but the present experiments which foreshadow the future.

The Old-fashioned College.—The three commonly accepted divisions of education into primary, secondary and higher stages, while fully recognized in America, are not followed rigorously in organization. Primary education is more clearly separable from secondary than secondary from the higher or university stage. The chief cause for this partial blending of the secondary and higher stages is the college. However illogical and indefensible such a mixture may appear, the historical outworking of this partial blending has been compelled by the exigencies of our history and has been fruitful in good results.

The American college, then, as contrasted with European schools, is a composite thing partly secondary and partly higher in its organization. It consists regularly of a four-year course of study leading to the bachelor's degree. Up to the close of the Civil War (1861-65) it was mainly an institution of secondary education, with some anticipations of university studies toward the end of the course, which, however, were usually taught as rounding out the course of disciplinary education, rather than as subjects of free investigation. The average age of graduation was about 20. The maximum course of preparation in secondary schools was four years. In the better schools they studied Latin and Greek grammar, four books of Caesar, six books of Virgil's 'Aeneid,' three orations of Cicero, three books of Xenophon, the two of Homer's 'Iliad,' together with arithmetic, plane geometry (not always complete) and algebra to, or at most through, quadratic equations, This the stronger colleges required for entrance; but many weaker ones were compelled to teach some of these preparatory studies in the first two years of the college course. With few and unimportant exceptions the four-year course consisted of prescribed studies, including English literature and rhetoric, Latin, Greek, mathematics, natural philosophy, chemistry, the ele-
ments of deductive logic, moral philosophy and political economy, and often a little psychology and metaphysics. Perhaps some ancient or genuine history was added. French and German were sometimes scantily taught. At graduation the student received the degree of bachelor of arts, and then entered some professional school, or went into business or into teaching in the primary or secondary schools.

College of Today.—At the present time things are very different. The old four-year course, consisting entirely of a single set of prescribed studies leading to the one degree of bachelor of arts, has grown and branched in many ways. The better preparation now given in thousands of schools has enabled colleges to ask for somewhat higher entrance requirements and to exact them. The age of entrance has increased. In some quarters the increasing age of the students has raised the question of shortening the course to three years or all. The last year is to be occupied with professional studies in order that young men may not be kept back too long from entering upon their professional studies. A generation ago a young man graduated at 20 without difficulty and after two or three years in studying law or medicine began to earn his living at 22 or 23. But to-day a college student is 22 years old at graduation and if he studies law or medicine he must wait until he is 25 or 26 to begin earning his living. Accordingly boys are now passing in considerable numbers directly from secondary schools, which do not really complete their secondary education, to the professional schools. The problem is an economic one, and it is affecting college courses of study. One solution, to shorten the course to three years, was advanced by Professor Eliot of Harvard. But this proposal has not met with general favor. Another proposal is to keep the four-year course and allow professional studies in the last year, thus enabling the student to save one year in the professional school. This is what is being worked out at Columbia and elsewhere. A third proposal is to keep the college course free from professional studies, but to give opportunities in the last year or the last two years to pursue liberal courses clearly underlying professional training, thus saving a year of professional study. This is the trend of recent experiments in Yale and Princeton. The only common consideration in favor of all these proposals is that a year is saved. Against the three-year course, it is argued that there is no need to abolish the four-year course in order to save a year. Against the admission of strictly professional studies it is argued that work done in a professional school ought not to count toward two degrees representing two radically different things. Against the proposal to allow the liberal studies which most closely underlie the professions, it is argued that this is a half-way measure, after all.

Alterations in the Course.—The four-year course, however, no longer leads solely to the degree of bachelor of arts, and this old degree has itself been modified. With the founding of schools of science, aiming to give a modern form of liberal education based mainly on the physical and natural sciences, the degree of bachelor of science came into use. Then intermediate courses were constituted, resting on Latin, the modern languages, history, philosophy, mathematics and science, and thus the degree of bachelor of letters or bachelor of philosophy came into use. Sometimes the various courses in engineering were made four-year undergraduate course with their degrees virtually rated as bachelor's degrees. Still other degrees of lesser importance came into vogue and there to mark the completion of a four-year college course. The dispersing pressure of the newer studies and the practical demands of American life proved too strong to be held in form or to be kept out by the barriers of the old course of purely liberal studies with its single and definite degree, and new degrees were added to represent the attempted organization of newer tendencies. Compared with the old course such courses lack definiteness of structure. They aimed to realize new and imperfectly understood conceptions of education, and were composed of studies whose inner content was changing rapidly, or else were halfl and-half forms of education, difficult to arrange in a system that promised stability, as in the case of studies leading to the bachelor of letters or bachelor of philosophy. A graver source of trouble was the admission of various engineering and other technical studies as parallel undergraduate courses. This tended to confuse in the minds of students the radical distinction between liberal and utilitarian ideas in education, by the attractiveness of the bread-and-butter courses, to diminish the strength of the liberal studies. When in addition it is remembered that the newer courses, whether liberal, semi-liberal or technical, exacted less from preparatory schools in actual study, the necessity of school work necessary for entrance into college, it will be seen that the level of preparation for college was really lowered.

The present drift of opinion in colleges which offer more than one bachelor's degree is more 'easing' than it was some 20 years ago. There is a noticeable and growing tendency to draw a sharper line between liberal and technical education and to retain undergraduate college education in liberal studies as the best foundation for professional training, thus elevating the latter to a professional dignity comparable with law, medicine, and divinity. The more this conception prevails the more will college courses in engineering be converted into graduate, or at least partially graduate, courses. Independent schools of technology may continue to offer their courses to young students of college age, but where such schools have been associated as parts of colleges or universities the tendency to a clearer separation of technical from liberal studies seems likely to prevail.

Another hopeful tendency gradually gathering strength is to give the various bachelor's degrees more definite significance by making them stand for distinct types of liberal or semi-liberal education. First comes the academic course, leading to general liberal education, consisting of classical and modern literatures, mathematics and science, with historical, political and philosophical studies, and leading to the bachelor of arts degree. The second aims to represent a strictly modern cul-
ture predominantly scientific in character, and culminating in the degree of bachelor of science. In this course the technical aspects of the science are taught in accordance with the demand for strictly technological instruction. So schools of science do little save produce experts in the various mechanical and chemical arts and industries. Conscious of this difficulty, many schools of science have been giving larger place in the curriculum to some of the more available humanistic studies, especially French, German and English. Economics, modern history and even the elements of philosophy have found place. Some improvement has also been effected by increasing the entrance requirements in quantity of school work. But the course still suffers from an inner antagonism between technical and liberal impulses, and until it settles into a strictly technical form, or else comes to represent a strictly modern liberal culture, its stability cannot be regarded as insured. In the independent scientific schools, unassociated with colleges, it seems probable the course will keep or assume a highly technical form. But wherever it exists side by side with other branches has a prize in the development of some form of liberal education, it will almost inevitably tend toward the ideal of a modern culture mainly scientific. The process, however, promises to be slow and difficult. There is not only a financial risk, but a serious theoretical difficulty in realizing this form of liberal education. The antagonism between the technical and liberal impulses in the course seems very difficult to eliminate completely. The utilitarian instinct of the time militates against devotion to the intellectual value of modern studies and tends more and more toward technical standards.

The third type of liberal college education is the intermediate course labeled with the degree of bachelor of letters or bachelor of philosophy. It differs from the other courses mainly in its treatment of the classical languages. To placate the practical spirit it drops Greek, but retains Latin both as an aid to general culture and as a help in learning the modern languages. At this point the national, and the nation serves a valuable end by providing many students, who do not care for the classical languages in their entirety, with a sufficiently liberal form of education to be of great service. Judged from the standpoint of the historical bachelor of arts course, it is a less general but still valuable culture. Judged from the standpoint of the bachelor of science course, it appears to escape the unhappy conflict between the technical and liberal impulses.

Science followed, as an example of Harvard under President Eliot, dealt with the bachelor degree very differently. The meaning of the degree was radically altered, so as to represent the free selections made by the students themselves out of the range of liberal studies. In such a plan the long stands for the completion of a definite curriculum composed of a few clearly related central studies constituting a positive type. What it does stand for is not easy to define, because of the variation of practice in different colleges and the wide diversity of selection on the part of the students. In the undergraduate college connected with the Johns Hopkins University at Baltimore choice is regulated by prescribing moderately elastic groups of cognate studies, the student being required to say which group he will choose. In Harvard College the student has been allowed to make what he prefers, subject to such limitations as the priority of elementary to advanced courses in any subject, and the coincidence in time of various courses. But the so-called "free-elective system" inaugurated by Professor Eliot has been definitely abandoned by Harvard and a system requiring concentration in one leading division of courses, with some work in each of the other leading divisions, has been introduced.

Other Phases of Change.—To what extent the undergraduate collegian has become a university student is the real question around which a controversy of vital importance is raging.

The profound change indicated by external symptoms has been in progress since the Civil War, and is still working along toward its consummation. The difficult thing in analyzing this change is not merely to understand the change from a uniform to a multiform mode of life and organization, but to understand that what is changing is the old-fashioned American college. But even the old-fashioned colleges, while aiming to follow out a single course of study ending in a single degree of single meaning, did not succeed in exhibiting such close individual resemblance to each other as is to be found among the lycées of France, the public schools of England or the gimnasias of Germany. Many colleges really served as preparatory schools for larger and stronger colleges, and many so-called universities did not attain and in fact do not yet attain to the real though less pretentious dignity of the better colleges. For the sake of simplicity then we discard from our consideration all except the better colleges which, when taken together, exhibit the dominant tendency.

How, then, have these better colleges changed? Speaking generally, they have changed in a way which reflects the diversified progress of the country, and yet they have had an important influence in leading and organizing. They too, the change is not merely a change of form, but of spirit. In the older days scarcely any college had as many as 400 or 500 students, and the range of studies was limited. The faculty of the college exercised a strong paternal anxiety and oversight on behalf of the morals and religion as well as over the studies of the students. The authority of the president was almost patriarchal in character. Not highly developed insight into the problems of education but plain common sense in governing students was the condition of a successful presidency. The range of studies has increased. With the strengthening of preparatory courses, the school preparation of students has improved, and at the same time their average age at entrance has risen. The number of professors has multiplied. The old-fashioned college professor, the man of moderate general scholarship and of austere yet kindly interest in the personal welfare of those he taught, still remains; but at his side has appeared the newer type of American college professor, the man of high learning in some one subject or branch, who considers it his primary duty to investigate, his next duty to teach and his least duty to...
exercise a personal care for the individual students. Perhaps the old type will be replaced but this result, however, would not be an unmixed gain, and our finest college professors to-day endeavor to combine high special attainments as scholars with deep interest in the personal well-being of their students. The authority of the faculty is still sufficient, but is exercised differently. Student self-govern-ment is the order of the day, and the more this prevails the less is exercise of faculty authority found to be necessary. The presidents of our larger colleges, and even of many of the smaller, are becoming more and more admin-istrative officers and less and less teachers. It is no doubt something of a loss that the students should not have the intimate personal acquaintance with the president enjoyed by students a generation ago, but mere numbers fre-quently make this impossible. Out-of-door sports have also entered to modify and improve the spirit of our academic life. They have de-veloped their own evils, but at the same time have done wonders for the physical health of the students, the diminution of student disorder, and the fostering of an intense esprit de corps. In the reaction from the asceticism of early college life there is little doubt athletics have gone too far. But the abuses of college athletics can be corrected, and are to some ex-tent self-correcting.

Nearly all our colleges are avowedly or im-pliedly Christian. A respectable minority of them are Roman Catholic. The large majority are under Protestant influences, which are seldom denial of moral. The student is expected to attend certain religious exercises, such as morning prayers; but often all such attendance is voluntary. The religious life of the under-graduates finds its expression in various societ-ies, which endeavor to promote the Christian fellowship and life of their members. While moral and religious convictions are freer and sometimes laxer than of old, the Christian life in our colleges is real and pervasive.

As a rule the student is so absorbed by the scholastic, athletic and miscellaneous activities of college that he should not think of his college life. This is particularly true in colleges which enjoy academic seclusion amid rural surround-ings, for here more than anywhere else is to be seen the natural unperturbed outworking of the undergraduate spirit.

Development of Elective Courses.—The non-scholastic aspects of our present college life are important in that they give tone to the whole picture, but they do not account for the great transformation which has been wrought for that transformation is distinctively it. It is caused by the increase of students, their better preparation and their greater age. The studies which made up the curriculum leading to the old bachelor of arts degree are now being completed before the end, sometimes by the middle of the college course. There is to-day no reason why a young man of 20 should not know as much as his father knew at 20. But at 20 his father had graduated with the bachelor of arts degree, whereas at 20 the son is only half way through his college course. As this fact forced itself upon the older and stronger colleges, experiments were made in granting a limited amount of elective freedom to students in the latter part of their course; first in the senior year and then in the junior year, until in some instances the whole four-year course is elective. Under these conditions a student may obtain the bachelor of arts degree without studying any science, or he may omit his classics, or he may know nothing of philosophy. To-day the problem of the rela-tion of prescribed to elective studies is a ques-tion of constant interest and perpetual readjust-ment. The solutions offered are many.

The first proposal, which has now scarcely an advocate, is plainly an impossible one. It is to insist on the old-fashioned four-year pre-scribed course. But the old-fashioned course cannot be restored, because it no longer suits our age. Young men will not go to college and remain there until the age of 22 years without some opportunity to exercise freedom of choice in their studies.

The second proposal is to constitute the undergraduate course entirely, or almost entire-ly, of elective studies. It is argued that when a young man is 18 years of age, he is old enough to choose his liberal studies, and it is by no means certain that his choice will be as satisfactory as that of those who choose themselves or who are guided more indi-vidually than any prescription the wisest college faculty may make. The advocates of this view admit its dangers. They see the perils of incoherence and discontinuity in the choice of studies. They see that many students are influenced, not by the intrinsic value of the studies, but by their liking for this or that instructor, or the companionship of certain students, or for the easiness of certain crowded courses. Yet they argue that the college student must be free at some time, that his sense of responsibility will be developed the sooner he is compelled to choose for himself, and that he will have the stimulating and sobering consciousness that what he does is his own act and not the prescription of others for him.

Those who oppose this view argue that the academic freedom here proposed belongs to university rather than to college students; that the American freshman is not a university student in the sense in which that term has been commonly understood in the educated world, because of his immaturity of mental growth, and his mental immaturity as compared with the English and Continental student. If, therefore, he is to be as well educated as they are, some of his time in college, the first two years should be spent in rounding out and en-larging his properly secondary education before entering upon that elective freedom which has a place, and a large place, in our present under-graduate courses.

A third proposal is a conservative modification of the one just mentioned. It is to pre-scribe groups of cognate studies with the object of concentrating attention on related sub-jects in that field which the student may prefer. The advantage claimed for this mode is that it allows the student to choose the field of study he likes, and then make his course consistent and coherency by requiring him to pursue a group of well-related courses in that field. The advoca-tes of wider freedom object to this as fet-tering spontaneity of choice, as not recogniz-ing the fact that there are many students for whom it is advantageous to choose a study here and there at will, as a piece of side work outside the chosen field of their activity. The objection to this plan of restricted groups and
also to the plan of practically unrestricted freedom is that it offers temptations to premature specialization at the expense of broad intellectual and cultural development.

Still another proposal remains to be considered. Its followers urge that the best type of liberal education is to be found in the historic academic course, which has been the center and strength of American college life. They concede that in the early course certain courses may give a valuable education to many, provided these courses are consistently organized. They hold that it is possible to ascertain with sufficient exactness just what studies ought to be prescribed as integral parts of these courses, and that the preliminary training given in these prescribed studies develops maturity in the young student and enables him to choose intelligently his later elective studies. At the present time, in their view, it is not wise to introduce a liberal education in the middle of the college course. These studies should be organized and related in a system, and connected with the underlying system of prescribed studies. The principle of freedom should be introduced in the elective system, and should lead to complete freedom as soon as it is clear the student is able to use it well. A form of this view which finds a good deal of support is that elective studies should be introduced first of all in the form of extensions of subjects already studied by the student, in order that he may make his first experiment of choice in an area where he is most familiar. According to this view the second stage of elective studies should be the introduction of large general courses in leading subjects, accompanied by special courses for students of exceptional ability in special directions, and finally leading to as high a degree of specialization as the resources of the college will allow.

Modes of Instruction.—Instruction is still mainly conducted by recitation and lecture, the recitation finding its chief place in the earlier and the lecture in the later part of the course. For purposes of recitation the classes are divided into sections of 25 or 30 students, and the lecturer divides his allotted portion of some standard textbook. Much has been done to improve the character of this exercise. The correction of mistakes, the attempt to lead the student to discover the cause of his mistakes, and the endeavor to teach the entire class through the performance of each individual, are the aim of the more skillful instructors. The professors most skilled in the art of conducting recitations, rather than those who depend wholly on lectures, leave the most abiding impression. While instruction by recitation continues with effectiveness in the latter part of the course, especially with smaller groups of students, yet instruction by lecture is the rule. The lecturer may have to face a class which enrolls as many students as the whole college contained a generation ago. He delivers his lecture, while those before him take notes, or as they listen read a printed syllabus prepared for the use of the class, and add such jottings as may seem desirable. In many lectures the recitation instructor is employed as an effective auxiliary. The "perceptorial" mode of counsel and supervision, in vogue at Princeton since 1905, has been valuable in meeting the difficulties of individual students, taken in small groups. Other forms of instruction find place. In all except elementary courses in science the laboratory plays a most important part, and even in lectures in introductory physics, chemistry or biology full experimental illustration is the rule. The library serves as a sort of laboratory for the humanistic studies. Students are encouraged to learn the use of the college library as auxiliary to the regular exercises of the curriculum. Certain books are appointed as collateral reading, and the written examination at the end of the term often takes account of this outside reading. That prolonged reading, which gives such wide and assuring acquaintance with the important literature of any subject, is as yet unattempted in a really adequate degree.

The academic year is divided into two (sometimes three) terms. At the end of each term the student is required to pass a fairly rigorous set of examinations. Here the examinations have largely disappeared. Very rarely a high record of attainment in recitations during the term entitles a student to exemption from examination. In awarding honors the old academic college confused itself and should lead to complete freedom as soon as it is clear the student is able to use it well. A form of this view which finds a good deal of support is that elective studies should be introduced first of all in the form of extensions of subjects already studied by the student, in order that he may make his first experiment of choice in an area where he is most familiar. According to this view the second stage of elective studies should be the introduction of large general courses in leading subjects, accompanied by special courses for students of exceptional ability in special directions, and finally leading to as high a degree of specialization as the resources of the college will allow.

Student Life.—At 18 the typical student of the older eastern colleges has completed a four-year course in some secondary school. He finds near at hand either the college entrance board's examination or a local entrance examination conducted by a representative of this intended college. The days and exact hours of examination and the examination papers are the same as for the examination held at the college. His answers are sent on to be marked and estimated. In a week or two he receives notice of his admission to the freshman class. Having passed his entrance examinations, he is now entitled to secure rooms in one of the dormitories, or else to find quarters outside the college campus in town. In the following autumn his name is enrolled in the matriculation book and his student career begins. His newness and strangeness naturally make his first notice on the part of the older students, especially those of the sophomore class. But these annoyances soon cease unless he be vain or "very fresh." The daily round of college exercises demands his attention, and in the classroom he begins to pass through a process of attrition more beneficial in its spirit. Under the steady measuring gaze of the instructor, and the unuttered but very real judgment of
his classmates who sit about him, he begins to measure himself and to be measured by college standards. He is learning something not down in the books, and what he is thus discovering is well illustrated in the words of Professor Hibben: "There is a fair field to all and no favor. Wealth does not make for a man nor the lack of it against him. The students live their lives upon one social level. There is a deep-seated intolerance of all snobishness and pretension. The dictum of the 'varsity field, 'No grandstand playing,' obtains in all quarters of the undergraduate life. It signifies no cant in religion; no pedantry in scholarship; no affectation in manners; no pretense in friendship. This is the first and enduring lesson which the freshman must learn. He learns and he forgets many other lessons, but this must be held in lively remembrance until it has become a second nature." His college comradeship continues and constitutes his social world.

In addition to this ever-present gregarious comradeship which environs and inspires him, our entering freshman finds the deeper intimacies of close individual friendship. As a matter of course he has some one most intimate friend, generally his chum. Side by side they mingle with their fellows. They stand together and, it may be, they fall together, and then rise together. And thus the class is paired off, and yet not to the lesserening of the deep classly fellowship. Here indeed is a form of communism, temporary and local, but most intense. They freely use things in common, not excepting the property of the college. They are welcome to enter each other's rooms at pleasure and use their friends' tobacco and stationery, or to borrow such articles of furniture and bric-a-brac as will brighten their own rooms for some special occasion. Money, however, stands on a different basis from other valuables. It is freely loaned for an indefinite time, but is strictly repaid. A student who lends his fellow money at interest cannot live in a college community.

Our student, unless he is an unusual recluse, takes some part in athletics. If he is not able to win a place on the football team or basball nine or crew, or as a director or manager of his alma mater in intercollegiate contests, he is very likely to be found playing ball in some organization improvised for the day, or trying his hand at tennis or golf.

He has still other interests outside the curriculum. He may be a member of the voluntary religious society of the students. Perhaps he gets a place on the glee club or dramatic club. He may become one of the editors of the daily college paper or of the monthly literary magazine. Perhaps he is manager or assistant business manager for one or another undergraduate organization. Then there are the whist clubs and time-consuming chess clubs. There are also circles for outside reading and discussion springing up around the course of study as well as the societies which train in speaking and debating. Perhaps he may win the distinction of representing his college in an intercollegiate debate, and success in intercollegiate debating is highly coveted. The contests are generally desired. For debating and athletics form the principal bond of union between the different colleges and give to their participants intercollegiate distinction.

Until the student passes out of freshman year, he is not always free to choose what kind of clothes he will wear. In some colleges freshmen are not allowed to wear the colors, except on rare occasions. But as soon as he becomes a sophomore he is free to do as he likes. Then he and his classmates suddenly appear wearing various hats, picturesque and often grotesque in appearance, and revel particularly in poling suits. Toward the close of the course their daily dress becomes more conventional, though the universal interest in athletics continues to affect the student mode to the end. He has other amusements besides athletics, and these again are found in the student circle. His briarwood pipe goes with him almost everywhere. In the evening, when the work of the scholastic day is done, he sits with his comrades at an unconventional 'smoker' or else they may gather round the table of some college restaurant. At such evening sessions the different phases of student politics are discussed again and again. College songs are sung, the air being carried in that sonorous baritone which is the dominant sound in all our student music. Tales and jests fill out the hour. At the end the college cheer is given as the men start strolling homeward, singing as they go. Arrived on the campus they disperse, and their good-night calls echo from the doors and windows of the different dormitories. And the day ends where it began; within that closed circle where every student lives in "shouting distance" of the others.

Our former freshman is getting on bravely toward the end of his course. The closing months of senior year pass swiftly. His class procession is preparing to march out into the world, and there take its place as a higher order of freshmen in the long file of the classes of alumni advancing with their thinning ranks toward middle manhood and beyond,—and when commencement is over his undergraduate life is ended.

What has he acquired in the four years? At least some insight into the terms and commonplaces of liberal learning and some discipline in the central qualities which represent his alma mater in intercollegiate contests, he is very likely to be found playing ball in some organization improvised for the day, or trying his hand at tennis or golf.

which explains the active interest shown by our alumni. In the best sense they advertise their college to the public, and it is to their exertion that the reputation and maintenance of many of our colleges is largely due.

Organization and Administration.—The form of government is simple. A college corporation, legally considered, consists of a body of men who have obtained the charter and who hold and administer the property. Where a particular State has established a college or even a university, which regularly includes a college, the members of the corporation are commonly styled regents, and are appointed by the State to hold office for a limited term of years. But most colleges have been established as private corporations. In this case the title is vested in a board of trustees, sometimes composed of members who hold office for life, or else composed of those associated with others who are elected for a term of years. Boards of trustees holding office for life usually constitute a close corporation, electing their own successors as vacancies occur. The two chief functions of such governing bodies, as well as those of any other name, are to safeguard the intent of the charter and to manage the property. They give stability to our college system. To carry out the main purpose for which the charter was obtained they create a faculty of professors and instructors and entrust the general headship to a president. The president and professors usually hold office for life. In many places provision is made for the retirement of professors on pensions as they grow old. This is usually done with help from the Carnegie Foundation. Instructors and sometimes assistant professors are appointed for a limited time, such appointments being subject to renewal or promotion. In the larger colleges the president is assisted in his administrative work by one or more deans. By immemorial tradition the president and faculty are charged with the conduct of the entire instruction and discipline. They have the power to admit and dismiss students. The conferring of degrees belongs to the corporation, but this power is constitutionally exercised according to recommendations made by the faculty. Honorary degrees, however, are commonly given by the trustees or regents on their own initiative.

In State colleges the income is derived from taxation; in others from endowments, often supplemented by annual subscriptions for special purposes. But the private colleges are cut off from dependence on the State, and have to rely on private gifts. This stream of private liberality flows almost unceasingly. The fact that many colleges are integral parts of real or so-called universities makes it difficult to say how much the specifically collegiate endowments and incomes amount to. But a few significant facts may be mentioned. No college president, unless he is at the same time the president of a university, receives as high a salary as $10,000 annually. He is more likely to receive $5,000 or $6,000. While $2,000 is considered a fair professor’s salary in small colleges, $3,000 is a usual salary in the larger colleges, while few professors receive more than $4,000.

The expenses of individual students vary greatly. In some places there is no charge for tuition; in others they must pay as much as $100 or $150 or more. In little country colleges the total cost for a year often falls within $300; in the larger old eastern institutions, patronage from all parts of the land, the student who must pay all his bills and receives no aid in the form of a scholarship can hardly get along with less than $600 or $700, exclusive of his expenses in the summer vacation. The average expenses in some of the oldest colleges, according to tables prepared by successive senior classes, is higher than this, running up to $800 or $900, or even more. But these institutions afford the student of limited means multiplied opportunities of self-help. In more recent years many colleges possess scholarships which are open to able students who need temporary pecuniary help. The young American of narrow means, if he be of fair ability and industry, can almost always manage to find his way through college.

The College Is American.—The college lies very close to the people. Distinctions of caste may manifest themselves occasionally, and yet the college is stoutly and we believe permanently democratic. The instruction of the college side of our national life has been profoundly intimate from the beginning. The graduates of Harvard and Yale in New England, of Princeton and Columbia in the Middle States, and of the College of William and Mary in Virginia contributed powerfully to the formation of our republic. Edmund Burke attributed the "intractable spirit" of the Americans to their education, and by this he meant the college education. "The colleges," wrote President Stiles, of Yale, shortly after the Revolution, "have been of signal advantage in the present day. When Great Britain withdrew all her wisdom from America this revolution found above 2,000 in New England only, who had been educated in the colonies, intermingling with the people and communicating knowledge among them." John Adams of Harvard delighted to find in President Witherspoon of Princeton "as high a son of liberty as any in America." Hampden-Sidney College in Virginia, founded about the time of the Revolution, incorporated in its charter the following clause: "In order to preserve in the minds of the students that sacred love and attachment which they should ever bear to the principles of the ever-glorious Revolution, the greatest care and caution shall be used in selecting such professors and masters, to the end that no person shall be so elected unless the uniform tenor of his conduct manifest to the world his sincere affection for the liberty and independence of the United States of America." And from that day to this the collegiate spirit and the national spirit have been at one. Rightly, indeed, did our appreciative French visitor, Baron Pierre de Coubertin, perceive that the place to find "the true Americans" is in our college halls; "les trois Ameri- cains, la base de la nation, l’espoir de l’avenir." Scarcely one in a hundred of our college youths of college age has gone to college. But this scanty contingent has furnished one-half of all the Presidents of the United States, most of the justices of the Supreme Court, not far from one half of the Cabinet and of the National Senate, and almost a third of the House of Representatives. It has furnished a great contingent to the professions and almost the
entire personnel of the best faculties of law, medical and divinity. It is increasingly represented in business and engineering and the leading newspapers and reviews. No other single class of equal numbers has been so potent in our national life. See American University; College, Entrance Requirements.

Andrew Fleming West,
Dean of the Graduate School, Princeton University.

American College in Rome, Italy. This pontifical college, the legal title of which is "The American College of the Roman Catholic Church of the United States, Rome, Italy," was founded 8 Dec. 1859 by Pope Pius IX for the purpose of training young men for the Catholic priesthood in the United States of America. A tablet in the building commemorates the visit of Pius IX on 29 Jan. 1860. By a pontifical decree it was placed under the direction of the Congregation of the Propaganda, the students being obliged to attend the courses of lectures given at the University of the Propaganda. The regular course embraces two years of philosophy and four years of theology, while preparatory classes are held for students who have not completed the college course in their own country. The American College opened with 12 students, three of whom afterward became archbishops: Michael Corrigan, of New York; Patrick Riordan, of San Francisco; and Robert Seton, titular of Helopoli. Ruben Parsons, the historian, was also one of the original 12. The college has trained many distinguished churchmen during its existence of 58 years. It is administered under the control of a board of four archbishops, those of New York, Boston, Philadelphia, and Baltimore. The officials immediately in charge are the rector, vice-rector and spiritual director. Thanks to the solicited intervention of President Chester A. Arthur in 1884 the college was saved from confiscation by the Italian government by virtue of statutes of 1852 and 1860 applying to the property of religious bodies.

American Commerce. See Commerce.

American Commonwealth, The, an important study of American political, social and economic conditions by James Bryce, the eminent historian of "The Holy Roman Empire," Part I treats of the Federal government. Part II considers the State governments (including rural and city governments), their departments, constitutions, merits and defects. Part III is devoted to the political machinery and the party system. Part IV discusses public opinion,—its nature and tendencies. Part V gives concrete illustrations of the matters in the foregoing chapters. Part VI is concerned with non-political institutions. The work is lucidly written and as easy for the laity to comprehend as for those familiar with the practical workings of our government. The chapters dealing with the professional and social sides of American life, and especially those devoted to the American universities, have been enthusiastically received by Americans.

American Conflict, The, an account of the American Civil War and its causes, by Horace Greeley. It is a great magazine of materials for the political history of the United States with regard to slavery.

American Cousin, Our, a well-known play by the English dramatist, Tom Taylor (1858). It was very popular just before the sixties, and it was while present at its representation in Ford's Theatre in Washington that President Lincoln was assassinated.

American Dialect Society. The need of an American dictionary like the English Dialect Dictionary, to record peculiarities of local American speech, led to the formation at Harvard University, under the auspices of James Russell Lowell and Francis James Child, in 1889, of the American Dialect Society. Since 1890 the society has issued annually (now semi-annually) a periodical, Dialect Notes, containing word lists and short articles which have dealt with some 20,000 terms. This may be found in the libraries of most large cities and colleges. The members, chiefly teachers in universities and colleges, meet annually in December in conjunction with the Modern Language Association of America, and read and discuss papers. The society is not limited to the speech of districts, the phraseology of occupations, as whaling, mining, and cowboy lingo, are considered; and the influence of foreign languages receives some attention.

American Diplomacy. It may be justly claimed that the United States, in its brief existence, has exercised a greater influence in the same period in molding international law than any other nation; and it has done much to raise the standard of diplomatic practice. From the beginning it has stood as the champion of a freer commerce, of respect for neutral and private property in war and of the most elevated ideas of national rights and justice.

When the United States entered the family of nations, there existed a marked contrast between the state of law which controlled the rights and intercourse of nations and that which enforced the rights and duties of the individual inhabitants of the respective nations. The civil law, which was in force in most of the countries of continental Europe and their colonies, was the accepted product of the ripened experience of many centuries of social life. The common law which prevailed in England and its colonies had been brought into an established system through the careful study and practical application of successive generations of renowned jurists. But the law of nations was then in its infancy. Only one century had passed since Grotius, who has been styled the father of international law, had compiled his treatise on the "Rights of War and Peace;" and Vattel had but recently published his "Law of Nations," and the principles he enumerated were far from being an accepted code. International law was still in a formative stage when the United States began its career. The latter had scarcely entered upon its organized life when the wars consequent upon the French Revolution forced it to consider its rights and duties as a neutral power. It soon learned that there were no established principles which warring nations respected. In referring to its early history, a Secretary of State in 1853 said to the British Minister of Foreign Affairs:
From the breaking out of the wars of the French Revolution to the year 1812, the United States knew the law of nations only as the victim of its systematic violation by the great majority of powers. Even then...

The first effort on its part toward the maintenance of international rules of conduct was in President Washington's neutrality proclamation of 1793, which, within less than a generation, brought about a complete change on this important subject. The paramount rule was the simple announcement of the neutral attitude of the government, and a warning to American citizens to observe it. But the significance of the act was in the strict impartiality of its enforcement, and the resulting legislation of Congress, which became a model for all other nations.

The power of the President to issue such a proclamation based solely upon the principles of international law, without any domestic legislation respecting offenses against neutrality, was seriously questioned, and in 1794 an act was passed defining what were offenses against neutrality and affixing penalties therefor. During the revolt of the Spanish-Americans colonies so much so that was compendious in the United States authorities that the law was carefully revised in 1818, and it has since practically remained unaltered. Hall, one of the latest English authorities on international law, says: "The policy of the United States in 1793 constitutes an epoch in the development of the usages of neutrality. . . . It represented by far the most advanced existing opinions as to what the obligations of neutrality were. . . . In the main it is identical with the standard of conduct which is now adopted by the community of nations."

The American colonies, in assuming their independence, established a diplomatic service similar to that of the European countries and it has continued to be so maintained. But the question has often been raised in and out of Congress whether, in the existing conditions of the world, the system is necessary and its utility justifies its expense. With many in the country the diplomatic service is regarded as a purely unproductive expense, and its maintenance a useless expenditure of public money. But whenever the question has been made the subject of inquiry by Congress, the various Presidents and Secretaries of State have given their opinions in favor of the utility and necessity of the service, and Congress has continued to authorize it; and it has come to be accepted as a permanent branch of the government.

While the United States has adopted the European system of a diplomatic and consular service, in one important particular the general practice of other nations has not been followed. The service is not made a life career, and no examination or previous experience is required for admission to the posts of minister or ambassador. Appointment of persons usually from civil life, and without any previous diplomatic experience. The two systems have their advantages. It does not necessarily follow that because a young man can pass a successful examination he is destined to make an able minister or ambassador. The British and other governments have frequently found it necessary to appoint to the highest posts in the diplomatic service persons from other branches of the administration or from civil life. On the other hand, the system followed by the United States exposes the government to the public sometimes to mortification and ridicule because of the inexperience or inaptness of its representatives. But appointments to the higher posts are generally of persons who have served and gained distinction in legislative bodies or in the professions, and although not experienced in the arts of diplomacy, they are usually able to cope with their colleagues on all subjects where great principles are involved. There is a growing sentiment, however, in the country in favor of at least placing the appointments as secretaries of legation and to the consular service upon a permanent basis. Under rules established by executive order no person is now admitted to the places of secretary of legation or in the consular service without first success in the examination, and promotions from the lower to the higher grades are based upon merit. This action has tended to give stability to these branches of the service.

Up to recent years the highest grade in the diplomatic service of the United States has been that of minister plenipotentiary, but these representatives sometimes complained that they were often humiliated and their usefulness sometimes impaired by the lower positions to which they were assigned in the diplomatic corps. The remedy suggested was to raise the rank to that of ambassador. Secretary Marcy declined to make the recommendation to Congress in 1856. A similar position was taken by Secretary Frelinghuysen in 1894, who said it would be an injustice to the ministers to give them higher rank without increasing their salaries, and that Congress would not vote the allowance commensurate with the mode of life of an ambassador. Later Secretary Bayard claimed that serious inconveniences would result from introducing "into our simple social democracy . . . an extraordinarily foreign privileged class."

Notwithstanding these objections, in 1893 Congress authorized the appointments of ambassadors to countries whose governments would reciprocate in such grade, and ambassadors are now sent by the United States to London, Paris, Berlin, Petrograd, Vienna, Rome and Mexico. Soon after the reception of ambassadors in Washington the question was raised whether they should have precedence over the Vice-President, but it has been decided against them. The "inconveniences" anticipated by Secretary Bayard have been experienced on more than one occasion, but the innovation seems to be permanently established.

The fiction of international law that ambassadors represent the person of their sovereign in a greater degree than ministers was created at an epoch when there was a recognized distinction between empires and monarchies and between these two grades and republics. All distinction between sovereign nations has been abolished and they now stand on an equality, but the ambassadorial pre-eminence is still recognized, even in the American democracies.

The diplomatic dress of the American representative, although an apparently trivial matter, has occasioned considerable dis-
discussion and a varied action on the part of the government. In the early years of its history the diplomatic representative was left without a commission, but with a right of negotiation under special instructions. When the commissioners to negotiate peace with Great Britain in 1814 went to Europe a simple uniform was adopted, and by a circular of the Department of State in 1817 this uniform was prescribed for the diplomatic representatives at foreign courts. This order was modified by President Jackson, up to the day of the revolution of 1853 in the United States, and then the uniform of the president's simplicity. In 1853 he issued a circular which became famous in diplomatic annals, in which the representatives of the United States were advised to appear on public occasions "in the simple dress of an American citizen" unless such costume was objected to by the court to which the representative was accredited. The circular was much criticized, but its spirit was practically approved by Congress in the passage of an act in 1867 prohibiting officials in the diplomatic service from wearing any uniform or official costume not previously authorized by Congress. As by law only officers of the army or navy or naval vessels authorized to wear a uniform in the diplomatic service, the great body of the corps came under this prohibition.

From the time of Dr. Franklin, the first minister to France, American diplomatic representatives have sought to be distinguished by entire frankness and straightforward conduct. This is indicated in the instruction to John Jay when he was sent abroad on an important mission by President Washington. The Secretary of State wrote: "It is the President's wish that the characteristics of an American minister should be marked on the one hand by a firmness against improper compliances, and on the other by sincerity, candor, and prudence, and by a horror of finesse and chicanery." Much is said in disparagement of the American diplomatic representative abroad, and it is not to be disguised that under the system of appointments some unfit and uncultured persons have been found in the service who have reflected little credit on the country. But their discreditable acts have been outdone by the misconduct of the representatives of foreign governments accredited to Washington. This misconduct has embraced flagrant violations of international law and practice, intermeddling with domestic politics, and official and social improprieties of various kinds. Within the first century after the organization of the government, a list was created of foreign diplomats dismissed by the government of the United States, or recalled in disgrace, which embraces three British ministers, two French, two Spanish, one Russian and one Austrian minister. No such record of dishonor can be compiled against American representatives as that made at the seat of government of the United States by the representatives of the most polished nations of the Old World.

The War of 1812, undertaken by the United States against Great Britain, was pre-eminently a struggle on the part of the former to maintain and enforce correct principles of international law. It involved the claim by Great Britain of the right of visitation of neutral vessels and the impressment of such of their crews as the visiting party saw fit; the doctrine that free ships make free goods, or the exemption of innocence in a neutral ship in time of war; and the paper blockades which were sought to be enforced by the warring powers. None of these questions were settled by the terms of the treaty of peace between the United States and Great Britain. But the contention of the United States that neutral ships have come to be accepted by all the nations of the world and by none of them more heartily than by Great Britain. The right of visitation and search of vessels was a frequent subject of negotiations, but while the British government relaxed the enforcement of its alleged right after the war, its claim was not finally abandoned until 1858, when it formally accepted the contention of the United States. A strange incident in connection with this question occurred soon after that date. During the Civil War the commander of a United States naval vessel arrested a British mail steamer, the Trent, on the high seas, visited her with an armed force and carried away as prisoners two Confederate diplomatic agents on route to Europe. In the United States the naval commander was hailed as a hero, but in England the act was regarded as an insult to the British flag and a just cause of war. A hostile conflict was avoided by the prompt surrender of the Confederate agents and a disavowal of the act, as in direct contradiction to the attitude of the government consistently maintained from its foundation of the immunity of the vessel carrying the American flag.

The claim of the right of impressment (q.v.) was connected with the subject of naturalization and expatriation, which has been the occasion of much diplomatic correspondence and controversy on the part of the United States with European powers. From the beginning of its existence the former has encouraged immigration; liberal laws for the naturalization of foreigners have been passed; and the right of expatriation has been maintained. In this branch of international law this attitude has had a marked effect upon the practice of nations. One of the chief causes of the War of 1812, it has been seen, was because of the impressment of seamen, naturalized citizens of British birth, taken from American vessels. The old common-law doctrine was that no British subject could denationalize himself and that he owed perpetual allegiance to the Crown; but the persistent claim of the United States was finally recognized by Parliament in the Naturalization Act of 1870. The doctrine of expatriation is now generally accepted by the nations and the United States has succeeded in having it embodied in many of its treaties.

The subject of free ships was given much prominence through the armed neutrality during the Revolutionary War, was one of the unsettled issues of the War of 1812 and was finally recognized as a principle to be incorporated into the international code by the great Powers of Europe, as embodied in the Declaration at Paris of 1856. This declaration consisted of four rules, which were, briefly stated, (1) the abolition of privateering; (2) the exemption from seizure of an enemy's goods under a neutral flag; (3) a like exemption of neutral
goods under an enemy's flag; and (4) that a blockade, in order to be valid, must be effective. All of these points were the object of long advocacy by the United States, and even the first had been incorporated in its treaty with Prussia of 1785. The latter was plainly in the interest of nations having a strong navy. Nevertheless, the United States was ready to accept them all as rules for the government of a long war, but Secretary Marcy proposed to the great Powers that they go one step further and declare that private property of belligerents at sea be exempt from capture. As private property of belligerents on land has been exempted by the rules of war, there would seem to be no sufficient reason why the same treatment should not be applied to like property at sea. President McKinley instructed the American representatives at The Hague Conference of 1899 to advocate it, but they were not successful. President Roosevelt continued to urge upon the nations this advanced measure to mitigate the ravages of war, but it has not yet been inserted in the international code.

The fourth rule of the Paris Declaration was, in effect, a formal recognition of one of the principles contended for in the War of 1812, that there can be no blockade by mere proclamation. Its application bore heavily upon the United States during the Civil War, but it consistently observed the principle by making its blockade of the Southern ports effective. An effort has been made of late years to establish what is known as a specific blockade, by which one or more states seek to bring constraint upon another state by closing its ports without a declaration of war. In the case of the blockade of Crete by the great Powers of Europe in 1897, the United States declined to concede the right as applicable to its commerce; and when a similar attempt was made in 1902 of a pacific blockade of Venezuelan ports by Great Britain, Germany, and Italy, the objection of the United States to its interference with American vessels led to the abandonment of the project and to the establishment of a real war blockade.

The subject of neutrality assumed an important development during the Rebellion, and the duties and responsibilities of a neutral state were the occasion of a heated controversy with the British government. Although the latter had incorporated in its laws the substantial provisions of the United States statutes of 1818, it disavowed from the position asserted by the United States as to its duties in the practical application of its acts of Parliament and the recognized principles of international law. The construction of Confederate cruisers in British ports and the aid afforded them in such ports was held to be a failure on the part of that government to discharge its duties as a neutral power, and for these acts the United States made grave complaint and filed a large claim for pecuniary damages. After these issues had been long submitted to the arbitration of a tribunal, which met at Geneva (see Geneva Convention). In the treaty providing for the arbitration there were inserted three rules as to neutrality which were given the arbitrators in their decision. These rules were based on the statute and mainly followed the contention of the United States. The result was a decision in favor of the latter, with a large award in damages. The two governments had agreed in the treaty that they would submit the rules to the other maritime powers for their acceptance, but this was never done, chiefly because of the extreme construction placed upon some of their clauses in the opinions of the neutral arbitrators. The general consensus of publicists is that these rules are a correct statement of existing international law.

The great European War has brought into discussion the various phases of the duties and privileges of neutrals, the freedom of the areas, the effect and requirements of a blockade, the attack on merchant ships by vessels of war and the changes in the modern methods of warfare. This discussion and the spirit of retaliation on the part of the belligerents, which has led to a disregard of heretofore recognized rules of international law, will make necessary a re-examination of these questions on the re-establishment of peace.

One of the conspicuous features of the relations of the United States with foreign nations is its readiness to accept arbitration for the settlement of questions that are not promptly susceptible of adjustment by diplomatic methods. It has been one of the foremost of the nations in advocating this method of arranging international complications, and in preserving peace by means of treaties of arbitration. The first treaty negotiated after the organization of the government under the Constitution—the Jay Treaty (q.v.) of 1794—was made with Great Britain to avert war which was then imminent. It contained provisions for the adjustment of three of the most irritating of the questions in controversy by a reference to arbitration, and three separate commissions were created for that purpose. The year following, the second treaty negotiated by the new government, that with Spain of 1795, also contained a provision for arbitration. The country was not so fortunate in its second controversy with Great Britain. The questions at issue were of such grave character that it did not seem possible at that day to settle them by any other method than a resort to war, but by the treaty of peace of 1814 and the subsequent stipulations were created to settle boundary questions. These all related to the frontier with Canada, which ever since the independence had been a source of almost constant discussion, often of angry controversy, and more than once had brought the countries to the brink of war. But in every instance when the usual method of diplomacy failed, arbitration has been resorted to with success.

During the two generations which followed the War of 1812 all questions of controversy with foreign powers, with one exception, have been settled by peaceful methods. In that period the United States created many courts and commissions of arbitration. The most of these have been with Great Britain, but more than 20 of them have been with other nations of Europe and America. The controversy growing out of the manner in which the British government enforced the neutrality laws during the Civil War for a time threatened the peaceful relations of the two countries. When the offer of the United States to submit the controversy by arbitration was made, the British government in the first instance assumed the position that its national honor was involved, and
that that could not be submitted to arbitration. But better counsels prevailed, and the Tribunal of Geneva was created to adjust the controversy. It was the most important arbitration in which the United States ever engaged, and was one of the most august and imposing ever held in the world. It involved questions of supreme importance and pecuniary claims of great magnitude; but its special significance was in the spectacle of two great nations being able to compose weighty matters, which had awakened the passions of their people to a high state of bitterness, by an appeal to reason and the arbitration of friendly powers in place of war.

Next in importance for the United States to the Geneva arbitration was that relating to the protection of fur seals in Bering Sea, held in Paris in 1893. The decision of the tribunal was against the contention of the United States, and as a result it had to pay about half a million of dollars in damages and sustained a heavy loss in its annual income from the seal islands. Disappointment was felt over the result, but the mature judgment of the country is that it was a wiser settlement of the questions at issue than to push them to the extreme of war.

One feature of the many arbitrations in which the country has engaged is worthy of special notice. A spirit of equity and fair dealing has always marked the conduct of the government in cases where any suspicion of fraud or exaggerated damages has attached to arbitral decisions. The commissions with Venezuela, Haiti, Mexico and other countries might be cited in illustration. They show that, though the government is sometimes misled by designing claimants or by the unwise action of its diplomatic agents, it has not hesitated when fully possessed of the facts to undo any injuries inflicted upon friendly powers by means of international commissions, and that fraud, once exposed, cannot reap the benefit of its iniqity under the cover of the finality of an award.

The Alaska Boundary Tribunal of 1903 is an instance of the settlement of a question not possible of adjustment by diplomacy and not deemed appropriate for reference to arbitration. A court was constituted, composed of three members from each country, and they were empowered to judicially settle the questions submitted to them. The danger feared was that there would be an equal division of the court, but in this case the matter was settled by an award rendered by a majority of the members which has been accepted by both governments.

This brief review shows that in its short career the United States has had an important part in molding the code of international law. The chief actors in the work done by this country have been the Secretaries of State and its diplomatic representatives abroad. But they have had worthy coadjutors in giving this code shape and permanence. The exposition of the law as made by the justices of the Supreme Court of the United States, has had a great influence in molding that law, and its opinions are recognized as of the highest authority by foreign publicists. Among authors in this department of law none carry greater weight throughout Story, Kent, Wheaton, Halleck, Woolsey, Wharton and other American writers. When the services are recalled of these diplomatic, judicial and scholastic representatives of the United States, it is but to say that no body of men in any country have done more to improve and enlarge the principles of international law, or have exercised a more salutary influence on the affairs of the globe. See Arbitration, International; Diplomacy; International Law; Monroe Doctrine; United States—The Diplomacy of.

JOHN W. FOSTER.

AMERICAN DIPLOMATIC RELATIONS. For the diplomatic relations of the United States with other countries see the articles on the diplomatic relations with the various nations under their respective titles, Africa; Austria-Hungary; Canada; China; Cuba; Great Britain; France; Germany; Italy; Japan; Russia; Spain, etc.

AMERICAN ECONOMIC ASSOCIATION, The. This association was organized in 1885 at Saratoga, N. Y. The purpose of the association is: (1) The encouragement of economic research, especially the historical and statistical study of the actual conditions of industrial life; (2) the issue of publications on economic subjects; (3) the encouragement of freedom of economic discussion. It has at present a membership of 2,500, composed of persons interested in the study of political economics or the economic phases of political and social questions. It has published many volumes consisting of papers on economic questions, and the association also issues a quarterly publication, The American Economic Review. The association holds an annual meeting, when papers are presented on economic questions, which are afterward published in the Proceedings of the Association and furnished free to all members.

AMERICAN ELECTRO-THERAPUTIC ASSOCIATION, a society formed in 1890 for the promotion of knowledge, which ever relates to the application of electricity in medicine and surgery. Membership 280.

AMERICAN EMBARGO. See Embargo.

AMERICAN ENTOMOLOGICAL SOCIETY, an association for the investigation of the character and habits of insects, founded at Philadelphia in 1859, incorporated in 1865, and known until 1867 as the Entomological Society of Philadelphia. The results of its investigations are published in its Proceedings and Transactions, beginning in 1861, and also in the Entomological News, the latter issued monthly with the co-operation of the entomological section of the Academy of Natural Sciences of Philadelphia. It owns a valuable entomological collection and library. Membership 140. Office of the Secretary, Philadelphia, Pa.

AMERICAN EXPANSION POLICY. There is no more significant movement in modern history than that of the migrating process which, by receiving its start from economic conditions and breaking barrier after barrier, swept across the American continent within the last century and finally established American influence and enterprise in the Pacific and at the portals of the awakening Orient. The feverish, ceaseless, onward movement from the tidewaters of the Atlantic coast, slow at first, but gradually gaining momentum
and force, furnishing new opportunities to interest and awaken delinquents, creating new necessities to stimulate inventive genius, adding territory after territory to the American Union, and extending American commerce and beneficent influence to distant lands and peoples, is a great fact in American history. Expansion, non-parasitic, vigorous and attractive, developing by affinity, contending against both restriction and secession, has been America's greatest feat. Expansion of national territory, which in earlier American history was a strong policy, has, with few exceptions, arisen from natural forces or some vital issue— from the necessity of meeting internal or foreign difficulties or from political and economic questions—and probably was inevitable. Although the opposition to slavery was an obstacle to expansion, the Southern desire to extend this institution was an important factor in all the acquisitions and the demands for expansion from 1820 to 1860. In the decade before 1860 annexation was urged by the congress of the International Nuisance. Jealousy or fear in regard to the plans of some European power exerted no considerable influence in determining the policy to incorporate Louisiana, Florida, Texas, California, Oregon, Alaska and other territories. In this ground the acquisition of Cuba and Yucatan was also urged. Although some acquisitions have been made by war, the greater part have been obtained under the desire to prevent war. The American policy, with few exceptions, is one of negotiation directly with the governments exercising authority over the territory desired, but in many instances diplomacy contributed principally to justify and confirm expansions already made by the people. The processes of annexation were mainly the fruit, not of artificial intrigue and machination, but of the natural economic and social development of people chiefly engaged in the great human occupation of making a quiet living by agriculture. Each acquisition excited both domestic and foreign opposition and also pessimistic prophecies; but time has proved that extension to the Gulf and to the remote Pacific added strength to the Union. In the dark days of the Revolution there was a buoyant American spirit urging that the Union should include Canada, British West India Islands and even Florida; but American expansion began with Clark's invasion of the Northwest, which aided American diplomacy to secure the extension of the western boundary to the Mississippi in the treaty of 1783. The Constitution of 1787 did not expressly provide for annexation of territory but its makers forewove annexation. In 1791, Jefferson, the great American expansionist, who had already favored exploration westward to the Pacific, acting as Secretary of State under Washington, opened negotiations for the acquisition of Florida and New Orleans from Spain. In 1803, as a result of the western struggle for the mouth of the Mississippi, driven by necessity and accident, before he knew exactly what he was doing, he began the American policy of peaceful expansion by the purchase of a vast empire, setting American bounds to the Rockies, bringing doubtful titles to Florida, Texas and Oregon, and making further expansion necessary and a great united nation possible. Already (in 1801) he had looked forward to the time when American multiplication shall expand itself and cover the whole northern, if not the southern, continent. In this he probably expressed an idea similar to that advocated by William Thornton in favor of extending the republican age in America, and South America and the adjacent islands, under 13 distinct sections but united by one central government on the Isthmus of Panama. Later, in 1816, T. L. Halsey, writing to Monroe from Buenos Aires, indicated that it was the American policy, "that the whole continent of America should be united, at least in commercial relations." Jefferson's example was followed long after his authority ceased. The imagination of the pioneer soon passed the limits of the treaty, but with loyalty to the United States, to struggle for disputed regions or for regions clearly foreign. Madison, from apparent necessity, took temporary control of the Gulf shores from the Mississippi to the Mobile and, in the War of 1812, planned expansion for the Mississippi and Canada. Monroe, for the same reason, seized Amelia Island and Galveston, finally extended the American domains to the Florida straits, and said that the acquisition of Cuba might become necessary to the internal tranquility and prosperity of the United States. By 1820, the national road and the steamboat were beginning the large influence which they later had in the development of the West and the Americans were preparing to make settlement on the far-away Columbia. Monroe, in 1822, discouraged the wishes of Guatemalans and Cubans for annexation. Jefferson, although opposed to annexation that would require the construction of a navy to defend it, favored the annexation of Cuba. John Quincy Adams, who in 1820 suggested the occupation of territory in the South seas and foresaw American destiny in the West Indies (especially in Cuba and Porto Rico), later announced that he was inclined to seek no acquisition of non-contiguous territory. His efforts in 1825 to purchase Texas which had been given up in 1819 were followed by the premature Fедродian republic of 1826 which foreshadowed the later struggle for Texan independence. Jackson continued the negotiations for the purchase of Texas, and also wished to acquire territory that would include the Bay of San Francisco on the Pacific, but he expressed no desire for insular possessions. In his administration, the natural course of events was preparing for expansion along the Gulf toward the Rio Grande; and in 1837-38 citizens along the northern frontier were ready to aid the movement for Canadian independence as a step toward annexation. In 1843, Oregon through an organization for the protection against wolves established a provisional government in preparation for American occupation. In 1844, American consuls in California were planning for American occupation to prevent supposed European designs for annexation. In 1845, after the annexation of Texas, the opportunity to meet American needs on the Pacific was furnished by the Texan boundary dispute, which enabled Polk to acquire a vast territory on the Pacific, and thereby to lay the foundations for making the United States a great railway nation and an arbiter in the affairs of
the Pacific. American expansion to California, increasing American interest in the Pacific and resulting in negotiations for isthmian transit routes across Mexico and Central America, stimulated agitation and negotiations for territory or protectorates both in the Pacific and in the Caribbean-Gulf region. In the twelve-year period of pro-slavery land hunger which followed, there were plans for acquisitions in Central America and Mexico. Many prominent men advocated the acquisition of isthmian and insular possessions, urging that the United States should hold the gate to the Pacific and the key which controlled it. They opposed the Clayton-Bulwer treaty because it restricted the right of occupying territory which might become necessary for the security of communications. Cuba, especially, standing warden to the Gulf of Mexico, having the institution of slavery which the South wished to see continued, and a system of commercial restrictions and arbitrary government which many others desired to see ended, became an object of anxious solicitude to a large party in the United States. Fulfilment of the policies by Congressional vote for the purchase of Cuba failed, and Fillmore considered that its incorporation would be perilous, but plans for its acquisition continued to be urged. Young America, intoxicated with the progress of a hundred years, and suffering from flights of oratory, joined hands with the slavery expansionists to preach from the text of "manifest destiny." Every addition to the territory of the American Union had given homes to European destitute and extended representative government, and it was now bold the peculiar institution led to the American nation was not to be circumscribed by narrow isthmuses and gulf streams. The feature which characterized the foreign policy of Pierce, and especially that of Buchanan, was the aim to achieve the long-desired result of securing control in the Gulf of Mexico, and the Americanization of the region thereabout. In 1856 Senator Bell of Tennessee said the Monroe Doctrine had become a doctrine of progressive absorption, annexation and conquest of Spanish America. The Pierce administration, continuing the controversy, opened negotiations for the purchase of Cuba, and, while Walker was filibustering in lower California, sent Gadsden to secure a large slice across Mexico from the Gulf to the ocean, but secured only the Mexican territory along the Gila River. In 1856, after a riot at Panama, the Pierce administration, in order to protect the transportation of persons and property on the isthmus, un成功地 attempted to obtain (by treaty) from New Granada a belt of land 20 miles wide from ocean to ocean and certain islands in the harbors at each terminal for naval stations. Seward said it was hard to conceive how the United States much longer could avoid the expansion which had not only brought the Americans to this country, but also had brought the United States to confront the islands and coasts of Asia. The need of coaling stations in the Pacific, and of an inter-oceanic canal, had been urged, especially since the rapid growth of California. Commodore Perry, and the American surmise, had recommended the establishment of colonies in the Pacific at the gates of China and Japan. When Buchanan stepped into the shoes of Pierce he announced expansion to be the future policy of the country. He continued to press the necessity of purchasing Cuba and to call for intervention in helpless, bleeding Mexico, where he hoped to secure additional territory or to establish a protectorate; recommended the occupation of Sonora and Chihuahua; proposed to send land and naval forces to Central America in order to protect the transit route; threatened the Fiji Islands, and was favorably disposed to the annexation of Alaska.

The Civil War, inaugurating changes of policy and resulting in the abolition of slavery, ended the agitation for the extension of dominion over tropical peoples disturbed by dissenion and strife, although the difficulties of the blockade of Confederate ports emphasized the need of harbors in the West Indies. The Lincoln administration found little time for a policy of acquisition, although it contemplated acquisition of tropical territory for the colonization of free negroes, and, in order to prevent lower California from falling into the hands of the Confederates, was willing to buy or take it as a pledge for a loan to Mexico to meet foreign obligations which endangered foreign intervention. While warning Spain against intervention in Spanish America, and assuring her that her rights in Cuba and Porto Rico were respected by the United States, Secretary Seward significantly added that Cuba must not be used as a base against the American Union. Later in the war (1864), when Spain feared American designs on Samana, he said the United States already had ample territory. At the close of the war, when Maximilian slept and the Fenians blustered, the American government, in spite of various predictions and certain tendencies, showed no disposition to interfere with the operation of natural forces by embarking upon a policy of conquest. Encouraged by friendly inviting conditions in the Red River region and in British Columbia and instigated by the desire to compel England to pay large damages for injuries resulting from Confederate cruisers built in English yards flagging as the privateers of British America; but the American government under President Grant refused to adopt the "flag-withdrawal" policy. The purchase of non-contiguous distant Alaska, however, was regarded, not only as a friendly part of a general policy to extinguish European colonial connection in America, but especially as a step toward the annexation of Canada and other territory. In the same year a representative of the American navy formally took possession of the Midway Islands in the Pacific. The public mind was at the time too much absorbed in domestic questions to consider additional annexations. A treaty of 1867 for the purchase of the Danish West Indies was never ratified by the American Senate and another of 1869-70 for the purchase of Samoa was partly with a view to the solution of the race problem, failed of ratification in the Senate. During the Cuban insurrection of 1868-78 the American government in order to secure peace was ready to guarantee a payment by the Cubans to Spain for the Island of Cuba, but several times disclaimed any desire for the island.
In 1873, when events in Hawaii threatened to precipitate the consideration of the expediency of its annexation, Secretary Fish, while reflecting upon the possible necessity of future expansion into mid-ocean, said the acquisition of territory beyond the seas meant the opposition of discreet and influential leaders who could not be adopted without grave deliberation. In 1874, after considering the question of assuming control of the Samoan Islands as a protectorate, he doubted whether their position and importance would be sufficient to justify the engagement of the United States in a protectorate. In 1875, it was proposed to the Congress that the annexation of the islands to the United States be in effect until such time as the United States should determine whether the islands should be preserved as a part of the United States. In 1881, Blaine in his annual message to Congress solicited a bill for the annexation of the islands. Blaine in 1881 and Frelinghuyzen in 1883 said that the American policy tended to avoid the formation of a protectorate, and not to extinguish the natural rights of the islands. In the annexation of the Pacific islands by European powers and the decline of native races, the annexation of the islands to the United States has been delayed by the refusal of the United States to accept the voluntary offers of other powers to place themselves under American sovereignty and protection. In 1885, Bayard informed Germany that the recorded dispositions of the United States to accept the voluntary offers of other powers to place themselves under American sovereignty and protection showed that the American government had no idea of acquiring control of the islands. But in 1886 he added that the United States had an equal right with Germany to assert a claim of possession to the islands. The inevitable incorporation of Hawaii was only delayed by the refusal of Cleveland to accept the results of the revolution of 1893. The tendency to favor the acquisition of distant islands for protection of American interests was shown by the annexation of Hawaii as a national interest in 1898, and was increased as an inevitable consequence of the dismemberment of Spanish dominions by the War of 1898. At the close of the war, the American government, a desire to avoid occasion for future collisions with Spain, and to secure naval and cable stations and provide for commercial interests, demanded and obtained Porto Rico, Guam and the Philippine Islands, and secured the independence of Cuba which became practically an American protectorate.

The recent acquisitions in the Pacific are the logical development of the old-time policy of steady expansion of American interests in the Pacific and the Far East, although by the acquisition of the Philippines the government has taken a step farther than heretofore.

As the result of the change to steam power for war vessels, the United States still needs coaling stations in the southern oceans and in various parts of Asia, Africa and Europe.

The successful object-lesson of American regeneration in Porto Rico and of American responsibilities in Cuba and Panama—and more recently in San Domingo, Nicaragua and Haiti—may result in additional acquisitions in the West Indies; but American policy in the entire Caribbean region is to guide the weaker states and not to extinguish their nationality.

The acquisition of the Danish West Indies in 1917 was largely the result of earlier negotiations begun to prevent danger of transfer to Germany, which has for years been desiring a means to secure control of all the islands of the Caribbean, and in 1902 influenced the Danish Landsting to reject an American-Danish treaty for the projected purchase of the islands.

In 1912-14 conditions in Mexico furnished another of the traditional opportunities for American expansion, and a bill for the annexation of northern Mexico was introduced. In March 1914, intervention was urged to prevent German intervention; but other methods for pacification were adopted. President Wilson asserted that the United States will never again seek one foot of territory by conquest.

AMERICAN FEDERATION OF CATHOLIC SOCIETIES, The. Founded in Cincinnati, Ohio, 10 Dec. 1901. The Federation is an organization of Catholics in the United States for the purpose of advancing their civil, social and religious interests. It is not a political organization, and does not control the political affiliation of its members; it asks no favors or privileges, but openly proclaims what is just and fair. It aims at the creation of sound public opinion on all important topics of the day; it stands for the Christian life of the nation itself; for the proper observance of Sunday; for the Christian education of youth; for the stamping out of immorality; for the sanctity and perpetuity of Christian marriage; for the safeguarding of the Christian home. It asserts the necessity of Christian principles in social and public life in the state, in business, in all financial and industrial relations. It combats all errors which are in opposition to Christianity and threaten to undermine the very foundation of human society. It is willing to co-operate with all loyal citizens who will use their intellectual and moral energies which work for truth and virtue. It exposes falsehood and injustice, whether in misrepresentation of history, doctrine or principles of morality. The aims of the Federation, therefore, are both religious and patriotic. Its membership is composed of the leading Catholic national organizations, of county and State federations, Catholic institutions and individual societies and parishes, with an approximate membership of 3,000,000. The organization has the endorsement of the American Hierarchy and of the Pope. The advisory board is headed by Cardinal Gibbons, Cardinal Farley and Cardinal O'Connell.

AMERICAN FEDERATION OF LABOR, a federation of trade-unions of the United States, Canada, Porto Rico and Panama, in which the rights of the subordinate bodies are preserved intact. As in the Federal government, all powers not expressly granted in the written constitution are reserved to the subordinate bodies, but still further, as in the Articles of Confederation, it has not power of
compulsion (except to suspend or expel a union) and any union can override its decision as far as its own action goes. To this is due its rapid growth and harmony. What concerns the union federations most of all is being controlled in matters pertaining to its own trade by persons outside that trade.

The Federation originated in 1881. Its predecessors had been the National Labor Union (1834-65), whose history is a career by entering into politics and nominating a candidate (David Davis) for the Presidency, and a number of sectional orders, of which the Knights of Labor was the chief (1869). The latter were generally hostile to trades-unions, holding them based on "false and selfish principles of temporary advantage, to the sacrifice of the general interests" of labor, and the Knights attempted to break down trade barriers in workers' action by organizing local assemblies of miscellaneous laborers. This antagonized those who believed that only members of a given craft, trade or industry had a right or the proper knowledge to direct its own action; and on 2 Aug. 1881, representatives from trade-unions, the Amalgamated Labor Union (a split from the Knights of Labor) and the Knights of Industry, got together in secret orders, held a conference at Terre Haute, Ind., ostensibly to establish a national labor congress, but in reality (as stated) to form a new order to supplant the Knights of Labor. This was defeated, and the conference issued a call for a convention at Pittsburg in November, where the Federation of Organized Trades and Labor Unions of the United States and Canada was constituted. On 8 Dec. 1886, this fused with a separate trade-union conference and changed its name to the American Federation of Labor; and in 1889 acknowledged the continuity of existence by dating the proceedings to 1881. Its membership is of local unions central of cities, State federation, national and international trade-unions. As a labor union, it belongs to three different superior bodies, with a possible conflict of jurisdictions, the Federation takes charge of these mutual relations. It recognized the national and international unions as having supreme jurisdiction, but it approves and urges State and local bodies as helpers in gaining common objects.

These objects, as stated in its constitution, are: (1) "The encouragement and formation of local trades and labor unions, and the closer federation and combination of such bodies, to secure legislation in the interest of the working masses." (2) "The establishment of national and international trade-unions, based upon a strict recognition of the autonomy of each trade," etc. (3) "An American Federation of all national and international trade-unions, to aid and assist each other," and (4) "The sale of union-label goods, and to secure national legislation in the interest of the working people, and influence public opinion by peaceful and legal methods in favor of organized labor."

(4) "To aid and encourage the labor press of America."

Its executive organization at first was a secretarial and legislative committee, and it announced that it would have no salaried officials; but for efficient working it has been compelled to modify this rule. It has a salaried president and secretary, a treasurer and eight vice-presidents, who together form the executive council, which meets quarterly. The president for many years has been Samuel Gompers (q.v.).

The funds are derived from a per capita tax in 1918 of 10½ cents per member of an affiliated trade-union, 15 cents per month from each member of a directly affiliated local union, and $10 each from central unions and State federations. Until 1887 it could not grant funds in a state, but in that year a revised constitution gave the executive council the right to call on the unions for financial aid to such strikes as it approved. This voluntary aid was insufficient, and in 1889 another amendment permitted it to levy a compulsory tax of one cent a week on each member of an affiliated union, for not over 10 weeks in any year, in aid of strikes or lockouts.

The policy of the Federation is fixed in open conventions held in a different city each year. For years the convention was held in November. The 1917 convention changed the time to the second Monday of June. The affiliated organizations are entitled to but one delegate until their membership reaches 4,000, two delegates up to 8,000, three delegates up to 10,000, four delegates up to 15,000, five delegates up to 32,000, five delegates up to 64,000 and so on. But delegates from organizations, either national, international or local unions, are entitled to cast one vote for every 100 members they represent. Thus the number of delegates is kept within such limits so that the conventions shall be really legislative bodies, and yet the spirit and purpose of democracy is maintained so that the delegates have voting power in proportion to the numerical strength of their respective constituents.

The American Federation of Labor confines its membership to wage workers, men and women, skilled and unskilled, not admitting even farmers who are employers of labor on their farms. The Federation realized that the organization had long to go to three different superior bodies, with a possible conflict of jurisdictions, the Federation takes charge of these mutual relations. It recognized the national and international unions as having supreme jurisdiction, but it approves and urges State and local bodies as helpers in gaining common objects.

Its activity in securing favorable and defeating unfavorable legislation for laborers has been very great and very successful. These are too many to detail; but it may be said that its first convention of 1881 demanded a national eight-hour day for government employees and exclusion of Chinese and contract laborers; and all these have been enacted into law. It also
secured the establishment by law of Labor Day. Since then it has steadily favored shorter hours, non-employment of children, better sanitary conditions, regulation of convict employment, abolition of “government by injunction,” etc.

The American Federation of Labor during the first part of its history followed the political policy of recommending to the members of its affiliated organizations the independent use of the ballot. This policy was pursued until 1900 when the American Federation of Labor, as a non-partisan political party, voted to support candidates for public office who were pledged to the welfare of wage-earners. It was felt necessary to make this change of policy because of the urgent need of remedial legislation. Abuse of the injunctive process and the perversion of the Sherman Anti-trust Law to apply to associations of wage-earners organized for profit constituted such a menace to the activities and the very existence of the organizations of workers that the enactment of laws, regulating and limiting the issuance of injunctions, especially taking associations of wage-earners from under the provisions of trust legislation, was imperative.

In 1894, the American Federation of Labor drew up its famous “Labor’s Bill of Grievances,” and recommended its passage by Congress to secure the protection of the rights and interests of wage-earners and for the reform of the judicial process. This political movement was given impetus by legal proceedings instituted against organized wage-earners. The two cases which were endorsed by the American Federation of Labor as test cases were the so-called Hatters’ case and the “Contempt” proceedings against President Gompers. Vice-President John Mitchell and Secretary Frank Morrison of the American Federation of Labor. Under these contempt proceedings the defendants were twice sentenced to 12, 9 and 6 months’ imprisonment, respectively, but the United States Supreme Court reversed the decision of the lower courts in both cases. In the course of the Hatters’ case, the Supreme Court of the United States decided that sections 1, 3 and 7 applied to associations of wage-earners. The contempt cases grew out of injunctions issued against the officers of the American Federation of Labor, forbidding them their constitutional rights of free speech and free press. These two cases were considered flagrant violations of the rights of citizens of a free government and demonstrated the imperative necessity for securing the remedial legislation which labor demanded.

The organized labor movement began a campaign to secure the nomination and election of representatives, regardless of party, who pledged themselves to the enactment of labor’s legislative demands. As a result of this political policy, there came into existence in Congress what is known as the Labor Group, a majority of which hold trade-union cards and are affiliated with labor organizations. This group has gradually increased in size until in the 65th Congress there are now belonging to it one senator and 16 members of the House of Representatives. As a result of this political activity, labor’s fundamental demands have been enacted into law. In the labor provisions of the Clayton Anti-trust Act, which became a law 15 Oct. 1914, section 6 of this act contains the most important legislative statement ever enacted into law, namely, “the labor power of a human being is not a commodity or article of commerce.” According to this declaration, associations of wage-earners cannot be classified as trusts and cannot be enjoined or restrained under the provisions of trust legislation. Section 20 of the Clayton Anti-trust Act provides for the limitation and regulation of the issuance of writs of injunctions to conform to labor’s demands. Another great humanitarian law that has been secured as a result of this political policy is the Seaman’s Act, which brings freedom to a group of America’s workers that could be imprisoned for failure to perform specific services.

In 1894, the American Federation of Labor succeeded in securing the enactment of a law establishing the Federal Bureau of Labor. After continued effort in 1913, a law was enacted which created the Federal Department of Labor, with a secretary at its head, who is a member of the President’s Cabinet. There was appointed, as the first Secretary of Labor, William B. Wilson, a member of the United Mine Workers of America and former secretary of that organization. This enables the workers of America to have representation in the councils of state at the time when plans and policies are in a formative state. Another law provided for the establishment of the Children’s Bureau.

In addition, many other humanitarian laws have been secured, such as the amended and improved eight-hour law for employees on government work, Workingmen’s Compensation Act and many others too numerous to mention, but which have made possible better conditions of work, greater safety for life and health of the workers of America. However, the fundamental policy of the American Federation of Labor has been that the economic power of the workers is fundamental, that power is derived from the creative labor power of the workers who render service in industry and commerce and that all other power is derived from their economic power. The economic demand which the trade-union movement holds to be fundamental is the shorter workday or the present demand for the eight-hour day. The shorter workday protects workers from physical exhaustion and gives them opportunities for rest, for improvement of their own abilities and for social contact with their fellows. The shorter workday makes of the workers different human beings. It is always accompanied by higher wages for the worker who, as a result of the shorter workday, is a better and more productive worker than the one who labors long hours.

The trade-union movement has held that personal relations in private industries must be determined by the wage-earners themselves through their economic organizations. A distinction is observed between employees in private industry and employees in the government. The American Federation of Labor holds that the economic organizations are the individualities through which workers in private industries must work out their salvation but that industrial relations for government employees must, of course, be regulated to some extent through legislation. However, even the
problem of securing the welfare of workers in government employment depends upon the power of the economic organizations of the workers—not only those in government employment but those of the whole country.

The American labor movement has consistently stood for internationalism and peace between nations. It has opposed militarism in all its phases. The Seattle Convention of the American Federation of Labor approved a proposition for a Naval Holiday during which period of time all nations should cease constructing war vessels. Although working for peace and hoping for peace, the Federation understood fully the meaning and the opportunities of the European War. The Federation realized that ideals of international peace had not been properly supported by provisions for constructive agencies. This problem was considered at several conventions held in 1914 in Philadelphia, and a resolution was adopted providing for the holding of a labor peace conference at the same time and place that the world peace congress should be held after the war. The labor organizations of all countries were urged to approve this idea and to make provisions for sending representatives. This plan was reaffirmed by the San Francisco 1915 Convention. The Baltimore 1916 Convention adopted an additional provision that the organized labor movements of all countries should urge upon their governments the justice of appointing workers among their national delegations of plenipotentiaries who would constitute the peace congress. This proposal, together with the proposed labor conference, was again reaffirmed by the Buffalo 1917 Convention of the American Federation of Labor.

The American Federation of Labor was closely in touch with those directing and concerned in the European War and understood that in the last analysis the war was labor's war and the fighting elements in the war were soldiers, sailors, and workers. Thus, the slogan of the war was to organize production. Workers performed an essential part in production and therefore demanded that they have a voice in determining conditions under which production shall be carried on.

As the war progressed and it became evident that institutions of democracy and freedom the world over were involved and that therefore the United States could not avoid becoming an active member of the Allies fighting against militarism and despotism, representatives of the organized labor movement of this country met in Washington on 12 March 1917 and adopted a declaration entitled 'American Labor's Position in Peace and in War.' That declaration clearly sets forth the duties and responsibilities of workers to a free republic, and made clear the loyalty of labor and its determination to render service to the republic in the time of peril. It also set forth the conditions under which labor could render service at the same time maintaining the principles of freedom for all. Workers, as representatives of labor, have been appointed to several important governmental committees and agencies dealing with war problems. The president of the American Federation of Labor, Samuel Gompers, was appointed by President Wilson as a member of the Advisory Commission to the Council of National Defense.

In order to facilitate war production and avert situations that might interfere with continuous work, representatives of the organized labor movement have entered into working agreements with the government to secure this end. The most important of these agreements were the agreement between the Seamen's organization and the Shipping Board; agreement between Samuel Gompers and Newton D. Baker, Secretary of War, providing for the union scale and hours in cantonment construction. This agreement was later approved for construction work in the Navy Department and extended to include repairs and the building of warehouses. An agreement was entered into between representatives of labor organizations concerned and the Shipbuilding Emergency Fleet Construction Corporation covering the construction of ships. The International Longshoremen's Association entered into an agreement with the Shipping Board under which all disputes involving their members should be settled by a labor board, and which also provided for union hours and wages. The United Leather Workers' International Union entered into an agreement covering war production with various employers and the War Department.

The organized labor movement aims to extend the number and the application of agreements covering war work in order that there may be established agencies for dealing with industrial difficulties as they arise, and thus prevent industrial struggle. It has also maintained the democratic principle that the workers ought to be represented on all war boards and agencies that deal with matters concerning the life and the work of wage earners.

The Federation has taken an important part in international affairs and has steadfastly opposed international conferences of working men in which there were to be representatives of labor movements of enemy countries. However, it has advocated the holding of a world labor congress at the close of the war at the same time and place where the international peace congress shall be held.

The President of the United States accepted an invitation to address the Buffalo (1917) Convention of the Federation. His address to that convention may be found in the printed Proceedings, and also in the American Federationist for January 1918.

The Convention adopted the following declaration as Labor's peace program:

1. The combination of the free peoples of the world in a covenant for genuine and practical co-operation to secure justice and the peace in the relations of nations.
2. Governments derive their just power from the consent of the governed.
3. No political or economic restrictions meant to benefit some nations and to cripple or embarrass others.
4. No indemnities or reparation based upon vindictive purposes or deliberate desire to injure, but to right manifest wrongs.
5. Recognition of the rights of small nations and of the principle: "No people must be forced under sovereignty under which it does not wish to be.
6. No territorial changes or adjustment of power except in furtherance of the welfare of the peoples affected and in furtherance of world peace.

In addition to these basic principles, which are based upon declarations of our President of these United States,
there should be incorporated in the treaty that shall con-
stitute the guide of nations in the new period and conditions
into which we enter at the close of the war the following
decisions fundamental to the best interests of all nations
and of vital importance to wage-earners:
1. No article or commodity shall be shipped or delivered
in interstate commerce in the production of which children
under the age of 16 have been employed or permitted to work.
2. It shall be declared that the basic workday in industry
and commerce shall not exceed eight hours.
3. Voluntary servitude shall not exist except as a punish-
ment for crime whereof the party shall have been duly
convicted.
4. Establishment of trial by jury.

The American Federation of Labor in 1887
published an official journal called the Union
Advocate. In 1894 it began the publication of
a monthly magazine, The American Federa-
tionist. In 1911 the Federation began issuing a
weekly news letter, for the purpose of the
use of labor press throughout the country. A
number of official pamphlets and publications
can be had from headquarters. Consult Ald-
rich, 'American Federation of Labor' (Vol.
III of 'Economic Studies' 1898); Gompers,
'The Labor Movement and Others'; McGuire,
'The American Federation of Labor'; and
annual reports of the Federation.

AMERICAN FOLK-LORE SOCIETY,
an association founded in 1888 for the study of
folk-lore in general and in particular for the
collection and publication of the folk-lore of
North America. It has helped largely to lift
folk-lore studies out of the mere antiquarian
stage and to make them a valuable auxiliary
in anthropological and ethnological investiga-
tions. Branches have been established in Cam-
bridge, Boston, Missouri and Texas, and
folk-lore societies are in existence in Ken-
tucky, North and South Carolina and Vir-
ginia. There is also a large membership-at-
large. The permanent secretary is Dr. C. Pea-
body, Harvard University, Cambridge, Mass.
It publishes quarterly The Journal of American
Folk-lore.

AMERICAN FORESTRY ASSOCIA-
tion, an organization formed in 1882 and
incorporated in 1887, devoted to the conserva-
tion of private, State and national forests and
to public education in the knowledge of trees, their
care and development. It is a voluntary or-
ganization for the inculcation and spread of
a forestry policy on a scale adequate for our
economic needs and any person is eligible for
membership. It is independent and has no of-
icial connection. The membership which ex-
tends to every civilized country is about 13,000.
The publication of the association is called the
American Forestry Magazine.

AMERICAN FORK, Utah, city of Utah
County, 30 miles south of Salt Lake City, on
the Denver and Rio Grande, the San Pedro,
Los Angeles and Salt Lake railroads. Pop. 2,797.

AMERICAN HISTORICAL ASSOCIA-
tION. A national organization of persons
interested in history and in the promotion of
historical work and studies. It was founded at
Saratoga, N. Y., in 1884, by a group of represen-
tative scholars, and in 1889 was incorporated
by act of Congress, its national character being
emphasized by fixing its principal office in
Washington and by providing for the govern-
mental publication of its annual reports. Its
present membership of 3,000 is drawn from
every State of the Union, from Canada and
South America, and from 13 other foreign
countries. The meetings are held annually in
December in cities so situated as best to ac-
commodate in turn the members in different
parts of the country. The society has exerted
wide influence in directing and stimulating his-
torical research, and its publications and mono-
graphs have covered a broad field of historical
study. Important committees of the society are
The Historical Manuscripts Commission and the
Public Archives Commission; the former is
concerned in the preparation of valuable manu-
scripts for publication and the latter in the
preservation of the public records of the various
States and smaller political divisions. The soc-
ociety publishes an annual report, usually in
two volumes, and appoints a board of editors for
the American Historical Review, published
quarterly. The society has published five vol-
umes of 'Papers,' about 40 volumes of Annual
Reports, a series of prize essays, two volumes
on 'The Study of History in Schools' and a
series of reprints of 'Original Narratives of
American History' in 20 volumes. Membership
is obtained through election by the executive
council, upon nomination by a member, or by
direct application.

AMERICAN INDIANS. See INDIANS,
AMERICAN.

AMERICAN INSTITUTE OF ARCHIT-
ECTS, a society organized in 1857. It has
39 chapters, 314 fellows, 809 members, 36 cor-
responding and 88 honorary members. It has
its office in Washington.

AMERICAN INSTITUTE OF THE
CITY OF NEW YORK, an organization
founded in 1828 for the promotion, by exhibi-
tions and fairs, of agricultural, commercial,
manufacturing and artistic interests throughout
the Union. It is now divided into five sections:
The Farmers' Club, the Henry Electrical So-
AMERICAN INST. ELECTRICAL ENGINEERS—AMERICANISMS

ciety, the Horticultural Section, the Photographic Section and the Polytechnic Section. It has a small library of 13,000 volumes.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS. This is the national organization representing the electrical engineering profession. It was founded in 1884. Its objects are the advancement of the theory and practice of electrical engineering and of the allied arts and sciences, the maintenance of a high professional standing among its members and the development of the individual engineer. The institute has contributed largely toward the remarkable progress that has taken place in the electrical field during the last three decades, and has been an important factor in advancing the interests of its members and of the entire engineering profession. The membership on 1 May 1916 was 8,212. The annual dues are $10; associates, $15; fellows, $20. Each class of members is fixed at $15 and $20, respectively. All branches of electrical engineering are represented in the membership. Meetings for the presentation and discussion of technical papers and other matters of interest to electrical engineers are held in New York City and in the principal electrical centres of the country. An annual convention and special conventions, as authorized by the board of directors, are held in different parts of the country. The principal publications of the institute are the Monthly Proceedings and the Annual Transactions. The policy of co-operation with other engineering societies in matters of mutual interest is encouraged by means of joint meetings and otherwise as opportunities develop. Upon invitation, the institute has appointed representatives and committees from time to time to co-operate with various branches of the Federal government, and its representatives have appeared at hearings before congressional and other legislative bodies on subjects involving the interests of the engineering profession. Briefly, the institute provides opportunities for and encourages co-operation, the interchange of ideas, the presentation, discussion and publication of papers, the formulation of standards and codes, the advance of ideals, the cultivation of the spirit of co-operation, and the inspiration which gives vision and incentive for new efforts and greater achievements. Executive offices and library, 33 W. 39th Street, New York.

AMERICAN INSTITUTE OF HOMŒOPATHY, a society organized in 1844, the oldest national medical organization in the United States. Membership about 2,000.

AMERICAN INSTITUTE OF INSTRUCTION, the oldest educational association in the United States, organized in 1830 at Boston. Its purpose was the diffusion of useful knowledge in regard to education. It has held annual meetings at each of which problems of vital interest were proposed. New England supplies the largest proportion of members. Its proceedings include practically all the names of well-known educators in the country; among them Ralph Waldo Emerson, William E. Channing, Samuel Howe, Lowell Mason, Henry Ward Beecher, Julia Ward Howe, etc. Some very important contributions to American education were first presented as lectures to this institution. Consult Barnum, P. F., 'American Institute of Instruction' (in American Journal of Education 1856, Vol. II, pp. 19-32, 241-55); Smith, 'Founders of the Institute' (in Proceedings of American Institute of Instruction, 1867, pp. 213-18; Winship, A. E., 'American Institute of Instruction', 1906, pp. 457-63).

AMERICAN INSTITUTE OF MINING ENGINEERS, an association of American mining engineers, organized in 1871 and incorporated in 1905. Its membership in 1916 was 5,785.

AMERICAN IPECAH. See Gillenia.

AMERICAN-IRISH HISTORICAL SOCIETY, founded in Boston, Mass., 20 Jan. 1897, to make better known the Irish chapter in American history. The organization draws its membership to creed lines and has published a number of books and pamphlets along its chosen line of work. The society is national in its scope, and has members throughout the country. The organization holds its annual general meeting in New York City, and publishes a nearly bound volume called the 'Journal' of the society. The membership is about 1,000. In addition to the national officers, there is a vice-president for each State.

AMERICANISMS, in language, are words or phrases peculiar to the English speech of the United States or of British America. They may be: (1) Forms originating in America; or (2) forms that have emigrated from Britain and that have continued in use here while they are obsolete there; or (3) that have undergone here an essential change of signification. Examples of words originating here or at least first introduced here into the vocabulary of the English language are Buncombe, Caucus, Gerrymander; of words here in current use but now antiquated in England we have Fall (the season), Whittle (verb); Corn (maize), Partridge (quail or ruffed grouse), Store (in England shop). These three process of new word coinage, or survival of meanings in one province of the language which in another province have become obsolete, and of essential change of signification, are inherent in all languages, and can be traced in a comparison of two counties as clearly as in two countries. Americanism expresses the character of English speech in America: it does not imply any inferiority of American English to British English; nor is American English subject to correction by the laws that British English prescribes for itself: Americanism and Briticism in speech are mutually on an equal footing; unlike Gallicisms, Germanisms or even Scotisms, Americanisms are not alien in English, but natives. Among the Americanisms to be noted in what follows are many words or phrases which belong to the vocabulary and phraseology of slang, and are universally regarded as vulgarisms and solecisms and victorious growths of the vernacular speech of America; as such they are Americanisms; but they are no more part of legitimate American speech than is costermongers' English part of the English language of the home country.
AMERICANISMS

In the front rank of Americanisms must be classed those which are most racy of the soil and that could not have been evolved in any social or physical environment other than was and is presented in this new world. The first settlers had little to clear the woods; forest which covered the land, and constantly to guard their lives and their possessions against the forays of the savages: they went always armed to their day's work. Such words and phrases as Going on the war path, Digging up the hatchet, Burrying the hatchet,lear the way, Tomahawk, forest, are all the hero-ales of American pioneering; and from the same period come Shanty, Blazing out, Clearing, Backwoods (in Canada, the Bush*). They took to the woods* or to the timber for refuge at the approach of the redskins in overwhelming force. In the sparsely peopled settlements the necessity for neighborly help in gathering in the harvest or in erecting a log cabin or in providing comforts for the winter led to the custom of the Raising-bee or Building-bee—a business of vast proportions that the origin of the word Bee in this sense is unknown; the custom itself survives in rural districts, and a few years ago a new sort of Bee—the Spelling-bee had great vogue; and that was far as Veldt is South of a "beech" tree, met with much popular favor in England. Logrolling is another example of co-operation among backwoodsmen, when neighbors associate to collect each other's logs for the winter fires. Logrolling came early into use as a term of the art of practical politics to signify the cooperation of members of a legislative body to promote one another's schemes. Literary Logrolling is when authors combine to create a market for each other's productions by mutual puffery. Salt springs to which the big game went to sport were Salt Licks; the spaces between stretches of water over which the pioneers had to carry their canoes were Portages. As settlers began to seek homes in the West on government lands, the distribution of the public domain became a business of vast proportions and a Land-Office business became a superlative term of comparison. A Section of land is a square mile or 640 acres; a very usual subdivision is the Quarter section, 160 acres. In the nearer West, as in the East, bodies of land were Parceled out in the shape of a square, the Rats; in the East, as the Rats; in the West, as the Rats. The verb to Deed is a pure Americanism: the phrase To convey by deed was too slow. A settler who acquired land from the government blazed his grant by cutting with his axe marks on the bark of trees: the word is from the French blaze, a term of heraldry. A Lot of ground is any distinct portion of land, and in towns and cities is a piece of ground with a definite frontage, usually 25 feet. The use of the word 'lot' in the sense of a parcel, to decide upon the policy to be supported by members of a party in the open sessions, is an American invention; of late it has been introduced in England. Spread-Eagle oratory has its name from the extravagant style of stump orators and Indians. Day spouters when they glorify the Bird of Freedom. High-falutin, a word that cannot be traced to its original source, denotes turgid, bombastic oratory. To Enthouse is unquestionably an Americanism, and it is base coin formed from the word enthusiasm, which, whether in Greek or English, has no corresponding active tran-
sitive verb form. Of party names and nicknames may be mentioned Whig and Tory of the pre-Revolutionary era, Federal and Republican of the period after independence, then Whig again, and instead of Republican either Democratic Republican or simply Democrat, with the nickname (about 1780) Jacobin, later to a body of radicals, who, in Tammany Hall, New York, after a meeting was officially dissolved and the lights put out, produced locofoco matches, rekindled the lights and continued the meeting: the locofoco match, or locofoco cigar was introduced in 1834, the word meaning "substitute for fire" —in loco foci. It was a cigar with friction-match attached. Other party names and nicknames are Republican, Silver-grays, Copperhead, Carpet-baggers, Lily Whites. The man in any political organization who possesses or is believed to possess authority to dictate the party’s policies is the Boss. The word is the Dutch baas and is the usual designation of an employer or overseer of workmen. A few years ago political terrorism in the South, designed to bar negro access to the polls, was known as Bulldozing, a word which cannot be traced to its origin with certainty, and which is no longer in use. Roofback is a false and injurious report set afloat in the crisis of a political campaign, usually a very short time before the canvass is closed, so that it may have damaging effect before contradiction or refutation can be made. The phrase “a good enough Morgan till after election” recalls an incident in the history of New York politics. William Morgan, author of a book purported to reveal secrets of Freemasonry, was kidnapped, and the anti-Masonic party charged the Freemasons with having murdered him. To counteract this charge, which was credited largely by public opinion, the Masonic society, or rather its friends in the Whig and Democratic parties, spread reports of the finding of the missing man; whether true or false, these reports furnished “a good enough Morgan till after election.”

As is equivalent to very, is by some writers classed among Americanisms; but that is an error, though undoubtedly the word is more commonly used in that way here than among the English. In the style Right Reverend, Right Worshipful, etc., Right has the meaning of very; in Tyndale’s Bible occur such phrases as Right sorry, Right humble, and in writers of the 14th century the same usage is to be seen. But Right here, Right now, Right away, Right off are Americanisms and are not found in the colloquial speech of Britain. In British English of these latter days Sickness is hardly used save in the sense of nausea; but the best British authors do not connotance that restriction of meaning. In the United States, outside the circles in which the time of day is given from London, the words Sick and Sickness have the same signification they have had in the general language at least from the 14th century, when mind-sick, mind-sickness, were current phrases; and in the King James version of the Bible. Sick is the word by which they have in the American vernacular. Ugly, in the sense of cross-grained, ill-natured, is an Americanism, though English usage has the nearly parallel phrase, an ugly customer. An American can ride in a coach; but an Englishman, if he is to ride at all, must go on horseback or be borne on the back of some other animal. Restriction of the meaning of Ride is inconsistent with the usage of the translators of the Bible, who make Joseph, for example, and Jehonadab ride in chariots. The garment which Americans style waistcoat is the English waistcoat. Peart, pronounced, and often written Peart, meaning lively, brisk, sprightly, without any suggestion of sauciness or freshness, is gone out of use, at least of literary use, in England; it is an Americanism, but its habitat, so to speak, is restricted. A special use of Peart is to signify the improved tone of one who is recovering from a sickness.

The place of business at retail which in England is a Shop is in the United States a Store. Of late a tendency has appeared toward adoption of the British usage of these terms. In regions unaffected by this tendency Shop is still what it was 50 years ago in this country, a work-place, and a Store is a place where goods are kept in store for sale. But even while Shop and Store are here called by the English names, there are numerous phrases current which are inconsistent with the American meanings of Store and Shop, for example, Shop-worn, Smelling of the shop, Shop-boy, Shoping, Shopkeeper, Shoplifter, etc. The grocer’s store or shop is here called a Grocery, not so in England; there Grocery signifies only the wares sold by a grocer. Unquestionably American is the use of the word Drummer in the sense of one who solicits or toasts for custom. For the phrase, He struck oil, will probably survive after all the oil wells have gone hopelessly dry.

What we call Baggage is by the British called luggage, though the reason of the difference can hardly be that we travel with less impediments than they. The development of our railway systems has brought many new words into the vernacular, but none more expressive than the verb Telescope.

The conversational speech of Americans at one time seemed to be seriously threatened with invasion by a host of spurious, illegitimate word-coinages, especially of verbs made out of nouns, as to Advantage, to Ambition, and of pompous verbs made out of nouns ending mostly in -ow, as Orate, Donate; but that danger was happily averted. The use of Transpire in the sense of happen, occur, is of American origin, but the use quickly spread to England; the solecism was promptly branded by scholars, but it still lives and flourishes. Balance, in the sense of remainder, is another Americanism which has attained a currency which it does not deserve. Mad, in the sense of angry, is an Americanism of the baser sort. To Wilt, on the other hand, a provincialism in England, but in America a word in universal use, is one of the vades-mecum of the American province of the English language to the mother tongue’s general store. The proverbial Whittling of the Yankee keeps alive an ancient native English word for knife.

Among the common phrases current in the United States may be mentioned Flying off the handle,—losing self-control through passion: one is then like the axe-head which has quit the haft. To Get religion, or even to Take religion, is a phrase constructed on the pattern
of "to take a cold" or "to take the measles." To be posted plainly had its origin in the counting-room.

**AMERICANISTS** (from Americanistse), all those who devote themselves to the study of (1) the native races of America—their origin, distribution, history, physical characteristics, languages, inventions, customs and religions; (2) the history of the early contact between America and the Old World. The name was probably first given to the members of the French Société Américaine de France, and later to students of any nationality who are interested in the archaeology, ethnology and early history of the United States. Since 1875 such students have met at irregular intervals in an association known as the Congrès International des Americanistes. This congress grew out of the Société Américaine de France, which was formed in 1857 by several French students who were interested in the pre-Columbian civilizations of South America and Mexico; after this society had flourished for 18 years its members decided to invite Americanists of foreign countries to a congress. The first international meeting was held in 1875 at Nancy, France, where addresses were adopted and plans laid for the continuance of the organization. Since then 10 other meetings have been held in various European cities and two in America (City of Mexico, 1895, and New York city, 1902). At first the intention was to hold biennial sessions, but after a few years it was decided to meet at irregular intervals, the council of each congress determining the time and place of the next session. The meetings have a polyglot character, as speakers use French, German, Italian, Spanish or English. The addresses may be either written or oral and are limited to 20 minutes in length. All papers presented may, with the approval of the committee, be issued in the printed *Proceedings* which are usually in French (Congrès International des Americanistes, Comité-Rendu), and published in two volumes for each meeting. In addition to the papers the reports contain lists of the members enrolled and minutes of the business transacted at each session. Any one interested in the subjects discussed may become a member of any congress by a subscription ($3, American money, or an equivalent in the currency of the country where the congress of Americanists was held in 1915-16 to take part in the sessions but to receive the reports of the congress and all other publications issued by it. The subjects considered at each meeting range through meteorology, geology, archaeology and ethnology to comparative philology, the history of the pre-Columbian arts and religions, the early discoverers of America and its early relations to European nations. Representatives from almost every nation, even from China and Japan, are found on the lists, which have included as members (not necessarily as attendants) many of the most eminent archeologists, ethnologists and anthropologists in Europe, England and America. For a full account of the 15th congress, held at the American Museum of Natural History in New York City 20-25 Oct. 1902, see *Science*, New Series, Vol. XVI, p. 884. Previous meetings are reported in *Nature*, Vol. XIV, p. 355; *Popular Science Monthly*, Vol. XXXIV, p. 686, and Vol. XXXVIII, p. 685. The 19th International Congress of Americanists was held at Washington in conjunction with the Anthropology section of the 2d Pan-American Scientific Congress.

**AMERICAN JEWISH HISTORICAL SOCIETY.** This society was founded at a meeting held in the city of New York 7 June 1892. Its purpose is to collect, preserve and publish material having reference to the settlement and history of the Jews on the American continent, and to promote the study of Jewish history in general, preferably so far as the same is related to American Jewish history or connected with the cause of Judaism in various parts of the world to this continent. In fulfillment of these objects the society maintains a library and museum in the building of the Jewish Theological Seminary of America in the city of New York and has issued a series of volumes known as the *Journal of the Society* of which have already appeared, and an index volume of the first 20. The researches of the society, which have covered South America, Mexico, parts of Europe and Asia and the whole of the United States, as embodied in the papers and material comprising these *Publications,* indicate the presence of Jews on this continent since 1494 and their participation in the upbuilding of the colonies and the later
American nation since 1655. The society had, on 1 July 1916, a total membership of 383 persons. Its first president was Hon. Oscar S. Straus, with Dr. Cyrus Adler as the first corresponding secretary. When, in 1899, Mr. Strus went to Turkey as United States ambas-

dor he declined a re-election as president and Dr. Adler succeeded him. The latter has been chosen in that office annually since this date. The corresponding secretaries of the so-

ciety during Dr. Adler's term as president, have been Dr. Herbert Friedenwald, Max J. Kohler and Albert M. Friedenberg. The last-named who is the present incumbent was first chosen in 1910.

AMERICAN LABOR. See AMERICAN FEDERATION OF LABOR; LABOR LEGISLATION; LABOR MOVEMENT, AMERICAN; LABOR UNION.

AMERICAN LAKES, Neutrality of the. During the War of 1812 each party struggled to secure control of the lakes. In the negotia-

tions for peace the British demanded military control of these waters to prevent the expense of rival armaments. This proposition of a combined disarmament was not accepted; but after the treaty of peace was concluded, the American government decided that mutual dis-

armament was the only assurance against col-

losion which might result from various sources of misunderstanding, and early in 1816 sug-

gested through John Quincy Adams to Lord Castlereagh at London that some such measure should be accepted by both governments to avert the threatened evil of rival naval forces upon the Lakes. After debates in Parliament, Lord Castlereagh instructed Mr. Bagot, the British Minister at Washington, "to take ad referendum any such proposal." In August 1816, Secretary Monroe submitted to Bagot the precise project providing for limitation of the force on the Lakes to one vessel on Lake Champlain, one on Lake Ontario and two on the upper lakes, each of 100 tons burden and with one 18-pound cannon. This force was to be restricted in its duty to the protection of the revenue laws, the transportation of troops and mails, and such other service as would not interfere with the armed vessels of the other party. Early in 1817, Castlereagh ac-

ceeded to the proposition and later in the year the agreement was completed by the exchange of notes between Mr. Bagot and Acting Secretary Rush. By the agreement all naval vessels except the four allowed were forthwith dis-

mantled and no other vessels of war were built or armed upon the Lakes. The arrange-

ment doubtless contributed to the century of peace along the boundary of 4,000 miles, the longest international boundary in the world. Consult Callahan, J. M., "Neutrality of the American Lakes" (1898); Foster, J. W., "The Agreement of 1817" (Ex. Doc. 1892).

J. M. CALLAHAN.

AMERICAN LANDSCAPE PAINTING.

Landscapes has always been a characteristic and distinctive element in American painting. Just as there is something especial in American writing on nature in the work of Thoreau, Bur-

roughs, Muir, so there is something especial in the American painting of nature. In the early days the natural scenery of America was of great interest to visitors from abroad and to many Americans who looked beyond practical matters. American scenery was magnificent and vast,—sublime. The unending forests, the

inland seas, the great rivers with their many waterfalls, and somewhat later the extending prairies and the enormous mountains, these were by all held to be American. In the early days there was little painting of any sort. By the end of the 18th century at-

tempts were made to render the remarkable things in American nature; there are not a few engravings of American scenery, in American, English, and European, but some by Americans of whom Jacob Hoffman is the only one remembered. With the new century there came a number of other renderings, topographical drawings, en-

gravings of gentlemen's country-seats (William and Thomas Birch), illustrations in the few magazines (Portfolio), landscape backgrounds in books on natural history (Wilson, but par-

icularly Audubon), collections of landscape engravings or aquatints. Such things show a widely developed taste, which, however, found no adequate expression until Thomas Cole came to New York in 1825. Earlier were W. G. Wall and W. Bennett, Thomas Doughty and Alvan Fisher. The first two painted American scenes which were often engraved and became popular. The last two had each a definite char-

acter, Doughty for his refined, painter's view of nature, Fisher as one who could paint a romantic story. Thomas Cole was the first to become generally recognized, the first to pre-

sent the view of romantic America that had long had its place in the general mind. He felt deeply the grandeur of the American scene, particularly in its wilder and fiercer aspects. He was not satisfied, however, with presenting these things as truthfully as he could, but sought to express the ideal conceptions that arose in his mind. ("The Course of Empire," "The Voyage of Life," etc.) in landscape form.

A. B. Durand held more strictly to the land-

scape ideal and also to a closer method. His work aimed first at a truthful representation of nature. He preferred quieter scenes and the more restful phases of nature. Cole and Du-

rand are of the older generation, and many of the landscape painters of their time, who are loosely grouped as the Hudson River School. Of these some—Kensett, Casilear and Whit-

ridge were more like Durand in their apprecia-

tion of a more informal, painter's view, even on a large scale. Others, like Cole, sought to render vast and grandiose aspects. Cole had confined himself chiefly to the Hudson and Lake George, the Catskills and the White Mountains, and so did many who followed him as Sanford R. Gifford. Birsearch Hill and Moran, however, came later and with the ex-

pansion of the country sought the greater scenery of the West, while F. E. Church not only painted the national wonder of Niagara, but ranged south to the Andes and north to the Arctic Circle, as well. Men and many others gave a view of romantic America which had long filled the public mind. George Inness, our greatest landscape painter, took a different view. With a much greater power of painting than his predecessors he sought to capture something of nature and to hand upon him by nature and to present the beauty of light and color which he everywhere per-

ceived. In this view he has been followed by
1 Autumn Oaks. By George Inness
2 Conway Peak. By Thomas Cole
most of our later painters—the most noteworthy being Wyant, Tryon, Homer Martin, and, chiefly in marines, Winslow Homer. They have sought to render, not so much the striking forms of crag and torrent, as the myriad phases of sunlight and shadow, color and cloud, of the landscape. In the last half-century too the influence of foreign methods of painting is far more important than in earlier days. The earlier landscape painters picked up their painting largely by themselves or learned of each other; they often gained breadth and definiteness and expressiveness when they had definitely formed their style and confided in their own way of doing things. In later years the growing cosmopolitan character of art has led to all sorts of influences. George Inness arrived by himself at many of the ideas embodied in the work of the great French landscape school of the middle of the century. Many others however learned much directly of the Barbizon school, of Düsseldorf or Munich, or more recently of the revolutionary technique represented in the public mind by the work of Monet. The older landscape was apt to present the striking phases of nature much as they might be seen by anyone who cared for them, and in much the same way (though more skilfully) as they might be rendered by anyone who had a gift for painting. The later landscape gives much more distinctly the painter's especial way of seeing nature and it is expressed more definitely in the painter's way. One cannot enumerate all those worthy of mention: Alexander Harrison is best known for his marines, R. A. Blakelock for a personal romanticism, Walter Palmer largely for his feeling for snow effects. J. F. Murphy and Bruce Crane impress one mostly for their "tonal" quality. Theodore Robinson, Childe Hassam, John H. Twachtman are the best representatives of the influence of Monet. Edward W. Redfield, Elmer W. Schofeld and Gardiner Symons have in common that they see nature with a largeness of view and a truth of rendering that is uncommon. There will be found among the painters of the present century even those who care for the wider aspects of nature that seemed so romantic to the America of earlier years.

Bibliography.—Isham, S., "The History of American Painting" (1905); Caffin, Charles H., "American Masters of Painting" (1905). For a view of American landscape as it appears to the general historian of art, consult Muther, R., "History of Art." For a view of the earlier landscape a little nearer its own point of view, consult Sheldon, G. W., "American Painters" (1879); Benjamin, G. W., "Art in America" (1880).

EDWARD EVERETT HALE, Professor of English, Union College.

AMERICAN LEGION, The. A society incorporated in New York, 6 March 1915. Its object is to enroll all citizens of the United States who, by previous military or technical experience in the war or by reason of age, are eligible to take part in the conduct of modern war, would be in a position to render special service and who would respond in case the government should at any time need their services. The information is carefully classified as to qualifications and localities, to a thorough system of central indexing and is held at the disposal of the government, the latter having no records of the addresses and qualifications of its honorably discharged soldiers, sailors and marines, nor of men trained in the various industrial fields now connected with the science of war. The management of the legion is vested in an advisory membership of 300 representative citizens from all sections of the country and headed by a council, composed of not more than nine members. The legion creates no new means of national defense. It merely collects, co-ordinates and renders instantly available the necessary advance information regarding citizens already trained to arms and in other essential occupations, so that in case of war the work of the government will be greatly facilitated.

AMERICAN LEGISLATIVE ASSOCIATION. The American Association for Labor Legislation is organized to investigate conditions underlying labor legislation and to collect and disseminate information leading to the enactment and efficient enforcement of laws for the promotion of the comfort, health and safety of the employees. In 1910 the association called the first American Conference on Industrial Diseases, the second in 1912. In 1912 it called a meeting for the discussion of the prevention of industrial accidents, in 1913 it called the first Social Insurance Conference, and in 1914 it called the first National Conference on unemployment.

AMERICAN LIBRARY ASSOCIATION. A national association "to promote the welfare of libraries in America." It aims (1) by organization and force of numbers to effect needed reforms and improvements, most of which could not be brought about by individual effort; (2) by co-operation to lessen labor and expense of library administration; (3) by discussion and comparison to utilize the combined knowledge and experience of the profession in perfecting plans and methods, and in solving difficulties; and (4) by meetings and correspondence to promote acquaintance and esprit de corps. The association was organized in 1876 and incorporated in 1879. The present membership is about 3,500. Annual meetings are held. Executive offices and a salaried secretary are maintained in Chicago in the Public Library building. This is the centre for the association's activities which may be roughly grouped as follows: (1) Editing and publishing the official Bulletin, issued bi-monthly, through which the membership is kept informed of the plans and work of the association and its committees. One number is entirely devoted to the Proceedings of the annual meeting and another to the Handbook, containing lists of officers, committees, members, etc. (2) Editing and publishing the "A. L. A. Booklist," a monthly guide to the selection and purchase of the best of the current books. (3) Publishing and sale of all publications of the association, some 250 publications on library economy and bibliography, having been issued in the past 30 years. (4) Correlation on all phases of library work, the executive office acting, so far as it is able, as a clearing house of library information. (5) Cooperation with the association committees, library commissions, state library associations and library clubs and other national educational
and civic associations. (6) Promoting better library architecture by collecting and loaning plans of library buildings. (7) Promoting general publicity of the aims and activities of the association and library work at large. Affiliated with the American Library Association are four national associations of kindred purpose: National Association of State Libraries, League of Library Commissions, American Association of Law Libraries and Special Libraries Association. The National Education Association has a library department closely connected though not officially affiliated with the American Library Association. Committees, standing and special, include those on bookbuying, bookbinding, public documents, library administration, library training, cooperation with other national associations, libraries in hospitals and charitable and penal institutions, work for the blind, international relations and Federal and State relations. Consult 'Papers and Proceedings of the American Library Association' (1876-date, published annually); Green, S. S., 'Public Library Movement in the United States' (1913).

AMERICAN LITERATURE. A hundred years ago and for half a century afterward, every assembly of students in this country was entertained by discussions on a "Possible Literature" of America,—how soon there would be an American literature was a favorite question, grief or complaint that there was not an American literature came if the speaker or hearer were of cynical vein. The introspection which was thus developed among people who were born for something better than introspection had its good results. Every printed word, one may say, was collected, which showed that between 1602 and the 19th century any man or woman had written anything in America. Such a collection as Samuel Kettell's 'Specimens of American Poetry' shows the eagerness with which critics who were forecasting a glorious future for our literature were willing to preserve all the crystals from the past and eager to persuade us that they were jewels. The truth seems to be that for the 12th and 18th centuries there was no class of men or women who would now be called "literary people." At the same time, the new settlers and the men and women of half a dozen generations which followed said what they had to say, and generally said it well. For they did not think much about the way of saying it, they did not talk much about it, they had no professional critics. There were among them those who "harked back" to English models. After the establishment of newspapers (see Newspapers), which runs back to the year 1704, the sad necessity of journalism compelled the press to create every week a given number of square inches of what is called "matter." Thus there appeared in the three cities a few of those writers who have to write as much as when they have nothing to say, when they eagerly proclaim something not known to the world before.

It was not until 1555 that in the printed books of England the first fruits of the discovery of America appeared. Richard Eden then published his translation of Peter Martyr's "De Orbe Novo," and in addition to them, some few narrative of voyages not described in the original.

An English translation of Ribaut's "Florida" was printed in 1563. In 1576 the first edition of Sir Humphrey Gilbert's plea for a northwest passage appeared, and an account of Frobisher's voyages was published in 1578. In 1582 we touch solid ground, as to any Englishman and were perhaps the first ever written. They were written 12 Aug. 1585 from what he calls Porte Ferdynando. One of them was to the famous Sir Philip Sidney. They were printed in 1600 for the first time in the 'Transactions of the American Antiquarian Society.' The English archives have now been thoroughly searched and have probably yielded up all that can be found in them of intercourse with America in this mythical century. There are two or three narratives of the adventures of sailors who straggled from Mexico, where the Spaniards had made them prisoners, to the fisheries of the northeast, where they were relieved by the fishermen. The earliest of these is dated in the year 1582. The collections of Hakluyt and Purchas will be found other narratives of a similar character which struggled into print in one way or another. Professor Tyler in his admirable survey of the subject sees the first note of the birth of American literature in the ode of Michael Drayton, published in 1607, the year always assigned as the birthday of the nation, the year of the birth of Virginia, the year of John Smith and Powhatan and Pocahontas.

The history and criticism which belong to this subject have been admirably handled by the Messrs. Duyckinck, by Professor Tyler's 'History of American Literature from Colonial Times,' by Mr. Kettell, who has been named, and by Prof. Charles F. Richardson's 'American Literature' (1607-1885). It must be enough here to say that Capt. John Smith in his various accounts of Virginia and of his voyages on the coast created a real interest in that "brave new world which hath such people in it." Dr. Tyler refers also to George Percy, William Strachey, Alexander John Pory and George Sandys. The original editions of the publications of these men are now among the most interesting nuggets of the book collectors. The Hakluyt Society has republished many of them and has proved its value to the students of our early history. There is one interesting tract of Strachey's which would answer one pathetic question. He says, "Before I have done I will tell you the story of the lost colony." But in nothing that has been found of Strachey's is that history told.

That school of historians whose habit is to draw a blue pencil, as the trade says, across everything entertaining in history is fond of claiming John Smith's voyages as an encroachment outside Sandy Hook or Lincolnshire or the Strand. It is the fashion of to-day to throw the story of Pocahontas overboard and even Dr. Tyler, who is sympathetic, calls it the "fable of Pocahontas." But this is to be said, when 100 men trained like cockneys embarked on an unknown sea, explored an unknown bay, tried
the adventure of an unknown river, talked in an unknown language with a savage chief who has never heard of such people before, the incidents of such acts when written by them will not be exactly like those of a London counting-room or of a college lecture. The Huguenot gentlemen, I believe, find Smith's account of Hungary and its Turkish wars intelligible and reliable. Smith's surveys of Massachusetts Bay are entirely intelligible and show an accurate acquaintance with the region which he describes. Now, it is hardly believable that you can verify an old author's personal narrative in nine cases out of ten, to say in the tenth case that he is a liar, simply because you have no material for verification, on the one hand, or contradiction on the other. Close after the literature of Virginian writers came the series of the Massachusetts historians. They also have been most carefully edited; and it is now only by a fortunate accident that a student of to-day is able to add any anecdote new to other students. But a book of historical society and preserved in which, according to the custom of their time, they offered to defend 54 propositions against all comers. It has been observed by modern critics that all these propositions are now known to be false. This is a somewhat cynical statement with regard to the traitors of the heath and the skies. Four of the number became clergymen. The name most distinguished in history is that of Sir George Downing, who did not distinguish himself for the courage of his convictions.

As early as 1639 the government of the colony had cared for its future education by the establishment at Cambridge of a printing press. This was done almost simultaneously with the establishment of Harvard College by the same authority. Sir Thomas Morton, in his book "History of Plymouth Plantation," the Massachusetts people may well call William Bradford's chronicle the beginning of the literature of New England. It should not be forgotten, however, that the letters containing the accounts of Gosnold's unsuccessful colony in 1602 were written before the time when Bradford began to write his history.

When the larger colony of Massachusetts Bay was formed the general court of that colony, according to a very early record, directs that paper books shall be furnished for preserving all journals by the first settlers. Fortunately for their successors, Gov. John Winthrop in the midst of all his other cares used his manuscript books, and his notes made almost daily are now cited as Winthrop's "History of New England." These books were printed from 29 March 1630, when he sailed from England, to 11 Nov. 1648. It is a convenient aid to memory that Winthrop's death followed close on the execution of Charles the First. Sadly enough all the other blank books thus furnished seem to have served other purposes from that for which they were intended. They were, perhaps, used for sermons now forgotten, or possibly for cartridges so soon as cartridges were invented. Such materials for the early history as have been preserved have generally been printed by the Harvard University Press or similar agencies. There is a charm about them such as belongs to all fresh narrative where the writers are thinking of the thing done and not of the methods of expressing it. This charm which hangs around Columbus' "Letters," Sir Thomas Malory's "Utopia," Defoe's "Robinson Crusoe," Swift's "Gulliver's Travels," is the same charm which is to be found in Purchas and Hakluyt and the early narratives of those who wrote by the light of a pine knot with pens made from a bird's wing. In such simple utterances we are to look for the first handiwork of American literature.

The first graduates of Harvard College made a class of nine young men, six of whom sought their fortunes in Europe. The year of their Commencement was 1639. England. The journal of William Bradford, one of the first governors of the Plymouth Colony, has a story which is dramatic. With a fortunate prescience of the value of every word which related to the Plymouth emigration, William Bradford wrote the "History of Plymouth Plantation." His sons and indeed all the people of the old colony knew of the exceeding worth of this volume. It was used by Morton, Prince and Hutchinson and the others of our earlier historians. Great part of it was copied and from the copy thus made it was consulted by our historians till the year 1855. In that year a quotation from it, which was not in our copies, appeared in Bishop Wilberforce's history of the English Church. On inquiry it proved that this gentleman had consulted the original which was in the library of the bishop of London in Fulham Palace. He immediately gave permission that the whole should be copied on the request of Mr. Charles Deane. Subsequently, as a result of the efforts of Senator Hoar, the various authorities in England gave back the precious manuscript to the State of Massachusetts, and it is now one of the treasures most sacredly preserved in the State House in Boston. As Dr. Tyler calls it, "The Bay Psalm Book," the work of Thomas Welde, John Eliot and Richard Mather.

Eliot already looking forward to his work among the Indians was making his first studies of the language of the people for whom he cared. The modern students speak of this language as the Natick dialect of the Algonquin tongue. Eliot's work was of the first importance, and before he died the publications in that language alone of books printed either in our Cambridge or in London makes a department in literature of more than 30 volumes. These books were printed to be used in wigwams and log cabins. The copies which strayed into libraries were but few and those Indian books of that century now preserved are the rarest treasures of the collectors. Of Eliot's "New Testament" in the first edition there are but 14 copies. Of the second revised edition, published more elegantly, there are 39 copies. The work that Eliot gave in translating the Bible into the Algonquin tongue has been
spoken of more than once as work thrown away. But to say this is absurd. Eliot proved himself to be one of the first philologists of any period of literature. His analysis of the Indian language is to this moment a guide to those who choose to study it. With the proven fact of discovery it has proved that the Algonquin language, of which the Massachusetts language was a dialect, was the language of more than half the Indians of our part of the continent. To the north it is spoken by the Iowas who are living in North Carolina, the Pamunkeys who are living in Virginia, by the Delawares who have been carried from Delaware Bay to Kansas, by the Micmacs, Penobschts and other Indians of Maine and of the northeast, and even by the Arapahoes in the west. Northward and westward it is spoken as far as the tribes of the great Ojibwa family, far beyond Lake Superior, and often near to the Arctic Ocean. Of 300,000 Indians, more or less, now in the territory of the United States, more than half would have little trouble understanding Massasoit and Philip. An admirable bibliog- raphy of Algonquin literature has been pre- pared by James Constantine Pilling. It is published by the United States Bureau of Ethnol- ogy. The work of the Massachusetts missionaries in Pennsylvania in the same lines belongs rather to the next century.

Among the early settlers of Massachusetts was Anne Bradstreet, a girl of 18. She was the daughter of Thomas Dudley, who became the second governor of Massachusetts. She was the person called the 'Tenth Muse' by Cotton Mather. Her poems, many of which were written before she came to America, are an interesting and curious memorial of the better educated colonists. She lived for most of her life at Andover in Middlesex County. Between 1642 and 1700 Increase Mather and Cotton Mather are the names most often referred to as we look back on our literary history. Of Increase Mather we have in print 85 publications, mostly separate sermons. Of Cotton Mather for colonists, the number of titles being 382. The modern fashion is to speak of the Mathers with a sneer as bigots and to dismiss them from the lofty consideration of our time. But whoever re- members the duties to which they had to put their hands is disposed to regard them more favorably. There was but little subdivision of work for the men who had been educated to be the leaders of their country. And certainly some allowance is to be made for ignorance of the laws of electricity when the teacher who you are judging has to study his electricity as Cotton Mather did while he encourages soldiers for warfare, while he checks the sickness by inoculation, while he is writing the history of the past and is caring for the poverty of to-day. Any value to the world, he owed it to Cotton Mather's son, that if he himself had been of any value to the world, he owed it to Cotton Mather's 'Essays to do Good.' It is rather hard to throw Cotton Mather overboard either as a quack or a fanatic when such a man as Franklin was willing to write for him such an epitaph. It is fortunate for this generation that at a comparatively early period of his life Mather brought together in his 'Magnalia' his- torical papers which he had already written, some of which had been printed. The date of the first edition of the 'Magnalia' is 1702, but the work belongs almost entirely to the 17th century. Cotton Mather was himself born in the year 1663, so that a good deal of his record of the history of the first settlement is put on paper at a time when the great event had been for- tunate error here has puzzled his readers. For instance, before the discovery of the original Bradford manuscript, we owed to Mather the statement that the Pilgrim Fathers came from Austerfield in the county of Yorkshire. This proved to be the missprint of the London printer for Austerfield. It was only on the discovery of this error by the late William Hunter that the American pilgrimages to Scrooby and Aus- terfield began. A good deal of injustice has been done Mather from what is in itself a com- paratively late invention in conversation, Massasoit and Philip. An admirable bibliog- raphy of Algonquin literature has been pre- pared by James Constantine Pilling. It is published by the United States Bureau of Ethnol- ogy. The work of the Massachusetts missionaries in Pennsylvania in the same lines belongs rather to the next century.

Among the early settlers of Massachusetts was Anne Bradstreet, a girl of 18. She was the daughter of Thomas Dudley, who became the second governor of Massachusetts. She was the person called the 'Tenth Muse' by Cotton Mather. Her poems, many of which were written before she came to America, are an interesting and curious memorial of the better educated colonists. She lived for most of her life at Andover in Middlesex County. Between 1642 and 1700 Increase Mather and Cotton Mather are the names most often referred to as we look back on our literary history. Of Increase Mather we have in print 85 publications, mostly separate sermons. Of Cotton Mather for colonists, the number of titles being 382. The modern fashion is to speak of the Mathers with a sneer as bigots and to dismiss them from the lofty consideration of our time. But whoever re- members the duties to which they had to put their hands is disposed to regard them more favorably. There was but little subdivision of work for the men who had been educated to be the leaders of their country. And certainly some allowance is to be made for ignorance of the laws of electricity when the teacher who you are judging has to study his electricity as Cotton Mather did while he encourages soldiers for warfare, while he checks the sickness by inoculation, while he is writing the history of the past and is caring for the poverty of to-day. Any value to the world, he owed it to Cotton Mather's son, that if he himself had been of any value to the world, he owed it to Cotton Mather's 'Essays to do Good.' It is rather hard to throw Cotton Mather overboard either as a quack or a fanatic when such a man as Franklin was willing to write for him such an
chief of North America. So it happens that in reviewing the literature of the country we have no longer such unaffected and simple narrative. But we find ourselves more in the walks of religious speculation and of theology. In the front of the writers on such subjects is Jonathan Edwards, who challenged the attention of the learned in the English-speaking world by studies and results which have become famous. In the penury of frontier villages, and living day by day in what seems very petty surrounding society. Another found himself in the infinite limits on the divine counsels and placed his poor limits on the infinite in methods and language which will survive all other American literature of the first half of the century. It is inevitable perhaps that in the midst of such discussions of the idea there shall appear on the other side of the horizon discussions of the fact, or of those realities which men can see with the eyes and hear with the ears. And in our case, Benjamin Franklin was born into the world in the year 1706. Before he was a mankind was in studying the English language which gave him afterward his power to express himself to men. Long before he was a statesman and diplomatist, he was conducting his experiments on electricity, and when he drooped the skies, he attracted the attention of all the learned world of his time. When we speak of the American authors of those 50 years the fame of Edwards and Franklin overshadows all the rest. With the discussions attendant on the American Revolution, a new school of authorship began. It now seems clear enough that the more thoughtful leaders of English opinion were from the very beginning amused, not to say delighted, with the simple dignity with which such men as the Adamses, Franklin, and Jefferson conducted the discussions, whether of matters of trade, of taxation, of government.

"History, my Lord," said Lord Chatham, in his famous address to the House of Lords, "has been my favorite study. It has taught me that in all my reading, and I have read Thucydides and have studied and admired the master states of the world, for solidity of reason, force of sagacity and wisdom of conclusion, no nation or body of men can stand in preference to the General Congress at Philadelphia. The histories of Greece and Rome give us nothing equal to it."

To this moment, indeed, no careful student of constitutional law or of the foundations of states can go far without reading with care the works of the American statesmen of that time.

It is interesting to observe that at the same time, perhaps from the same cause, the theological literature of America becomes less and less interesting. The mind and heart and soul of the educated men of America was steadily drifting into an interest in the present relations between God and man and the present away of the eternal law, much more important to men and women, and among the rest, of men of letters, than theological explanations of the secrets of the universe. The student of to-day finds it worth while to read the publications of Thomas Mayhew, of Boston, of Dr. Witherspoon, of Princeton, of Dr. Samuel Johnson, of New York. But this is not because he cares so much for what is called theology in its narrow definition, but because these men enter as champions of the people into that larger theology of men who really believe that they themselves and all men may be partners of the divine nature.

Franklin with his genuine instinct for "Together" did not live long in Philadelphia without bringing together one and another club of men of inquiring disposition. One of these clubs still exists in the American Philosophical Society. Another founded the fire department of Philadelphia. And, indeed, most of the activities which had given that city distinction, even before 1775, may be traced to such origins. Franklin's own newspaper, the Evening Post, may be spoken of as really a literary journal. Poor Richard's Almanac was not only an index of time and weather, but it was in its way a philosophic treatise. It was soon translated into French. Le Bonhomme Richard was known in French hamlets which knew nothing of the tea tax or the stamp tax. So soon as peace was declared he founded the American Academy of Arts and Sciences, as the Massachusetts Historical Society, as Tammany in New York, which was originally a scientific and philanthropic institution, came into being. The governors of the evening of the skies, he attracted the attention of all the learned world of his time. When we speak of the American authors of those 50 years the fame of Edwards and Franklin overshadows all the rest. With the discussions attendant on the American Revolution, a new school of authorship began. It now seems clear enough that the more thoughtful leaders of English opinion were from the very beginning amused, not to say delighted, with the simple dignity with which such men as the Adamses, Franklin, and Jefferson conducted the discussions, whether of matters of trade, of taxation, or of government.

A curious illustration of the increasing confidence in home and the literature of home, as years went by, would be found in the series of college addresses of which the first were published at Cambridge in 1796. The Phi Beta Kappa Society, founded in 1776 at Williams and Mary College in Virginia, soon outgrew its first limitations; and its annual exercises at Cambridge and New Haven were attended by graduate members who liked to renew their college memories. Branches of it were founded in Brown College in Providence, in Dartmouth College in New Hampshire, and as years passed on, in other similar institutions. The early addresses by scholarly men in these societies were almost uniformly exhortation that the people of America must pay more attention to scholarship and literature. Meanwhile, and under such incentives, there grew up of course, in one centre or another, small coteries of literary men and literary women. With an amusing regard to tradition such men seemed to have felt that there could be no literature without an epic or two on which it should be built. Timothy Dwight's 'Conquest of Canaan,' Joel Barlow's 'Columbiad,' which are all but forgotten, and several others which are forgotten, were the result of such duty in this regard. No one can suppose that either of these men was inspired by any divine influxus of the poet. As you read the dreary lines you feel that the writer thought that there must be an epic and that because there must be he would write it, with the same feeling that a column of soldiers storms a redoubt. By the side of such men, however, there came men and women who loved to clothe great thoughts with charming or fitting dress.

It is interesting to see that almost all of the
early books which we should now class as "efforts" in literature were published by subscription. And there is something pathetic in the memoirs of the earlier literary men where they describe their personal visits from place to place as they solicited subscriptions to pay for the printing of their books. President Dwight himself visited the camp of Washington in 1775 and obtained the subscription of Washington and the other distinguished men around him for the publication of the 'Conquest of America.' The reader must remember that the practical introduction of stereotyping in England or America is as late as the beginning of the 19th century. It was necessary, therefore, to test the market in some way when a book was first printed, so that the printer or publisher or author might know how many copies should be printed. It must be remembered, also, that the printers had no capital which would enable them to keep in type the cumbrous pages of a book which passed the size of a pamphlet. Painstaking that for Samen, in 1776, was probably the first book which attained at once a circulation in the least approaching the large editions of to-day. The trade, as the book-selling community still likes to call itself, now begins putting out as a corer a small edition. In our day in a vault in the side of a mountain, or perhaps in a vault under a sidewalk we preserve such plates from which a book has been printed, and according as the demand may prove, new editions can be issued at a comparatively small expense. But up to the year 1813 there was no such resource.

The pecuniary poverty of the printers of the end of the 18th and the beginning of the 19th century caused many American authors to go to England for the printing of their production. Barlow's 'Columbiad' was printed in England. Irving's books appeared first in London. Indeed, Irving's wide reputation may be said to have been English before it was American. And he spent much of his early life in Europe, perhaps from the feeling that America was a home while America was a wilderness. James Fenimore Cooper made Europe his home for many years, feeling apparently that he could not find society of his own kind in his own land. The same is true of other American writers as far down as the thirties of the 19th century. That was the worse for the infant literature of the nation. Writers watched painfully for the expressions of English criticism, and one line from a Grub street critic was sweeter to them and worth more than any words from their own countrymen. It is indeed impossible to overstate the effect which was eventually produced by the "American system," as it was called, in the discussions of tariff legislation which followed the introduction of English literature. From the American printer when the American printer could send out to the world books as well printed as the printers of England, one may trace new strength in American authorship. The International Copyright Law of 1891 compels the publishers of all books which claim American copyright to print them in America. In a truly celebrated article in the Edinburgh Review of 1820, of which no other line is remembered, Sydney Smith said: "Who reads an American book? Who looks upon an American picture?" The men who painted American pictures were very mad, as their vernacular would say; and the men and women who wrote American books were equally mad. The writers had a better chance to express their anger than the painters. The sneer implied was the more the more for purposes of literature it was true. Probably it had some share in the growth; almost from that moment, of a literature which can fairly be called American. The worst of it was, perhaps, that Sydney Smith was an advance guard of the American in England. He could not be called the product of an "effete civilization," and his words could not be ascribed to Tory jealousy. American readers had known how to prize him and they read his articles if they did not read their own. But really an American author had little right to complain so long as Mr. Cooper called a woman a female simply because Walter Scott did so, and as long as our writers knew more of robin-red-breasts and bulfinches than they knew of bluejays or mocking birds, or sparrows. But as London as Edinburgh Review and the London Quarterly and the New Monthly Magazine as they read no American journal. The American college boy knew much more of the love and hates of literary men in England, one might almost say, than the English boy of the same time did. The English reviews and magazines passed from hand to hand in the American reading-rooms while their American rivals died a slow death due to the incompetency of the rest of the writers. But as the 19th century advanced the tide turned. Dr. Holmes in a happy phrase, quoted as often as Sydney Smith's which has been cited, fixes Emerson's first Phi Beta Kappa address as "our intellectual declaration of independence." I heard the address in 1837, and half a century afterward I heard his second Phi Beta address. Whoever will compare the two will see what Dr. Holmes means. To the thoughtful reader now it seems impossible that Emerson's first Phi Beta would be as extravagant or in any way, indeed, out of the common to the men of that time. But it did seem so then.

It is true that ever since the century began such addresses on Commencement days or on other literary occasions have still been not fifth of the time to pathetic appeals to young men to create an American literature. The orators, generally clergymen or lawyers, did not understand that such books as Lewis and Clark's journals were American literature, that Pickman's statistics was a book of American literature, that Flint's 'Mississippi' or Pike's 'Adventures' were vigorous bits of proper national literature, that the Constitution of the United States or John Adams' proposals for the State Constitutions with Emerson's "eighteen American authors as the Waverley Novels belong to Scotch literature, or Petrarch's 'Sonnets' to Italian literature. But by the middle of the 19th century, people had found out that literature is not a thing by itself to be worshipped and loved like some lonely classical statue in some separate shrine in a gallery, but that literature is simply the expression of what is. In the matter of American literature it proved that Americans had to state for the world the foundation principles of government. They had to describe
for the world physical features of a continent of which the larger world knew nothing. And even the language in which they spoke would bear marks of the climate, the soil and the history of that continent. So soon as we throw aside the follies of talking about literature, as if it were a separate idol, so soon American literature can be spoken of as a thing in any sort distinct from the literature of the feudal system or other literature of the ancient world.

To review in the very briefest way the literary advance of the nation from the era of independence we have to look first at the speeches and letters and pamphlets of the statesmen; and next at the reports of the explorers. There are individual poems and a few sporadic books in prose which linger in the remembrance of antiquaries — Philip Frena's Revolution poems, one or two sermons, perhaps may be classed among such memorials. To speak in a broader sense the first work of Irving stands as the first work in the large calendar of our modern literature. His amusing studies of early New York were known then, but the 'Sketch Book' as it was published in London in the years between 1820 and 1822 at once obtained a wide reputation, both in London and in America. Irving showed from the first that he could handle American subjects with a pen as light and a fancy as charming as gave life to 'Bracebridge Hall' or his other English studies. In 1823, when Navarre's first published in Madrid the original documents of Columbus' voyage, Alexander H. Everett, who was then our minister in Spain, called Irving's attention to these invaluable memoirs and suggested his work on the life of Columbus. Irving went at once to Madrid and was attached to the American legation there while he studied the subject which is so closely identified with his name. And afterward, when the Spanish people received him as our minister there he enjoyed his well-deserved fame. Here was an American who could meet English writers on their own terms, writing was marked as well as they of whatever is meant by style or method in literature, whatever secret of the guild there is.

In our time there is no longer a patron who shall give a book as an envoy or might endow an opera house at his capital. For a time or a nation without patrons, you must have such patronage of the public in advance as Dr. Dwight sought for with his subscription book; or, as it has proved, in 150 years, you must have magazines. This means, if one speaks to the Philistines, that you cannot have large wholesale business, no, and you cannot have manufactures unless there be retail business. Dr. Johnson and Oliver Goldsmith had found this out when they worked for Cave and the Gentleman's Magazine. One and another adventurer tried the magazine experiment in Boston or Philadelphia or New York. But alas, the printers of the magazines were almost as poor as the authors were. The people of the country were very poor in other affairs. As late as 1834 Dr. Holmes wrote for the New England Magazine the first papers of the 'Autocrat of the Breakfast Table.' But the New England Magazine, even with such contributors, died for want of readers. The new series of the Autocrat, in 1857, begins with the words, "As I was saying when you interrupted me," which referred to the death of the first series a quarter century before. Still, the names of those old magazines are interesting gravestones which show the roadway for a struggling national literature. The Harvard Register of 1807 is one of the earliest. The Lyceum follows the Collegian, Harvardiana, and now almost every university gives this excellent field for the tournament of squires and even of pages who look forward to golden spurs of knighthood. A few lines of the Harvard Lyceum of 1810 may be worth copying. They are from a clever parody of Barlow's 'Columbiad,' and describe an early steamboat. They are among the boy amusements of Edward Everett.

So where high Hudson belts his hundred hills, Winds his wide wave, and York's broad basin fills; With engine force the fluid fields to plough, The mighty Steam-boat points his sailless prow. Knees from the wind no gales, the sea no tides, His wheel car, and o'er the river rides. Lo with what art the nice machinery turns With what fierce force the pitchy pine pole burns. See the black Boiler, in whose dark womb, The prison'd water vapours into flame: The hollow Cylinder, whose shining side, Cramps the crook'd Chain, and turns the densing tide: Btc., etc., etc.

Of those of the magazines proper which were manfully and loyaly sustained for many years is the Knickerbocker which was published in New York monthly for several years. Most of the authors who won distinction in the literature of the century made their maiden contributions to its pages. In Boston a beginning, which proved to be a foundation, was made in the issue of the Monthly Anthology, of which the first number was printed in 1809. It was the work of a literary club, and was very creditable to the literary life of the day. Some original translations from the minor poems of the great German poets slipped in. And by this time, America had found out the resources of the German colleges. George Bancroft, Frederick Hodge, Edward Everett, Henry F. Quitman, George Ticknor studied in the German colleges. The success of the Anthology and perhaps a certain jealousy of the literary tyranny of the London Quarterly and the Edinburgh Review led William Tudor, with the spirited young fellows who wrote for the Anthology, to announce the North American Review of which the first number was published in 1815. It may be said of the North American Review that a desire to imitate the English quarters weakened it for perhaps a quarter of a century. But its tone was always dignified and on really national questions it was American. In the earlier numbers of the Review it admitted poetry and some short articles which did not pretend to be criticism of books. The successive editors of the Review were William Tudor, Edward Tyrrel Channing, Edward Everett, Jared Sparks, John G. Palfrey, Francis Bowen, Andrew Preston Peabody, Alexander Everett, and James Russell Lowell. A few years after the Civil War it was removed from Boston to New York under the charge of Alten Thornideke Rice. In Philadelphia what was called the American Quarterly Review was published under similar auspices.

Meanwhile what had attracted attention at once to a very great extent was the success of Cooper's novels. The later novels of Scott
were still engaging the attention of readers when Cooper's earlier stories were published. He had left Yale College without a degree, disgusted with something or other as youngsters are at those colleges, and had joined the United States navy. This, as it proved, was fortunate for the literature of America. After the short war with England, he was stationed on Lake Ontario, which was at that time in the wilderness. At his father's home he had already made acquaintance with the wrecks of the Seneca and the Six Nation Indians. At Oswego he fell in some exultation with the last of the Mohicans. His study of a real forest and his studies of the forebearage of American ships are both genuinely national, and although he could not resist the spell of the "great enchanter," and imitated Sir Walter Scott whenever he got a chance, the early Cooper novels have the great charm of being interesting. To this hour the school boy reads them as his grandfather read them and regards them among his best books. In Cooper's later novels there may be seen a tinge of ill temper because he fancied that he had not been esteemed fairly by his own countrymen. But the early novels have established themselves in a well-assured place in the literature of his country. Few people remember them, but it is said that the German novels on American subjects by Sealsfield were the inducement for a time of the great German emigration which began as soon as these spirited books began to be printed. His German name was Karl Postel.

Meanwhile the leaders of the nation had found out that a republic stands or falls according to the education of its people. It is impossible to estimate the change produced by the early determination of the more civilized States to improve the education of every child born in their borders. At the beginning of the century you might say that there was nobody to buy books, even if angels or archangels had descended from heaven to write them. But even in the middle of the century an army of readers, men and women, had been created. It began to be evident that a good book in the English language had more readers in America than it had in England. It began to appear that the reputation of English writers depended quite as much upon the American readers as upon those of the British Islands. Scott, Byron, Wordsworth, Coleridge and Southey had more readers on this side of the ocean than on their own. The same was true later of Macaulay's "History" and of other books of permanent value. Disraeli said as early as 1845 that America was the present posternity for the Englishman,—that an English author knew what posternity would think of him by learning what the American of to-day thought of him. The creation of such a body of readers led to the growth of a genuine American demand for what could be called an American literature. A school of history grew up first in which Irving had led the way in which the great historical addresses of Webster and the great orators were an essential part. The subservience to English critics diminished as more and more scholars came from France and Germany. It would be fair to say that Bancroft, Prescott and Motley, as historians, Emerson as a philosopher, Longfellow, Lowell, Holmes and Whittier as poets made a distinct American school after the year 1830 when Bancroft announced his plan for his history, or more definitely perhaps in 1833. So far as this was a New England school it was somewhat affected by the literature of the Continent of Europe, but this effect has been overstated. Emerson was not at all indebted to Germany in his work. Longfellow's poems are distinctly American when they are not translations. Lowell won his English reputation by the admirably national characteristics of the "Biglow Papers." Still a distinct ripple on the tide of literary advance may be found in all the seaboard States when in the twenties of the last century the Holy Alliance exiled from Germany Lieber, Follen, Beck and some other young students who had displeased Metternich.

What is familiarly called the Lyceum System introduced an element of value constantly increasing in the higher education. It ought to be remembered that the Lyceum introduced Ralph Waldo Emerson to the people of America in a much shorter time perhaps than any published writing would have done without its assistance. Where the trustees and faculties of colleges would have refused to invite Mr. Emerson to speak, the students of college societies would gladly send him an invitation. Once heard he was of course sure to be remembered. Not to speak of other lecturers who were instructing all the northern States, arousing curiosity as to subjects on which they hardly touched, Ralph Waldo Emerson when he took up the work of a prophet unlimited by the restrictions of the priesthood led the way in a revelation which has affected all the literature of his time, whether in America or in England. In the smaller New England circle, Margaret Fuller, afterward the Countess Ossoli, by conversations and published essays called the attention of many young people to the wider realms of thought and especially to the more modern movements of philosophy and literature.

With the existence of a sufficient body of readers large circulations became possible for magazines. The first which succeeded peculiarly were those which told the most stories, and it was on the basis of story telling that the Southern Literary Magazine, Graham's Magazine, the Godey's Lady's Book, the Boston Miscellany of Literature and Fashion came into being, and by their success with the public created the literary magazine of to-day. When a Boston publisher could say in 1841, "We sell 1,000 copies every month to the Lowell factory girls," the word was spoken which showed that a sufficient supply of readers is necessary in the creation of a literature, and will in its time bring into being a sufficient number of writers. The Knickerbocker, the New England Magazine and the Port Folio had failed to enlist anything like the public support which waited on all decent magazine work after the public schools had created their army of readers. One and another ineffectual effort was made to turn away the current of the English magazines and to introduce an American circulation in its stead. It is interesting to see that the early numbers of Harper were written almost wholly by English writers and large editions of Fraser's Magazine, of the Dublin University Magazine and of Blackwood's stood in the popular reading of the reading-rooms. But in 1857 the Atlantic Monthly was created with
such writers as Bancroft, Prescott, Motley, Holmes, Lowell and Longfellow among its very earliest contributors, and one may say, on its working staff. Lowell was an office editor for American Monthly, in New York, sprang full armed into existence. It introduced itself by an article which awakened curiosity, and perhaps one may say national pride, on the question, "Have we a Bourbon among us?" From that day to this, the magazine has held an important place in the work of the better literary men of America.

The short story, as Dickens and Thackeray had shown, gave admirable opportunity for feeling the public pulse. It is amusing today to read that the publishers of the Anti-Slavery Standard doubted whether they should pay James Lowell $400 a year for his contributions to that journal, contributions among which are some of the best poems which he ever wrote. This is only one among the many illustrations which peep out from the books of biography as to what Dr. Johnson or Goldsmith would have called the patronage of the readers of magazines and their editors. The encouragement to authors was little but it was enough. In the year 1849-50 the people who read anti-slavery newspapers began to talk of the serial issues in which the story of 'Uncle Tom's Cabin' was going forward in a newspaper called The National Era. The Southern writers on the Civil War ascribe to that book the complete change in American politics and in the questions which led to the war which belongs to the middle of the century. In 1851 the story was published in book form and at once became known not simply in America, but in England and in all the literature of the civilized world by means of translations. Its circulation in England, for instance, was the first circulation of a book on what was called popular prices. One edition of it appeared in a newspaper issue at the rate of one penny a copy. Mrs. Stowe's supremacy as a writer of fiction established itself at once, and from that moment to this American literature can make the boast that it has furnished the book of which more copies have been printed than any other in the English language. It is a little curious that its only possible rival, if one considers simply the number of copies printed, is 'Robinson Crusoe.' Mrs. Stowe's story is that of a fugitive slave; Defoe's story is that of a shipwrecked slave trader.

After the Civil War the men and women of America learned that for the criticism or for the education which belonged to this nation, they must study their own country. In truth the society of America is American society, the laws of America are American laws, the prospects and hopes are those of a democracy. As the strata of its rocks and the growth of its trees are different from those of England, so are the foundations of the state and the customs of its citizenry. It is in the least detail the methods of different writers who have won the love and admiration of their countrymen in the years which have followed.

The central observation is that as soon as America furnished readers enough a proper American literature followed the demand. As soon as the system of the country made possible first-rate printing offices in rivalry with the best printing houses in England, the American demand for American books could be satisfied at home. In naming Cooper and Irving we have named the two writers distinctly American whose published work was first everywhere known. Other authors printed their books which were forgotten. There was perhaps something ludicrous in the effort to cultivate an artificial enthusiasm which did not exist. For instance, any early copy of the North American Review will show the standing advertisement on the cover that the publishers had a "supply of the 'Yamoyden' kept constantly on hand." The 'Yamoyden' was a poem on a supposed hero or heroine of Algonquin origin named the 'Yamoyden.' But the publishers spoke of the volume as a commission house might speak of so many bushels of wheat or barley. Books or essays of purely American type struggled into existence and some of them are still remembered. Edgar Allan Poe was born in the year 1809 and died in the year 1849. Warren Burton's 'District School,' Mrs. Gilman's 'New England Housekeeper,' and Judge Paulding's sketch of a young American published in the North American Review itself while it imitated aspects of the English quarterlies always carried an American chip on the shoulder and defied all foreign travelers or foreign critics who did not find perfection in everything American. A story of pure American life, most instructive to the student of that older time, is Sylvester Judd's story of 'Margaret, a Tale of the Real and Ideal, Blight and Bloom.' Judd was a poet, but this prose novel has proved his best work.

The exquisite genius of Nathaniel Hawthorne would have worked its way through any difficulties. In his own nation his favorite earlier subjects, drawn so largely from the traditions of the early colonists, were planted in the English language. It is a little curious that its only possible rival, if one considers simply the number of copies printed, is 'Robinson Crusoe.' Mrs. Stowe's story is that of a fugitive slave; Defoe's story is that of a shipwrecked slave trader.

Defoe's story is that of a shipwrecked slave trader.
AMERICAN LITERATURE

this is no place to enter into an analysis or further discussion of the work of different American authors and of their hold upon the national life. When one remembers that no prose writer of our country is more likely to be generally read three centuries hence than the despatches of Ulysses Simpson Grant, he hesitates before he shall say who are the literary men. Give time enough and Washington becomes a literary man, and Judge Marshall. But this may be said, that of the heroes in the New York Hall of Fame, Thomas Jefferson, James Kent, Joseph Story, Asa Gray, Jonathan Edwards, William Ellery Channing, Horace Mann, Henry Ward Beecher, Ralph Waldo Emerson, Nathaniel Hawthorne, Henry Ward Longfellow and Washington Irving, would not have been named among the most distinguished Americans except for their work with the pen. Franklin might be numbered as a naturalist, Washington or Grant as soldiers; but the 12 who have been named won their place simply as authors. And every one who is in any way familiar with their work understands that this work is distinctly American. You cannot transplant it. If you read 25 pages from any of these authors, you would know that he was brought up under the institutions of a republic and that the width of horizon, may one say, comes in as a part of the atmosphere to which in the omnipotence of God the American is accustomed. In naming those of whom the country owes the growth of its literary taste, the charm of great travelers and great historians should be added to the great statesmen. But the list as far as it goes is not useless, for it shows what is the current of thought of the people of America. The people of America is sovereign of America and as everywhere the sovereign is the fountain of honor. We could choose no better instance of the encouragement given by the people to the author of first-rate genius and ability than is found in the literary career of John Fiske. Fiske owed none of his success to official position. No distinguished review called attention to the way a young man needed encouragement, but simply Fiske had a great deal to say and he said it. He read a time he said it to a nation of people who had been educated to appreciate and enjoy what he said. He used to say that even in his young life he was looking forward to history as the study which he was to pursue through his life. The opportunity came for the gratification of this passion. He seized upon the opportunity, and the American people recognized the hand of a master. But Fiske was not to be shut up within any narrow range of study or of authorship. He had his own views of life and duty, of ethics and of destiny, and he wrote them down. He said what he wanted to say in a form which won the sympathy of all thoughtful people, and there were enough readers trained to careful thought to welcome the gifts which in such style the man brought. Later on, perhaps, speaking of this instance we are speaking simply of the step forward which the conscience and heart of the whole nation made in obedience to the word of Ralph Waldo Emerson, who gained a welcome in all quarters,—in the miner’s cabin or in the sanctuary of kilndried seminaries. It has been said that of the early volumes of Emerson’s ‘Essays,’ millions of copies might be found to-day in the hands of the most ignorant of the most uneducated man, and millions of men who never heard his name are living under the inspiration of his prophecies. It is said by the English critics that Longfellow’s poems are better known by the people of England than are Lord Tennyson’s. Perhaps this is true.

It has also been curiously true that more than one English reputation has been first made in America. Carlyle’s first books were well known here before the critics of England honored them with their approval. The English writers whined a good deal so long as they had no protection at American law for their copyrights. This nation was creating a reading class at an expense such as monarchs never dreamed of, such as England has never thought of, and it was the fashion to chide Americans because at the outset they did not throw open the market thus created to the writers of a nation where there was not one reader for a hundred in America. The International Copyright Act has remedied this grievance. But it has not proved that either the English or American author has gained readers by any of the accidents of publication. The rule holds which Abraham Lincoln laid down so well that the people who like that sort of thing will read that sort of thing. But so far as statistics of the trade in books go, it is evident that the rank and file of American readers are interested in American subjects treated by writers who feel the American impulse and were early baptized in the ways of democracy. For the work of individual writers see the following article and the separate biographies in this Encyclopedia.

EDWARD EVERETT HALLE.

AMERICAN LITERATURE, Synopsis of. The first great American poem was ‘Thanatopsis’ by William Cullen Bryant (1794-1878). There had been rough ballads and songs on the one hand, and literary odes and epics—by John Trumbull (1750-1831), Timothy Dwight (1752-1817), Joel Barlow (1755-1812), and others—while there were snatches of feeling in the poems of Edward Frenaye (1752-1832). But the first American poet to make a deep impression on people abroad as well as at home was Bryant. With all his interest in the picturesque and romantic in all ages and in all countries, he was generally most himself in his pictures of American life and in his expression of American conditions. Besides Bryant, and about his time were a number of other men of letters in New York whose poetry pleased their time, but who are remembered now by the tradition of perhaps a single poem. Such are John Howard Payne (1792-1852) the author of ‘Home, Sweet Home’ whose real work in life was in the drama, Samuel Woodworth (1785-1842) the author of ‘Old Oaken Bucket’ and George P. Morris (1802-44) perhaps the only one of whom that ‘Tree’ is remembered if not often read. James Rodman Drake (1795-1820) and Fitz-Green Halleck (1790-1867) wrote together and separately poems which delighted their contemporaries. At the same time appeared the poetry of the ‘Transcendental’ group, and others wrote all sorts of things—poetry, stories,
critical and other articles—for the magazines, some good and some bad, often under the spur of necessity. But among his poems may be found a few which have that peculiar and individual lyric quality that belongs especially to the poet, and not to any particular nation or time. With less pure poetic genius, perhaps, but more sense of the beauty and romance that charms people, and more of an easy gift of verse, Henry Wadsworth Longfellow (1807-82) had a career with reigning gas of the poetry of other peoples. He was a college professor, widely read in the literatures of other nations, and his earliest poetry not unnaturally was the rendering of what had charmed and interested him in his reading. But he, as well as the rest, was impressed by the romance of American life; indeed, his very first poem is on a subject from American history. And in "Evangeline," "Hawthorn," "The Courtship of Miles Standish" as well as in many shorter pieces he fixed in beautiful forms, figures and legends from the American past. American though he was Longfellow saw American life largely through the glasses of traditional literature. A more direct view of American life and one of the glories of New England life, was that of John Greenleaf Whittier (1807-92). Though he knew English literature well yet his poetry does much to give a true idea of New England country life as it appears to a real country nature of a most delicate and refined type. Nearer still, however, to the ordinary average American life (or at least aiming to be) was Walt Whitman (1819-92), who used every effort to give his work the character of free uncontrolled democracy. His poetry is of a wholly unconventional form and his view of life is equally direct, free and unrestrained. To many readers, especially abroad, he is the most representative American possible. James Russell Lowell (1819-91) is better remembered as an essayist than as a poet, yet his "Biglow Papers" have not only the qualities of the best poetry but a naturally homely character that is as rare of its kind as anything in literature. Oliver Wendell Holmes (1809-94) is the law, the field of light and humorous verse, in which vein he had few equals and no superior, although he also wrote essays and fiction. Other New England poets of those years should be noted, although their works have not survived: Mrs. Lydia H. Sigourney (1791-1865), James Gates Percival (1795-1856), Jones Very (1813-80), Samuel Longfellow (1819-92) are but a few of the many gifted and cultivated spirits of that generation of New Englanders. There were fewer poets in the rest of the country, but Bayard Taylor (1825-78), who wrote much beside poetry, and John G. Saxe (1816-87), should be mentioned, while Henry Timrod (1829-67) and Paul Hamilton Hayne (1830-86) wrote much that showed poetic feeling and appreciation (of the South) of nature, although it appears to have lacked the preserving quality of true genius.

Poetry has been mentioned first in this sketch because it came first to general public notice, but the first great American man of letters to be recognized as such at home and abroad was Washington Irving (1783-1859), who wrote almost everything except poetry. He had to a marked degree the essayist's gift of sympathetic and humorous observation joined to a power of easy expression which had been refined by an affectionate study of the English masters. He had not only a delight in the romance of Europe but a pleasure in things American, and he pleased not only America but Europe by his own; he had the gift of being delightful to his own day because of the quality that he was able to give it. As the New Englanders of his day tended to poetry so the New Yorkers, or the "Knickersbocker School" as it was called after Irving's famous fiction, are best remembered by their essays. James Kirke Paulding (1778-1860), Gulian C. Verplanck (1786-1870), N. P. Willis (1806-67) are more properly to be called men of letters than anything else, though they wrote stories and poems, Three who came a little after them are more noteworthy: Donald G. Mitchell (1822-1908), who under the name of "Aik Marvell" wrote the "Reveries of a Bachelor," George William Curtis (1824-1900), who described New England and did much else for which he became justly distinguished, never surpassed the charm of his early meditations on "Prue and I," and Charles Dudley Warner (1829-1900) whose homely and somewhat humorous books of reflection and travel were a good deal read. It is not right to speak of Ralph Waldo Emerson (1803-82) specifically as a great essayist nor can he be mentioned especially as a great poet or a great philosopher. Philosophy he of course had, and poetry, and he expressed himself in lectures that easily took the form of essays. But his true position is something outside of philosophy or literature; he has been an immense spiritual influence; in America touching alike the cultivated and those with hardly a touch of education, influencing those devoted to one of the philosophies of the world and those whose experience came from daily life alone. He himself once said that he was the voice of New England speaking as it had to speak, by which he meant that he was a representative of all the ideals of American life. Whether we think of him as man of letters or philosopher, as essayist or critic, we shall have to recognize that no other American has been so active a factor in arousing and stimulating the higher life of the people. One special form of his influence is especially characteristic of American literature, that which has colored the view of certain writers on nature. These gained a great inspiration from Emerson which they strengthened by keen power of observation. Of these the chief is Henry David Thoreau (1817-62) a man of great originality, but more of a philosopher than naturalist. John Burroughs (1837- ) is more of an observer and a naturalist, but of an unusually suggestive and vital spirit, John Muir (1838-1914) may also be mentioned here though much of his work appears to have been merely private record for his own satisfaction. It may stretch the ordinary idea of literature to include the name of John James Audubon (1785-1851). His chief work was with the pencil; his journals are full of his own brilliant and poetic personality, and also, it should be added, give a view
of America and its people and its natural resources that can be gained in no other way.

There had always been American historians, until there was a definiteness that history was written closely, from the days of John Smith (1579-1631) and John Winthrop (1588-1649). In the first half of the 19th century, history still lacked some of the limits that have grown about it and was as often found in the historical overtone of Daniel Webster (1782-1852), of Edward Everett (1794-1865), or in the picturesque narratives of Washington Irving as in the more regularly historical work of Jeremy Belknap (1744-98) or Jared Sparks (1789-1866) or the other scholarly students of history or biography. With George Bancroft (1800-91), however, a more definite historical tradition began, to be distinguished by an equal and devoted care for original sources and literary style. William H. Prescott (1796-1859), John Lathrop Motley (1814-77) and Francis Parkman (1823-93), form a very remarkable group of historians. The great orators of our earlier days were chiefly statesmen,—the names of Daniel Webster (1782-1852), Henry Clay (1777-1852), John C. Calhoun (1794-1857) and Edward Everett (1794-1865) coming at once to mind, although the last named was noted also in other forms of public life. Among the great orators of a later generation, however, the most distinguished have, as a rule, not been in politics. There were Edward Everett (1803-80) and Henry Ward Beecher (1813-84) and Phillips Brooks (1833-93) will probably be better remembered as orators than Charles Sumner (1811-78), Stephen A. Douglas (1813-61) or Chauncey M. Depew (1834-). It is in this place that we should mention the great name of Abraham Lincoln (1809-65). No part of the energy of his remarkable mind and character was ever given to the production of anything that he conceiv'd as literature. Yet his powers of thought were so intensely right, his passion of love so strong for the country of his birth, that his books were as the best English written, and both were used with so single an eye to the real needs of the occasion and so certain an understanding of what the need demanded, that what he said or wrote had a quality that could not be gained by the best care. His Gettysburg Address, therefore, not only makes an immense impression even now, but it was influential in changing the style of oratory of the nation. We ought to mention a number of writers as characteristically American as any other writers. From an early day there had been those who presented a humorous view of the situation in a peculiarly quaint manner. The names of Jack Downing (1811-52) and the Widow Beddott (1792-1852), even of Artemas Ward (1834-44) and Josh Billings (1816-85) are now all that will be remembered of their voluminous works. But the work of Samuel Clemens (1835-1910) known throughout the world as Mark Twain* had some of more enduring qualities which make real literature. The qualities that endeared him to people in general. Later writers whose gift is chiefly that of humorous interpretation of life are Peter F. Dunne (1867, widely known as "Mr. Dooley"), and George Ade (1866-). The thing we more remember in American fiction has been its presentation of American life. Even the stories of Brockden Brown (1771-1810), our first novel writer of real ability, beside the extravagant horrors and mysteries of their time, have a certain actuality that makes them still worth reading. Of the stories of Irving, Paulding and others the best are generally those which present the old Dutch life of the Hudson River. James Fenimore Cooper (1789-1851) was and is still best known for his stories and characters of the American wilderness. John P. Kennedy (1795-1870) and W. G. Simms (1806-70) are still interesting for their pictures of Southern life. It is one of the remarkable things about Poe that his work has little of the particular character of his country; his best stories of horror or mystery are still well known, especially those in which he anticipated the detective story of the present day. Fitz James O'Brien (1828-62) wrote some excellent stories in which an idea of fantastic imagination is presented in very realistic form. Such too are the stories of Edward E. Hale (1822-1909) whose "Man Without a Country" gained belief by its realism and appealed to all by its imaginative passion.

There were many romantic story-writers (and some especially national) in the generation before the war of whom the best remembered are J. H. Neal (1793-1876), Herman Melville (1819-91), Theodore Winthrop (1828-61) and Harriet Prescott (1835--). Harriet Beecher Stowe (1811-96) ("Uncle Tom's Cabin") belongs even more to history than to literature, but this book as well as "Old Town Folks" owes its interest to being a close picture of life. Something of this strain will be found in Nathaniel Hawthorne (1804-64). His earlier tales of realistic observation as well as of poetic imagination, of historic life and character as well as of delightful fancy, were not at once popular, but his great novels, though by no means realistic, are thoroughly American. In the years after the war came the slow growth of the fictional art, that is, the considerably realistic, both in short story and novel, of that fiction which takes for its subject the everyday life around us and finds its chief interest in the study of character and the observation of life. Here we have William Howells (1837--) and Henry James (1843-1916), who began to write stories about this time, and who came to general acceptance as our representative novelists 15 or 20 years later. Each was a master of the short story as well as the novel and each wrote also for the stage and for criticism. James took for his chief subject the American abroad, while Howells found his chief interest in the great mass of average Americans in their own country. Their example led others to turn their attention more particularly to an especial study of American life as it developed particularly in particular places. By 1880 the novel especially devoted to local color was a definite form, Sarah Orne Jewett (1849-1909) and Rose Terry Cooke (1827--92) in their "Eternal" and "Gentle Eggleston" (1837-1902) Mark Twain (1835-1910) and Bret Harte (1839-1902) in the great Central States, the Southwest, and the Far West, were noteworthy names out of many. At this time George W Cable's (1844--) and the "grand-dissimes", and other stories of Creole life in the South, and Miss Mary N. Murfree's (1850--) stories of the Tennessee Mountains, published
under the name of Charles Egbert Craddock, aroused the attention and interest of writers and readers alike. Mary Wilkins wrote of New England, Harold Frederic (1856–98) of life in the Mohawk Valley, F. H. Smith (1838–1912) of New York City, T. N. Page (1833–99), J. C. Harris (1845–1909), James Allen Lane (1848–1904) and G. W. Stoddard (1855–1918) in 'The Virginian' of the Far West, Alice French (1850–) (as Octave Thanet)2 and Hamlin Garland (1860–) of the Middle West. F. Marion Crawford (1854–1909) was one of the few who at this time held to what would be called the romantic ideal, but he remained popular through waves of realism. Frank Stockton (1834–1902) also stood on one side of the general movement by his remarkable gift of whimsical invention and delightful humor. In the nineties arose a liking in stories of adventure for American historian F. J. Stimson's (1855–) was one of the first to revive an old form, but he was immediately followed by P. L. Ford (1865–1902), Weir Mitchell (1829–1914), Winston Churchill (1871–), Mary Johnston (1864–) and a new generation. The half of the century was a noteworthy seedtime for fiction; all sorts of new paths were struck out; novels of adventure, Rex Beach (1877–), or of mystery, Anna Katherine Greene (1846–1932) became popular; novels of great transactions of commerce, H. K. Webster (1875–), of the great outdoors, S. E. White (1873–), of all sorts of exotic life, of anything which would arouse and stimulate the imagination. The best representative of this kind of fiction was Jack London (1876–1916), who, with a love of wild adventure joined an active spirit of social reform; O. Henry (1862–1910), whose stories rise from the emotions and feelings to be found in unexpected corners of the life of our great cities, is another characteristic writer. Among all these insistent passions for wide horizons and stimulating motives the representative of the careful study of actual life as we see it all about us is Mrs. Edith Wharton (1862–). Such, too, is the work of the chief novelists of the period in the adjustment often of some study or interest in current social problems. The work of Willa S. Cather (1873–), Dorothy Canfield (1879–), Ellen Glasgow (1874–), Henry S. Harrison (1880–), Robert Herrick (1864–), Mary Watts (1868–), Theodore Dreiser (1871–), which is the best fiction of the last few years, is the general sort.

In the poetry of the generation immediately after the Civil War we have a group of poets of less ability. The American historian Newland Asher Edmund Clarence Stedman (1833–1908), Thomas Bailey Aldrich (1836–1907), R. H. Stoddard (1827–1907), and later Richard Watson Gilder (1844–1909), were poets of a commercial society growing in a material way beyond people's belief of conception. Such a world allows a man to pause for a while at a fine thought or a fine deed, but rarely gives the leisure and experience so generally necessary for the development and experience of genius. Bret Harte should also be mentioned for his earlier poetry, though his reputation rests chiefly on his stories of California in the days of the goldminers. Two other western poets were Joaquin Miller (1841–1913), whose 'Songs of the Sierras' gave him a great reputation, and Edward Rowland Sill (1841–87), though he lived in California had the refined literary expression of other civilizations. Sidney Lanier (1842–81) was a Southerner and some of his most beautiful poetry is inspired by Southern scenes. In later years the most noteworthy poets were James Whitcomb Riley (1833–1915) with poems of Hoosier life, Eugene Field (1850–95), whose best poems are inspired curiously enough by literature or by children, William Vaughan Moody (1869–1910), a man more of broad and general poetic character than any of his time, and George Cabot Lodge (1873–1910), who died before his truly poetic insight had developed to its full power. The last 10 years have seen a greater interest in poetry both by reader and writer than has existed for half a century. Of the number who must still be called minor poets who are the most noteworthy, Edith Armitage Robinson (1869–), whose great insight is for character and satire and for a close reality of language, and Edgar Lee Masters (1869–), whose 'Spoon River Anthology' by its poetic realism has gained a wide recognition, are the best of other recent poetry. The others are generally noteworthy for an effort at breadth of experience and freedom in poetic form. Of the latter the best known names are Vachel Lindsay (1879–), Edwin Markham (1852–), Amy Lowell (1874–), Robert Frost (1881–), Hoosier Poet (1885–), James Oppenheim (1882–), Louis Undermyer (1885–) and Harriet Monroe (1890–). Of those who more commonly keep to the older, more traditional forms the chief are G. E. Woodberry (1885–), Percy MacKaye (1888–), Herman Hagedorn (1882–), Fanny D. Davis, Witter Bynner (1881–) and Sarah Teasdale (1884–).

**Edward Everett Hale**,
*Professor of English, Union College.*

**AMERICAN LOYALISTS.** The American colonies were all infested with internal enemies during the Revolution. This hostile element, while averse to the oppressive measures of the British government, was still more averse to independence. Its guiding principle was loyalty to the Crown; hence the name "Loyalists," which has found general acceptance among historians of the present day.

In the New England States the Loyalist party was relatively weak, and its numbers were considerably lessened by the flights of many of its zealous and persecuted members in the early days of the war. The proximity of the Canadian posts north of Lake Champlain and along the Saint Lawrence, which were used for military purposes by the English at the beginning of the Revolution, enabled numbers of fugitive Loyalists to find protection and volunteer for service in "provincial" regiments. These regiments were gradually filled by sending recruiting officers into the enemy's country, and were employed on marauding and rescue expeditions. No less than 10 corps, several of which reached a maximum of 500 or 600 men, were thus maintained in the Canadian Division during the Revolution. While a proportion of these refugees came from the New England States, many others had found their way from northern New York. Often they were followed by their wives and children, who were brought in by the recruiting agents, or were conveyed
under flags of truce over the waters of Lake Champlain. Burgoyne's expedition in 1777 was joined by hundreds of Loyalists, who sooner or later escaped into Canada. In 1780 Sir John Johnson delivered 150 from the Mohawk Valley, and a little later Majors Carleton and Houghton brought in scores of families from south of Lake George.

From Maine, New Hampshire and Massachusetts other Loyalists early began to sail for Nova Scotia in search of kindred. This movement overseas was given a marked impetus by the battle of Lexington. In July 1775, Judge Curwen of Salem, Mass., arrived in London, where he found an army of New Englanders already there, "cementing their own and their country's unhappy fate." And yet, at the end of January 1776, over 2,000 adherents of the Crown remained with the British army in Boston, nearly one-fourth of whom were refugees from the country. About 1,100 of these sailed for Halifax at the evacuation of the following March. The New York numbered several Tory regiments raised in Boston under Howe's orders.

When the British army left Halifax for Staten Island in June 1776, it was accompanied by many of the refugees from Boston. These were joined by two regiments of the New York Volunteers but recently sent to the Nova Scotian capital. The arrival of Dunmore's fleet a month later brought in another large accession of Loyalists, together with many negroes, this time from Norfolk, Va. From this time on to the end of the Revolution New York city and the neighboring islands received increasing numbers of fugitives from all the other colonies, as well as the region south of Albany. The prevailing loyalty of the province, of western Connecticut and of New Jersey made possible the formation of not less than 20 corps of Loyalists in and about New York during the years 1776 to 1781, inclusive. These corps ranged in numbers from 29 to 1,100 men, and probably totaled 15,000. The loyal militia in the South numbered 8,500 men after General Howe gained possession of Long Island in August 1776. Hundreds of Loyalists from both Connecticut and Rhode Island found refuge there, forming a settlement on Eaton's Neck. Howe allowed both places.

The occupation of Newport, R. I., by a part of the King's forces in December, called out loyalist addresses from the Quakers of that province, and from many of the inhabitants of Newport, Portsmouth, Middletown and Jamestown. In June 1778, two provincial regiments arrived at Newport from Kingsbridge, N. Y., and soon a body of 112 loyal New Englanders was enrolled, while small groups of Tories from Freetown and elsewhere came in for protection. When the British and provincial troops evacuated Rhode Island in October 1779, about 40 families departed with them, leaving other Tories behind. Those departing were posted in Saint George's Manor on the south side of Long Island, but most of them were taken prisoners soon after. The movement of Howe and his army to Philadelphia in 1777 caused the local patriots to flee from that city, thus turning it into a Loyalist centre to which numerous Tories resorted from the surrounding region. It also stimulated the formation of six Loyalist regiments in southeastern Pennsylvania and one in south-ern New Jersey, beside enlistments in other provincial corps which had accompanied Howe. Clinton, the successor of Howe, assumed command in Philadelphia in May 1778, and promptly decided to evacuate the place. With his troops marched the Loyalist regiments of the neighborhood, and over 3,000 other adherents of the Crown boarded the British fleet in the Delaware to be transported to New York.

The seat of war now shifted to the South. In November, 1780, a British force embarked from Sandy Hook for Savannah with a force including four Loyalist regiments. As a large part of the people of Georgia was friendly to the British cause many men joined Campbell's standard after his capture of the post at Savannah. Sunbury was taken with the aid of 400 Carolina King's Rangers under Col. Thomas Browne, as was also Augusta, Colonel Boyd and 800 Loyalists of South Carolina cooperating. Thirty miles above Augusta 300 Tories under Col. Daniel McGrath were active. The patriots and Tories who were in Georgia were garrisoned by Loyalists, and there was scarcely a skirmish or battle that was not participated in by Loyalist troops. The burden of the defense of Savannah against the Americans lay chiefly on the Tory contingent, including the Georgia militia, but part of this Tory force consisted of men from New York and New Jersey, and part of those from the Carolinas. Tarleton's British Legion (over 1,000 men), Ferguson's Corps (140 men), and the New York Volunteers (350 men) helped to take Charleston, S. C., in May 1780. Only two Loyalist regiments seem to have been organized in Georgia. Some Tories fled from this province early in the war.

In contrast with Georgia the Carolinians furnished nine corps of Loyalists, several being of good size. Most of the nine were embodied under the orders of Cornwallis, who had succeeded to the command of the British forces in the South. The South Carolina corps were principally garrisoned by these troops, which had many encounters with the patriots, and at Camden in August 1780, outnumbered the British regulars by several hundred. They defeated the American troops at Edgefield; Gates, "the hero of Saratoga." A few days later Tarleton with the British Legion and the corps of Light Infantry destroyed the last organized patriot force in South Carolina: Preliminary to his advance into North Carolina, Cornwallis sent messengers thither to rouse the "friends of government," and despatched Ferguson with 1,200 men, five-sixths of whom were Loyalists, to the western border of the province to gather recruits and harass the Americans. But Ferguson's operations also brought out a force of sturdy pioneers that turned the tide of war against the British at King's Mountain. Much the same story was repeated at the Cowpens in January 1781, where Tarleton was defeated. With Cornwallis near the Virginia line, Green swept the Loyalists from every stronghold in South Carolina. Thus, only Charleston was left to serve as an asylum for the hunted Tories of the province.

Meanwhile General Arnold had been attempting to make a diversion in Virginia with an English force, including the American Legion
and the Queen's Rangers, two Loyalist regiments from New York. These and other such troops were used in carrying on raids into the interior, but without gaining many recruits. The negroes were recruited more from the Virginians who had left the country for England, New York and elsewhere during 1775 and 1776. The recovery of the lower States by the British, and the Tory and Indian raids from Detroit in 1779 and 1780, served, however, to revive loyalty in the rebellious Pennsylvania and in Maryland. Certain Tory leaders of the frontier claimed to have raised 1,300 Maryland Royal Retaliliators up to June 1781, but nothing was accomplished because several of the promoters of this force were arrested and executed. Col. John Connolly, who was in command of the Loyalists of Virginia and North Carolina on the peninsula between the James River and Chesapeake Bay, had been counted on to co-operate with the Marylanders. But in September 1781, he was captured and sent to Philadelphia, and in the following month the surrender of Cornwallis occurred, four Loyalist corps being included (747 men). The King's vessel Bonetta sailed for New York filled with Tories. The black slaves and their negroes now left the Southern States for Jamaica, the Bahamas, and Great Britain. When Savannah and Charleston were evacuated in July and December 1782, other thousands sailed with the troops. Up to May 1783, the population of East Florida was increased by about 13,000 whites and blacks. Jamaica gained approximately 5,000 white immigrants and 7,500 negroes from the Floridas, which were ceded to Spain, and from Savannah and Charleston. The increase in the Bahamas amounted to nearly 6,000, of which more than a quarter came from New York in 1783.

West Florida had been partly settled early in the war by Loyalist refugees from Georgia and the Carolinas. Several troops of these fugitives were quartered there, and were assisted by a large body of associated men of the Natchez District and some of the neighboring Indian tribes in repelling the expedition of Captain Willing from Pittsburg. These local troops, reinforced by a thousand men from New England, the Maryland and Pennsylvania Loyalists, also resisted the Spaniards from Louisiana, but without avail. On the surrender of West Florida in May 1781 the Natchez associations fled, some to Savannah, some to the Cumberland settlements in Tennessee, while some were caught and carried down to New Orleans.

The British posts along the Great Lakes, including Carleton Island, Oswego, and Fort Niagara, attracted Loyalists from the back country in large numbers. A little colony of refugees sprang up on Carleton Island; many Loyalists were registered at Oswego while passing into Ontario to settle; and in the fall of 1775 Fort Niagara became the rendezvous of those coming in to join Butler's Rangers, a corps that comprised eight full companies in 1779. Brant and the Six Nation Indians also operated from this centre. Sullivan's raid up the Genesee River increased the number of savages at the post to more than 5,000. A Loyalist settlement on the west side of the Niagara River in 1780, which spread round the shores of the entire Niagara Penin-

sula and beyond by 1791. Both banks of the Grand River were colonized by the Mohawks and representatives of other tribes. At the west end of Lake Erie, Detroit was the headquarters of Tory refugees and the Wyandot and other Indian tribes. Here Lieutenant-Governor Hamilton embodied the Detroit Volunteers, who gained leadership when Capt. Alexander McKee, Simon Girty, Matthew Elliott and several other Tory conspirators came in from Fort Pitt in the spring of 1778. Hamilton had been sending raiding parties to the upper Ohio and promising land bounties to those who would join in the King's defense. These measures seem to have led the Loyalists of the frontier to associate for the purpose of aiding the British cause. However, numbers of the plotters were apprehended, and others were suspected, including the officers in the Indian Department at Fort Pitt, namely, McKee and Girty, and Elliott who was an Indian trader. At length, in March 1778, they fled to Detroit, where they were given employment in the Indian Department. Girty became the instigator of war parties, which harried the frontier and gathered in adherents of the Crown. When peace was signed in 1783, the organization of the region east of the Detroit River began. The King's ships brought in without charge disband ed Loyalists, and others had only to cross the river, as at Niagara. Within a few years three townships on the lake front, four on the river Thames, and extensive tracts along the Detroit and Saint Clair rivers were settled by willing exiles from the neighboring republic. See also Loyalists in Canada.

Wilbur H. Siebert, Professor of European History, Ohio State University.

AMERICAN LYCEUM ASSOCIATION, an organization founded in 1831 for the purpose of (1) securing better legislative provision for schools; (2) to improve the qualifications of teachers; (3) to secure closer relationship between the common schools and the colleges; (4) to improve the methods of instruction and school discipline; (5) to introduce the natural sciences into the course of study; (6) to provide schools with books, apparatus and teaching appliances; and (7) to arouse an interest in the education of girls and women. Annual meetings were held, at which important reforms were advanced. The proceedings of the Association — to except the first — appeared in the American Annals of Education; and the American Monthly Magazine.

AMERICAN MATHEMATICAL SOCIETY, an association established in 1888 as a local organization in New York, and reorganized in 1894 under its present name, to encourage an active interest in mathematical science. Admission fee, $5; annual fee, $5. Membership 700. Members meet at Columbia University, New York city; meetings are also held in Chicago and other cities. The society publishes two journals, the Bulletin and Transactions.

AMERICAN MEDICAL ASSOCIATION, The. On 5 May 1846, a National Med-
ical Convention of delegates from "medical societies and colleges in the whole union" convened in New York City. A second meeting was held in Philadelphia the following year and on 5 May 1847 this body resolved itself into The American Medical Association. The annual sessions of this organization are attended by delegates representing the several constitutions of the association, who assemble as the House of Delegates, transact the business and frame the policies of the organization; the sessions are also attended by those members of the organization who qualify as Fellows and meet as the Scientific Assembly for the discussion of scientific subjects. This Scientific Assembly includes an opening general meeting at which the president-elect is installed as president and delivers his presidential address; and 15 sections, in which are presented scientific papers on subjects related to the branch of medicine to which the particular section is assigned. The following are the sections of the association: Practice of medicine; surgery, general and abdominal; obstetrics, gynecology and abdominal surgery; ophthalmology, oto-rhino-laryngology and rhinology; diseases of children; pharmacology and therapeutics; pathology and physiology; stomatology; nervous and mental diseases; dermatology; preventive medicine and public health; genito-urinary diseases; orthopedic surgery; and gastro-entcro-entero-anatomy and proctology. As the constitution states: "The object of this Association shall be to promote the science and art of medicine. Contributing to this end, the Association shall endeavor to unite into one compact organization the medical profession of the United States for the purpose of promoting microscopical studies by granting aid to members from invested funds and by publication. It has a membership of 350 and $4,000 in research funds.

AMERICAN MUSEUM OF NATURAL HISTORY, New York City, situated in Manhattan Park, occupies a palatial building extending along the whole front of the north side of 77th Street, between Central Park West and Columbus Avenue. The institution was incorporated under a charter of 6 April 1869, and is administered by a board of trustees, under a contract executed and recorded in Feb. 1912. The foundation stone of the building was laid 2 June 1874. The Peary and other meteorites, the anthropological and ethnological collections made by the Morris K. Jesup expedition to the North Pacific regions, totem poles of the Ilaida Indians, masks and dishes from British Columbia, carvings from Viking, Inca, and Ayacucho, and utensils of the Chilcoten and Chilkitat Indians, articles and models illustrating the life of the Eskimos of North America, the Shoshone Indians, the Gros Ventres, attract the attention of the visitor on the ground floor and approach the free lecture hall, with a seating accommodation for 1,500, which occupies a separate building at the extreme north of the museum. The Jesup collection of woods; archaeological remains of New York; the Hyde collection of the fauna, carnivores, cacti, and burial-caves of the Southwest; the collection of reproductions and casts of the ancient monuments, bas-reliefs of Mexico and Central America presented by the Duke of Losbat, as well as other rare specimens, all illustrate the pre-Columbian period. Animals, singly and in groups, masterpieces of the taxidermist's art, conspicuous among which are the cases of moose, bison, and musk-ox, are undoubtedly the finest in the world. Of particular excellence are the collections of birds, especially the bird-rock group and the waterfowl group, and the butterflies and insects. Of great value is the collection of minerals, including the Tiffany exhibit from the Paris exhibition of 1899 purchased and presented by J. Pierpoint Morgan; collections of meteorites and geological specimens, including the collection of the late Prof. J. Hall; and specimens of vertebrate palaeontology, Cretaceous fish; an ichthyosaurus with young, showing it to have been viviparous; and hundreds of other specimens of prehistoric animals, paleontologists. On the top floor are the mounted skeletons of antediluvian monsters, the brontosaurus, giant sloth, mammoth, etc., the collection of shells, a laboratory for photography and a library containing over 55,000 volumes on natural history, a historical and geological cabinet, including that of the Lyceum of Natural History founded in 1817 and incorporated in 1818, since 1876 known as the New York Academy of Sciences affiliated to the Museum.

AMERICAN MYTHOLOGY. American is here used with the signification of the United States. The myths to be dealt with and the social systems built up about them are much wider-reaching than the territory included within the American Union. They extend as far north as Hudson Bay, spreading over Ontario and the Canadian Maritime Provinces; while from Alaska they form an almost integral link with the beliefs, myths and institutions of the Eskimos, thus embracing all the Arctic lands of America. On the south some of the myths of the United States reach far into Mexico. Where necessary, therefore, these myths shall be followed to their habitat beyond the borders of the United States, provided in so doing their dominant characteristics may be the better presented. This article deals neither with the history of American mythology nor with the various systems of its interpretation, since these are still in an evolutionary stage; their literature is voluminous and an account of it is readily accessible. Moreover, this literature is largely personal while the object of the
present article is to present a condensed yet comprehensive view of the mythologies of the aborigines of the United States and the related mythologies of the Indian tribes, primitive beliefs, social evolution and peculiar modes of these peoples.

The study of American Indian mythology takes us into a condition of society different in most respects from our own. Here the laws of nature are unknown; and the Indian attributes life not only to everything that moves but to all the inanimate things of nature, the plants, earth, rocks, stones and water. To him the Sun in his daily journey was a very regal personage, possessed of great power and surrounded by other powerful spirits, warriors, faithful servants and followers; while the Moon was the sovereign lady of the night. The Sun and the Moon and the Stars were relatives and ruled the heavens, a region sometimes above, sometimes below that of the Thunder Spirits. The Four (or six) Winds were the Cloud-pushers and they ruled the Four Quarters of the earth. They sent the Sun with his peculiar costume, fire, and his weighty rain, heat and cold, and they were generally the benefactors of mankind. To the Indian mind it was self-evident that the rivers, streams, lakes, oceans, plants and mountains had life, for were they not continually manifesting their activity in some way or other? And as the hills were the children of the mountains they must also necessarily be living beings. The Indian mind was ever awake to the voices of these sentient beings, the creation of his own imagination and want of knowledge. For him the wildebeast, whose life was spoken, whistled, chanted, they moved restlessly, they crept, they ran, they leapt, they jumped, they rushed with the force of a hundred armies and their roar drowned the mightiest shout of the biggest war party. And they fought and struggled among themselves with greater fierceness, with mightier intensity and with more fearful weapons than the cunning of the wisest Indian tribes had been able to devise. Necessarily they could not do all this unless they were endowed with life. This life was essentially the same as that of the Indian for he knew of no other and could picture no other. He accounted for the extraordinary power of the various phases of nature by picturing them as possessed of great magic (medicine). These magic powers he extended alike to animate and inanimate objects; for as they were a thing apart from the being possessing them, and were in themselves supernatural beings, it was just as easy for them to reside in a dead stump as in a live tree, in a sleeping hill as in a heaving volcano, in a placid lake as in a roaring cataract. These unseen powers were constantly at war with one another and with mankind; and they had to be fought like the other enemies of the human race or placated when possible. The natural way to fight them was with their own weapons, incantations, charms and the whole paraphernalia designated for the purpose. So absurd is this idea of a universal, actual life throughout all nature sprang a vast mass of myths, traditions, folk-stories, ritual and ceremony which constitute a very important part of the mythologies of the races of the American continents. The priests or medicine men were the interpreters of the religious and philosophical knowledge of the tribes. They were also, for the most part, the depositories of the supernatural powers which man was constantly waging against the supernatural powers by which he was surrounded. Hence the religious ideas of the Indian races are always associated with their Philosophy, their attention stricken for the origin of the universe and all that is contained therein, together with the various forms of animate and inanimate nature, the peculiar habits, shapes, markings and characteristics of fishes, reptiles, birds, other animals, men and the imaginary creatures who peopled the water, the air and the earth with the regions round about its outer edge, below it and within it. The Indian accounted, by means of a heterogeneous mass of myths and stories, for the position, form, color and shape of mountains, hills and valleys, of forest-covered lands and barren wastes, of smooth, water-washed seacoast and wild, wind-swept, desert sand-dunes. Everywhere he has written his peculiar myth full of the influence of primitive culture upon his institutions, his myths and his stories. But to understand these we have to be able to place ourselves in his position and to see through his eyes that curiously-real world of fancy that populated his universe.

Metamorphosis.—The belief in the power of certain enchanters to take upon themselves at will the forms of animals, fishes, birds, flowers, plants, sticks, stones and other objects was general throughout the American continents. Sometimes it was not an individual but a whole tribe that possessed this power. Animals could also metamorphose themselves. The Supernatural People who are sometimes identified with the souls of the dead and sometimes looked upon simply as strange non-human beings are, in Indian myths, fond of assuming the forms of animals. Thus Wakiash, the Kwakiutl hero, on his long journey in search of knowledge to impart to his tribesmen, came to the village of the Supernatural People just as they were holding a great animal dance. He inadvertently restored them to their human form and gained a great store of information from them. This belief in metamorphosis fits in with that of the Indian doctrine of the universal wisdom of all created things, their relationship to man and their close communion with him. It is quite common among the Indians of the United States and Canada and it is one of the most familiar features of their myths and stories. Even in much more cultured Mexico and Yucatan the people firmly believed that the priests could change themselves into dogs, pigs, tigers and other beasts. Any one encountering them in this form was almost sure to meet with sudden death. Women giving birth to misshapen children were thought to have been bewitched before childbirth by one or more of these sorcerers. Even the dead are believed to have the power of assuming many forms by means of their great sorcerer knowledge, thus making themselves doubly powerful, fearful and dangerous. This belief was carried even further. The sorcerer could not only change himself into innumer-
able shapes, but he could visit the land of the dead and marry the dead; and spirits from the land of the dead were universally believed to have carried off young women and made them their wives and to have had children by them. The Sun, the Moon, the Evening Star, the Wind Gods and the Thunder Spirits frequently visited this earth and made love to earthy women and begot children earthly in form but possessed of the wonderful powers and attributes of their divine parents. Hiawatha’s grandmother fell from the moon, and his mother, born upon earth, was betrayed by the handsome West Wind. Though born upon earth, Hiawatha inherited all the powers and attributes of his divine parents. From his mother he received the arts of healing and of producing growth, and through his father he had all the active qualities inherent in the winds and was the messenger bringing supernatural knowledge to his people.

As the inherent power of animals, men and spirits was essentially the same in all cases, do not a man greater than theirs. The powerful magicians of the earth went to the land of the dead and even to the home of the gods and overcame the most powerful of the spirits of the Supernatural Lands. When the spirits of the clouds and the air withheld the rain the most renowned medicine men of the tribe with their strongest medicine were called upon to overcome them and to force them to comply with the wishes and supply the necessities of man. Frequently the whole tribe was summoned to take part in these incantations on the principle that each member of the tribe possessing his own special aiding spirit, the whole combined ought to be more effective and powerful by adding it to the knowledge and formulae of the priests. This cojoint power of the tribe is very important when it is remembered that upon it depend, in the Indian imagination, their enjoyment of rain in season, harvests, good and bad weather, sunlight, heat and cold, sickness and health, life and death, and even the rising and setting of the sun and the moon and the regular coming and going of the seasons. Upon the placation of the non-human spirits or the contravention of their magic evilly directed depended also the fertility of the human race, and hence its preservation. So young girls about to be married and sterile women resorted to magic to assure that fertility for which they longed. These generally took the form of prayers and powerful incantations and offerings to the Moon Goddess, the greatest of the divinities of growth.

Province of the Myth.—Story-telling was common among most of the American Indians. They are characteristic of savage and barbarous races. It is the evidence of their social and intellectual progress. Before the popularization of education man perpetuated his acquired knowledge in the form of stories, whether in prose or verse. The whole body of these stories contained his philosophy of life, his customs, his traditions, his history and his explanations of all the phenomena of nature. At the time of the coming of the white man the races of the New World were some of them in the stages of savagery and others in the advanced stages of barbarism. So a wide stretch of the highway to civilization separates the lowest of the American races from the highest. Yet they are all distinguished by certain racial characteristics whose ear-marks are constantly in evidence in their social and religious systems, in their presentation of scientific truths and in the general aspect of their very numerous myths and folk-tales. Even in Mexico, Central America and the west coast of South America, where several races had attained to a comparatively high degree of culture and become acquainted with many of the elementary principles of science, the masses of the people still displayed, at the time of the conquest, an all-reaching, unreasoning credulity. The origin of the world, the creation of the human race and the lower animals, the vegetable and animate kingdoms, the sun, the moon and the other planets and their movements; the peculiar markings and characteristics of animals, the typical customs and institutions of men, language, medicine, social and religious institutions, all knowledge in short, by magic greater than theirs. The powerful magicians of the earth went to the land of the dead and even to the home of the gods and overcame the most powerful of the spirits of the Supernatural Lands. When the spirits of the clouds and the air withheld the rain the most renowned medicine men of the tribe with their strongest medicine were called upon to overcome them and to force them to comply with the wishes and supply the necessities of man. Frequently the whole tribe was summoned to take part in these incantations on the principle that each member of the tribe possessing his own special aiding spirit, the whole combined ought to be more effective and powerful by adding it to the knowledge and formulae of the priests. This cojoint power of the tribe is very important when it is remembered that upon it depend, in the Indian imagination, their enjoyment of rain in season, harvests, good and bad weather, sunlight, heat and cold, sickness and health, life and death, and even the rising and setting of the sun and the moon and the regular coming and going of the seasons. Upon the placation of the non-human spirits or the contravention of their magic evilly directed depended also the fertility of the human race, and hence its preservation. So young girls about to be married and sterile women resorted to magic to assure that fertility for which they longed. These generally took the form of prayers and powerful incantations and offerings to the Moon Goddess, the greatest of the divinities of growth.

Province of the Myth.—Story-telling was common among most of the American Indians. They are characteristic of savage and barbarous races. It is the evidence of their social and intellectual progress. Before the popularization of education man perpetuated his acquired knowledge in the form of stories, whether in prose or verse. The whole body of these stories contained his philosophy of
clans for defense or other purposes, the blending of races through conquest or peaceful annexation of one tribe by another, all aided in the mixing of myths and folk tales and the blending of customs and beliefs; so that, in the study of the myths of the American continent, we are confronted with a tangle of threads of myth, legend, story, custom, religious beliefs and practical superstitions. Yet amid this tangle the parent myth is often discernible. The cycle of stories relating to Nanabozho, the great culture hero of the Algonquins, is one of these. This myth, with slight variations, is or was the common property of the many tribes and sub-tribes of the Algonquin race, and similar myths are to be found in neighboring tribes.

Superstitions in regard to Animals.—Most of the Indian races of the North American continent had a peculiar superstitious fear of animals, which they believed exercised a strong influence over their lives, their well-being and their ill-being. There were a number of ways in which this animal power might be invoked. Incantations and prayers, charms and other shamanic medicines were often effective and a piece of the animal feared carried about the person was generally strong medicine in warding off the threatened danger. This belief, which was not peculiarly American, survives among white people in the custom of carrying a rabbit’s foot or similar charms against ill luck. And we talk about working a rabbit’s foot on some one. Among certain of the Algonquin tribes it was a rabbit’s foot was looked upon as very strong medicine. The Indian hunter carried a rabbit’s foot in his hunting bag and with it parts of the animals he expected to hunt. This he believed was an effective way of preventing the spirits of the animals he killed from troubling him or doing him harm. This Indian dread of animals is well illustrated in an Algonquin myth, which is found in various forms among other Indian tribes. As man became more and more powerful through the knowledge he had acquired and the weapons he had invented or secured, his power over the animal creation became more and more dominant. For this reason he was greatly hated by them. At last he slaughtered so many of them that fearing extinction, they called a meeting of all their kind, with a view to devising some means to curtail man’s power over them. Among the animals there were as great or greater wisdom men than among men; and they finally decided to visit upon the human race all the plagues known to their combined enchantments. Each animal medicine man was called upon to do his worst in this direction. The deer agreed to visit man with rheumatism, lumbago and all like muscular diseases; the reptiles offered to trouble him with fearful dreams; the poisonous animals agreed to penetrate him with their stings and bites; the birds contracted to affect him with lung troubles, coughs and colds; while the insects agreed to inject into his system all sorts of malarial fevers. Thus came disease into the world. As this myth was ever present in the mind of the Indian hunter he was scrupulously exact in the observance of the means offered him to avoid such evil effects, and in none of them from the enmity of the animals he killed in the chase. Many Indians would not kill the animal represented by the totem of their clan, while others were in the habit of begging the pardon of the animals they were about to slay, explaining to them, at the same time, that the killing was done only as an act of necessity. It was the firm belief of the Algonquins and other tribes that the deer hid the power of visiting his slayer with lumbago, rheumatism and other similar diseases. This belief was no doubt largely influenced by the disease myth already related. The Cree and other Rocky Mountain tribes held the same belief with respect to the bear; and they also begged his pardon and addressed him as brother before killing him. Western tribes and the Plains Indians believed that certain of the bird tribes had the power of bringing trouble upon mankind; and numerous myths deal with the means used to divert the danger. Some of these gradually became elaborate ceremonies.

How a Knowledge of Medicine Came to Man.—It is good to have the chipmunk near the home because he has always been the friend of man and brings good luck with him. He rode with Hiawatha on the bow of his self-moving, wonder-made canoe, and the Indian prophet called him his very good friend. The Indian will never kill a chipmunk because, after man had been visited with a plague of diseases by the animal council, the chipmunk alone among all the animal creation was sorry for him; so he went among the trees and plants, told them what had happened, represented vividly the wretched plight of his good friend man and obtained their help to fight the new plagues. The pines, the balsams and the spruces gave their gums and balsams, the slippery elm its bark, the sassafras its roots, the mandrake its apples, the wintergreen its berries and the catnip and bonnet their teas to cure colds. Ginger, gentian, sarsaparilla, peppermint and all the medicinal plants each helped in his own way; and the little chipmunk and squirrel it was who brought all these remedies to suffering mankind. So it is quite natural that he should take a quite peculiar and proprietary interest in the human race; and it is only reasonable that humanity should remember its debt.

Petishes.—The fear of the secret power of animals exhibited by the American Indian; his belief in their superhuman attributes and his conviction that these powers can, under proper control, be used to his own advantages, are embodied in the use of amulets or fetishes, which are thought to be the seat of magical power, actually or symbolically. The eagle, the most powerful member of the feathered tribe known to the Indian, was supposed, under certain circumstances, to possess magical powers. He was the representative of the Great Thunder Bird to the Plains people; and as such was held in great respect. His feathers constituted the badge of honor most highly esteemed by the Indian chief over a wide extent of United States and Canadian territory. It is quite natural, therefore, that his talons, the symbols of his power, should constitute powerful fetishes; and as such they were carried by many a brave on his war expeditions. The fetish, which consisted of some object, could be transferred.
bought or sold. It therefore formed an article of some considerable importance in Indian commerce. According to a Zuni myth, in the early days, the animals of prey were possessed of great strength and cunning; and as they were superior in qualities, attributes, powers, and virtues in a quiescent state, without the power to exercise them for harm to man; but they were permitted to use these powers for his benefit when they felt so disposed. This is why a fetish of one of these transformed animals is often very efficient in bringing luck to the possessor. This luck, however, depends upon the will of the spirit enclosed within the fetish itself, whose attitude can only be learned by experiment. So the Indians were not infrequently seen with fetishes; and those which were found not to be well disposed to help their possessors were discarded, sold, traded or exchanged for others. This fate happened to tribal as well as personal fetishes; for one of the most precious possessions of the tribe or clan was its traditional fetishes, handed down for generations and having attached to them wonderful myths and stories of their origin, history and magical powers together with many folk-tales of the help they had brought, from time to time, when their aid was urgently needed and solicited. Thus it will readily be inferred that a fetish which was not disposed to help one person or tribe might be all powerful when in the possession of another; since it was only a question of willingness on its part.

A great number of stock fetishes like the eagle's talons, the feet of the rabbit, the paw of the bear, the teeth of the tiger and the most symbolical parts of other fierce animals were suggestive of the natural and super-natural qualities of the animals to which they belonged. Among many tribes the rabbit fetish was even more feared than those of the fiercest animals; for he obtained his reputation as a personage of his kind in the totem of the culture god Nanabozho, one of the greatest of magicians known to Indian mythology. The survival of the rabbit superstition is still strong among the Indians of the Plains and of the wooded countries to the north and east. Half-breeds of the Canadian Northwest and the negroes of the South of the United States alike have assimilated the Indian faith in the efficacy of the rabbit's foot. It was and still is an Indian belief that the fetish, in return for the good done its possessor, demanded special deference and attentions in the shape of prayers, incantations and sacrificial offerings, which were duly given it. Great festivals were often held by the tribes in honor of the tribal fetishes. Many of the so-called ornaments of the American Indians were primarily fetishes. It is therefore very difficult to draw the line which separates the fetish from the ornament. The many legends of talismanic jewels so implicitly believed in by the tribes, and even in more recent times, among all classes and races in Europe, show that the fetish, in becoming purely ornamental, still retained, in the minds of many, in particular cases, its traditional powers. The tribal fetish, like the oyaen, guiding spirit of the Iroquois, might be, and frequently was, revealed in a dream or vision, and the Indian youth, when performing the fasting customary before entering upon the duties of manhood, had one or more powerful fetishes revealed to him. Sometimes he was favored with one or more of these which had not the ability to impart their revelations to the voice of the tribe. In such cases the youth was sure to become a medicine man of note; which did not prevent him also becoming a great warrior. In this way some of the fetishes contained in the medicine bags of the medicine men were obtained. While the objects in the medicine bags were symbolical of ritualistic ideas, many of them, if not all, are supposed to have been fetish in origin and powers.

A fetish may be a stone, a rock, a piece of wood, an arrowhead, a feather, in fact anything. It may have real power residing within itself as in the case of a rock or stone; it may have derived its power from being a part of a well-known whole, as the feather of the eagle; or it may have a power derived from its symbolism, as the foot of the rabbit, the totem of a divinity. The fetish associations may make a hero of one of the most stupid of animals, as in the case of the rabbit just cited; around which have been woven countless stories, in which the totem of Nanabozho is generally the hero and the conqueror on account of his natural shrewdness, his cunning and his miraculous powers. Trophies obtained from slain enemies often proved most effective fetishes; and it is very probable that the scalp taken by the American Indian from his fallen foe was primarily looked upon as a fetish, since numerous superhuman Indian characters could be wounded only in the crown of the head; or, in other cases, like Sampson, their strength resided in their hair. This myth was as widely spread in America as in Europe and Asia.

Ceremonies.—The many Indian ceremonies observed throughout the American continents at all periods, and until quite on account of his being driven out of his country by the voyages of relationships of society, of the individuals to society as a whole and to one another. They referred to birth, childhood, manhood, marriage, death and every important movement of life. The ceremonies, however, are naturally largely taken up with the food supply, war and the preservation of the tribe and the individual from the dangers that threatened them from the magic power of ill-disposed magicians. This latter include the means taken to assure mankind against disease, always caused by the wiles of the enchanter who send evil spirits into the human body. Among the more cultured tribes elaborate ceremonies are made use of to pay due deference to the most revered or feared of their divinities. The ceremonies of the American Indian are ritualistic and the order of the ritual must be implicitly followed to assure results. Ceremonies consist of two classes,—secret and public. In the former only the initiated can take part, while in the latter, the whole tribe, in most cases, participate. The secret ceremony is nearly always preparatory to the public ceremony. It is pre-
pared all the paraphernalia to be used in public by priest and layman, such as dresses, masks and headdresses. They replaced the stamp of sacredness belonging to all things and ceremonies connected with the Sacred Tepee. Ceremonial smoking, prayers and sacrifices form a part of the secret ceremo-
nial. An altar almost always occupies a prominent position in the place of ceremonies and on it are laid symbolical representations of the chief tribal gods, of the Spirits of the Four Winds (or six) and the Four Quarters of the World governed by them, of vegetation, thunder, lightning, the rainbow and other personifications of the more prominent phases of nature. Possessions of priests, traditional and tribal songs, music and dancing accompanied by rattles, drums and whistles, costumes of special ceremonial significance, tattooing and body painting form part of the ceremonial of a tribal festival. Each distinct ceremonial performance has its own ritual, costume, dances and symbolical representations. The more cultured the Indian tribe or nation the more number of annual ceremonies that complete the complex. The Peruvians, the Aztecs, the Mayas and other more highly cultured races of Mexico, Central and South America and the Pueblo Indians had a network of ceremonies which covered a fourth to a half of the year; and symbolized almost every conceivable activity of life. They began even before the child was ushered into the world and continued after the individual was dead and buried. The Hopi Indians still have 13 great ceremonies each of nine days' duration, all of which are performed with a very elaborate obligatory ceremonial; and, in addition to these, they have others which cover only one day. As their land is dry the rain god plays a very prominent part in all their ceremonies. In ceremonial significance, variety, richness of detail and strictness of ritualistic observance these tribal festivals of the Hopi Indians are equalled on the American continents only by those of the civilized nations of Mexico, Central America and Peru at the time of the conquest. The ceremonies of the American races vary widely between the broad extremes of extended symbolism just instanced and the almost purely medical dances of some of the more primitive of the tribes. Among the Pawnee and the Kwakiutl the ceremonies are almost altogether priestly functions, as they were in Mexico and Central America. The Sun Dance is a ceremony in use among all the Plains Indians, some of whom observe it as an annual event in the tribal life, while among others it is resorted to only on some special occasion. It lasts from one to 8 or 10 days and is generally held about the time of the summer solstice. The first days of the ceremony are devoted to the rites of the sacred (secret) tepee and the others to public ceremonies in which all the members of the tribe take part, in varying capacities according to their rank, age and relationship to the tribal traditions. The sacred tepee rites commemorate and represent the acts originally performed by their inventors on the Sacred Mountain. The Sun Dance of the Plains Indians had its origin in days of famine now long past. An Indian with his wife went into a mountain, where he fasted, prayed and met a great medicine man from whom he learned the sacred ceremonies of the Sun Dance. On his return he performed these ceremonies and the famine ceased, for the buffalo came in vast herds covering all the plains. At the time of the holding of the Sun Dance the rank of the chiefs was renewed, the young chiefs were singled out for their bravery and publically commended, and the dead were remembered. Often, too, it was a season for renewing tribal friendships. The ceremonies included a dedication of the Four Earth Quarters; special honor was paid to the Sun as the Great Mystery and the "Very Great Medicine Man Above." He was represented by symbolical characters painted upon the centre pole of the tepee. In the dance ceremonies four old men represented the four wind gods of the four quarters of the world; while all the dancers wore wreaths symbolical of the Sun, the Moon, the Morning Star and the Four Wind Gods. Whistles were frequently used to symbolise life (the whistle was in its active mood), and the ceremonies the Thunder Bird's flight through the clouds driven by the winds, the Cloud Pushers. The whole dance ceremony formed a great aboriginal dramatic representation, a far-reaching and wide-influencing myth developed under the influence of the priestly classes to keep vividly alive the tribal traditions embodied in the acts of the several days of the dance.

The Thunder Bird, which was symbolically represented in the ceremonies of the Sun Dance, is a personification of the thunder and the lightning. The myths relating to it cover a vast extent of territory stretching from the Atlantic to the Pacific. Sometimes the myth presents one great bird, sometimes several, in the latter case all of different colors. In general the Thunder Bird was the helper of man, and in this respect he may be classed with the culture heroes; for to him the culture gods of the Pacific were beholden, on several notable occasions, for the things which they taught mankind. Waklash, the great hero god of the Kwakiutl, made his memorable journey down the Pacific coast countries on the back of the Great Thunder Bird whom he met in the mountains after a long fast, prayers and other observances preparatory to being a medicine man; and it was with the aid of this same supernatural agent that he was enabled to bring back with him the first totem pole and house known in the land of the Kwakiutl. AMERICAN PARTY, the name of three separate political organizations in the United States:

1. The only one of great importance, usually styled "Know-Nothings." The genesis of this party lay deep in the nature of American settlement and history. The Constitution crystallized political parties definitely into Federalists and Anti-Federalists: the one upholding firm government on the general European model, with the local aristocracies in the ascendant; the other desiring the least possible government of any sort, and no upper-class ascendancy. Immigrants who had left Europe because of too free indulgence in freedom of speech, thought and action, allied themselves with the Anti-Federalists, which led the incensed Federalists, on gaining power in 1795, to raise the term for naturalization from two to five years, and in 1798 to 14 years, besides passing the Alien and Sedition Laws (q.v.). The Republicans, coming into power with Jefferson in 1801, in 1802 repealed the obnoxious acts and restored the term to five, swelling their ranks for years with a relay of acrid foreign democrats. Six members of the Congress which declared the War of 1812 against Great Britain were members of the Society of United Irishmen; and the Federalist Hartford Convention of 1814 brought forward a provision against aliens holding office. Quiescent for many years, the movement revived (1835) in New York city, where

a compact and clansman foreign body of immigrants, avid of office and openly allying themselves as foreigners against the natives, was accumulating; one procession bore a transparency lettered "Americans shall rule us." The religious question was also then, as since, a formidable factor in the trouble. In 1843 the Democrats carried the city by a close vote, and distributed the majority of the offices to foreigners, with the result that in the November election for state senator an "American Republican" candidate polled nearly a fourth of the vote, and the next spring a "Native American" candidate defeated the Democrat by 4,000, and the regular Whig party nearly vanished in the city. The excitement spread to New Jersey and Philadelphia; riots between natives and foreigners cost some lives and much property, including two Catholic churches. The Whigs voted with the Native party to secure its vote for Clay; but finding that its result in Native local officials at Democratic presidential majorities, drew off, and by 1847 the Native party had pretty much disappeared. Clay in 1844 had six Native American electoral votes, four from New York and two from Pennsylvania; and for some years the Middle States cast small votes for the party.

A new birth came to it about 1852. The Fugitive Slave Law of 1850 had largely dissolved and recombined both Whig and Democratic parties, and those of the former who wanted the status quo on slavery; by the agitation cast about for a new issue to keep their organization together. The Native American issue was temptingly at hand, and indeed had never ceased to be a sore in the Whig mind. The tremendous flood of foreign immigration set going in part by the Irish famine of 1847, in part by the revolutionary movements of 1848-50 on the Continent, had kept a steady stream of reinforcements pouring into the Democratic party which almost swamped the Whigs and made it quite impossible for the Whigs except at some sacrifice of political principle or consistency; they felt it a genuine wrong to the native or long-resident classes, and there was nothing in the use to which the other party put their victories to make them feel otherwise. They now developed a secret oath-bound society whose real name was "Sons of '76, or Order of the Star-Spangled Banner;" but its name or precise object (of course they knew its general aim) was not revealed to members till the "lodges," which they instituted in imitation of the Masons, had raised them to the higher degrees. Hence their stock answer to questions concerning it was "I don't know," which became the popular motto of the order and gave them the nickname of "Know-Nothings." The evil it "viewed with alarm" was the increasing number of the Roman Catholic Church, the vast sudden flood of immigration which was taking the control of the United States out of the hands of its citizens, and the greed of foreigners for office which greatly multiplied danger. It won their actual number. Its motto, or at least the essence of its principles, was "Americans must rule America,"—doubtless with a reminiscence of the foreign motto before mentioned; and the countersign at its lodges was an order said to have been issued by Washington at some un-
specified occasion, "Put none but Americans on guard to-night." It acted in politics, not by putting up separate men, and which would have kept its full 8 of the other parties a clear target and open victory, but by endorsing select- 
ed candidates of the others in secret convention of delegates from lodges, at which every member must vote or be expelled. This could not be known till election, and which would have confounded all political calculations and left the workers beating the air. The Kansas-Nebraska Bill, which extinguished the Whig and created the present Republican party, and made the slavery issue one of life or death, drove it to the Know-Nothing party a vast number of the moderate section not yet ready to oppose the South; it now took or was given the name of the American party, and came into the open field. In 1854 it carried Massachusetts and Delaware and polled over 120,000 votes in New York State. Thus far it had been almost wholly a Northern party; but in 1855 it made deep inroads in the South as well, where foreigners were few and the issue was locally innocuous. In that year its leaders in Congress, 1859, had become a Border State party, with one Senator from Kentucky and one from Maryland, and 23 Congressmen,—three from Maryland, five from Kentucky, seven from Tennessee, one from Virginia, four from North Carolina, two from Georgia and one from South Carolina. The campaign of 1860 its members largely made up the Constitutional Union (Bell-Everett) party, which tried to avert the war. The party was by no means without its use: it brought forward many strong leaders who did good service in the real parties when the issues had shown themselves inevitable.

2. A party directly adverse to the first in being founded on opposition to secret societies: organized by the National Christian Association at the adjournment of its convention at Oberlin, Ohio, in 1872. Organization was completed and the name adopted at a convention in Syracuse, N. Y., in 1874. At Pittsburg, 9 June 1875, a platform was adopted demanding recognition of the Sabbath, introduction of the Bible into public schools, prohibition of the sale of liquors, withdrawal of the charters of secret societies and prohibition of their oaths, international arbitration, restriction of land monopolies, resumption of specie payments, justice to the Indians and direct popular vote for President and Vice-President. James B. Walker of Illinois was nominated for President; in 1880 it again made nominations; in 1884 S. C. Pomeroy was nominated but withdrew in favor of John P. St. John, the Prohibition candidate.

3. A party organized at a convention in Philadelphia, 16-17 Sept. 1887. Its platform demanded a 14-years' residence for naturalization; exclusion of anarchists, socialists and other dangerous characters; free schools; the building of a strong navy and coast fortifications, and internal improvements; prohibition of alien proprietorship; permanent separation of church and State; and enforcement of the Monroe Doctrine.

AMERICAN PATRIOTIC SOCIETIES. See PATRIOTIC SOCIETIES.

AMERICAN PEACE AND ARBITRATION LEAGUE. The corporate purposes of this organization favor universal peace by conciliation and arbitration through a permanent international court, arbitration treaties between
all nations, and adequate armament for national security.

AMERICAN PEACE SOCIETY. This society was organized in New York city on 8 May 1828, and was formed by the merging of many State and local societies, the oldest of which, The New York, dated back in 1815. Located in Boston from 1828 to 1911, its headquarters were removed to Washington, D.C., 1 May 1911.

AMERICAN PHILOLOGICAL ASSOCIATION, a society inaugurated by William D. Whitney, of Yale, at Poughkeepsie 1869 as an outgrowth of the Oriental Society, Classical Section. Its object is the advancement and diffusion of philological knowledge; it publishes an annual volume of Transactions and also Proceedings, detailing its meetings and giving titles of papers presented. It has a membership of some 718.

AMERICAN PHILOSOPHICAL SOCIETY. The, is the oldest scientific society in America. Benjamin Franklin, in his "Autobiography," states that in the year 1727, under the influence of well-informed persons of his acquaintance into a club which we called the Junto, the object of which was to improve our understandings. As the population of the colonies grew, Franklin saw the need of another society of larger scope and usefulness than the Junto; therefore, in 1743, he issued a circular, entitled "A Proposal for promoting useful knowledge among the British plantations in America," in which he urged that one society be formed of virtuous or ingenious men residing in the several colonies, to be called the American Philosophical Society, who are to maintain a constant correspondence. That Philadelphia, being the city nearest the centre of the colonies, communicating with all of them northward and southward by post, and with all the islands by sea, and having the advantage of a good, growing library, be the centre of the Society.

The proposition was favorably received, and in the following spring Dr. Franklin wrote to Colonel Garden, of New York, that the Society is actually formed and had had several meetings to mutual satisfaction. He gave a list of the members, and added that there are a number of others in Virginia, Maryland, Carolina, and the New England colonies who expect to join us as soon as they are acquainted that the Society has begun to form itself.

In January 1769 this Society united with the Junto, which had in the meantime changed its name to "The American Society held at Philadelphia for promoting Useful Knowledge," and the united societies took the fused name of "The American Philosophical Society held at Philadelphia for Promoting Useful Knowledge," and elected Benjamin Franklin its first president, and he held this office in successive annual re-elections until his death in 1790.

The Society at once entered upon arrangements to carry out a notable scientific undertaking of great magnitude for those days, namely, to make observations of the expected transit of Venus of June 6, 1769, a rare phenomenon which had not occurred for 130 years and would not recur for 105 years. It erected three temporary observatories and appointed a committee, of which David Rittenhouse was the head, to have charge of the observations. On the day of the eclipse the weather in northern Europe was cloudy, but in the neighborhood of Philadelphia it was perfectly clear, and a high European authority has said that the first approximately accurate results in the measurements of the spheres were given to the world, not by the schooled and salaried astronomers who watched from the magnificent Royal observatories of Europe, but by unpaid amateurs and devotees to science in the youthful province of Pennsylvania. The results of these observations were printed in the first volume of the Society's "Transactions," published in 1771. The publication of the quarto "Transactions" still continues, and in addition the society publishes "Proceedings" in octavo for foreign countries.

Franklin was succeeded in the presidency by David Rittenhouse, the eminent astronomer, who held the office for five and a half years, until his death in 1796, and he in turn was succeeded by Thomas Jefferson, who held the office until 1813, including the eight years of his incumbency of the Presidency of the United States. "The doing the useful pursuits of science," he wrote, were his "supreme delight," and the most exciting political duties could never withdraw him from them. Jefferson was succeeded in the presidency by Dr. Caspar Wistar, the eminent anatomist, and subsequent incumbents were Dr. Robert Patterson, Chief Justice Tilghman, Peter S. Du Ponceau, Robert M. Patterson, Dr. Nathaniel Chapman, Dr. Franklin Bache, Prof. Alexander Dallas Bache, Judge Kane, Dr. George B. Wood, Professor R..models, Edgar F. Smith and Dr. William W. Keen.

The membership of the Society since its foundation has included names distinguished in science on both continents. The number of members who may be elected in any one year is limited to 15 residents of the United States and three foreign residents. The election of members is held during the general meeting in April of each year. The ordinary meetings of the Society are held on the first Friday of each month, from October to May, inclusive. The Society possesses a library of over 10,000 volumes, which is specially rich in the files of the publications of the learned societies of the world, and is housed in a fire-proof building erected on Independence Square in the city of Philadelphia, on land granted to it by the State of Pennsylvania in 1785.

I. MINIS HAYS, Secretary American Philosophical Society.

AMERICAN PLATE. See Silverware.

AMERICAN POLITICAL ISSUES, 1788-1852. By this term is here meant the issues which swayed the voters in the Presidential elections, and in the Congressional elections of the Presidential years. These elections were the "round-up" or accumulation drift during the four years previous, and formed one of the influences deciding the drift during the next four. They fall into five periods: 1788-1800, 1804-12, 1816-20, 1824-40, 1844-52. In the first, the Federalists are in power; the following issues are those of a strong v. weak government, and of deference to the educated classes v. the vox populi. In the second, the Federalists are the opposition,
flying away the excuse for their existence, and some casual sectional resentments, called "Tuskegee." In the third, there are no issues and no party, properly speaking; the candidate is accepted by inertia from the old line of leaders, and the administration is able to grant the chief wishes of both the old sections. In the fourth, the former anti-Federalist elements reconcile under new names, with the basis of a strong pending and nationalism government, replacing the dead issue of a strong executive one. In the fifth, the slavery question is the central issue. The division over candidates has usually, and naturally coincided with the division over policies; but in the first election, of 1788, it was not so. There was but one possible candidate, Washington; he represented all parties. He had seen the Revolution nearly aborted first, and the Confederation nearly wrecked afterward, by the weakness of the central government; this confirmed his natural bias as a "nationalizing" Federalist, anxious above all things for a government which could keep order, pay its debts, and secure respect from other nations. On the other hand, as a Southern farmer, he commanded the confidence of that section, which distrusted the Northern commercial interests; and as Washington, he was the idol of the masses everywhere. Furthermore, the very basis of the election had cut the ground from under the chief opposition party. The overshadowing issue, almost the only one, of the Confederation,—which had no president nor regular elections, but only scattering "by-elections" of Congressmen,—whether it should be replaced by a stronger government; the adoption of the Constitution had settled that, and the Anti-Federalists were shut down to voting for the personnel to administer a system they disliked and dreaded. Besides this, all their ablest sympathizers were Federalists for the time being, not from love of a strong government but experience of too weak a one; so that "Federalist" for election purposes meant not so much a party as almost every one in the country of the same experience, or business or intellectual standing.

1792.—Again Washington was the unanimous candidate. The same men substantially were sent to Congress; indeed, there were few Anti-Federalists to send who would not dis- credit and weaken the cause. But the Anti-Federalist voters had the less hesitation, because their natural leaders had now begun to split away and lay the foundations of the Democratic-Republican party. Jefferson was the first to take a stand against the Federalist policy, in the matter of the Bank; shortly reinforced by Madison and Edward Randolph.

1796.—Washington, who could have held the office for life, refused it further. There was now a contest over policies represented by candidates identified with them, and each representing a section as well: John Adams stood for the Northern commercial States, with most to lose from conflicting local impositions on commerce, or foreign deprecations and embargoes which a government could not repel; Jefferson, the lifelong exemplification of the extreme democratic principle,—the least government, the cheapest, and the most unshby, possible,—stood for the mass of farmers, largely in the South and West, who simply wished to be let alone and have no taxes, and thought commerce of no benefit or concern to them. The latter also formed a part of the rapidly growing mass who hated the Federalist claim that political office needed any superior ability or training, and were eager to pass it around in rotation. Quite as strong as either was the sympathy of the masses for the French Revolution, which the Federalists detested. The latter won, but only by grace of two Southern electors and in reality by a single vote; they lost save for these the entire South beyond Maryland, and all but one electoral vote of Pennsylvania as well. In a word, the party had represented a temporary national necessity which was ceasing to be imperative, and a minority business interest; and as the former vanished, it was shrinking to the basis of the latter.

1800.—For the personal feuds which rent the Federalists in twain, see Adams, John, and Hamilton, Alexander; but the influence of these in defeating the party is always overrated. If Hamilton had loved Adams like a brother, and all Adams' Cabinet and all Adams' Cabinet, the general result of the election would not have been different; unless we are to suppose that New York Federalists voted for Jefferson because their chiefs hated each other, or that the party's recent policy had gained it votes since 1796, which is notoriously the reverse of truth. It had not only angered the Democrats, but displeased many of its own moderates, by the Alien Law for deporting all foreigners politically disagreeable to it, and the Sedition Law to shut the mouths of its opponents (see Alien and Sedition Laws); the Hamilton wing had tried to force through a war with France to strengthen its domestic policy; the growing popular sentiment now was to make the United States a political island, severed from all relations with the rest of the world which would cause us difficulties. The election was decided for Jefferson by the reversal of New York's 12 electoral votes; local feuds had something to do with it, Burr's political "bosomship" much; but beyond all, the growth of the country was away from Federalism, and at best the party had not one electoral vote to lose without being displaced.

1804.—Had the relations of the parties remained the same as in 1800, there is still no reason to think there would have been any return to a Federalist administration. From 1789 to 1797 their program had been not merely the best, but the only one as a whole possessing either utility, dignity or even safety; yet the disintegrating forces were so strong, and the guarantor of the Confederation so thoroughly forgotten, that the party barely escaped expulsion in the very prime of its usefulness. Even in the next four years, its errors were trivial compared with its services, especially in creating the navy; yet it was beaten—not very heavily, but with incidents proving that its lost sections would not come back to it. But so far from the issues remaining the same, the Federalist representatives, with that egregious blindness to the sources of popular strength which is never seen except in "practical politicians," committed the amazing folly of attempting to tie their opponents' hands by borrowing all their discarded doctrines. The Democrats in power had at once become converts to a strong government and a liberal construction of the Constitution;
the Federalists, instead of outdoing them and claiming support as the originators of the policy and the defenders of its enforcement, and the decentralizing policy of their opponents. The Democrats having appropriated the Federalists' strength, the latter revenged themselves by appropriating their enemies' weakness. This was especially glaring in the case of the Louisiana Purchase, an extreme Federalist measure, and by far the greatest title of Jefferson to the name of statesman: it is quite incredible that the Federalists should have opposed this, even as partisans, or as possessing the rudiments of political common-sense. Their astute policy received its fitting reward; in 1800 Jefferson had won by 73 to 65; in 1804 he received 162 to 14.

1808.—The Democrats, having had full power to put in force their cherished theories of insularity and independence of international ties, at once proceeded to make a reductio ad absurdum of them, and hang them like a sack of stones about their town necks. Jefferson was placed between the upper millstone of the English right of search, and the lower, in the bloody outrage of the Leopard on the Chesapeake (q.v.), and the nether of his own resolve not to fight, the disbelief of all parties alike in our ability to fight a naval war with England, and the determination of the North, which possessed most of the fighting resources, not to use them against England. He solved the problem by the Embargo (q.v.), which saved the need of fighting by sacrificing the commerce he did not value, and the prosperity of the section he was quite resigned to see unprosperous. The moribund Federalist party gained a galvanic life from this, which, for the time looked like a real one: in 1804 it had carried only Connecticut and Delaware and part of Maryland; in 1806 it carried all New England but Vermont (the one State which had no commerce to lose), three votes from North Carolina and Delaware, and the two Marylanders as before,—47 in all.

1812.—The same causes which had operated during the four years had continued with ever-growing efficacy during this year. The feeling against England among the Democrats, the feeling among the Federalists that England was fighting the world's battle against Napoleon and must not be crippled, ever grew in intensity; the misery and hate in New England with its hamstrung commerce kept pace with either; a generation of youth was growing up who never saw the Revolution.—The War of 1812 was officially determined by four Southerners between 26 and 29; and the conquest of Canada, instead of a naval war where it was universally believed our entire fleet would be at once seized and impressed into the British navy, had struck the war party as a happy resource. The political campaign of 1812 was thus on the issue of war or a repeal of the Non-Intercourse Act. Madison was given a second term on the express condition of his approving the war; he detested it as strongly as Jefferson, but as the majority had its teeth set, felt that he might as well head it as a worst one else. He secured it by 189 to 89; the Federalists by a fusion had carried, besides their old States, New York and New Jersey and more of Maryland. A new era seemed coming for the Federalists; but it was an illusion. They had no party principles, and not even a party candidate except a borrowed one (George Clinton); and their entire basis of life now was on an issue by its nature temporary.

1816-20.—The close of the War of 1812 extinguished the old issues. The mostly inglorious land war had been forgotten in the blaze of New Orleans; and it was generally agreed that our navy not only could fight the queen of the world on equal terms, but would never again be wantonly defied; the people were full of satisfaction at coming out so well, and of anger at the Federalists, whose chief section had carried opposition to the point of discussing secession. Federalism was in many minds tainted with treason. Furthermore, the New England capital driven out of commerce by the embargo and the war had begun to re-embark in manufacturing, wished for a protective tariff, and the issue in 1816 the Democrats carried 16 States with 183 votes, including the rest of New England. The government had bid for these votes by a United States Bank and a light protective tariff; and in 1820, the "Era of Good Feeling," or rather of "No Issues," Monroe was elected unanimously save for the vote of one elector, disgusted with the business "rings" growing up around the administration.

1824.—The administration still further carried out Federalist ideas by a great system of internal improvements and by strengthening the tariff. In a word, while nominally Democratic-Republican, its policy had become so Federalized as to have a stronger hold on its new allies than on its old constituents, and the issue in 1824 was whether that policy should be sustained or reversed. John Quincy Adams and Henry Clay represented the former, in different sections; Andrew Jackson the reaction to old-fashioned Democracy, with strict construction, economy and no interference with the press development; William H. Crawford the regular Democratic "machine," with no ulterior purpose but office. Thus divided, no candidate had a majority. Jackson had the most; Adams was elected by the House of Representatives, still so far dominated by educated politics as to consider Jackson an ignorant and pestilent demagogue; he made Clay—who had the lowest vote of the four, but was the Southern leader most in accord with his policy and the most of a statesman—Secretary of State. This "Coalition" (q.v., No. 2) was denounced by the enraged Jacksonites as a corrupt bargain, and the House election as defeating the people's will; but there is no reason for assuming, as is currently done, that the anger gained Jackson any electoral votes.

1828.—The Democratic reaction had gained strength and the Jackson enthusiasm swept all the factions into his fold, by virtue of the State conventions which had now assumed the effect of nominating. On that side the issue was much more Jackson than any definite party program; but Jackson as representing the hatred of the masses, especially the Southern and Western masses, for the "money power," for all
AMERICAN POLITICAL ISSUES

activities of government beyond keeping itself alive, for tariffs and government subventions, and for all claims of superiority in the educated class and all political initiative except by spontaneous popular movements. In short, Jackson was the agent of a Democratic revolution, which supported him with a swarm of new men and approved policies, but turned out the trained officials neck and heels. Adams held his vote well; the stock reasons for his defeat—his ungraciousness, his refusal to employ patronage, his revulsion of charges against the New England Federalists—are absurd in face of the fact that he had but one vote less than in 1824 and of Jackson's enormous plurality. No candidate representing trained statesmanship, culture and a liberal government policy, could have won this election.

1832—The Democratic tide swept on overwhelmingly. Jackson's unprecedented use of the veto power to defeat internal-improvement schemes voted for by members of his own party, only bound the majority more tightly to him; his war against South Carolina for attempted nullification deprived him of reinforcements from the nationalist section; his hostility to the Bank of the United States was a prominent issue in the canvass, and was that of his constituents. Nothing better proves the senility of Adams, of giving great political results by personal fact or squabbles than the fact that Adams in 1824 and 1828 had more electoral votes than all Jackson's opponents together in 1832.

1836—The issues of this year were the carrying on of Jackson's policy, though its great objects had been accomplished,—the deposits had been placed in State "pet banks" instead of the United States Bank,—and his dictation of his own successor. To oppose this dictation, one party sprang up with the ardent Jacksonian Hugh L. White as nominee, another as a Georgia State Rights faction,—though Jackson had championed the Georgia rights in the matter at issue (see CHEMORE CASE); Jackson's influence, however, was powerful enough to nominate Van Buren, as he, the "Democrat" and he was elected by a much reduced vote from Jackson's.

1840—Few men had a worse legacy than Van Buren received in the Presidency; and few men made a better record. Almost his entire term was occupied by the panic of 1837 and the three years of hard times which succeeded it; caused entirely by Jackson's "monkeying" with the currency of which he knew nothing. The State banks which replaced the United States Bank as depositaries and were used as Democratic political machinery, instead of managing the funds with discretion as the old bank had done, issued masses of notes till a tremendous inflation of the currency had created a vast land speculation; then he suddenly withdrew their power to print. The paper currency and brought the whole structure down with a crash. Van Buren was a politician, but he was a sound statesman and financier and an honorable public man; he would have no more meddling by the Government with the bank business for which he was unfit, even to extricate his own administration from a scrape; and after three years' struggle he established the Sub-Treasury system, to the lasting benefit of the country. But with the customary popu-

lar perspicacity, he was made the scapegoat for calamities which he had not caused and whose renewal he had prevented. Furthermore, the Whigs outbidding the Democrats in avowed submission to the "popular mandate," their candidate Harrison promising to disuse the veto; they outdid them in the "popular hero" line by turning a useful but not very brilliant Indian battle into a second Marathon, or rather repeating the name without discussing the details; capped their swarms of mythical anecdotes of Jackson's homespun habits and unpretentious heroism by an equal number about Harrison, models of his hypothetical "log cabin" and bibulous reproduction of his "hard cider" days; they made bargains and absorbed both the Southern free-lance opposition parties; and by all this and their campaign "noise, numbers and nonsense," carried all but three old States and four small new ones, 234 to 60—a majority which suggests that possibly the noise and nonsense were not needed nor efficacious, and a quieter campaign of sensible argument might equally have won, with a real leader like Clay and no ruinous bargainist. 1844.—Harrison had barely survived his inauguration; and the usual policy of "placating" the strongest part of the opposition by giving them the Vice-Presidency (Tyler) had produced its usual and deserved result of distrust in the administration over for the whole four years to the Nullification party, except so far as the Whigs tied its hands. This under Clay's leadership they did, consolidating the party by steady war on Tyler, and heartening themselves at last to do what they had not before and but once again—put forth a platform. It was a very compact and well-expressed one, excellent from the Whig or present Republican standpoint; but it was displaced as an issue by far more exigent and pungent practical ones. The tariff of 1842, which was almost weeded of protectionist features by the joint efforts of Tyler and the Democrats, was made one of the arguments; but the decisive one was Texas. For years the great object of the Calhoun wing of the Democrats had been partly to increase slave territory and balance Northern growth, partly with the immediate aim of disrupting the Whig party by forcing it to take a position which would drive away either the Northern or the Southern wing. Tyler, deprived of Whig support, again drew near to the Calhoun party to which he had formerly belonged; in 1844 Calhoun was made Secretary of State; and with this administration backing, the Calhoun party obtained control of the Democratic national convention, committed it to Texas annexation and gave the nomination to the Southerner Polk instead of the Northerner Van Buren. Clay was asked to declare himself on this point; he wrote an evasive letter which cost him the support of the political abolitionists (see Liberty Party), was caused to lose a ticket of their own with disastrous results to both. The three tickets were those of Polk, Clay and Birney; the first on the issues of protection, distribution of land sales, cutting down Presidential pensions; the second on the two phases of the slavery question; the second on the "reoccupation of Oregon and the re-annexation of Texas"; the third on immediate abolition of slavery. The last-named cast only 62,300 votes; but enough of those were in New
York and Michigan to turn the former's 35 and the latter's 6 electoral votes from Clay to Polk, electing the latter, bringing in Texas and bringing on the Mexican War.

1848.—The Mexican War had been the dominant issue for a couple of years before, and the Democrats had striven to make it destructive to the Whigs by forcing them into obnoxious declarations of principle; but the latter voted supplies for it and evaded abstract pronouncements as to its righteousness. The Wilmot Proviso (q.v.) was a heavier blow, for the Southerners looked on it as a primary touchstone of sectional loyalty, which stood above party loyalty. The one salvation was a popular moderate candidate who could be accepted by the voters to whom the Democrats were simply impossible; and such a one was found in Gen. Zachary Taylor. A Louisiana slaveholder, no Southerner could suppose he would sign a bill endangering his own property; known to dislike the veto, he could be trusted by the North to obey the verdict of Congress if it passed the Proviso; a popular hero, he commanded the general who was directing the armed forces, which were restoring military and civil functions somehow related. He was elected by reason of a split in the New York Democracy, the country being about evenly divided; that he was elected at all, however, is remarkable proof of the terror of the conservative masses at having the slavery firebrand thrown into politics. It was this vote which elected the Whigs Clay and Taylor (the former really elected so far as the Democratic candidate for Vice-Pres.), and the Democrats Pierce and Buchanan, each in the hope of suspending the question altogether.

1852.—Taylor died in 16 months and the Vice-President, Fillmore, completed the term; but all through the four years each of the two parties of unlimited slavery extension and slavery restriction was drawing its ranks together and forming into the parties soon to contest the final mastery. In place of Whig and Democrat, it was increasingly North and South. Unfortunately, the South was willing to fight and the North as yet was not; and so-called Compromise of 1850, like most compromises, was practically all on one side, the Northern Whigs letting the measure go by default. They did not like it, but the South insisted and they had the majority in the House of Representatives and the qualifications of their own constituents for adhering to it than the South for not doing so; once passed, therefore, they proclaimed it a sacred and irrepealable decision, as being a compromise, and the Fugitive Slave part as being a sacred obligation to uphold. As always, the "reopening of agitation" was executed by the Southern wing; before the Presidential nominations were made, they had determined to force the Whigs to an absolute declaration of party policy, a touchstone of legitimate membership. First at the Whig caucus of 20 April, then at the Baltimore national convention of 16 June, they insisted on the party recognizing the Compromise as a finality; in the platform, the last article, of great length and minuteness, made the Fugitive Slave Law finally, thirdly, of legitimate membership. This was death, and the Southern Whigs must have so intended it. General Scott, as a military hero, was made the candidate. The Southern Whigs, instead of voting for him on account of the Fugitive Slave plank, largely voted against him because the anti-slavery men in the convention, for no assignable reason, had voted for Seward, and it was said to be partial to Seward; the Northern Whigs largely voted against the platform and the Whigs carried only four States, Massachusetts, Vermont, Kentucky and Tennessee, and less than a third of the next Congress even nominally, a third even of the men who soon became Democrats. The Whig party was no more; "died of an attempt to swallow the Fugitive Slave Law" was the epitaph proposed for it.

Connecticut Historical Society.

American Political Issues, 1865-1918. Reconstruction. The predominating question that presented itself for settlement in the years immediately succeeding the Civil War was Reconstruction, or the conditions under which the seceded States should be re-admitted into the Union. Reconstruction was not officially complete until 1867, when Georgia, the last State to return to the Union, was readmitted; scarcely any other question was considered during the administration of President Johnson. But although, technically, the Southern States were restored to self-government, and the two administrations of General Grant saw vigorous military force employed to control the complexities of an anomalous situation, it was not until the middle of President Hayes' administration, or 13 years after the war closed, that an end was finally put to Federal interference in the local concerns of the Southern States. See United States—Reconstruction in the.

Rise of New Parties.—During the first administration of President Grant steps were taken toward the reform of the civil service, March 1871. It was about this time that the Prohibitionists first put a national ticket in the field, and this period was noted also for the appearance of organized labor in the arena of national politics by the formation of a Labor-Reform party. A Liberal Republican party was also formed, and the decadence of old issues and use of new ones was graphically indicated by the fact that there were five party tickets in the field in the election of 1872. The formation of this Liberal Republican party, which chose Horace Greeley as its standard bearer, should receive further notice, for it dominated political formations and alignments, down to 1892. It took with it many of the great abolition leaders of the old Republican party—men like Sumner and Phillips who claimed that the old party no longer stood for the principles from which it had gained its strength and life. These men were the predecessors of the later Independents and Mugwumps. These recalcitrants were met halfway by the Democratic party, that made haste to drop the old Doughface and Copperhead issues and catch-words, and nominated their bitterest foe because he seemed to impersonate the Republican revolt. The immediate result was defeat, but it had the effect of the organic death of the party (view, according to the point of view) in 1876 and the election of Cleveland in 1884, and definitely committed the Democratic party to an attitude that faced the future instead of the past.
The "Grangers" and the Money Question.—The seething process was still going on, for from 1874 the genesis of at least two new issues appeared: one was the "Grangers" movement, which, though primarily organized to promote co-operative buying and selling and securing laws favorable to the farming classes, became the seed, which flowered later, of attempts, not always well advised, to curb railroad rates and prevent discrimination in rates and prices. Another great issue to assume large importance at this time was that of national finances. Occasioned by the terrible panic of 1873, and by a supposed public demand that gold should be used only to pay the interest on the national debt, a "Greenback" party was organized in 1874 which took part in the three following national elections, and, under the name of the Greenback-Labor party, polled more than a million votes in the congressional elections of 1876. After 1878 it was made legal tender and given limited coinage. But in 1874 President Grant vetoed the "Inflation Bill" which would have added $44,000,000 to the currency; and on 7 Jan. 1879, in President Hayes' administration, the "Fendler Bill" was resubmitted after a suspension of 17 years, and greenbacks have ever since been payable in gold on demand.

The Civil Service.—The assassination of President Garfield led to a radical reform in the civil service. The vicious system taken over by Jackson from that of New York—classic in Marcy's sentence, "To the victors belong the spoils," had become so deeply rooted that perhaps nothing less than the martyrdom of a President could have effected a change in public policy at this period. But on 1 Jan. 1883, the "Fendler Bill" provided a constitutional, practical and effective measure for the remedy of the abuse known as the "spoils system." Many States have enacted laws along the same lines, and the classified lists of those subject to civil service examinations have been increased by the executive orders of successive Presidents, until, on 30 June 1915, of 476,363 officers and employees of the Federal civil service, 306,106 were civil service employees, and 170,257 were employed after competitive examinations under civil service rules; and the practice of levying assessments for partisan purposes has long since been discomteanced by law.

Anti-Chinese Legislation.—Anti-Chinese feeling on the Pacific coast made it necessary in 1876 for both great parties to insert anti-Chinese planks in their platforms. A bill to restrict Chinese immigration was passed in 1879, but was vetoed by President Hayes because it violated the Treaty of 1868. In 1880, a new treaty was negotiated with China, under which the United States was to regulate, but not to prohibit absolutely the entrance of Chinese. The limitation was to apply to Chinese laborers only. An act of 1882 suspended the immigration of Chinese laborers. This act was amended in 1888 to prohibit the return of Chinamen once here' who went back to China. A treaty pending with China at this time was denied ratification by the latter because of the amendment. In 1892 the Act of 1882 expired and a new law was passed containing the exclusion for a further period of 10 years. In 1902 an act was passed continuing existing legislation until further enactment should be made and extending the exclusion laws to the island possessions and forbidding the migration to the mainland or to other island groups of Chinese dwelling in one group. See Chinese Immigration.

Railroad and Commerce Regulation.—It was during President Cleveland's first administration, 1887, that the first great measure looking to the regulation of railroad and commercial interests was passed—the Interstate Commerce Act (see Commerce, Interstate); this was amended in 1893 by the Elkins Act, which omitted the penalty of imprisonment. The original act was amended in a drastic way in 1910, the Elkins Act being left in force. The amendment is known as the Mann-Elkins Amendment to the Act to Regulate Commerce. It contains 24 sections, which specify the companies and organizations subject to the Act, and forbidding discrimination, rebates and preferential rates of all kinds. See its provisions see Railways—Government Regulation of. An Interstate Commerce Court was established in 1910 to hear appeals from decisions of the Interstate Commerce Commission. See Interstate Commerce Commission; United States Commerce Court; Trusts.

Formation of Other Parties.—It was at about this time, which seems to have been one of great political initiative, that 8 political parties appeared, Union Labor and United Labor; and in the next presidential election (1892) the Socialist Labor party and People's party or "Populists" were born. The Populists demanded the free and unlimited coinage of silver; national ownership of all public means of communication and transportation; a graduated income tax; popular election of United States Senators; and, it is interesting to note, the adoption of the initiative and referendum (q.v.). Many of these measures have since been brought into prominence by the Socialists or have been adopted into the platforms of one or both of the greater parties. The Populists were also pioneers in denouncing the imperialistic policy of the government in 1900. In 1890 the Populists polled 500,000 votes, and in the two following elections fused with the Democrats (see Imperialism). To indicate still further the political restlessness of this period we may recall the fact in 1896 there were seven parties in the field and, in 1900, eight. The Socialists had now divided, or increased, into two parties, of which the new one was to prove the stronger. In the election of 1900 it polled nearly three times as many votes as the Socialist-Labor party; by 1910 it had 30 times as many votes. In 1912 it was again 30 times greater than the other party, but in 1916 it received almost 50 times as many votes, although it polled only 59 per cent of its 1912 vote and the Socialist Labor party only 32 per cent.

The Tariff.—This question was in the forefront of the platform during Arthur's administration in 1882. The clamor against the exorbitant rates had been so vociferous that the President appointed a commission to report on conditions. The commission, manifestly favorable to the President's personnel, was expected to "stand pat" and report against lowering the tariff; but they astounded the country by recommending a 20 per cent reduction through the entire list. Congress,
however, calmly ordered an increase of 10 per cent and there the subject rested, if the country didn't, until the famous "Tariff Message" of President Cleveland in 1887. The basis of this message was that the existing tariff was the cause of burdensome taxation which could be relieved only by a reduction of the duties on raw materials, especially wool.

The resulting Mills Bill failed to pass the Republican Senate but, in 1890, under President Harrison, the McKinley Act was passed which raised, instead of lowered, the duties on most articles. In 1894, under President Cleveland's second administration, the Wilson Bill became law, its principal feature being free admission of wool. In 1897, under President McKinley, came the Dingley Act; the duty was again imposed on wool and other rates were advanced. In 1909, under President Taft, the Payne-Aldrich Tariff Act was passed with no general lowering of the tariff wall. A tariff board was created not only to secure information on the maximum and minimum provisions of successive tariff bills but upon the relative costs of production at home and abroad. The Payne-Aldrich Tariff of 1909, which was so irregular and unscientific that President Taft had hesitated to sign it, although he afterward held it to be "the best tariff that the country had ever known," was also assailed by President Wilson. Four other bills for tariff reform passed by Democrats and Progressives had been vetoed by President Taft. These now paved the way for the Underwood Tariff Act which became law 3 Oct. 1913, and fixed a high rate on luxuries and a low revenue rate on the necessities of life. The results were unfortunate; duties were so lowered that the customs receipts fell off $25,000,000 in the following year. Further depression was caused by the outbreak of the European War in 1914 which upset all calculations. On the revival of business in 1915-16, while the Republican party stood firm for a protective tariff, less was heard about a general revision, and more about certain changes of detail. A Tariff Commission was created by the General Revenue Act of 1916, to consist of six members. It is the duty of the Commission to investigate the administrative, fiscal and industrial effects of the tariff laws. The free-sugar clause of the Underwood Tariff Act was repealed in 1916.

In conjunction with President Taft's tariff policy, an attempt was made in 1911 to crown previous reciprocity arrangements with different countries by a Canadian Reciprocity Agreement. This was designed to secure admission into the United States of Canadian manufactured products in return for the repeal of Canadian duties, such as wheat and other grains, fresh fruits and vegetables, dairy products, fish, eggs, poultry, cattle, sheep and other live animals, on American cotton goods, fruit, etc., with reduced rates on agricultural implements and other manufactured articles. This bill was passed by Congress but rejected by the Canadians in a special election.

The previous reciprocity agreements referred to were: first one with Canada in 1854, which lasted for 12 years. Its provisions as regards Canada were almost identical with those of 1911, except that manufactured articles were not included—only raw materials which both countries produced. It is curious that the objections to it in England and Canada were almost exactly identical to those heard later, viz.: The fear that the United States was attempting to weaken the bonds between England and Canada with a view to annexation of the latter to her neighbor on the south. In 1875 a reciprocity treaty was made with Hawaii, and in 1899, duty free, in return for a long list of manufactured articles. This treaty remained in force until the annexation of Hawaii in 1898. Under the terms of the McKinley Bill in 1890 reciprocity treaties were made with Germany, Austria and several South American countries, but these were repealed by the Wilson Bill in 1914. See United States—Reciprocity; United States—History of the Tariff; Foreign Relations.—It is necessary to go back to the administration of President Harrison to note the first real growth of public interest in the foreign relations of the United States, both commercially and diplomatically. The meeting of the Pan-American Congress (q.v.) in Washington in 1889, for which the far-seeing President Garfield of 1881, who must receive most of the credit, did much to prepare the way for commercial reciprocity and for a more liberal attitude toward the outside world. This event marked the first entrance of the United States into world politics since 1815. Before that its greatest interest had been in foreign affairs, as became a satellite of its mother; since then the outside world was almost forgotten except when certain portions of it were menaced as in the Civil War. It was in 1899 that we strode into the world arena once more but under widely different auspices; for there followed the Expansion Period, the creditable part borne by the United States in the Boxer troubles in China, the "Open-Door" policy of Secretary Hay, the successful offices of President Roosevelt in establishing peace between Japan and Russia and other notable evidences that the United States had at last taken her place as a world power. See United States—Territorial United States—Commercial Development; Anti-Trust Legislation.—The Sherman Anti-Trust Act of 1890 had led to a number of secret agreements between interested parties which sought to evade the provisions of the act, while still dominating the various markets. When Colonel Roosevelt became President, he resolutely instituted an investigation of these evils, and in 1903 the Attorney-General was instructed to bring suit to dissolve the iron and steel combines and the Northern Securities Company, as a combination in restraint of trade with interests which would permit the control of the nation's railways passing into the hands of three or four persons. In 1904 the combination was declared illegal by the Supreme Court. The Railway Rate Regulation Act of 1906 made concessions to the railroads, but President Roosevelt's attitude antagonized large banking, corporation and other commercial interests. Under President Taft, regulation of railways and corporations was not favorably looked upon, and this with further leniency toward moneyed interests, led to the formation of the Progressive Republican party, which joined with the Democrats,
when opportunity offered, to promote legislation favorable to their views. This movement created opposition, led by ex-President Roosevelt, to President Taft’s re-election. The result was a Democratic party victory with the election of Woodrow Wilson by a minority vote—2,500,000 less than the combined votes of his Republican opponents. President Wilson was not in sympathy with consolidated business interests, which he described as “so great that it is almost an open question whether the government of the United States can dominate them or not,” and he proposed that Congress should pass new laws curbing monopoly. In 1914, the Rayburn Bill, an anti-stock watering measure, was introduced and passed the House, but was stopped in the Senate as it was discovered that the financial condition of railroads made it inadvisable to press further legislation. The Federal Trade Commission Bill and the Clayton Anti-Trust Act, however, became law; the first to deal with corporations not engaged in transportation but in retail business or with a foreign country; the second to meet difficulties that had arisen through efforts of corporations to create monopolies by indirect dealing, such as offering their products at special low prices until their competitors were driven out of business.

Income Tax.—When in 1895 the Supreme Court set aside the Income Tax Law of the previous year, on the ground that it was a direct tax, and therefore must be apportioned among the States according to population, an amendment to the Federal Constitution seemed the only remedy. On recommendation of President Taft, both Houses of Congress, with almost no opposition, submitted such an amendment to the States in 1909, allowing an income tax without proportional distribution. It was ratified by the necessary 36 States—to which six others were promptly added—and became a part of the Constitution, 25 Feb. 1913.

Senatorial Election by Popular Vote.—During the first decade of the 20th century there was constant agitation for an amendment providing that senators should be elected by popular vote. Such an amendment was reported by the Senate on 15 May 1912 and it went through with such rapidity that it was put in force 31 May 1913. From that time all vacancies as they occurred were filled by popular election. The result was that many senators who had never been chosen to any office by popular vote found that they could not meet that test and dropped out. By 4 March 1919, this amendment had its full effect, every senator thereafter being chosen by direct popular vote.

Liquor Legislation.—In recent years the liquor question has grown into an issue of vast national importance. Prohibition and local option have made great strides across the continent, though it cannot be said that the consumption of intoxicating beverages has fallen off in proportion, the per capita figures for 1916 being slightly greater than those for 1902. Whereas prior to 1 Jan. 1915 there were only nine States which had adopted prohibition, by 1 March 1917 there were 25 States on the "dry" list, with an aggregate population of 35,380,568 (1910 census). In 19 States prohibition laws were effective while in the other six the law became operative at different dates during 1917 and 1918. Hence it was estimated at the time that more than 55,000,000 of the population of the United States were living under prohibition and more than 60 per cent of the entire area of the nation was prohibition territory. In the Presidential election of 1916 the Prohibitionist candidate, Mr. J. F. Hanly of Missouri, received little over 221,000 votes, about 13,000 more than the candidate in the previous (1912) election, but considerably less than were obtained by the Prohibition candidates in the elections of 1888, 1892, 1904 and 1908. But if the party prohibitionists were not supported in the popular voting, their cause was greatly advanced in the referendum voting on liquor laws and prohibition amendments. Though the joint resolution providing for the submission of a prohibition amendment to the Constitution was not voted upon during the 64th Congress, the consideration which was given it in both Houses indicated a strong sentiment in its favor. Enormous changes were wrought by the Food Control Act of 1917 as a war measure, and further modifications were introduced by the November elections of that year. See Liquor Legislation; Prohibition.

Woman Suffrage.—The issue of votes for women made large advances between 1913 and 1917. It was one of the most widely discussed questions in the range of popular government. By 1916 women voted on equal terms with men at all elections in 11 States and in the Territory, Alaska; partial suffrage existed (1917) in six other States. An amendment to the Federal Constitution, Article 11, to strike out the word "male" was defeated on 12 Jan. 1915 by a majority of 204 to 174 in the House of Representatives. In Indiana a suffrage bill passed 22 Feb. 1917 was declared unconstitutional and void 17 September. The campaign of 1915 in the three great Eastern States, New York, Massachusetts and New Jersey, was defeated by large majorities. The elections of 1917 revealed a great surprise when New York State declared for suffrage by a majority of 100,000 votes, to which the city of New York contributed a considerable portion, after having given nearly a 90% majority against it two years before. This brought the number of complete suffrage States to 12. According to statistics compiled by the officials of the National Woman Suffrage headquarters in November 1917 there were (together with New York) 10,121,931 women in the United States who may vote in Presidential elections, of which number 5,759,021 may vote on all issues. Total number of States, 19. On 4 March 1917 the first lady congressman took her seat in the American legislature. After sweeping the State in the primaries in August 1916, Miss Jeanette Rankin was elected (November 1916), as one of the two congressmen-at-large from the State of Montana. See Woman Suffrage.

AMERICAN PRINTING TRADE. See Printing Trade, American.

AMERICAN PROTECTIVE ASSOCIATION, OR "A. P. A.," a secret order organized throughout the United States and Canada. Its
chief doctrine, as announced in its declaration of principle, is that *subjection to and support of any ecclesiastical power not created and controlled by American citizens, and which claims equal, if not greater, sovereignty than the government of the United States in America, is irreconcilable with American citizenship*; and it accordingly opposes *the holding of offices in national, State, or municipal government by any subject or supporter of such ecclesiastical power*. Another of its purposes is to prevent all public encouragement and support of sectarian schools. It does not constitute a separate political party, but seeks to control existing parties and to elect friendly and defeat objectionable candidates by the concerted action of citizens affiliated with all parties, much after the style of the American or *Know-Nothing* party. The order was founded 13 March 1887 and once claimed a membership of over 2,000,000.

**AMERICAN PSYCHOLOGICAL ASSOCIATION.** A society founded in 1892 for the advancement of scientific psychology. Persons are eligible to membership who are engaged in this work. Membership, 227. Office of secretary, Smith College, Northampton, Mass.

**AMERICAN PUBLISHING.** See Publishing, American.

**AMERICAN QUARRYING.** See Quarrying.

**AMERICAN RAILROADS.** See American Street Railways; Railway Systems in the United States.

**AMERICAN REPUBLICS,** Bureau of. See Pan-American Union.

**AMERICAN REVOLUTION.** See United States—American Revolution.

**AMERICAN RIVER,** in north-central California, is formed by the union of its northern and southern forks near the western boundary of the county of El Dorado, whence it flows southwest between the counties of Placer and Sacramento and falls into Sacramento River near the city of Sacramento. For about six miles it has been rendered navigable for small steamers. The north fork, considered by some as the true American River, rises among the hills at the base of the Sierra Nevada, flows west-southwest, forming the boundaries between Placer and El Dorado counties for 100 miles, and unites with the south fork 30 miles above the city of Sacramento. The south fork flows from Bonpland Lake through El Dorado County and forms part of the division between the counties of Sacramento and El Dorado.

**AMERICAN-SCANDINAVIAN FOUNDATION, The.** The foundation was incorporated in 1911 under the laws of New York with the object of cultivating closer intellectual relations between the Scandinavian countries and America and strengthening the friendly bonds between American-Scandinavians. It was endowed by the late Niels Poulson, president of the Heka Iron Works in Racine, who died in 1905. The income from one-half million dollars is administered by a self-perpetuating board of 15 trustees. The Foundation maintains an office with a salaried secretary and staff and an organization of associates numbering upward of 4,000. It awards annually six fellowships to Scandinavians for study in the United States and a number of scholarships to Americans for research work in Scandinavia. It regularly publishes two series of books, *The Scandinavian Classics* and *The Scandinavian Monographs,* and a bimonthly illustrated magazine, *The American-Scandinavian Review.* Address, 25 West 40th Street.

**AMERICAN SCENIC AND HISTORIC PRESERVATION SOCIETY.** A national organization of men and women incorporated by the legislature of the State of New York in 1895. Its aims are the protection of natural scenery, the preservation of historic landmarks and the improvement of cities. In pursuance of these objects it is empowered to receive by purchase, gift or otherwise, and to hold in fee or trust, real or personal property necessary thereto; and it is required to make to the legislature an annual report of its affairs. Among its activities as set forth in its constitution are the following: The purchase of the New York State Park at Stony Point, and of Washington's headquarters in New York city, the creation of a State reservation at Watkins Glen, laws for the protection of Niagara Falls, and the site of Major André's execution; and it has charge of Fort Brewerton, and Philipse Manor Hall.

**AMERICAN SCHOOLS OF LAW.** See Law, American Schools of.

**AMERICAN SCULPTURE, Historical Subjects in.** American art in the Colonial and Revolutionary periods was confined chiefly to portrait painting. At the beginning of the 19th century there was to all practical purposes no such thing as an art of sculpture in the United States. Mural painting, as a branch of art adapted especially for depicting historical subjects, was still farther away in the future. The country was not ready for the development of art along the lines of history and commemoration of historical characters. It was not until the latter half of the 19th century that there began to be real attempts in this direction. At first, when statues or busts of pioneers and patriots began to be in demand for public institutions or places, notably the national capitol at Washington, it was customary to go abroad to find some artist, possibly a Frenchman or Englishman, capable of doing the work. And when there began to be Americans of real talent who devoted themselves to sculpture they at first were chiefly absorbed in producing gods and goddesses of Greece and Rome, more or less poor imitations of those of classic times, rather than in creating things having to do with their own country and its annals and customs. It is chiefly in the past 25 or 30 years that American sculptors have found their main inspiration in American life, and have made for themselves so largely to themes associated more or less directly with American history.

A great influence upon this phase of American art has been exercised by the wars of the nation, chiefly the Revolution and the Civil War, while the recent centenary of the War of 1812 and the close of a century of peace with Great Britain witnessed the dedication of a strikingly large number of works of art having to do with
AMERICAN SCULPTURE

1 George Rogers Clark (By Elsie Ward)
3 Gen. Alexander Macomb (By A. A. Weinman)
2 Sieur de La Salle (By L. A. Gudebrod)
4 Pere Marquette (By Cyrus K. Dallin)

2 Francis Scott Key Monument, Baltimore. By Niehaus
3 Lafayette and His Servitor, Prospect Park, Brooklyn, N. Y. By Daniel C. French
this commemoration and furnishing proof of the good effect of such celebrations and the influence of art.

Another influence which should be noted is that of the great international expositions of the last quarter century. Most of them had some historical motives which have been expressed in the architectural schemes and in the decorative restorations and the latter, which are usually temporary, have exerted a powerful and far-reaching force, affecting public taste in many ways and often leading to more permanent decorations of similar type in connection with public places and institutions. Hence there has been, partly as a result of the influence emanating from these expositions, a marked increase in the application of the art of the sculptor to the embellishment of buildings like capitol, court-houses, libraries and even business premises of a semi-public character. There have arisen within this period the Congressional Library at Washington, one of the most interesting and educational buildings in the world, in its artistic features, so largely and at the same time and the others; the Pennsylvania State capitol at Harrisburg, with its sculptures by George Grey Barnard, historic or symbolic of national types; the Court-house at Baltimore, with its many excellent decorations; the Appellate Court Building in New York, with its sculptures typical of law and government; the New York Custom House, with its facade figures by Daniel Chester French and others; the State capitol of Wisconsin and Iowa, with their splendid adornments typical of the West; the Jefferson Memorial Building at Saint Louis, an outcome of the Louisiana Purchase Exposition, with its imposing group by the late Karl Bitter showing Marbois, Livingston and Monroe signing the Louisiana Purchase Treaty; and the statue, also by Bitter, of Thomas Jefferson, during whose administration this momentous purchase was negotiated; and the Cleveland Court-house, with its historical sculpture, including Chief Justice Marshall by Herbert Adams.

The artistic merits of the creations of later years in this field are evident from a comparison between them and earlier efforts of similar type. When the Virginia assembly wished to have a statue of Washington erected at the State capitol there was apparently no American sculptor equal to the task, and Jean Antoine Houdon (q.v.), the French sculptor, was engaged to model one. He came to this country in 1785 for the purpose, and the statue, the original of which is now in the capitol at Richmond, was dedicated in 1788. Another French sculptor, David d'Angers, executed the first statue which was made of Jefferson. By 1832, when the centenary of the birth of Washinton was observed, Horatio Greenough, Thomas Crawford and Henry Kirke Brown were coming upon the scene. Greenough was then but 27 and studying in Florence, Italy, but Congress commissioned him to execute a statue of Washington, with the stipulation that it should not be equestrian and that the countenance should correspond to that of the Houdon Washington. Greenough devoted the greater part of eight years to his commission and received $20,000 for his work, quite a sum in those days. The statue, which is of Carrara marble, was brought from Italy in a special ship. It represents the First President with bare legs and a Roman toga, which has slipped from his shoulders, lifting a finger of warning and advice to the nation. It is in the nature of a characterization of him as an Olympian Zeus. It was recently removed from the square in front of the capitol to the Smithsonian Institution. There has been much controversy over this figure and no little ridicule has been cast upon it. Considering the time and circumstances it was no doubt a work of merit but does not, in spite of the classic atmosphere with which it was supposed to be invested, give us that impression of dignity and intellectual force in the Father of his Country which we associate, for instance, with John Q. A. Ward's fine figure of the same statesman in front of the Sub-Treasury in Wall Street, New York, or the splendid equestrian statue by Daniel Chester French in Paris, France, or Henry Kirke Brown's equestrian statue in Union Square, New York. The latter may be classed among the earlier examples of American Historical sculpture, but it holds its own in spite of the opposition of artistic standards. Another historical work, also by Brown, is the spirited statue of Gen. Winfield Scott in Scott Circle, Washington, D. C. Launt Thompson was another of the early American sculptors who did meritorious historical work. His statue of General Scott at the Soldiers' Home, Washington, is an example. Thomas Ball was another. His equestrian statue of Washington is in Boston Common. Clark Mills executed equestrian statues of Andrew Jackson and George Washington, which are famous. The national capital has the original of his Jackson and New Orleans a replica.

The historical work of the earliest American sculptors consisted almost entirely of sculpture in the round—statues and busts. The idea of portraying historical subjects in reliefs, upon the bases of monuments, or upon panels in doors or upon the walls of buildings, though familiar abroad, was a later development in American art. Perhaps one of the first examples of it was the work of Thomas Crawford. Crawford was one of the pioneers of American sculpture and famous for his statuary in ideal subjects. But he did much of the earlier sculpture of the national capitol illustrating American history and was the sculptor of the bronze doors opening from the Senate portico of the capitol. Its eight panels illustrate such subjects as the "Death of Warren at Bunker Hill," "Washington in the Camp of General Charles Lee at Monmouth," "Hamilton's Gallantry at Yorktown," "Washington's Reception at Trenton" and his first inauguration. Crawford designed the House portico doors and Rinehard modeled them. Hiram Powers' groups in the Senate portico are a notable feature of the decorations of the capitol and illustrate "American Development and the Decadence of the Indian Race."

Statuary Hall at the capitol is notable for its historical associations, contained in its gallery of portrait sculptures by many artists, and some more or less crude and archaic, of the men and women who from the very beginnings of the nation have been the makers of its history. In the decorations of the Congressional Library history and allegory
are so intimately mingled that it is hard to
draw the line between them. The wealth of
adornment runs the gamut of archaeology, his-
tory, mythology, allegory, poetry, music, the
drama and the arts, but in the statues and
bas-reliefs, medallions, mosaic work, etc., one finds a multitude of records in
art of the men and women who founded the
nation or guided it upon its destiny.

Revolutionary characters and episodes have
been most fruitful in recent years in inspira-
tion to the sculptors. This is owing to many
causes but not a little to the work of the patri-
otic societies, which have been unting in their
study of the period and zealous in efforts to
keep green the memory of American warriors
and statesmen. Numerous tablets commemo-
rating Revolutionary incidents have been dedi-
cated, some containing sculptural reliefs more
or less elaborate, and some statues of Revolu-
tionary characters are traceable to such influ-
ences, an example being the figure of Nathan
Hale, stop Boyfaret, at the Society of the
Monnies, in City Hall Park, New York, dedi-
cated in 1893, erected by the Society of Sons
of the Revolution in the State of New York.
This figure, which is superb as a work of art,
is scarcely so truthful a portrayal of Hale, how-
ever, as are the statues of him executed recently
by William Ordway Partridge and Bela L.
Pratt, which are the result of very careful
historical study. One of Mr. Partridge's Hale
figures stands in a park in Saint Paul, Minn.,
and is the gift of the local Nathan Hale Chap-
ter of the Daughters of the American Revolu-
tion. Another is in Washington, D. C. Mr.
Pratt's work is on the Yale campus at New
Haven, Conn., opposite the room Hale occupied
as a student at Yale, and was placed there in
1914.

On the Columbia University campus, New
York, is Partridge's statue of Hale's friend and
fellow officer in the Revolutionary army, Alex-
ander Hamilton, which was recently dedicated.
Within the same period, through the efforts of
the Sons of the Revolution and Daughters of
the American Revolution, one of Long Island's
Revolutionary heroes, Gen. Nathaniel Wood-
hull, president of the Provincial Congress of
New York in 1775, who was taken prisoner by
the British near Jamaica, L. I., because he would not say "God save the King,"
has received sculptural honors, including a fine
bronze tablet by Albert Weinert picturing the
incident of the attack upon him by the enemy.
A movement is in progress at this writing to
erect a statue and monument to the principal
hero of the battle of Long Island, Gen. Lord
Alexander Stirling. The deeds of his com-
mand, a militia regiment of Marylanders, are
commemorated by a monument in Prospect
Park, Brooklyn, but there is as yet no adequate
memorial to Stirling though it was largely be-
because of his gallantry in engagements of this
battle that the American army was saved from
complete destruction and Washington was en-
abled to give his masterly retreat afterward
to New York.

Lafayette, too, has been honored by the dedi-
cation of a monument to him at the Ninth
Street entrance to Prospect Park, Brooklyn, in
May 1917, on which occasion Louis B. R. P.
Rohrer, a hero of the battle of the Marne,
was the guest of honor. A citizen of Brooklyn,
the late Henry Marteau, left $35,000 for this
purpose and the commission for the execution
of the work was awarded to Daniel Chester
French, who completed the model on Lafayette's
birthday, 6 Sept. 1916. Many regard it as one
of the finest things that has come from Mr.
French's studio. The monument symbolizes
Franco-American unity, past, present and to
come. It embraces a number of features, the
central one of which is a bronze tablet upon
which in bold relief the sculptor has portrayed
Lafayette standing by his horse which is held
by an aide. Lafayette wears the uniform of a
general of the Continental Army. His drawn
sword is in his right hand and his left reposes
upon his hip. On each side are accessories
relating to the hero's career which round out the
composition as a whole.

To the Revolutionary period belong also
Mr. French's "The Minute Man," at Concord;
the group at Princeton, N. J., by MacMonnies,
commemorating the turning of the tide of the
Revolution by Frederic M. Olschers, the equestrian statue of Franklin, at Princeton; the equestrian
statue of Gen. Anthony Wayne at Valley Forge, Pa.,
by H. K. Bush-Brown, and H. K. Brown's
equestrian statue of Gen. Washington, in Wash-
ington, while to this and the period imme-
diately succeeding belong Miss Helen Farns-
worth Mears' portrait bust in Milwaukee of the
soldier and pioneer, Gen. George Rogers
Clark, a notable example of historical sculpt-
ure by an American woman and a gift of the
Society of Children of the Revolution.

The placing of tablets or other forms of
memorial marking the scenes of Revolutionary
incidents has occurred chiefly, of course, in the
vicinity of such battlegrounds and in some
cases restoration of the redoubts and fortifi-
cations where famous episodes of war trans-
pired has been attempted and tablets, often of
considerable artistic merit, have been erected.
A case worthy of mention is the restoration
of Fort Conderoga which has been done at
the Americans; C. A. Heber's portrait statue of
Franklin, at Princeton; the equestrian statue of Gen. Anthony Wayne at Valley Forge, Pa.,
by H. K. Bush-Brown, and H. K. Brown's
equestrian statue of Gen. Washington, in Wash-
ington, while to this and the period imme-
diately succeeding belong Miss Helen Farns-
worth Mears' portrait bust in Milwaukee of the
soldier and pioneer, Gen. George Rogers
Clark, a notable example of historical sculpt-
ure by an American woman and a gift of the
Society of Children of the Revolution.

AMERICAN SCULPTURE

at Baltimore, designed by Niehaus, and but recently finished. The Hudson-Fulton celebration in New York State in 1909 and the Champlain Tercentenary in New York State and Vermont in about the same period furnished occasion for some records in art of characters and events commemorated, including a monument to Champlain with sculpture by C. A. Heber.

The Mexican War provided the motives for comparatively few notable works of sculpture aside from statues of generals like Winfield Scott who belong also to other periods of history. Among works of recent date associated with the history of this war is a relief at the National Museum, Washington, by Isidore Konti, picturing the incident of Kit Carson, the scout, and Edward F. Beale, afterward a general, hailing Commodore Stockton's flagship at the conclusion of their adventurous trip through the desert and the Mexican lines to bring news of re-enforcements to the beleaguered garrison. It has also been pictured in a group by Augustus Lukeman and F. G. R. Roth showing the scout mounted and in picturesque pose and costume. It is at Trinidad, Col.

The Civil War has occasioned more historical and commemorativc art projects than any other event in the nation's history, not even excepting the Revolution. Some of these achievements are crude, or at least archaic, as viewed from the art standpoint, yet are the outcome of a national impulse in which patriotic sentiments were mingled with artistic ambition. And while there may be a degree of monotony in the long list of statues of heroes of that period, there are not a few which rise above the mediocre in conception and execution and form noble and enduring achievements,—landmarks by which the progress of the nation in its aesthetic development may be noted. This is particularly true of the equestrian statues, which are often instinct with life and action. The finest example, no doubt, is the statue of Gen. William Tecumseh Sherman by the late Augustus Saint Gaudens at the Fifth Avenue entrance to Central Park, New York, which many regard as the noblest product of his remarkable genius. On the other hand, while the portrait works, was perhaps most conspicuous as a military chieftain during the Mexican War, but he began his career with very gallant exploits in the War of 1812 which have been commemorated in art and survived to participate in the defense of the nation at the outbreak of the Civil War. He is represented by Miss F. E. Elwell, on the battlefield of Gettysburg.

Nor have the heroes of the Confederacy been forgotten, or the women who made sacrifices for the "Lost Cause," a group by Augustus Lukeman in honor of the "Women of the Confederacy," while Gen. John B. Gordon is commemorated in an equestrian statue at Atlanta by Solon H. Borglum. Jefferson Davis, President of the Confederacy, is portrayed by Edward Valentine in an emotional rôle, pleading for his cause, one hand outstretched in gesture and the other resting upon the open book of history. The figure is half encircled by a colonnade and may be seen at Richmond, Va. The bronze equestrian figure of Gen. J. E. B. Stuart, the Confederate cavalry leader, the work of Frederick Moynihan. The gallant military leader of the Confederacy, Gen. Robert E. Lee, became president, after laying down his arms, of Washington and Lee University at Lexington,
VA., and here he is memorialized in a meritorious recumbent statue by Valentine, while there is also on the field of Gettysburg a memorial of him, and at Richmond, VA., in the Capitol Square, there stands an equidistant statue surmounting a massive pedestal, the sculptor being Mercie. Lee's remains rest in a vault under the statue of him at Washington and Lee University.

Wendell Phillips, the great Abolitionist leader, is the subject of a recent work by French, forming a fine example of the art of this distinguished American sculptor, while one of the best known and justly famous of J. Q. A. Ward's achievements was his statue of the eloquent Abolitionist preacher, Henry Ward Beecher, in front of Brooklyn's Borough Hall. In another statue of Beecher in Brooklyn, placed not long since in the arcade between Plymouth Church and the Arbuckle Memorial Building, and the work of Gutzon Borglum, his character is further interpreted in an interesting way. It emphasizes his services as prophet-reformer and the slave girls at his side recall the scenes when he sold slaves in Plymouth Church at auction to obtain their freedom and was repeatedly arrested against slavery. The work represents him at the height of a splendid maturity, possessing both the vigor of youth and the dignity of middle age.

Nor should the sculpture signifying the services of the man who fought so forcefully with his pen for the cause of the Union, Horace Greeley, be forgotten. A seated figure in bronze was long in front of the office of his newspaper, the New York Tribune, and was recently removed a short distance away, while at Chappaqua, N. Y., where he had a farm, a fine standing figure by Partridge was not long since dedicated through the efforts of the Greeley Memorial Association.

The Spanish War gave us the Dewey Arch on Fifth Avenue, New York, with its emblazoned sculpture by many of the leading men in that branch of art in the United States, and though it was but a temporary achievement, it pointed the way to others more permanent. Later French and Andrew O'Connor collaborated in the strong figure at Indianapolis of General Custer, who fell in the battles in the Philippine Islands. After the assassination and death of President McKinley at the Pan-American Exposition in 1901 the nation was moved as by one impulse to do honor to his memory through some of the forms of art. There resulted the noble McKinley Monument at Buffalo, with its lions by A. Phimister Proctor at the four corners, the imposing mausoleum at Canton, Ohio, with its statue and accessory sculpture by MacNeil, the Columbus, Ohio, Memorial by H. A. MacNeil, and the four statues by MacNeil, in Philadelphia, by C. A. Lopez and Isidore Konti, and many others, while at Niles, Ohio, the birthplace of McKinley, there has just been erected (1917) a most unique patriotic shrine and museum, wherein McKinley relics may find a safe and available place of custody in an architectural and sculptural setting noble in conception and appropriate in details of execution. The architects of the memorial are McKim, Mead and White and the sculptor J. Massey Rhind. The piece is of Georgia marble and in the centre is a court of honor supported by 28 monolithic columns. In front of this court is a statue of the dead President, and the colonnade contains busts of members of his cabinet and others associated with his administration, while in the relic rooms, libraries, and auditoriums are works of art forming tribute to the heroism of those who participated in the Civil and Spanish-American wars. It is described as "not simply a monument, not simply a memorial building, but both and more."

Memorial buildings bearing the name of Lincoln are now in progress of creation or have recently been dedicated, and the sculpture in which his features are preserved is plentiful throughout the land, the works by Saint Gaudens, Gutzon Borglum, Niehaus and MacNeil being of special merit; and that by George Grey Barnard, having been a subject recently of much controversy, both highly praised and severely criticized.

In recent years the most important work of an historical nature, whether in painting or sculpture, has been done upon commission in the decoration of public buildings like some of those mentioned. Thus, instead of isolated works there result mural paintings in logical series, in panels or other architectural features of the edifice, or reliefs and tablets or sculpture in the round, all having an artistic and historical relation, often portraying episodes in the development of nation or commonwealth, like the work of Miss Violet Oakley and George Grey Barnard for the Pennsylvania State capitol. Often it is difficult to draw lines between work that is mainly decorative and that which is primarily historical. In general historical art has a decorative motive. This is especially true in the case of exposition sculpture, of which much that was worthy of preservation has been done. This applies to such achievements as Solon Borglum's picturesque figure of "The American Pioneer" for the recent Panama-Pacific Exposition at San Francisco; to Cyrus E. Dallin's splendid Indian types in sculpture, some originally executed for exposition adornment; to Albert Weinert's "Primitiv Man" and MacNeil's "Adventurous Bowman," at the San Francisco Exposition, and works there by Calder and Aitken, and others.

At several of the great expositions of the past there has been given in the decorative sculpture to the portrayal of the American Indian and such work has much historical value. H. K. Bush-Brown's superb model of the "Buffalo Hunt," representing an Indian on horseback attacking a buffalo, was accorded the place of honor at the Jamestown Exposition. Dallin, whose fame rests largely on his depiction of Indian subjects, has contributed much work of the kind to expositions and this has resulted in commissions for permanent groups like his "The Appeal to the Great Spirit" in Boston, and "The Signal of Peace," Chicago. Edwin Willard Deming is also a valuable contributor to such records of the Red Man, and though his art has been applied mainly in the direction of painting, it includes some interesting Indian sculpture. Some of the most striking of MacNeil's early successes were his "The Sun Vow," "The Last Act of the Moqui Snake Dance" and "Welcoming the White Man," a group for the city of Portland, Ore., commemorating the arrival of the white men of the Lewis and Clark expedition on the shores of the Pacific.
There are Indian figures also in Mr. MacNeil's reliefs for the Marquette Building, Chicago, showing scenes in the life of the hero-priest, Father Marquette. Frederic Remington's cowboy types are graphic portrayals of a picturesque vanishing, like that of the Indian, one of them being his "Cow Boy" in Philadelphia, while cowboys, Indians and pioneers have been the themes inspiring Solon Borglum's most original work, which is typical of the American. In all such art there is historical as well as decorative motive and the influence that flows from it is educational and patriotic, even though it is imparted without the conscious effort of the beholder and the artistic emotion seems to be the predominating one. See SCULPTURE IN THE UNITED STATES.

AMERICAN SHIPBUILDING. See SHIPBUILDING, AMERICAN.

AMERICAN SILKWORM. See SILKWORM.

AMERICAN SOCIAL SCIENCE ASSOCIATION. See SOCIAL SCIENCE ASSOCIATION, AMERICAN.

AMERICAN SOCIETY OF CIVIL ENGINEERS, an association organized 5 Nov. 1852, in the city of New York, its object being the professional improvement of its members, the encouragement of social intercourse among men of practical science, the advancement of engineering in its several branches, and of architecture, and the establishment of a central point of reference and union for its members. Among the means to be employed for attaining these ends are periodical meetings for the reading of professional papers and the discussion of scientific subjects, the foundation of a library, the collection of maps, drawings and models, and the publication of such parts of the proceedings as may be deemed expedient.

The early life of the society was a struggle for existence and it was not until 1867 that the organization had a permanent headquarters and began its work in earnest. The first publication was the address of President James P. Kirkwood, delivered 4 Dec. 1867, and printed in Vol. I of 'Transactions' bearing date of 1872. The first annual convention was held in New York 16 June 1869, 55 members being present. The second and third conventions were also held in New York, but the fourth was held in Chicago and the annual conventions are now held at widely separated points. In 1869 the membership of the society was 150; the membership in 1916 was about 8,000. The society has a splendid library of over 85,000 volumes, thoroughly classified and indexed and which is kept up to date by new additions. A monthly publication of Proceedings is issued in which are printed the professional papers in advance of their presentation at the monthly meetings. These papers with all the discussion to which they give rise, are subsequently printed in 'Transactions,' two and sometimes three volumes of which are issued annually. The society owns its house at 220 West 57th Street and has no debt.

The organization is in no sense a local one, and it has 15 local associations of its members, located in the larger cities of the United States. Its membership is made up of practitioners engaged in all branches of civil engineering, the broadest interpretation of that term being used. From the beginning, admission to its privileges has been dependent solely upon professional experience and personal character.

That the society is beneficial to the profession is evidenced by the eagerness with which membership in it is sought. The reasons for this are apparent, inasmuch as among its objects are to assist the young engineer professionally during the earlier years of his career, and, when he has proved himself worthy, to stamp him as one qualified to direct 'the great sources of power in nature for the use and convenience of man.' That its influence is far-reaching is shown by the fact that it has members in 51 of the 54 subdivisions of the United States, as well as in 46 foreign countries. This foreign membership constitutes 9½ per cent of the total list.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS, a professional organization composed of engineers principally in the department of generation, distribution and utilization of mechanical power and the processes of manufacture by mechanical processes. It is one of four organizations of engineers, national in its character and with a considerable foreign membership, also, which exists for the purpose of the reading and discussion and publication of papers on engineering subjects and for the advancement of the profession of engineering in any direction within its scope.

The society was formed in 1880 by a group of persons in and near New York city, who recognized that the existing societies of mining and civil engineers did not naturally and instinctively offer a scope for the developing strength of mechanical engineering in the United States. Its first meeting was held in New York city in the autumn of 1880. Since that two meetings have been held each year; the annual meeting in the city of New York and other meetings in various cities of the Union; meetings have been held in Providence, Philadelphia, Altoona, Buffalo, Pittsburgh, Cleveland, Minneapolis, New Orlean, Indianapolis, Nashville, Richmond, Saint Louis, Chicago, Washington and San Francisco. These meetings last three or four days and are always made the occasion of visits to such engineering enterprises in the city which is entertaining the society. Usually from 15 to 20 papers are read and discussed at each of these meetings and the papers with their discussions are issued to all members in the form of an annual volume, averaging a thousand pages and copiously illustrated. These volumes which are designated 'Transactions' are an accumulation of most valuable professional literature, results of tests and experiments, researches into new fields and are filled with recorded data of observation. The society was incorporated as a national organization under the laws of New York State in 1881 and has maintained its executive offices in New York city. For seven or eight years its headquarters were in office buildings in the business district, but in 1889 the movement was started of having its library of professional literature open in the evenings and for this purpose the society rented quarters in the Mott Memorial Library Building, Madi-
son Avenue near 27th Street. The success of the evening opening of its library warranted the step which was taken in 1890 of purchasing the property which had been altered by the New York Academy of Medicine for this purpose and which included not only a library space and equipment, but a convenient auditorium of small size for the holding of meetings. The society later became a participant in the provision of a wealthy engineer and donor whereby three of these national societies are accommodated in a special building designed specifically for the needs of organizations of this class at 29 West 39th Street.

In addition to the publication of an annual volume the society issues a monthly periodical called The Journal of the society, which contains current professional literature of a high order and full abstracts of similar material from foreign societies and journals. It also conducts a free public reference library of engineering. This library is particularly rich in the current contributions to other scientific and engineering societies both in English and in all languages and in periodical literature published through the journals of technical journalism, both at home and abroad. This class of literature is of special significance in lines in which professional men are engaged in the industrial departments of engineering. The library contains (1917) over 60,000 books and 10,000 pamphlets. It has also a valuable collection by bequest of antiquities in engineering and scientific matters, and obtains by exchange the scientific publications of the United States government and corresponds with the important technical societies of Europe and the continent. The cozy auditorium and the library exhibit much material in portraits, busts and memorials of engineering achievement. It is specially rich in drawings and other documents belonging to the work and history of Robert Fulton and early steam navigation.

The society has also discharged a valuable function by the service of professional committees on special subjects. These professional committees have mainly been concerned with the work of formulating the best procedure in various lines, with a view of having such procedure a species of standard whereby uniformity might be secured. Committees of the society have reported on uniform methods for conducting tests of boilers, on uniform methods of conducting tests of engines, on uniform standards in structural material, and have prosecuted research on the fire-resisting properties of material, advisable methods for conducting tests of strength, and similar problems. These reports are made by the best experts connected with the society, and while the society officially never adopts their recommendation by legislative action, these recommendations carry great weight by reason of their origin. The society is governed by a council, consisting of a president, six vice-presidents, nine managers, a secretary and a treasurer. A recent achievement in this field has been a code of accepted practice in design and operation of steam-boilers; and another has been a standardization of proportions of flanges for joints in pipe. It has been active in the movement to conserve the natural industrial resources of the country.

AMERICAN STATE GOVERNMENT—AMERICAN STREET RAILWAYS

AMERICAN STATE GOVERNMENT. See State Government, American.

AMERICAN STREET RAILWAYS. The idea of the street railway grew out of the steam railroad agitation when the first steam railroad was built in the United States in 1829. This idea rapidly materialized and the first street railway was built in New York city in 1832, the tracks being laid on the Bowery and Fourth Avenue from Prince Street to Harlem, the rail consisting of strips of flat-iron laid on granite blocks. This railway was put into operation in June 1833, the first cars running from Prince Street to Murray Hill. The cars resembled the stage coach then in use and were mounted on flanged wheels. This road being a financial failure, it was not until 1836 that the next street railway was built in Boston. After this time street railways were built in all large American cities and between 1860 and 1880 the horse railway had become an established institution. As cities grew and distances within their limits became longer there was a demand to propel the cars faster than horses could draw them. In some cases steam locomotives were used in the suburbs of large cities, but this was considered objectionable on account of the noise, dirt and danger.

Numerous systems of propulsion were proposed and large expenditures were made in tests and trials. The first practicable method found was that of drawing the cars by an endless wire cable and this method was first used in San Francisco in 1873 when the cable car system was in operation where it was well suited for roads with heavy traffic and steep grades. This system was used in nearly all the large cities during the next 15 years, but as the cost was over $100,000 a mile, only the largest cities could make it profitable. It was soon conceded, however, that the cable system was not the ideal one for moving cars as there were certain mechanical difficulties in its operation which were extremely burdensome, and experiments were continued with other systems between 1880 and 1890, mainly with electric motors. The names of Edison, Field and Thomson are identified with this work. The first electric line in the United States was an exhibit run by Van Depoele at the Chicago World's Exposition in 1892-93. In 1884 Henry in Kansas City, Mo., and Bentley and Knight in Cleveland, Ohio, constructed and operated electric lines. The first street railway to be entirely equipped with electric cars and successfully and continuously operated was a road 12 miles long in Richmond, Va., built in 1888 by Frank J. Sprague, called the "father" of the electric street railway. As soon as this road demonstrated that the electric motor could propel street cars reliably and economically, horse roads all over the United States were changed to electric roads, and many new roads and extensions were built into the suburbs of the great cities.

The electric railway, a distinctly American institution, was soon introduced all over the world. In the United States in 1912 there were 41,065 miles of electric railway track, covering an investment of $4,596,563,292, employing 282,461 persons and daily transporting about 33,250,000 people. Besides the 76,162 cars de-
voted to the transportation of passengers, there were 7,794 express and freight cars, mail cars, parlor cars, and even funeral cars on the street railways of American cities. Intermountain electric railways have been built in the outskirts of the large cities and between towns on a large scale and there are now very few towns of more than 5,000 inhabitants which are not connected with their neighbors by means of an electric railway. The total car mileage on in 1912 was 1,921,620,074, operated by 3,665,051 horsepower of which 471,307 horsepower was produced by water-power and the remainder most by steam. Of the total track mileage, 36,958 miles were operated by overhead trolley; 1,395 miles by third rail; 352 miles in New York city and Washington by conduit trolley; 65 miles by storage battery; 76 miles by steam; 58 miles by horses; and 56 miles by cable. Of the whole mileage, 40,532 were on the surface; 420 miles were elevated; and 113 miles were in subway and tunnel. The gross income for the years 1912 was $385,930,517; the operating expenses were $332,896,346; and the net income was $61,910,773.

In 1912 approximately 1,044 miles were added to the electric railway mileage of the United States, as compared with 946 in 1914. Of the total added in 1915, 596 miles represented new electric railway track built, and 448 miles modified steam mileage. According to the Electric Railway Journal the total electric railway mileage of the United States in 1916 was approximately 46,454 miles; and the electric railway companies operated 99,405 cars and locomotives. There were 1,027 companies operating the total mileage of 46,454, with 98,893 cars and 512 electric locomotives. Complete data of electric railway earnings are not currently available, the latest detailed and complete statistics being those of 1912 as furnished above.

Many problems in electricity have arisen in the development of the street railway, the latest of which is the question of the alternating current. It is readily seen that an alternating current system of electric traction which would permit the use of a high transmission line potential and avoid the transformation to direct current by means of the rotary converter would give an impetus to the electrical solution of transportation problems greater even than that which followed the introduction of the rotary converter. The direct current, because of its limitation as to voltage, is inadequate as a system for the distributing of power over a wide area. The alternating current system, permitting a change of potential by means of the simple and efficient static transformer, has already successfully met the requirements of transmission and distribution of electric power. The necessity of using direct current for the operation of cars has, however, greatly restricted its application to general railway service, involving, as it does, the introduction of the rotary converter with its auxiliary apparatus, increasing the cost both of installation and operation and reducing the commercial efficiency of the system as a whole.

However, the direct current was in use in 1916 on nearly all city lines and on a large proportion of the interurban lines. The city lines are operated at 500 or 600 volts and the suburban lines at 1,200 to 1,500 volts. It is claimed for the alternating current system that it saves 20 per cent in power required. The cars, however, are more expensive and this tends to offset the cheaper equipment required in alternating sub-stations.

Catenary line construction is intended for high tension trolley roads, operated at potentials up to 6,000 volts or more. It is especially designed for use in conjunction with single phase alternating current railway equipment and marks one step further in the movement to secure a greater degree of economy and efficiency in the operation of electric trolley lines. The employment of high tension currents for traction purposes necessitates the use of an improved trolley equipment possessing an efficiency and a reliability of a high order.

The speed attained upon interurban lines makes it difficult to obtain satisfactory service with a trolley wire which dips between supports and sags and sways with every impulse. Increased precautions against accidents and faulty construction are also necessary because of the increased liability of damage from any diversion of the line current from its proper channel. Study of the traffic reports of interurban roads has shown that the passenger traffic to be expected on street railways in the United States ranges from 70 rides (fares) per capita per year in cities of 15,000 population, to 240 fares per capita in cities of 1,000,000 population. The intermediate figures are: 120 fares per capita in cities of 50,000 population; 150 fares to each of 100,000 population; 180 fares to each of 200,000 population; 210 fares to each of 300,000 population; 220 to each of 500,000 population.

In late years there has been a rapidly increasing demand for a controlling system applicable to trains of motor cars as well as to cars operated singly. This demand has been met by the development of the unit switch system of multiple control, which consists of a skillful combination of electro-magnetic and pneumatic devices, each applied to those operations in which experience has shown it to be most effective. The construction is noticeable for the liberal design of its working parts and contacts and the great simplicity available for their operation; while the general design and simplicity of operation insures great reliability of service and low cost of maintenance.

See Street Railways.

For extended discussion of technical and operating problems, consult Bureau of the Census Bulletin 124; Austin's Single Phase Electric Railways (1915); Harding's 'Electric Railway Engineering' (1916); Norris's 'Electric Railways' (1913); Smith's 'Electric Traction' (1905).
equipment and timber and other lands owned in fee or through ownership of the entire capital stock of constituent companies, are valued at $47,246,442. The total assets of the company on 31 Dec. 1916 aggregated $129,979,775; the capital stock on the same date consisted of $45,000,000 preferred and $45,000,000 common. In 1916, the profits of the company, on an income of $9,756,370, the interest on loans and deposits $792,990, the income from investments reached $2,905,737, and the total dividends declared during the year amounted to $6,299,972.

**American Sunday-School Union**, a religious association having for its object the organization and support of Sunday-sCHOOLS in needy neighborhoods, or those where religious sentiment is too divided to sustain denominational ones; the publication and circulation of moral and religious publications and the dissemination of useful information. It is not a union of churches but of Christians of various denominations, requiring no common creed but a belief in the essential truths of Christianity held in common by all evangelical denominations and a desire to save souls and teach the truths that Christ taught as plainly as He taught them. The members of the society are either deacons or laymen of every citizen of the United States who contributes $3 annually and is approved by the board being eligible, but its affairs are directed by a board of officers and 36 managers, all of whom must be laymen. The managers are elected by the members and the former annually elect the officers. There are also four standing committees appointed by the board, namely, publication, missions, finance and executive. During 90 years of work it has had, for presidents—Alexander Henry, John McLean, John A. Brown, Robert L. Kennedy, William Strong and Morris K. Jesup and the present president, Martin L. Finckel. Its headquarters are at Philadelphia, where it first came into being. Its germ was the First-Day School Union, founded in 1817, whose managers petitioned for free schools in Pennsylvania; this led to the formation of the Philadelphia Sunday and Adult School Union in 1817 which later united with similar societies and changed its name to the present title in 1824. The second year of its existence the Union printed an average of 90,000 pages per day besides periodicals and over 600,000 Scripture tickets; since then its progress in every field of endeavor has been very rapid. It introduced the first selected, uniform lessons—for which graded instruction was later provided—and the system known as «Union Questions.» It trained innumerable teachers and maintained missionaries to organize schools throughout the West and South, particularly in the Mississippi Valley, and later in foreign lands. To supply literature with which to seed the minds of the nuclei of thousands of churches, it created the first juvenile literature of a moral and religious type; stimulating the use of music in Sunday schools; organized a $12,000 American Missionary campaign; founded the first weekly Sunday School Teacher; organized the first National Sunday School Convention in America; issued the first $10 libraries of 100 volumes for Sunday schools and distributed millions of dollars worth of literature including Bibles and Testaments. In the last 25 years (1890-1915) the society has organized 25,000 new schools, has 169,016 teachers and 1,503,975 pupils besides reorganizing or reviving 9,000 other schools. Its missionaries have increased forty-fold. By 1897 all debts had been paid and the society placed on a firm financial basis. Its income-bearing funds and property now amount to about $2,000,000. It spends $225,000 annually in missionary work. Publications are furnished at cost but several thousand dollars worth of free literature is annually distributed in homes, hospitals, reformatories, etc. Consult 'Encyclopaedia of Sunday Schools' (New York 1915).

**American Sycamore.** See **Plan.**

**American Tract Society**, The. This society was organized in New York city on 11 May 1825. Its work is interdenominational and international in scope, and is commenced by all evangelical denominations. The design of its founders was to establish a central society for the whole Union, inviting the co-operation of Christians of all the Protestant churches, and of other tract associations as auxiliaries, in publishing and circulating whatever tends to diffuse a knowledge of Christ as the Redeemer and promote the interests of true religion and sound morality. The society has published the Gospel message in 178 languages, dialects and characters. It has carried on a useful work among the foreign-speaking people in the United States, and its missionary colporteurs are distributing Christian literature in 33 languages among the immigrants, and making a house-to-house visitation among the spiritually destitute, both in the cities and rural districts, leaving all kinds of Christian literature in the home. During the past 75 years the society's colporteurs have made 18,612,843 family visits, in the course of which they have distributed 17,382,454 volumes. The total number of distinct publications, annuals, periodicals, that have been issued from the society's home office is 9,136. The grand total of its publications, including tracts, books and periodicals, issued from the home office during the past 91 years, is 14,69,700 copies. In Spanish and Portuguese the society has issued 14,748,588 copies of volumes, tracts and periodicals, including 126,000 Spanish hymnals. For Latin-America 14,748,588 copies of volumes, tracts and periodicals have been issued, amounting in value to $633,545. For publishing Christian literature in foreign lands the society has forwarded cash appropriations to the amount of $799,456.39, and has granted electrolytes to the value of $61,177.96, making a total expenditure of $860,634.35, by means of which many million copies of tracts and tracts and periodicals have been published at mission stations abroad. During 1915 the society gave away Christian literature to the value of $16,684.91. The grand total value of its gratuitous distribution is $2,634,305.89, which is the equivalent of 5,269,010,000 tracts pages. Grasped the first group of missionaries, army and navy chaplains, pastors and Christian workers of every description. The society publishes four periodicals, *The American Messenger*, an illustrated religious...
monthly; *The Amerikanischer Botschafter*, a German paper for the home; *Apples of Gold*, an illustrated weekly for the Sunday school, and *Manzanas de Oro*, an illustrated Spanish weekly for the Spanish-speaking Sunday schools.

**AMERICAN UNIVERSITY.** The. A postgraduate institution, located at Washing- ton, D. C., incorporated under the government of the District of Columbia in 1891, and later with enlarged charter from Congress of the United States; founder and first chancellor, Bishop John Fletcher Hurst; opened in 1914 by President Woodrow Wilson; campus of 93 acres at intersection of Massachusetts and Nebraska avenues. Total assets, $3,000,000. Library of 25,000 volumes. Awarded its first fellowship in 1915 and conferred its first degrees in 1916. Conducts courses leading to the master's and doctor's degrees, gives fellowships for research at other institutions and presents university extension lectures to the public.

**AMERICAN WAR COMMISSION TO RUSSIA.** On 1 May 1917 it was announced that Elihu Root had been appointed head of the war commission from the United States to Russia, and a fortnight later the commission left Washington, carrying greetings to the new democratic government of Russia and authorized to pledge aid from the United States, not only in the prosecution of the war against the Central Powers, but also in the rehabilitation of Russia. With Mr. Root were: John R. Mott, S. Reading Bertron, Cyrus H. McCormick, James Duncan and Charles Edward Russell, envoy extraordinary; Maj.-Gen. Hugh L. Scott, chief of staff of the army, military representative of the President; Rear-Admiral James H. Glennon, naval representative of the President; Col. R. E. L. Michie, aide to the chief of staff; Col. William V. Judson, military attaché to the diplomatic mission; Lieut.-Col. T. Bentsy Mott, military aide to the ambassador extraordinary, Harry; Surgeon Holton C. Orgel, United States Navy; Lieut. Alva D. Barnhard, United States Navy, aide to Admiral Glennon; James McKenna, disbursing officer of the mission, and a number of clerks, etc. The commissioners traveled to the Pacific coast, and then boarded a fast warship for the voyage. On 13 June the commission arrived in Petrograd, where it was greeted by a large delegation of Russians and Americans. The American ambassador, David R. Francis, issued a statement explaining the aims of the mission, which have been given above. On 15 June Mr. Root, addressing the Council of Ministers, expressed the desire of the people of the United States to defend and preserve democracy. M. Teren'chuk of Foreign Affairs, responding in behalf of the council, expressed the cordial attitude of the Russian government toward the United States, and said that the Russian people considered the war inevitable and would continue to do their part. On 23 June, in Moscow, addressed six important organizations; and in company with the Foreign Min- ister he subsequently visited staff headquarters at Mohilev, where he was welcomed by the commander-in-chief, General Brusiloff. Major-General Scott and aides, escorted by officers of the Russian staff, visited Kiev and the south- western front. The members of the commission in general received favorable impressions of the new Russia; their association with Russian purposes and their authoritative promises of co-operation proved to be of great service in nullifying the effects of German intrigue; and their diplomatic efforts received valuable support from the activities of the American Railroad Commission, which entered Vladivostok about the beginning of June, to assure and to provide indispensable aid to Rus- sia in the construction of railways and the supply of materials. Preparations to fulfill such engagements on a vast scale were already far advanced in the United States, when the commission made its report and its appeals for public approval of the new Russia at Washing- ton and New York in August. The commis- sion's leader then said: "We took to the Russians a message of faith and democracy. We return to repeat it."

**AMERICAN WATER-COLOR SOCIETY.** See WATER-COLOR SOCIETY, AMERICAN.

**AMERICAN WHIGS.** See WHIGS.

**AMERICAN WOOD-PRESERVERS' ASSOCIATION.** Organized at the World's Fair at Saint Louis in October 1904. Incorporated in Illinois on 7 March 1911, as the Wood-Preservers' Association. Title changed 6 March 1912 to the American Wood-Preservers' Asso- ciation. The objects of the association are to promote the knowledge of the materials, methods and principles involved in the economic design, location, construction, maintenance and operation of wood-preserving works; the standardization of specifications for wood preservative for and for the introduction into the material to be preserved and the maintenance of high standards of business ethics in the wood-preserving industry. The association holds meetings annually for the presentation and discussion of reports of the experiences and investigations of its members and others, and publishes its "Annual Proceedings" and a quarterly magazine, *Wood-Preserving*. The membership, numbering 287 on 1 June 1916, consists of corporate, associate, probate and honorary members. The association has paid from the initiation fees and dues of members, and the management is in the hands of the ex- ecutive committee, which comprises the president, two vice-presidents, secretary-treasurer and seven other members. On 1 Jan. 1916 there were 102 plants in this country preserving wood with creosote, zinc chloride and other chemicals for the purpose of protecting it against decay and thereby aiding in the con- servation of our forest resources.

**AMERICA'S CUP.** See YACHTS AND YACHTING.

**AMERICUS, Ga., town and county-seat of Summer County, on the Georgia & A. and Cen- tral of Ga. railroads, about 75 miles southwest of Macon. It was settled in 1832, and is gov- erned under a charter granted in 1889. There is a mayor and council of six. It is the busi- ness centre for a large cane and cotton region and has also several manufacturing industries. Pop. (1910) 8,063.

**AMERIGHI, a'mā-rē'gěi** Michelangelo. See CARAVAGGIO.
AMERIGO VESPUCCI, á'má-ré'gô vés-poo'chê. See Vespucci.

AMERIND, a word suggested by Maj. J. W. Powell to describe the American Indians as distinguished from other Indians.

AMERLING, á'mér-ling, Friedrich, Austrian painter: b. Vienna 1803; d. there in 1887. He studied painting in Vienna, and also in London, Paris and Munich, and spent some years in Italy. Upon his return to Austria he was selected to paint a portrait of the Emperor Franz I, and from that time ranked as the most prominent portrait painter of that country. His portraits number about 1,000, and are distinguished by brilliant coloring, but sometimes fail of definiteness of characterization. Consult Bodenstein, ‘Hundert Jahre Kunstgeschichte Wiens’ (1888); and Frankl, ‘Life’ (1899).

AMERSFOORT, á'mér-fört, Holland, town in the province of Utrecht, and 12 miles northeast of the town of Utrecht. By the Eem, on which it stands, it has a navigable communication with the Zuyder Zee. It manufactures woolen goods, tobacco, glass and silk-yarn, and carries on an extensive trade in grain. The Roman Catholic church of Saint Mary, built in the 11th century, has a Gothic tower 308 feet high, considered to be one of the finest in Europe. There is a college of the Jansenists in the city, it being one of the chief centres of this sect, which does not now exist outside of Holland. The Grand Pensionary of Holland, Jan van Oldenbarnevelt, commonly called Barneveldt, was born here. Pop. 24,000.

AMERY, Leopold Charles Maurice Stennett, English journalist and politician: b. Gorakhpore, India, 22 Nov. 1873. Educated at Harrow and Balliol College, Oxford, he secured several ‘Firsts’ and the Ousley scholarship in Turkish, as well as a fellowship for history at All Souls' College, Oxford. In 1896-97 he was private secretary to Mr. Leonard (now Lord) Courtney, and in the latter year set out on an extensive tour through southeastern Europe, contributing articles to English newspapers, which led to his joining the editorial staff of The Times in London. He went to South America shortly before the Boer war broke out, met President Kruger and the Boer leaders, and actually received permission from General Joubert to accompany the Boer army. Mr. Amery spent the first week of the war in the Boer camp at Sandspuit, when he was informed that his life was not safe. He proceeded to Cape Town and organized the staff of war correspondents of The Times—some 20 men attached to the various British columns. On his return he undertook the editorship of The Times' 'History of the War in South Africa' (7 vols., London 1900-09), meanwhile writing regularly on military, economic and imperial questions in the columns of that paper. His book, 'The Problem of the Army' (1902) was largely responsible for the subsequent reorganization of the War Office. He became a barrister in 1902, but never practised. In 1903 he followed Chamberlain in the great tariff reform struggle, in which he opposed Britain's Free Trade policy in the press and on the platform; his 'Fundamental Fallacies of Free Trade' (1906) being regarded as one of the best contributions to the controversy. After four unsuccessful attempts to enter Parliament—in 1906, 1908, January 1910 and December 1910—he was returned unopposed for South Birmingham as a Unionist in 1911. Though short of stature and slim in build, he delights in neck-breaking adventures, having climbed in the Alps, the Himalayas, and the Drakensberg Mountains. He traversed the Fraser River for 300 miles in a boat (1909) and in 1910 accompanied the late Lord Grey, then governor-general of Canada, on a 400 miles' canoe expedition. Shortly after the outbreak of the European War Amery received a commission with the rank of captain and attached to the staff in France as interpreter. In 1915 he was sent on a special mission to the Balkans, appointed general-staff officer in 1916, and assistant secretary to the War Cabinet in 1917. Mrs. Amery is a Canadian lady, sister of Lieut.-Col. Sir Hamar Greenwood, Member of Parliament.

AMES, Adelbert, American soldier: b. Rockland, Me., 31 Oct. 1835. Graduating at West Point in 1861 he was assigned to the artillery and served through the Civil War with distinction; was wounded and brevetted for gallantry there; took part in nearly all the battles of the Peninsula campaign, in Fredericksburg, Chancellorsville, Antietam, Gettysburg and before Petersburg; was brevetted colonel, was brevetted major-general of volunteers for conduct at the capture of Fort Fisher and major-general in the regular army for general conduct in the war. From 1868 to 1876 he was in the thick of the "carpet-bag" troubles; upheld by United States troops, the negro vote and recent immigrants, and bitterly fought by the mass of the white inhabitants. Mississippi was among the last of the revolted States to accept Reconstruction or the War Amendments as fixed facts and the preponderant negro population made the race problem more acute there than anywhere else in the South. The elements at Ames' disposal were unfit to base even a decent civilized structure upon, and the State soon went into anarchy tempered by local vigilance committees. In 1873 he was elected governor of Mississippi. His governorship was charged with sacrificing the civilized interests of the State to the blacks, and on 7 December there was a sanguinary race riot at Vicksburg, followed by others throughout the State. Ames sent to Washington for more troops to maintain order, the white party countered with fresh charges, a congressional investigating committee was appointed, and for two years the State had—like several Southern States through this period—a formal government perfectly powerless, and a real government consisting of the rough consensus of interest among the larger white landowners. The legislature which met in January 1874 impeached Ames and all his executive officers; the State administration was paralyzed; the national administration was not able to secure any possible local governments; and Ames finally agreed to resign if the impeachment were withdrawn. He at once removed to New York; later to Lowell, Mass. In the Spanish-American War he was a brigadier-general of volunteers.
AMES, Charles Gordon, American Unitarian clergyman, editor and lecturer: b. Dorchester, Mass., 18 Apr. 1912. He was graduated at the Geauga Seminary, Ohio, and ordained in 1849 as a Free Baptist, but later became a Unitarian and succeeded James Freeman Clarke as pastor of the Church of the Disciples, Boston. He was editor of the Minnesota Republican, the first Republican paper in the Northwest, in 1854, and the Christian Register of Boston, 1877-80. He wrote 'George Eliot's Two Marriages' (1866); 'As Natural as Life' (1894); 'Poems' (1898); 'Sermons of Sunrise' (1901); 'Five Points of Faith' (1903); etc. He was always deeply interested in social and philanthropic questions.

AMES, Edward Raymond, American clergyman: b. near Amesville, Adams county, Ohio, 20 May 1805; d. Baltimore, Md., 25 April 1879. He was educated at Ohio University, Athens, Ohio, but left at the end of his junior year and became the first principal of Lebanon Seminary, afterward McKendree College. In 1830 he joined the Illinois Conference of the Methodist Episcopal Church; 1840-44 he was one of the three corresponding secretaries of the missionary society. In 1852 he was elected a bishop. During the Civil War he, with Bishop Simpson, often aided President Lincoln by their counsel. The War Department gave into his care many uncounchoned children of the M. E. Church South. This was done as a war measure.

AMES, Fisher, American orator and statesman: b. Dedham, Mass., 9 April 1758; d. there, 4 July 1808. His father died when he was six. A precocious scholar, he was graduated from Harvard at 16; taught school some years to support his impoverished family, cultivating himself by wide reading and profound study of the classics and the Scriptures; studied law, and began practice in Dedham in 1781. He made a reputation as *Brutus* and *Camillus* in the Boston papers, was sent to the legislature in 1783, won laurels, and was elected to the convention to ratify the Federal Constitution. His speech there on biennial elections gave him fresh repute as one of our foremost orators. In December he was elected (Federalist) Representative to Congress, and re-elected through Washington's administration to 1797; he was chosen to pronounce the congressional address to Washington on his retirement; and on 28 April 1796 delivered his masterpiece of eloquence and effectiveness, on the appropriation to carry Jay's treaty of 1794 into effect — so impressive that the other party protested against taking a vote until after an adjournment, because the House was too excited to decide rationally. Retiring from public life on account of feeble health, he spent his later years mainly on his Dedham farm, though writing papers in 1798 to urge the Federalists to resist French aggressions, which was pouring oil on a conflagration (see Adams, John; Alien and Sedition Laws, and the names of the various political parties of the time) serving for a time on the State council, and delivering an eulogy on Washington before the legislature. He declined the presidency of Harvard in 1804. He was an orator by inspiration, studying his subject and taking notes to expand on the moment, and full of flashing egos and pregnant laconics. A large public school in Dedham Centre commemorates his name. Consult 'Works and Life' (1 vol., 1809: 2 vols., 1854, by his son Seth); selected speeches, 1 vol., 1871, by his grandson.

AMES, Sir Herbert Brown, Canadian legislator: b. Montreal, 23 June 1863, of American parents. He was graduated B.A. at Amherst College, Massachusetts, in 1885. An alderman of Montreal 1886-1900, and chairman of the municipal board of health 1900-04, he has represented the Saint Antoine division of Montreal in the House of Commons in the Conservative interest since 1904, and since 1911 has been chairman of the House's standing committee on banking and commerce. He is honorary secretary of the Canadian Patriotic Fund and was knighted in 1915. He is a close student of economic and social conditions, and is the author of 'The Machine in Honest Hands' (1894); 'The City Below the Hill' (1897); 'The City Problem' (1901), etc.

AMES, Joseph, painter: b. Roxbury, N. H., 1816; d. New York, 30 Oct. 1872. Though wholly self-taught he early began portrait-painting, opened a studio in Boston, and had success enough to obtain means to go to Rome and study. While there he painted a fine portrait of Pius IX. He was elected member of the National Academy of Design, 1870, and soon had more orders than he could fill. Some of his best known portraits are those of Ristori, Prescott, Emerson, Rachel and President Kelton of Harvard. 'Maud Muller' and 'The Death of Webster' are his best known ideal paintings.

AMES, Joseph Sweetman, American physicist: b. Manchester, Vt., 3 July 1864. He was graduated at Johns Hopkins University in 1886 and is professor of physics there. He is author of 'Theory of Physics' (1897); 'Manual of Experiments in Physics' (1898); 'Free Expansion of Gases' (1898); 'Induction of Electric Currents' (2 vols., 1900); editor 'Scientific Memoir Series,' 'Fraunhofer's Papers'; assistant editor *Astro-Physical Journal*; *American Journal of Science*.

AMES, Nathan P., American manufacturer: b. 1803; d. 23 April 1847. In 1820 he established cutlery works at Chicopee Falls, Mass., which attained a national reputation, their swords especially being largely bought by the United States. In 1834 he removed the works to Cabotville (Chicopee), where he lived and died; and incorporated with others the Ames Manufacturing Company, which in 1836 added a bell and bronze cannon foundry that had equal fame and furnished the larger part of the government's brass cannon in the Civil War, as well as the bronze statues of De Witt Clinton in Greenwood Cemetery, Brooklyn, N. Y., of George Washington in Union Square, New York, and of Benjamin Franklin in School Street, Boston. The works supplied the British government just before the Crimean War with machines for making muskets.

AMES, Oakes, American manufacturer and promoter: b. Easton, Mass., 10 Jan. 1804; d. 8 May 1873. The son of a blacksmith who had become a manufacturer of highly reputed picks and shovels, he trained himself in his father's
works, and with his brother joined the firm as Oliver Ames & Sons. The opening up of California in 1848 and Australia in 1851 by the gold discoveries created an immense demand for their goods in mining, settlement and railroad building, which raised his firm to a national rank in business and wealth; and in the Civil War they had great contracts for shovels, swords, etc. Mr. Ames was in the Massachusetts executive council 1861, and Congressman 1862 till death. In 1864 the failure of attempts to carry through the nationally exigent Pacific Railroad led President Lincoln's government to call on Mr. Ames to undertake it. He risked financial ruin if it failed, investing $1,000,000 and making his whole fortune responsible for the rest; it could not be expected that he should forego a corresponding profit if it succeeded. The work was finally accomplished by organizing a construction company (see Credit Mobilier of America), which paid itself largely in stock and bonds of the Union Pacific, practically buying the two companies one, and enabling the former to charge the latter its own prices for work and supplies, the government paying the bills. Credit Mobilier stock became enormously valuable, and the directors were charged with cheating the government and using the stock to buy congressional support for the fraud. Mr. Ames' anomalous position as Congressman, director in both companies, contractor for immense supplies to the railroad, and the ablest manager of the whole enterprise, caused the chief fury of the assault to fall on him; and in the tremendous public scandal and investigation which followed he was censured by the 42d Congress and died shortly after. His son Oliver (q.v.), however, induced the Massachusetts legislature to re-examine the case, and on 10 May 1883 (the 14th anniversary of the completion of the railroad) it passed a resolution exonerating Mr. Ames. The Union Pacific Railroad erected a monument to his memory at Sherman, Wyo., the crest of the road, 8,830 feet above the sea.

AMES, Oliver, American manufacturer, brother of Oakes above: b. Plymouth, Mass., 5 Nov. 1807; d. 9 March 1877. His brother's partner, he was a sharer in all his business enterprises; president pro tempore of the Union Pacific Railroad 1866-68, formal president 1868-71; a director in the Credit Mobilier. After his brother's death he became head of the manufacturing firm. He was a member of the State senate, 1852 and 1857.

AMES, Oliver, American manufacturer, son of Oakes above: b. North Easton, Mass., 1831; d. 1895. He was trained in his father's works, and as his heir spent several years in paying off the obligations of millions of dollars incurred by the Union Pacific Railroad and other undertakings. Entering public life avowedly to vindicate his father's memory, he was lieutenant-governor of Massachusetts 1882-86; in 1883 obtained the vindicatory resolution he sought; and 1886-88 was governor.

AMES, Samuel, American jurist: b. Providence, R. I., 6 Sept. 1806; d. there, 20 Dec. 1865. Was graduated at Brown, 1823; studied law with Judge Gould at Litchfield, Conn. He served in the state assembly, being speaker 1844-45. He was elected chief justice of the State Supreme Court 1856, but resigned in 1865 on account of ill-health. In 1839 he married Mary Throop Dorr, daughter of Thomas W. Dorr, leader of the rebellion in 1842. Author and editor of "Angell and Ames on Corporations," and Vols. IV-VII of the "Rhode Island Reports."

AMES, Iowa, city of Story County, on the Chicago & N. W. Railway, and on the Lincoln Highway, 38 miles north of Des Moines. Settled in 1864 and named after Oakes Ames, one of the railway pioneers of the region, it was incorporated in 1869. The city maintains electric lighting plant and water works, a Carnegie library, and has manufactures of pennants and banners. Its chief claim to distinction is the munificently equipped Iowa State College of Agriculture and Mechanic Arts. Pop. 5,500.

AMESBURY, Mass., town in Essex County, situated on the Merrimac River and on the Boston & Maine Railroad, 27 miles north of Salem. It has manufactorys of automobiles and automobile fittings, carriages, motor boats, boots and shoes, hardware, etc. The United States census of 1914 showed 59 establishments, of factory grade, employing 1,628, of whom 1,451 were wage earners receiving annually $1,009,000 in wages. The capital employed totalled $2,604,000, and the value of the output was $3,554,000; of this, $1,746,000 was added by manufacture. The town was originally a part of Salisbury, but was set off in 1654 as New Salisbury. It was incorporated in 1666, and a year later received its present name. Amesbury was long the home of the poet Whittier, who died here in 1892. Pop. 9,894.

AMETABOLA, those insects in which development is direct, there being no metamorphosis.

AMETHYST (from the Greek amethystos, "not intoxicated"). In mineralogy (1) a violet or purple variety of crystallized quartz, the color being probably due to traces of manganese or iron. It is esteemed as a gem, and was worn by the Greeks in the belief that it lessened the intoxicating effects of alcoholic drinks upon its possessor. It is widely distributed, but specimens pure enough in color to be used as gems are not common. The purple amethysts come from Brazil, India, Siberia, Pennsylvania and North Carolina. (2) The precious (or Oriental) amethyst is a crystalline oxide of aluminium, violet in color from the presence of traces of some other metallic oxide, and very brilliant and beautiful. Mineralogically the Oriental amethyst is a variety of corundum (q.v.).

AMHARA, äm-härä, a district of Abyssinia, lying between the Taccázé and the Blue Nile, but of which the limits are not well defined. The Amharic language, next to the Arabic the most widely used of all the Semitic languages, has gradually gained ground in southern and central Abyssinia, and has become the court language. It has a literature of its own, including a version of the Scriptures.

AMHERST, Jeffery, Baron, British soldier remembered for his American services: b. Kent, England, 29 Jan. 1717; d. 3 Aug. 1797. He was a duke's page in England, a captain in the Rhode Island State assembly, being speaker 1844-45. He was elected chief justice of the State Supreme Court
trian Succession, 1741–48, and was at Dettingen (1743), Fontenoy (1745) and Roncoux (1746); in the Seven Years' War beginning 1756 he was at the French victory of Hastenbeck, 1757. He had become noted as a brilliant soldier and ranked as lieutenant-colonel. In 1758 Pitt selected him to co-operate with Prideaux in conqueriing Canada from the French, made him major-general, and gave him command of the expedition against Louisburg, which he speedily reduced, 27 July. In the following September he superseded Abercromby as commander-in-chief of the English forces in America and captured Crown Point and Ticonderoga the following year. On 8 Sept. 1760 he captured Montreal and ended the French domination in Canada. For this he was made governor-general of the British possessions in America, thanked by Parliament, and made a Knight of the Bath. But in face of Pontiac's conspiracy (1762) he failed, as other English commanders had so often before, from insisting on conducting Indian like European warfare, and despising the American Indian and American experience. American trivialities as Pontiac's war were unknown or unregarded in England, Amherst on his return in 1763 was received with immense enthusiasm as the conqueror of Canada; and as he was the heir of George III, and actively supported the policy of coercing the colonies through the years before the Revolution, his honors did not cease. He was titular governor of Virginia 1763–68, without going there, governor of Georgia from 1771, of Nova Scotia from 1772 to 1777, of New York 1772–82 and of Virginia 1783–93, commander-in-chief of the British army, and was made a field marshal on resigning his command. In 1776 he was raised to the peerage. In 1780 he took an active and most humane part in suppressing the London "no popery" riots.

AMHERST, Burma, a town and district in the Tenasserim division, about 30 miles south of Moulmein. It was founded by the British in 1826, and named after the governor-general of India of that day; but in 1827 the headquarters were transferred to Moulmein. Amherst has been eclipsed by the latter city, as now is merely a bathing-place for Moulmein. The district forms a narrow strip of land between the Indian Ocean and the mountains which separate it from the independent kingdom of Siam. It has an area of 7,062 square miles and a population of about 300,000; it consists partly of fertile valleys and partly of a rich alluvial tract. The highways of the Salween and the Gyaing rivers bring down inexhaustible supplies of rice to Moulmein, the chief town of the district. There is a heavy rainfall approaching 150 inches in the year, but the temperature is uniform (at about 80° F.) throughout the year.

AMHERST, Canada, port of entry and capi
tal of Cumberland County, Nova Scotia, situat
ed on the arm of Cumberland Bay, an exten
dion of Chignecto Bay, the extreme northeast
ern arm of the Bay of Fundy; on the Inter
colonial Railway, 138 miles north by west of Halifax, Nova Scotia, and about midway be
tween that city and Saint John, New Bruns
cwick. It has a hospital and law courts, a college, and is the railway terminus of the northward line of the Canadian National Railways. Amherst is the centre of a rich agricultural and lumbering district; has factories, ironfoundries, tanneries and ship-building establish
lments; and has an especially large trade in lumber and ship-building. Some of the richest coal mines in the province are near here, and grindstones and gypsum are quarried in the vicinity. Pop. (1911), 8,973.

AMHERST, Mass., a town in Hampshire County, on the Boston & Maine and the Central Vermont railroads, 23 m. N.W. of Springfield. It has manufactories of paper, straw and palm-leaf hats and leather, and is best known as the seat of Amherst College (q.v.), the State Agricultural College and the State Experiment Station. Pop. (1916), 5,300.

AMHERST COLLEGE, one of the best known institutions of learning in the United States, is situated in Amherst, Hampshire County, Mass. The cornerstone of the present South College, the first of the college buildings, was laid on 9 Aug. 1820, and upon this occasion an address was delivered by Noah Webster. Exercises of dedication and inauguration were held on 18 Sept. 1821, and on the following day, with a president, two professors and 47 students, the work of the college was begun. The first president was the Rev. Zopheriah Swift Miller, and he resigned the presidency of Williams College in order to come to Amherst, and who brought with him 15 students from Williamstown. After two adverse votes in the legislature the college finally secured a charter from the Commonwealth, the date of its approval being 21 Feb. 1825. A number of students in the intervening classes, being compelled to graduate without a degree, received their degrees from Union College, on suitable certificates from Amherst. Of the charter just mentioned a few words are all that the present sketch permits, or that are pertinent to present conditions. As to the board of trustees, it provided, that the number of members (including the president of said college for the time being, who shall ex officio be one of said corporation) shall never be greater than seventeen; and as to keeping that number good, it was in the same section provided, further, that as vacancies shall occur in said board, they shall be so filled that the board shall as soon as may be, and forever after, consist of seven clergymen and ten laymen. The first five vacancies that occurred in the board were filled by vote of the legislature; but when, 50 years after the founding of the college, the number of alumni had become sufficient to warrant it, the alumni were empowered to choose five members of the board, electing one each year as their terms of service expired. Regarding instructors and students, it was enacted, that no instructor in said college shall ever be required by the trustees to profess any particular religious opinions as a test of office; and no student shall be refused admission or denied any of the privileges, honors or degrees of said college on account of the religious opinions he may entertain. An act approved 4 Feb. 1916, that part of the act of 1825 which required that the board of trustees should consist of seven clergymen and ten laymen was repealed. Amherst College is a college of liberal arts and sciences, and the students take to provide a technical training. The course of study, normally requiring four years, and leading to the degree of bachelor of arts, is
partly prescribed and partly elective. The requirements for admission are based upon the subjects usually studied during a four years' course in the best high schools. In order to secure a degree a student must complete 40 semester courses which shall include one year of English, one year of mathematics, one year of history or philosophy, two years of Greek or two years of Latin, two years of science in the group, biology, chemistry, physics, and he must have a knowledge of either German or a Romance language (French, Italian or Spanish). In addition to the 40 courses, work is required in public speaking and in physical education. On the other hand, the fact that many courses are elective allows a student to follow to some extent his own inclinations; in fact it is possible for a student to so shape his college course that after graduation he may secure an engineering degree from a technical school by two years of additional study. The college also offers to holders of the bachelor's degree a year's course of study leading to the degree of master of arts. For many years the college offered a course leading to the degree of bachelor of science. The requirements for this degree placed less emphasis upon the classical languages and more upon the sciences than those of the course leading to the degree of bachelor of arts. No candidates have been accepted in this course, however, since those who entered college in 1913. The catalogue for the academic year 1915-16 shows a student enrolment of 429, and a faculty of 48 actively engaged in teaching. Since the college was founded about 9,000 students have been enrolled, and of this number about 5,000 are living. The buildings and equipment are valued at approximately $1,200,000 and include, besides recitation halls, laboratories, dormitories, etc., an infirmary, a gymnasium, two large athletic fields and a skating rink. The college has also many valuable collections. Among these are the Adams collection of shells, a part of Audubon's celebrated collection of birds, the Woods collection of minerals, the Shepard collection of meteorites, the famous Hitchcock ichnological collection, an anthropological collection and an unusually complete and interesting collection of Indian relics. The total funds of the college amount to over $2,800,000, of which the income of more than $420,000 is available annually for fellowships, scholarships and prizes. The corporate name of the institution is "The Trustees of Amherst College."

AMHERSTBURG, Canada, a town in Essex County, Ontario, on the Michigan Central Railway, near Sandwich. It is situated on the Detroit River, and among its industries are an automobile factory and a knitting factory. Valuable limestone quarries and a soda ash plant are in the neighborhood. Pop. (1911), 2,560.

AMIANTHUS, á-mé-an-thu'z ("undefiled"), a name applied to the fiber kinds of asbestos in consequence, it is said, of the mineral being unaffected by fire. Some of the finest amianthus, with long, silky, flexible fibres, occurs in the district of the Tarentaise in Savoy.

AMICÉ, á-mi's, or AMICT (Lat. amicus, girt around), a vestment worn by priests in the Roman Catholic Church during the celebration of mass. After the general adoption of the cravat had rendered the amice unnecessary as a neckcloth, it was retained for the significance which it had acquired as an emblem of the cloth wherewith the Jews the night before his crucifixion.

AMICI, á-mé-ché, Giovanni Battista, an Italian savant: b. in Modena 1786; d. 1864. He studied natural history at Bologna, and mathematics at Modena. He became professor of mathematics at the College of Panaro, and for some time general inspector of education in Modena, where in 1831 the Grand Duke of Tuscany appointed him director of the Florence observatory, as successor of the celebrated comet-discoverer, Luigi Pons. This office he held until his death, publishing every year the result of his astronomical observations, at the same time contributing important papers on natural history to the Memorie della Società Italiana. Science is especially indebted to him for his improvement of the telescope, of several microscopes, and of the camera obscura, named after him by Hooke and Wollaston. He seems to have from his earliest life devoted much attention to optical instruments, and before he was 20 he made a telescope of a mixture composed by himself. In 1827 he made dioptric microscopes, which are sold with his name attached, and, notwithstanding the improved microscopes of Oberhouser, are still in great favor. He was assisted in his labor by his son, Vincenzo Amici, who was professor of mathematics at the University of Pisa.

AMICIS, á-mé-ché, Edmondo de, Italy's foremost descriptive writer: b. Onglia, of Genoese parentage, 21 Oct. 1846; d. Bordighera, 11 March 1908. Educated at Coni and Turin, he attended the Modena military school; entered service 1863 as sub-lieutenant, acted against the Sicilian brigands and served through the Austro-Prussian War of 1866. He remained in the army till the occupation of Rome in 1870; but his literary vocation was plain. In 1867 he took charge of a Florentine paper, L'Italia Militare. In 1868 his first volume, Military Sketches, a short story of the phases of a soldier's life, had sweeping success and marked him as the coming Italian litterateur; and in 1871 he settled at Turin and devoted himself to authorship. His next work was 'Recollections' (of 1870-71), dedicated to the youth of Italy; a fresh collection of stories followed. But a craving for travel turned him into the path which has given him his greatest fame: the foreign world at least knows him mainly by the brilliant, glowing volumes describing the countries of Europe and other continents he visited, their national characteristics and habits, and, most of all, the springs of their life and thought. They are enthusiastic, sympathetic, optimistic, full of sensuous delight in beauty, rich in color and vivid in clearness of portrait; but it is not too marvelously keen analytic power as well as acute photographic sensitiveness to impressions and marvelous literary skill in translating them into language. The greatest of these perhaps is 'Holland' (1874). An angularly fine analysis of the essence of Dutch life and the sources of Dutch art in that life; others are 'Spain' (1873), 'Recollections of London' (1874), 'Morocco' (1876), 'Recollections of
Paris (1878), 'Constantinople' (1878). He published also in these times 'Literary Portraits' (1881), sympathetic studies of Daudet, Zola, Dumas, Jr., Augier, Coqetin and Désiré. 'The Friends,' and 'The Young Men's Mistress' (1882); historical novelettes, a collection in part old, entitled 'The Gate of Italy' (1884); 'On the Ocean' (1889). Later, educational and social problems deeply occupied his mind: his 'Cuore' (Hearts; Englished as 'The Heart of a Schoolboy'), a juvenile in which a pupil tells the events of a school year by day, has sold nearly 200,000 copies in Italy; a novel for adults on similar lines is 'The Workmen's Mistress' (1895); followed the same year by 'The Father of a Master' (1895), which has a strong socialistic bent. He avows himself that he thinks Socialism the only available spring of a vital Italian literature now. His latest works are: 'Everybody's Wagon' (1899), 'Memories' (1899), 'Hope and Glory' (1900), and 'Records of Infancy and School' (1901). See Cuore.

AMICUS CURIE, in law, a person who acts in a suit to instruct the court as to facts or as to law. Usually a person so acting is an attorney-at-law, and he may inform the court either on matters of fact or on points of law of which the court is doubtful. He has much less action than an attorney of record, but in some jurisdictions he may move to quash an indictment or set a proceeding aside.

AMIDE (am'id; from ammoniа, + ide), in chemistry, a general name for a class of bodies which may be regarded as derived from ammonia, NH₃, by replacing one or more of the hydrogen atoms in that substance by an even number of monovalent acid radicals. Thus formic acid, H.CO.OH, may be regarded as a hydrate of the acid radical HCO; and the compound HCO.NH₂, which is known as formamide, and obtained by the action of ethyl formate upon ammonia, may be regarded as derived from ammonia by the substitution of the radical HCO for one of the hydrogen atoms in NH₂. Similarly, acetic acid, CH₃.CO.OH, may be regarded as a hydrate of the radical CH₃.CO.; and the compound CH₃.CO.OH₂, has the formula C₂H₅.O.H₂O, and is produced by the action of ethyl acetate upon ammonia, may be regarded as derived from ammonia by the substitution of the radical C₂H₅.O for one of the hydrogen atoms in the ammonia.

Taking the general formula of a normal fatty acid as X.CO.OH, where X represents an alcohol radical (see Alcohol), an amide may be formed by substituting the monovalent acid radical, XCO, for one of the hydrogen atoms in NH₂. The resulting substance, XCO.NH₂, is known as the normal amide or acid radical XCO. By the further substitution of XCO for one of the atoms of hydrogen remaining in the primary amide, a secondary amide of the same acid radical is obtained, having the formula X.CO.NH₂. It is evident that a tertiary amide, having the formula (XCO)₂N, is also possible.

For some purposes it is convenient to regard the primary amide, X.CO.NH₂ of the monobasic acid X.CO.OH, from the opposite point of view; namely, as derived from the acid by the substitution of the radical NH₂ for the hydroxyl group OH. Obviously the result is the same in either case; but this latter view makes the departure of dibasic acid radical easier to describe. Thus in the dibasic acid Y (CO.OH)₂, (where Y is a divalent radical), the first result of the substitution of NH₂ for OH is the formation of the body Y (CO.OH) (CO.NH₂), which is both an acid and an amide—an amide because it is obtained by the substitution of NH₂ for OH, and an acid because it still contains one molecule of hydrogen that is replaceable by a monovalent metal or radical (namely, the molecule of H in the OH). Bodies of this type are called amic acids. If the molecule of OH remaining in an amic acid is replaced by a further substitution of NH₂, the resulting substance, Y (CO.OH)NH₂, is called a di-amide, and may be regarded as formed from two molecules of ammonia by the substitution of the divalent acid radical Y (CO.), for one-third of the total hydrogen present in these molecules.

The chemistry of the amides is very involved. They are mostly solid bodies, neutral to litmus, but capable of forming compounds with acids. The amides may be formed in several ways: (1) By the action of ammonium on ethers; (2) by the action of ammonia on acid chlorides; (3) by the dehydration of ammonium salts; (4) by the action of ammonia on anhydrides; (5) from nitriles and cold concentrated hydrochloric acid; (6) by heating acids with ammonium sulphocyanide for several days. The most familiar example of the class is the primary amide of acetyl or acetamide. This substance, which is usually obtained by the dry distillation of acetate of ammonium at temperatures exceeding 375° F., has the formula C₂H₅.O.NH₂, as noted above, and forms hexagonal crystals. It melts at about 180° F., boils at about 432°, and is quite soluble in water. Diacetamide, (C₂H₅.O)₂.NH, and triacetamide, (C₂H₅.O)₃.N, are also known. See Amine; Imide; Nitrile.

AMIDO-ACIDS, substances derived from organic acids by the substitution of an NH₂ group for one or more of the hydrogen atoms in direct connection with the carboxyl radical. They often form intermediary products in the metabolism of proteins. In the process of digestion notably, the proteids (albumens) undergo a gradual series of transformations whereby the complex proteid molecule is broken down into simpler and simpler compounds, until at the end of the process the basic anhydride, water, urea, uric acid, ammonia, etc., are the results. While these end products of metabolism are well known, the intermediary products are the object of much inquiry. In the intestinal canal, under the prolonged action of the pancreatic juice ferments, simpler nitrogenous principles are found, leucine, tyrosine, aspartic acids —these belong to the general group of the amido-acids. Schützenberger has described 1. (1) The leucine class, C₅H₁₁.N₂O₅—such as alanine, propionic, butaline; (2) of the acrylic series, C₅H₈NO; (3) amido-acids of the glucoprotein class, sweet in taste, with the general formula C₂H₅N₂O₅; (4) amido-acids such as tyrosine, tryptophane and glutamic acid. Con-

AMIÉL, â‘myâł', Henri Frédéric, Swiss essayist, philosophical critic and poet; b. in Geneva, 27th July 1803; d. there, 11 March 1881; was for five years a student in German universities, and on his return home became professor of philosophy in the Geneva Academy. He is author of several works on the history of literature, as 'The Literary Movement in Roman Switzerland', 2nd ed. (1849); 'Study on Madame de Staël' (1878); and of several poems, among them 'Millet Grainz' (1854). But his fame rests principally on the 'Journal', which appeared after the author's death, and translated into English by Mrs. Humphrey Ward. This journal is a complete revelation of a cast of mind expressing great passion and full of original power and spiritual yearning. It is fascinating and subtle rather than stimulating or strong, and is esteemed more for its beauty of form than for any definite teaching it contains. Arnold, Matthew, 'Essays in Criticism'; Bourget, 'Nouveaux essais de psychologic contemporaine' (Paris 1885); Vadier, 'Life of Amiel' (ib. 1885). See Amiel's Journal.

AMIÉL'S JOURNAL INTIME. Henri Frédéric Amiel, though for more than 30 years professor in the Academy of Geneva, is remembered almost solely for his 'Journal Intime', to which he confided thoughts and impressions, chiefly psychological, that he could not find the will to publish during his life. He bequeathed it, a manuscript of 1,700 pages, to Genevese friends that they might publish it whatever it seemed to possess interest as thought or value as experience. A first volume appeared in 1883 with a notable introduction by Edmond Scherer. A second and last followed in 1884. Both have been exceptionally well translated, with a thoughtful introduction, by Mrs. Humphrey Ward. The 'Journal' made an immediate and deep, though not wide, impression as being, in the words of Renan, 'the perfect mirror of a modern mind of the best type, matured by the best modern culture, and giving a living picture of the sufferings which beset the sterility of genius.' The morbid introspection that numbed action in Amiel, as in Shakespeare's 'Hamlet,' seems to have been intensified by the conditions attending the recognition of his talent that he gained on his return to his native Geneva after six years' philosophical study, chiefly in Germany. A democratic revolution had displaced in the city the old governing aristocracy in which was comprised nearly all its culture. To this new government he owed his professorship, an appointment which involved an almost complete social isolation of which the psychic effect is constantly reflected in the 'Journal.' Beauty of expression, psychological insight, unerring intellectual interest, and above all a power of revelation in the literature of sentiment, spiritual uncertainty, in Scherer's words, 'will which wished to will but was powerless to furnish itself the motives for willing,' which other over-refined and meditative minds feel to be akin to their own, assure the 'Journal' a high place in the literature of confession. There is a 'Life of Amiel' by B. Vadier. Consult Arnold, Matthew, 'Essays in Criticism,' and Bourget, 'Nouveaux essais de psychologie contemporaine.'

BENJAMIN W. WELLS, Author 'Modern French Literature.'

AMIENS, â‘myâ̅n̩', an old French city, once the capital of Picardy, and now of the department of Somme, on the many-channeled navigable Somme, 81 miles north of Paris by rail. Its fortifications have been turned into charming gardens, but it still retains its old citadel. The Cathedral of Notre Dame is a masterpiece of Gothic architecture. Begun in 1220, it is 470 feet long, and has a spire (1529) 420 feet high; but its special feature is the loftiness of the nave, 141 feet. In his little work called 'The Bible of Amiens,' Ruskin says this church well deserves the name given it by Viollet-le-Duc, 'the Parthenon of Gothic architecture,' and affirms that its style is "Gothic, pure, authoritative, and unaccused." Other noteworthy buildings are the 'Hotel de Ville' (1600-1760), in which the Peace of Amiens was signed; the large museum (1864), in Renaissance style; and the public library, founded in 1791. Amiens has considerable manufactories of velvet, silk, worsted goods, ribbons and carpets. Peter the Hermit and Du Cange were natives, and there are statues to both of them. The "Mise of Amiens," was the award pronounced by Louis IX of France, in 1264, on the controversy between Henry III of England and his people as to the "Provisions of Oxford." The Peace of Amiens (27 March 1802) was a treaty intended to settle the disputed points between England, France, Spain and Holland. By it England retained possession of Ceylon and Trinidad and an open port at the Cape of Good Hope; the republic of the Ionian Islands was recognized; Malta was restored to the Knights of St. John; Spain and Holland regained their colonies, with the exception of Trinidad and Ceylon; the French were to quit Rome and Naples; and Turkey was restored to its integrity. In the Franco-Prussian War, on 27 Nov. 1870, General Manteuffel inflicted, near Amiens, a signal defeat on a French army 30,000 strong, and three days later the citadel surrendered. During the European War, with its defenses strengthened, it was an important as a garrison railway and supply depot for the allied armies. Pop. about 92,000.

AMINA, the sleep-walking heroine of Bellini's opera 'La Sonnambula.'

AMINE (am-in; from ammonia + ine), a general name for a compound derived from ammonia by substituting one or more of its hydrogen atoms with an equivalent number of metallic atoms or basic organic radicals (Compare AMIDE). The reactions of the amines depend upon the class to which the substituted alkyl belongs—whether (1) all aliphatic; (2) part aliphatic and part aromatic—with the nitrogen ring attached to the aliphatic residue (as benzylamine); (3) part aromatic and part aliphatic with the nitrogen attached to a carbon atom of the benzene ring (as methylamino); and (4) pure aromatic amines (as aniline, diphenylamine, etc.). Group (1) is known as the aliphatic amines; (2) as the aromatic amines; (3) and (4) as the aromatic amine compounds. As in the case of the amides,
a given monovalent radical can form three compounds of this sort according as it replaces one, two or three of the hydrogen atoms of the original ammonia. For example, the monovalent basic radical "ethyl," \( \text{CH}_3\text{H}_2\), forms primary ethyl amine (or "ethylaniline") \( \text{CH}_3\text{H}_2\text{NH}_2 \), when it replaces one atom of \( \text{H} \) in \( \text{NH}_2 \); secondary ethyl amine (or "diethylaniline") \( \text{CH}_3\text{H}_2\text{NH}_3 \), when it replaces two atoms which have their origin in organic matter; or tertiary ethyl amine (or "triethylaniline") \( \text{CH}_3\text{H}_2\text{N} \), when it replaces all three of the hydrogen atoms in the ammonia. The base by which the hydrogen in the ammonia is replaced need not be organic. Potassium, for example, may replace an atom of \( \text{H} \) with the formation of potassium monamine (or "potassiumammonium"), \( \text{K}\text{NH}_2 \). A derivative of ammonia, in which one atom of the typical hydrogen is replaced by a monovalent acid radical, and another by a monovalent basic radical or by a monad metal, may be considered to be an amine or an amide. Thus \( \text{CH}_3\text{H}_2\text{NH}_2\text{Cl} \), NH, in which one atom of the hydrogen has been replaced by the basic radical "methyl" \( \text{CH}_3 \), and another by the acid radical "acetate" \( \text{CH}_3\text{CO}_2\text{H} \), may be described as a modified mono-ammonium acetamide. These amides are found in nature chiefly in the vegetable alkaloids. They occur also in the blood of some animals and generally among the decomposition products of both animal and vegetable organisms and also in decomposed minerals or organic matter.

There are several methods by which amines may be prepared: (1) by the action of ammonia or its alkyl derivatives on substitution products of the hydrocarbons; (2) by the reduction of nitrogen-containing substances; (3) by the action of bromine and potash on the amides; (4) by the action of alkalis on alkyl isocyanates; (5) by hydrolysis of the alkyl esters of thiocarbahymines and isocyanides with concentrated acids; (6) from compounds which contain substances which form alkyl halides, by distillation of amino-acids with baryta. In addition, aliphatic primary and secondary amines may be obtained by the action of potash on the \( \beta\)-nitroso derivatives of secondary and tertiary aromatic amino-compounds, and tertiary amines may be secured by heating primary and secondary bases with an excess of potassium alkyl sulphate. Secondary and tertiary aromatic amino-compounds (dimethylaniline, etc.) are prepared on a large scale by heating the primary amines under pressure with alcohol and hydrochloric or sulphuric acid, at a temperature of from 300° to 400° F.

When ammonia is added to a cold solution of a salt of an amine, the amine is expelled from its combination and precipitated.

The aliphatic series are generally inflammable gases, or volatile liquids with a low boiling point and a density about 75 per cent that of water. They have a fishy odor, are decidedly alkaline, and are freely soluble in water. Some of the highest members of this class are odorless solids, becoming carbonates upon exposure to moist air. The aromatic amines (benzylamine, etc.) are comparatively few; they resemble generally the aliphatic amines, but are not so strongly basic.

The most important amines in the arts, are methyamine, and aniline (q.v.).

AMINTA. The unchallenged pre-eminence of the 'Aminta' of Tasso in the field of pastoral drama is due to the unusual manner in which the technical problems of the genre are solved. The stock objection to the pastoral as a whole is its artificiality, its failure to correspond to life — its violation, in a word, of the Aristotelian canon of "probability." In the 'Aminta' in the light of Tasso's 'Dialogues on Poetry,' it is apparent that he intended to evade this criticism in the typically pedantic fashion of the Renaissance: Aminta is of divine descent, and Silvia, his lover and future bride, is a nymph of Diana. In a world of divinities even the aesthetic shepherds of the pastoral are "probable" as well as possible. If we hold that this evasion is as futile as the objection itself, it is nevertheless clear that Tasso's poetic instinct served him better than his logic. The reality that fails to return through the divinity of his characters does arise from the atmosphere of humorous fancy into which the whole invention is thrown. A playfully mechanical plot—with two resurrections and a bloodless combat—continued in its character drawings humanly conventional (the philosophic spinster and the vanquished Diana), compensates by its gentle mirth for the absurdities inherent in the nature of the Arcadian world. It is only in the realm of fancy that the impossible becomes probable and necessary. And when this has been conceded, Tasso is free with all sincerity to yield his spirit to the voluptuous melancholy, the suppressed joys, the mellow anguish of sensuous passions experienced in an imagination aspiring to the ideal. This idealized sensuousness of the 'Aminta,' sustained by imagery free from crudeness but brilliantly visualized, is enriched by suggestions of sadness and unsatisfied yearnings, prickling the intellect with paradox and metaphor and the memory with a wealth of erudite allusion, gave new direction to Italian Petrarchism generally and to the mores of pastoral poetry in particular. In the 'Aminta,' as well as in the 'Jerusalem Delivered,' the Marinists of the 17th century found the poesia serena, for their "lasciviousness." It was the delight of the précieux salons of Paris under Louis XIII and Louis XIV. Twenty-eight English translations have been made of this work. Of a dozen English renderings the first, by Abraham Faunce, appeared in 1591, and the best, by Leigh Hunt, in 1820. The 'Aminta' was composed as an entertainment for Giambattista Pigna, Prime Minister of Duke Alfonso of Ferrara, and produced for the first time at Belvedere-on-the-For, Pigna's country estate, 31 July 1571.

ARTHUR LIVINGSTON,
Western University.

AMIOT, a'myô', Jean Joseph Marie, French missionary: b. Toulon, February 1718; d. Peking, 9 Oct. 1793. He entered the Society of Jesus in 1737 and was sent in 1750 as a missionary to China. He soon won the confidence of the Emperor Kien-lung and was saved from certain death. He spent the last years of his life at Peking. Amiot was eminently fitted to make good use of the advantages which his situation afforded, and his works did more than had ever been done before to make known to the Western World the thought and life of the Far East. His 'Dictionnaire taira-branchou-
français) (1789) was a work of great value, the language having been previously quite unknown in Europe. His other writings are to be found chiefly in the 'Mémoires concernant l'histoire, les sciences et les arts des Chinois' (15 vols., 1776-91); the 'Vie de Confucius,' the 12th volume of that collection, is complete and accurate.

AMIRANTE, am'ri-ránt, ISLANDS, a group of small islands in the Indian Ocean, lying southwest of the Seychelles. They were taken possession of by Great Britain in 1814 and form a dependency of Mauritius. They produce cocaanuts, and turtle and fish are abundant. About six are inhabited.

AMIS ET AMILES, a'mé' z a'mel', a chanson of the Middle Ages, dating from about the beginning of the 13th century. The work consists of 3,500 lines, in which are narrated the adventures of two friends.

AMISTAD, a'mestäd', CASE, in United States law, one of the landmarks of the slavery question. The Spanish government, by decree of December 1817, forbade the importation of slaves from Africa into its dominions after 30 Dec. 1820, on penalty of confiscation of the slave ship and immediate freeing of the negroes. The trade nevertheless went on under transparent disguises. In the spring of 1839 the slave-hunters in Africa made a large capture of Sierra Leone natives, including their chief, Cinque, and sent them to Havana; where two months afterward two Cuban planters, Pedro Ruiz and José Montez, bought 38 youths and men, three girls and a boy, and shipped them on 27 June for Guanaja, Puerto Principe, on the schooner L'Amistad, under passport from the governor of Cuba obtained by falsely alleging that they were domestic slaves. Cinque organized a plan for revolt, and when four days out they rose, killed the captain and one of the crew, wounded two others in the contest, and forced the remaining whites to surrender; but they then them no violence, and set all on shore except the two planters, whom they managed to make understand that they must steer for Africa. These gradually changed course in the nights and fogs, and brought the vessel north off Culloden Point (near Montauk), and the Island of Long Is.; on 26 August she was noted as "suspicious" by Lieu- tenant Gedney of the coast survey, on the brig Washington. He sent a boat to her, and one of the planters declared himself the owner of the negroes and claimed United States protection. Some of them had gone on land in a boat; Gedney seized them as under New York State jurisdiction, and the vessel as a "prize rescued from pirates," and brought them to New Lon- don, Conn. The negroes were committed for murder on the high seas, to be tried at the Circuit Court of 17 September at Hartford, and meantime lodged in New Haven jail. The planters claimed them as slaves, appealed to the Spanish minister, Calderon, and he demanded their surrender of the United States district attorney for Connecticut. The latter wrote to the Secretary of State (Forsyth of Georgia) asking if the negroes under treaty with Spain might not be surrendered before the court sat; the Secretary transmitted the question to the President (Van Buren), but warned the district attorney to take care that no court whatever put the vessel, cargo or slaves beyond the control of the Federal executive. Meantime the anti-slavery interest had stirred itself and secured funds, able counsel and an interpreter of African; and the Circuit Court (Judge Thompson) decided on the 23d that the killing of the captain of the L'Amistad, being an incident of the slave trade, was not a crime against the law of nations. The negroes were remanded to jail till the Dis- trict Court in November should decide whether they were free or slave. The next day the United States Attorney-General, Felix Grundy of Tennessee, was ordered to prepare an official opinion on the Spanish minister's request and the claim of Gedney et al. for prize money. He replied in November that ship, cargo and negroes should be surrendered according to article 9 of the treaty of 27 Oct. 1795, as the United States under international law had no power to investigate the truth of facts stated in Spanish official papers,—in other words, whether the governor's passport was obtained by fraud, and the negroes were brought to the Spanish law already cited; though hardly one could speak a word of European and none much more, and the planters were obviously perjured in swearing ignorance of their being recently imported. But this article any way related only to vessels and goods rescued on the high seas from pirates; and under this interpretation the negroes were once the pirates and the cargo, and had committed piracy in seizing themselves from their owners. The Spanish minister protested that no United States court had any jurisdiction. The administration, not daring to take the case out of its courts, went as far as it could by ordering the district attorney to act as legal adviser to the planters and file another indictment for them with new pleadings; sent a ves- sel to lie off New Haven in order to carry the negroes back to Cuba as soon as the District Court pronounced them slaves, as was taken for granted (this was the first trial for violating the slave-trade laws that had taken place except in slave States, where of course no convictions were ever found), and to do it instantly unless an appeal were interposed, which was "not to be taken for granted"; ordered that Gedney should go to the Island, where on 26 August he was noted as "suspicious," and the coast survey, on the brig Washington. He sent a boat to her, and one of the planters declared himself the owner of the negroes and claimed United States protection. Some of them had gone on land in a boat; Gedney seized them as under New York State jurisdiction, and the vessel as a "prize rescued from pirates," and brought them to New London, Conn. The negroes were committed for murder on the high seas, to be tried at the Circuit Court of 17 September at Hartford, and meantime lodged in New Haven jail. The planters claimed them as slaves, appealed to the Spanish minister, Calderon, and he demanded their surrender of the United States district attorney for Connecticut. The latter wrote to the Secretary of State (Forsyth of Georgia) asking if the negroes under treaty with Spain might not be surrendered before the court sat; the Secretary transmitted the question to the President (Van Buren), but warned the district attorney to take care that no court whatever put the vessel, cargo or slaves beyond the control of the Federal executive. Meantime the anti-slavery interest had stirred itself and secured funds, able counsel and an interpreter of African; and the Circuit Court (Judge Thompson) decided on the 23d that the killing of the captain of the L'Amistad, being an incident of the slave trade, was not a crime against the law of nations. The negroes were remanded to jail till the Dis- trict Court in November should decide whether they were free or slave. The next day the United States Attorney-General, Felix Grundy of Tennessee, was ordered to prepare an official opinion on the Spanish minister's request and the claim of Gedney et al. for prize money. He replied in November that ship, cargo and negroes should be surrendered according to article 9 of the treaty of 27 Oct. 1795, as the United States under international law had no power to investigate the truth of facts stated in Spanish official papers,—in other words, whether the governor's passport was obtained by fraud, and the negroes were brought to the Spanish law already cited; though hardly one could speak a word of European and none much more, and the planters were obviously perjured in swearing ignorance of their being recently imported. But this article any way related only to vessels and goods rescued on the high seas from pirates; and under this interpretation the negroes were once the pirates and the cargo, and had committed piracy in seizing themselves from their owners. The Spanish minister protested that no United States court had any jurisdiction. The administration, not daring to take the case out of its courts, went as far as it could by ordering the district attorney to act as legal adviser to the planters and file another indictment for them with new pleadings; sent a ves- sel to lie off New Haven in order to carry the negroes back to Cuba as soon as the District Court pronounced them slaves, as was taken for granted (this was the first trial for violating the slave-trade laws that had taken place except in slave States, where of course no convictions were ever found), and to do it instantly unless an appeal were interposed, which was "not to be taken for granted"; ordered that Gedney should go to the Island, where on 26 August he was noted as "suspicious,"
Baldwin, the district attorney, admitted in open court that they were newly from Africa when bought; and on 9 March the court (Taney, C. J.) pronounced them illegally held as slaves and liable to no punishment for their acts. The case roused the fiercest excitement in both the free and slave sections of the country. In 1844 the astounding bill was reported by the chairman of the House committee on foreign affairs to pay Ruiz and Montex $70,000 compensation; but it was laid on the table and never appeared. This ends the “case,” but a word may be added on the negroes. They were removed to Farmington, Conn., well cared for and instructed in the rudiments of education by a competent professor. Cinque kept them under stern discipline; they were excellently behaved and much liked; and some of them, being unusually quick of intelligence, were exhibited for proficiency in New England towns. About the end of November they were sent back to Africa with some missionaries, and a mission was afterward established in the district.

AMITE, La., town and parish-seat of Tangipahoa Parish, 65 miles northwest of New Orleans and on the Mississippi river and the Illinois Central Railroad. It is located in a thriving agricultural region and has a good trade in corn, cotton, fruit and vegetables. Irrigation is an important factor in crop raising. The town was destroyed by a cyclone in 1902, but was reconstructed within a few months. Pop. 2,200.

AMITOSIS. See Mitosis.

AMITYVILLE, N. Y., village of Suffolk County, on the Long Island Railroad, 30 miles east of New York city. It contains a sanitarium, an infirmary, an academy, club houses and several churches. Located on Great South Bay it is a popular summer resort, with ample bathing, boating and fishing facilities. It is also a residential place for New York business men. Pop. 2,850.

AMIWCH, ám'luk, a seaport town in north Wales, on the north coast of the island of Anglesey, and 14 miles northeast from Holyhead. The harbor is partly cut out of a solid rock. There are copper mines near the town, and mining is said to have been carried on here by the Romans. Pop. 5,000.

AMMAN, Jobst, ám'mán, Swiss painter and engraver: b. Zurich 1539; d. Nurnberg 1591. Little of his personal history survives. It is supposed that before leaving Switzerland, he studied under some glass painter of that country, for stained glass is almost all that constitutes Amman’s claim to be considered as a painter. His main work is in his engraving, which consists of no less than 540 pieces. It obtained for him a notable measure of success in Nurnberg, where he settled in 1560. He handled etching and wood-engraving with great skill, and has left a considerable body of work in his pen drawings. While not free from the mannerism that came in with his period, a sufficient measure of the excellence of his predecessors remains to make his work worthy of study. His aquarelles and wash drawings are also important. The entrance of Emperor Maximilian II into Nurnberg contains 450 figures. Of the greatest importance are his drawings for wood cuts, through which he exercised the widest influence of any artist of his time. He drew directly on the wood, and sometimes even cut the engravings himself. Among his etchings may be mentioned the portraits of Admiral de Coligny, of Martin Luther and of Hans Sachs, the ‘Four Seasons,’ ‘The Twelve Months,’ and religious works. The museum of Basel has the only well-authenticated painting by Amman, also a collection of designs for stained glasses executed in 1557. Consult Amman, ‘Geschichte der Familie Amman von Zürich’ (Zurich 1904) and AndreSEN, ‘Der deutsche Finte-Graveur’ (Leipzig 1864-66).

AMMAN, Johann Conrad, Swiss physician: b. Schaffhausen 1669; d. Warmdour about 1730. After graduating at Basel in 1687 he began to practise at Amsterdam, where he gained a great reputation. He was one of the earliest writers on the instruction of the deaf and dumb, and first called attention to his method in his ‘Surdus loquens’ (1692). His process consisted principally in exciting the attention of his pupils to the motions of his lips and larynx while he spoke, and then inducing them to imitate these movements till he brought them to repeat distinctly letters, syllables and words.

AMMANATI, ám'ma-ná-'tè, Bartolomeo, Florentine architect and sculptor: b. Florence 1511; d. 1592. He studied under Bandinelli and Jacopo Sansovino, and closely imitated the style of Michelangelo. He was more distinguished in architecture than in sculpture. He designed many buildings in Rome, Lucca and Florence, an addition to the Pitti Palace in the last-named city being one of his most celebrated works. He was also employed in 1569 to build the beautiful bridge over the Arno, known as Ponte della Trinita—one of his celebrated works. The three arches are elliptic, and though very light and elegant have resisted the fury of the river, which has swept and several other bridges at different times. Another of his most important works was the fountain for the Piazza della Signoria.

AMMEN, Daniel, American naval officer: b. Brown County, Ohio, 15 May 1820; d. 11 July 1868. He entered the U.S. Navy 17 July 1836 as midshipman. He was in the Wilkes exploring expedition 1838-42, in the East India squadron, and on the coast survey; on the expedition to the Paraguay River 1853-54. He commanded the Seneca at the capture of Fort Royal, 7 Nov. 1861; promoted to commander 21 Feb. 1863; in charge of the Patapsco at the assault on Fort Macallister, 3 March 1863, and on Fort Sumner, 7 April; commanded the Mohican in the attacks on Fort Fisher, December 1864 and January 1865. He was commissioned captain 1866, was chief of the bureau of yards and docks 1869-71, and of the bureau of navigation till 11 Dec. 1877, when he was made rear-admiral on the retired list. He designed the Ammen life raft and the ram Katahdin. He wrote: ‘The American Trench-onetric Ship Canal Question’ (1880); ‘The Atlantic Coast’ (1883); ‘Country Homes and Their Improvement’; ‘The Old Navy and the New’ (1891).

AMMERGAU, am’mer-gou, a district or gau on the river Ammer in upper Bavaria. The inhabitants are occupied in making figures of
saints, crucifixes, toys, etc., of wood, ivory and glass, from which a considerable trade arises, having its centre in the villages of Ober and Unter Ammergau. The former village is famous on account of the Passion Play (q.v.).

AMMETER. See Galvanometer.

AMMIANUS, Marcellinus, the last Roman historian of importance: b. Antioch about 325 A.D.; d. Rome about 398. He entered the army at an early age and served in several campaigns. Eventually he settled in Rome, where, at an advanced age, he wrote (in Latin) a history of the Roman Empire from the accession of Nerva to the death of Valens (96–378), thus forming a continuation of the work of Tacitus. This history was originally in 31 books; of these the first 13 are lost, the 18 which remain cover the period from 353 to 378. It is extremely valuable, being a clear, comprehensive and impartial account of events by a contemporary of soldiers' honesty, independent judgment and wide reading. In his description of the Empire — the exhaustion produced by excessive taxation, the financial ruin of the middle classes, the progressive decline in the morale of the army — we find the explanation of its fall before the Goths 20 years after his death.

AMMON, an Egyptian deity, whose worship spread all over Egypt and other parts of North Africa, and many parts of Greece. The Egyptian hieroglyphic monuments call him Amun, the Greeks identified him with their supreme god Zeus, while the Romans regarded him as the representative of Jupiter. His worship was centered in the Egyptian Thebes, which the Greeks therefore called Diospolis or the City of Zeus. He is represented as a ram, as a human being with a ram's head, or simply with the horns of a ram. His most celebrated temple was in the oasis of Siwa in the Libyan desert.

AMMON, Otto, German anthropologist and editor: b. Karlsruhe 1842. He was educated as a civil engineer and was engaged in that profession from 1863 to 1868. From 1868 to about 1885 he was a publisher and editor. In 1883 he engaged in literary work and made several investigations in anthropology and sociology. He is the discoverer of "Ammon's law," that the Teutonic race has everywhere manifested a tendency toward city life. He demonstrated this law by a series of measurements of physical characteristics among army conscripts. His investigations have shown radical differences in the form of the head in city and country and even between the upper and lower classes in the larger cities. He has written: 'Die naturliche Grundlage der Menschen' (Jena 1893); 'Die Gesellschaftsordnung und ihre natürlichen Grundlagen' (3d ed., Jena 1900); 'Zur Anthropologie des Badenes' (ib. 1899); 'Die Körpergrössen der Wehrpflichtigen in Baden, 1840–64' (Karlsruhe 1899); 'Anthropologische Untersuchungen der Wehrpflichtigen in Baden' (1890); and 'Die Geschichte einer Idee' (in Rundschau, Berlin 1896); 'Der Abänderungsspiegel' (in Natur-Wissenschaftliche Wochenchrift, Berlin 1896); 'Die Menschen im Europa' (in Rundschau, Berlin 1896).

AMMONIA (supposed to be so called because originally procured from the dung of camels near the temple of Ammon, in Egypt), a gaseous compound of hydrogen and nitrogen, having the formula NH₃. It may be formed in small quantities by the direct combination of its elements under the influence of the silent electric discharge; but in the arts it is commonly prepared by the decomposition of nitrogenous matter. Formerly it was manufactured in large quantities by the destructive distillation of horns, hoofs and hides, and from this fact it was known as 'spirits of hartshorn.' It is now chiefly obtained as a by-product in the manufacture of coal-gas. Coal suitable for the manufacture of gas contains nitrogen, often to the extent of 2 per cent of its weight; and in the distillation of such coal the nitrogen combines with a portion of the hydrogen that is present, and is driven off in the form of ammonia; or more often it combines with the sulphur present and is obtained in the form of a sulphate. Salts of ammonia also occur in nature, sometimes in considerable quantities. In Tuscany ammonia sulphate is obtained as a by-product in the manufacture of boric acid. See BOUSINGUALITITE; LARDERELLITE; MASCAGNITE.

Ammonia (NH₃) is a colorless gas at ordinary temperatures and pressures, but at 60° F. it condenses into a colorless and expansible liquid upon the application of a pressure of about seven atmospheres. At the freezing point of water a pressure of 4.4 atmospheres suffices to liquefy it; and at about 29° below zero, F., it condenses into a liquid at ordinary atmospheric pressure. Ammonia thus liquefied by pressure is much used, in the arts, for the production of low temperatures and the manufacture of artificial ice. (See Refrigeration.) It freezes at about 103° below zero, F., into a white crystalline solid. Liquid NH₃ dissolves the alkali metals without chemical changes, forming blue solutions.

Ammonia gas is very soluble in water at ordinary temperatures, the solution constituting the so-called *ammonia* or *aqua ammonia* that is familiar in every household. At 32° F. and at ordinary atmospheric pressure water will absorb 1,148 times its own volume of NH₃; and at 68° F. it will absorb 740 times its own volume.

Both ammonia gas and its solution in water possess strongly alkaline properties, turning red litmus paper blue and combining with acids to produce definite salts. The solution of ammonia gas in water is attended by a considerable development of heat, and it is usual to consider that a definite compound of ammonia and water is formed. The formula of this compound may be written NH₃.H₂O, but many considerations suggest that NH₄OH is a better and more logical form. NH₃ is here considered to be a radical, analogous in its chemical deportment to the familiar alkali metals sodium and potassium. According to this view ordinary 'aqua ammonia' should be regarded as a solution of the hydrate of the radical NH₄, and for many years past chemists have admitted the existence of such a radical, which they have called *ammonium.* Upon adding hydrochloric acid to a solution of ammonia gas, a compound known as *ammonium chloride* is obtained, which is used largely in electric bat-
AMMONIACUM — AMMONITES

The reaction by which this substance is formed may be written \( \text{NH}_3 + \text{HCl} = \text{NH}_4\text{Cl} \); or if the existence of a definite hydrate in the "aqua ammonia" is admitted, we may write the reaction \( \text{NH}_4\text{OH} + \text{HCl} = \text{NH}_4\text{Cl} + \text{H}_2\text{O} \), in which case the reaction is in all respects analogous to that by which potassium chlorid (for example) is formed when hydrochloric acid acts upon potassium hydrate: \( 2\text{KOH} + \text{HCl} = \text{KCl} + \text{H}_2\text{O} \).

All the ammonium salts that are formed by the combination of ammonia with acids can be similarly expressed by admitting the existence of the radical \( \text{NH}_4 \) and treating it, in the formulæ, as though it were a metal of the alkali group.

All the "ammonium" compounds are isomorphous with the corresponding potassium compounds.

Aqua ammonia, or "caustic ammonia" (as it is sometimes called), is used for many purposes in the arts, notably in the production of soda by the ammonia process (see SODIUM), and in dyeing and calico-printing. Large quantities of the sulphate are used in fertilizers and in the manufacture of ammonia alum (see ALUM). The chloride of ammonium is used (as above noted) in certain common forms of electric batteries, and also in soldering, in dyeing, and in many minor ways. Carbonate is largely used in the manufacture of baking powders and for scouring wool.

Ammonia is expelled from all of its compounds by quicklime, and the usual test for ammoniacal compounds consists in heating the substance to be examined, together with caustic lime or caustic soda or potash. If ammonia is present in any considerable amount it is liberated by this treatment and may be recognized by smell or by its action on litmus paper. Nearly all of the compounds of ammonia are batteries, and also in soldering, in dyeing, and the double platinic chloride being the chief exceptions.

Ammonia forms the starting point for an extraordinarily long list of compounds, many of which are exceedingly complicated. See AMIDE; AMINE.

AMMONIACUM is a gum resin derived from the stems of Dorema ammoniacum, a forest plant of Persia. Other species of Dorema yield similar products.

The plant has an abundant supply of milky juice which exudes spontaneously and hardens in various-shaped masses. Fine tears, varying in size from two to five mm. up to the size of a hazel-nut, are obtained from insect-punctured wounds, while the so-called ammoniacum amygdaloïdes is obtained from the root of the plant.

Ammoniacum consists of a mixture of varying proportions of ethereal oils, 1 to 2 per cent; resins, gums, 65 to 70 per cent; and pectin-like bodies. Ash 20 per cent. A certain amount of water is always found in the commercial product. The ethereal oils are found in small quantities only, generally less than 10 per cent. It may contain a carbon disulphide. The resin itself is to be distinguished from other resins in that its alcoholic solution gives a red reaction when added to a bromide of sodium solution, 30 gr. NaOH in 500 gr. Ag. 1 liter. Umbelliferon would seem to be absent.

AMMONITES, ām'mōn-ītēz, or "children of Ammon." In the cuneiform inscriptions their land is called Bit-Amman, as if Amman were a personal name; but Genesis says that Ammon was the father of the Moabites, and Ammi was perhaps a local god. Their land was in the eastern part of the district now called Belka, on the northeast of the Dead Sea next the desert; its capital Rabbah or Rabath-Ammon. Their real history begins with Saul, though Jephtha the Javanite who is supposed to have delivered Israel from them, and one tradition represents Balaam as an Ammonite—but this is thought a later excuse for excluding them from the Jewish body. They were in a state of chronic border warfare with the Hebrews, their close kinsmen, and speaking a closely related dialect. Nahash, King of Ammon, besieges Jabesh-Gilead (1 Sam. xi), and offers terms for its capitulation on condition of putting out the chief men's right eyes—but Saul wins a crushing victory over the besiegers. David as Saul's enemy is well treated by Nahash; but when he takes Saul's place the old feelings are resumed. Hanun, the son and successor of Nahash, treats David's messengers of congratulation with great insult (2 Sam. x); David wins a victory over them and the Syrian allies they have called in, and exacts a frightful vengeance from them, putting his captives to the torture quite in the Assyrian fashion, and leaving us to infer that there was little to choose in savagery. They probably recovered their independence after Solomon's death. Later they were subjugated by the Assyrians, as the inscriptions of several kings prove. Under Jeroboam II they make incursions into Gilead and are blamed for inhumanity. After the Israeliteish deportation of 734 they occupied the land of Gad; under Jehoiakim they are incorporated into Judah; under Zedekiah they are allied with him against Assyria, but seem to have drawn out in time for safety, and Israeliteish fugitives find refuge with their King, Baalis. Later they intermarried with the Jews, and there was a village of them in Benjamin; Judas Maccabaeus defeated them; but they were gradually absorbed by invading Arab tribes. Their great local god was Milcom.

AMMONITES, ām-o'-nî-tēz, the general name for the fossil cephalopod mollusks of the order Ammonioidae, given originally because of a fancied resemblance of the coiled specimens first known to a ram's horn, the symbol of Jupiter Ammon. Subsequently it served as a generic name for a group, but this has been abandoned in the light of later information. The Ammonioidae are one of the two orders of chambered tetrabranchiate cephalopods, the other being the Nautilioidae (see NAUTILUS). Their remains are found fossil in marine Paleozoic rocks from the Devonian to the close of the Mesozoic Age. More than 5,000 species have been described, grouped into about 100 families, and these into nine sub-orders in two divisions, (1) Intrasiphonata and (2) Extraterrestrial. The first group contains a single primitive (Devonian) sub-order having the siphuncle dorsally situatd in all the remainder, which agree in having the siphuncle ventral. The classification is based upon the complexity lobed pattern of the sutures, or lines of union between the septa or partition walls of the chambers and the outer wall of the
shell (See CEPHALOPODA). The shells of ammonites were typically coiled in a single plane and ran in size from an inch or two in diameter to two or more feet; but this varied greatly, even in the shell of an entire straightness. The outer face of the shell, too, was in many cases smooth and polished or slightly ridged, while in others it was roughly ringed or covered with cross-lines, spikes and tubercles, in handsome variety. Some shells were so compressed as to have the proportions of a watch; while others were almost globose.

As Hyatt states, ammonoids experienced a progressive evolution from the early Devonian until the upper Jurassic, when the group reached its summit of importance and was represented in great numbers and variety in all parts of the world: that is, when it attained the summit of its evolution in complexity of structure, form and ornament. Ammonoids exist in great abundance in the rocks of this period in the western United States, especially those of the irregular group called Ceratites, which succeeded the Palaeozoic Goniatites, and other primitive forms. The Jurassic ammonoids show a mixture of retrogression with some progressive features. Part of their losses is regained by the evolution of the vast number of new forms and modifications during this period, but there are numerous localized signs of retrogression, due perhaps to unfavorable surroundings. Indications of this kind occur sporadically throughout the Jurassic time and become general in the Cretaceous period. Many of the later forms were openly or grotesquely coiled, or coiled only when young, becoming nearly or quite straight when they grow older, as in Ptychoceras, Turrilitae, Scaphites, etc. These degraded "old-age" types were evidently due to the waning forces of life or to disease, because similar though much less marked uncoiling of shells, due to unfavorable condition of the water, have been observed in the fresh-water Planorbus of Steinheim, Germany, and elsewhere. (See EVOlUTION; SENESCENCE). Hyatt thus infers that there was in the European seas, at least, a widespread unfavorable change in their physical surroundings, "similar to, but not exactly like, that which affected European forms during the Lower Oolite," and to this influence he ascribes the uncoiling of the shells of Spiroceras and its allies. At the close of the Cretaceous period the ammonoids entirely disappeared. We thus see in the vast and more or less complete and continuous series of these beautiful shells, in which the imperfections of the geological record are less marked than in other groups, the process of rise, culmination, decline, and death of a type, presenting also beautiful illustrations of the biogenetic law (q.v.). The type begins with infantile and larval forms, then evolves youthful, mature, and finally old age forms, which present in their simple and closely coiled shells a return to the original simplicity of the infancy and childhood of the type.

Concerning the animals which made the shells, nothing is known except by inference. The growth of the shell begins with the formation of the primitive conically-shaped shell called "procone," and then the secondary shell begins to grow and becomes coiled up in one plane. Like the nautilus the mollusk lived in the outer chamber of its shell, from which it periodically advanced. The aperture of this outer chamber was closed when the animal withdrew into it, either by a single horny plate (anaptychus) or by a pair of calcareous plates (aptychus). The very earliest appear to have been swimmers, like the nautiloids; but the great bulk of the ammonites undoubtedly lived gregariously alongshore, where they crawled about, carrying or partly dragging their shells, and searching for the animal food upon which they subsisted. The least careful shell points out that their shells were proportionately less bulky than those of the nautiloids, and correspondingly less buoyant; and the probability is that they swam little and were rarely active. There is reason to believe that in the case of some species the eggs were retained within the shelter of the living-chamber until they hatched, and that the young remained there until somewhat grown. See Goniatites.

AMMONIUS SACCAS, a Greek philosopher who lived about 175-250 A.D. Originally a porter in Alexandria, he derived his epithet from the carrying of sacks of corn. The son of Christian parents, he abandoned their faith for the polytheistic philosophy of Greece; this is denied, however, by Eusebius and Jerome. His teaching was historically a transition stage between Platonism and Neo-Platonism and he may be regarded as the founder of the latter school. Among his disciples were Plotinus, Longinus, Origen the Christian, Origen the Neo-Platonist, Herrenius, Antoninus, Theodosius, etc. He wrote numerous books but his tenets were propagated by his pupils, especially by Origen, Herrenius and Plotinus.

AMMONOIDEA, an order of tetrabranchiate cephalopods. It contains more than 5,000 species, all of which are extinct and found in a fossil state in marine rocks of the Devonian, Carboniferous and Mesozoic ages in all parts of the world. It is akin to the Nautiloidea and was a crawler instead of a swimmer. Its especial interest consists in that it furnishes the best illustrations of evolution, the laws of growth and decline, of ontogeny and ptyogeny. See AMMONITES; CEPHALOPODA.

AMMONOSUCUS, the name of two small rivers in New Hampshire which rise in Coos County and flow in a southwest direction, emptying into the Connecticut River. The lower Ammonoosuc is about 100 miles long and the upper 75 miles long.

AMMOPHILA, a genus of grasses, common on sandy beaches of European and eastern North America, coarse perennials with running root-stocks. They are valuable as sand-binders, and are often planted on sand dunes to prevent drifting.

8 Ammonites cavernosus  9 Ammonites rotula  10 Ammonites Humphryi
AMMUNITION. Ammunition is prepared at the various arsenals and by numerous private manufacturing companies. Bags of serge, in enormous number, are cut out and made, and filled to form cartridges for small arms; while the ball-cartridges are enclosed in thin copper cylinders. The tubes and combustibles for war-rockets and fuses are also manufactured, and cartridges for all arms (rifled muskets, carabines and pistols) are made in millions; since it is on those that the main offensive operations of an army depend. It has been calculated that an army of 60,000 men, comprising a fair average of infantry, cavalry, artillery and engineers, ought to be provided with no less than 18,000,000 ball-cartridges for small-arms, for six months' operations. These would require 1,000 ammunition-wagons and 3,600 horses to convey them all at once. It is, therefore, deemed better that, under any such circumstances, there should be established entrepôts for supplying the troops from time to time. The wagons constructed for this kind of service will carry 20,000 rounds of small-arm ammunition each; ten such wagons, packed in boxes, and the wagons are drawn by four horses each. Several wagons are organized into an "equipment," under the charge of a detachment of artillery, and there are several such equipments for an army of the magnitude above mentioned—one for each division of infantry, a small portion for the cavalry, and the rest in reserve. It has been laid down that an army of 60,000 men ought to have 2,680,000 cartridges with them, besides those in reserve; and that the conveyance of such a quantity, with a few forges and storage-rooms, would require 150 ammunition wagons, 830 men and 704 horses. The equipment would return to the entrepôt for a new supply when needed. In the Peninsular War, and at Waterloo, the English used two-horse carts, carrying about 10,000 rounds of small-arm ammunition each; but a superior kind of wagon has been since introduced. In the field, an infantry soldier usually carries about 60 rounds, but in compartments in his pockets.

The packing-boxes for field-ammunition are made of well-seasoned stuff (generally white pine), 1 1/4 inch thick, dovetailed with the tenon on the ends. The top of the box is fastened with six 2-inch screws. The box has two handles of 1/4-inch rope, attached to brackets at the ends. The boxes are painted on the outside different colors to indicate the contents of the box. Those containing shot are painted olive; shells, black; spherical case-shot, red; and canister, light drab. The kind of ammunition is marked on each end, in large white letters. The place and date of fabrication are marked on the inside of the cover. The boxes are packed as follows:

For Smooth-bore Guns. Shot, spherical case and canisters, fixed.—Laid in two tiers across the box, the shot or canisters alternating with the cartridges at each side. The shot or canisters of the upper tier rest on those of the lower and not on the cartridges. Canisters are packed in the same manner, omitting the strips of wood in the bottom. For 12-PDR. Mountain-howitzer. Shells and cast-shot, fixed.—Placed upright, the balls down, resting on strips of wood as for the other howitzer. Canisters are packed in the same manner, resting on the bottom of the box.

For Rigged Guns. Shells and Case-shot.—Placed upright, the shells resting on strips of wood as for the howitzer. The iron part of the balls rests against strips of wood 4 inches wide and 2 1/2 inch thick, nailed to the side and ends of the box at the bottom, and similar strips placed between the rows of the balls to prevent the soft metal cans from bearing against the box or against each other and being bruised; the cartridges are placed on top of the projectiles. Canisters are packed in the same manner as the case-shot, omitting the strips of wood on the bottom of the box. In all the boxes the small stories are placed in the vacant spaces on top of the ammunition. A layer of tow is placed in the bottom of each box, and the whole contents are well packed in tow, filling the box so as to be pressed down by the cover. About three pounds of tow are required for a box.

Ammunition is supplied to troops in campaign in the following manner: It is shipped from arsenals to ammunition depots at the base of operations; it is then carried by line of communications to the advance supply depot and there delivered to the ammunition trains. The combat trains are replenished from the ammunition trains, though in exceptional cases issues from a supply depot may be made direct to combat trains. From the latter ammunition is delivered to the troops. At the beginning of a general engagement two wagon companies for each division engaged (including the cavalry division) are loaded—one with small arms and the other with artillery ammunition—and held in readiness at the advance supply depot.

Ammunition Trains.—The ammunition train of a full division is normally loaded as follows: (a) For small arms (three wagon companies, 81 wagons), 77 wagons, each with 25 boxes (1,200 rounds per box) of rifle and 1 box (2,000 rounds) of revolver ammunition, and 1 wagon with 300 boxes of revolver ammunition. (b) For artillery (2 wagon companies, 54 wagons), 51 wagons, each with 25 boxes (4 pounds per box), and 1 artillery stores. If available, caissons instead of wagons may be used for carrying artillery ammunition. Each caisson carries 106 rounds, or 48 caissons would carry about the same as 51 wagons. During combat the ammunition train takes station as ordered. It is generally in a protected position, near good roads if possible, where the empty battalion ammunition wagons or caissons can be replenished. It may be advisable to divide the train and assign the parts to different positions in rear of the line. A brigade commander may select a rendezvous station for the empty battalion ammunition wagons of his command and request that wagons from the ammunition train be sent to that place to refill battalion wagons. The position of an ammunition train, or detached part thereof, is marked by a red flag during the day, and by a red lantern at night.

Combat Trains.—The small-arms ammunition wagon (2 for each infantry battalion and 1 for each squadron) in addition to extra tools, etc., is usually loaded as follows: Infantry, 22 boxes of rifle ammunition; cavalry,
AMMUNITION SERVICE

20 boxes of rifle and 4 revolver ammunition. Ammunition in the artillery combat trains is carried in caissons. Battalion commanders are charged with keeping their ammunition wagons properly filled and replenished.

As a rule, combat trains march immediately in rear of the battalion unit to which assigned, though when combat is not probable they may be assembled in rear of their respective regiments, or sent to join the trains.

Artillery.—The distribution of small-arms ammunition allows 330 rounds per rifle, with a reserve for machine guns, etc. Engineers or signal troops requiring ammunition draw from the nearest ammunition wagons. Cavalry and other men armed with both rifle and revolver carry in the belt 90 rounds of rifle and 20 rounds of revolver ammunition.

In campaign all officers and non-commissioned officers endeavor to keep the belts of their men filled with ammunition. Not only must advantage be taken of every opportunity to replenish the supply, but prospective expenditures must be anticipated by issuing ammunition in advance. As troops go into combat two bandoliers from the combat train are issued to each man, unless otherwise ordered. If additional ammunition is needed during the combat, the lead mules of battalion ammunition wagons may be converted into pack mules and ammunition delivered to the firing line in that manner. If this is impracticable, small squads of men under non-commissioned officers may be detailed to carry ammunition to special parts of the firing line, or reinforcements may be given extra ammunition for that purpose. If available the division pack train is used to carry ammunition to ground impracticable for wagons, or wherever it may be urgently needed.

Every lull in the fight must be utilized to renew the supply, and to equalize the same in each company. The contents of the belts of the dead and wounded are distributed whenever practicable, though the latter must not be left wholly without means of self-defense. In no case are men sent to the rear for ammunition, if it can be obtained in any other manner. When ammunition is running low, officers caution the men to preserve a few rounds each for emergency. The men following an engagement should find the firing line and all ammunition wagons replenished.

Artillery.—When the battery goes into action each piece is supplied from its own caisson. With the firing battery are two additional caissons from which the gun caissons are replenished. This replenishment is ordinarily effected by the cannoniers during lulls in the action. The ammunition in the gun limbers is kept intact as a last reserve, and whenever used is replaced as soon as practicable. The emergency ammunition on the guns is used only in extreme cases, and must be immediately replaced. Caissons from the reserve (combat train) replace empty caissons of the firing battery. Empty caissons are either refilled from the members of the reserve caisson or sent to the ammunition train to be refilled. If necessary, wagons or caissons from the ammunition train may be sent direct to the firing battery. Horse batteries in a cavalry action draw ammunition from the limbers; the ammunition so used should be replaced as soon as practicable.

Cavalry.—Ammunition Train.—The ammunition train of a cavalry division is normally loaded as follows: (a) For small-arms (2 wagon companies, 54 wagons) — 52 wagons, each with 20 boxes of rifle and 4 boxes of revolver ammunition. (b) For artillery (1 wagon company, 27 wagons) — 25 wagons, each with 25 boxes, and 1 wagon with 12 boxes and artillery stores. Rations, forage and the necessary intrenching tools are also carried, but the loads are kept as light as possible. The ammunition for a cavalry division is carried, distributed and replaced substantially as in the case of infantry, the cavalryman carrying 90 rounds of rifle and 20 rounds of revolver ammunition in the belt, and, when combat is imminent, 60 rounds of rifle and 20 of revolver ammunition in the saddle bags. Combat trains of cavalry acting independently generally march with the horse artillery, if any; otherwise in rear of their squadrons or regiments or with the ammunition train. As cavalry in campaign is liable to be separated from its combat and ammunition trains, it is authorized, in such emergencies, to draw from the most available ammunition wagons or source of supply. The use of pack animals is often necessary.

Ammunition Supply for a Field Army.—To replace ammunition used in combat an amount not less than that carried by the mobile forces should be kept at or near the advance supply depot, and an additional amount approximately equal to all ammunition in advance of the base should be available at the base of operations or other depots. This distribution, in rounds, is shown in the foregoing table. See CARTRIDGES; EXPLOSIVES; SHRAPNEL.

AMMUNITION SERVICE. This resembles the service of supply (q.v.), but differs in that no ammunition can be replenished by foraging. The ammunition service is organized by the field artillery, and its commander is directly under the commander of the latter. Ammunition on the man and on the caissons of the firing batteries is replenished by the captured or organized combat trains, which are ordinarily refilled from the divisional ammunition train, though they may be refilled from the line of communications. Economy and a continuous supply of ammunition must be attained by the concerted efforts of all. The normal course of ammunition is from the railhead in the line of communications by the ammunition column to the refilling point, where the zone of active operations commences. From there it is transported to the distributing points by the ammunition train, which may be subdivided into two companies or battalions acting tandem, the one refilling from the other. From the distributing points it is brought to the separate organizations in their own combat trains. The whole organization continually advances as far as possible, bringing the distributing and refilling points to the front, and shortening the hauls of the combat and ammunition trains. Any part of the route indicated may be eliminated or omitted: for instance, the refilling point may be at the railhead. In the present war, there is a tendency to replace the various units of the ammunition service, up to the heavier guns, by their own distributing points, by the infantry and some of the lighter guns, by narrow-gauge railways.
AMMUNITION TRAINS. See AMMUNITION.

AMNESIA, ā-mē'ni-sə. See APHASIA.

AMNISTRY, an act of oblivion passed after an exciting political period. Express amnesty is one granted in direct terms. Implied amnesty is one which results when a treaty of peace is made between contending parties. Amnesty and pardon are very different. Amnesty is an act of the sovereign power, the object of which is to efface and to cause to be forgotten a crime or misdeed. A pardon is an act of the same authority which exempts the individual on whom it is bestowed from the punishment which the law inflicts for the crime he has committed. 7 Pet. (U. S.) 160. Amnesty is the abolition and forgetfulness of the offense; pardon is forgiveness. A pardon is given to one who is certainly guilty or has been convicted; amnesty, to those who may have been so.

AMNISTRY PROCLAMATION. An act passed 25 Dec. 1868, granting amnesty to all who were guilty of treason against the United States or adhered to their enemies during the Civil War and included domiciled aliens. But the proclamation did not entitle one whose property had been sold under the Confiscation Act of 1862 to reclaim the proceeds after they had been paid into the treasury of the United States.

AMNION. See EMBRYOLOGY.

AMOEBA, or PROTOZOO ANIMAL-CULE, a protozoo classified as one of the rhizopods, which is present almost everywhere in fresh water, and sometimes in moist earth, and is commonly taken as the type of the unicellular animals. It is a mere drop of animated jelly (protoplasm, q.v.), hardly visible to the unaided eye, which under the microscope is seen to be divisible into an inner granular mass (endosarc) and an outer clearer part or envelope (ectosarc); but there is no essential difference in substance between them. Imbedded in the interior granules is a large spherical globule, the nucleus, consisting of a clear chromatic substance containing minute granules of chromatin. A contractile vacule lies in the ectosarc, and manifests more or less regular and rhythmical expansions and contractions; this seems to serve the purpose of an excretory organ. The amoeba continually throws out irregular threads and extensions (pseudopods), so that its shape is more often like that of a drop of any thick liquid which has fallen and spattered, than of a globule; this shape is changing incessantly as the creature slowly creeps about. Whenever it touches any edible particle of organic material it slowly enfolds it, and the particle sinks into the body, where it is gradually dissolved, its nutritive material is digested and assimilated, furnishing food and fuel to the protoplasm, and the innutritious parts are finally gathered into the vacule, whence they are squeezed out and discarded. Amoeba reproduces itself by a simple process of division. A constriction takes place at a point where the nucleus will be divided, and goes on until the animal becomes dumbbell-shaped. Finally the two parts separate, and each becomes a distinct and perfect whole, each with its half of the original nucleus, which at once becomes, in each case, a whole nucleus. After a time these individuals in turn undergo a similar division and so on. It may therefore be said that amoeba never ceases to exist—never dies; but simply multiplies indefinitely by repeated divisions.

Certain forms of Amoeba, notably A. coli, are the cause of a distinct kind of dysentery now termed amoebic dysentery. This disease mostly of the tropics, but is also found endemic in the United States. Occasionally the parasite may infect the liver, causing an abscess in that organ. The disease is difficult to treat.

AMON-RE, a-mōn-rē (originally Re and later Amon Re), the national god of Egypt during the greater part of its history. His worship was a form of sun-worship. The insignia of the god was the "solar disc encircled by the poisonous uraeus serpent." In the 12th dynasty, to strengthen the hold of Thebes on the country, the local Theban divinity Amon was transformed into the sun-god Amon-Rē. His worship extended beyond the confines of Egypt. Thebes was the centre of the worship and for a time his high-priests were the rulers of Egypt. His consort was Mut, the mother of the gods.

AMONTONS, a-mōn-tonz', Guillaume, French experimental philosopher: b. Paris, 31 Aug. 1663; d. there, 11 Oct. 1705. He devoted himself particularly to the instruments employed in physical experiments. In 1687 he presented to the Academy of Sciences an hygrometer of his own invention, and in 1695 he published his only book "Re- marques et expériences physiques sur la construction d'une nouvelle clepsydre, sur les baromètres, les thermomètres et les hygromètres. In 1699 he published some investigations on friction, and in 1702-03 two noteworthy papers on thermometry. He experimented with an air-thermometer, in which the temperature was defined by measurement of the length of a column of mercury; and he pointed out that the extreme cold of such a thermometer would be that which reduced the "spring" of the air to nothing, thus being the first to recognize that the use of air as a substance led to the inference of the existence of a zero of temperature. In 1704 he noted that barometers are affected by heat as well as by the weight of the atmosphere, and in the following year he described barometers without mercury, for use at sea.

AMOR, the god of love among the Romans, equivalent to the Greek Eros. He had no place in the national religion of the Romans, who derived all their knowledge of him from the Greeks. According to the later mythology Amor is the son of Venus and Mars, the most beautiful of all the gods; a winged boy with bow and arrows, sometimes represented bird-shaped. His arrows inflict the wounds of love, and his power is formidable to gods and men. He is not always a playful child in the arms of his mother, but appears sometimes in the bloom of youth, for example in the story of Psyche. He is brother of Hymen, the god of marriage, whom he troubles much by his thoughtlessness. According to the earlier mythology he is the oldest of all the gods, and existed before any created being. In English the
god of love is less frequently called Amor than Cupid; yet with the ancients cupidus denoted, properly, only the animal desire.

AMORGOS, Ἀμόργος, an island in the Grecian Archipelago, one of the eastern Cyclades, 22 miles long, five miles broad; area, 106 square miles; has a town of the same name, with a castle and a large harbor. Pop. 5,000.

AMORITES. Though made a separate tribe in the varied and rhetorical lists of the peoples in Canaan ousted by the Israelites, the name is used by Amos in the 8th century as a general term for the primitive inhabitants of Canaan, with attribution of gigantic size and power, as most old nations do with their special aboriginal predecessors. Some critics think, however, that “Canaanite” is used for the peaceful settlers of the plains, and “Amorite” for the warlike tribes on the hills to the north. At any rate, the latter term is always used when hostile tribes are meant. Moses’ foes include Sihon and Og, the Amorite kings, and Joshua deals with 12 kings of the Amorites west of the Jordan. The Amarna letters show that the coast as far north at least as Sidon was called Kinah (Canaan), and perhaps the Amorites were the people of the interior; but the usages, may be due to the writers coming from different sections.

AMORPHISM, a term used in chemistry and mineralogy to denote the absence of regular or crystalline structure in a body.

AMORTIZATION, (1) the act of satisfying, liquidating or reducing, as a debt, usually by a sinking fund. The term has a wider application and is more commonly used recently in this sense than formerly. It is often applied to securities in figuring their investment value. For instance, if a security is bought at a premium or at a discount, a part of the premium is charged off or a part of the discount is credited so as to bring the value of the security to par at maturity. In each case the transfer is made from investment to investment, or from the common fund to the individual owners. The common application of the term in this sense is to investments having a life of limited duration, as mines. Dividends on such investments are treated not only as interest on capital but also as the return of capital itself. As an illustration, if securities in a mine are purchased and such securities yield an annual dividend of 12 per cent, 6 per cent may be treated as income and 6 per cent as return of capital. If the 6 per cent treated as return of capital is again invested at 4 per cent interest, a simple mathematical calculation will determine the number of years required for the return of the investment originally made. The term is also often applied to the paying off of a mortgage by instalments or by a sinking fund.

(2) The process of satisfying, liquidating or reducing, as a debt.

(3) The alienation of lands to a corporation having perpetual succession; the conveyance of lands in mortmain. Formerly this was applied to ecclesiastical corporations only, but later it was applied to any corporation which by its nature could be perpetual. Alienation of lands to corporations is governed by statute in Great Britain and in some States in this country.

AMORY, Blanche, a shallow, selfish, worldly girl in Thackeray’s novel ‘Pendennis.’

AMORY, Robert, physician: b. Boston, 3 May 1842; d. 1910. He was graduated at Harvard 1863, M.D. 1866, and studied in Paris and Dublin. He was lecturer at Harvard on the physiological action of drugs 1869, then professor of physiology at Boston Medical College till 1874. Author of ‘Bromides of Phosphorus and Ammonium’ (1872); ‘Action of Nitrous Oxide’ (1870); and important papers on ‘Chloral Hydrates,’ ‘Pathological Action of Prussic Acid’ and ‘Photography of the Spectrum’; the volume on ‘Poisons’ in Wharton & Stillé’s ‘Medical Jurisprudence’; and ‘Electrolysis and Its Applications to Treatment of Disease’ (1886).

AMOS, a prophet of ancient Israel, lived in the middle period of the 8th century B.C. His home was Tekoa, a mountaintop village about 12 miles south of Jerusalem, on the border of Judah and Benjamin, and described himself as a shepherd and a tender of sycamore fig trees, denying all connection with the sons of the Prophets. Though a citizen of Judah, Amos preached at Bethel, one of the royal sanctuaries of northern Israel, in the latter half of the prosperous reign of Jeroboam II (2 Kings xiv, 23–28). He is the earliest of the ‘writing prophets,’ i.e., those whose oracles have been preserved as separate books.

The book of Amos is made up of (1) An opening address to the throng at the Bethel sanctuary (Chaps. i–ii). (2) A group of three addresses each beginning “Hear this word” (Chaps. iii–vi). (3) A series of symbolic visions with mingled exhortations (Chaps. vii–ix), and an historical statement (vii, 10–17). The book is thus one of the most systematically arranged of all the Prophets and, at the same time, exhibits the variety of structure that enters into the composition of the prophetic writings — oratory in poetico form and diction, a bit of song (v, 2), symbolic vision, biographical narrative. Expressing himself in the name of the Lord, the writer is a master of vivid illustration from nature and history, of rhetorical period or terse antithesis, of emotional appeal and concrete picturing of facts. In the pages of this tiny book the horrors suffered by the people of the east-Jordan districts, over whose territories the wars of Israel and Damascus had raged in former reigns, are still most vivid, while the vices of Israel in Jeroboam’s victorious reign are most realistically presented. Bribery in the law courts, dishonesty of the merchants with their false balances and measures, oppression of the poor to secure the means for the coarse or elegant indulgences of the newly rich and their gross wives are some of the social conditions pictured as existing in conjunction with abundant ritual of sacrifice and music, and outward observance of sacred days. With the skill of a consummate orator Amos could lead his hearers on from accepted and congenial truths to new and unwelcome ideas, or with a concise description of hard fact to symbolic vision.

The message of Amos by its originality and significance marks one of the greatest advances
in religious history. Now for the first time the God of Israel is clearly presented as the God of nations who will punish injustice done by Moab to Edom as well as that done by Edom to Israel, and who uses the warring nations of the world to carry out his own righteous purposes. This great God of history is also conceived as one whose essential service consists in righteous conduct toward men rather than in war, justice or any form of communal. As a corollary of such conceptions, Israel's past privileges are counted ground of her greater responsibility rather than earnest of greater material blessings. Earlier teachers had made ethical demands in the name of Jehovah, but Amos first clearly pictures him as the just God of nations whose primal demand is for justice in economic and international relations.

The book of Amos has suffered relatively less expansion by subsequent hands than many of the Prophets. The principal section generally regarded as a later addition is ix, 8-15.

Important recent commentaries are those of G. A. Smith, 'Book of the Twelve' (in 'Expositor's Bible'), and W. R. Harper, 'Amos and Hosea' (in 'International Critical Commentary'). The book is discussed in the Old Testament Introductions of Driver, Cornill, McPadyen, Creelman, in Fowler, 'History of Literature of Israel,' and in the recent Bible dictionaries.

Henry T. Fowler,
Professor of Biblical Literature, Brown University.

AMOY, ą-moi', China, a city and treaty-port in the province of Fuh-kien. It is a large and exceedingly dirty place, about nine miles in circumference, and is divided into two parts, an inner and an outer town, which are separated from each other by a ridge of hills, on which a citadel of considerable strength has been built. It possesses two commodious harbors. There are dry-docks and an excellent anchorage. The chief articles imported are sugar, rice, raw cotton and opium, as well as cotton cloths, iron goods and other European manufactures. The chief exports are tea, porcelain and paper. The trade carried on by means of Chinese junks is said to be large, and the native merchants are considered to be among the wealthiest and most enterprise in China. The annual imports are about $10,000,000; the exports $2,000,000. The falling off of exports in recent years is due to the decreased demand for China tea, for which Amoy was one of the chief centres. Amoy was captured by the British in 1841, after a determined resistance, and is one of the five ports that were opened to British commerce by the treaty of 1842. It is now one of the largest of the unit called the amperes. Since electric currents may be either continuous, i.e., unidirectional, or alternating, and the latter of high or of low frequency, amperes may be divided into those (a) for continuous, or direct currents, (b) for low frequency alternating currents, and (c) for high frequency alternating currents. A continuous electric current of one amperes is defined to be one which deposits electrolytically 0.001118 of a gramme of silver per second from a neutral solution of silver nitrate. An alternating current of one amperes is defined to be one which produces the same heat in a second in a wire as the unit continuous current defined as above to one amperes. These definitions provide a basis on which the calibration of amperimeters can be conducted. They are therefore classified according to the physical principle on which they are constructed. An electric current is recognized by its ability (a) to create heat in a wire through which it passes, (b) to produce a magnetic field round the conductor or wire. The heat makes itself evident by raising the temperature and therefore elongating the wire, whilst the magnetic field creates mechanical
forces which act on pieces of iron or other conductors conveying electric currents when placed in proximity to the conductor in question. Hence, (a) Ameters are classified into (a) Thermal; (b) Electromagnetic; and (c) Electrodynamic instruments.

AMPHIBIA, a class of back-boned creeping animals comprising the newts, frogs and toads, together with several extinct groups, which is classified between the fishes and the reptiles. The most prominent characteristic is indicated by the name, which refers to the fact that these animals are provided with a respiratory apparatus which enables them to breathe both water and air. It is not meant, however, that the Amphibia are able to breathe in either or water at the same time, but that the young are provided with gills and live in water up to a certain age, or in rare cases permanently, after which they acquire lungs and thereafter breathe atmospheric air. As these young as a rule are different from their parents and must undergo metamorphosis from the larval to the adult condition, amphibians of the class are usually said to undergo metamorphosis, but this is equally true of some fishes and it is not true of all amphibians. The evidence not only of modern similarity of structure, but that obtained from a study of the fossil forms, makes it plain that the Amphibia are the result of the evolution of a branch from an ancient fishstock, probably by way of the lung-fishes or Dipnoi (q.v.). On the other hand they are related in a not very different reptiles. The connecting link, according to Gadow, is formed by the Stegocephali; all the recent orders are far too specialized. The line leading from Stegocephali to fossil reptiles is extremely gradual, and the same consideration applies to the line which leads downward to the fishes; but the great gulf within the Vertebrata lies between fishes and amphibians, that is, between absolutely aquatic creatures with internal gills and fins, and terrestrial four-footed creatures with lungs and fingers and toes. No great phylogenetic importance attaches to the possession of external gills, as it is not unlikely that in the Amphibia these organs owe their origin to entirely larval requirements.

Although in the Palæozoic age the great stegocephalous amphibians (more usually called labyrinthodonts, q.v.), flourished as the only terrestrial vertebrates of importance, the class never attained a dominant position. Intermediate between the aquatic fishes and the gradually rising terrestrial reptiles, the amphibians were pushed aside in a double way by the struggle of evolution, until now most of them have become extinct. The remainder persist only because they have found shelter in the nooks and corners of the world to which they have become adapted by small size and aquatic habits; and only one group, the frogs and toads, fortunate in their plasticity, have spread over the whole globe and exhibit some richness in forms.

The class Amphibia is divided into two subclasses: (1) Stegocephali (q.v.), which is wholly extinct; (2) Lissamphibia, which includes all of the modern forms, contained in three orders: (1) Apoda, or Gymnophiona, composed of the family Cæcilidae (see Cæci-

IAN); (2) Urodela, including the long-tailed, smooth-skinned, aquatic salamanders, newts, mud-puppies and the like; (3) Anura, comprising the tailless forms, or frogs and toads, of which there are two divisions,—the few Aglossa, which have no tongue, and the tongue-bearing Phaneroglossa, which includes the great majority of forms. The existing species number about 1,000.

Fossil Amphibia.—The modern frogs and salamanders are a small and scanty remnant of the Amphibia of Palæozoic times. During the Carboniferous and Permian periods they were the dominant form of life and of great variety in form, including some of very large size, 12 feet or more in length. All these ancient Amphibia belong to an extinct group, the Labyrinthodontia (sometimes called Stegocepha-

lida), or *armored amphibians,* distinguished by having the wide flat head completely roofed over with bone, and the body more or less armored with bony plates and scales. The skull has two openings for the ears at the front margin for the nostrils and a single one in the middle for the pineal eye. Like modern amphibians, they breathed by gills when young, but by lungs when adult. All had long tails and most of them short, some elongated and snake-like, others tadpole-like with large heads shaped like a broad arrow (Diplocaulus) and no limbs; others, and these the largest, heavy-bodied, with flat conical or semi-circular heads, short legs and five-toed feet (Labyrinthodon, Eryops). These ancient amphibians illustrate various stages in the evolution of the backbone of modern Vertebrata from the notochord or segmented rod of cartilage from which it was derived. In the smaller and more primitive types the segments of cartilage are but slightly ossified in a number of separate plates or incomplete rings of bones. In others each vertebra is composed of two or four pieces, which remain separate during life instead of consolidating into a single bone, as in modern vertebrates. In others, again, the vertebra is completely united. The oldest known labyrinthodonts are from the Carboniferous rocks, and are related to some of the older Palæozoic dipnoan fishes, from which they may have been descended. In the Permian they attained large size and great abundance, and continued into the Triassic period, by the end of which they had become extinct. Their foot-tracks, often preserved in muddy sandstones of these periods, are sometimes curiously like the impressions of a human hand, whence they received the name of Chiro-

therium, or *beast-with-a-hand,* before their nature was recognized. The frogs and salamanders are probably descended from primitive labyrinthodonts, but are very little known as fossils. One fossil species, allied to the giant salamander of Japan, was found in the Miocene strata of Oeningen many years ago (1726) and was supposed by an early naturalist to be the fossil skeleton of a man, and described as *homo diluvii testis et thecoscopus*—the man who was witness to the Deluge and saw God—a quaint reminder of the geological speculations of two centuries ago. For breeding habits, distinctive characteristics and modes of life see special articles under the various species. For good recent treatment of the Amphibians
AMPHIBIA

1 A Spanish Salamander (Pleurodires waltii)
2 European Crested Newt (Triton cristatus)
3 Menobranch (Necturus maculatus)
4-5 East African Toad (Brevicps mossambicus)
6 A Mexican Toad (Rhinophrynus dorsalis)
7 An Amphibiens (Siphonops annulatus)
8 Horned Frog (Ceratobatrachus Guelberi)
9 Flying Frog (Rhacophorus pardalis)

AMPHIBIOUS PLANTS. Certain plants, such as some liverworts, the knot-weed, Polygonum amphibium, Sagittaria heterophylla, the water-buttercup, Ranunculus aquatilis, and the mermaid-weed, Proserpinacea. pallustris, can grow and flourish either in water or in air; and are consequently called amphibious. The same plant will often assume great differences in form in the two environments. This is especially shown in the leaves. Those of Polygonum amphibium, hairy in air, are smooth in the water. Sagittaria has ordinary leaves in the air, but phyllodes in the water. Ranunculus and Sagittaria have dissected leaves in the water, but leaves of the familiar broad-bladed form on land, with transitional forms at the surface of the water. It has been shown that the stimulus which produces this change in leaf-form is the transpiration which the leaf undergoes in air. Stems growing under water become flaccid at the surface, and the same plant which in the air has strength enough to hold itself erect will depend in the water on the surrounding medium for its support. Consult Coulter, J. M., Barnes, C. R., and Cowles, H. G., 'A Text-Book of Botany' (Vol. II, New York 1911).

AMPHIBOLE, am'ﬁ-ból (from the Greek amphibolos, "doubtful") in allusion to the difficulty of distinguishing it from pyroxene). In mineralogy, (1) a common mineral, crystallizing in the monoclinic system, and varying greatly in chemical composition. The name was first given by Hauy in 1801 as distinguishing a species—regarded by Hauy as hornblende and actinolite as varieties. In 1809 he included tremolite also. In general, the species may be described as a normal metasilicate of calcium and magnesium, associated with iron, manganese, sodium, potassium and hydrogen.

(2) Amphibole Group.—An important group of minerals, including the species described above, and taking its name therefrom. Its constituent species are widely different in chemical composition, and are closely allied to the members of the pyroxene group. All the species of the amphibole group have a prismatic cleavage of from 54° to 56°, and they also exhibit close relationships in the optical properties. All the species of the pyroxene group have a fundamental prism with an angle of 93° and 87°, the corresponding angle in amphibole being 56° and 124°. The specific gravity of the pyroxene is usually higher than that of the species of the amphiboles with which they are likely to be confused. Alkalis are met with more commonly in the amphiboles, and magnesium is also more prominent in that group. The amphibole group is divided into three main sections according to the crystalline forms of its species. Dana's classification is as follows:

A. ORTHOHOMNIC SECTION. Anthophyllite. (Gedrite).

B. MONOCLINIC SECTION. Amphibole:
Non-aluminous varieties:
- Tremolite.
- Actinolite.
- Cummingtongite.
- Dammernite.
- Glaucite.
- Richterite.
Aluminous varieties:
- Edenite.
- Paraglass.
- Hornblende.
- Glaucophane.
- Riebeckite.
- Crocidolite.
- Añfvedsonite.
- (Backovičite).

C. TRICLINIC SECTION. Magnesite.

AMPHIBOLOGY, an equivocal phrase or sentence, not from the double construction, as "The duke yet lives that Henry shall depose." The words that may be ambiguous, and consequently the sentence may be an example of equivocation, not amphibology. Fallacies of amphibology are purely verbal, and seldom found apart from other types of verbal fallacy. They are so obvious that they do not constitute a serious source of unsound thinking.

AMPHICYTONIC LEAGUE OR COUNCIL, in ancient Greece, an assembly composed of deputies from 12 Greek tribes, each of which sent two deputies, who assembled each year at Delphi, and again at Thermopylae, with great solemnity; composed the public dissections, and the quarrels of individual cities, by force or persuasion; punished civil and criminal offenses, and particularly transgressions of the laws of nations and violations of the temple of Delphi. It forbade the destruction of a city of the league or the obstruction of its water-supply in war or peace. After the decision was published a fine was inflicted on the guilty state, which, if not paid in due time, was doubled. If the state did not then submit, the whole confederacy took arms to reduce it to obedience. The assembly had also the right of excluding it from the confederation. An instance of the exercise of this right gave rise to the Phocian War, which continued 10 years (a. c. 355-346). The council also administered the Pythian games. Consult Tittmann, 'Über den Bund der Amphicytonymen' (Leipzig 1880); Freeman, 'History of Federal Government' (2d ed. London 1893).

AMPHICYON, a genus of extinct mammals, found fossil in Miocene rocks, which is usually placed among the extinct Canidae (dogs), but has many bear-like features, such as plantigrade, five-toed feet and the structure of the ulna and radius. The largest species was about the size of a bear, but with a very dog-like head. It belonged to the Old World, but a closely allied American Miocene form is Daphnus.

AMPHINEURA. See MOLLUSKS.

AMPHION, in Greek mythology, son of Zeus and Antiope, his twin brother being Zethus. He is represented as being the oldest of
the Grecian musicians. In Lydia, where he married Niobe, the daughter of King Tantalus, he learned music and brought it thence into Greece. He reigned in Thebes, which he partly built, and it is said that at the sound of his lyre the stones voluntarily formed themselves into walls; also that wild beasts, and even trees, rocks and streams followed the musician. With the aid of his brother Zethus he is said to have avenged Antirrhan and been imprisoned and ill-used by his father, and to have bound Dirce, his stepmother, to the horns of a wild bull. This incident is supposed to be represented by the famous piece of sculpture, the Farnese bull, in the Farnese Palace at Rome.

**AMPHIOXUS**, the lancelet, a small animal of the marine sub-phylum Cephalochordata, of the great phylum Chordata (q.v.), to which the vertebrates belong. Its scientific name is Branchiostoma. From its somewhat worm-like form it was for a long time regarded as a worm by some authors and originally as a mollusk (Limax) by Pallas. It is now named Branchiostoma lanceolatum; lives buried in the sand just below low-water mark, the head or 'oral hood' projecting above into the water. It also swims in a vertical or upwards position, also frequently lying on one side on the sand; and burrows head foremost rapidly downward in the sand. It extends along our coast from the mouth of Chesapeake Bay to Florida; also on the eastern coast of South America, in the Mediterranean, the East Indies and Australia, the species being truly cosmopolitan. Another very closely allied genus, Asymmetron, includes two species, one of which occurs at the Bahamas and the other in the Louisade Archipelago, southeast of New Guinea.

The body of *Amphioxus* is about two inches in length, slender, compressed, pointed at each end, hence the generic name (*Amphioxus*, αμφί both, ος, sharp), the head-end being thin and compressed. The 62 Y-shaped muscular segments are distinct to the naked eye, and alternate on the two sides. From the mouth to the vent is a deep ventral furrow and a slight dorsal fin extends along the back and beneath as far front as the vent, forming the ventral fin, while the wider portion at the tail is the caudal fin. The oral hood has a large median external opening, which is oral, surrounded with a circle of ciliated tentacles supported by semi-cartilaginous processes arising from a circumoral ring. At the bottom of this opening is the small mouth which leads directly into a large broad pharynx or 'branchial sac', protected at the entrance by a number of minute ciliated lobes. The walls of this sac are perforated by long ciliated slits, of which there are more than a hundred pairs, comparable with those of the branchial sacs of ascidians and of Balanoglossus. The water which enters the mouth passes out through these slits, where it oxygenates the blood and enters the peribranchial cavity, thence passing out of the body through the aboral pore (atriopore). The pharynx leads to the stomach with which is connected the liver or cecum. There is a system of blood-vessels, but no heart. A contractile median vessel, the ventral aorta, beginning at the free end of the liver and extending along the underside of the pharynx, sends branches to the sac and two anterior branches to the dorsal aorta. On the dorsal side of the pharynx the blood is collected by the two anterior trunks from the branchial veins which carry away the aerated blood from the branchial bars, and poured into a great longitudinal trunk or median dorsal aorta, by which it is distributed throughout the body. There are also vessels to the liver, and returning vessels, representing the portal and hepatic veins. The blood-corpuscles are white and nucleated.

The vertebral column of the true vertebrates is represented in the lancelet by a notochord, a long, flexible, cylindrical rod pointed at both ends, which extends to the end of the head far in front of the nervous cord. The nervous cord is a rod-like structure which lies over the notochord. It is not divided into a true brain and spinal cord, though the cord is slightly enlarged at the anterior end, where a rudimentary ventricle is said to exist. The nerve-cord sends off a few nerves to the periphery, with a nerve to the single minute median eye. An olfactory pit opens externally on the left side of the snout and communicates with the central canal of the brain. The principal excretory organs are about 90 pairs of peculiarly modified nephridia, situated above the pharynx and in relation with the main coelomic cavities. These have no common duct but empty into the peribranchial cavity. The reproductive organs of both sexes are situated in the coelomic cavities as pouches, of which there are about 26 pairs attached in a row on each of the walls of the body-cavity. The individuals may be male or female, the only sexual difference being in the reproductive glands.

The eggs may pass out of the mouth or through the pore. Kowalevsky found them issuing in May from the mouth of the female and fertilized by spermatocysts likewise issuing from the mouth of the male. The eggs are about 1.5 millimetres in diameter. The eggs undergo total segmentation, leaving a segmenta on cavity. The body-cavity is next formed by invagination. The blastoderm now invaginates and the embryo swims about as a ciliated gastrula. The body is oval and the germ does not differ much in appearance from a worm, starfish or ascidian in the same stage of growth. No vertebrate features are developed. Soon the lively, ciliated gastrula elongates, the alimentary tube arises from the primitive gastrula cavity, while the edges of the flattened side of the body grow up as ridges, which afterward, as in all vertebrate embryos, grow over and enclose the central nervous system. When the germ is 24 hours old it assumes the form of a ciliated flattened cylinder and now resembles a small ascidian, there being a nerve cavity with an external opening which afterward closes. The notochord appears at this time. In the next stage observed the adult characters have appeared, the mouth is formed, the first pair of gill-openings are seen, 11 additional pairs appearing. It thus appears that while the lancelet at one time in its life presents ascidian features, yet, as Balfour states, "all the modes of development found in the higher vertebrates are to be looked upon as modifications of that of"

AMPHIPODA, an order of Crustacea, in which the body is compressed and usually arched. There is no carapace or distinct cephalothorax, but a small head, bearing two pairs of antennae, a pair of jaws (mandibles), and three pairs of maxillae. The thoracic segments are separate and like those of the abdomen, not being fused and united with the head segments. Respiration is performed by lamellate or leaf-like gills arising from the thoracic feet. The three anterior abdominal segments bear swimming feet, while the three posterior bear posteriorly directed feet adapted for springing. The heart lies forward, and the eyes are simple. The amphipods are represented by the common beach-flea or beach- or sand-hopper (Orchestia agilis); by Gammarus, or 'scud,' species of which live both in the sea and in fresh water. The former is the ghost-like or skeleton-like attenuated Caprella, abounding in eel-grass below low tide; and which in walking loop the body somewhat like a geometrid caterpillar. Another form is Chehera terebrans, which burrows in wood, in company with the grubs of a wood-boring beetle, and is destructive to submerged piles. Other forms are eyeless and live in caves or dark wells.

AMPHIPOLIS, an important city of Thrace or Macedonia; at the mouth of the Strymon River, 31 miles from the Aegean. It was founded as an Athenian colony about 436 B.C.; was captured by Sparta in 424 B.C.; and near it the Spartans defeated the Athenians in 422 B.C. in a battle in which Cleon, the Athenian general, and Brasida, the Spartan conqueror of Amphipolis, were both killed. Subsequently it became a Macedonian possession; was called Popolia in the Middle Ages; and its site is now occupied by the Turkish town of Yenikeui.

AMPHIBIANA, one of the degraded worm-shaped lizards of the family Amphibianidae, which lead an entirely subterranean life, burrowing like earthworms. They have a soft skin forming numerous rings and containing only vestiges of scales except upon the head. External limbs are absent (except in one genus), and only vestiges remain of any limb-bones. Their tails are so short and blunt that they are popularly said in some countries to have two heads, whence the scientific name of the group. There is also an amphibian which, cut in two, the two ends will find one another and reunite. This notion is strengthened by their ability to move either forward or backward with equal ease. About a dozen genera and more than 60 species are known, most of which inhabit the warmer parts of America and Africa; some also live in Asia Minor and in Spain. They are frequently found in ants' nests, and have been called "mothers of ants" in consequence. Their eyes and ears are concealed. One species is found in South America and the West Indies (Amphibiana fuliginosa) is checkered black and white, and is from one to two feet in length. Like the others it feeds upon worms and small insects found under the surface of the ground. They are quite harmless.

AMPHITEATROV, Alexander Valentinovitch, vă-len-tín-o-vich ăm-fĕ-tă-trof, a popular Russian writer of the naturalistic school. He was born at Kaluga (central Russia) of ecclesiastical parentage in 1862, and studied music and jurisprudence, the latter at the Moscow University. His literary career began in 1887, when his light verse and prose commenced to appear in various humorous periodicals. As special correspondent of the foremost Russian daily, Novoye Vremia, he at one time attracted considerable attention under the pseudonym of "The Old Gentleman." In 1902 he was exiled to Siberia for certain advanced views expressed in his own periodical, Russiya. Since 1905 he has been living abroad, where he edited a progressive periodical called The Red Banner. Among his extra-literary achievements perhaps the most important was the founding at Paris of The Russian School of Social Science, at which he delivered courses of lectures.

Amphiteatrov has been an extremely prolific writer, whose literary output, if collected, might easily fill half-a-hundred volumes. His works already published include numerous novels, dramas, critical and biographical essays, studies in history and an endless variety of humor. As none of these are available in English, it would be superfluous to enumerate them in a general reference work intended for English readers. A few characteristic titles of his more important novels are 'The Bela Alimov' (1884), a decidedly zolaesque work with which the author first attracted general attention; 'Fiedka the Murderer' (1892), a study in hereditary predisposition; 'Victoria Pavlovna' (1907), a most interesting work dealing favorably with the woman question; 'The Duck of the Demigods' (1908), a two-volume work depicting the vanities and tribulations of actors, playwrights and singers, and 'The Men of the Eighties and Nineties' (1907-10), also in two volumes, constituting the initial works of a projected series which was intended to picture, in leisurely Balzac fashion, Russian society from 1880-1910. His non-fiction includes 'A Literary Album,' a volume entitled 'Humor,' and a very creditable study of antisemitism. His dramas are commonly adaptations from his novels and sometimes the author reverses this process of literary manufacture.

Amphiteatrov is not in any sense a great Russian writer—not even when judged by contemporary Russian standards. He lacks the originality of Gorky, the inventiveness of Andreyev and the art of Artsybashev (qv.). Although he, too, is a realist, his realism is rather of the simple physiological kind of Zola than of the great Russian variety developed by Gogol, Tolstoy and Dostoevsky (qv.). His special interests in human nature lie with the play of temperaments and hereditary predispositions, both well illustrated in 'The Duck of the Demigods,' teeming with alcoholics, and in 'The Men of the Eighties and Nineties' the slow decadence of literary curiosity. This interest in the abnormal and subnormal human types, which is suggestive of Dostoyevsky and which links Amphiteatrov somewhat with Andreyev, makes most of his
novels and dramas really studies in social pathology, which naturally renders their vogue ephemeral. Indeed, it is not as a writer of novels and plays that Amphitheatrov has won his real fame; his special field is literary journalism and humorous improvisation, as he has himself avowed, and in this field he ranks easily among Russia’s greatest writers.

DAVID A. MODELL.

AMPHITHEATRE, with the Romans, a building without a roof, of a round or oval form, destined for the combats of gladiators or of wild beasts. In the middle was the arena, a large space covered with sand, on which the fights were exhibited. Round about were the vaults or caves in which the animals were kept; above these was the gallery, from which ascended successive rows of seats, each of greater height and circumference than the preceding. The first 14 were for the senators and judges, the others for the common people. Julius Caesar erected the first large amphitheatre at Rome for his gladiatorial exhibitions. It was of wood. Statilius Taurus, 20 years later, built the first stone one. The Coloseum at Rome is the largest of all the ancient amphitheatres. (See COLISEUM.) In Verona there is one the interior of which still shows the whole ancient architecture and is carefully preserved. See HIPPODROME.

AMPHITRITE, in Greek mythology, a daughter of Oceanus and Tethys, or of Nereus and Doris. Poseidon wished to make her his wife, and as she hid herself from him he sent a dolphin to find her, which brought her to him, and received as a reward a place among the gods. As a goddess and queen of the sea she is represented as drawn in a chariot of shells by tritons, or riding on a dolphin, before which a cupid swims, with the trident of Poseidon in her hand.

AMPHITRION, in Greek mythology, King of Thebes, son of Alcèus, and husband of Plateia, and after him Molion, have made the trick played upon him by Zeus (in assuming his form in order to enjoy the embraces of his wife) the subject of amusing comedies, in which the return of the true Amphitryon, and his meeting with the false one, occasion several humorous scenes.

AMPHIONIA, a genus of Amphibians that lose their tadpole gills, but retain a gill slit. See KONGO SNAKE.

AMPHIUMIDÆ, âm-i-ú-me’di, a family of urodele Amphibia (q.v.). There are no gills in the adult, but a single pore-like branchial fissure may persist on each side. Respiration is pulmonary, but the inspirations occur only at intervals of several minutes. The vertebrae are biconvex but, like the remainder of the skeleton except the cartilaginous carpi and tarsi, are well ossified. There is no ethmoid bone, and the internal ear is separated from the brain by membrane only. A maxillary bone is developed, and teeth are borne on the margins of both jaws, as well as on the vomers, but not on the paraphenoid. The eyes are very small and devoid of lids; two pairs of limbs are always present, and the tail is permanently provided with a fin. Two genera are known: Cryptobranchus, which contains the American hellbenders, and the giant salamander of eastern Asia, and Amphibia, with very much reduced limbs and persistent gill-clefts, found in the Southeastern States.

AMPHORA, a vessel used by the Greeks and Romans for holding various liquids, particularly wine. They were of various forms, but most commonly tall and narrow, with a pointed end which fitted into a hole or socket to enable them to stand upright. Properly an amphora was a two-handled vessel, from Greek amphí, both, and phero, to carry.

AMPHOTERIC, a chemical property of many organic substances, urine, milk, blood, etc., to show acid to blue litmus and alkaline to red litmus, thus paradoxically being both acid and alkaline.

AMPLITUDE, in astronomy, the distance of any celestial body or other object (when referred by a secondary circle to the horizon) from the east or west points; the complement to the angle, also a vessel for distance, from the north or south point, is called the azimuth.

AMPTHILL, âm-thîl, Odo William Leopold Russell, 1st Baron, British diplomat and ambassador: b. Florence, 20 Feb. 1829; d. Potsdam, Germany, 25 Aug. 1884. He was educated at home, and became attaché at Vienna, and later at Florence. In 1855 he moved to Rome where he remained 12 years as the real though unofficial representative of England at the Vatican. In 1871 he became ambassador at Berlin, where he rendered great service at the congress. He kept on the best of terms with Bismarck, carefully avoiding everything that could give any cause of offense to that most jealous minister, whom he, however, did not hesitate to withstand when his unscrupulousness went the length of deliberately attempting to deceive.

AMPUDIA, âm-poo-dya, Pedro de, Mexican soldier. He first appears in the wars against Texas, Santa Anna (q.v.) making him a general in 1840. He engaged in forays and fights here for some years, coming into conflict with Summerville's Texas troops and commanding the land forces in the later campaign against the Mexicans. Compelled to retreat 26 June 1843, he went to Tabasco, and in 1844 captured and summarily executed Sentmanat who had assaulted it. The act was loudly condemned and he was dismissed. He reappeared in the United States-Mexican War under Arista; was in the battle at Matamoras, 11 April 1846; was given command of Monterey, but surrendered to Taylor 24 September and vanishes from history.

AMPULLA (Lat.), in antiquity, a vessel belling out like a jug, that contained unguents for the bath; also a vessel for drinking at table. The ampulla has also been employed for ceremonial purposes, such as holding the oil or chrisms used in various church rites and for anointing monarchs at their coronation.

AMPULLARIA. See APPLE-SHELL.

AMPUTATION. See SURGERY.

AMRAM, âm-râm, Jewish educator: d. 875. A famous geonb or head of the Jewish Academy of Sura (Persia) in the 9th century. He was the author of many Responsa, but his chief work was liturgical. He was the first to arrange a complete liturgy for the synagogue, and his prayer-book (′Siddur Rab′ Amram′)
was the foundation of most of the extant rites in use among the Jews. The 'Siddur' was published in Warsaw in two parts (1865).

AMRAOTI, ûm-rûrû, India, a town and district capital in the central provinces. The district was reconstituted in 1905, when that of Elichpurn was incorporated with it. It is the richest town of Berar, with the most numerous and substantial commercial population. It possesses a branch of the Bank of Bombay and cotton mart, where an average of 80,593 bojas of cotton are bought and sold annually. It has also a large grain market, cotton presses, ginning factories and oil mills. The population of the town is about 35,000. The district of Amraoti has an area of 4,754 square miles. It is an extensive plain, about 800 feet above sea-level, the general flatness being only broken by a small chain of hills, running in a north-westerly direction between Amraoti and Chandor. The principal towns, besides Amraoti, are Karinj, Kolapur and Badnera, which lie on the Great Indian Peninsula Railway, the main line of which crosses the district. Pop. about 810,000.

AMRAPHEL, King of Shinar (=Sumer, the Sumerian or south Babylonian plain), a monarch mentioned in Gen. xiv as an ally of Chedorlaomer, King of Elam, in subduing his revolted Palestinian vassals. Two other allied kings are named: Arioch of Ellasar (Larsa, South Babylonia) and Tidal of Goim (translated "nation") in Authorized Version; identified by some with Chubum in Media, by others with "the tribes" (=the wandering Kurds). Neither of the names nor any mention of the raid is found on the inscriptions; and the expedition, with its capture of Lot and the successful recapture by Abraham, has no critical standing. Nevertheless it is most interesting historically; for the non-Jewish names are apparently genuine, and the conditions are precisely those of the times which the names would imply. Arioch would correspond to the Babylonian Eriakku supposed to be found in an epic, connected with the invasion of Babylonia; Tid 'al to a Tadhkula or Tushghula also said to be recognizable there; and Chedorlaomer to Kudur-Laghamar, the first half of which is found in other Elamite royal names, as Kudur-Mabuk, etc., and the last is probable. As to Amraphel, he is very plausibly Hammurabi (q.v.), the great reviver of the Babylonian monarchy about 2250, after its conquest by the Elamites; or rather Hammurabi-ilu (the divine name el or ilu added, as common in Babylonian and Egyptian; cf. Joseph-el and Jacob-el against the Hebrew Joseph and Jacob), or perhaps Hammu-rapaltu, a probably dialectic variant of Kimita-rapashtu actually found written. Chedorlaomer's expedition is like other known ones of Babylonian kings against the lands west of the Medes, with which he claimed as tributaries. But there is a closer verisimilitude, which makes it practically certain that the substance of the story was taken from a Babylonian tablet describing an actual occurrence; Amraphel in the story being the absurdly advanced ally of Chedorlaomer and the historical Hammurabi was apparently a dependent sub-king of Babylon under the Elamites before he threw off their yoke. The added Abraham story may represent a tradition welded with the other in later times.

AMR IBN AL-ASI, umr-ibâb-âl-azi, Arabian general; d. 6 Jan. 664. He was a violent opponent of Mohammed until his conversion to Islam in 629 A.D. Abu Bckr entrusted him with a high command in the army destined for the conquest of Syria, and to Amr is chiefly due the success of the expedition. In 639 he led an army into Egypt for the purpose of subjugating that country. After a long siege he reduced Alexandria and signed a treaty of peace 8 Nov. 641. Amr supported Moawiya against Ali in the contest for the caliphate and was thus instrumental in establishing the Omayyad dynasty. In 658 he reconquered Egypt and governed it till his death. His administration was beneficial and its moderation facilitated the spread of Islam in that country. He re-opened a canal 80 miles long from the Nile to the Red Sea with the object of renewing communication between the latter and the Mediterranean. To Amr has been attributed the burning of the famous library of Alexandria. But this crime was quite inconsistent with his character and the story may well be regarded as untrue, as it was not even attempted until six centuries after Amr's death by Abulfaragius. Consult Butler, 'Arab Conquest of Egypt' (Oxford 1902); de Goeje, M. J., 'Mémoire sur la conquête de la Syrie' (Leiden 1900); Gibbon, E., Decline and Fall of the Roman Empire, Muir, Sir W., 'The Caliphate' (London 1891).

AMRITSIR, um-rît'sir, or UMRITSIR (that is, "the pool of immortality"), a town of Hindustan, capital of a district of the same name, in the Punjab, the principal place of the religious worship of the Sikhs. It is, on account of its favorable situation between Cabul and Delhi, Cashmere and the Deccan, a place of great trade, and has considerable manufactures of shawls and silks; but its chief attraction to the natives is the sacred pond constructed by Ram Das (one of the earlier pontiffs of the Sikh faith), in which the Sikhs immerse themselves that they may be purified from all sin. This holy basin is 150 paces square, built of brick, having in its centre the chief temple of the Sikh religion. Under a silk canopy in this temple is deposited the book of Sikh religion and laws, called the Granth. The voluntary contributions of the people and devotees support this place, to which 600 priests are attached. Pop. about 164,000 (including cantonments). The district of Amritsir lies between the rivers Ravi and Bias. It is intersected by numerous canals. Its area is 1,601 miles. Pop. about 2,500,000.

AMROHA, India, a town in the Morada-bad district of the United Provinces. It contains the tomb of a Mohammedan saint, Shaikh Saddu, and has been for many centuries a Mohammedan centre. Pop. about 40,000.

AMRU, originally an opponent and subsequently a zealous supporter of Mohammed, and one of the ablest of the Mohammedan warriors. He brought Egypt under the Caliph Omar in 648 and governed it wisely till his death in 663. The burning of the famous Alexandrian Library has been generally attributed to him, though only on the authority of a writer who lived six centuries later.

AMSDORF, äms'dorf, Nicolaus, a Protestant reformer of the 16th century: b. in
Amsler — Amsterdam

Gross-Zschope, near Wurzen, on the Mulde, 3 Dec. 1483; d. 14 May 1565. He was educated at Leipzig, and then at Wittenberg, where he was one of the first who matriculated (1502) in that newly-founded university. He obtained various academical honors, and became professor of theology in 1511. He joined Luther at the very beginning of his struggle (1517); continued all along one of his most determined supporters; was with him at the Leipzig Conference and the Diet of Worms, and was in the secret of his Wartburg seclusion. He assisted the first efforts of the Reformation at Magdeburg, at Goslar, and at Einbeck, took an active part in the debates at Schmalkald, where he defended the use of the sacrament by the unbelieving, and spoke out strongly against the bigamy of the Elector of Hesse. He urged the separation of the High Lutheran party from Melanchthon, got the Saxon dukes to oppose the Frankfurt Recess (1558), and continued to fight for the purity of Lutheran doctrine until his death.

Amsler, Samuel, one of the most distinguished of engravers: b. in Schinznach, in the canton of Aargau, 1791; d. 18 May 1849. Amsler's principal engravings are: 'The Triumphal March of Alexander the Great' and a full-length 'Christ,' after the sculptures of Thorwaldsen and Dannecker; the 'Burial of Christ,' and two 'Madonnas,' after the pictures of Raphael; and the 'Triumph of Religion in the Arts,' after Overbeck, his last work, on which he spent six years.

Amsterdam, formerly called Amstelredam, the chief city of the Netherlands, is situated in the province of North Holland, at the influx of the Amstel to the IJ or Y (pronounced eye), an arm of the IJzer Zee. The city is built in the shape of a semicircle, and within this semi-circle four canals — the Prinsen Gracht, Keizer's Gracht, Heeren Gracht and the Singel Gracht — extend in the form of polygonal crescents, nearly parallel to each other, while numerous smaller canals intersect the city in every direction, dividing it into about 90 islands, with about 300 bridges. The city was originally a salt bog, and all its buildings rest upon piles that are driven from 14 to 60 feet through a mass of loose sand and mud until they reach a solid stratum of firm clay. This foundation is perfectly secure as long as the piles remain under water. At the beginning of the 13th century it was merely a fishing village, with a small castle, the residence of the lords of Amstel. In 1240, Giesebricht III of Amstel built a dam to keep out the sea, but in 1296, on account of the share of Giesebricht IV in the murder of Count Floris of Holland, the rising town passed out of the hands of the counts of Amstel and shortly thereafter, with Amstelland (the district on the banks of the Amstel), it was taken under the protection of the counts of Holland, and from that time a several privileges which contributed to its subsequent prosperity. In 1482 it was walled and fortified. After the revolt of the seven provinces (1565) it speedily rose to be the first commercial city and a great seaport for the Flemish Protestants; and in 1585 it was considerably enlarged by the building of the new town on the west. The establishment of the Dutch East India Company (1602) did much to forward the well-being of Amsterdam, which, 20 years later, had 100,000 inhabitants. In the middle of that century the war with England so far reduced the commerce of the port that, in 1653, 4,000 houses stood uninhabited. Amsterdam had to surrender to the Prussians in 1707, to the French in 1795, and the union of Holland with France in 1810 entirely destroyed its foreign trade, while the excise and other new regulations impoverished its inland resources. The old firms, however, lived through the time of difficulty, and in 1815 commerce again began to expand;

an expansion greatly promoted by the reconstruction of the harbor, the opening in 1876 of a new and more direct waterway between the North Sea and the city, and by the building of the Merwede Canal in 1892, which places Amsterdam in direct connection with the Rhine.

The city has a fine appearance when seen from the harbor or from the high bridge over the Amstel. Church towers and spires, and a perfect forest of masts, relieve the flatness of the prospect. The old ramparts have been leveled, planted with trees and formed to promenades. Between 1866 and 1876 many spacious streets and an extensive park were added to the city. Tramways have been successfully introduced and the harbor greatly improved. There are suburban steam and electric tramways and railway communication with all parts of the country and of Europe. An extensive system of canals and sluices and rich grassy meadows surround the city. On the west are a great number of windmills for grinding corn and sawing wood. On either side of the three chief canals, with a row of trees and a carriage-way intervening, are handsome residences. The building material is brick, and the houses have their gables toward the streets, which gives them a picturesque appearance. Amsterdam is the centre of the national system of defense. There is a fort at the entrance of the harbor and sluices several miles from the city which can flood in a few hours the surrounding land. The population, which from 217,024 in 1794 sank to 106,179 in 1815, rose again in 1908, of whom the majority belonged to the Dutch Reformed Church. Of the remainder, about 95,000 were Catholics, 60,000 Jews from east Europe and 5,000 Portuguese Jews. The chief industrial establishments are sugar, camphor and borax refineries, engineering works, mills for polishing diamonds and other precious stones, ship-building yards, manufactories of sails, ropes, tobacco, silks, gold and silver plate and jewelry, dyes, chemicals, candles, cobalt blue and machinery, rice mills, glass blowing establishments, lumber mills, breweries, distilleries, with export houses for corn and colonial produce, Amsterdam being the chief market for the Dutch East Indian trade. There is a vast system of docks, quays and storehouses, and the headquarters of the large shipping companies are here; 2,152 vessels (tonnage 2,310,000) entered the port in 1913 and 1,707 (tonnage 1,844,000) cleared. It is also the financial centre of Holland. The present Bank of the Netherlands dates from 1814, Amsterdam's famous bank of 1609 having been dissolved in 1796.

The great focus of life is the Dam. Here stands the former Stadhuis ("townhouse"),
AMSTERDAM — AMU

converted in 1808 into a palace for King Louis Bonaparte, and still retained by the reigning family. Built by Van Kempen in 1648-55, and raised upon 13,659 piles, it extends 262 feet in length by 208 feet in breadth, and is sur-
mounted by a round tower rising 182 feet from the base. It is adorned on the exterior and in the interior with sculptures by Artus Quellinus, and has a hall 120 feet long, 57 wide and 90 high, lined with white Italian marble — an apartment of great splendor. The cruciform Nieuwe Kerk (Old Church), built in 1408, is one of the finest ecclesiastical structures in the city, with a splendidly carved pulpit, and the tombs of Admiral de Ruyter, the great Dutch poet Vondel and various other worthies. The Old Church (Oude Kerk), built in the 14th century, is rich in painted glass, has a grand organ and contains several monuments of naval heroes. Literature and science are represented by a university supported by the municipality (till 1876 known as the Athenaeum Illustre), with a library of over 400,000 books on national literature; by academies of arts and sciences, by museums and picture galleries, a palace of national industry, one of the finest botanical gardens in Europe, six theaters, of which the Rijksmuseum contains a truly national collection of paintings, its choicest treasure being Rembrandt's "Night-watch." The Six Gallery contains a small but priceless collection of Dutch masters. Modern art is represented in the Municipal and Fowler museums. Rembrandt (q.v.) made Amsterdam his home, and his statue (1852) now fronts the house he occupied.

Spinoza was a native. There are many hospitals and benevolent institutions, well supported and managed on good principles, including the celebrated Society for Public Welfare, with branches over all Holland, and various orphan asylums. A water supply was introduced in 1853. The exports from the Amsterdam district to the United States attained the value of $30,183,704 in the first nine months of 1916, which is larger than the total for any corresponding period. The increase was due chiefly to the transfer to Amsterdam of the business done at Antwerp before the war. Area 184 square miles. Pop. (1909) 506,131; (1913) est. 595,258.

AMSTERDAM, N.Y., city of Montgomery County, 33 miles northwest of Albany. It is located on the Mohawk River, the Erie Canal and the West Shore Railway and is a busy manufacturing centre and Barge Canal shipping terminal. Amsterdam has numerous industries, producing such diversified objects as carpets, knit-goods, rugs, wagon-springs, paper, silk, paper-boxes, brooms and gloves. The United States census of 1914 reports 117 manufacturing establishments of factory grade, employing 11,411 men, 19,237 women, and 10,774 wage earners, receiving $4,908,000 annually in wages. The capital employed is $22,645,000, and the value of the product is $22,475,000; of this, $9,310,000 was added by manufacture. There are also foundries and machine-shops; three daily newspapers. Here are located an academy, a hospital, a board of trade and chamber of commerce, numerous churches and a Roman Catholic institute. There are well-paved streets, a fine system of drainage, an excellent water supply, an electric lighting system and free garbage disposal plant and collection service. Amsterdam was first settled about 1778, and until 1804 it was known as Veerdraw. It was incorporated as a village in 1830 and as a city in 1885. Pop. (1910) 31,267; (1915) 35,119.

AMSTERDAM, Bank of. This institution was established in 1609, much upon the plan of the Bank of Venice. Its chief and at first its only function was that of affording a discount for payment of bills of exchange drawn upon the merchants of that great commercial port, in full-weighted coins; the coins in common circulation being more or less below standard by reason of attrition, filing, sweating or other means of degradation. In order to give effect to the plan of the bank, the municipal law provided that all bills of exchange above 600 guilders should be payable only at the bank. Its capital consisted entirely of its customers' deposits, whose desire to meet their bills of exchange promptly induced them to place their money at the bank, in full confidence that it would be safe and above all, that the bank would guard against mismanagement, its principal officers and made frequent examinations of its accounts. For this guarantee the bank charged the depositor and paid the city 10 guilders for each account opened, besides other small fees on transfers, amounting in the aggregate to between 150,000 and 200,000 guilders per annum. *Bank money* (guilder or florin) was not coined until 1720. By this time the bank had become so assured of the value and respectability of its notes that it began to issue them in larger denominations than 10 guilders. In circulating money, the agio representing the difference between newly minted coins and those in circulation. It was the common belief that for every guider represented by the bank's receipts or acknowledgments for deposits there was a metallic guider in the vaults of the bank, so that it appears to have made no loans and indulged in no enterprises or speculations. In 1672 when the French King Louis XIV was at Utrecht, the bank paid in coins, which, by the marks of fire upon them, must have lain in its vaults more than half a century. However, upon the second French invasion, 1793, the bank was found to be entirely destitute of money, the deposits having been drawn down and concealed for greater safety. After a useful career of more than two centuries the bank was wound up in 1820. For the history of other ancient banks see list under the heading BANKS, ANCIENT AND MODERN.

AMSTERDAM, an uninhabited and almost inaccessible island in the Indian Ocean, in lat. 37° 47' S. and long. 77° 34' E., about 60 miles north of Saint Paul Island, and nearly midway between the Cape of Good Hope and Tasmania. It is an extinct volcano, rising 2,989 feet from the sea. It was discovered by Anthony Van Diemen in 1603 and annexed by France in 1893. In 1893 the British frigate Megaera was wrecked here, and most of the 400 persons on board had to remain upwards of three months on the island. The Memoires of a Frenchman, Capt. Francois Peron, who was marooned three years on the island (1792-95), are of much interest.

AMU, a-moo', or AMOO DARYA (Arab. Ghion), river of central Asia, the ancient Oxus. It takes its rise in the eastern Pamir near the boundary of eastern Turkestan, flows at first
AMULETS

Among the ancients we find the Greeks favored as amulets rings of iron. Roman amulets consisted largely of necklaces, bracelets, metal diadems, precious stones, and, especially, black coral (gorgonia antipathes). They often enclosed their amulets in lens-shaped receptacles (bulle), and attached them to the necks of their boy children. Roman lawyers wore a baby's caul as bringing prosperity. The Germanic peoples used the symbol of Thor's hammer, luck-stones, herbs, pieces of certain roots, also the prehistoric flint arrowheads mounted in gold, etc. The Jews bound thongs, containing verses of the Law, round the head or arm (phyllactery) for protection from evil; the figures of gods or stars, magic rings, etc., were illicitly worn.

In the Middle Ages, when such amulets were placed under the ban of the Christian churches of Constantinople (Byzantium) and Rome, the Agnus Dei and Holy Virgin medallions took their place, or pieces of parchment were carried inscribed with the beginning of the Gospel of St. John. The Agnostic stones carried (in rings or in the clothes) by the Hermetics were strictly amulets. The early Christian, pierced ivory, glass, and bronze fishes were, undoubtedly, amulets. The encyclopia of the 4th century also belongs to the same category. Rings mounting a "loadstone" were worn by women to keep bad fairies from their newborn babes.

generally west (to long. 66° E.), thence generally northwest, and empties by a delta into the southern part of the Aral Sea. It receives several affluent from the mountains of Turkestan and the Hindoo Koosh. About 1,600 miles in length, it is navigable by light draught vessels for about 800. As a means of irrigation, it is of considerable importance. See OXUS.

AMULETS. In general an amulet may be described as a charm made of stone, metal, earthenware, parchment, paper or other material, having incised or inscribed magic figures, characters or a bare inscription on it. The amulet is used to protect the wearer against witchcraft, sickness, etc. It has been usually worn suspended from the neck. The words "amulet" and "talisman" are commonly considered as synonymous. But, while the amulet is supposed to be limited to protecting the bearer from all malignant outside influences, the talisman is supposed to have, besides this power of protection from danger to its wearer, also miraculous influences on others. The talisman is supposed to be able to enforce, for its possessor, the love and influence of others.

Much study and discussion have been devoted to the derivation of the word amulet. The opinion that it was from the Arabic (necklace, sword-belt), or hamate (something suspended), is wavering. Pliny said the country folk called the cyclamen which they planted in the house to make all poisonous drugs harmless, amuletum. This derivation receives more general acceptance.

Faith in the power of amulets has existed in every nation from time immemorial. Among the ancients the most prominent Orientalists to attain a fixed amulet cult were the Chaldeans, Babylonians, Persians, Indians, Chinese and Japanese. But foremost in the popular cultivation of the faith in amulets must be placed the ancient Egyptians. Among the ancient Nile-dwellers the oldest and far most prolifically used form of amulet was the scarab (q.v.). Many thousands are to be found in the museums and other collections. These, with a multitude of peculiar amulets, are found on the mummy bodies in every Egyptian tomb, each for its specific future purpose, buried to keep the deceased free from the numerous torments of the underworld.

4. USHABTI AMULET. Acted as servant in the underworld.
5. UAT. Papyrus column amulets. Rendered the wearer immortal and immune from injury.

1. ANKH. Called "girdle of Isis." Symbol of Life.
2. THET. Symbol of blood of Isis. Cleansed wearer from sins.
3. DAD or DAD (front and side views). Backbone or Ovaris. Cured for the wearer in the underworld.
6. MASONS' PLUMB LINE. Purpose uncertain.
In the present day Mohammedans carry as amulets faith-stones, rings, pieces of paper inscribed with magic formula or with the "Attributes of Allah," or verses of the Koran. They also adopted from the Egyptians the hand amulet ("hand of Fatima"), to suspend in their dwellings or wear, to ward off the "Evil Eye"; all in spite of the laws of the Koran. Italians attach small images or pieces of coral to their children's necks against the Evil Eye. They even suspend amulets to their domestic animals for this purpose. In southern Europe we find coral used also as a protection from hemorrhages, pieces of elk horn as cure for epilepsy, not to mention abracadabra tablets and amulet coins. In England the widest known amulet at this day is, probably, the baby's caul, for which been shot from the heavens by the fairies. These are used by the Italians also who know them as "tongues of Saint Paul."

CLEMENT W. COUMBE.

AMUNDSEN, a'mún-sén, Roald, Norwegian explorer: b. Borge, Smaalenene, Norway, 16 July 1872. He studied medicine for two years at the University of Christiania, then entered the Norwegian naval service, went to sea in 1893, and in 1897 became first officer on the Belgica, of the Belgian South Pole Expedition (1897-99). In 1901 he made oceanographic researches off the northeast coast of Greenland with the Gjøa, a small vessel registering 47 tons, and after studying terrestrial magnetism at Wilhelmsfahen, Hamburg and Potsdam set sail in June 1903 in the Gjøa to relocate the position of the Magnetic North Pole. Taking up his headquarters on the southeast side of King William's Land he made during 19 months a magnetic survey of a considerable region around the pole and was thus able to prove that it has probably no stationary position but is in continual movement. His observations were taken to Norway where their reduction is still in progress. During this expedition Amundsen was also the first and only man to accomplish the long attempted feat of taking a ship from the Atlantic to the Pacific through the North West Passage. He reached Herschel Island on 13 Aug. 1905, having accomplished one of the most important tasks ever performed in geographic exploration. In 1909 Amundsen planned an expedition in Nansen's ship, The Fram, with the object of drifting across the North Polar Sea, but sufficient funds for this purpose were still lacking when he learned of Peary's discovery of the North Pole. Fearing that the incentive for further contributions had been removed, he secretly resolved to make his objective point the South Pole, believing that he had sufficient equipment for an Antarctic expedition. He started on 9 Aug. 1910, first announced his change of plan to the world from Madeira, and on 14 Jan. 1911, arrived in the Bay of Whales, which he made his base, and pitched his winter camp on the Great Ice Barrier. In October 1911 he started with four companions his dash for the pole, which he reached on 16 Dec. 1911, a month before his English competitor, Captain Scott. Amundsen owed his success not only to his superb courage and endurance, and to favorable weather conditions,
but also to his attention to the smallest details of his equipment, and to his use and knowledge of dogs as draught animals. After his return he lectured in most cities of Europe, North America and Australasia; and his book 'The South Pole,' was translated into many languages and published in English in 1912. His long-delayed drift across the Arctic Ocean, on which he had planned to start in 1914, was indefinitely postponed on the outbreak of the European War, as Amundsen felt the Norwegian government might have other uses for their $40,000 appropriated for the purpose. Amundsen also wrote 'The North West Passage,' published in English in 1908.

AMUR, am-ör', river formed by the junction (about lat. 53° N. and long. 121° E.) of the Shilka and the Argun, which both come from the southwest. From the junction the river flows first southeast and then northeast, and, after a total course of 3,000 miles, falls into the Sea of Okhotsk opposite the island of Sakhalin. It is very valuable for navigation, and carries a considerable fleet of steamers; but on account of the bar at its mouth goods are generally disembarked and carried overland to Alexandrovsk. In 1636 Russian adventurers made excursions to the lower Amur, and in 1666 built stations and a fort at Albazin. In 1685 both stations and the fort were taken by the Chinese, but were promptly retaken by the Russians, who in 1689 abandoned the whole territory of the Amur to the Chinese. In 1854-56 two military establishments were constructed by Count Muravieff, who established the stations of Alexandrovsk and Nikolaevsk. In 1858 China agreed to the Treaty of Tien-tsin, by which the boundaries of Russia and China were defined. The left bank of the Amur and all the territory north of it became Russian; and below the confluence of the Ussuri both banks. In 1860, after the occupation of Pekin by the British and French, General Ignatieff secured the signature of Prince Kung to a treaty by which Russia acquired the broad and wide territory comprised between the river Amur and the mouth of the Tumen, extending 10° of latitude nearer the temperate regions, and running from the shore of the north Pacific eastward to the banks of the river Ussuri, a principal affluent of the Amur. In September 1900 Russia took formal possession of the right bank of the river. This vast territory falls into two Russian provinces—the Maritime Province between the Ussuri and the sea, and the government of Amur north of the river. The latter has an area of 175,000 square miles. The country is richly timbered, and is admirably adapted for pasture and agriculture, though the climate is severe. Fur-bearing animals are still plentiful and the river abounds in fish. The capital is Khabarovka. Nikolaevsk, once the only important place in these regions, is on the Amur, 26 miles from its mouth, where the river is 1/2 miles wide, and in places 15 feet deep; but the political centre tends southwest to the more temperate Maritime Province (area, 130,000 square miles), near the southern end of which is situated the important harbor of Vladivostok ('Rule of the East'), or Port May, which in 1872 was placed in telegraphic communication with Europe by the China submarine cable, and is now the capital of the Amur provinces. The island of Sakhalin (Sahalinen), north of the Japan group, along a portion of the coast of Asiatic Russia, and formerly possessed partly by Russia and partly by Japan, is also a part of the Amur region in the wider sense.

AMURATH I, a-mo-o-rāt, a sultan of the Turks; succeeded his father, Orchan, in 1360. He founded the corps of Janissaries, conquered Phrygia and on the plains of Cassova defeated the Christians. In this battle he was wounded, and died the next day, 1389.

AMURATH II, one of the more illustrious of the Ottoman emperors, succeeded his father, Mohammed I, in 1421, at the age of 17. In 1423 he took Thessalonica from the Venetians; in 1435 subdued the despot of Servia, besieged Belgrade, which was successfully defended by John Hunniades; defeated the Hungarians at Varna in 1444, and slew their king, Ladislaus. He died in 1451.

AMURATH III, succeeded his father, Selim II, in 1574. His first act was the murder of his five brothers. He added several of the best provinces of Persia to the Turkish empire. He was noted for his avarice, and his sensual excesses made him prematurely old. He died in 1595.

AMURATH IV, succeeded his uncle, Mustapha X, 1623. After two unsuccessful attempts he took Bagdad from the Persians in 1638 and ordered the massacre of 30,000 prisoners who were thereby disarmed. The excessive cruelty and debauchery of Amurath IV have earned for him the character of being one of the worst sovereigns that ever reigned over the Ottomans. He died in 1640.

AMURATH V, Sultan of Turkey: b. 21 Sept. 1840, and succeeded to the throne in 1876 as the result of a revolution that caused the overthrow of his uncle, Abdul Aziz. His reign was for a few months only, as he developed strong symptoms of insanity and was deposed in August 1876.

AMUSAT, Jean Zulema, a-mu-sa zhōn zū-lē-ma, French surgeon; b. 1796; d. 1856. He entered the army in early life as an assistant surgeon at the Salpêtrière Hospital and a member of the Paris faculty of medicine. He was the inventor of many surgical appliances and first adopted the method of torsion of the arteries in haemorrhage. He was the first to perform the operation for opening the large intestine at a point where it is not covered with peritoneum. It is still practised and is known by his name. He wrote on the nervous system and on the torsion of arteries.

AMY'CLE. (1) An ancient town of Lacedo-
nia, on the eastern bank of the Eurotas, 2½ miles southeast of Sparta. It was the home of Castor and Pollux, the "Amylean brothers." It was conquered by the Spartans only before the First Messenian War. (2) An ancient town of Latium, which claimed to have been built by a colony from the Greek Amycla.

AMYGDALIN, a-mig-da-lin (from the Latin amygdald, "almond"), a crystalline substance occurring in bitter almonds, in the kernels of apples, pears and peaches, in the leaves of the laurel (Cerasus lauro-cerasus) and in the leaves and bark of various species of the
genus Prunus. It has the formula CaH₇NO₃+ 3H₂O, and is of special interest to the chemist because it was the first known of the numerous classes of glycosides, for which see special treatises

It is obtained by extraction, with boiling alcohol, of the pulp left after the expression of the oil from bitter almonds. The alcoholic solution is concentrated by evaporation and the amygdalin precipitated by the addition of ether, in which it is insoluble. Like most of the sugars, amygdalin does not form salts with acids, but is decomposed by them in the formation of glucose. Amygdalin, while of a bitter taste, is not poisonous. When dissolved in water it undergoes no change but if some dilute mineral acid such as emulsion be added, a kind of fermentation sets in and the amygdalin is gradually decomposed into benzaldehyde, glucose and hydrocyanic acid. Amygdalin has been produced synthetically by Emmerling from mandelic nitrii, glucose and alcohol, with maltase, a constituent of yeast.

**AMYGDALOIDS**, a-mig'da-loidz, cellular lavas, the cavities of which have been made by expanding steam before the lavas completely solidified, and which are usually filled with secondary minerals, frequently the zeolites (q.v.). The cavities are called amygdaloids and the rocks are said to be amygdaloidal. Amygdaloids are characteristically extrusive. On Keweenaw Point, Mich., they are of particular interest, because the cavities are filled with native copper and constitute the source of much of the mined in that region.

AMY'LYL (from the Latin amyllum, a starch, its first-known compounds being obtained by the distillation of fermented starch matter), an important organic radical having the formula CH₃₄, and belonging in the fatty series. It is also called a-pentyl, because, in the long list of analogical radicals having the general formula CaHₙ₊₄, amyxl is the particular radical in which n = 5. Amyl cannot exist in the free state, but two of its molecules can combine to form the paraffin decane. CaH₁₀₂, which is a liquid boiling at about 320°F. The radical amyxl can have no less than eight different isomeric forms, and the chemistry of its compounds is correspondingly complicated. Of the many compounds that are known, however, only three are especially important in the arts. These are:

1. Amyl alcohol, (2) amyl acetate and (3) amyl nitrite.

1. Eight isomeric amyl alcohols are theoretically possible, one for each of the theoretically possible isomeric forms of the radical itself, and seven of these are actually known. Five of the seven are of no particular importance in practical chemistry, but the remaining two, known respectively as the active and inactive amyl alcohols, constitute the greater part of the fuel-oil (q.v.) that is obtained abundantly in the manufacture of potato brandy and less abundantly in the preparation of many other kinds of distilled liquors. Active amyl alcohol has the formula CH₃ CH₂ CH₂ CH₂ OH, boils at about 202°F, and takes its name from the fact that it gives rise of polarized light to the left. Inactive amyl alcohol has the formula (CH₃ )₂ CH₂ CH₂ OH, boils at about 209°F, solidifies at —4°F, and has no effect upon polarized light. These two kinds of amyl alcohol may be obtained, mixed, by washing fusel-oil with water and subsequent rectification. They may then be separated by fractional distillation or by other more exact methods, for which see special treatises.

(2) Amyl acetate (more exactly, 4-isooamyl acetate, since six acetates are known) is prepared by distilling a mixture of the foregoing amyl alcohols with sodium acetate and sulphuric acid. It is a liquid, boiling at about 252°F, and possessing a strong fruity-like smell. It is used for flavoring cheap confectionery.

(3) Amyl nitrite, CH₃ N₂O₃, may be formed by distilling a mixture of the foregoing amyl alcohols with potassium nitrite and dilute sulphuric acid. It is a yellow liquid, with an ethereal, fruity odor. When its vapor is inhaled it paralyzes the vasomotor nervous system and lowers the blood pressure. Amyl nitrite is often administered in the form of glass capsules or "pearls" containing one to three drops, which are crushed in the handkerchief and inhaled. It is used in arteriosclerosis, angina pectoris, migraine, asthma, haemorrhage and toxic rise of blood pressure. Its effects are powerful and almost instantaneous, and it should never be tried except under the guidance of a physician.

AMYLENE HYDRATE, an alcohol used as a hypnotic. It is technically a tertiary isoamyl alcohol [(CH₃ )₃ C(OH) CH₂ CH₃], and is a lipid, colorless, neutral fluid with a peculiar odor and a burning taste. It is miscible with eight parts of water and freely miscible with alcohol, chloroform and fixed oils. It has an action on the human body similar to that of other alcohols and is a useful hypnotic, occupying a position between chloral, which is twice as strong, and paraldehyde, which has about half the strength of amylen hydrate. In large doses it is a heart depressant.

AMYLOPSIN, a chemical (or unorganized) ferment, occurring in the pancreatic fluid, together with steapsin and trypsin. The chief function of amylpsin, in intestinal digestion, is to effect the conversion of starches and similar substances (amyloses into maltose, isomaltose and glucose). The conversion takes place in the small intestine. Amylopsin is often called the "pancreatic diastase." See PANCREAS.

AMYLASE, any carbohydrate (q.v.) which can be classified as starch, dextrin, cellulose or natural gum. The remaining members of the carbohydrate group are classed as glucose or saccharoses. The general formula of an amylase is (CaH₁₀₂)ₙ. See CARBOHYDRATE; CELLULOSE; DEXTRIN; STARCH; GUM ARABIC.

AMYNOCODENTS, a group of primitive solid-hoofed animals, fossil in American Eocene rocks, especially in the White River beds. They were large, heavy, short-legged animals, allied to the rhinoceros, but having probably more the appearance and habits of a hippopotamus. Well-known genera are Amynodon and Metaamynodon.

AMYTAS, a-min'tas, the name of various characters in ancient Greek or Macedonian history, especially kings of Macedonia. Amytias I was a son of Alcetas, reigned about 540 to 500 B.C. and was succeeded by his son, Alexander I. Amytias II, sometimes called Amyntas III, was King of Macedonia, son of Philip and
AMYNTOR, a:min-tór, Gerhard von (pseudonym of Dagobert von Gerhardt), German novelist and poet: b. Liegnitz, Silesia, 12 July 1831; d. 1910. He entered the army in 1849, took part in the campaigns of 1864 and 1870-71 as a major, was severely wounded in the former and resigned in 1872; settled in Potsdam in 1874. His principal works are 'Peter Quidam's Rhine-Journey' (1877), an epic song; 'A German Night Watchman' (1878); 'The New Parnassus' (1880); 'The Poem' (1881), an epic; novels, 'It Is You' (1882); 'A Problem' (1884); 'Praise of Woman' (1885); 'Gerke Suteminne' (1887), a historical romance; 'A Struggle for God' (1902).

AMYOT, Jacques, â-mô-6', a French author: b. 30 Oct. 1513; d. 6 Feb. 1593. He is famous for his translations from the Greek, which, owing to their elegant style, are considered classical literature. They are the 'Theagenses and Chariclea' of Heliodorus; 'Seven Books of Diodorus Sicius'; 'The Daphnis and Ch superclass of Longus; and 'Plutarch's Lives,' which was used by Corneille as a source for his antique tragedies, and by Shakespeare (in its English version by Sir Thomas North) for some of his plays.

AMYOT, Joseph M. See AMIOT.

AMYRAUT, a:m-rô, Môise, French Calvinist theologian: b. in Bourgoin, in the province of Anjou, 1596; d. 1664. He was educated at Saumur, where he was himself afterward a professor of divinity. By his talents and moderation he soon acquired reputation and influence. In 1631 he attended the Synod of Clarendon and was commissioned to present the king the remonstrances of his brethren against the infraction of the edicts of pacification. In his mission he acted with such judgment and dignity that he succeeded in relieving the Protestant deputies from the disgraceful obligation of addressing the king on their knees. Although he was a Protestant, his amiable temper and courteous manners commanded the regard of the Catholics and he was held in particular esteem by Cardinal Richelieu. He endeavored to bring about a complete union between the various Protestant Churches; this object he pursued with the utmost success. Among his works, especially in a Latin tract, 'De secessione ab ecclesia Romana, deque pace inter Evangelicos in negotio religionis instituenda.' Moreover, acting in concert with Richelieu, he aimed at a reconciliation between the Protestants and the Roman Catholic Church. The favor and respect with which he was treated by the heads of the French government Richelieu and Mazarin, are to be ascribed to his opinions concerning the power of the princes. He publicly maintained on several occasions the doctrine of implicit obedience to the sovereign authority, which, indeed, had also been held by the great founders of the Reformation. Amyraut was a finished scholar and wrote Latin and French with equal ease. His numerous writings, which were received with marked favor in his time, are now nearly forgotten and not easy to be procured. Among the number we may mention 'A Treatise on Religions, Against Those Who Esteem Them to Be Indifferent'; 'Christian Morals'; 'A Treatise on Dreams'; 'Against the Millenarists'; 'Considerations on the Laws of Nature Regulating Marriage.'

AMYRIDACEAE, a natural order of tropical plants, consisting of trees or shrubs with opposite or alternate compound leaves, frequently stipulate and dotted; the flowers are usually bisexual, but are sometimes unisexual by abortion. They yield resinous and balsamic juices, which are sometimes used medicinally and receive such names as bdelium, elemi, frankincense, myrrh, olibanum, andambool (See these articles). Among the chief genera of the order are Amyris, Balsamodendron, Boswellia, Canarium and Icaca. They are sometimes classed as a suborder of Anacardiaceae.

AN, or ON, the Egyptian name of the city of Heliopolis.

ANA, a comparatively modern designation applied to collections of the sayings and observations of eminent persons, as well as to gossip or criticism pertaining to them.

ANABAPTISTS (Greek, ἀβάπτω, to baptize), those who baptize again persons admitted to their communion, when such converts have been baptized in their infancy or have been merely sprinkled and not immersed in baptism or have been baptized as infants without being capable of declaring the doctrines which they believe and giving a reason for the hope that is in them. Baptists (q.v.) of the present day are not properly to be styled Anabaptists, as they lay no capital emphasis upon the necessity for rebaptism; they have very definite canons on the subject of immersion.

Anabaptists of the early Church.—In the 3d century of the Christian era, the century which witnessed such violent and bitter controversies, the question of baptism came also under discussion. In the Eastern Church, including Asia Minor, Egypt, northeastern Africa and Constantinople, it was definitely maintained that baptism was invalid unless it was administered by one of the clergy with proper matter and form. In the Western Church, including Italy, Gaul, Spain and northwestern Africa, it was held that the virtue of baptism lay in the invocation of the Trinity and the ceremonial sprinkling with or immersion in the water. The baptizer was not ministered by a person of either sex, but by a clergyman or a layman, was equally valid. When two children in their play mimicked the act of a priest whom they had seen baptizing an infant, Saint Augustine of Hippo declared that the boy who imitated the priest's act in this manner turned his companion was a real and actual partaker of the benefits and bound by all the vows pertaining to this sacrament. The controversy between the East and the West continued,
however, to rage with such fury that two councils were called to settle the question. The one was held in Iconium, Asia Minor, in 235, the other at Sardis in 256. At these theological synods the decision arrived at was that rebaptism was unnecessary for those who had been baptized by heretics. The storm of controversy swept westward to northern Africa as far as Carthage, where Tertullian supported the position of the Eusebians in opposition to that of Saint Augustine and other Western doctors. Agrippinus, bishop of Carthage, maintained against the bishop of Rome that baptism under certain circumstances ought to be repeated. His followers were called Agrippinians and his defiance of the bishop of Rome took the form of a conciliar decree which was issued by a synod which he convened and which endorsed the sentence of Iconium. In the year 253 Stephen, bishop of Rome, fulminated a bull of excommunication against all the bishops of Asia Minor, including Cappadocia, Galatia and Phrygia, whom he styled Rebaptizers and Anabaptists, in an opprobrious sense.

**Münster Anabaptists.**—In the 16th century, the Münster Anabaptists in Eastern Europe were known as Anabaptists, whose main tenets carried the principles of the Reformation to the extreme limit of that revolutionary movement. Their principles were those of revolt against mediaeval feudalism and against ecclesiastical authority. They were socialists as well as reformers, mystics and fanatics. Their existence was one of the results of the Renaissance as interpreted to the common mind. Their views were democratic and individualistic. They rejected all authority, all tradition, all dogma, everything in short that militated against the absolute independence of the individual mind and spirit. This tendency acquired at length the character not only of liberty but of license, and the term Anabaptist has thus become associated with every extreme, not only of license but of licentiousness, of rebellion and political outlawry. It is quite absurd to associate the term Anabaptist as employed historically with any phase of Catholic thought. It is only in recent times that the term really is a term applied to those who at a turning point in the history of European thought, social, political and religious, became intoxicated with the idea of individual liberty and the result was violence and excess of the worst character.

The history of the movement is as follows: The doctrine of adult baptism was first put forth by Thomas Münzer, the Lutheran pastor of Zwicking in Saxony, in the year 1520. Münzer soon obtained many followers who joined him in his uprising against all civil and religious authority. Although openly belonging to the Reformation movement they very soon became completely repudiated by the followers of Luther and his adherents. But the spirit of insurrection against feudal tyranny prevailed amongst all the common people on the Rhine, in Westphalia, Holstein, Switzerland, Flanders and throughout the whole Netherlands, and the increase of Münzer's followers became so dangerous that the magistrates and civil authorities found it difficult to restrain them. Münzer was compelled to leave Zwicking; he visited Bohemia, resided for two years at Alstadt and Thuringia and in 1524 was found propagating his doctrines in Switzerland. He was the principal inciter of the Peasants' War, which was entered upon with a view of establishing the ideal Christian commonwealth with communistic institutions. This war reached its culmination in 1525, when Münzer led his forces against the representatives of established order and was defeated at the battle of Frankenhausen 15 May 1525. Münzer was taken prisoner and with several of his associate leaders was tried, condemned and executed. But all this was looked upon by the Anabaptists as merely a form of welcome persecution. New associations were formed; new prophets and teachers arose; the propaganda was extended amongst the peasants and serfs of Germany, Austria and Hungary in every direction. It may be necessary to state that the tenets of the Anabaptists are to be summarized in their own words as follows: 'Impiety prevails everywhere. It is therefore necessary that a new family of holy persons should be founded, enjoying, without distinction of sex, the gift of prophecy, and skilled to interpret Divine Revelations. Hence, no need for learning; for the spiritual understanding is better than the outward expression. No Christian is to be allowed to go to law, to hold an office in the civil government, to take an oath in a court of justice or to possess any personal property; everything amongst Christians must be in common.'

John Bochhold, or Bockel, a tailor, of Leyden, aged 26, and John Matthias, or Matthiesen, a baker of Haarlem, came, in 1553, to Münster in Westphalia, a town whose inhabitants followed the doctrines of the Reformation. Here they soon won the adherence of the excited populace, and among the rest, of Rothmann, a Protestant clergyman, and the Councillor Knipperdolling. The magistrates in vain excluded them from the churches. They took violent possession of the council-house, and toward the end of the year a treaty was signed securing the religious liberty of both parties. Being strengthened by the accession of the restless spirits of neighboring cities, they soon made themselves masters of the town and drove out their adversaries. Matthiesen came forward as their prophet, and persuaded the people to devote gold and silver and movable property to the common use, and to burn all books but the Bible; but in a sally against the bishop of Münster, who had laid siege to the city, he lost his life. He was succeeded in the prophetic office by Bochhold and Knipperdolling. The churches were destroyed, and 12 judges were set over the tribes, as in Israel; but even this form of government was abolished, and Bochhold, under the name of John of Leyden, raised himself to the dignity of king of New Zion, as the Anabaptists of Münster called their kingdom, and as such was ceremoniously crowned. From this period (1534) to 1535 Münster was the scene of all extravagance, licentiousness, lust and cruelty. The introduction of polygamy, and the neglect of civil order, concealed from the infatuated people the avarice and madness of their tyrant and the increase of danger from abroad. Bochhold lived in luxury and magnificence; he sent out seditionary proclamations against the Pope and Luther, as well as the neighboring authorities; he threatened to destroy with his mob all who differed in
opinion from him; made himself an object of terror to his subjects by frequent executions, and, while famine and pestilence raged in the city, persuaded the wretched, deluded inhabitants to a stubborn resistance of their besiegers. The city was at last taken, 24 June 1535, by treachery, though not without a brave defense, in which Rothmann and others were killed, and the king, with the Anabaptists destroyed by the execution of the chief men. Bohchod, and two of his most active companions, Knippeidol and Krettching, were tortured to death with red-hot pincers, and then hung up in iron cages on St. Lambert’s steeple, at Münster, as a terror to all rebels. In the meantime, some of the 20 apostles, who were sent out by Bohchod to extend the limits of his kingdom, had been successful in various places; and many other teachers, who preached the same doctrines, continued active in the work of founding a new empire of pure Christians, and propagating their visions and revelations in the countries above mentioned. It is true that they rejected the practice of polygamy, community of goods, and intolerance toward those of different opinions, which had prevailed in Münster; but they enjoined upon their adherents the other doctrines of the early Anabaptists and certain heretical opinions in regard to the humanity of Christ, which seemed to result from the controversies of that day about the sacrament. The most celebrated of these Anabaptist prophets were Melchior Hoffmann and David Joris. The former, a furrier from Suabia, first appeared as a teacher in Kiel in 1527; afterward, in 1529, in Emden; and finally in Strasbourg, where, in 1540, he died in prison. He formed, chiefly by his bold promises of a future elevation of himself and his disciples, a peculiar sect, whose scattered members retained the name of Hoffmannists in Germany till their remains were lost among the Anabaptists. They have never owned that Hoffmann recanted before his death. David Joris, or George, a glass-painter of Delft, born in 1501, and rebaptized in 1534, showed more depth of mind and warmth of imagination in his various works. In his endeavors to maintain the discordant parties of the Anabaptists, he collected a party of quiet adherents in the country, who studied his works (as the Gichtelians did those of Böhme), especially his book of miracles, which appeared at Deventer in 1542, and revered him as a kind of new Messiah. Unsettled in his opinions, he traveled a long time from place to place, till at last, to avoid persecution, in 1554, he became a citizen of Basel, under the name of John of Bruges. In 1556, after an honorable life, he died there among the Calvinists. In 1539 he was accused, though without much reason, of profligate doctrine and conduct, and the Council of Basel ordered his body to be burnt. 

Undoubtedly by no means all the Anabaptists of Germany indulged in social and political excesses; for the character of the early Anabaptists is sufficiently explained by the tendency of human nature to rush into extremes. The iron hold of the ecclesiastical hierarchy, which had cramped the Church for ages, being suddenly relaxed, men had yet to learn how to exercise the freedom thus granted them in the forms of civil or religious liberty. But these considerations were overlooked, and the reformed churches, with one consent, regarded the Anabaptists with horror and disdain. The correspondence of the Reformers is full of allusions to the subject. Anabaptists are spoken of with reprobation, and a distinction is not sufficiently made between the sober Christians and the worst fanatics of the party. It is probable, at least, that their faults have been exaggerated even by the best writers. Menno Simons inaugurated a new and prosperous era for the Anabaptists. He gathered together the scattered remnants of the sect and founded numerous congregations in Germany and the Netherlands. Later they became known as Mennonites, and are now known as Taufgesinnte in Germany, and as Doopsgezinde in Holland. These terms are very close to the English term Baptists, and avoids all association with the early Anabaptists. Menno explained his doctrine in his work ‘Elements of the True Christian Faith,’ which is still authoritative among the sect. Especial emphasis was placed upon the doctrines of Scripture with simple faith and conforming one’s life to them, at the same time making no special prize of learning or the scientific explanation or elaboration of doctrines. Oaths, war, revenge, infant baptism, divorce, except for adultery, are also undertaken by the functions of magistrates, who are regarded as a necessary present evil, in no wise necessary to God’s kingdom. Grace is universal and the Church is the community of the saints, whose purity is to be maintained by strict discipline. In Germany and Switzerland their worship is closely akin to that of the Lutherans. Bishops, elders and instructors receive no remuneration. Children receive their name at birth, adults joining the body are rebaptized and baptism takes the place of worship. About the beginning of the last century all the congregations of Holland were merged into one body. Consult Lindsay, ‘History of the Reformation’ (Vol. II, New York 1907). 

ANABASIS. The Anabasis is the story in which Xenophon tells how the Ten Thousand (really some 14,000) Greeks in the year 401 B.C. went up with the younger Cyrus to help him oust Hystaspis of the Persian throne. ‘The Anabasis’ proper, i.e., the going up, covers only the first book; the remaining six books tell how these Greeks, under Xenophon’s leadership, came back down to the sea and finally got home. Xenophon’s story, which has been for ages the first book read by students in a classical course, has made the brilliant and generous but unfortunate young Persian prince one of the best known characters in the world’s literature; as the inimitable account of perhaps the most famous retreat in military history, it has also immortalized the author and made him one of the most fascinating figures in Greek history. It is mainly a story of adventure in distant lands and in large part among almost unknown primitive peoples, offering a wealth of material, ethnological and geographical; incidentally also valuable information as to the constitution of the Greek army and its spirit, so much like that of the popular assembly at Athens. The purpose of the book? It may have been intended partly as an apologia or refutation of criticism of Xenophon’s conduct of the expedition. It was probably intended also to indicate to his countrymen how rotten at the core was the Persian
empire, ready for some other Agamemnon to lead against it another victorious Hellenic host, as indeed Agistes assumed to do in 396 B.C. Xenophon could not see all that was meant in the future by the expedition in which he shared as soldier and historian; yet the premonition of it is everywhere cheerfully present; and even in the later books, when little has to be told but of trial and loss, there is still apparent the serene confidence of a nation that was already preparing itself for another Anabasis, which should be no mere brilliant and inept but the sure foundation of a new order of things. It is in this way that the Anabasis of Cyrus, as recorded by Xenophon, was the prologue and preparation for the mighty conquests of Alexander. (Marshall).

For the general reader the 'Anabasis' will remain simply a very interesting account of the most important episode in Xenophon's experience — a story of warlike adventure and exploit told in clear and simple, if not always the purest, Attic Greek. It is very far from being 'Xenophon's duty shift' as 'we force upon our boys,' as the editor of the 'Review of Reviews' said to a classical club. So the classics must suffer sometimes even from would-be friends. I found the story fascinating when I read it in Greek at fifteen and when I came to edit it at fifty kept thinking, 'How ridiculously interesting and easy it is!' A few years ago a professor of English, who is author of half a dozen books in prose and verse, came to me, after rereading the 'Anabasis,' jubilant over the interest of the story and the art of the story-teller. 'A more delightful yarn it would be hard to find,' he said. Its best lesson to the modern, in the way of style, will doubtless always be its clearness and simplicity, in proof of which let one passage, which is perhaps the best of many fine ones, be cited. The weary and footsore Greeks had been for many months marching and fighting through desert and mountain wilds when at last a guide came and told them he could lead them to a place whence they could see the sea. 'If I don't,' said he, 'you may put me to death.' On the fifth day they came to a mountain named Tethes. And when the foremost reached the summit a great shout arose and all the rear guards heard it and thought other enemies were attacking in front. But as the cry grew louder and nearer and the men as they came up ran forward to join those that were shouting, and the cry became louder as the number grew larger, Xenophon, thinking it something serious, mounted his horse and with Lycius and the horsemen went to the rescue. Soon they heard the soldiers shouting 'The sea, the sea!' and passing the cry along. Then all ran, even the rear guards, and the pack-animals and horses were left and when all reached the summit they wept for joy and embraced one another and the generals and captains. Suddenly someone gave the word and they brought stones and made a great heap, on which they placed a crowd of raw hides and straw and captured shields, the guide himself cutting up the shields and exhorting others to do this. Under somewhat similar circumstances many a man has since remembered this scene and repeated the cry. General von Moitke relates that when he and his attendants first saw near Samsun the gleaming sea, 'the same that drew from the Greek soldiers their celebrated ἱσσαρία, they too broke into shouts of joy.' Best of all is Virgil's imitation:

ιτιαμ, Ιτιαμ πριμος κονταλατ Αχατες,
Ιτιαμ ιτοιτοι οικι τιμοι αντιτ.

For an extended discussion of the 'Anabasis,' both from a historical and military point of view, consult Goodwin and White's 'Anabasis'; the introduction to 'Xenophon' (Vol. I); article 'Xenophon' in 'Dictionary of Greek and Roman Biography'; Hertzberg, 'Der Feldzug der Zehntausend Griechen.'

Charles Forster Smith, Professor of Greek and Classical Philology, University of Wisconsin.

ANABLEPS, a genus of fishes of the order Malacopterygii Abdominales, family Cyprinidae (Cuvier), family of Cyprinodontidae (Agassiz). It is characterized by a structure of the eyes to which belong in any other vertebrated animal. This consists in a division of the cornea and iris into two somewhat unequal elliptical parts by transverse bands, so that the creature seems to have four eyes, and there are really two pupils on each side. This peculiar structure is supposed to have been formed for the purpose of enabling the fish to see both above and below water, as it swims along the surface. The fish itself is elongated, scaly, with a flat, rounded back and depressed head. The young are born alive and in a considerably advanced stage of development. It occurs along the coasts and the rivers of South America, keeping to the shallow waters. The creature cannot dive to any depth, but is capable of moving over mud flats.

ANABOLISM, the building-up process of organic life. The term metabolism (q.v.) is used to express the interchange of the life process constantly going on in living plants and animals.

ANAOCOA, an'ā-xā'ō-nā, or GOLDEN FLOWER, Haitian princess, sister of Behechio and wife of Caonabo, both chiefs of the Indians of Haiti when Columbus discovered that island, in 1492. On her brother's death she became the head of the tribe, and after the death of her husband remained on friendly terms with the Spaniards until 1503, when she gave a feast in honor of Ovando, the Spanish governor, in the midst of which she was put to death by his order.

ANACARDIACEAE, an'ā-kār'di-ā'ē, a family of dicotyledonous plants, consisting of trees and shrubs, with acrid, resinous sap, sometimes irritating and poisonous. It embraces about 50 genera and 500 species, mostly confined to the only species indigenous to the United States. to the tropics. The sumach and poison oak are The most important genera are the Mangifera, Spondias, Rhoeas and Semecarpus. Resins and tannins are obtained from all, and are valuable for the manufacture of lacquers, varnishes and tanning materials. Wholesome and agreeable fruits are produced by some of the species, and are extensively cultivated in the tropics. See MASTIC GUM; MANGO; PISTACIA; SUMAC.

ANACHARSIS, an'ā-kār'sis, the name of a Scythian philosopher who flourished about
600 B.C. and was a friend of Solon, by whose influence he was received into Athenian society. Returning to Scythia, he was put to death because of his performance of certain Greek religious ceremonies. Modern readers have been familiarized with the name through J. J. Barthélemy’s famous ‘Voyage du Jeune Anacharsis en Grèce’ (1788).

ANACHRONISM, an inversion of chronological relation, unintended or otherwise. In common parlance it is confined to the antedating of customs or events, particularly in imaginative works with a basis of history.

ANACONDA, Mont., city, the county-seat of Deer Lodge County, 27 miles northwest of Butte, on the Northern Pacific, Great Northern and Butte, Anaconda & Pacific railways. It was founded in 1884, following the erection of its great copper-smelting works, which are the largest in the world. They treat daily between 5,000 and 10,000 tons of ore mined in the vicinity. The copper produced by the Washoe Reduction Works of the Anaconda Mining Company comprises 10 per cent of the world’s output. Deposits of graphite and saphires are found near the city. Anaconda has also large railway shops, brick works, machine-shops and other manufactories, banks, telephone and telegraph service, and daily and weekly newspapers. It has parks, likewise a race track and fair grounds, Hearst Free Library containing about 6,000 volumes, two opera houses and a daily and weekly newspapers. Anaconda has grown rapidly with the development of its great copper industry. In 1880 it was a small mining camp; 10 years later its population was 3,975. Pop. (1910) 10,134; (1913) 12,500.

ANACONDA, a South American constricting serpent, the water-boa (Eunectes murinus). This is the largest of the boas (q.v.), and like the Ceylonese python (to which the name originally belonged), may exceed 30 feet in length. It inhabits the swampy forests of the Amazonian region, where it is unpleasantly numerous and greatly feared by the natives, although not at all aggressive toward mankind, which it seeks to avoid rather than to attack. Like other boas it may hang from tree-limbs awaiting chance prey passing beneath, which it may seize and, by throwing powerful folds about its body, crush to death, meanwhile holding firmly to its support by its prehensile tail. Having crushed the animal, if large, into a sausage-like mass it descends and slowly swallows it, after which it lies quiet for a long time while the meal is digested. In captivity, for these reptiles are common in zoological gardens, several months sometimes elapse before another meal is wanted. It is rarely found far from water, and the larger part of its time, as a rule, is spent lying in the water or partly submerged on the bank, where it can seize small aquatic animals and swimming birds, which constitute most of its fare. The nostrils in this species open at the top of the head. Without water in adaptation to this aquatic habitat. During the day these water-boas live in holes in the bank, whose entrances are likely to be under water, and usually go forth only at night in search of food. Although strong enough to overcome animals as large as a jaguar or a crocodile, it will not attempt to swallow one larger than a medium-sized dog. The females produce their young alive at irregular but long intervals and in varying numbers, one captive specimen in New York yielding 34 at a birth; but few of these survive the risk of drowning or the attacks of eagles, peccaries and other enemies.

The markings of the anaconda are leopard-like, the coat being greenish yellow above with one or sometimes two series of large, bluish cross-spots, and a lateral line of dark spots with white centres. The belly is gray spotted with black.

ERNST INGERSOLL.

ANACORTES, Wash., city in Skagit County, 90 miles north of Seattle, on the Great Northern Railroad. It is a port of call for several steamship companies. The prominent features of the city are the Carnegie library, Cap Santa Park and Deception Pass. It has good water power facilities which are used to advantage in the city’s industries, comprising lumber mills, fish-processing and canning plants, oil and glue works, glass and box works and shipyards. The city is governed by a mayor and council. Pop. 6,000.

ANACREON. The Anacreon of history was born at Teos in Asia Minor (hence Byron’s “Teian muse”) in the 6th century B.C. and, driven thence by the Persian invasion, lived at the courts of Polycrates of Samos and Hipparchus, tyrant of Athens. He sang in a variety of lyric measures of love and wine and revelry, and also wrote hymns to the gods and some serious epigrams in the Greek sense of the word. The Alexandrian scholars possessed his poems in five books, of which about 15 pages of fragments remain. Here are two specimens in rough renderings:

Love’s purple ball my heart hath hit
And with a dainty-slippered chit
He beth me to play
But dear less’ns, island rare
Disdainful view’s my whitening hair
And looks another way.

Why with timid sidelong glance
Doest thou see from my address
Thracian colt, and in thy fancies
Hold my cunning in disdain?
Hear that I but come near thee,
I could bridle, bit, and gear thee
And around the stadium steer thee
Past the goal with skillful rein.

Anacreon thus became the type of the Dionsyan old man, the white-haired bard of wine, love and song. It was later a fashionable literary exercise to compose in his name little verses on these themes. Thus without any conscious intention of forgery arose the collection of so-called Anacreontea which, preserved in the Palatine Anthology, has usurped the name and fame of the true Anacreon. They are not in the Ionic dialect; they do not refer to the details of Anacreon’s life; they are rarely if at all quoted by the ancients as of Anacreon; they are composed not in the variety of Greek lyric measures, but in a monotonous tripping iambics; for the mighty god Eros Anacreon they substitute a bevy of Alexandrian or Pompeian Eroses; they are obviously spurious.

The publication of Stephanus’ edition of the Anacreontea in 1554 was a literary event of the
ANAconda (Eunectes murinus)
revival of letters which Ronsard saluted in this strain:

To Stephanus I quaff this cup
Through whom black Hell hath rendered up
And given back to our desire
Anacreon's lost sweet Teian lyre.

From France the fashion of Anacreoniana passed to Germany where successive generations of 17th and 18th century rhymers and readers delighted in such verse as Gleim's

Rosen pfücken, Rosen blühen
Morgen ist nicht heute!
Keine Stunde lass entweichen.
Fluchtig ist die Zeit.

In England Anacreonitas were written under that name perhaps first by Cowley, and in form of paraphrase, free translation or imitation by William Oldys, John Sheffield, Duke of Buckinghamshire, John Phillips, Charles Cotton, John Hughes, William Hamilton, John Cunningham, William Shenstone, William Thompson, William Somerville and other bards buried in Chalmers' Johnson's poets, as well as by Brock, Gray, Prior, Garth, Parnell, Allan Ramsay and Tom Moore.

Among the favorite motives of Anacreonistas and Anacreonetics are the order for a picture (paint the portrait of my love); Eros swallowed in a draught of wine; lines to a drinking cup; the women tell me I am old—but; his countless loves—mille et tre; to a swallow; to the dove; to the happy grasshopper; all things drink, why not I; aain would I sing of epics and war, but the strings of my lyre echo only love; I would I were thy mirror, etc., the motive of the song in Tennyson's 'Miller's Daughter'; bulls have horns and lions teeth and women beauty; the origin of roses; love and the bee; love the lost child admitted from the midnight storm and rewarding his benefactor by a shaft from his bow—a theme varied in countless imitations.

PAUL SHOREY.

Greek Department, University of Chicago.

ANACREONITICS (from the name of the Greek poet Anacreon), the title given to short lyrical pieces, of an easy kind, dealing with love and wine. The English word was first used by Abraham Cowley in 1656, who called a section of his poems anacreontiques because they were paraphrased out of the so-called writings of Anacreon into a familiar measure which was supposed to represent the metre of the Greek. Half a century later John Phillips (1631-1706) laid down the arbitrary rule that an anacreonic line consists of seven syllables, without being tied to any certain law of quantity. The best known anacreonists are those of the Irish poet, Thomas Moore.

ANADARKO, Okla., city and county-seat of Caddo County, 50 miles southwest of Oklahoma City, on the Washita River, and on the Chicago, Rock Island and Pacific. It is located in a prosperous agricultural district and has a large trade in corn, cotton, wheat, vegetables, fruit and other agricultural products. It contains cotton-gins, grain elevators, and oil and flour mills. The principal features of the city are its Indian schools, the county courthouse, Chautauqua auditorium and city park. The city owns the electric-lighting plant and the waterworks. The electric plant is operated by water power secured by a dam in the Washita River. Pop. 4,000.

ANADIR, án'à-dir, or ANADYR BAY, a large inlet of Bering Sea, much frequented by whaling-vessels. It is about 250 miles wide, a peninsula of half that breadth lying between it and the Arctic Ocean.

ANADIR, or ANADYR, the most easterly of the larger rivers of Siberia. It rises in the Stanovoi Mountains, and falls into the Gulf of Anadyr after a course of some 400 miles.

ANADYOMENE, án-à-di-om-e-ne, a surname of Venus, and referring to her as rising from the sea. It was applied by the ancients to a picture by Apelles, which represented the goddess emerging from the waters.

ANADOLI HISSAR, also called GUEL HiSSAR, a village and castle on the Bosporus, seven miles northeast of Constantinople, of which city it is a suburb. The castle, which is variously ascribed to Bayazid I and Muhammad I, consists of four round towers and a central square keep, which latter is called the Black Tower, from the darkness of its walls, within which many state prisoners ended their days. The castle is now in ruins and a habitat for numerous cranes, which are held in great respect by the Turks. Near by are the Sweet Waters of Asia (q.v.).

ANÆMIA, literally without blood, popularly poorness of blood. In medicine, however, it may signify a reduction of the amount of the blood in its entirety, in its corpuscles red or white, or in one particular or important ingredient, as the red coloring matter of the blood, the hemoglobin. Anemia is divided into primary and secondary anæmia. Primary anæmia includes two diseases entitled: Chlorosis (q.v.) the green-sickness of young girls; and pernicious anæmia (q.v.), a disease of the blood-making organs. Secondary anæmia may be broadly subdivided into acute and chronic anæmia. Acute anæmia is due to hemorrhage either external or into one of the body cavities. Chronic anæmia on the other hand may be due to a number of causes which may be generally noted as follows: Continued losses of blood, inanition, infectious diseases, malignant and long-continued wasting diseases, parasites, notably in the hook-worm disease, Unicaria (the poor whites of the South, earth-eaters, etc., seem to be typical examples); or from intoxications from inorganic poisons, lead, mercury, copper, arsenic, carbon dioxide, etc., or from organic internal intoxication as in nephritis and pregnancy. See Blood Diseases.

ANÆSTHESIA. In its simplest sense this term means simply absence of feeling and has been handed down to us from a very respectable Greek antiquity. We cannot get behind this. There may be anæsthesia of a part of an organ or of a special sense or of the entire sensibility, but it is all want of feeling, want of sense perception in the part or the whole. The term, like so many of the Greek terms, is basic and inclusive. We moderns are accustomed to say there is a general and a local anæsthesia according as the entire sense of feeling is obliterated or only a sense is lost. There is a general anæsthesia in sound sleep, in profound stupor or coma, in surgical shock, in
the unconsciousness which comes from the inhalation of certain vapors and the influence upon the sensory centres of poisonous drugs, and in the rare conditions called trance and intense mental concentration when mind seems to be carrying on an independent existence apart from matter. The examples of local anaesthetics are innumerable; tie a string around your finger, cutting off its nerve and blood supply, and feel in the finger disappears; continue this long enough and you can have the finger cut off without knowing it, or the finger may drop off, being dead and no longer a part of the living organism. Interfere with the circulation of your foot by pressure or constrained position, and you say it is asleep and has no feeling in it; freeze it and you may cut it or prick it or pinch it without wincing. Inject under the skin solutions of certain drugs or even distilled water and if properly done you may cut the skin and the tissues which are under it and even invade one of the cavities of the body and cut out organs or new growths without excessive pain, perhaps with very little or none as is now being done by skillful surgeons every day. Such is the marvelous control which men have gained by experience and investigation over the natural operations of physical functions.

How is this brought about? Consciousness is governed by the interaction of the blood and the nervous system. Remove a sufficient quantity of blood from anybody and consciousness ceases. If you were to look at the brain, the centre of consciousness, of one who had lost this blood, you would find it pale instead of red as it is when the blood is flowing through it; its blood vessels would be more or less collapsed instead of distended. This is probably what happens during natural sleep. There may be other factors, too, about which there has been much speculation and investigation, but this is the principal one.

When the brain is anemic or when the blood flowing through it is poisoned by certain drugs there is an arrest of consciousness. This is general anaesthesia; there is no feeling either of pain or pleasure in any portion of the body. The skin, including the mucous membranes lining certain cavities of the body, is the principal organ of sensation, and the eyes, the nose, the ears, the mouth, but the skin, the organ of touch, is by far the most extensive and there is no portion of it which does not respond more or less actively to the impression of contact with matter in any form, to heat and cold, hard and soft, solid, fluid and gaseous.

We are conscious of this contact by means of the peripheral nerves, the sensory nerves, which are distributed to each infinitesimal portion of the skin and which converge to trunk nerves going to the spinal cord, by which the impressions are conveyed to the brain and there interpreted. If this line of communication is cut or otherwise interrupted the impression cannot reach the brain and there is local anaesthesia or want of feeling at that portion of the skin where the contact was made and where under ordinary circumstances there would be consciousness of the contact.

Among the most important applications of general anaesthesia has been the abolition of painful impressions in the skin by the influence of medicine and surgery. Ancient medicine knew of drugs that would relieve pain, but not many of them. We read of the somniferous poppy, and mandragora and hellebore rubbed into the skin or taken into the stomach, and wine has been celebrated from time immemorial as the unfailing remedy for hurts of mind and body. Ancient surgery was even more deficient than medicine in its means for relieving pain. Those who were compelled to undergo surgical treatment, whether in civil or military life, usually endured it, if they could, and they had the consciousness of pain just as we do. If they could not bear it they succumbed, and that was the frequent accomplishment of surgical operations, far more frequently than now. The abolition of pain in very many of the hurts of life, in the painful neuralgias, in the throes of childbirth, in civil and military surgery is now a relatively simple matter by both general and local anaesthesia.

When the anæsthetizing influence of the inhalation of vapors of ether and chloroform was announced to the world it was the dawn of a new era; it was a gift which can be appreciated only by remembering the pains of those who were deprived of it. Modifications and variations of these two substances have been devised from time to time, but they have not lost their supremacy and probably they never will. The unfavorable effect which their use often has upon those whose organs are diseased, especially the liver, kidneys, lungs and heart, has led to the wide application and employment of local anaesthesia in surgical practice. The seat of painful sensations resting principally in the skin, it has been found that by infiltrating the skin or injecting into the cellular tissue beneath it suitable solutions of such substances as cocaine, stovain, novocain, etc., sufficient detachment of the peripheral nerves added to the anæsthetizing effect of the drugs upon the nerves will permit of the painless or nearly painless performance of even very extensive operations, and this is of the greatest advantage to those in whom anaesthesia would be inadmissible or at least unadvisable. Anaesthesia by way of the rectum and the spinal canal are devices of recent years which have had their day and a brief one, too. They have failed in their purpose, and surgeons generally and it is doubtful if they will ever come into general use. The use of scopolamine and morphine in obstetric practice, which has had a vogue in certain quarters within the past few years, but which is now subsiding, is not properly a method of anaesthesia, but of analgesia or amnesia.

ANDREW F. CURRER, M.D.

ANÆSTHETICS, agents used to produce anaesthesia, a word first employed by Dr. Oliver Wendell Holmes. In early times it was known that pressure on the carotid arteries on each side of the neck could bring about temporary unconsciousness and resultant anaesthesia. The gentle art of local anaesthesia is an old knowledge. Ancient peoples used opium, Cannabis indica, and alcohol to produce anaesthesia, particularly analgesia, or relief from pain, but it was not until the early part of the 19th century that the discovery of the general anaesthetics, nitrous oxide, ether and chloroform, was made, and still later the wonderful
developments made in the art of local anæsthesia by the use of cocaine and its congeners. For remedial measures anaesthesia may be local or general. Cold, frozen mixtures of ethyl chloride, etc., is a very efficient local anaesthetic for the performance of small operations, such as opening boils, felon,s etc. A large number of drugs have the power of numbing the sensory nerves of the skin and are extensively employed to relieve itching and soreness. These are mostly of the phenol or carbolic acid group, thymol, menthol, etc. Even more efficient in its action on the sensory nerve filaments is the alkaloid cocaine, obtained from the South American coca plant. Applied in an appropriate watery solution (2 to 4 per cent) to the mucous membrane of the ear, eye, nose, throat, urethra, vagina or rectum, it quickly brings about loss of all pain sensations, or, injected into the skin, causes complete anaesthesia over a circumscribed area, permitting of cutting operations. When injected into the spinal canal it brings about complete loss of pain sense in all portions of the body below the site of the injection, sometimes even more extensively. This method of inducing anaesthesia with cocaine has some very advantageous features in surgical procedures and was first practised by a New York physician, Dr. J. Leonard Corning. Stovaine, discovered by Fournier in 1904, is less dangerous in spinal analgesia than cocaine, and in this use has largely superseded that drug. Stovaine, when employed for this purpose, is often combined with strychnine. Alpin, novocaine and other drugs have in recent years been used in spinal analgesia and have been found satisfactory. Other related alkaloids, eucaine, holo- caine, have similar properties to cocaine. Still other compounds made by the synthetic chemist have been widely employed, principally as analgesics (q.v.).

General anaesthesia is usually brought about by the inhalation of some vapor. Nitrous oxid gas, chloroform, ether, ethyl chloride, etc., are those most frequently employed, especially the three former. Nitrous oxide (q.v.) was the first of this series to be suggested. It was made by Sir Humphry Davy in 1800, but was not used in practice until about 1844, when Dr. H. Wells, an American dentist, employed it in the extraction of teeth.

The anesthetic properties of ether were known for some years before put to practical use. As to its first use there is much controversy. It seems certain that one Dr. Crawford W. Long of Georgia first used ether as a general anaesthetic, but to W. T. G. Morton, a dentist of Boston, should be given the credit for demonstrating its value and use to the medical profession. Long did his first operation under ether 30 March 1842, for the removal of a cystic tumor of the jaw. He reported his experiments to the Georgia State Medical Society in 1842. Morton’s work was begun in 1846, on 30 September, when he extracted a tooth while the patient was under the influence of ether. He subsequently demonstrated his method at the Massachusetts General Hospital, and then patented his product under the name Leetheon. The following year Sir J. Y. Simpson of Edinburgh announced the discovery of the anaesthetic properties of chloroform and demonstrated its value in obstetrics. At the present time all three of these anaesthetics are extensively employed. In recent years ethyl chloride has been employed quite extensively as a general anaesthetic in the same class of operations as nitrous oxide. It is inhaled, and is usually given by means of a mask fitting closely to the face and a small rubber bag connected with a bottle containing the drug. The patient becomes unconscious in a very few seconds. Its after effects occasionally are nausea, headache and vomiting. The mortality, it is claimed, is intermediate between that of chloroform and ether. In Europe chloroform is preferred; in this country ether is used more often. The statistics of deaths following these two shows ether to be the less dangerous, although it has more disagreeable after-effects than chloroform. Chronic bronchial and kidney disease contra-indicate the use of ether, while in respect to people with weak hearts chloroform is to be avoided. See CHLOROFORM; Ether; NITROUS OXIDE. Consult Williams, Probyn, ‘Guide to Administration of Anaesthetics’ (New York 1901); Packard, F. R., ‘The Discovery of Ether in the History of Medicine in the United States’ (Philadelphia 1901); Overton, E., ‘Studien über Narkose’ (Berlin 1901). Smith, Ely Jelliffe.

ANAGRAM, a-nä-agram, a name applied to the great central plateau of Mexico, elevated from 6,000 to 9,000 feet above the sea and including more than the area of the republic. It contains several lakes, and Popocatepetl is the loftiest of the volcanoes which rise from it.

ANAHTIS, a-nä-ih-tis, the Persian water goddess of antiquity, extensively worshipped in the East.

ANAKIM (long-necked ones=giants), a general term, like Amorites or Rephaim, used by the Hebrews for the pre-Jewish inhab-
ANALCITE, a-nal’sit (from the Greek word meaning “weak,” in allusion to the feeble electric properties it manifests when heated or rubbed), a mineral usually classed as a zeolite, or hydrated double silicate of sodium and aluminum, with the formula NaAlSiO₄·H₂O; although Doelter maintains that the water cannot be water of crystallization, and writes the formula thus: NaAlSiO₄·2H₂SiO₄. Analcite is commonly colorless or white, with a vitreous lustre. Its hardness is from 5 to 5.5, and its specific gravity about 2.26. It occurs in a variety of forms, but usually in trapezohedral crystals. There has been much controversy over its crystallographic structure, owing to certain optical anomalies that it exhibits; but it is now usually referred to the isometric system, the weak double refraction that it often exhibits being probably due in part to anomalous interstratifications, and in part to a loss of water, and a consequent modification in molecular structure. Beautiful crystals of analcite are found near Mount Asina and in Nova Scotia. In the United States the mineral occurs in the trap rocks of northern New Jersey, Colorado, California and the Lake Superior region. See LEUCITE.

ANALEMMA, a geometrical term implying the projection of a sphere upon the plane of a meridian with the point of sight an infinitely distant point of the radius perpendicular to that plane. This projection is sometimes styled orthographic. The sun-dial has been called an analemma, and the term has also been used to indicate a scale showing the declination of the sun and the equation of time of various periods of the year.

ANALGESIA (a, nega, δ' angel's, pain), the loss of power to feel pain without loss of consciousness; e.g., in some nervous diseases or due to certain drugs. See ANALGESICS.

ANALGESICS, remedies used to control pain. These have come largely into use during the past 10 to 15 years. As the profession had to rely chiefly on a few drugs, notably opium, cannabis indica, and their allies, for the relief of pain of nerve and muscle: neuralgia, acute rheumatism, sick headache and other transitory or persistent affections of the sensory nerves. Synthetic chemistry has introduced a large number of new drugs that have been found very useful in allaying pain and discomfort of many conditions heretofore borne with heroic stoicism. The commonest of these new remedies are antipyrine, acetanilide or antifebrin, and phenacetin. These are but a few of a large list of similar drugs. The numerous drug-store mixtures sold as headache powders, etc., are usually mixtures of the cheapest of these, acetanilide or antifebrin, with other products. See ACETANILIDE; ANASTHETICS; ANTIPYRETICS; PHENACETIN.

ANALOGUE, a term in comparative anatomy employed to denote resemblances, as an organ of an animal or plant performing the same function as another part in a second animal or plant differently organized. It is much used by geologists in comparing fossil remains with living specimens.

ANALOGY, a correspondence of relations between one thing and another. In logic it implies the resemblance of relations, a meaning given to the word first by the mathematicians. To call a country which has sent out various colonies the mother country implies an analogy between the relation in which it stands to its colonies and that which a mother holds to her children.

As more commonly used it is a resemblance on which an argument falling short of induction may be established. Under this meaning the element of relation is not especially distinguished from others. Analogical reasoning may be reduced to the following formula: Two things resemble each other in one or more respects; a certain proposition is true of one of the one, therefore it is true of the other. If a conjunction between a property in the one case and a property in the other finds its place in an established system of correlations, the argument rises above analogy, becoming an induction on a limited basis; but if no such conjunction has been made out, then the argument is one of analogy merely. If two bodies or processes agree closely in certain respects, it is reasonable to suppose that they will also agree in those respects which have been found to be associated therewith. Metaphor and allegory address the imagination, while analogy appeals to the reason. The former are founded on similarity of appearances, of effects or of incidental circumstances; the latter is built up on more essential resemblances which afford a proper basis for reasoning.

In zoology analogy is applied to the resemblance between the entire bodies, or between special structures of organs, in animals of unrelated types. Thus a whale is analogous in form to a fish; its paddles analogous to the fins of a fish. The wings of an insect are analogous to those of a bird. Analogy implies a dissimilarity of the ontogenetic and phylogenetic history of two organs, with identity in
their use or function, as the legs of a bird or quadruped and those of an insect. These analogies are of the animal to similar habits, modes of life or like environment, and result in convergency (q.v.), parallelism, and sometimes mimicry (q.v.) (see also Homology). Osborn defines analogy in evolution as embracing similar changes due to similar adaptation in function both in homologous and in homonymous organs, both in related and in unrelated animals. The different grades of analogy are shown by Osborn in the following table:

**ANALOGY IN EVOLUTION.**

**Analogue Variation (Darwin):** Similar congenital variations in more or less distantly related animals and plants.

**Convergence:** Independent similar development of unrelated animals, bringing them apparently closer together.

**Paralogy:** Independent similar development of related animals, plants, and organs.

**Homopy (Lamarck):** (Homonymy, Fürbringer): Independent similar development of homologous organs or regions giving rise to similar new parts.

**ANALOGY OF RELIGION.** The, a famous work by Bishop Joseph Butler, published in 1736. The full title is "The Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature." The author lays down three premises — the existence of God; the known course of nature; and the necessary limitations of our knowledge. These enable him to take common ground with those whom he seeks to convince — the exponents of a loose kind of deism. In no sense a philosophy of religion, but an attempt to remove common objections thereto, the work is necessarily narrow in scope; but within its self-imposed limitations the discussion is exhaustive, dealing with such problems as a future life; God's moral government; man's probation; the doctrine of necessity; and most largely the question of revelation.

**ANALYSIS.** The act of decomposing or dissecting a thing, such as a substance, a process, or a logical concept, into its component elements, and of exhibiting its structure. The term is also used for an inventory of the results of this dissection such as we often find printed as a long and intricate article on any subject, and also occasionally for the state resulting from the dissection.

As mathematics is the study of pure structure, all mathematics which devotes itself to existing structures is of the nature of analysis. Accordingly, the word analysis, like the words calculus and algebra, is often used as a synonym of mathematical discipline, as in the names "Analysis Situs," "Combinatory Analysis," etc. That phase of mathematics, however, which puts together old elements in new forms is sympathetic in character. Now, though both these phases go hand and hand in the history of every mathematical subject, the usual representation of geometrical entities has made the method of construction or the synthetic method peculiarly easy and universal there. On the other hand, algebra and, more especially, those sciences whose roots are in the infinitesimal calculus are characterized by the prominence which the analytic method possesses in their investigations and are often known by the collective name of analysis. Geometry and analysis usually appeal to different types of mathematicians, who are known respectively as geometer or analysts.

Another mathematical use of the term is its application to the method in which you suppose the theorem you wish to prove demonstrated, reason back to some admitted truth, and then try to retrace the steps by which you have attained it. As an analysis in chemistry see Chemical Analysis.

**ANALYSIS SITUS.** Let a geometrical figure — say a closed surface in common space — be subjected to any change of form (bending, stretching, etc.) that does not involve any tearing or joining. An extensible rubber model will suggest the possibilities of such deformation. Whatever properties of our figure are unalterable by this process from the subject matter of analysis situs, which may therefore be defined as the theory of invariants of the group (or groups, see this term) of continuous deformations. Its scope, however, is not confined to common space, but embraces, in general, m-dimensional figures in n-dimensional space (more briefly: $K_n$ for n-space, also m-surfaces for m-dimensional surfaces, etc.).

The effect of tearing a surface or making an incision on it along a line is to double the latter. As the incision proceeds it substitutes for each point $P$ of the line two points, $P_1$ and $P_2$, henceforth not to be considered as consecutive, and whose successions separately constitute the left and right edges of the incision. Joining is the opposite process, each point of the junction consisting of twin points merging into one. Corresponding definitions apply to incision and junction along surfaces of two or more dimensions, or when the elements considered are straight lines, planes, etc., instead of points.

It will here be noticed that this figure which are not continuously deformable into one another, or equivalent, in n-space, may become so by virtue of the additional freedom of deformation that n + 1-space affords. The figure of two concentric circles in a plane is not equivalent to two circles excluding one another but becomes so in 3-space. Hence a distinction arises between absolute analysis situs, which places its figures in space of any suitable number of dimensions, and analysis situs in a given space or surface within which all deformation must take place.

C. Jordan has shown that in the case of 2-dimensional surfaces the following four invariants form a complete system. This means that any two surfaces agreeing in these data are equivalent: (1) the number of detached portions of which they consist, and with regard to each of these: (2) the number of curves bounding it; (3) its connectivity; (4) its laterality (unilateral or bilateral type). Evidently the first and second of these could be changed by incision or junction.

**Connectivity.** A surface is connected if it permits of continuous passage on it between any two of its points. The standard of connectivity is the area of a plane triangle, circle or equivalent figure, which is called simply-connected or elementary. On it any two curves $C_1$, $C_2$, (not intersecting themselves or each other) between two points, $A$, $B$, are equivalent, and taken together they form a closed curve which divides the plane into two separate portions. This latter property received analyti-
ceral demonstration from Jordan (hence "Jordan curves") and has lately been based on the theory of deformable curves by Veblen. Using Poincaré's notation we write

$$C_1 \equiv C_3 \text{ or } C_1 - C_3 \equiv 0,$$

where the negative sign means that the curve is to be taken in the opposite direction (from B to A), and equivalence to zero means unlimited contractibility. A spherical or ellipsoidal surface is also simply connected, with this difference, that closed curves, if one obstacle (a small circle or "puncture" of the surface) be placed in the way of their contraction, may still be reduced to zero by deformation in the opposite direction. Consider, for instance, the intersection of such a surface with a movable plane as the latter moves parallel to itself in either of two directions.

Extending our definition of equivalence to zero, to sums of curves on any surface, it becomes necessary to stipulate (1) that the order of terms of a sum must be preserved (non-commutative addition) and (2) that any portions of curves, if deformed so as to coincide and form negatives of one another, shall cancel. Thus on the surface of the double ring (Fig. 1) we have

$$C_1 + C_4 = C_5 \text{ or } C_1 + C_5 = C_4 \equiv 0.$$

Curves form an independent set on a surface if none and no sums of them are equivalent to zero. Curves containing portions equivalent inter se (as when coiling several times about a cylinder) shall here be excluded. Multiply-connected surfaces are then said to have connectivity c if they permit of c independent paths between any two points A, B. The connectivity of a closed surface, i.e., one without boundary and yet having all its points at finite distances, is not changed by puncturing it. For instance, the intersection of the double ring of Fig. 1 with a plane containing one of its curves (and to zero) no matter how the plane moves.

Taking B at an infinitesimal distance from A all paths between them but those equivalent to the shortest one approach closed curves (Fig. 2). Hence there are c - 1 independent closed curves on a surface of connectivity c. Conversely, an independent set of c - 1 closed curves does not divide the surface (for this would give rise to an equivalence between those bounding any portion of it) and can readily be so connected with two points A, B, as to form (after slight changes) c - 1 paths from A to B, in addition to which there is the direct line joining the two points.

Connectivity is often investigated by the method of sections. The latter are incursions of three types: (1) cross-sections between two points on the boundary. They may be bound-

**Fig. 1.**

**Fig. 2.**

sewing, if drawn between points of the same bounding-curve, or bound-joining, if between different ones. The former increase, the latter diminish, the number of boundaries by unity; (2) re-entrant sections, along closed curves, each furnishing two new rims; (3) σ (sigma-) sections starting at a boundary point and ending at a point of their own right or left edge. These contain a re-entrant bound-joining section, and increase the number of bounding-curves by unity. For exceptions to these statements see the paragraph on unilateral surfaces.

Limiting our investigations to surfaces any sufficiently small area of which may be considered simply connected, we may divide any one, or system of several, of them by a sufficient number (q) of cross-sections into (say, e) elementary areas. Since cross-sections start at a boundary, we must give a boundary to closed surfaces by puncturing them, i.e., taking out an infinitesimal area somewhere. The difference e - q then proves characteristic of our system of surfaces, and in fact is known as its characteristic: $K = e - q$.

To prove this, let a second division, by q' cross-sections, yield e' elementary areas. Superpose the tracings of both divisions and let there be t crossings of the proposed incisions. Then the e areas left whole by the first division will be cut q' + t times by the second, or the e' areas of the second q + t times by the first. The sets of incisions thus furnish $e + q' + t = e' + q + t$ parts, which proves the proposition. We also see that the characteristic of a system of surfaces is the sum of their individual characteristics.

Any surface can be rendered simply connected by means of $1 - K$ cross-sections, for let the q cross-sections which divide it into e elementary areas be traced, and let them meet in v vertices. Consider this division as a map of $e$ districts, the edges counted from vertex to vertex, being its frontiers. Between any adjacent districts obliterate one frontier (thereby also removing two vertices). Repeat this operation on the new map, etc., until but one district remains. By what we have proven, the totality of remaining frontiers then constitute $1 - K$ cross-sections.

On the other hand the $c - 1$ nearly closed curves connecting A with B (see above) can readily be turned into cross-sections if we first draw a re-entrant section in a circle of diameter AB, thereby "puncturing" the surface. Hence, on closed surfaces, $c - 1 = 1 - K$, or $c = 2 - K$, and if we retain this formula, the connectivity of a system of m surfaces will prove to be the sum of the individual connectivities, diminished by the number $(m - 1)$ of punctures necessary to make one surface of the system:

$$e = \Sigma c_i - (m - 1) = 1 + \Sigma (c_i - 1).$$

Kronecker's researches have led to an analytical expression for the characteristic of a closed analytical surface $f(x, y, z) = 0$. Let $f(x, y, z)$ be negative in the interior of this surface, and consider the family of surfaces $f(x, y, z) = \lambda$. As $\lambda$ increases $(-\infty)$ to 0, the surface has no real part at first, then, through the stage of isolated points or curves, real surfaces will develop. An isolated point develops into an ellipsoidal surface, increasing $K$ by 2, while a closed curve (without multiple
points) becomes an anchor-ring, leaving $K$ unchanged. This, or the opposite, may occur several times as the parameter increases. Also, double points of the surface may arise, in the neighborhood of which the surfaces resemble one- or two-sheet hyperboloids, changing from the one shape to the other as the double-point stage is passed. In each of these cases the increase of $K$ is found to be

$$-2 \text{sgn} \left[ \frac{f_u f_v f_w}{f_u f_v f_w} \right], \text{sgn (signum) meaning} \pm 1$$

according as the determinant is positive or negative, and 0 if it is 0, and

$$f_1 = \frac{\partial f_1}{\partial x}, f_2 = \frac{\partial f_2}{\partial x}, f_3 = \frac{\partial f_3}{\partial x}, f_4 = \frac{\partial f_4}{\partial x}, f_5 = \frac{\partial f_5}{\partial x}, \text{etc.},$$

being partial derivatives.

**Examples.**—(1) The surfaces formed by rotation of the lemniscates

$$[(x+a)^2 + y^2] \left[ \frac{(x+y)^2}{x^2} \right] = \lambda, \text{ (Fig. 3)}$$

for positive $\lambda$, pairs of sheets of elliptic connectivity ($K=2$), for negative $\lambda$, single sheets of elliptic connectivity ($K=2$). Within an infinitesimal sphere about the origin the transition is from the one-sheet to the two-sheet hyperboloid, as $\lambda$ decreases through zero. At $\lambda = -a$ the two sheets become isolated points and vanish ($K=0$). (2) The surfaces formed by rotation of the same

the quantities $w_1 \ldots w_n$ will turn out equal. In these points we assume connection between the corresponding sheets, and denote them as branch-points. Such connection may not be feasible where other sheets intervene. In 4-space this difficulty would not arise. Limited as we are to 3-space, we may still suppose passage possible in these points between the sheets in question. Further, we find that whenever, starting at $z_k$, we take $z$ in a loop (in all sheets simultaneously) about a branch-point, on returning to $z_k$ the values $w_1 \ldots w_n$ will have undergone a permutation typical of that branch-point. We prevent such loops, and render the branches single-valued, by means of incisions through all the sheets concerned, from $z_k$ to each branch-point. We further join every left edge of these incisions with the right one that exhibits the same $w$-values. This process (which, strictly speaking, again calls for a fourth dimension) completes our Riemann surface.

If we use a circular punch to cut out neighborhoods of the $n$ branch-points (through all the sheets), the portion punched out at $b_j$, where first $\beta_1$ then $\beta_2$ . . . sheets are connected, will show $n \left( \beta_1 - 1 \right) \left( \beta_2 - 1 \right) \ldots$ distinct simply connected parts. Thus all branch-points furnish $\Sigma n - \Sigma \left( \beta_1 - 1 \right)$ elementary areas. The neighborhood of $z_k$, similarly punched out, yields $n$ separate circles. The remainder falls into $n$ elementary surfaces by means of $n$ incisions from $z_k$ to the branch-points, through all the sheets, therefore each counting for $n$ cross-sections. Hence

$$K = 2n + 2 \left[ n - \Sigma \left( \beta_j - 1 \right) \right] = nm = 2n - \Sigma \left( \beta_j - 1 \right).$$

**Laterality.**—Granting that within a sufficiently small neighborhood of any point $P$, any of the surfaces we consider has two sides (right and left) distinguished by the two perpendiculars to be drawn from $P$, it may happen that some continuous path on the surface starting at $P$ on the right side arrives at $P$ on the left side. The surface is then called **unilateral** in the absence of such a possibility, **bilateral**. We have hitherto tacitly assumed the bilateral type for our surfaces.

Moebius called attention to the fact that a rectangular strip of paper $aba'b'$, if its sides $ba, a'b'$ be joined after a twist of $180^\circ$, as Fig. 4

![Fig. 3.—Lemniscate.](image)

![Fig. 4.—Moebius sheet.](image)
rectangular strip into triangular shape as in Fig. 5. The folds may be distinguished as positive or negative according as, on our way from $ab$ to $a'b'$, we pass from the lower to the upper sheet or the reverse. Each corresponds to a torsion or $\pm \pi$. Positive folds will cancel against negative ones. Evidently a strip folded into the shape of a polygon of an even number of sides will thus represent a bilateral surface; if the number of sides be odd, a unilateral one. Ruled surfaces of the third order contain the Moebius sheet (Mascckke). Closed surfaces without double points are bilateral.

Indicatrix.—The two half-normals at a point $P$, not being in the surface, are more conveniently replaced by a small circle about the point, taken in a definite (say counter-clockwise) rotation about $P$. On the other side (of this point's neighborhood) the same rotation will be a counter-clockwise one about $P$. Similarly, within the surface two infinitesimal perpendicular straight lines may be drawn, which if produced would form a right-handed Cartesian co-ordinate system (see ANALYTIC GEOMETRY) on one side (which we may define as the right one) and a left-handed one on the other. Such alternating contrivances are called indicatrixes (Klein). They may be distinguished as right and left, or as positive and negative. If constructed continuously (i.e., without sudden transition to the opposite one) on continuous paths for all points that can thus be reached, one indicatrix will result for each point on a bilateral surface, while on a unilateral one a point will have both of them. Hence the term double surfaces for the latter type.

Unilateral Surfaces.—It will be noticed that Moebius' sheet has one continuous edge. Also, if we pursue any closed path, our direction of progress and a direction on the surface perpendicular to the former and pointing to the left may be taken as an indicatrix. Along some closed paths the latter will be reversed. A line closely following such a path on its left will not close, as its beginning and end will be on opposite sides of the path. An incision along the latter evidently leaves our surface connected. Thus, on a unilateral surface, at least one non-dividing re-entrant section can be made. We shall call it a bilateralizing one. In fact, the number of bilateralizing re-entrant sections will be that of independent paths along which the indicatrix is reversed. This type of the re-entrant section, however, yields only one new bounding-curve. For only after completing a double circuit about the above closed path will the line following it on the left close in its turn, showing that the two edges of the incision blend into one. There also becomes possible a new kind of cross-section that leaves unchanged the number of boundaries (bilateralizing cross-section), as we see by merely tracing a bilateralizing re-entrant section and then making a cross-section that crosses the trace once between two points of one boundary.

Let our surface possess $B$ bounding curves; let it become simply connected by virtue of $b$ bilateralizing, $s$ bound-severing, and $c$ bound-joining cross-sections. Then $j = c - 1 - b - s$, and $B + s = (c - 1 - b - s) = 1$ or $B + 2s + b = c$. Since $b$ is not zero, the number of boundaries of a unilateral surface will always be less than its connectivity: $B < c$.

Two Types of Unilateral Surfaces.—Draw a line connecting two points on different bilateralizing re-entrant sections. Make the bound-joining cross-sections $\overline{ab}$ and $\overline{ab}$ immediately to the right and left of it, and rejoin the re-entrant sections along the small portions $\overline{ab}$. The result will be a common re-entrant section. For follow by a line immediately to the left the re-entrant section from $\overline{a}$ to $\overline{b}$, the cross-section from $\overline{b}$ to $\overline{a}$, the other re-entrant section to $\overline{a}$ and, finally, the cross-section to $\overline{b}$. It will be seen that this line is closed, and so is the corresponding edge of the whole incision. After this process of uniting bilateralizing
re-entrant sections has been repeated as often as possible, if \( b \) is even, no bilateralizing re-entrant sections remain; if \( b \) is odd, there will remain one. Accordingly, there are two types of unilateral surfaces:

1. \( B + 2 \left( s + \frac{b}{2} \right) = c \), \( b \) even: \( B = 2 - c \), when the surface is unbounded \( (B=0) \), becomes \( 2, 0, -2, 4 \ldots \)

2. \( B + 2 \left( s + \frac{b-1}{2} \right) + 1 = c \), \( b \) odd: \( K = 2 - c \)

The above surface (Fig. 9) is of the first type, even if extended so as to lose its boundary; \( K=0 \). Steiner's surface, which is equivalent to the projective plane, is of the second type; \( K=1 \).

Steiner's Surface.—Project the points of the projective plane from a centre \( C \). On each projecting ray, whose length \( CP \) we call \( r \), lay off the segment \( \frac{1}{1+r} \) from \( C \). The line at infinity will thus furnish a circle of radius unity, whose diametrically opposite points represent the same point (at \( \infty \)) of our plane. Now let the entire new surface, consisting of the ends of the segments laid off from \( C \), be deformed into the plane area of this circle (Fig. 6). Cut the latter from \( C \) to \( E \), roll it into a cone, putting \( CE \) on \( CE' \) (the edges of the incision on different sides). Join the edges of \( CE \) (creating a double line) and also, by adjacent points, the two basal circles of the cone. This second juncture, by deformation of the surface, may be made to show continuous curvature, and the apex of the cone may be made to coincide with the centre of the circle of juncture. This is Steiner's surface (Fig. 11). By punching out its centre and cutting by a plane perpendicular to the double line we get three elementary surfaces. Hence \( K=1 \), also \( c=1 \), \( b=1 \), \( B=0 \).

Boy has devised similar surfaces and investigated the connection between the characteristic and Gauss total curvature in such cases.

Two connected surfaces possessing the same number \( (B) \) of bounding-curves, the same connectivity and, in case they are unilateral, the same number of bilateralizing re-entrant sections, can now be made simply connected by means of the same number of independent re-entrant sections. After a correspondence has been decided upon between the bounding curves,
tions in (i.e., tangent to) the surface perpendicular to each other. There will be only two indicatrices (right and left), since we may bring about coincidence between a first pair of axes of different indicatrices, then between a second pair, etc. To do this, in the case of the 4th pair, we have $m - k$-space at our disposal. This becomes a common plane for the $m$-first pair. For the last pair there remains a line only, so that coincidence, if not existing, cannot be forced. As a consequence, unilateral and bilateral $m$-surfaces must be distinguished.

**Examples.**—The indicatrix of a line is the line-element (or the tangent) taken in one of two possible directions. A closed curve with a cusp might be considered one-sided, as the direction here changes abruptly as we make the circuit. A four-sided prism $abca'd'b'c'd'$ in $K_{m}$ can be twisted like Moebius' sheet and its face $abcd$ joined to $c'd'a'b'$. The resulting surface is bounded by one bilateral $2$-surface (from $ab$ to $cd=a'b'$ and back to $c'd'=ab$) and two unilateral ones. We may further join these two latter $2$-surfaces, their juncture only forming a unilateral surface such as we may imagine inside any solid. There will remain only one bounding bilateral $2$-surface of spherical connectivity, just as Moebius' sheet has one edge. This further shows that an incision is possible along a surface of spherical connectivity, which does not divide our $3$-surface, but renders it bilateral (bilateralizing closed section).

We shall now consider bilateral $m$-surfaces. They may be given by making the co-ordinates $x_{1} \ldots x_{m}$ of a point in $m$-space, functions of $m$ parameters $l_{1} \ldots l_{m}$. Then $x_{k}=x_{k}(l_{1} \ldots l_{m})$. $m$-planes will then be linear functions. Lines common planes, etc., are $m$-planes for $m=1, 2, \ldots$ in $m$-space, we call surfaces complementary if their dimensions add up to $n$, dual if they add up to $n-1$. In $K_{m}$, lines and $2$-surfaces are complementary, while lines are dual to lines (self-dual).

Closed $m$-surfaces are boundless and contain no points with infinite co-ordinates. They separate the dual planes of $n$-space into interior and exterior parts. By cutting any complementary plane ($m$-$m$-plane) that does not intersect the closed $m$-surface, we can move into it any exterior dual plane ($n-1$-$m$-plane) without allowing it to intersect the surface on the way, can reverse it there by turning it through $180^\circ$, and bring it back to its original position along the path on which it was brought. An interior $n-1$-$m$-plane, if we attempted to do the same, would describe an $n$-$m$-surface which must intersect the given $m$-surface. Besides distinguishing between the interior and exterior of our closed $m$-surface this also shows that the interior is bilateral, the exterior unilateral, with regard to the dual planes.

**Examples.**—(1) The limiting case of a closed figure without dimension is a couple of points. In $1$-space (straight line) it bounds a segment. It separates the straights of $2$-space (common plane) into those passing between it (interior) and the exterior ones, and the same for the $2$-planes of $3$-space. (2) The interior of a circular circumference is an area in $2$-space; in $3$-space it consists of the straight lines passing through it. Take a plane not intersecting it: An exterior straight line may be moved into the same without coming in contact with the circle, may there be turned through $180^\circ$ and brought back.—Although points cannot be reversed, it is as natural in an analysis situs as in projective geometry to assume unilaterality for the infinite plane. This is merely to extend to a limiting case what is true generally.

**Interiors of Different Orders and Degrees.**—In a plane a closed curve may have overlapping portions so as to contain a certain area twice or $r$ times. In $3$-space it may, without having any double points, coil $r$ times about certain straight lines of its interior, which thereby become an interior of the $r$th order. But if, as we follow the curve in a given direction, it coils $p$ times in an assumed positive rotation about this interior of $r$th order, and $r-p$ times negatively, we may then call $p-(r-p)=2p-r$ the degree of the interior. The curve $C$ (Fig. 13) has an interior of order $2$ and degree $0$.

In $n$-space a closed $m$-surface may be locked with a closed $n-1$-$m$-surface, as are the links of a chain. Through neither of them can a surface one dimension higher than it be laid that does not intersect the other. Examples: A point-couple and a circle enclosing one of its points in a plane. Two linked curves in $K_{m}$. For the latter, according to Gauss, the double integral

$$
\frac{1}{(x'-z)(y'dy'z'-dx'dy')} + \frac{1}{(x-z)(y'dy'-dx'dy')}
$$

and

$$
\frac{1}{(x'-z)^{2}+(y'-y)^{2}+(z'-z)^{2}}
$$

$x, y, z$ being a point of one curve, $x', y', z'$ one of the other, $l_{1} \ldots l_{m}$ the value $1$. In the case of one curve coiling repeatedly about the other, the order and degree of their intersecting may again be distinguished in accordance with the reflections of the preceding paragraph. Gauss' integral then gives the degree, which may hap-
pen to be 0 if the order be even. Two spherical surfaces transplanted into \( R \), may interlock.

**Knots.**—Closed \( m \)-surfaces, in \( 2m + 1 \)-space may lock with themselves. They are then said to form **knots**. The various shapes of knotted curves in common space have been extensively investigated (Listing, Tait, Simony). These researches have been referred to as **topology**, a word also used synonymously with analysis situs. The simplest knot is the so-called trefoil knot. It is formed by a curve of the sixth order whose equation in tetrahedral co-ordinates is given by Brill. It was thought that these knots might be forms of vortex-rings accounting for the differences of chemical elementariness and the torsion in polyhedra. But we shall assume that the surfaces considered possess all these connectivities. With regard to any of them they may be multiply-connected. Connectivity as to points (c) is the special case treated above. It has been referred to as cyclosis or periphery (Maxwell) in the case of portions of 3-space. The interior of an anchor ring, e.g., has c = 2.

The \( c - 1 \) closed curves by means of which we determined the connectivity of a closed surface in 3-space will lock with other closed curves either in the space enclosed by the surface or in the exterior. We are thus led to consider the connectivity of the portion \( R \) left after subtracting from \( R \) the points of our surface \( S \).

**Betti's Numbers of a Closed \( m \)-Surface S.**—Imagine \( S \), if necessary after continuous deformation, placed in \( m + 1 \)-space. Find the connectivities \( c_1, c_2, \ldots, c_m \) of the remainder \( (R_m + - S_m) \) with regard to points, lines, \( m - 1 \) planes, \( m - 2 \) planes, \( c_1 \) of the surface \( S_m \). (\( c = P_k \)). This means that in \( (R_m + - S_m) \) there \( P_k \) independent closed \( k \)-surfaces with which certain \( m - k \)-surfaces within \( S_m \) may lock. Obviously, the \( m - k \)-surfaces may be deformed out of \( S_m \) into the remainder \( (R_m + - S_m) \), while at the same time, and never ceasing to lock with them, the \( k \)-surfaces are deformed so as to be on \( S_m \). This shows that \( P_m - k \) is at least equal to \( P_k \), and vice versa, so that finally \( P_m - k = P_k \) on any closed bilateral \( m \)-surface without double points. Betti's number \( P_k \) for a 2-surface is at the same time its connectivity \( c_k \).

**Euler's Polyhedron Formula.**—The theorem holds for any division of a spherical surface into simply connected districts by frontiers bounded by the vertices in which they concur, that \( v - f + d = 2 \), \( v \), being the number of vertices, \( f \) of frontiers, and \( d \) of districts. Such a map is **regular** if each district has the same number \( f_a \) of frontiers, and if an equal number \( f_{a_i} \) of these concur in each vertex. We have \( v = 2f_a, d = 2f_a, \) and \( f(2f_a - f_{a+2f_a}) = 2f_a \), where \( 2f_a - f_{a+2f_a} \) must evidently be positive. This gives rise to only five regular maps corresponding to the regular polyhedral surfaces of the tetrahedron (self-reciprocal), cube and octahedron (reciprocal to each other), dodecahedron and icosahedron (reciprocal). The regular 4-dimensional polyhedra are found to be six, viz., two self-reciprocal ones bounded by five tetrakaidecahedra and 24 octahe dra respectively, one bounded by eight cubes reciprocal to one bounded by 16 tetrahedra, and one bounded by 120 dodecahedral reciprocal to one bounded by 600 tetrakaidecahedra.

**Euler's formula,** extended to maps on closed 2-surfaces of connectivity \( c: v - f + d = 3 - c \) leads to a superior limit for the number of districts that may be adjacent each to each on such a surface. Heffter has investigated under what conditions this limit is actually attained, while H. S. White shows what regular maps (called by him **reiterations**) are possible for any given \( c \). Generalizing still further, Euler's formula for a map on any \( m \)-surface, i.e., a division of it into simply connected parts, the dividing \( m - 1 \)-surfaces again being divided into simply connected partitions, etc., becomes:

\[
\sum_{q=0}^{m-1} (-1)^q e_q = 1 + \sum_{q=0}^{m-1} (-1)^q (P_{m-q} - 1),
\]

where \( q \) is the number of \( q \)-dimensional parts or partitions on the map. Since for closed \( m \)-surfaces we have \( P_k = P_{m-k} \), if \( m \) is even this becomes

\[
\sum_{q=0}^{m-1} (-1)^q e_q = 3 - P_0 + P_m \text{ if } m \text{ is odd},
\]

\[
\sum_{q=0}^{m-1} (-1)^q e_q = 0 \text{ (Poincaré)}.
\]

**Literature.**—Since no treatise on analysis situs has been published, a few of the main papers on the subject will here be mentioned. W. Dyck (Math. Annalen 1881, p. 57) gives the literature preceding this article (1888). The pertinent publications of the savants named above are as follows: Listing, 'Der Censous raumlicher Complexe' (Göttinger Abhandlungen 1861), and 'Vorstudien zur Topologie' (Göttinger Studien 1847); C. Jordan, 'Sur la déformation des Surfaces' (Liouville's Journal sér. 2, 11 1866); Klein, 'Über die Zusammenhang der Flächen' (Math. Annalen 1874); Moebius, 'Werke,' Band 2; Gauss, 'Werke,' vol. 3; Kronnecker (Berliner Monatsberichte 1868, p. 59, 1873, p. 117, 1878, p. 95); Betti, 'Sopra gli spazi di un numero qualunque di dimensioni' (Annali di matematica 1870); Tait, 'On Knots' (Trans. Roy. Soc. Edinburgh 1879, 1884, 1886; also Proceedings of the same society, 1876 to 1879); Simony (Math. Annalen 19 and 24); Brill (Math. Annalen); Heffter (Math. Ann. 38); Symony (Math. Ann. 57); Tait (On Electricity and Magnetism) (Vol. 1, p. 18); Veblen (Trans. Am. Math. Soc. 1905, p. 83).
Consult also the article on Analysis Situs by M. Dehn in the 'Encyclopädie der Mathematischen Wissenschaften,' and R. L. Moore, 'On the Foundations of Plane Analysis Situs.' (Trans. Am. Math. Soc. for 1916). The subject of analysis situs of higher dimensions, especially of 4-space, has been greatly advanced by the following six recent papers by H. Poincaré: 'Analysis Situs' (Journal de l'Ecole Polytechnique 1895); 'Complément à l'A. S.' (Proc. London Math. Soc. 1900); 'Second complément à l'A. S.' (Rendiconti del Circolo matematico di Palermo 1899); 'Sur certaines surfaces algébriques' (Bull. Soc. Math. de France 1902); 'Sur les cycles des surfaces algébriques' (Journal de Math. 1902); 'Cinquième complément à l'A. S.' (Rendic. Circ. mat. di Palermo 1904).

PAUL WERNICKE.

ANALYST, in modern times, a person professionally skilled in chemical analysis. He may be called upon, in the discharge of his profession, to analyze a wide range of substances. Apart from private practitioners and those engaged in large manufacturing concerns, analysts employed by public bodies are termed public analysts. In most large manufacturing establishments there is usually a staff of analysts, whose duty it is primarily to exercise constant watchfulness over the processes of manufacture, to test the purity of the substances used, as well as that of the final products. The services of analysts are constantly required in judicial enquiries, sometimes in purely criminal cases, sometimes in civil proceedings, such as offenses against the customs or excise or under the various Food and Drugs Acts.

ANALYTICAL METRICS, or NON-EUCLIDEAN GEOMETRY INTERPRETED ANALYTICALLY. For a historico-critical account of the notion and developments of Non-Euclidean geometry from the standpoint of pure geometry—from the point of view of Lobatschewsky and Bolzai—the reader is referred to the article 'Non-Euclidean Geometry,' in this work. The aim of the following paragraphs is only to illustrate an important epoch-making concept by means of ideas familiar in analytical projective geometry, the point of departure and method being those of Cayley as modified and improved by Klein.

General Considerations Concerning Geometric Measurement.—Every problem of geometric measurement is reducible to one or the other or both of two fundamental problems: (1) to find the distance between two points; (2) to find the angle between two (intersecting) lines. Any two points belong to a range; any two (intersecting) lines belong to a pencil; a range and a pencil are one-dimensional spaces; so it is seen that the fundamental problems constitute the problem of measurement in one-dimensional space. In the projective geometry of the plane (see Geometry, Projective, and Geometry, Modern Analytical) we learn that the range and the pencil are related by the principle of duality, or reciprocity. A range and a pencil if rendered projective, i.e., if the range can be obtained by the repeated projection of the range established by the pencil on one of its transversals, are so related that the anharmonic ratio of any four points (or lines) is equal to that of the corresponding four lines (or points). Countless examples are met of the fact that in general to any point (or line) proposition there corresponds a line (or point) proposition; such pairs of propositions being so related that either proposition of a pair of reciprocals being given, the other can be found by merely exchanging the notions of point and line. This reciprocity does not, however, at first appear to be universal and all-pervasive. For example, the distance, \( \sqrt{(x_1-x_2)^2+(y_1-y_2)^2} \), between two points \((x_1, y_1), (x_2, y_2)\), or \(x_1 + y_1 = 1 = 0, x + y = 1 = 0\), is an algebraic function of the co-ordinates; while the angle, \( \tan^{-1} \left\{ \frac{(x_2-x_1)(y_3-y_2)-(x_3-x_2)(y_1-y_2)}{(x_2-x_1)(y_3-y_2)+(x_3-x_2)(y_1-y_2)} \right\} \) of the lines \((\ell_1, \ell_2), (\ell_2, \ell_3)\) or \(\ell_1 + \ell_2 = 1 = 0, \ell_1 \times \ell_2 = 1 = 0\), is a transcendental function of the co-ordinates. Sign being disregarded, a segment of a range is uniquely determined, while an angle of a pencil may have any one of an infinite series of values differing from each other by multiples of a period \(\pi\), or 180°. Again a given segment is divisible by a straight compass into any chosen number of equal parts, while, by the same means, such division is possible in case of an arbitrarily given angle only if the division is to be bisection, quadrisection, etc., but not if it is to be trisection, for example.

It is such discrepancies in the general scheme of reciprocity that furnish the motive for seeking to generalize the ordinary conception of distance and angle measurement in such a way that the discrepancies shall disappear and that the principle of duality shall apply without exception. Such being the motive, on the one hand, the possibility, on the other, of making the needed generalization lies in the fact that, despite the differences indicated, the ordinary notion of distance and the ordinary notion of angular measurement have two fundamental properties in common. These are: (1) That the distances between points of a range or the angles between lines of a pencil are added in such a way that, if 1, 2, 3 denote three such points or the three lines, the first case sec. 12 + sec. 23 = sec. 13, and, in the second case, \( \angle 12 + \angle 23 = \angle 13 \). In particular, sec. 11 = 0 \( \angle 11 = 0 \), whence it follows that sec. 12 = sec. 21, and \( \angle 12 + \angle 21 < 0 \); (2) the second of the common properties is that distance and angle are not altered in magnitude by displacement, where displacement of the pencil consists in rotating it as a rigid figure about its centre or vertex, and displacement of the range consists in moving it as a rigid figure along its base. These properties come clearly to light if we scrutinize the way in which distance and angle are not altered in magnitude. For this purpose we use a scale, which in case of the range consists of a segment divided into equal intervals by points, and in case of the pencil consists of an equal number of equal intervals by lines. Each interval is a unit of distance or angle. Then to measure the distance (say) between two given points, we place any division of the scale on one of the points, and then count the number of intervals to the other, given point. Analogously for angles. The first property above mentioned is used in determining the distance by counting the in-
tervals. The displacement property is employed in that we are indifferent as to which division of the scale we start with; that is, the distance or angle is found to have the same size if we measure, then displace the scale and measure again.

Generation of Ordinary Scale by Linear Transformation.—It is important to notice that the displacement property enables us to construct the ordinary scale by means of a special linear transformation. Thus if \( x \) denote distance from a point assumed as origin in the range, then the transformation \( z' = x + c \) will serve to generate the distance-measuring scale in which the unit, or interval, is \( c \). If \( x \) be the distance from the origin to the point 1 chosen for initial point of the scale, then \( x' \) will denote the second division point 2. A second application of the transformation will convert point 1 into point 2 and point 2 into a third point 3 of the scale; and so on. The transformation for generating the angle-measuring scale is \( z'' = \pi + \tan \gamma' \gamma \), \( (1 - x \tan \gamma') \gamma \) being the unit of \( z'' \) and \( \gamma \) being tangent of the angle of any line of the pencil with a line assumed as origin.

Generalization by Means of Transformations \( z = (az + b) : (cz + d) \).—The ordinary scale being generically transformed by special linear transformations, the possibility is suggested of generating by more general transformations more general scales that shall involve and disclose more general concepts of distance and angle. We will first suppose the fixed elements of the transformation to be distinct (real or imaginary). Taking these as elements of reference \( O_1 \) and \( O_2 \) for homogeneous co-ordinates \( x_1 \) and \( x_2 \) in range or pencil, the transformation will assume the form \( z = \frac{ax + b}{cx + d} \), where \( x = x_1 \), \( x_2 \), and where \( \lambda \) is the characteristic constant of the transformation. The constant \( \lambda \) will be subject to the condition that real elements (points or lines) \( z \) shall be converted into real elements \( z' \) and that, in case the reference elements \( z = 0 \) and \( z' = 0 \) are real, \( \lambda \) shall be positive.

If we now apply the transformation successively to an arbitrarily chosen element \( z = 0 \), we shall obtain a series of elements \( z = k \lambda^m \), \( k \lambda^2, k \lambda^3, \ldots \). This series of elements constitutes our scale. Obviously this scale is converted into itself by the transformation \( z = k \lambda^m \), by which it was generated just as the old scales are converted respectively into themselves by the transformations generating them. Just as the interval between two successive divisions of the old scale is called unit of distance or angle because one application of the generating transformation carries us over that interval, so for the same reason we name unit of distance or angle the magnitude extending from any division to the next in the new scale. Accordingly the distances or angles from the points or lines \( z, z_1, z_2, \ldots \) to point or line \( z_3 \) are \( 0, 1, 2, 3, \ldots \) respectively. By means of the new scale we can measure distances and angles whose magnitudes reckoned from \( z \) are expressible as whole numbers. In order to render the scale available for measuring distances and angles whose magnitudes are any rational numbers, we have merely to subdivide the scale intervals already obtained into \( n \) equal parts. This is done by applying \( n - 1 \) times to the elements at the beginning of each interval, a transformation which repeated \( n \) times reproduces the transformation \( z' = \lambda z \). The transformation required is therefore \( z' = \lambda^{n-1} z \) where that one of the \( n \) roots of \( \lambda \) must be used that secures that the element \( \lambda^{n-1} z \) shall fall between \( z \) and \( \lambda z \). We can then measure all distances or angles from \( z_1 \) to \( z \) where \( z' \) is of the form \( z = \lambda z_1 \), \( a \) and \( \beta \) being integers. The distance or angle from point or line \( a + \beta \lambda \) to \( z_1 \), is precisely \( a + \beta \lambda \).

If now we suppose the subdivision extended indefinitely and if we admit the notion of irrational number, then obviously we must regard the distance or angle from the point or line \( z_1 \) to the point or line \( z \equiv \lambda z_1 \) as being expressed by \( \lambda \) where \( a \) may be any positive real number whatever, whole or fractional, rational or irrational.

From the last equation we have \( a = \log \lambda / \pi; \log \lambda \). Hence: The distance or angle of a point or line \( z \) from the point or line \( z_1 \) is the logarithm of the ratio \( z/z_1 \), divided by the constant \( \log \lambda \).

The point or line \( z_1 \) was arbitrarily taken as initial element of our scale and our formula gives the distance or angle from \( z \) to any other point or line. The general linear transformation \( z = (az + b) : (cz + d) \) involves three parameters, two of which are determined by requiring the elements \( O_1 \) and \( O_2 \) to remain fixed. By means of the third parameter, the element \( z_1 \) may be brought to any desired position \( z \) of range or pencil. Accordingly: The distance or angle from point or line \( z \) to any other point or line \( z' \) is \( \log \lambda \lambda + c \log \lambda = \log \lambda - c \log \lambda \) where \( c = 1 \); \( \log \lambda \).

It is readily seen that, as ought to be the case, the addition property of the old magnitude concept is preserved in the new concept just defined. That is to say, Distance (angle) \( z_1 + \text{distance (angle) } z_2 = \text{Distance (angle) } z_3 \); for \( c \log z = c \log z_1 + c \log z_2 \), \( -c \log z = c \log z_1 - c \log z_2 \) identically. Also \( c \log z = 0 \), whence \( c \log z' = c \log z' = c \log z' \) conformably to the like property of the ordinary notion of measure. The displacement property, too, is preserved; for the scale-generating transformation \( z = k \lambda z_1 \) converts distance (angle) \( z \) into distance (angle) \( \lambda z \). These magnitudes are plainly equal, for the former is \( c \log z = c \log \lambda z \) while the latter is \( c \log \lambda + c \log z \).

Geometric Meaning of the New Concept of Distance (Angle).—Let \( z = z_1 \) and \( z = z_2 \) be any two points (lines) of the range (pencil). The anharmonic ratio \( (0, z_2, z) \) of the pair \( (z_1, z_2) \) to the pair \( (0, \infty) \) of fixed elements is \( \lambda \infty \infty = (0, z_2) (z_1, z_2) = z_3/z_2 \).

Hence the distance (angle) of two points (lines) is an arbitrary constant \( c \) times the logarithm of the anharmonic ratio of the two points (lines) to the two fixed points (lines) of the range (pencil).
and $z'$ will be of the form $z = a + bi = a' + b'i$, where $a, a', b, b'$ are real and $i = \sqrt{-1}$. Now \[ z = r \ e^{i \theta} \quad \text{and} \quad z' = r' \ e^{i \phi}, \] whence

\[ z' = (r : r') \ e^{i (\phi - \theta)} = \rho e^{i \phi}. \]

Hence the distance (angle) $z' = c = \log z' = \log (\rho e^{i \phi}) = \log (\rho e^{i \phi}) + \pm c \log \in 2\pi$

\[ e = c \log z' = (\pm 2\pi n), \] where $n$ is an integer.

It so appears that in the generic concept of measurement in hand distance (angle) is not a one-valued function but is an infinitely many-valued function, viz., a periodic function of period $2\pi n$. The periodicity of the angle in the ordinary system of measurement is a special case of the preceding. Let $\phi$ be the angle between the lines $y = mx + b$ and $y = m'x + b'$; then tan $\phi = (m - m')(1 + mm')$. As tan $\phi = tan (\phi \pm 2\pi n)$, we have tan $\phi = tan (\phi - (2\pi n)) = (m - m')(1 + mm')$, whence $\phi = (2\pi n) - tan^{-1} (m - m')(1 + mm')$; hence $\phi = tan^{-1} (m - m')(1 + mm') \pm 2\pi n$.

### Infinite Distances and Angles in the Generalized System of Measurement

We will present a brief account of the infinite elements in the ordinary system of measurement. For this system the scale-generating function for the range $z = z + c = (z + c) = (0 + 1)$; for the pencil it is $z = z + c = (z + c) = (0 + 1)$.

In the range (absolute) lines of the pencil make with the origin (initial or reference line) angles whose tangents are $\pm i$ and $\mp i$. Such lines are of course imaginary. Are the angles $\infty$? And does every other line (real) of the pencil make the same $\infty$ angle with these fixed lines? To answer, take any finite point for vertex of the pencil and choose this vertex for the origin of Cartesian axes. Then the angle $\phi$ of any real line $y = mx$ with the pencil line $y = yx$ is given by $\phi = tan (m - i)(1 + im) = 1:1$. Hence $\phi$ is independent of $m$, and hence all real lines are equi-inclined to the line $y = yx$. The same is true for line $y = yx$. Hence as $y = mx$ rotates about the vertex of the pencil, it keeps a constant angle with each of two imaginary lines of the pencil. This fact suggests that tan $i$ and tan $i$ (-i) are each infinite, and they are readily established as follows: From Euler's equations $e = cos x + i sin x$, $e^{-i} = cos x - i sin x$, we have $tan x = i (e^{i x} - 1) (e^{i x} + 1)$. In the present case $tan z = z$, whence $z = \infty$.

The question arises: Has a range two points equidistant and infinitely distant from all its other points, and has a pencil two lines equi-inclined to and making an $\infty$ angle with all other lines of the pencil, in case of the generalized system of measurement? The answer is affirmative. In this case, the fixed elements of the scale-making transformation, as we may take for origins $O_1$ and $O_2$. Their equations are $z = 0$ and $z = \infty$. Now let $z'$ be any point or line. The distance (angle) from $z \equiv z'$ to $z = \infty$, being $c \log (\infty : z')$, is $\infty$. Hence the distance (angle) between either of the absolute points (lines) of a range (pencil) and any other point (line) of the range (pencil) is infinite (logarithmically).

### A Restriction Removed

We will now abandon the supposition that the origins $O_1$ and $O_2$ coincide with the absolute elements. The absolute elements will, of course, be given by writing $z' = z$ in the transformation $z' = (az + b) : (cz + d)$; i.e., they are given by the equation $cz + d = z = z'$ for varying $z$ are the co-ordinates of a variable point (line) of the range (pencil). This variable element will coincide with an absolute element for such and only such values of $\lambda$ as satisfy the equation

\[ a(x' + \lambda x^2) + 2b(x' + \lambda x^2) + c(x' + \lambda x^2) = 0 \]

or

\[ \lambda = \frac{a Z x^2 + 2b Z x^2 + c Z x^2}{\Omega Z x^2 + \omega Z x^2} = 0. \]

These values are

\[ \lambda_1 = \frac{\Omega Z x^2 + \omega Z x^2}{\Omega Z x^2 - \omega Z x^2}, \]

\[ \lambda_2 = \text{conjugate of} \lambda_1. \]

The anharmonic ratio of the element pair $(x_1, x_2)$ and $(x_1', x_2')$ to the pair of absolutes is $\lambda_1 : \lambda_2$. Hence, if we denote $x_1 : x_2$ by $z$ and $(x_1 : x_2')$ by $z'$, we have the proposition:

Distance (angle) $z' = z$$

\[ \begin{align*}
\Omega & = \frac{\Omega Z x^2 + \omega Z x^2}{\Omega Z x^2 - \omega Z x^2} \\
\omega & = \frac{\Omega Z x^2 - \omega Z x^2}{\Omega Z x^2 + \omega Z x^2}
\end{align*} \]

The metric number of distance (angle) measured in accordance with the generalized system or scale. From it Cayley's expression is obtainable and such. If $\infty$ be any number, then $\log n = 2i \cos \frac{n}{n + 1} : 2 \sqrt{n}$, a fact verifiable thus:

\[ n = e^{i 2 \cos \frac{n}{n + 1} \sqrt{n}} = \cos \frac{2 \cos \frac{n}{n + 1} \sqrt{n} + i}{2} + i \sin \frac{2 \cos \frac{n}{n + 1} \sqrt{n} - i}{2} \]

\[ \begin{align*}
\frac{n + 1}{4n} & = \frac{(n + 1)^2}{4n} - 1 + \frac{(n + 1)^2}{4n} + \\
\frac{n}{4n} & = \frac{n + 1}{4n} \sqrt{1 - \frac{(n + 1)^2}{4n}} = n.
\end{align*} \]
Analytical Metrics

Applying that fact to the Kleinian expression, we readily obtain
\[
c \log K = 2\pi c \cos^{-1} \left( \frac{\Omega_{x'} x'}{\sqrt{\Omega_{x'} x' \Omega_{x'} x'}} \right)
\]
whence, on letting \( c = -i \omega \), we obtain
\[
\cos^{-1} \sqrt{\frac{\Omega_{x'} x'}{\Omega_{x'} x' \Omega_{x'} x'}}
\]
which is Cayley's expression for distance (angle) of the elements \( x' = x' \cdot x' \cdot x' \), and \( x' = x' \cdot x' \cdot x' \).

Application to Real Elements, Absolute Elements Distinct.—Two cases arise according as the absolute elements are real or are imaginary. Accordingly in order the case where they are real. For the sake of convenience we shall first consider the range. Denote the absolute points by \( F_1 \) and \( F_2 \). Two points \( x \) and \( x' \) may be situated (1) both of them between, (2) neither of them between, or (3) only one of these and the point \( F_1 \) and \( F_2 \) is situated (1) and (2) the anharmonic ratio of the pairs \( (x, x') \) and \( (F_1, F_2) \) is positive; in the remaining situation, negative. Accordingly in the former case the logarithm of the anharmonic ratio is imaginary, while in the latter case, the logarithm is real and the imaginary period before indicated. Hence in order that the distance between two points not separated by \( F_1 \) or \( F_2 \) shall be real, we must assign \( c \) for our distance function a real value. This being done, we have the theorem: The absolute points being real and distinct, the distance between two real points \( x \) and \( x' \) is real or imaginary according as the points are not or are separated by one of the absolute points. If, with Cayley, we assigned to \( c \) a pure imaginary value, viz. — \( i \omega \), then in the last case we should have to interchange the words “real” and “imaginary,” or else the phrase “not separated” and “separated.” The Cayleyan choice is logically allowable. It is rejected as being inexpedient. It gives a generalized scale needlessly unlike the ordinary scale. For example, if 1, 2, 3 denote successive divisions of the Cayleyan scale such that the successive divisions shall be a unit apart, then, if division 1 falls between \( F_1 \) and \( F_2 \), division 2 must fall without, division 3 within, etc. Hence distance \( 13 \) regarded as the sum of 12 and 2 is 2 and is real but segment 13 measured directly is imaginary.

In order that all distances between real points shall be real, it is necessary to confine ourselves to one of the two segments into which the line is separated by the absolute or infinite points, \( F_1 \) and \( F_2 \). Each of these segments is infinite in length, i.e., the distance from any point in either segment to either \( F \) is infinite, as before shown.

Let \( z \) be a point of either segment. Suppose the point to move in accordance with a transformation that leaves \( F_1 \) and \( F_2 \) unchanged. We may name velocity of displacement the ratio of the distance traversed to the time consumed. The distance, of course, to be reckoned in the new way. If now we suppose the point to move with a constant velocity toward \( F_1 \) or \( F_2 \), it will approach nearer and nearer to \( F_1 \) or \( F_2 \), but will never reach either \( F_1 \) or \( F_2 \), since it would have to travel an infinite distance. If the point be supposed to be endowed with intelligence, it could never by any motion possible to it or by any experience assure itself of the existence of \( F_1 \) or \( F_2 \). If the point refused to assume the existence of \( F_1 \) and \( F_2 \), its geometry would so far forth be Euclidean in character. It could assume the existence of \( F_1 \) and \( F_2 \). It could still choose between the supposition that the \( F \)'s were coincident and the supposition that they were distinct. The former supposition would bring its geometry into the category of Parabolic geometries, like our own Euclidean geometry, while the second supposition would lead to a so-called Hyperbolic theory, such as the geometry of Lobachevsky and Bolyai.

Imaginary Absolute Elements.—If the absolute elements are imaginary, let them be of the form \( a + bi \) and \( a - bi \). The anharmonic ratio of these to a pair \( (x, x') \) of real elements is imaginary of the form \( e^{i\beta} \). Hence we have
\[
c \log (x, a + bi, x', a - bi) = i(\phi \pm 2\pi n i),
\]
which is pure imaginary or real according as \( c \) is taken to be real or pure imaginary. Hence in order that the distance between two real points may be real when the absolute points are conjugate imaginaries, it is necessary and sufficient to assign \( c \) a pure imaginary value, say \( i \phi \). The absolute points being imaginary, the range contains no real infinite points, or points at \( \infty \). Hence the range of strain upon itself like a finite closed curve. The distance between any two of its points is periodic, of period \( 2\pi c = 2\pi i\phi = -2\pi \phi \). Hence in this system of measurement the length of the straight line is \( 2\pi \phi \).

It is this metric theory that characterizes the so-called Elliptic Geometry of Riemann and Helmholtz. The measurement of segments of the straight line of this theory is analogous to the ordinary measurement of arcs of a circle of radius \( c \).

Extension to the Pencil.—The foregoing conclusions respecting the range are readily extensible to the pencil. If the two absolute lines \( F_1 \) and \( F_2 \) be real and distinct, the angle made with either of them by any other real line of the pencil is infinite and real. If any line rotate in accordance with any transformation leaving \( F_1 \) and \( F_2 \) unchanged, the angle between forever without reaching either \( F_1 \) or \( F_2 \)—a fact that profoundly distinguishes this metric system from the ordinary one, for in the latter if a line rotate with any constant finite velocity, no matter how small, it will in course of a finite time return to its initial position. This possibility of thus returning is owing to the fact, already pointed out, that in ordinary angle measurement the pencil has no real lines at \( \infty \), but, on the contrary, these lines are conjugate imaginaries, viz., the familiar so-called isotropic lines of the pencil. If the absolute lines be conjugate imaginaries other than the isotropic lines of ordinary geometry, the resulting theory of angular measurement is that which belongs to the Elliptic Geometry. In this case, as in that of the range, we must take \( c \) to be pure imaginary in order that the angle between real lines shall be real. If we set \( c = i \phi \), the angle between two lines is periodic, of period \( 2\pi \phi \), and the whole angle about the vertex will be \( 2\pi \phi \). In ordinary geometry the whole angle is \( \pi \); hence to pass from the elliptic theory of angle measurement to the ordinary system, we
must let \( \epsilon = \frac{1}{2} \), or \( \epsilon = + \frac{i}{2} \). This done, the general expression for the angle between two lines \((x', y')\) and \((x'', y'')\) becomes

\[
\cos^{-1} \left( \frac{x' x'' + y' y''}{\sqrt{x' x' + y'^2} \sqrt{x'' x'' + y''^2}} \right),
\]

where, as the absolute lines are to be the usual isotropic lines, we take \( x' = x' + y' \), and hence \( x' = x' + y' \), \( x'' = x'' + y'' \), and \( x'' = x'' + y'' \), whence the expression for angle becomes

\[
\frac{x' x'' + y' y''}{\sqrt{(x' x'' + y'^2) (x'' x'' + y''^2)}},
\]

and this, as should be the case, is the familiar expression for the angle between two lines \(x_1 x + x_2 y = 0\), \(x_3 x + x_4 y = 0\). We have then the theorem in the ordinary Euclidean geometry, the angle between two lines is \( \frac{1}{2} \) times the logarithm of the anharmonic ratio of the given pair of lines to the pair of isotropic lines through their common point. This definition is due to Laguerre. (Consult Nouvelles annales de Mathématique, 1889). If the lines are perpendicular, i.e., have slopes \( m \) and \(-\frac{1}{m}\) respectively, then the anharmonic ratio in question is

\[
\left( m, i, -\frac{1}{m}, -i \right) = (m - i \frac{1}{m}) (i + m) = -1;
\]

hence we have in ordinary Euclidean geometry the following definition of perpendicularity: Two lines are perpendicular when and only when they are harmonic to the isotropic lines through their common point.

**Absolute Elements Coincident.**—We turn now to the case where the absolute elements are coincident. The anharmonic ratio of the pair \((x_1, x_2)\) to the pair \((z_1, z_2)\), being \( (z_1 - x_1) \frac{z_2 - x_2}{z_2 - z_1} \), is equal to 1, if the elements of a pair, \(x_1, z_2\), coincide. Hence if \(z_1 = x_2\) be the absolute elements, the distance (angle) \(z_1 z_2 = a^2 \log \frac{1}{c}\) if \(c\) be finite. The same fact appears from the distance (angle) expression

\[
2i c \cos^{-1} \left( \frac{x' x'' + y' y''}{\sqrt{x' x' + y'^2} \sqrt{x'' x'' + y''^2}} \right),
\]

where \( x' x'' = a^2 + 2b x_1 x_2 + c \), for, if the absolute elements are coincident, then (and only then) \( \Delta = 0 \) or \( c = 0 \), and \( \Delta = \frac{(x_1 + y_1)(x_2 + y_2)}{2} \), whence the distance (angle) expression becomes

\[
2i c \cos^{-1} \left( \frac{(x_1 + y_1)(x_2 + y_2)}{2} \right)
\]

This expression approaches coincidence. To this end observe that \( x_1 x_2 - x_1 x_2 = (x_1 x_2 - x_1 x_2) \Delta \).

Now

\[
2i c \cos^{-1} \left( \frac{(x_1 x_2 - x_1 x_2)}{2} \right)
\]

a new expression for distance (angle), admitting immediate application of the relation \( \lim (\sin a a^2) = 1 \) as \( a \) approaches zero. As the absolute elements approach coincidence, \( \Delta \) approaches zero, and hence the sine (in the above expression) approaches zero; so that we may replace the sine by its \( \sin^{-1} \). We thus get for distance (angle)

\[
2i c \sqrt{\Delta} \sqrt{(x_1 x_2 - x_1 x_2)}
\]

where we choose \( c \) so that \( k = 0 \) as \( \Delta \) approaches zero. The last expression gives us the distance (angle) of two elements \((x'_1, x'_2)\), \((x''_1, x''_2)\) when the absolute elements \((p_1 x_1, + p_2 x_2)\) of \((p_1 x_1, + p_2 x_2)\) coincide. Consider the expression \( E = \frac{(x_1 x_2 - x_1 x_2)}{(p_1 x_1 + p_2 x_2)}\). It is readily seen that \( E = k \frac{(x_1 x_2 - x_1 x_2)}{(p_1 x_1 + p_2 x_2)}\), provided we make such obviously possible choice of the \( q\)'s that \( q_1 p_1 - q_2 p_2 = k \). The form \( E \) shows that the addition property of distance (angle) is valid also when the absolute elements are coincident. For let three elements be \((x'_1, x'_2), (x''_1, x''_2), (x''_3, x''_3)\). Substituting in \( E \), it readily appears that distance (angle) between elements one and two + distance (angle) between two and three = distance (angle) between one and three. Also distance (angle) between \((x_1, x_2)\) and itself is \((x_1, x_2) = \frac{(p_1 x_1 + p_2 x_2)}{(p_1 x_1 + p_2 x_2)}\). As to the displacement property, it readily appears that \( E \) is the difference of two anharmonic ratios, for the form \((q_1 x_1 + q_2 x_2) = \frac{(p_1 x_1 + p_2 x_2)}{(p_1 x_1 + p_2 x_2)}\). The absolute elements of \((q_1 x_1 + q_2 x_2) = \frac{(p_1 x_1 + p_2 x_2)}{(p_1 x_1 + p_2 x_2)}\). A change of \( E \) will remain unchanged, i.e., the displacement property is preserved also when the absolute elements fall together.

**General Metric Determination in the Plane.**—We have hitherto attached the generalized concept of measurement to one-dimensional spaces: the range and the pencil. It is easy to carry the concept into spaces of two dimensions, namely, the plane regarded as an ensemble of points (pencils) and of lines (ranges). The pair of absolute elements (of range, pencil) has for analogues in the plane the conic viewed on the one hand as locus and on the other as envelope. Accordingly the Ab-
Pouring new wine into old bottles, we may call the locus in question a (generalized) circle. Its centre is the point \( x_0 \) and its radius is \( 2i \cos^{-1} k \). Regarding \( x_0 \) as a parameter, the equation \( S'xx = k^2 S'xx' S_{xx} \) represents the family of concentric circles about \( x_0 \) as centre. They are all tangent to the absolute at the same contact points. The circle \( k = 0 \) is degenerate, being the polar (counted twice) of the centre \( x_0 \). Its radius is \( 2i \cos^{-1} 1 = \pi ci \). If \( k = 1 \), the radius is \( 2i \cos^{-1} 1 = 0 \), and the circle, \( S'xx' \), is tangent to the absolute, being the polar of the fixed point.

We may represent \( C \) in homogeneous coordinates by \( S_{xx} = ax^2 + bxz + cz^2 + 2dxz + 2exz + 2fxyz = 0 \). Let \( S_{xx}' = S_{xx} - S_{xx} \cdot S_{xx}' \) denote the result of replacing in \( S_{xx}' = S_{xx} \) for \( x \) and let \( S_{xx}' = S_{xx}' - S_{xx} \cdot S_{xx}' \). Any two points \( x_1 \) and \( x_2' \) determine a range. This cuts \( C \) in two points. The anharmonic ratio of this pair and the given pair is

\[ S_{xx}' + S_{xx} - S_{xx} \cdot S_{xx}' = R \]

and hence the distance between the points is \( c \log R \), or

\[ 2i \cos^{-1} \left( \frac{S_{xx}'}{\sqrt{S_{xx} \cdot S_{xx}'}} \right) \]

where \( c \) is a fixed arbitrary constant, the same for all ranges of the plane.

Reciprocally, if \( 2i \cos^{-1} \left( \frac{S_{xx}'}{\sqrt{S_{xx} \cdot S_{xx}'}} \right) = \) the line equation of the Absolute, the angle between two lines \( \xi_1 \) and \( \xi_2 \) is

\[ c' \log \frac{S_{xx} - S_{xx} \cdot S_{xx}'}{\sqrt{S_{xx} \cdot S_{xx}'} - S_{xx} \cdot S_{xx}'} \]

where, again, \( c' \) is an arbitrarily chosen constant, the same for all pencils of the plane.

Displacements of the Plane.—There being \( \omega \) collinearities of the plane, and a conic depending on five essential constants, it is seen that a conic can be transformed into itself by \( \omega \) collinearities of the plane. By such a transformation any point \( P \) of the conic is converted into a point \( P' \) of the conic, and \( P' \) is in general different points; but any transformation converting a conic into itself converts at most two of its points each into itself. Suppose a transformation \( t \) converts the absolute into itself and that \( P \) and \( P' \) are the two points of \( C \) that are unchanged in position. Then \( P \) converts into itself, and \( P' \) into the tangent at \( P \), the tangent at \( P' \) and the point Q common to the two tangents. That is, \( t \) only leaves \( C \) unchanged but also the triangle, \( P', P', Q \). Query: How many of the \( \omega \) collinearities leaving \( C \) unchanged leave also unchanged the particular triangle in question? Taking this triangle for triangle of reference, the equation of \( C \) is \( x_1 x_3 - x_2 = 0 \). The most general collineation that leaves fixed the sides of the triangle is that defined by the equations:

\[ x_1 \rightarrow a_1 x_3, x_2 \rightarrow a_2 x_3, x_3 \rightarrow a_3 x_3. \]

This transformation converts \( C \) into an \( a_1 a_2 a_3 x_1, x_3 - a_3 x_3 \). This is identical with \( C \) when and only when \( a_1 a_2 - a_3 = 0 \), i.e., when the ratios, \( a_1 a_2 : a_3 \), are subject to one condition. Hence the answer to the query is a simple infinity of collinearities. All these transformations convert into itself the quantity \( x_1 x_3 / x_3 \). Hence they convert into itself each conic of the pencil \( x_1 x_3 - k x_3 = 0 \) of conics. This pencil consists of all the conics tangent to \( C \) at the points where it is cut by \( x_3 = 0 \), the polar line of the point common to \( x_1 = 0 \) and \( x_3 = 0 \).
The collineations in question fall into two classes according as $a_i = + \sqrt{a_i}$ or $a_i = - \sqrt{a_i}$. The first class constitute a group, or closed system; i.e., combination of two of them is always one of the class. Thus the transformation $x_1 = a_1 x_1$, $x_2 = a_2 x_2$, $x_3 = + \sqrt{a_3} x_3$ followed by the transformation $x_1' = \beta_1 x_1$, $x_2' = \beta_2 x_2$, $x_3' = + \sqrt{\beta_3} x_3'$ is equivalent to the transformation $x_1 = a_1 x_1$, $x_2 = a_2 x_2$, $x_3 = + \sqrt{a_3} x_3$, $x_1' = \beta_1 x_1$, $x_2' = \beta_2 x_2$, $x_3' = + \sqrt{\beta_3} x_3'$; and the same class while, if the negative sign be used in the component transformations, the resultant contains $x_2 = + \sqrt{a_2} \beta_2 x_2'$, hence the second class closed, is not a group. Geometrically the two classes are distinguished by the fact that the transformations of the first class convert into itself each of the segments of $C$ into which $C$ is separated by the contact points of $x_1=0$ and $x_2=0$, while the transformations of the second class exchange these segments. To the collineations of the first class Klein has given the name displacements of the plane for the reason that they correspond to the collineations of displacements—that in the ordinary Euclidean plane leave the line at $\infty$ unchanged. The second class correspond to collineations in the ordinary theory that convert figures into inversely congruent figures.

We have, therefore, the proposition: The group of displacements leave fixed not only the absolute $C$ but also all the conics (circles in this theory) tangent to $C$ at the two fixed points. The equation of these circles is $x_1 x_2 - k x_3^2 = 0$. Through any point $x'i$ there passes in general one and but one of these circles, viz., that whose equation is $x'i x_1 x_2 - k x_3^2 = 0$. A displacement of the plane causes each point to move on that circle on which it chances to lie. Accordingly each displacement is a rotation of the plane about a fixed point, all other points describing concentric circles (generalized) about this point. Those displacements in which the centre of rotation is at $\infty$ are specially noteworthy. To be at $\infty$ the centre must be on $C$. Hence the circles of motion have $4$-point contact with $C$ at their common centre. In the ordinary, or parabolic, geometry the centre would be on the line $\infty$, and the circles would have their centre at $\infty$, i.e., they would be a system of parallel lines. Motion along these is translation. Hence translation in ordinary (parabolic) geometry corresponds to those displacements (in the generalized doctrine) where the centre of rotation is on the absolute conic $C$.

Distances (Angles) Invariant Under Displacements.—Let $x'i$ and $x'i'$ be any two points and let their range cut $C$ in $u_i$ and $u'i$. The anharmonic ratio of these points is unchanged by collineation. Now a displacement converts $u_i$ and $u'i$ into points $v_i$ and $v'i$ of $C$, and $x'i$ and $x'i'$ pass into $y_i$ and $y'i$ collinear with $v_i$ and $v'i$. Hence distance between $x'$ and $x'i' = $ distance between $y_i$ and $y'i$. Similar argument shows that angles are unchanged by displacements. Neither are distances and angles changed in the non-group class of collineations not changing $C$.

Generalized Measurement for Sheaf of Lines or Planes.—The line geometry of the sheaf is analogous to the point geometry of the plane, and the plane geometry of the sheaf is quite parallel to the line geometry of the plane. The four theories may be studied simultaneously by means of the same algebraic machinery. In order to transfer the geometry of the plane to the sheaf, we take for absolute in the latter a cone of second order (class) having the carrier point $P$ of the sheaf for vertex. The angle of two lines $L$ and $L'$ of the sheaf will be an arbitrary constant $c$ times the logarithm of the anharmonic ratio of these lines and the pair of lines common to the absolute and the plane (pencil) of $L$ and $L'$. Reciprocally, the angle of two planes $\pi$ and $\pi'$ is an arbitrary constant $c$ times the logarithm of the anharmonic ratio of these planes and the two planes tangent to the absolute cone and containing the common line of $\pi$ and $\pi'$. Developments in case of the sheaf quite similar to those found for the plane are obviously obtainable in similar manner and need not be further pursued.

The Elliptic and Hyperbolic Theories of the Plane.—Returning to the plane, it is obvious that two theories will arise according as the absolute $C$ is real or is imaginary. If $C$ be imaginary, the two absolute points of every real range (line) will be considered imaginants. These being the infinite points of the range, this will have no infinite real points. The line will be finite in length, the length depending on the value assigned to $c$. No pencil will have real tangents to $C$. No two real lines will intersect on $C$, i.e., at $\infty$, and parallel lines can be parallel. The resulting theory is the so-called Elliptic geometry of the plane. If our plane really is elliptic instead of being, as we commonly assume, Euclidian (or parabolic) then the infinite region of it is an imaginary conic section.

If $C$ be supposed to be real, the resulting theory accords with that of Lobachevskev and Bolyai. It is that called Hyperbolic by Klein. The real points now fall into two classes; the class $E$ of points such that from each two real tangents can be drawn to the absolute; and the class $I$ such that no real tangents proceed from its points to the absolute. These classes may be respectively described as exterior and interior. Similarly real lines compose two classes: those that cut $C$ in two real points, and those that cut it in imaginary points. Suppose, as we must make a choice, we confine ourselves to the class $I$ and to the lines that go through the points of $I$. No pencil has real lines at $\infty$, i.e., no real tangents to the absolute. The absolute lines of any pencil are imaginary (like the isotropic lines of ordinary projective geometry). Hence, as before indicated, we take $\epsilon^{s_1} = \epsilon^{s_1'}$, pure imaginary. The sum of the angles of any pencil is, therefore, $\epsilon 1\infty$. On the other hand, every real straight line has two points at $\infty$, namely, the points where it cuts the absolute. Accordingly we regard $c$ as a real quantity. Owing to our choice of $\epsilon$ and $\epsilon'$ the angle of any two lines intersecting within the absolute is real, and real also is the distance between any two points of $I$. But two lines may not intersecting within the absolute make an imaginary angle with each other; and the distance between two points, one in $I$ and the other in $E$, is imaginary. The distance from
any point to the absolute is infinite. The angle of two lines intersecting on the absolute is zero. Such lines are parallel.

Suppose we are situated at some point $P$ of $I$. Suppose further that we are capable of only such motions as are furnished by displacements, transformations, that is, that leave the absolute $I$ as the absolute. Just as in ordinary geometry, so here, since the total angle about $P$ is finite, a finite time would suffice to make a complete rotation about $P$ by turning at any finite rate, however small. Again, just as in ordinary geometry, so here we could travel on any straight line in either direction (sense) at any finite velocity however great, without, in any finite time, however great, reaching, much less passing, the absolute conic $C$. The dwellers within $C$ could not escape from the region $I$ by any combination of displacements. For those inhabitants their plane, the region $I$, is strictly limited by the absolute. By no experience possible to them could they assure themselves that $C$ existed, or, $C$ being granted, that there is a region beyond, outside of $C$. In the plane $I$, then, the geometry within $I$ becomes a detailed picture of the Lobachevskian, or hyperbolic, geometry so far as concerns the plane. For example, one of the L. propositions is that through any point of the plane two lines can be drawn parallel to a given line. This proposition is matched or pictured by the fact that through any point of $I$ two and but two lines can be drawn meeting any line within $C$ where the line cuts $C$. These two lines are parallel to the third line, meeting it at its infinite points. Another L. proposition is that if a point recedes from a line, the angle of the two parallels through the point to the line increases and approaches the value $\pi$ as the distance becomes infinite. The-like holds within $C$, for when the point common to the parallels is a point of $C$, the parallels to the given line become parallel to each other, one of their angles being zero and the other $\pi$. Again, the sum of the angle of a triangle within $C$ is less than $\pi$ and decreases as the triangle increases, becoming zero when the vertices are infinitely away from $C$, i.e., a fact agreeing with the L. geometry. Once more, in the L. geometry, two lines perpendicular to a third do not intersect. Now two lines within $C$, to be perpendicular to a third line within $C$, must belong to the pencil vertex at the pole of the third line. But this pole is outside of $C$. Hence the perpendicular, as regarded by geometries within $C$, do not intersect, for, as we have seen, the region $E$ does not exist for such geometries. They might indeed posit such a region but then it would have only ideal as distinguished from intuitional or experiential existence. Still again, in the L. geometry we have the proposition that a circle of infinite radius is not a straight line. Now, in theory of the region $I$, any circle of anharmonic ratio of the given pair of points and of the pair of (absolute) points cut from $S$ by the line joining the given points. Reciprocally, the angle of two planes is an arbitrarily chosen constant $c$ times the anharmonic ratio of the two planes containing the line common to the given planes and tangent to $S$. There are $\omega^4$ collimations of space that convert $S$ into itself. These fall into two classes according as they do or do not preserve the two systems of generatrices of $S$. The collinites of the first class — called displacements
—constitute a closed system, or group. The second class is not a group.

The locus of a point at a given distance from a fixed point is a second order surface—generally a hyperboloid or a cone cut from S by the polar plane of the given point, the sphere centre. S itself is a sphere, viz., the locus of all points at \( \infty \), of all points, that is, that, in the metric system in hand, are infinitely distant from any point not on S.

If S is imaginary, all lines are of finite length. The sum of the angles of an axial pencil of planes is finite. This general theory passes into the Elliptic geometry if we set \( \epsilon = 1/2 \), the sum of the angles of an axial pencil being then \( \pi \).

If S is real (and not ruled), the geometry of the interior of S includes the Hyperbolic geometry as a special case, namely, when \( \epsilon = 1/2 \).

The special metric that arises on taking S to be a degenerate surface passes over into ordinary Euclidean geometry when the degenerate S is (as locus) the locus (counted twice) of the Desarguesian points of space and (as envelope) is the imaginary circle at infinity. See GEOMETRY, NON-EUCLIDEAN; GEOMETRY, PROJECTIVE.

CASSIUS J. KEYSER,
Adrain Professor of Mathematics, Columbia University.

ANALYZER, the portion of a polychrope (q.v.) employed in the examination of polarized light. Nicol prisms, tourmaline plates, double-refracting crystals and movable mirrors are each used for this purpose.

ANAM, or ANNAM, an Asiatic country on the east side of the Indo-Chinese Peninsula, along the China Sea, about 850 miles long, with a breadth varying from over 400 miles in the north to 100 in the middle. It is composed of Tonquin or Tonking in the north and Cochinchina and Chiampa in the south. The area is 52,100 square miles, and the population (1913) 4,702,446.

Its coast is much indented, affording many fine harbors, and a mountain range extends its entire length. The Mekong, the principal river, is the boundary between Anam and Siam and is navigated by steamboats. The capital and largest city is Huê. Rice, cinnamon, sugar-cane, coffee, tea, tobacco, the areca nut, mulberry, betel, manioc, bamboo, caoutchouc, cardamons, dye, medicinal plants and cotton are the chief productions, though silk is manufactured to some extent and fine woods are exported. Iron, copper, zinc and gold are found. The mines are worked by natives. Coal mines are situated at Nongson. Cattle-rearing is becoming important; in 1916 there were 215,000 head of cattle in the country. The chief imports are cotton-yarn, cottons, tea, petroleum, paper goods and tobacco; chief exports are sugar, rice, cotton and silk tissues and paper. The government is a monarchy, the king being nominally assisted by a council of six, but French influence predominates. The King Thanh Thai, who succeeded to the throne in 1886, abdicated in accordance with the wishes of the French government, in favor of his second son, Duc Tan, b. 1900, who is under the control of a Council of Regency. The ports of Tourane, Qui-Nhon and Xuan-Day are open to European commerce and the customs revenue conceded to France. French troops occupy part of the citadel of Huê, the capital (Pop. 60,611). Bin-Dinh, the largest town, has 74,400 inhabitants. Anamite functionaries, under the control of the French government, administer all the internal affairs of Anam.

The inhabitants are from two races, the Mountain Mois and the Anamese proper, and generally under the middle size and less robust than the surrounding peoples. Their language is monosyllabic and is connected with the Chinese. They have adopted for the most part Buddhism, but the educated classes hold the doctrines of Confucianism; besides which there are 420,000 Roman Catholics. Anam was conquered by the Chinese in 214 a.p., but in 1426 a.d. completely won its independence and became actively in its affairs in 1847 on the plea of protecting the native Christians. By the treaties of 1862 and 1867 they obtained the southern and most productive part of Cochinch
China, subsequently known as French Cochinchina; and in 1874 they obtained large powers over Tonquin. By the treaty of 1884, ratified at Hué, 1886, Anam was declared a French protectorate. ANAMORPHISM. See METAMORPHISM.

ANAMORPHOSIS, a term applied to a drawing so executed as to present a distorted image of the object represented, but which, if viewed from a certain point, or reflected by a curved mirror or through a polyhedron, shows the object in true proportion.

ANANIAS, a member of the Church at Jerusalem, struck dead with his sapphire because of an attempt to misrepresent the amount of their gifts to the Apostle Peter. This borne by a Damascus disciple named in connection with Saul's adventure there and by a high-priest in Jerusalem belonging to the Sanhedrim.

ANANTAPUR, India, a town and district in the Madras presidency. The town has a station on the Madras Railway, 62 miles southeast from Bellary. Pop. about 8,000. The district was constituted in 1882 out of the unwieldy district of Bellary. It has an area of 5,557 square miles and in its northern and central portions is a high plateau, generally undulating, with large granite rocks or low hill ranges rising here and there above its surface. In the southern portion of the district the surface is more hilly, the plateau there rising to 2,600 feet above the sea. There is a remarkable fortress rock at Gooty, 2,171 feet above the sea, and a similar but larger rock at Penukonda, with an elevation equal to that of Bangalore, about 3,100 feet. Gooty fortress was a stronghold of the Mahrattas, but was taken from them by Hyder Ali. In 1789 it was ceded by Tipoo to the nizam, and in 1800 the nizam ceded the district to the British in payment for a subsidiary British force. The principal crops are millet, rice, other food grains, pulse, oil seeds and cotton. There are several steam factories for pressing cotton. Pop. about 790,000.

ANAPA, ana-pa, a seaport town of Russia, situated on the Black Sea. It has been variously the possession of Turks and Russians, but has belonged to Russia from 1829. Pop. about 7,000.

ANAPEST, in prosody, a foot consisting of two short syllables and one long one. In the comedies of Aristophanes it was the dominant measure, and Greek choruses employed it in their exits and entrances. From this latter circumstance it was frequently styled the marching rhythm.

ANAPHODISIACS, an-a-fród-i-sí-aks, are remedies that are supposed to diminish sexual power or desire. They may act directly on the vegetative genital synapses in the spinal cord, indirectly through the circulation on the brain, or peripherally on the sense organs. Inasmuch as local irritation is a frequent cause of stimulation of the genital sense, attention to cleanliness is imperative and the removal of all sources of irritation important. In case of analastic applications, such as weak solutions of carbolic acid—1 to 2 per cent.—or oxide of zinc ointment with carbolic acid, are useful. Of the general anaphrodisiacs the bromides are the best. Bromide of sodium or potassium is most frequently employed. Special medical advice is needed in the treatment of persistent genital excitement.

ANAPHYLAXIS, an exaggerated susceptibility on the part of certain individuals to certain chemical substances, chiefly proteins, which may either be taken into the stomach, such as mussels, crab meat, strawberries, etc., breathed, such as various hay fever and asthmatic reactions to various plant pollens, or which may be injected into the body, such as horse serum. Richet, a French physiologist, first studied it extensively in connection with muscel poisoning, although the studies of Jenner on smallpox and cowpox were really studies of this phenomena, as well as those of Magendie in 1839, Behring in 1901, but Richet first gave the name. When such substances, to which the individual is susceptible, are brought into contact with the body, they produce their sudden reaction: in some instances with a skin urticaria (hives), skin rashes, eruptions; at other times swelling of the joints, or of the mucous membranes, such as in some hay fevers, some asthmas; again with nausea, vomiting and profuse diarrhoeas (often incorrectly called ptomaine poisoning).

The causes for these anaphylactic reactions are extremely complicated and not yet thoroughly elucidated. They are not pure chemical phenomena, but are mediated by the vegetative nervous system, and are more striking in a certain group of individuals who are termed vagotonic (q.v.). Consult an early edition of the Handbook of Medical Sciences (Vol. 1, 1913).

ANAP'TOMORPHUS, a fossil lemur from the Eocene of Wyoming, allied to the modern tarsier. Some authorities have considered this animal as related to the ancestral line of man.

ANARCHISM, a theory of social organization, numbering, it is said, about 1,000,000 adherents. Its doctrines represent the extreme of individualism. It looks upon all law and government as invasive, the twin sources whence flow nearly all the evils existent in society. It therefore advocates the abolition of all government as we now know it. To-day, in order to understand the term, save that originating in voluntary co-operation. Anarchists do not conceive of a society without order, but of an order arising out of the law of association, preferably through self-governing groups, for it is said that, with here and there an exception, anarchists regard mankind as gregarious. "Our object is to live without government and without law," said Elisee Reclus, the eminent geographer, and in his day the leading anarchist of France. Anarchists do not ignore the enormous economies resulting from the law of association, but insist that the law will be better served in a state of freedom and in the absence
of all compulsion. They believe that everything now done by the state can be better done by voluntary or associative effort, and that no restraint upon conduct is necessary, because of the natural tendency of mankind in a state of freedom to respect the rights of the individual. The repression of crime, where crime might arise, could safely be left to spontaneously created organizations, such as the Vigilance Commissions of early California, where no State government existed. In the view of Prince Kropotkin, the leading Russian anarchist, no cause for litigation would arise after we had abolished the present system of class privilege and unjust distribution of the wealth produced by labor, that creates and fosters crime. To quote further from Kropotkin: "We are nurtured from our birth to believe that we must have government. Yet the history of man proves the contrary. When small bodies or part of humanity broke down the power of their rulers and resumed some part of their foreordained freedom, these were always epochs of the greatest progress, economically and intellectually. In the direct ratio to the freedom of the individual he advances." But attempts at individualism were those of W. Thompson in England and J. Warren in the United States. In 1827, Warren opened a "time store" in Cincinnati, where labor was exchanged hour for hour in different kinds of goods.

It is not easy to sum up in a few paragraphs the leading doctrines of any economic sect and at the same time retain absolute accuracy of statement. It should therefore be said that anarchists, while agreeing that the doctrine of laissez faire should be extended to all departments of human activity, are by no means in agreement on all points. There are evolutionary and revolutionary anarchists, and communist and individualist-anarchists. The point on which all are agreed is in their opposition to compulsory forms of government, and in regarding the necessary despotism of majorities in a democracy as only a little less hateful than the despotism of a monarchy. "Governments are the scourge of God," says Proudhon, with whom the philosophy of modern anarchism may be said to have begun.

Pierre Joseph Proudhon was born in Besançon, France, in 1809, and died in 1865. Germs of the doctrine of which he is the founder may be traced to much earlier, even ancient periods. Among his modern precursors is William Godwin (b. in Wismes, England, 1756; d. in London, 1834), who is better known as the author of the novel, 'Caleb Williams,' but who in his 'Inquiry Concerning Political Justice,' which appeared in 1793, advocated the abolition of every form of government, and forming a kind of true communism. But modern anarchism as a force in sociologic thought began with the publication of Proudhon's famous essay, 'What is Property?' (1840). In it he rejects all law and authority, but in a work which appeared in 1852 entitled 'The Free State,' he seems to have modified in a measure his former theory of government and favors the formation of self-governing communities. In the former work occurs the phrase which is destined to be forever associated with the name of Proudhon, but which was uttered by the Girondist Brissot a half century earlier, 'Property is robbery.' It was upon the notion that he had furnished a demonstration of this thesis that Proudhon especially prided himself. But this phrase as used by the father of anarchism must be held to apply rather to modern methods of acquisition than to property itself, for Proudhon was an individualist, not a communist-anarchist, and showed such skill he was in making himself understood, rather to refine than to destroy the idea of property. In all his reasoning on this point there is much dialectic subtlety, of which, with perverted ingenuity, Proudhon was overfond; but it may be said that what he really sought was the overthrow of all prevailing theories of property with a view to rendering it unassailable from the standpoint of exact equality and social justice. His chief American follower was Benjamin R. Tucker, who started a journal 'Liberty,' in 1881, and combined Spencerianism with the views of his master. In Germany Proudhon founded adherents in Hess and Grün, who showed a strong Hegelian influence. The doctrines of anarchism in the hands of Michael Bakunin were without a change of radicality, and the theory of Bakunin was in a purely peaceful revolution to one of force. Bakunin was born in 1814, died 1876. He was prominent in the Paris Revolution of 1848, was surrendered to Russia and sent to Siberia, but succeeded in making his escape. His principal work, in addition to innumerable pamphlets and addresses, is 'Dieu et l'État.'

The propaganda by action, as it is termed, by which it was hoped to inspire such dread and horror as to compel the adoption of measures of social amelioration, or perhaps the overthrow of the state itself, has borne abundant fruit in the attempted assassination of Emperor William in 1878, in the attempt upon the life of the German princes in 1883, in the assassination of President Carnot, of France, in 1894, of the Emperor of Austria, in 1898, of King Humbert, of Italy, in 1900, and of President McKinley, by Czolgosz, in the autumn of 1901. Other anarchist crimes were the throwing of a bomb in the French Chamber of Deputies, in 1893, by Vaillant, the bomb explosion in Paris, caused by, too many attempts at assassination, to mention in that city, four to the gallows, two to life imprisonment and one to a term of 15 years, aroused the attention of the whole civilized world. It is now seen, after the lapse of 17 years, that these men, even if dangerous to the community, were convicted more largely by the existing state of public terror than by any actual evidence connecting them with the throwing of the bomb. The fact that the pardon of the three who escaped the gallows was petitioned for, after the terror of the time had
died away, by some of the most prominent citizens of Chicago, is proof of the change the public mind underwent regarding the accused. The controversy over the justice of their conviction is still unsettled. With these acts of murder and vengeance the purely economic doctrines of anarchism have of course no relation. The propaganda of action is repudiated by those who are sometimes termed philosophical anarchists, to distinguish them from the Malatestian wing. This latter school regards force as fundamentally at war with their ideals. It does not believe that the social revolution can be accomplished by the methods of Bakunin and his school. Proudhon never preached force.

With the policy of propaganda by action in this country is linked the name of Johann Most, a former member of the German Reichstag; in France, that of Charles Malato ("I love and admire Vaillant just as some English Republicans love and admire Cromwell, who was a giant—Charles Malato"); but in Italy, that of Enrico Malatesta, an anarchist, like Kropotkin, of noble family. ("It seems to me that in the natural order of evolution violence has as much a place as the eruption of a volcano, and that progress has been paid for by streams of blood. I cannot see how the present conditions based upon force can be changed in any other way than by force, and so long as they use force against us we must in self-defense employ violent methods."—Enrico Malatesta.)

As Proudhon was the father of anarchist individualism, Kropotkin is as indisputably the father of anarchistic communism. Theoretic anarchism for some time subsequent to the advent of its French founder was rigidly individualistic. Max Stirner, a follower of Proudhon in Germany, whose philosophy was more of a blank negation than that of his master, pushed the ego to a point where it more resembles a caricature than a dogma, and Bakunin hated the idea of communism. But in Kropotkin it must be said that the idea of property has reached its disappearing point, and the ideal of anarchism is at the least purely communist. Kropotkin's life and his romantic career, united with the vast store of knowledge he possesses, give to his professions of anarchism a fascination and a weight. Communist anarchism is essentially the doctrine of Tolstoy, who combines it with religious motives.

ANASTOMOSIS, in anatomy the joining of the branches of a vessel with other vessels of the same or a different branch. Anastomoses are found in the arteries, veins and lymphatics. Anastomoses of nerve and muscle fibres are also spoken of.

ANATASE, a mineral more correctly known as OCTAHEDRITE (q.v.).

ANATH, ā'nath, is the name of a goddess worshipped in Palestine, as apparently appears from the name of a city mentioned in Joshua and Judges—Beth-Anath, meaning the house of Anath. Anathoth, which may be the plural, is mentioned in the prophecy of Isaiah. A. H. Sayce thinks it is a Chaldean deity worshipped by the Canaanites. The name Anath is said to be found on Egyptian monuments of the 18th dynasty. Anathoth was the home of Jeremiah the prophet.

ANATHEMA, a word used in a form of excommunication from the Church. It is properly a Greek word, and was originally applied to an object set apart and devoted to a deity, such as a gift hung up in a temple (being derived from the Greek anathēthēma, I lay up); but it came to mean separation from God and men, something accursed; and latterly to pronounce an anathema, to anathematize, became much the same as to curse. Anathema occurs repeatedly in New Testament Greek, in the English version being generally rendered "accursed," but once the original word is retained (1 Cor. xvi, 22) along with maranatha, the latter serving apparently to intensify the curse, though it is properly a Syriac expression signifying "the Lord will come." The Greek and Roman Catholic Churches both make use of the anathema. In the latter it can be pronounced only by a Pope, council or some of the superior clergy. The subject of the anathema is thus declared an outcast from the Church. When councils declare any belief heretical the declaration is couched in the following form: Si quis discretit, etc., anathema sit, "If anyone says (so and so) let him be anathema." The anathema was thus pronounced by the Vatican Council against opponents of the doctrine of papal infallibility. In the Middle Ages the anathema was freely used. See EXCOMMUNICATION.

ANATHHEMA. Andreyev's five-act drama (Anathema,) published in 1909, betrays the effect made upon him by the book of Job. In the prologue as well as in the epilogue the Devil, who is throughout named "Anathema, the Accursed One," appears before the eternal dual Arbitrator who guards the entrance "beyond the iron Gates," and boasts of his coming conquest of David Leizer, "a sick and foolish old Jew whom no one knows" and who seems forgotten even of God. The five acts of the play show David given over like Job to the machinations of Anathema, who, finding him in the midst of sordid poverty, brings to him as if from his brother, dead in America, a fortune of 2,000,000 rubles. At the death of his rich husband David hires a palace; his beautiful daughter Rose tries to make the most of her attractions; his son Naum, dying of consumption, takes dancing-lessons. David is unhappy and resolves to give away all his possessions. He commands Anathema, who, under the name of Nullius, has stayed with him as his adviser, to summon all the poor and unfortunate to share his worldly goods. The great fortune is utterly inadequate to meet such demands. The sick and the blind come to him for cure; those that have lost loved ones demand a miracle of him. He tries to escape; they follow him into the wilderness, and, when they find he can do nothing for them, they stone him to death. Anathema exults and again appears before the dread guardian of the Beyond to boast of his victory, but is told that "David has attained immortality and lives forever in the deadness of light which is life." Anathema refuses to believe such a tale and goes away, still blaspheming the name of Truth. There is nothing of Faust in David Leizer. He is unchanged by his new riches. Anathema is a cringing Mephistopheles who leads his victim on to apparent destruction by seeming to meet all his benevolent desires. The purely realistic scenes of the work are full of humor and pathos. These passages are practicable on the stage, but as a whole it is rather a closet-drama than one adapted for the modern stage. It was translated into English by Herman Bernstein and published in New York in 1910.

NATHAN HASKELL DOLE.

ANATHOTH, a town in Palestine, assigned to the Levites, the birthplace of the prophet Jeremiah and the home of Abiathar the high-priest. It was about three miles northeast of Jerusalem, and the small village of Anata occupies its site.

ANATIDE, the family of birds that includes the fresh-water ducks (q.v.). The typical genus is Anas, represented by the mallard.

ANATOL. Arthur Schnitzler, past-master of the Viennese drama, opened his career as playwright in 1893 with 'Anatol,' a series of seven scenes from the life of a sentimental philanderer. Anatol is a fashionable worldling who seeks relief from society in the companionship of this or that pretty child of the people. Each scene exhibits some phase of an affair with a different charmer. Now he hesitates to ask his Cora, who likes hypnotherapy, whether she has been faithful, lest his illusion be dispelled. Now he confesses to a gang of his own class his joy in his humble mistress of the moment, a girl who lacks beauty, elegance, and wit, but from whom emanates the soft lure of a spring evening and the spirit of love itself. Now Anatol grows almost tearful as he meditates upon the romance of a by-gone hour and all he must have meant to little Bianca, who presently reappears, unable even to recall him. Now he rages against his Emilie, not because she has had another lover, but because she would keep, for its price alone, the black diamond he had given her. Now he tenders a farewell supper to a ballet dancer, dreading to break to her the news that he has found a fairer friend, but only to learn that Annie has replaced him by an artist of her own. Now he chafes to hear his inamorata citing against him her husband's tastes and preferences; and now on his marriage morning he finds himself embarrassed to dispose of Iona, who has frolicked with him the night before and little dreams that he is to leave her. Thus sentiment
mingles with cynicism, melancholy with humor, in scenes which, despite their sensual implications, are delicate and refined. Technically, 'An Affair of State' is a story of brilliant dialogue, an exciting fusion of the realistic drama story a series of impressionistic pictures linked but loosely by an art deriving less from the stage than from fiction. Schnitzler's dialogue is delightful, quick to respond to every shift of emotion, suggestive, restrained, and evincing a freshness and freshness and an evident eagerness to please his readers and playgoers, the piece has been pleasantly paraphrased by Granville Barker as 'The Affairs of Anatol' (1911).

ANATOLI, an'a-tól'i, Jacob, Hebrew scholar: b. 1194; d. 1256. He was invited to Naples by the enlightened ruler, Frederick II, and under this royal patronage and in association with Michael Scot, made Arabic learning accessible to western readers. Among his most important services were translations of works by Avemroes.

ANATOLIA, the modern name of Asia Minor. See ASIA MINOR.

ANATOMY, literally a cutting up; but anatomy usually signifies the special study of the structure of organic bodies, morphology (q.v.) and applies to both animals and plants. Animal morphology is the study of human or other animal forms, the study of the relationship between the forms constituting Comparative Anatomy (q.v.). The study of the minute or microscopical anatomy is termed Histology (q.v.). Developmental Anatomy is the study of the gradual growth of the animal, Embryology (q.v.). In the plant world there are also the correlated branches of Plant Morphology, Comparative Anatomy, Histology and Embryology. The study of the microscopical structure of the single cell is termed Cytology; of collections of related cells and tissues constituting organs, Organology; thus the study of the bony system is termed Osteology, of the structures of circulatory system, of the nerves structures Neurology, of the muscles Myology, of the viscera Splanchnology, etc. Each in its turn has its special departments of investigation.

The study of anatomy may be approached from the purely descriptive side, Descriptive Anatomy, or may deal with the anatomy of related organs in related animals, as Systematic Anatomy. Applied or Practical Anatomy, or that branch dealing with its study as an aid in the diagnosis and treatment of disease, may be designated as Medical or Surgical Anatomy. Regional and Topographical Anatomy deals with the study of special parts or the special relations to surrounding parts.

History.—The beginnings of human knowledge of the structure of organic bodies are preserved from the earliest times in fragments only, but there are very good reasons for believing that much more was known many thousands of years before the Christian era than there is written evidence to substantiate. The historical morphological anatomy was closely related with the history of medicine, and even in very early times inquiries were made concerning the structure of the human and animal body.

It is usual to ascribe to the Greeks the first foundations of anatomical knowledge, but it seems that Chinese culture, which was highly developed when the peoples of Europe were in a very primeval condition, had a well systematized medical lore, including some pharmacological knowledge, with some few anatomical facts, although the anatomy of the early Chinese was largely speculative. Section of the human as well as lower animal bodies was forbidden by at least two of the religious sects of early Chinese culture, the Aishops and Buddha worshipers. It is interesting to note that as early as 2638-2699 B.C., Shinnong was a half-mythical medicine man in China, and it is said that Chinese works on medicine were written as early as 2698-2590 B.C.? (Hwang Ai).

In India the sacred work of the Ayur Veda, supposed to date from between the 14th to the 9th centuries B.C., at least 100 years before the cult of ?Esculapius had begun, contains descriptions of the human body obtained from dissections, and it has been maintained that Charaka and Susrutha, the earliest of Indian physicians, should be considered the earliest anatomists. Inasmuch as the probable dates of these Indian worthies is much more recent than was formerly supposed (100 A.D.), little can be made of these claims. At all events their anatomy was much cruder than that of the Hippocratic school circa 400 B.C. Egypt contributed somewhat to the knowledge of anatomy, and the Papyrus Ebers, 1553 B.C., is a monument of old Egyptian medicine. It is of interest to note that some of the Hippocratic nomenclature of anatomy is of Egyptian origin. The influence of religion, however, was very strong in the shaping of Egyptian medicine. Embalming was largely practised and undoubtedly led to the collection of many anatomical facts, the importance of which has become lost to students. It is certain, however, that the school of medicine situated in Greece, on the island of Cos, laid the firm foundations of our knowledge of anatomy. It was in Greece also that the physician's profession was amply recognized. This early Hippocratic age gave rise to a professional conscience, and the "Physician's Oath," or the "Hippocratic Oath," a monument of the highest rank in the history of civilization (Gomperz: 'Greek Thinkers').

There were at least seven physicians with the name of Hippocrates who taught in the early times. Hippocrates II (430 B.C.), however, was the great Hippocrates, but the knowledge of anatomy then possessed must be considered as the accumulation of the school rather than the work of any one man, for, as has already been pointed out, some of the Hippocratic nomenclature is Egyptian in origin (v. Oezele). Inasmuch as the Hippocratic writings are partly preserved, a better idea of the anatomical knowledge of the times may be gathered from them than from the mythical, traditional, and fragmentary remnants left by other peoples. The school of Cos had a fairly accurate and extensive knowledge of the human skeleton, and they knew the general shapes and varieties of most of the internal organs. Their physiological hypotheses, however, were crude but suggestive. From the time of Hippocrates II the school of Cos seemed to deteriorate, although Polybus, the son-in-law of Hippocrates II, Syenness, Diogenes and Praxagoras, the last named being noted for his anatomical knowledge, kept alive many of the traditions of the
school. With Aristotle (384-323 B.C.) there came a period of more exact science and the dissection of the lower animals was practised, hence Aristotle may be termed the father of Comparative Anatomy. His researches in anatomy were wide and deep and his work on animals contains much that is still taught.

The Alexandrian period, 300 B.C., during which the culture of Rome and of Greece was encouraged in Egypt under the Ptolemies, shows as a bright spot in the history of anatomical science. With the foundation of the Alexandrian Museum, the analogue of a modern university, the practice of human dissection became authorized. This period was a brilliant one in the history of medicine. Herophilus and Erasistratus were among the early leaders, the former making some noteworthy contributions to the knowledge of the anatomy of the brain. He maintained that it was the organ of thought and the origin of motion. He also described the luteals and the lymphatics, and was an intuitive inhaler for the seat of this of which he placed in the floor of the fourth ventricle of the brain, the place now known to be the site of the cranial nerves, that are indispensable for the function of breathing. Herophilus also is credited with the destruction of the doctrine that the brain held air, hitherto the veins only having been thought to contain blood.

Erasistratus first described the valves in the veins, made the general subdivision of sensory and motor nerves, and drew the generalization of the complexity of the convolutions and mental development. He also first suggested the thought of anatomies between the arteries and veins. Many others followed, but the rise of the Imperial school (q.v.) was the forerunner of the gradual decay of the Alexandrian school. It was to the newly arisen empire of Rome that the stream had turned, and until the time of Cato Greek physicians flourished in Rome. Asclepiades (126-56 B.C.) was one of the founders of the first great school of medicine. Rufus (7 B.C.-A.D.) was a student of the schools of both Ephesus, with A. Cornelius Celsus (25 B.C.-40 A.D.) among those who have left definite anatomical landmarks. Celsus is known as a brilliant man, a compiler of the work of his predecessors. His anatomical work was insignificant, but he contributed largely to therapeutics. The last dying ember of this Alexandrian transplanted school showed in Claudius Galen, a Greek from Pergamos, a town already noted for its Esculapian temple. Galen was a man of great brilliancy, an independent thinker, and it was to his literary efforts that much of the history and treatment of the Hippocratic school has been preserved to us. His works on anatomy alone were at least 15 in number, nine of which are preserved. Galen systematized much of the art of the time, and although much of his data was drawn from the study of animals it was to pass muster in the service of human anatomy. He was perhaps the first to make any experimental physiological studies. His descriptions of the relations of the brain to the spinal cord and his knowledge of the cranial nerves were in advance of his predecessors. Galen's work stands out as the last systematic work of the Greek period, and following his death began the dark era of the barbaric inroads of the northern races and the dispersal of the culture of the East.

For a period of many centuries history is comparatively silent on the subject of medicine. No great schools arose, yet the doctrines of the ancient Greeks were kept alive in many places by obscure scholars and by many peoples, although it is known that the Saracens were largely instrumental in keeping intact that which Galen had handed down, without adding much, however. The Intellectual development took place in the Byzantine countries, and many universities were founded by the Arabs, where the Roman-Hellenic culture was mingled with the Christian-Oriental ideas to found a new culture. Among the most famous of the Oriental physicians was Sergios von Resaina (536). He translated both Galen and Hippocrates into Syrian. Orebasios was also a commentator of the Greeks; Avicenna (980-1036) was the Galen of the Orientals. This period of medical history has been called the Arabic period, and not until the influence of the Crusades commenced to make itself felt did the period of the Renaissance begin.

The history of medicine (anatomy) now becomes more and more complex; new schools begin to be founded. Salerno, Naples, Montpellier, Venice, Bologna, Prague, Vienna, and Oxford successively built universities and attracted the ablest minds in medicine. Scholars traveled from university to university to learn from a professor here and a professor there, and the fortunes of the universities rose and fell like the tides of the sea. In 1224 it is said that the University of Bologna alone had 10,000 students. Among the early names of this period of transition may be mentioned Lisfranc (1295); Mondino (1275-1327), who wrote the first anatomy since the time of Galen, and which reached 25 editions—he also suffered persecutions for his zeal in dissecting; Linacre (1461-1524), of England, was one of the earliest scholars to return from the East and to bring the knowledge of anatomy to Oxford and to Cambridge; and Sylvius, or Jacques Dubois, a Frenchman, was another of these great early anatomists of the reconstruction period. Sylvius first arranged all of the muscles of the human body and gave them the names which, for the most part, they now carry.

Andreas Vesalius (1514-54), a Belgian, first studied at Louvain, and later became a pupil of Sylvius at Paris. At the age of 22 he became professor of anatomy at Padua, and at 29 issued a monumental work on anatomy, the best that had been given up to that time. He corrected many of Galen's errors and had a checkered career. General gross anatomy under Vesalius, who was a son, grandson and great-grandson of a physician, began to assume more definite shape. In his student days at Paris under Sylvius, anatomy was taught upon the animal cadaver. Sylvius, however, was an uncompromising Galenist, and, although he made dissections, he followed Galen's treatises in very servile fashion. He was practically the last of his school, and his doctrines were swept away by the light thrown by this indefatigable seeker after truth as drawn from nature rather than from books. "My study of anatomy," said
ANATOMY

be, "would never have succeeded had I, when working at medicine at Paris, been willing that the viscera should be merely shown to me and to my fellow students by another public dissection by wholly unskilled barbers, and that in the most superficial way. I had to put my own hand to the business." Human dissection was rapidly and superficially practised, but Vesalius is known to have haunted cemeteries and gibbets to obtain human material. The results of his studies were published in 1543 in his masterpiece, "De Humani Corporis Fabrica. Libri VII," the first of a long series of more distinct modern treatises on physiology as well as anatomy. Vesalius may truly be said to have been the founder of modern biological science. "He brought into anatomy the new spirit of the time, the young men of the time who listened to the new voice."

Of the contemporaries of Vesalius many were almost as famous as he. Eustachius at Padua and Fallopius at Padua, Ferrara and Padua corrected many of Vesalius's details, and Eustachius may be said to have been the first to call attention to the study of embryology as an aid in the interpretation of gross anatomy. Both Eustachius and Fallopius made studies of respiration which led to the knowledge of the ear. These were the days of enthusiasm in the discovery of new facts, and so great was the striving for the new culture that it is said that criminals were utilized for purposes of experiment and dissection, probably after smothering. A large coterie of brilliant men lived at this time. Servetus (1509–53), a Spaniard, first made out many of the true facts of the pulmonary circulation. Casalpinus (1517–1603), a highly cultured scholar and a great botanist, was among the first to speak of the circulation of the blood. Varolius (1543–75) furthered the knowledge of the anatomy of the nervous system. Spigelius (1578–1625) made noteworthy studies of the liver. Realdo Colombo (1494–1559), who succeeded Vesalius at Padua, and was subsequently professor of anatomy at Pisa, filled out the outline of Servetus. Some authorities claim that he stole the ideas and correctly described the pulmonary circulation, although he did not appreciate the corollaries of his discovery. He imitated Vesalius and his work in a bold reproduction of his friend's studies; and Fabricius (1537–1619), who succeeded Fallopius at Padua, built a special anatomical amphitheatre where he taught anatomy to England's great anatomist Harvey.

The time had now come for a mind who could take this accumulating mass of anatomical facts, which after all were extensions in detail only of the old Hippocratic anatomy, and to discover new physiological principles, for it was noteworthy that although newer and better ideas of structure had been given, yet many of the old notions of function were still taught.

This was done by William Harvey of England. He was born in 1578, studied at many universities, mainly at Cambridge and Padua, and in 1615 first clearly demonstrated the correct action of the heart and the history of the circulation of the blood. Harvey's old anatomical preparations of this age are still in existence. From this time onward newer interpretations were possible, and the study of anatomy and physiology, now correctly linked, made rapid strides. These newer vantage grounds of interpretation were further extended by the discovery of the microscope, and by this instrument the field of microscopic anatomy, or Histology (q.v.), was opened up, leading to far-reaching and important results to the welfare of mankind. The period of detailed and special advance may be said to have been foretold in the newly revived study of physics by Borelli and his school, and the newer chemistry of Van Helmont won from the mysticisms of alchemy. These united to interpret the results of anatomical research, and the general history of the subject of anatomy widens out, fan-like, into its several specialties. The subject of anatomy now becomes lost in the history of interpretations and applications, and the further developments of these are considered in these volumes under their special heads where the developments of the various branches of anatomical research are considered. See ANATOMY, COMPARATIVE; ANTHROPOLOGY; BIOLOGY; CHEMICAL PHYSIOLOGY; CYTOLOGY; EMBRYOLOGY; HISTOLOGY; PATHOLOGY; PHYSIOLOGY; SURGICAL ANATOMY.

Bibliography.—The most extensive of modern works on the history of anatomy is found with complete bibliography in Neuberger and Pagel's "Handbuch der Geschichte der Medicin," (2 vols., 1903); Garrison, "History of Medicine" (1915); Buck, H. "History of Medicine to 1800" (1917). Of descriptive anatomies there are many: Testut and Poirier in French; Bardelben and Spalteholz in German, the latter translated by Barker into English in 1903; Morris, Quain, Gray in English; Leidy, Gerrish and Huntington in America. The bibliography of the special subjects will be discussed in their sections. See MEDICINE, HISTORY OF.

SMITH ELY JELIFFE.

ANATOMY, Comparative, is that subdivision of the science of zoology which deals with adult forms and structures of animals with a view to determining their relationships. Comparative Anatomy and Embryology, the latter dealing with the immature forms and structures of animals, constitute the science of Morphology, which treats of the structure, development, classification and relationships of animals as contrasted with Paleontology, which deals with their functions. In contradistinction to special anatomy, which has for its aim the description of all the structures and parts of any one animal,—for example, man,—the method of comparative anatomy is to compare corresponding parts in many different species, noting their modifications and transformations with the ultimate purpose of determining the affinities or relationships of these species to one another. In the earlier history of this science the expressions "relationship" or "affinity" were used in a metaphorical sense, signifying merely relative positions in a system of classification. With the growth of the evolution idea, however, they have acquired a new and literal meaning, since the aim of modern morphology is to determine the genetic or block line of descent of animals to one another and thereby to trace the evolution not only of the species but also of the various organs and parts. The great value of the comparative method in science is nowhere better illustrated than in the study of
anatomy. There are probably not fewer than 1,000,000 known species of animals belonging to well 12 distinct types. These animals exhibit the various organs of animal life under a great variety of forms, and by means of comparison it is possible to determine in each case what is universal and essential and what is merely local and accidental, and also to indicate the steps by which similarity or difference in some character or function has been attained. Furthermore the comparative method throws a flood of light upon the significance of problematical and rudimentary structures such as the thyroid, the thymus and pineal glands of man, the purpose of which is now so puzzled the earlier anatomists. In fact it may fairly be said that it is impossible to comprehend properly any structure of the human body without considering it in relation to similar structures in other animals.

I. Principles of Comparative Anatomy.— It is obvious that in the study of animals various standards of comparison might be employed; for example, they might be compared as to color, size or length of life, but it is at once apparent that the comparison of different animals of the most diverse characteristics in other respects. As contrasted with such a purely artificial classification it was long the aim of naturalists to find a natural system expressing the "affinity" between organisms which could frequently be better felt than described. It was the great merit of Cuvier, often called the founder of comparative anatomy, that he insisted upon the importance of comparing the totality of the internal structures as well as the external characteristics of animals. By means of such comparisons he reached the conclusion that there were four great independent branches or types of animal organization, namely, Vertebrata, Mollusca, Articulata, Radiata, each consisting of forms fundamentally like one another but unlike those of other types. The principal criterion used by Cuvier for determining this fundamental likeness or unlikeness was the relative positions of corresponding parts, particularly of the nervous system. The type is the relative position of parts" (Von Baer). Richard Owen, a pupil of Cuvier, introduced the term homology to describe this fundamental likeness, defining it as "morpological correspondence in the relative position and connection of parts." He contrasted this physiological correspondence of parts, which he named analogy. In closely allied animals, organs which are homologous are usually also analogous, but in less closely related ones this may or may not be the case. Organs having the same function may be structurally very unlike, for example, the wing of a bird and that of an insect; on the other hand, organs structurally similar may have very different functions, for example, the fore leg of a quadruped and the wing of a bird. This conception of homology lies at the very foundation of all morphological studies; it is the one criterion for determining likeness or unlikelihood between organisms. Owen further distinguished between special and general homology, the former signifying fundamental likeness between all animals, the latter distinguishing parts of different animals, as in the case of the arm of man and the fore limb of a quadruped; while the latter refers to similar parts of the same individual, as in the case of the fore and hind limbs of a quadruped or the right and left sides of the body. Since the term general homology as used by Owen is liable to misinterpretation it would be well to be explicit in employing it. The term meristic homology (Bateson), signifying by this term morphological correspondence between parts of the same individual which may be repeated in any relation whatever. Meristic homology would thus include correspondence between parts which are repeated in a series, for example, the vertebrae of the spinal column (serial homology, homodynamy), between parts repeated on the right and left sides of the body, for example, right and left limbs (lateral homology, homotypy) and between parts repeated in any other relations, for example, the fingers of one hand, upper and lower teeth, etc. (vertical homology, homonymy).

Significance of Homology.— To Cuvier and his followers homology meant "conformity to type," to the "archetypal type" established by the Creator. In the light of evolution, however, homologies are believed to be family or hereditary likenesses due to inheritance from some common ancestor. For this reason special homology may replace it by the expression "lateral homology", "lateral homomorphy" (Lankester) or homophy. Contrast with this are such morphological resemblances as are not due to inheritance, but to similarity of environment acting upon forms of dissimilar descent; such false homology is called homoplasies (Lankester), homomorphy (Gegenaur) or convergence. It is the task of comparative anatomy to apply to animal structures these criteria of likeness or unlikeness and to distinguish between these various kinds of homology. These various forms of homology are summarized in the following table:

| Special Homology | Homodynamy (Serial) |
| Homology (Meric Homology) | Homotypy (Lateral) |
| False Homology | Homonymy (Vertical, etc.) |

II. General Structures and Functions of Animals.— Although the differences between the highest and the lowest animals are enormous there are nevertheless certain structures and functions which are practically the same in all animals whatever else their other characters may be. All animals and plants without exception are composed of cells, while all the functions of living things are the results of the aggregate functions of the cells of which they are composed. The cell is thus the universal unit of organic structure and function (Cell Theory of Schleiden and Schwann), and has been defined as a mass of protoplasm enclosing a nucleus (M. Schultz). Protoplasm or living matter is a substance, usually semi-solid, of unknown but undoubtedly very complex chemical composition. It is probably composed of several complex compounds of C, H, O, and N, which do not form a mere mixture but are united in a definite and orderly way. Both the cell body and the nucleus are composed of protoplasm, though of very different quality in the two cases. That which forms the chief mass of the cell, the cell body, is called cytoplasm, while that constituting the nucleus is known as karyoplasma. At least these two kinds of protoplasm are found in every cell and are necessary to the continuance of vital activities. The cytoplasm
and karyoplasm are each composed of two or more different substances of visibly different structure, and all these parts are put together in an orderly manner so that they bear definite relations to one another. The cell, therefore, no less certainly than a complex animal, shows organization, that is, differentiation of unlike parts and integration of these parts into a single and complete whole.

As all organisms are composed of cells, so all living things have certain activities or functions in common. The most important of these are the following: (1) Metabolism, or the transformations of matter and energy within the living thing; this may be subdivided into anabolism, or the change of the matter and energy of food into the matter and energy of protoplasm; and katabolism, or the destructive changes in protoplasm by which the living matter is transformed into less complex substances (secretions, waste products, etc.), while its energy appears in various forms (heat, light). Metabolism, therefore, involves nutrition, growth, waste and repair, movement, secretion and excretion. (2) Irritability, or the capacity of receiving, transmitting and responding to stimuli. (3) Reproduction, or the formation of new individuals from the substance of an old one. These general functions are characteristic of every living thing, plant or animal, simple or complex. From them all the functions of the most complex animal are built up, and as they are manifested in some degree by every cell it will be seen that the cell is the unit not only of organic structure but also of organic function.

All animals begin their individual existence as a single cell, but while some remain in this condition throughout life, others by repeated divisions of this initial cell become multicellular: the former constituting the group Protozoa, the latter the Metazoa. Protozoa are animals in which the entire body consists of a single cell, which usually leads an independent existence, though in some cases several may be united into a colony. In some forms the substance of this cell consists of protoplasm showing very little differentiation; in others it is differentiated into many unlike parts, each with its own specific function. The most general differentiation, arising from that of nucleus and cell body, is into a superficial dense layer, the ectoplasm, and a more fluid, granular interior, the endoplasm. Further specializations are shown by the more complex forms in the formation from the ectoplasm of contractile vacuoles, serving as organs of excretion; of thread-like processes, serving as organs of locomotion (cilia, flagella) of contractile fibres (myophan striations) which act like muscle fibres; of stingling threads (trichocysts) which serve as organs of defense; of a mouth and gullet through which food is taken into the interior of the cell, and of a calcareous or silicious skeleton, frequently of great complexity and beauty. All of these structures are differentiations of a single cell; they show how complex a cell may become, and they indicate that the Protozoa are, in the words of one of the old zoologists, "perfect animals."

In all Metazoa the body is composed of many cells differing among themselves in certain respects. These cells have all arisen from a single one, the egg, which by repeated divisions (cleavages) gives rise to a group of connected cells. In typical cases these become arranged in a single layer, forming a hollow sphere, the blastula, which then, by the migration of certain surface cells into the interior, becomes a two-layered sphere; the gastrula, containing a central cavity; the archenteron, or primitive digestive tract, which opens at one place to the exterior by a pore, the blastopore or primitive mouth. The outer layer of the gastrula is called the ectoderm, the inner one the endoderm, while between them a third layer, the mesoderm, usually appears, being derived from one or both of the primary layers. These three layers are known as the germ layers and from them all the organs of the adult metazoan are derived. The ectoderm gives rise to the outer covering of the body, the nervous system and sense organs; the endoderm to the alimentary canal and its outgrowths, while from the mesoderm arise muscles, skeleton, circulatory, excretory and reproductive systems.

In all Metazoa the ectoderm and endoderm and frequently also the mesoderm consist of cells, flattened, cuboid or columnar in shape, pressed together side by side into a layer. This simplest and earliest grouping of cells in the metazoan body is called an epithelium. From one or more of these epithelial layers cells may escape into the space between the ectoderm and endoderm and there become branched and irregular in shape, forming a loose grouping of cells known as mesenchyme. Epithelium and mesenchyme are the primary tissues of the metazoan body. They are the first formed in the development, and from them all other tissues are derived. The cells of one or both of these primary tissues may undergo further differentiation into contractile or muscle cells and into irritable or nerve cells, while the mesenchyme cells may give rise to non-living cell products such as fibres, spicules, cartilage, bone and fat. When cells of any one of these groups are united they constitute a tissue, so that in the body of a metazoan we recognize, in addition to epithelial and mesenchymatous tissue, muscular, nervous and sustentacular or connective tissue. Further consideration of these tissues belongs to Histology rather than to Comparative Anatomy.

In all Metazoa two or more of these tissues may be united to form organs, which are structures of definite shape and function for their purpose the carrying on of specific functions. Finally two or more organs may co-operate in a common function and are then known as an organ system. The principal systems of organs in the metazoan body are the following: (1) Integumentary; (2) Nervous; (3) Motor; (4) Skeletal; (5) Alimentary; (6) Respiratory; (7) Circulatory; (8) Excretory; (9) Reproductive.

III. Fundamental Form of the Metazoan Body—Although the forms of multicellular animals are extremely varied they may all be referred to a single ground form, the gastrula. From the egg stage to the gastrula all Metazoa travel essentially the same road in their development: beyond the gastrula stage they diverge in many directions. The gastrula is therefore the latest developmental stage common to all Metazoa and must be taken as the fundamental form from which they all have been derived. It is typically a double-walled sac surrounding the archenteron or primitive digestive cavity, which opens at one pole to the exterior by the blastopore or primitive mouth. It is radically sym-
metrical around an axis connecting the oral and aboral poles; this is the primary or gastrular axis. In a few types — for example, sponges, hydroids, jellyfishes — this axis becomes the chief axis of the adult body; such animals constitute the group Protosasia. In others (all bilateral animals) the chief axis of the adult lies almost at right angles to the gastrular axis, and it is derived in large part from one of the secondary axes of the gastrula; these forms are known as Heterosasia or Bilatera. Among the Protosasia the adult form is radically symmetrical and differs but little from the gastrula; this is especially true of the hydroids, some of which are practically gastrulas throughout life which are attached by the aboral pole and with a row of tentacles around the mouth. Among the Heterosasia, on the other hand, the adult of the secondary axes elongates, becoming the principal axis of the adult, and the body becomes bilaterally symmetrical with reference to a plane passed through this axis and the original primary axis. The apical pole of the gastrula becomes the anterior pole of the adult; since brain and sense organs usually develop at this pole it might also be called the sense pole. The position of the oral pole of the gastrula with reference to the adult axis shows considerable variation in different groups, but among invertebrates it generally lies on the ventral side, while in the case of the vertebrates it is dorsal. The chief axis of the adult connects the anterior and posterior poles and is therefore known as the antero-posterior axis. The side of the body generally directed downward, and at the anterior end of which the mouth usually lies, is ventral, while the opposite side is dorsal and the line connecting these two is the dorso-ventral axis.

There are a few apparent exceptions to the rule that Heterosasia are bilateral forms; some Heterosasia are apparently radially symmetrical (starfish, sea-urchin), while others are asymmetrical (snails, amphioxus, flounders, etc.). The starfishes and sea-urchins are five-rayed animals which were classed by Cuvier among the Radiata, but a careful study of the larval as well as the adult form shows that they are really bilateral and that their radial structure has developed from a bilateral form, probably through the influence of peculiar life conditions, such as persistent attachment or fixation to foreign objects. Snails are generally spirally coiled and asymmetrical, but here also the study of their development shows that at an early stage they are bilateral, and even in the adult condition the head and ventral parts of the body are usually bilateral; the asymmetry of the dorsal part being due, perhaps, to its elongation and the shell formation covering it. In the case of other asymmetrical forms, like amphioxus, flounders, etc., it is certain that we are dealing with modifications of bilaterality due to peculiar conditions of life.

Another modification of the original metazoan ground form, the gastrula, which almost all Metazoa show, is due to the formation and development of a middle layer in a space, the blastocoele or primary body cavity, between the ectoderm and the endoderm, namely, the mesoderm. In the lowest Metazoa this consists of branched cells (mesenchyme) which are loosely packed together and contain no considerable spaces, or if present these spaces are only parts of the primary body cavity. Among the higher Metazoa the middle layer is usually divided into an inner portion lying next to the endoderm and an outer one next to the ectoderm. Between these two layers of mesoderm there remains a space which is the secondary body cavity or coelom. This is lined by flattened mesoderm cells, the peritoneum, and is usually divided into right and left halves by two longitudinal partitions, the dorsal and ventral mesenteries, one of which lies dorsal to the alimentary canal and the other ventral. In animals one or both of these may be destroyed. In segmented animals the coelom may be further divided into a series of chambers by transverse partitions, the dissepiments. The excretory and sexual organs are developed in large
part from the walls of the coelom and project into its cavity. The portion of the coelom surrounding the heart is usually separated from the remainder of this cavity and is called the pericardium; while in the highest vertebrates (mammals) the anterior portion of the coelom which contains the lungs is separated by the diaphragm from the posterior part containing the abdominal viscera.

A further complication of the metazoan body is introduced by the repetition of the principal organs of the body in a series, one behind the other; such repetition is known as metameric segmentation, and each segment of the body is called a metamere or somite. Many of the higher Metazoa (annelids, arthropods, vertebrates) show this form of segmentation. In the simplest cases each of these somites has its own section of the coelom and its own sensory, nervous, muscular, alimentary, respiratory, excretory and sexual organs, and each may bear a pair of limbs or locomotor organs. Each somite, in short, contains all of the important organs and may properly be called a little body (somite). In more highly organized segmented animals the various segments are no longer alike (homonomous), but show physiological divisions of labor, some being differentiated for one function and some for another (heteronomous). In this way some of the organs named above disappear in certain segments while others become greatly enlarged or modified. Finally this specialization of the somites is carried one step farther in higher arthro-

forms of which group show segmentation of the axial skeleton (vertebrae and ribs) and attached muscles, of the nerves, of the gills and their blood vessels, and of the excretory and sexual organs; while in the higher vertebrates (reptiles, birds and mammals) segmentation is limited in the adult to the axial skeleton, muscles and nerves. The fusion of somites is most pronounced at the anterior end of the body; the head of insects contains three or four somites, while the vertebrate head is composed of not fewer than nine. Among arthropods the section of the body immediately behind the head and known as the thorax is composed of a number of fused somites, while in the posterior section of the body, the abdomen, the somites do not usually coalesce. Primitively the limbs are all alike and a pair is borne on each somite; however in higher annelids and arthropods they disappear entirely from certain somites and in others undergo great modifications of structure to fit them for particular functions. In the case of vertebrates they are limited to but two pairs, and it is probable that these are derived from a continuous lateral fin by the suppression of intervening portions. The great modifications and complications which have here been briefly sketched lead far from the simple form of the gastrula, and yet comparative anatomy and embryology show that the gastrula is the ground form of all Metazoa and they indicate in many cases the steps by which these most complex parts have arisen.

IV. Classification.—Although there is much difference of opinion as to the number of types
or phyla in the animal kingdom it is certain that there are more than the four recognized by Cuvier, the number being probably not less than 10 or 12. The present tendency among zoologists is to increase this number rather than to reduce it; but the absolute separateness and independence of these types is not now generally maintained. Many of them have important characters in common, and while sufficiently distinct to mark the primary subdivisions of the animal kingdom are yet evidently related to one another. The primary divisions or phyla which are now most generally recog-

nized are the following: (1) Protozoa, (2) Spongiaria, (3) Cnidaria, (4) Cleinhora, (5) Platyhelminthes, (6) Nematothelminthes, (7) Rotifera, (8) Chaeognatha, (9) Annellida, (10) Arthropoda, (11) Molluscoida, (12) Mollusca, (13) Echinodermata, (14) Chordata. Some forms cannot with certainty be assigned to any of these groups, and new phyla may need to be established for them; on the other hand future work may show that two or more of the groups named may be combined under a single phylum. The value of these phyla so far as the number and variety of animals included in them is concerned is very unequal; some of them including but a single order and but a few genera, while others include many classes, orders and genera; in fact, about one-half as many species are known in a single order of the class Insecta as in all the remainder of the animal kingdom put together. A tabular classification of each of these phyla and of the classes into which it is subdivided is given on the following pages:

V. Organ Systems.—When two or more organs are associated in carrying on a common function they constitute an organ system. Those systems most widely represented among animals, and therefore the most important, are those concerned with the general functions of all animals, namely, metabolism, reproduction and irritability. The first of these consists of several distinct though related functions, each with its own system of organs; accordingly we recognize the following systems: (1) digestive, (2) respiratory, (3) circulatory, (4) excretory, (5) motor, (6) reproductive, (7) nervous, (8) sensory; to these may be added those less important systems which serve for protection and support, namely, (9) integumentary, (10) skeletal. These organ systems will now be compared in broad outlines, with a view to showing their relationships in the leading phyla of the Metasoea. For the sake of convenience the integumentary, skeletal and motor systems will here be considered before any of the others.

1. Integumentary System.—In all animals the outer covering of the body consists of a layer of epithelial cells, the ectoderm. Beneath this layer a basement membrane is present, which in some animals is thick and serves for protection and support (Cnidaria, Platyhelminthes). This epithelium is frequently ciliated and it always contains gland and sensory cells and in addition may contain nerve and muscle cells as well as stinging cells (Cnidaria). In some animals the epithelium, which in these cases is called hypodermis, secretes on its outer surface a cuticular covering which may be a thin and flexible membrane or cuticle (hydroids, trematodes, cestodes, annelids, rotifers), or it may be thick and flexible (nematothelminthes) or dense and inelastic except at the joints (arthropods). In other cases the epithelium secretes skeletal structures in certain regions only, thus giving rise to calcareous shells (corals, mollusks, brachiopods). In arthropods this epidermal secretion is particularly dense and tough and is known as chitin; it may become calcified in certain portions. In mollusks the superficial epithelium remains naked except in a certain region, the embryonic shell-gland, where it first secretes a cuticular covering and then forms beneath this a dense calcareous layer, the shell; at the margins of the shell-gland (mantle edges) the secretion of these layers continues throughout life.

CHIEF SUBDIVISIONS OF THE ANIMAL KINGDOM.

A. PROTOZOA: One-celled animals without gastric cavity, germ layers, or tissues.

Class 2. Flagellata: With one or two vibratile protoplasmic processes (flagella). Example, Monad.

Class 4. Sporozoa: Parasites without mouth or organs of locomotion. Example, Gregarina.

B. METAZOAA: Many-celled animals with gastric cavity, germ layers, and tissues.

A. PROTAXONIA (= Caelenterata): Metasoea with gastrula-like body, persistent gastrular axis and radial symmetry.
ANATOMY

CHIEF SUBDIVISIONS OF THE ANIMAL KINGDOM — Continued.

B. METAZOÀ: Many-celled animals with gastric cavity, germ layers, and tissues — continued.

A. PROTA XONIA ( = Calenterata): Metazoa with gastrula-like body, persistent gastrular axis and radial symmetry — continued.

I. SPONGIARIA: Fixed aquatic animals with numerous pores in body wall through which water is drawn into the gastric cavity and thence expelled through a large opening, the osculum. Complicated colonies are formed by incomplete budding.

Order (2). Non-calcareous: With silicious, fibrinous, or gelatinous skeleton. Example, commercial sponge.

II. CNIDARIA: Aquatic animals either attached (polyps) or free-swimming (Meduse) with stinging cells (cnidae). By incomplete budding the polyps may give rise to plant-like colonies (hydroids), or by complete budding to jellyfishes (Meduse).

Class 1. Hydrozoa: Gastric cavity without septa and without ectodermal oesophagus.
Order (1). Hydromeduse: Usually with alternation of hydroid (asexual) and medusoid (sexual) generations. Examples, hydroids, small jellyfishes.

Class 2. Scyphozoa: With radial septa in gastric cavity and with ectodermal oesophagus.
Order (1). Scyphomeduse: The solitary polyp divides into a series of jellyfishes with notched margins. Example, large jellyfishes.

III. CTENOPHORA: Two-rayed radiates with sense organ at apical pole of gastrula, with mouth and ectodermal oesophagus at opposite pole and with eight meridional rows of vibratile plates which serve as locomotor organs; without stinging cells. Example, the Venus girdle.

B. HETERAXONIA ( = Bilatera): Animals in which the chief axis of the adult body is not that of the gastrula; symmetry bilateral.

IV. PLATYHELMINTHES: Flatworms with mouth usually on ventral surface and with apical (sensory) pole of gastrula near anterior end of body; primary body cavity filled with mesenchyme, no true coelom.

i. PLATODA: Gastric cavity, when present, with but one opening to the exterior, the mouth.
Class 1. Turbellaria: Free living forms; body covered by cilia. Example, planarians.
Class 2. Trematoda: Parasites without coat of cilia but with external cuticle; with suckers for attachment to host. Example, flukes.
Class 3. Cestoda: Parasites without mouth or alimentary canal; with external cuticle, but without cilia; usually incompletely divided into segments (proglottides). Example, tapeworms.

ii. Nemertinea: Free living worms with external covering of cilia; with mouth, alimentary canal, and anus; with protrusible proboscis at anterior end of body. Example, Cerebratulus.

V. NEMATHELMINTHES: Round worms, mostly parasitic, with long, unsegmented bodies covered by a dense cuticle; with primary body cavity; without cilia.

i. Nematoda: Thread worms without mesenteries or peritoneum; with nerve ring around oesophagus and dorsal and ventral nerve trunks. Examples, pinworms, vinegar-eels.

ii. Gordiacea: Hair worms parasitic during part of life; with mesenteries and peritoneum; with nerve ring and ventral nerve trunk. Example, horsehair worms.

iii. Acanthocephala: Internal parasites without alimentary canal; with proboscis and hooks for attachment to host. Example, Echinorhynchus.

VI. ROTIFERA: Wheel animalcules with body divisible into head (trophical disk), trunk and tail (foot); with wheel or crown of cilia around head; with primary body cavity and with grinding stomach (mastax). Example, wheel animalcules.
CHIEF SUBDIVISIONS OF THE ANIMAL KINGDOM — Continued.

B. METAZOA: Many-celled animals with gastric cavity, germ layers, and tissues — continued.

B. HETERAXONIA (= Bilateria): Animals in which the chief axis of the adult body is not that of the gastrula; symmetry bilateral — continued.

VII. CHÉTOGNATHA: Small marine worms with three body segments, namely, head, trunk and tail; with horizontal fins around tail and on sides of trunk; with bristles (chaetae) on sides of mouth; with true coelom (secondary body cavity). Examples, arrow-worms.

VIII. ANNELIDA: Ringed worms with segmented bodies and true coelom; the segments (somites) are typically similar (homonomous) and each encloses a section of the coelom and of the vascular, excretory and nervous systems.

Class 1. Chatopoda: Worms with bristle-like appendages (chaetae), which usually serve as organs of locomotion, on every somite. Example, earthworm.

Class 2. Gephyrea: Marine worms with few traces of segmentation; with crown of tentacle around mouth and with U-shaped alimentary canal, the anus opening near the mouth.

Class 3. Hirudinea: Worms with flattened bodies and rudimentary coelom, without chaetae, but with anterior and posterior suckers. Example, leeches.

IX. ARTHROPODA: Animals with jointed bodies and legs; without cilia, but with the entire surface of the body covered by a coat of dense substance, chitin.

i. BRANCHIATA: Aquatic animals with gills.

Class 1. Crustacea: With two pairs of antennae (feelers) and usually with gills borne on the legs. Examples, lobster, crab.

ii. TRACHEATA: Land animals with internal respiratory cavities (tracheae, lung books).

Class 1. Onychophora: Worm-like animals with numerous short legs. Example, Peripatus.

Class 2. Myriopoda: Animals with head and many-jointed body, every segment bearing one or two pairs of legs. Example, centipedes.

Class 3. Insecta: Animals with body divisible into head, thorax, and abdomen; with four pairs of appendages on head, three pairs of walking legs on thorax, but without appendages on abdomen. Example, grasshopper.

Class 4. Arachnida: Body divisible into cephalo-thorax and abdomen; with six pairs of appendages on former, but none on latter. Examples, scorpions, spiders.

X. MOLLUSCOIDA: Unsegmented animals, usually stalked and attached, living singly or in colonies; with a crown of ciliated tentacles around the mouth; generally with U-shaped alimentary canal and with anus opening near mouth.

Class 1. Phoronida: Single, stalked animals with body cavity partially divided into three portions. Example, Phoronis.

Class 2. Brachiopoda: Single animals with calcareous shell consisting of dorsal and ventral valves. Example, brachiopods.

Class 3. Polyzoa: Stalked animals which usually give rise to colonies by incomplete budding. Example, Bugula.

XL MOLLUSCA: Unsegmented animals with reduced coelom; differing greatly in form, but usually having a head, with tentacles and eyes; with a rasping organ (the lingual ribbon or radula) in the mouth; with dorsal visceral sac containing most of the viscera; with a free fold of the body wall, the mantle, which usually secretes a shell, and with a ventral muscular foot.

Class 1. Plectronula: Bivalve mollusks without head or lingual ribbon; with filiform or plate-like gills. Examples, clams, oysters.

Class 5. Cephalopoda: Active, predaeous mollusks with unpaired mantle and shell and with eight or ten arms which bear suckers. Example, squid, octopus.
CHIEF SUBDIVISIONS OF THE ANIMAL KINGDOM — Concluded

B. METAZOA: Many-celled animals with gastric cavity, germ layers, and tissues — concluded.

B. HETERAXONIA (= Bilateria): Animals in which the chief axis of the adult body is not that of the gastrula; symmetry bilateral — concluded.

XII. ECHINODERMATA: Five-rayed and most marine animals, with dermal skeleton of spines or plate; with ambulacral system of tubes which are filled with sea-water.

Class 1. Holothuroidea: Soft, worm-like animals with reduced skeleton; the mouth surrounded by retractile tentacles. Example, sea-cucumbers.

Class 2. Echinoida: Spherical or oval forms with complete armor of dermal plates. Example, sea-urchins.

Class 3. Asteroidea: With five arms radiating from a central disk; with open ambulacral grooves on the oral side of arms. Example, starfishes.

Class 4. Ophiuroidea: With arms and central disk, but with closed ambulacral grooves. Example, brittle stars.

Class 5. Crinoidea: The cup-shaped body bearing many branching arms is usually attached by a stem. Example, stone-lilies.

XIII. CHORDATA: Bilateral, segmented animals with an axial skeleton, the notochord, on the dorsal side of which is the tubular nervous system and on the ventral side the alimentary canal; with gill slits opening laterally through the walls of the pharynx.

i. Hemicordia: Worm-like animals which burrow in the sand. Example, Balanoglossus.

ii. Urochordia: Sac-like animals enclosed in thick tunic (Tunicata) in which are inhalent and exhalent openings. Example, sea-squirts.

iii. Cephalochordia: Fish-like animals, pointed at both ends, which burrow in the sand; without skull or brain (Acrania). Example, Amphioxus.

iv. Vertebrata: Chordates with skull and brain; with relatively few gill slits; the notochord serves as a foundation for the vertebral column; usually with two pairs of locomotor appendages.

(a). Anamnia: Aquatic vertebrates with functional gills; without embryonic membranes.

Class 1. Cyclostomata: Eel-like fishes without jaws, but with circular sucking mouths; with single olfactory organ; without paired fins. Example, lamprey.

Class 2. Pisces: Cartilaginous and bony fishes with paired olfactory organ, movable jaws, persistent gill clefts, two-chambered heart, paired and median fins, and dermal exoskeleton of scales. Examples, sharks, trout, mackerel.

Class 3. Amphibia: Vertebrates with pentadactyl limbs with gills and gill clefts in larval life which may be lost in the adult; heart three-chambered. Examples, frogs, newts.

(b). Amniota: Air-breathing vertebrates in which the gills are never functional; the embryo is surrounded by embryonic membranes (amnion and allantois).

Class 4. Reptilia: Body covered by horny scales or plates; heart usually three-chambered; one occipital condyle; both aortic arches persistent. Examples, snakes, alligators, lizards, turtles.

Class 5. Aves: Birds with body covered with feathers and usually fitted for flight; with four-chambered heart and single occipital condyle. Examples, sparrow, ostrich.

Class 6. Mammalia: Animals with the body covered with hair; with mammary glands for suckling the young; with four-chambered heart and with two occipital condyles. Examples, duck-bill, opossum, man.

In reptiles, birds and mammals the superficial epithelium (epidermis) becomes many layers thick, and the outer layers of cells die and are transformed into horny or cuticular substance, an adaptation to life out of water. In these three classes of vertebrates there are also a number of characteristic epidermal outgrowths: in reptiles these take the form of horny scales or plates; in birds they appear as feathers, which are only modified scales; and in mammals as hair, while nails or claws are formed from the epidermis in all of these classes. In the mammals there are also epidermal ingrowths which give rise to various types of glands, such as sweat, oil, wax and milk glands, all of which are epidermal in origin.

Beneath the surface epithelium, which is always ectodermal in origin, there is in many animals a fibrous or connective tissue layer known
as the dermis or leather skin, since leather is always derived from this layer of skin. This layer is thickly developed among certain vertebrates and invertebrates, in which it may give rise to skeletal spicules or plates, thus forming a dermal exoskeleton. Among vertebrates this is especially well developed in the fishes, the scales which cover the body being of dermal origin. In these dermal scales are covered by enamel which is derived from the epidermis. The same is also true of the teeth of vertebrates; the inner portion or dentine is of dermal origin, while the enamel comes from the epidermis; teeth are in fact only modified scales.

2. Skeleton.—An internal skeleton, not the product of the integument, is present in relatively few invertebrates, but is found in all vertebrates. Such a skeleton is found in sponges in the form of calcareous, siliaceous or horny spicules; in cnidarians and ctenophores as supporting jelly; in many invertebrates as a system of connective tissue cells and fibres; in cephalopods and certain arthropods as cartilages surrounding the central nervous system. On the other hand, the notochord is one of the chief characteristics of the Chordata; in addition to this there are generally present in this phylum many other skeletal elements which are usually cartilaginous or bony. In all vertebrates the notochord becomes surrounded by cartilage, and the whole is then constricted into a series of segments, the centra of the vertebrae; on the dorsal side cartilaginous arches develop around the spinal cord, while other skeletal arches, the ribs, surround the trunk and become connected with the vertebral column; finally the ribs may be united ventrally, thus forming the sternum; these parts constitute the axial skeleton. In addition there is the skeleton of the head (the skull) and that of the fins (the appendicular skeleton). In the lower vertebrates and in the embryos of all higher forms the skull consists of a cartilaginous cranium partially surrounding the brain, and of paired cartilaginous rods forming the skeleton of the jaws and gill arches. In higher vertebrates these cartilaginous elements undergo ossification, and in addition dermal bones are formed which partially overlie this cartilaginous basis. The appendicular skeleton consists of the two limb-girdles partially enclosing the trunk on the ventral side, the pectoral and pelvic arches, and of the skeleton of the limbs themselves. In the fishes the arches and limbs are peculiar and it is difficult to homologize their skeletal parts with those of higher forms; in all vertebrates above the fishes, however, the relations of these parts are similar and their homologies not difficult to determine.

3. Motor System.—All animals at some time in their lives have the power of locomotion, though in some cases this is lost before adult life is reached and the animal becomes fixed like a plant (hydroids, sponges, cnidoids, molluscs and many parasites). However, in all these cases certain parts of the body preserve the power of movement, though the animal as a whole is incapable of locomotion. Animal movement is of three fundamental types: amoeboid, ciliary and muscular. See Muscles. (1) Amoeboid movement is manifested especially by free cells and exhibits a streaming of semi-fluid protoplasm: it is typically illustrated by the protozoan Amoeba. In this protozoan small lobes or pseudopodia may appear anywhere on the body, and into one or more of these the endoplasm, with all that it contains, may be seen to flow. At the conclusion of such a pseudopodium the lobes are withdrawn from other lobes. This flowing may continue for some time in a given direction, the outflow of protoplasm at one end of the body being compensated for by the inflow at the other end, thus producing an actively progressive movement. The mechanism of this movement is obscure, but in some cases it seems to be associated with temporary inequalities in the tension of the surface of the cell; at points where the surface tension is reduced an outflow of protoplasm occurs, forming a lobe or pseudopodium, into which protoplasm from the main body continues to flow so long as the surface tension is least in this direction. Usually several points of reduced tension exist at the same time on the surface of an ameboid cell, so that several lobes or pseudopodia are found radially in possession of a given point, and in other cases it is, perhaps due to the general contractility of protoplasm, local contraction in one part of a cell causing an outflow in another part.

(2) Ciliary movement consists in the rhythmic beating of innumerable small protoplasmic threads (cilia) which project from the free surfaces of certain cells and which act somewhat like oars. Among one-celled organisms the entire cell may be covered by these cilia; in multicellular animals such movements are limited to the free borders of certain epithelial cells. The beating of a cilium includes two movements,—the stroke, which is rapid and by which the cilium is sharply bent in one direction, and the recovery of the original position, which is relatively slow and weak. It is probable that the cause of this beating is the unequal contraction of the protoplasm on different sides of a cilium, by which it is bent first in one direction and then in the other. All the cilia covering a free surface beat in unison in the stroke; in one direction, and the movement is so timed that beginning at one end of a ciliated tract it seems to pass in a wave-like movement to the other end.

(3) Muscular movement, the principal type of motion in higher animals, is caused by the contraction in one direction of a muscle fibre consisting of a kind of protoplasm especially differentiated for this purpose. During the contraction or expansion of a muscle there is no change in its volume, the shortening of a fibre in one axis being compensated for by its expansion at right angles to that axis. Such a change in the shape of a fibre could be produced only by a change in the shape of the particles of which it is composed or by a change in their relative positions. The latter is probably the real cause of muscular contractility.

All of these types of movement are found in certain Protozoa and in many Metazoan. Amoeboid movements are, however, usually restricted to free cells without membranes or dense cortical layers of protoplasm, such as certain egg cells, embryonic cells, endoderm cells, excre-
tory, pigment and lymph cells of various Metazoa; in no case is this type effective in the movement of large bodies. In the phyla of the nemathelmintes and arthropods, locomotion is brought about, at least in part, by cilia, and even among the adult forms of many lower metazoans this is the principal type of locomotion (ctenophores, turbellarians, nemertines, rotifers). Among the nemathelmintes and arthropods cilia are entirely lacking throughout the whole life cycle. Among large animals locomotion is effected entirely by muscular contractibility, while cilia are limited to certain regions where by their beating they produce currents. Muscle fibres are found in all Metazoa with the possible exception of sponges; they are of two kinds, striped and non-striped, or smooth; the latter are of very wide distribution throughout the Metazoa, the former are limited to a few phyla (mollusks, arthropods, chordates). Smooth muscle is contractile to a much greater extent than striped muscle, but is much slower in action. The muscular system may consist of isolated fibres such as are found in many cnidarians, platodes and rotifers, or these fibres may be united into bundles or sheaths as is the case in most higher animals; these groups of muscles show many differences and can be compared only in a general way. In general the arrangement of the body muscles depends upon the presence or absence of a skeleton. Animals which have no skeleton usually have the body musculature arranged in the form of two coats: an outer layer of circular fibres and an inner of longitudinal ones, while the intestinal musculature is also arranged in two coats, the outer (next the coelom) longitudinal and the inner circular. If an exoskeleton is present, as in arthropods, these muscular layers of the body wall are broken up into bundles which become attached to the skeleton; if an endoskeleton is present, as in vertebrates, the muscles become attached to the bones, which serve as levers, and thus the muscles come to lie at a deep level. The locomotor apparatus of echinoderms is unique, consisting of a great number of tube feet, which are hollow muscular tubes, closed at the end by a sucking disk. The cavity of each tube is connected with the water vascular (ambulacral) system within the body, from which water can be forced into the tube feet. In this way they are protruded until the sucking disk touches and becomes attached to some object; then by contraction of the muscles of the foot the water is forced back into the water system, and by simultaneous action of many of these feet the body is slowly warped along.

4. Digestive System.—With the exception of a few internal parasites which absorb their food in a digested condition from the bodies of their hosts, some form of digestive system is present in all animals.

Digestion is the process of rendering insoluble foods soluble. One of the distinguishing characteristics of animals is that they, unlike plants, take in solid food (much of which is in a colloidal condition) through a mouth opening (ingestion), and from the former a digestion some of this insoluble food is rendered soluble and hence capable of diffusing to all parts of the organism, where by a mysterious process known as assimilation some of it is built up into the substance of the protoplasm itself. After the substances rendered soluble by digestion have been absorbed, the indigestible remnants are cast out of the body in solid form (egestion). Among the Protozoa digestion occurs within the body of a single cell, that is, it is intracellular. The same is true of the sponges, in which the food, consisting of microscopical animals (Arachnoidea), is taken in by certain epithelial cells lining the cavities of the sponge and by them passed over to other cells and tissues by which the food particles are digested, digested and assimilated. In all animals above the sponges intracellular digestion is limited to endoderm cells and to certain mesoderm cells, such as white blood corpuscles (leucocytes) and it is of decreasing importance as one ascends the scale. In all animals except the lowest, digestion occurs principally in a digestive cavity surrounded by cells which pour their secretions into the cavity. By the action of these secretions certain insoluble food substances are transformed into soluble ones. This digestive cavity is in all cases derived from the archenteron or digestive cavity of the gastrula and in the simplest cases is little more than a sac whose walls may be folded into ridges or septa, thus enlarging the digestive surface (Anthozoa), or they may be extended to form tubular canals, by means of which the digested food is distributed to all parts of the animal (Scyphozoa, Ctenophora, Turbellaria). In all Cnidaria except the lowest class, and in all animals above the Cnidaria, the ectoderm surrounding the mouth is folded in at the mouth opening, forming an ectodermal tube, or oesophagus, which opens at the inner end into the gastric cavity. Among chordates this ectodermal invagination forms only the mouth cavity, the oesophagus being derived from the endoderm. In all Cnidaria, Ctenophora and Platyctena there is but one opening into the gastric cavity, the mouth, and through this single opening food is taken in and undigested remnants cast out. In the Nemertinea, and with a few exceptions in all higher animals, there is a second opening into the gastric cavity, namely, the anus, through which the ejecta pass. The anus is formed by an infolding of the ectoderm which meets and fuses with a portion of the archenteric wall; this terminal ectodermal portion of the digestive tract is the hind gut (of invertebrates). With the formation of an anus the digestive tract becomes tubular, with mouth at one end and anus at the other, and the entire canal is divisible into three portions, an ectodermal fore gut, an endodermal mid gut and an ectodermal hind gut. The relative development of these three portions differs much in different phyla; for example, among chordates the fore gut is limited to the mouth cavity and the hind gut to an insignificant terminal portion of the intestine, while the endoderm gives rise to all the intervening portions of the digestive tract. Among arthropods, on the other hand, the mid gut is limited to an extremely small portion of the digestive tube between the stomach and intestine, while all the remaining portions are derived from the fore gut. In the higher animals the fore and mid guts may be subdivided into mouth cavity, pharynx, oesophagus, stomach and intestine and in some cases these portions may be further subdivided, as,
for example, in birds, where the esophagus gives rise to an enlargement, the crop, the stomach is divisible into a glandular stomach and a grinding stomach or gizzard, and the intestine consists of two portions, the small and the large intestine. Finally into a portion of the blind gut be ductory and sexual ducts as well as the intestine may open, in which case this common chamber is called the cloaca. Various portions of the fore gut may be armed with teeth, usually of a horny character among invertebrates, and the pharynx may be protrusable. The absorptive surface of the mid gut may be increased in three different ways, either (1) by an increase in length, in which case it becomes folded or coiled, or (2) by folds which project into the canal, or (3) by diverticula, that is, blind sacs or tubes, which open out from the canal; in many higher forms all of these methods coexist in the same individual. The extent of the digestive surface depends primarily upon the character of the food; if the latter is highly nutritious the digestive surfaces are much smaller than where it is poor in nutrition. In carnivorous mammals, for example, the alimentary tract is from four to five times the length of the body, whereas in certain herbivora it may be from 20 to 30 times the length of the body. In the simplest Metasoa it is probable that all the cells lining the digestive cavity are alike and that they all secrete the same digestive fluids; in more complex animals the cells differ in structure and function in different portions of the tract. By a specialization of the diverticula or blind tubes opening out from the canal, large digestive glands are formed which pour digestive secretion into the alimentary canal. The most generally distributed of these are the salivary glands, opening into the fore gut, and the liver and pancreas (or where both are united, as often happens among the invertebrates, the hepatopancreas), which open into the mid gut. In all of the lower invertebrates except the nematodes the food is moved about in the alimentary tract by means of cilia or by general contractions of the body. In all higher forms the contraction of muscle fibres surrounding the canal play an important part in this movement, though cilia may also be present. In the chordates both longitudinal and circular muscles surround the canal and by their rhythmic contractions produce a wave-like contraction of the canal (peristalsis), which passes along the canal from mouth to anus.

5. Respiratory System.—Respiration consists in the exchange of gases between the body and the medium which surrounds it. The gas given off from the body is principally carbon dioxide, one of the products of combustion within the body, while that which must be supplied to it is oxygen. Since oxidation is the one essential feature of destructive metabolism which occurs in all living matter, it follows that respiration is a universal function among organisms. Among small and simple animals this exchange of gases takes place directly between the living cells and the surrounding medium and occurs all over the surface of the body. In more complex forms with body fluids the exchange takes place between the tissues and the fluid (internal respiration) and then between the fluid and the surrounding medium (external respiration). This exchange may take place through the general integument of the body without the aid of any specific organs, as is the case in all small animals and in many larger ones,—for example, flatworms, roundworms, rotifers, small annelids, and certain vertebrates, such as the lungless salamanders. However, in most animals of any considerable size, special organs exist to facilitate this exchange. In such as dwell in water vascular processes are present which serve to bring the blood into close relation with the water. These processes, which are called branchiae or gills, are covered by a thin epithelium through which an interchange of the gases contained in the blood and in the water can readily take place. To facilitate this interchange the gills are usually much folded or branched so as to afford a large surface, and they are frequently covered by cilia which serve to keep the water in motion, while at the same time the blood is circulated through them. The most primitive type of gill is that of a simple ciliated tentacle, which may also serve other functions, such as is found among the Moluscoidea and some Molussa; such gills may become branched or plume-like or may fuse together into plates (Lamellibranchia). Gills are situated on those parts of the body where they will be most exposed to fresh water, and occur in the most extraordinary different positions in different phyla; thus they may be found on the limbs (Crustacea, some annelids), on or around the head (sedentary annelids, molluscosoids), along the sides of the body (primitive mollusks), on the lateral walls of the pharynx (phorids) or as outgrowths of the hind gut (holothurians). Homology being "correspondence in the relative position and connection of parts," there can of course be no homology between structures occurring in such diverse positions, and yet within a given phylum
they may be homologous and of high morphological value (for example, chordates). Among the chordates, a series of gill-crests opens right and left through the walls of the pharynx, and in the lower classes of the phylum the gills are found as highly vascular plates or tufts on the outer sides of the arches separating these crests; water is taken in through the mouth and then forced out through the gill-crests and thus over the gills. In the higher classes of the phylum (fishes, birds, and mammals), the gill-crests are present during embryonic life, though at no time in their entire life-history do these animals have gills and respire water. The constancy of gill-crests among vertebrates gives this character a high value in determining the affinities of such doubtful forms as Balanoglosus, Cephalodiscus, and Tunicata.

In animals which do not dwell in water and in some few which do (insect larvae, lung fishes, etc.), certain infolded portions of the body occur into which air is drawn and from which it is again expelled. Among invertebrates these infolded portions are generally derived from the skin; among vertebrates from a portion of the alimentary canal, the pharynx. In the case of the amphibians (for example, the frog) these infolded portions have the form of much-branched tubes, the trachea, which reach to all parts of the body, the terminal twigs of the tracheal system of tubes being found in connection with almost every bit of tissue in the body. These tracheae open to the exterior through closepore openings, the stigmata, situated on the sides of the body; air is taken in through these pores and by means of the tracheal tubes penetrates to all parts of the body, the exchange of gases taking place directly between the tissues and tracheae. Among vertebrates lungs develop as an evaginated portion of the pharynx; in most fishes this is a hydrostatic apparatus, the swimbladder, but in the lung fishes (Dipnoi) it becomes highly vascular and may serve as a lung. In all higher vertebrates this sac is paired, and its walls, which in the lower classes are relatively simple, become much infolded and very richly supplied with blood vessels. The exchange of gases here takes place between the blood and the air within the lung, and in most vertebrates the oxygen-carrying capacity of the blood is increased by the presence of hemoglobin (the coloring matter of red blood corpuscles) which enters into a loose chemical combination with the oxygen.

6. Circulatory System.—The physiological significance of the circulation of fluids within the body is the distribution of nutriment and in some cases oxygen to all the parts. In the simplest Metazoa (Cnidaria, Ctenophora) there is no circulatory or digestive apparatus other than that which is furnished by the gastric cavity itself; this may branch and extend to various parts of the body or hydroid colony, thus forming a gastro-vascular system, through which the distribution of nutriment takes place. The branched gastric cavity of certain turbellarians serves also a similar function. Circulation of body fluids also occurs in many lower animals without the aid of any special circulatory apparatus; in such cases lymph, containing the products of digestion, is distributed through all the intercellular spaces in the primary body cavity, and by the contractions of the general musculature of the body it is kept in irregular movement. With the single exception of the nemerteans a blood vascular system is found only among animals with a secondary body cavity or true coelom and is lacking even in some of these, particularly such as are quite small or are evidently degenerate forms. With a few exceptions it is present in mollusks, echinoderms, annelids, arthropods and all chordates. In its simplest form it consists of branching and anastomosing tubes which contain blood. The walls of the tubes are composed of flattened epithelial cells (endothelium) which may be surrounded on the outside by muscle or connective tissue fibres. The blood which fills these vessels consists of a fluid or plasma within which floating cells or corpuscles are almost invariably present. With increasing complexity of this system the walls of the vessels become thicker by increase of the muscular or connective tissue coats, and in certain parts of the system the vessels become larger. The muscular walls may be pulsatile throughout the entire length of a vessel, or this function may be limited to a small portion of a large vessel, which is then known as a heart; even in the highest animals the heart is only a differentiation of a simple pulsatile blood vessel. The vessels leading away from the heart are the arteries, those through which the blood flows back to the heart are the veins, while the small thin-walled vessels connecting the two, and through the walls of which plasma escapes into the tissues, are the capillaries. Among the annelids there is a large dorsal vessel and a ventral one, which are connected in each somite by commissural vessels. The dorsal vessel is pulsatile along its whole length, and peristaltic contraction waves can be seen in a living worm to pass from the posterior to the anterior end; correspondingly the blood flows forward in the dorsal vessel, down through the commissural vessels into the ventral one, and then backward through the latter to the posterior portion of the body, where the blood ascends through commissural vessels to the dorsal vessel, after which the same circuit
is repeated. Throughout this whole course the blood flows through vessels with definite walls, and the circulation is said to be closed. Among the molluscs and arthropods a heart is present.

which is more concentrated and complete than among the annelids. In the arthropods this consists of a thick-walled, pulsatile tube lying on the dorsal side of the body and extending through several somites; in each somite are a pair of openings, the ostia, which open into the heart from the pericardium, and through which returning blood enters the heart. Among the molluscs the heart is also of a compact type and is divided into auricular and ventricular portions. Primitively two auricles are present, though in some gastropods this number is reduced to one; in all molluscs there is but one ventricle. In primitive arthropods and molluscs the blood flows out of the ventricle at both the anterior and posterior ends; in more highly differentiated members of these phyla, out of the anterior end only. Among the arthropods the vascular system is very incomplete, the arteries soon end in lacunar spaces in the tissues, and from these spaces the blood is gathered into large sinuses and thence flows back to the heart. These lacunar spaces and sinuses are not true vessels, since they do not have definite walls, but are derived from the primary and secondary body cavities; the circulation is therefore an open one. Among the molluscs the vascular system is more extensive than among the arthropods, but here also the circulation is open, except in the cephalopods, the arteries being connected with the veins by a system of lacunar spaces instead of capillaries. Finally among the echinoderms and chordates the circulation is closed as among the annelids; that is, the blood throughout its entire circuit is contained within definite vessels.

The manner in which blood is supplied to the respiratory organs is of great importance in explaining the structure of the circulatory organs in air-breathing vertebrates. Among annelids, arthropods, and molluscs the blood flows directly from the heart to all parts of the body, whence it is gathered into trunks which carry it to the gills; from these organs it is then returned purified to the heart. In the fishes the blood passes from the heart directly to the gills, whence it is gathered into the dorsal aorta and distributed to all parts of the body; it is then returned laden with waste product from the tissues to the heart. In these animals the heart consists of a single auricle and ventricle, essentially a simple tube more or less bent upon itself. In air-breathing amphibians a part of the blood passes directly from the heart to the lungs, whence it returns to the heart oxygenated, while a part of it goes at once to the body; the former is known as the pulmonary, the latter as the systemic circulation. In these animals the heart is incompletely divided by a partition which separates the auricular chamber into two auricles, but which leaves the ventricle undivided. The blood returning from the body is carried into the right auricle, while that from the lungs goes into the left; in the ventricle both kinds of blood mingle to a certain extent, though by a peculiar arrangement of folds and valves the larger part of the oxygenated blood which enters the left auricle is pumped to the anterior part of the body, while the blood from the right auricle goes to the lungs. Finally in all birds and mam-

**Excretory System.**—Excretion is the process of removing non-gaseous waste products, particularly urea and allied compounds, from the body. These nitrogenuous waste substances are formed as the result of proteid combustion within the body, and as this form of metabolism is universal among animals nitrogenuous waste substances are everywhere formed. With few exceptions all animals pos-
s ess some form of excretory organ; in fact this is one of the distinguishing characteristics of animals as contrasted with plants. Among the Protosoa the excretory organ is a pulsatile vacuole which gradually fills with fluid containing these waste products and then suddenly contracts, forcing this fluid out of the body. Among coelenterates excretion is probably performed by isolated gland cells, so that no single organ exists for this function; even among higher animals excretion is performed to a limited extent by individual cells or small glands; for example, the chlorogogue cells of annelids, the dermal glands of Crustacea and the sweat-glands of mammals. In all higher animals a special excretory organ exists; this usually consists of minute tubules formed of cells which take up the waste substances and pass them into the tubule, whence they are carried to the exterior; such an excretory tubule is known by the general name of nephridium. The forms of nephridium differ considerably in different phyla, but two principal types may be recognized; these are the protonephridium, or water vascular system, and the metanephridium (Hatschek). The protonephridium is found in the flat worms and rotifers; that is, among worm-like animals without a secondary body cavity; it is also found as the larval excretory organ (head kidney) in annelids. It consists of a pair of more or less branched tubules opening at one or more places to the exterior, while the internal terminations of the tubules each end in a single large cell which closes the end of the tubule and bears a tuft of long cilia projecting into its lumen. This tuft beats with undulatory movement and looks somewhat like the flickering flame of a candle, whence it is called a “flame” and the large cell which bears it a “flame cell.” The tubule itself is usually composed of a single series of long glandular cells so perforated that the lumen is intracellular. In larger branches of the protonephridium the walls of the tubule may be formed of many cells which are ciliated on the side next the lumen. These cilia as well as the flame drive fluids within the lumen to the exterior. It is probable that these fluids are transuded by fluids forced out at the ends of the walls. The waste substances is brought about by the activity of the cells which form the walls of the lumen.

The metanephridium is found among annelids, molluscs, molluscoïds, prototretaetes, and chordates, while a modified form of it exists in crustaceans. Typically it consists of a tubule opening to the exterior at one end and into the body cavity or some portion of it (pericardium or blood sinus) at the other. Where it opens into the body cavity the tubule is widened and covered with long cilia and is known as the ciliated funnel or nephrostome. Following this is the glandular portion of the tubule, consisting of a single series of perforated cells, or in other cases of an epithelium, composed of many cells, which forms the walls of the lumen. In either case these cells are glandular in character and are the real excretory cells, taking up from the blood and passing it into the lumen of the tubule. The latter is ciliated throughout, and by the action of these cilia, together with those of the ciliated funnel, ectonomic fluid is drawn into the tubule through the funnel and driven to the exterior, thus flushing the tubule and carrying away the excreted substances. Finally the terminal portion of the tubule, which is derived as an invagination from the ectoderm, serves as a collecting tube or reservoir. Generally a single pair of these tubules is found in unsegmented animals, such as Mollusca and Molluscoïdes; this number may be reduced, however, as in the Polyzoa, where they are entirely lacking, or in certain Gasteropoda, where one of them is suppressed, or it may be increased as in the case of certain Cephalopoda (Tetrabranchia), where two pairs are present. In segmented animals, such as annelids, prototretaetes, and chordates, it is probable that originally one pair existed in every somite, and this is still approximately the case in some of the simplest members of these phyla, while in higher forms they are limited to certain segments and have disappeared from others. The segmental character of these organs is so characteristic in the phyla named that they are called “segmental organs.”

Among the Chordata these organs undergo modifications which deserve especial mention. They lie at the dorsal side of the body cavity
and on each side of the notochord. Only in *Amphioxus* do they open individually to the exterior; in other chordates the peripheral ends of the tubules unite on each side into a duct which grows backward and opens into the cloaca near the anus; this is the segmental or Wolffian duct. This earliest system of segmental tubules in chordates is known as the pronephros, and it extends throughout the entire trunk region of the lowest vertebrates (cyclostomes), though in all higher forms it is limited to a few anterior somites and is usually a purely embryonic organ. Among these higher forms longer and

Diagrams illustrating the development of the urino-genital organs of a vertebrate (after Parker and Haswell).—A, pronephros and segmental duct; B, atrophy of pronephros, development of mesonephros; C, appearance of Müllerian duct; D, development of metanephros, male type; E, the same, female type. The sex gland, ovary, or testis is obliquely shaded; pronephros and mesonephros unshaded; metanephros stippled; Müllerian duct heavily shaded. The large chamber to the right, into which these ducts as well as the intestine open, is the cloaca.

more complicated tubules are formed in the somites behind the pronephros, which also open into the segmental duct at one end and into the body cavity at the other; near the ciliated funnel a knot of blood vessels forms on the side of the tubule and projects into its lumen; this is the glomerulus or Malpighian corpuscle. Many of the tubules in this region then lose their ciliated funnels and no longer open into the body cavity, the tubule being flushed out by transudated plasma from the glomerulus; at the same time the tubular part of tubules originally present in each somite may give rise to others by budding, so that several may be found in each somite. This second form of the nephridial system of vertebrates is known as the mesonephros, and is the permanent excretory organ of fishes and amphibians, as well as the only embryonic organ in reptiles, birds, and mammals. Finally, in the last named classes, the definite kidney or metanephros appears in several of the somites posterior to the mesonephros. Its tubules, while similar to those of the mesonephros, are still more complex, having no trace of a ciliated funnel, and by budding very many of them are formed in each somite. The duct into which they open, the ureter, is an outgrowth of the segmental duct. It is thus to be seen that the very complex excretory system of vertebrates can be derived, step by step, from the simple nephridial system of such invertebrates as the annelids.

Finally, the nephridia may carry off from the body cavity not only coelomic fluid, but also cells which are set free into this fluid; some of these cells in the annelids may be loaded with urates which are thus carried to the exterior (chloragogue cells), but the most important of the cells which thus escape from the coelom are the sex cells, ova and spermatozoa. The nephridia may be especially modified for carrying off these sex cells, in which case they are known as gonoducts. Even among vertebrates the oviducts and sperm ducts (vasa deferentia) may be derived from the nephric system. The former in some vertebrates arises in the embryo as part of the segmental duct and opens into the body cavity at its anterior end through a pronephric tube; in animals above the amphibians, which have a metanephros and ureter, the segmental duct serves exclusively as a sperm duct in the adult.

8. Reproductive System.—Reproduction among animals is both sexual and asexual; the former occurs among all animals, the latter is limited to the lower forms and to the constituent cells of higher ones. Sexual reproduction or amphigony consists in the union of two cells, the sex cells or gametes, to form a single cell of double origin, the oosperm or zygote, from which a new individual similar to the parental form develops. If the gametes are approximately equal in form and size their union is spoken of as conjugation, if they are very unlike in these respects they are called ova and spermatozoan, and their union is known as fertilization. Both conjugation and fertilization occur among the Protozoa, whereas all Metazoa reproduce by means of differentiated sex cells, namely, ova and spermatozoan. In a few animals ova have the power of developing without previous fertilization, the process being known as parthenogenesis. If such development without fertilization occurs in larval forms which have not completed their development it is known as paedogenesis. In most animals the sexes are separate,—that is, ova and spermatozoan are produced by different individuals, males and females, and the species is dioecious; in some cases, however, both kinds of sex cells are produced by the same individual, which is then said to be hermaphrodite, and the species to be monocious.

The essential reproductive organs are the gonads, or the glands which produce ova and spermatozoan, namely, the ovaries and the testes. In sponges the reproductive cells are scattered
through the mesoderm so that in these animals the ova cannot be said to exist. In the lowest cnidarians (Hydra) the sex cells are mesodermal in origin, and there is no indication of the presence of germinal epithelium, but they actively migrate to certain portions of the hydroid stem where reproductive buds are being formed, and, aggregating here, form gonads. In all higher animals definite gonads are present. No genital ducts are present in the sponges, and these are not excluded, since the sex cells can escape directly into the water. In animals above the coelenterates the sex cells are mesodermal in origin, and in most cases form a part of the epithelium lining the coelom. In animals without a true coelom the sex cells arise within tubes or glands the cavities of which may perhaps represent the coelom. In flatworms the gonads occur in considerable numbers in a single individual. In roundworms they are limited to one or two pairs. In rotifers and chaetognaths, and echinoderms they are confined to one or at most a few sex glands, while in segmented animals they are found in primitive forms in every body somite, though with advancing organization the number of the somites is limited to one. In most animals above the coelenterates some form of duct exists for carrying the sex cells to the exterior; among the flatworms, roundworms, and rotifers these ducts are never the excretory tubes, though they may possibly represent the coelom of higher animals. In these higher forms they are frequently metanephridia, or modified excretory ducts.

In many animals the ova and spermatozoa escape directly into the water, and the eggs are fertilized while undergoing development; it is probable that in all of these animals the escape of ova stimulates the males to eject spermatozoa so that both kinds of sex cells are shed at about the same time. In such cases enormous numbers of sex cells are produced and very many are wasted. A slight advance over this condition is found in those animals (frogs, bony fishes, etc.) in which the openings of the male and female ducts are placed close together, so that fertilization can take place while the two individuals are in contact. This is known as external copulation. In other cases the spermatozoon only escape from the body, and by means of currents of water they are carried into the body of the female, where they fertilize the ovum in situ, as in sponges, or in certain receptacles into which the eggs are collected, as in fresh-water mussels. In other animals copulatory organs exist which serve to introduce spermatozoa into the sex ducts of the female, thus increasing the chances for fertilization. In the cells of these is known as internal copulation. In many cases copulation occurs but once, and the spermatozoon are stored in a seminal receptacle which opens into or near the oviduct. Internal copulation is a necessity in all land animals and in parasites, and it also occurs in many phyla of invertebrates (flatworms, roundworms, rotifers, gastropods, cephalopods, annelids, arthropods).

In certain animals the sexes differ not only with respect to the sexual apparatus but also in many other regard; when such differences are very marked they constitute what is known as sexual dimorphism. In such cases the male is frequently very degenerate in form, being sometimes not more than a hundredth part the size of the female and entirely lacking alimentary canal, sense organs and nervous system (rudimentary males of rotifers, barnacles, etc.).

In asexual reproduction or asexual propagation there is no formation of new individuals by division of an old one. In one-celled organisms and in the constituent cells of higher animals this takes the form of cell division. In the lower Metazoa asexual reproduction is limited to cell division, but the entire body or part of it may undergo constriction and subsequent division, thus giving rise to new individuals. This division may be into equal parts, in which case it is called fission; or into unequal parts, when it is known as budding or gemmation. In animals which reproduce both sexually and asexually there is a more or less regular alternation of one method with the other; this is known as alternation of generations (q.v.) or metagenesis. The alternation of amphigony with parthenogenesis is called heterogony.

9. Nervous System and Sense Organs.—Sensation and co-ordination are manifestations of protoplasmic irritability, or that capacity of receiving and responding to stimuli characteristic of every cell. Animals, even the simplest, are sensitive to a variety of stimuli, among which may be mentioned mechanical, chemical, thermal, and electrical, as well as light, gravity, etc. These stimuli, acting on the organism, start changes in the protoplasm (impulses) which are transmitted to portions of the body distant from the point first stimulated and call forth the co-ordinated activities of many different parts. In higher animals there are special sense organs for receiving certain of these stimuli and specialized protoplasmic fibres (nerve fibres) for transmitting impulses, while nerve centres for co-ordinating activities appear very far down in the animal scale. In the lowest animals, however, there are neither nervous system nor sense organs, and yet through the irritability of the general protoplasm these functions are performed.

A protozoan reacts to all stimuli in the same way, and it is probable that however different the stimuli may be they produce essentially the same changes in the cell. The reactions of Protozoa, if they can be said to have sensations, must be of the most general and indefinite sort, just as their responses to stimuli show the most monotonous sameness. The same thing is probably true of sponges, where none of the cells are differentiated for receiving and transmitting stimuli. In all other phyla, however, certain cells of the body are set apart for these particular functions, and the greater the differentiation in these respects the more definite and varied are the sensations, the more swiftly impulses are transmitted to the motor system and the more complicated are the responses.

Nervous System.—The elements out of which the nervous system is built are nerve cells and fibres, the latter being merely out-growths of the former. In practically all Metazoa these cells are derived from ectoderm, and in a great many animals the sense organs and entire nervous system remain throughout life a part of the superficial epithelium which lines the body (Coelenterata, Chordata, certain Annelida, Molluscoidea, many Echinodermata, Balanoglossus); such a nervous system is said to be epithelial. In all other Metazoa the nerv-
ous system, though formed from epithelium, separates from it in the process of development, so that brain, ganglia, and nerve trunks come to lie some distance from the surface of

the body; this is known as an epitheligenous nervous system. In addition to the two classes just mentioned, which are based on the relations of the nerve cells to the body layers, four types of nervous system are found among Metazoa which are based upon the relations of nerve cells and fibres scattered throughout the superficial epithelium is the simplest type known and is found among such animals as sea-anemones (Actinostola); the nerve cells are here connected together by means of the fibres into a ganglionic plexus. (2) The next step in increasing complexity is represented by a linear nervous system such as is found in the jellyfishes; here many nerve cells and fibres are aggregated into a double nerve ring around the margin of the umbrella, thus forming a central nervous system; other nerve cells remaining, scattered throughout the epithelium, serve to connect the ganglia with the muscles. (3) The ganglionic type. In ctenophores, a sense organ from which nerves radiate, is found at the apical pole, and in a great many of the higher animals the earliest formed and most widely represented portion of the nervous system is a sense organ and ganglion which appear at the apical pole of the gastrula, and

becomes in the adult the cerebral ganglion or brain, lying on the dorsal side of the esophagus. Nerve trunks are always given off from this ganglion, and very generally two of them run down on each side of the esophagus to its ventral side, thus forming a circumesophageal nerve ring. In different phyla longitudinal nerve trunks may be given off from different parts of this ring; among annelids, arthropods, mollusks, and molluscsoids from the ventral side, and in annelids and arthropods this forms the "ventral chain," which consists typically of a pair of ganglia in each somite connected with those in front and behind by nerve cords. The first one in the chain is the subesophageal ganglion, connected with the cerebral ganglion by the circumesophageal commissures. In the mollusks the nervous system consists of a pair of supra- and sub-esophageal ganglia (cerebral and pedal) which with their connectives form an esophageal

ring. To these is usually added a pair of pleural and of parietal ganglia forming a loop, which extend back into the body, while ventral trunks (ventral cords) may be present in the foot. (4) The tubular type of nervous system is found only among the chordates; here the nervous system develops from an epithelial plate (neural plate) on the dorsal surface of the embryo, which becomes invaginated in such a way as to form a longitudinal groove, the neural groove. This then separates from the

![Diagram of vertebrate brain with cavities exposed](image)

**Fig. 26** - Dorsal view of vertebrate brain with the cavities of the right side exposed (after Parker and Haswell).

epithelium as a tube, which in all vertebrates is enlarged at its anterior end to form the brain. This neural tube, while apparently a continuous structure, is really composed of segments, the neuromeres, one neuromere being found in each body somite; the neuromeres are thus comparable to the ganglia of the ventral chain of arthropods and annelids. This segmentation of the central nervous system of vertebrates is indicated even in the adult by the segmental arrangement of the spinal and cranial nerves. In the embryonic development of all vertebrates the brain consists of three enlargements or vesicles, the fore brain, mid brain and hind brain; the first gives rise to the cerebrum and 'tween brain of the adult, the second remains as the mid brain, while the third gives rise to the cerebellum and medulla. The portion of the neural tube posterior to the brain becomes the spinal cord of the adult. With the differentiation of nerve cells and fibres in the walls of the neural tube these walls increase greatly in thickness, while the originally large cavity of the tube becomes restricted in size, forming in the adult the ventricles of the brain and the central canal of the cord.

**Sense Organs** — The simplest sense organs are the scattered sensory cells found in the superficial epithelium of many animals; these may be solitary or aggregated into buds. They are elongated epithelial cells with a hairlike process at the free border and a fibre at the deeper end connecting with the branches of a ganglion cell. They are organs of general sensation—that is, they are capable of receiving various kinds of stimuli, such as mechanical, thermal, electrical, and chemical, and are therefore largely undifferentiated, though probably chiefly subserving the sense of touch. These integumentary sense organs are found in almost every group of animals. Among the vertebrates they are present in primitive form over the general body surface; in the fishes and amphibia they are aggregated into buds, forming the lateral line organs, while among those vertebrates which do not dwell under deeper living organs, of modified type, are found (tactile cells, corpuscles, and bulbs). In addition to these organs of general sensation, higher Metazoa generally possess specific sense organs, namely, those differentiated for the reception of particular kinds of stimuli. These are organs of (1) smell and taste, (2) equilibrium and hearing, (3) vision.

(1) Organs of smell and taste are present in all vertebrates and in many invertebrates. Their structure is extremely simple, being but slightly modified from the type of the primitive organs described above. In fact the olfactory sense cells of vertebrates are merely scattered sensory cells, while the organs of taste (taste buds) are simple aggregations of such cells. Throughout the Metazoa the organs of taste and smell are generally located in ciliated pits or depressions of the integument either on the head or at least near the mouth or respiratory organs. In these positions they serve in the one case to test food and in the other the quality of the medium used in respiration. Among fishes the olfactory organs are located in pits on the front of the head; in all air-breathing vertebrates these open posteriorly into the mouth cavity or pharynx, and thus form the anterior part of the respiratory tract. The organs of taste are of course in or near the mouth. Among the molluscs a sense organ which is probably olfactory in function, the osphradium, is located near the gills. Among the arthropods we find notable modifications of these organs owing to the fact that the entire body surface is there covered with an impermeable chitinous coat. These sense organs are here peculiar hollow tubes, the olfactory tubes or cones, which are borne on the anterior portion of the body, usually on the antennae and mouth parts; these hairs are filled with fibrillar protoplasm which connects with sense cells at the base of the hair.

(2) Organs of hearing and equilibration are very widely represented throughout the animal kingdom. It is advisable to consider these two
organ systems together, since the two functions which they subserve are united in the same general organ in the vertebrates, while in lower forms it is by no means easy to distinguish between the two. It has long been customary to speak of all vesicular sense organs containing free solid bodies as auditory in function, but it is much more likely that in the lower Metazoa they serve to acquaint the animal with its bodily positions — that is, that they are organs of equilibration. In many respects the simplest type of organ of this class is found among certain jellyfishes. It here consists of a short tentacle situated in a depression of the ectoderm and bearing a solid body or otolith near its free end; by the movements of the tentacle the hairs or protoplasmic processes of surrounding sensory cells are stimulated. In other Medusae the sensory cells may entirely enclose the tentacle, thus forming an auditory vesicle or otocyst. The auditory organs of most vertebrates, as well as of most invertebrates, can be traced back to this simple type. The sensory cells forming the walls of the otocyst are similar to tactile cells — that is, they bear processes projecting into the cavity of the otocyst, while the bases of these cells are connected to ganglion cells. By the movements of the otolith, usually a calcareous concretion, these cells are stimulated and impulses thus generated are conveyed away by the nerve fibre. Otocysts of this type are possessed by molluscs, certain annelids, tubellarians, and brachiopods. In the case of arthropods organs of a different type are generally found: owing to the fact that the body is here covered by chitin and that the fine protoplasmic processes or cilia are absent. Among the crustaceans the auditory organ usually consists of a cavity in the basal joint of the first antenna, which is open to the exterior and which contains water and grains of sand; the wall of the cavity bears chitinous processes or auditory hairs which have a nervous connection at their base; these hairs are stimulated by the movements of the water and sand within the auditory sac. Many insects have a true tone-perceiving organ, the chordotonal organ; in principle this consists of a few elongated cells, the chord, which are attached directly to the integument at one end and by a ligament to an opposite point of the integument; when this apparatus is thrown into vibration impulses are conveyed to the nerve cells attached to some portion of the chord. In other insects (Orthoptera) a tympanal organ may be present, consisting of a vibrating membrane overlying a tracheal chamber; sense cells are present between the membrane and chamber, and when the membrane is set into vibration

![Fig. 28](image)

**Fig. 28** — Auditory or equilibrative organs of molluscs (from Hataseh).

by sound waves the sense cells are stimulated. Among aquatic vertebrates a system of integumentary sense buds is found along the lateral borders of the body and over the head, which is known as the lateral line system. The function of these organs is not surely known, but it is probable that they are organs of touch and also of equilibration. In all vertebrates it is probable that the auditory organs, as well as the organs of smell and taste, have been derived from integumentary sense organs homologous with those of the lateral line. In the process of development the ear appears as a pit-like invagination of the skin which is then infolded to form a vesicle; this vesicle then becoming partially divided into two chambers, the utricle and the sacculus. In most vertebrates the former bears three pairs of semicircular canals which are organs of equilibration, while the latter gives rise to a recess, the lagena, which becomes the cochlear duct in mammals and is a true auditory organ. Calcareous concretions or otoliths are present in

![Fig. 29](image)

**Fig. 29** — Internal ear of different vertebrates. I, Fishes. II, Birds. III, Mammals. (From Clauz.) — U, utriculus with semicircular canals; S, sacculus; D, utriculus and sacculus; C, cochlear duct; L, lagena; Cr, canalus reuniens; R, recessus vestibuli.

![Fig. 30](image)

**Fig. 30** — A, section through the open eye-pit of a limpet (Patella); B, the two kinds of retinal cells, pigmenty and sensory (from Hataseh).

this much-folded and complicated otocyst. This sensory portion of the auditory organ is known as the inner ear; to this is added in all animals above the frogs and toads a middle ear or tym-
panum which transmits the sound waves from the surface to the inner ear. Finally, in the mammals there are folds of the integument around the tympanic membrane which serve to collect sound waves and which constitute the external ear.

(3) Visual Organs.— Animals without any trace of eyes are sensitive to light (certain

![Figure 31](image)

Protozoa, Tubellaria, Larvae), and it must therefore be assumed that protoplasm may be directly stimulated by light without the intervention of any special organ. In its simplest form an eye consists of one or a few transparent cells partially surrounded by pigment in the form of a cup, so that the light can enter only from one side; the pigment not only absorbs light rays, but it optically isolates the

![Figure 32](image)

**FIG. 32**

Fig. 32.—Section through the cup-shaped eye of a gastropod (Helixas) (from Hatachek).—1. epithelium covering body; 2. vitreous body; 3. retina; 4. nerve.

cells within from those without this cup (some Medusae, Tubellaria, Annelidae). The function of such an eye is probably to determine the direction of light, since it could give no image of luminous objects. A slight advance over this simplest type of eye is found in the cup-shaped eyes of certain mollusks; here certain superficial epithelial cells are infolded to form a cup; in some cases deeply pigmented, while other intermediate cells remain clear and unpigmented. The latter are the sensory cells and are connected at their bases with nerve fibres. If this cup-shaped eye becomes infolded still further and its opening grows smaller and finally closes altogether, it forms a vesicular eye such as is present in certain mollusks and annelids. The wall of this vesicle, which is turned toward the surface, is transparent and may become thickened to form a lens; the opposite wall of the vesicle is pigmented and is known as the retina. In such an eye the free ends of the retinal cells are turned toward the cavity of the vesicle, while the opposite ends, which are directed away from the vesicle,

![Figure 33](image)

**FIG. 33**

Fig. 33.—Longitudinal section through the pineal eye of a lizard (Sphenodon) (after Baldwin Spencer). The eye is located in the middle of the dorsal side of the head and is covered by translucent scales. The outer wall of the eye vesicle is thickened to form a lens, while the inner pigmented wall is the retina from which the nerve proceeds.

are prolonged into fibres; such an eye has a direct retina. This type of eye reaches its highest development among the cephalopods, where it bears a striking superficial resemblance to the vertebrate eye. A rudimentary eye of this type is present in all vertebrates as the pineal organ or gland. This is an unpaired structure on the dorsal side of the 'tween brain and in certain reptiles is plainly a vesicular eye with direct retina. The paired eyes of vertebrates are also vesicular, but in them the retina is inverse—that is, the free ends of the retinal cells are directed away from the cavity of the vesicle, while the ends which bear the fibres are directed toward it. The explanation of this remarkable condition is found in the study of the development of these eyes. They arise as
ANATOMY OF MELANCHOLY

lateral evaginations of the walls of the embryonic fore brain, are then constricted from the brain, and become vesicles connected with the fore brain by only a stalk. At this stage the vertebrate eye is like the invertebrate one save only that it has arisen from the neural instead of the superficial epithelium. All the cells which form the vesicle have their free ends directed toward its cavity, while their basal ends are directed away from it. The outer wall of this optic vesicle is then infolded until it comes into contact with the inner wall, thus forming a cup open toward the skin. The ectoderm over the opening of the optic cup is then infolded to form the lens, which completely separates from the surface and lies in (Leipzig 1898–1901); Hertwig, ‘Lehrbuch der Entwickelungsgeschichte des Menschen und der Wirbeltiere’ (9th ed. R., ‘A Treatise on Zoology’ (London 1900); Parker and Haswell, ‘Text-Book of Zoology’ (London 1897); Sedgwick, ‘Students’ Text-Book of Zoology’ (London 1897–1909); Wiedersheim, ‘Vergleichende Anatomie der Wirbelthiere’ (7th ed., Jena 1909; abr. tr. by Parker, London 1908).

EDWIN GRANT CONKLIN,
Professor of Zoology, Princeton University.

ANATOMY OF MELANCHOLY, The.

Robert Burton spent all his mature life at Oxford in scholarly retirement. He was a library student, not a man of affairs, and not a practical physician but a divine. So it is easy to understand why his subject in his ‘Anatomy [i.e. analysis of] Melancholy’ as a malady of both soul and body, and he busied himself with writing his book, so he says, to cure himself of melancholy, one of the chief causes of which he declared to be idleness. The book was a serious effort, carefully planned in its large outlines. But the main outline seems often forgotten, and is filled in with a great mass of various detail. The ‘roving humour’ to which he confesses gave Burton an opportunity to provide a running commentary on men and morals, politics, religion, business, pleasure, love, and any other topics suggested to him by the books which he had ‘confusedly tumbled over.’ The book has been continuously read since the appearance of the first edition in 1621, and in a way has remained popular with the lovers of quaint literature. The sources of interest in it for the modern reader are above all its quaintness, not always intended by Burton, its out of the way scholarship which seems often grotesque nowadays, and its fidelity as a picture of a certain type of 17th century mind. It treats, moreover, with good humor and constant vivacity of feeling, of subjects which affect all mortal men. It abounds in wise counsel, in charming illustration, and, mixed with its credulity, it exhibits not a little skill in analyzing the states of mind and body of mankind. ‘I have laid myself open (I know it) in this treatise,’ says Burton, ‘turned my inside outward,’ and the book has not a little similarity to the numerous confessions of a later day.

The style of the ‘Anatomy’ is one of its most notable characteristics. Burton had first intended to publish his treatise ‘more contract in Latin’ but to the Latin book printed, though ‘any scurrile pamphlet is welcome to our mercenary Stationers in English.’ Perhaps it is fortunate that he did not find a willing publisher for the Latin version, for when he came to write in English he certainly spoke more from ‘the strings of his heart’ than he would have done in writing a foreign idiom. He declared that he wrote ‘with as small deliberation as I do ordinarily speak, without all affectation of big words, fustian phrases, jingling terms, tropes, strong lines, that like Acestes’ arrows caught fire as they flew, strains of wit, brave heats, eloqies, hyperbolical exorations, elegancies, etc., which many so much affect. I am aqua
potor, drink no wine at all, which so much improves our modern wits, a loose, plain, rude writer. This passage, if it does not describe Burton's style adequately, illustrates at least some of its main features. It is not a neat and meticulous style, nor is it ornate, and ingenious. It is rather an easy, discursive essay style, often elaborated until it attains a kind of robustous eloquence. It is characterized also by a monstrous heaping of citations and quotations, like a medieval sermon, or as a modern scholarly dissertation would be if the footnotes were inserted in the body of the text. To read Burton with pleasure, one must regard these quotations as interruptions, not part of the rhythm of his phrasing. When they are omitted or are not present, the style moves along easily and rapidly, not unlike the style of one conversing with some degree of animation.

Professor of English, Columbia University

ANATOMY OF PLANTS. See PLANTS.

ANATTO. See Annatto.

AN'AXAG'ORAS, Greek philosopher: b. Clazomene, in Ionia, about 500 B.C.; d. in Lampscus, about 428. Settling at Athens, his pupils included Pericles, Euripides and Socrates. In middle life he was publicly charged with impiety and condemned to death, but the sentence was commuted to perpetual banishment. Anaxagoras held that there was an infinite number of different kinds of elementary atoms, and that these, in themselves motionless and originally existing in a state of chaos, were put in motion by an eternal, immaterial, spiritual, elementary being, from which motion the world was produced.

AN'AXAR'CHUS, a native of Abdera, who was a friend and counselor of Alexander. He was put to death by Nicocreon, Prince of Cyprus.

ANAXIMANDER, Greek philosopher, mathematician and astronomer: b. in Miletus 611 B.C.; d. 547. The substance of his philosophical teaching is that the source of all things is an undefined substance infinite in quantity. According to his theory the universe is a series of concentric cylinders surrounding the cylindrical earth. Anaximander occupied himself much with mathematics and geography, and to him are ascribed the invention of geographical maps, the first application of the gnomon or style fixed on a horizontal plane to determine the solstices and equinoxes, and the discovery of the obliquity of the ecliptic.

ANAXIMENES, an'äks-im'é-nëz, of Lampscus, Greek historian: b. Lampsacus, Asia Minor, about 340 B.C. To him is attributed the 'Ars Rhetorica ad Alexandrum' found among the writings of Aristotle. Only fragments of his histories of Philip of Macedon, Alexander, and Greece remain.

ANAXIMENES OF MILETUS, Greek philosopher: b. Miletus, and flourished about 550 B.C. He affirmed that air was the first principle of all things. Finite things were formed from the infinite air by compression and rarefaction of celesstial motion; and heat and cold resulted from varying degrees of density of the primal element.

ANAYA, an'nä'yä, Pedro Maria, Mexican commander: b. Huichapan 1795; d. 1854. Entering the army in 1811 he attained the rank of brigadier-general in 1833. He held several cabinet positions, was acting President of Mexico for a few weeks in 1837, and at the time of his death was Postmaster-General under Santa Ana.

ANCACHS, an-käch'z', or ANCASH, Peru, a department bounded on the north and northeast by La Libertad, on the east by Huánuco and Junin, on the south by Lima and on the west by the Pacific Ocean. It is estimated to contain 16,562 square miles. The ports are Santa, Chimbote, Samanco, Casma, and Huarmey. The rivers rise on the western slopes of the Cordillera, with the exception of the Santa, which, rising east of the Cordillera, flows first through the valley of the Callejon of Huarás, but in the northern part of the department turns west, unites with the Chuquisaca and passes through a deep gorge in the Cordillera to the Pacific (compare observations on the Patia River, article COLOMBIA). Its total length is about 180 miles. The valley of the Santa is extremely fertile. It is connected with the port of Chimbote by a railway running as far as Tablones. The departmental capital is Huarás. Agricultural products are sugar, rice, cereals, grapes, maize and a special kind of potato (the Carés variety) which matures in three months. Among the mineral resources we note particularly the coal (bituminous generally, but anthracite near Chimbote and Huarás), petroleum, gold, copper, silver and lead. Pop. 317,000.

ANCEUS, an-ke'us, the name of two of the Greek Argonauts, one the son of Poseidon and steersman of the Argo, the other a son of the Arcadian Lycurgus. Each was killed by a wild boar.

ANCELOT, an'söl', Jacques Arène Françoise Polycarpe, French novelist, dramatist and poet: b. Havre, 9 Feb. 1794; d. Paris, 7 Sept. 1854. His tragedy, 'Louis IX.,' brought him a pension in 1819, but he lost it through the revolution of 1830. He produced pleasing verses, epigrammatic satires; an epic, 'Marie de Brabant' (1825); a novel, 'L'Homme du Monde' (1829), as well as other works, but 'Louis IX.' remains his most important achievement. His wife, Marguerite Virginie Chadron, b. Dijon, 15 March 1792; d. Paris, 21 March 1875, wrote novels and plays sometimes with him, but also independently, and won some attention as an artist.

ANCESTOR, one who has preceded another in a direct line of descent; an descendant, a former possessor; the person last seized. Termes de la Ley; 2 Shars. Bl. Com. 201. In the common law, the term is understood as well of the immediate parents as of those that are higher; as may appear by the statute 25 Edw. III. De nativ. ultra mare, by the statute 6 Rich. II c. 6, and by many others. But the civilians' relations in the ascending line, up to the great-grandfather's parents, and those above them, they term majors, which common lawyers aptly express by retrospect or ancestors, for in the descendants of like degree they are called posteriores. Cary, Litt. 45. The
ancestor is applied to natural persons. The words predecessors and successors are used in respect to the persons composing a body corporate. Consult 2 Bl. Com. 209; Bacon, Abr.; Ayliffe, Pand. 58; Reeve, Descents.

ANCESTOR-WORSHIP. See MAN.

ANCHIETA, ân-shâ-tâ', Jose de, Portuguese missionary, to Brazil: b. Laguna, Tenerife, 1533; d. 1597. He was a Jesuit and founded in Brazil the first institution for the conversion of the inhabitants. He was the author of 'Natural Productions of Brazil.'

ANCHISAURUS, ân'ki-sâ'rûs, a carnivorous dinosaur of the Triassic period. It has many primitive characteristics, notably small size, four complete toes in the hind foot and five in the fore foot.

ANCHISES, ân-ki'sez', a legendary hero of Troy, to whom Venus, in the guise of a Phrygian shepherdess, bore a son, Æneas. At the burning of Troy Æneas carried his father away on his shoulders, and their voyage to Sicily is described in Virgil's Æneid.

ANCHITHERIUM, ân'ki-thê'rî-üm, one of the three-toed fossil horses of the Middle Miocene period. Its remains have been found in Europe and North America; a complete skeleton was uncovered at Pawnee Buttes, Colo., in 1901 and is now on view in the American Museum of Natural History, New York. The animal was about the size of the Shetland pony; the middle toe of each foot was well developed; the lateral toes, one on each side of the middle toe, reached the ground, but were unable to support any weight owing to their delicate construction. It was formerly held that this animal was the ancestor of the modern horse, but it is now regarded as an offshoot from the main line of evolution of the horse. See also FOSSIL; HOOF.

ANCHOR, a heavy instrument of iron, intended to be dropped from a ship to the seabottom, to hold her in a desired position. It usually consists of a shank, having at one end a ring, to which the cable is fastened with a cross-piece or stock, and at the other end two arms with blades at the end, called flukes. One form of anchor the stock is not a cross-piece in the sense of lying transversely to the direction of the arms, but lies in the same direction. In the Homeric times large stones were used for anchors; afterward they are said to have been sometimes of wood loaded with lead. In some places baskets full of stones or sacks filled with sand were employed for the same use. All these were let down by cords into the sea, and by their weight stayed the course of the ship. Among the Greeks of later times anchors were composed of iron. Sometimes there was only one tooth or fluke, but generally there were two. Anchors with two flukes appear from ancient monuments to have been much the same as those used at present, but the transverse piece of wood fastened to the shank (the stock) is wanting in all of them. Every ship had several anchors, one of which, surpassing all the rest in bigness and strength, was peculiarly termed, in Greek, hiera, and in Latin sacra, and was never used but in extreme danger; whence sacrum ancoram solvere is proverbially applied to such as are forced to their last refuge. When an anchor of the usual form is let fall from the vessel, it generally strikes the bottom with the crown or curve of the arms, and then falls over on one of the ends of the stock, the arms lying flat on the ground. In this position it cannot bite, so that it has to be canted or turned over till the stock lies flat, and the point of one of the flukes (the bill) or over the ground. The canting is effected by the vertical pulling at the cable, and the longer the stock and the shorter the arms the less is the force required to perform the operation; for this reason the stock is always made longer than the arms. The anchor will now either drag or penetrate the ground, the readiness with which it does the latter depending on the sharpness of the bill, the angle at which the fluke rests on the ground and of course the nature of the bottom. Fortunately the arms used to be rigidly attached to the shank of the anchor; but in 1838 Mr. Porter took out a patent for an anchor of a new construction (though the principle was known before, however), in which the arms were movable around a pivot at the shank of the shank, the plane of the pivot being perpendicular to the direction of the stock. The advantages of this anchor are, that there is almost no possibility of fouling it—that is, of the cable becoming entangled with one of the arms; it cannot lodge on the stock end; it presents no upper fluke to injure the vessel to which it is attached, or others, in shoal water (since the swivel movement enables the peak of the upper fluke to come close to the shank when the anchor is fixed); it is not so liable to break, is more conveniently stowed on board, etc. This form of anchor as improved by Trotman is now largely used in the merchant service. In the navies both of Great Britain and of foreign countries the anchor perhaps most commonly employed is the admiralty anchor with fixed arms, the chief recommendation of which is the excellence of its proportions. Another favorite is Rodgers', the chief peculiarity of which is its small flukes. The inventor claims for this anchor that it holds the ground better than those with large flukes. Still another excellent anchor is patented by a Frenchman named Martin. In his anchor the stock lies in the same direction as the arms, the consequence of which is that when the anchor reaches the ground it inevitably falls flat, with both stock and arms resting on the bottom. The arms are capable of turning in a socket through an angle of 30° in such a manner that when the anchor is lying flat on the ground the flukes of both arms may sink into the ground at an angle of 15°. The weight of the arms and the pull of the vessel cause them to do this. It will be understood that the flukes are not, as in other anchors, perpendicular to the direction of the arms, but lie in the same direction. Besides holding the ground more firmly than any other anchor of equal weight, this anchor has the advantages of being free from liability to foul and easily stowed. The latter circumstance particularly recommends it for use in unmanned trett ships, almost all of which are equipped with it.

The different kinds of anchors are bow, sheet, stream, stern, and kedge anchors. The bow anchors are so called from their being stowed in the bow. When one bow an-
ANCHORAGE — ANCIEN REGIME

ANCHOR is heavier than the other it is called the best bowler and is stowed on the starboard side. Sheet anchors are stowed in the waist of the ship as far forward as convenient. The stern anchor is used in a sheltered place where a large anchor is not required. The stern anchor is stowed in the stern, and is employed with a bow anchor where there is no room for a vessel to swing with the tide. The kedge anchor is a smaller one placed on the ship from place to place; that is, the anchor is carried to a distance in a boat, and the ship is then pulled up to it by means of the cable. A large iron-clad carries eight anchors: two bowers, two sheet and two kedge anchors, with one stream and one stern anchor. The anchor is said to be a peak when the cable is perpendicular between the hawse and the anchor, and come home when it does not hold the ship. To shoe an anchor is to fix boards upon the flukes so that it may hold better in a soft bottom. Riding anchor is the state of the vessel when moored by the anchor or anchors. Dropping or casting anchor is letting it down into the sea. Weighing anchor is raising it from the bottom. Mooring anchor is a stationary anchor in a harbor or roadstead, with a buoy attached to it by a cable, enabling a ship to moor by simply fastening itself to a ring-bolt on the buoy. These anchors should not project above the bottom, or the ship may receive injury by grounding on them. Mooring anchors are of various kinds, and in some cases a heavy block of stone or cast iron serves as such. One of the most powerful mooring anchors yet invented consists of a wrought-iron shaft with a pointed screw end, and near the lower end a cast-iron screw flange three and one-half feet in diameter. The anchor is screwed down into the solid ground, and its holding power is more than equal to that of a cast-iron anchor weighing seven tons. The making of anchors used to be a most formidable piece of smithy work, but it has been much facilitated by the invention of the steam hammer. The shank of a large anchor, nearly 20 feet long and 10 or 12 inches thick, requires to be built up of a number of bars of iron, which are then welded together. Crucible steel is now to some extent used for anchors.

ANCHORAGE, a suitable place for anchoring. A good anchorage should have a soft bottom and a depth of from 10 to 20 fathoms. When deeper than this the cable bears too nearly perpendicular and is apt to drag up the anchor. The length of cable paid out by a ship in anchoring in ordinary weather is about three times the depth of the water. Anchorage also means dues paid by a vessel anchoring. As a rule a ship sheltering from stress of weather and not discharging cargo at the place where it anchors is not required to pay dues, but shore-dues are payable whether a ship anchors or not.

ANCHORITE, ANCHORET or ANCHORET, one who has renounced the world and retired into a seclusion remote from habitation. The anchorite is traditionally Christian; it manifests itself in all religions and in all ages. Anchorites of various Hindu ascetic sects are at present to be found among the jungles and hills of India, and the Orient has always been a land of them. The peculiar

ANCHOVY, an-chan'yi (of uncertain origin, perhaps literally a dried or pickled fish, from Basque, antzuoa, dry), a small, richly flavored, herring-like fish (Engraulis encrasicolus), of the family Engraulidae. It is caught abundantly along the sea-coasts of southern Europe when coming in from the deep sea to spawn in early summer. The Mediterranean fishers in particular salt and dry it in large quantities for export. Closely allied species are found on the eastern and western coasts of southern Europe and off southern Asia. A Californian species (Engraulis mordax) is extremely abundant in large schools and is a valuable food fish. In general, anchovies are five to seven inches long, shaped like herrings, and have a pointed head and projecting upper jaw.

ANCHOVY-PEAR (Grias cauliflora), a tree of the family Lecythidaceae, found in moist districts of the West Indies. It grows to the height of 50 feet, has oblong leaves two or three feet long, and large white blossoms carried on short peduncles. Its fruit, somewhat larger than a hen's egg, is pickled and eaten like the mango, which it strongly resembles in taste.

ANCHUSA, an-chu'za. See ALKANET.

ANCYLOSTOMIASIS, an'ki-lo-sto'mi-a'sis, disease due to the presence of an intestinal parasite, the *Ankylostomum duodenale* (Ucinaria duode-
nalics). This parasite lives in the upper portion of the small intestine, where, by means of a series of tooth-like hooks about the mouth, it attaches itself to the mucous membrane. It is particularly prevalent among Italian and Polish laborers, especially among those who work in confined spaces, as masons, tunneleers, etc.

The chief symptoms are those due to the loss of blood which the worm constantly sucks from the wall of the intestine. Gastro-intestinal disturbance, progressive anaemia, diarrhoea and colicky pains with shortness of breath and swelling of the limbs are among the important symptoms. The diagnosis can be made by means of a microscopical examination of the faeces, in which the eggs are found, and also by the microscopical examination of the blood. Careful attention given to the drinking water is one of the most important prophylactic measures. See PARASITE.

ANCIEN RÉGIME, an-'zhah rä'zhem', a French phrase commonly used, even by English writers, to denote the social and political system established in France under the old mon-
ANCIENT DEMESNE—ANCÓN

archy, which was swept away by the revolution of 1789. The phrase is generally applicable only to France, for in no other country, with perhaps the exception of Japan, has there been in modern times so clearly marked a division between the old order and the new.

ANCIENT DEMESNE, a term employed in English law to denote ancient estates belonging to the Crown. They are mentioned in Domesday Book as Terra Regis.

ANCIENT LIGHTS, a term denoting windows so long existent that they have obtained a right to the light entering them and cannot be interfered with by the owner of the property whence the light enters. Rights of this nature cannot commonly be acquired by prescription in the United States. Ancient lights in England are now regulated by a statute calling for but 20 years' existence to create the right.

ANCIENT MARINER, The. The best known of the poems of S. T. Coleridge. It should be read, as it was doubtless written, as a poem of strange, romantic adventure full of the swing and charm of the old ballads. The story with its incidents and its pictures, the language with its phrases and figures, the poetic movement both in single lines and in structure is perhaps the best of its kind and may give keen poetic pleasure. The poem, besides these things, is informed with a fine thought particularly expressed in the last words of the old sailor, which should not be neglected. The poem, however, is also some what of a landmark in English literature and has significance in literary history. Coleridge was a leader in that movement at the beginning of the 19th century which gave to English poetry once more the charm of mystery, wonder, adventure and romantic beauty. He has himself told us ("Biographia Literaria" Chap. 14) of the plan of "Lyrical Ballads" by Wordsworth and himself. The two friends talked over their literary hopes and their poetic ideals and decided to publish their poems together. Wordsworth's part was to show how much poetic beauty there was in the simple life of every day; Coleridge was to "deal with strange supernatural subjects," so as really to arouse emotion and feeling. The Ancient Mariner was the chief of Coleridge's few contributions and has always stood, if not exactly for the qualities which the author ascribes to it, for the essentially romantic in poetry.

EDWARD EVERETT HALE.

ANCIENT ORDER OF HIBERNIANS. See Hibernians, Ancient Order of.

ANCIENT ROME IN THE LIGHT OF RECENT DISCOVERIES, an archaeological work by Rodolfo Lanciani: b. 1847. In his character of official investigator Professor Lanciani has grouped in this volume various illustrations of the life of ancient Rome as shown in its recovered antiquities. From these he reads the story of the wealth, taste, habits of life, ambitions and ideals of a vanished people.

ANCIENTS, Council of, the upper one of two branches of the legislative body of France, 1795–99. It included 250 members and its function was to consider measures submitted by the lower branch, the Council of Five Hundred.

ANCILE, a shield reported to have fallen from heaven in the time of Numa. It was believed to be the shield of Mars, and as the prosperity of Rome was held to depend upon its preservation, 11 facsimiles of it were made, that anyone wishing to steal it might not know which to take. It is conjectured to have been originally a lump of meteoric iron.

ANCILLON, an'se-yōn', Charles, French Protestant leader: b. Metz, 28 July 1659; d. Berlin, 5 July 1715. He studied at Marburg, Geneva and Paris, where he was called to the bar. He became director of the Huguenot colony at Berlin and published several works on the revocation of the edict of Nantes and its consequences. His chief claim to remembrance is the work that he did in Prussia, and the share he took, in co-operation with Leibnitz, in founding the Academy of Berlin. Of his numerous works the only one still of value is the "Histoire de l'établissement des Français réfugiés dans les états de Brandebourg" (1690).

ANCILLON, Johann Peter Friedrich, a German historian of French extraction: b. Berlin, 30 April 1767; d. there, 19 April 1837. Besides "Mélanges de Littérature et Philosophie" (1801) he was the author of a "View of the Revolutions of the Political System of Europe since the 15th Century" (1814–1845), which secured him the post of royal historiographer. From 1832 till his death he was Minister of Foreign Affairs.

ANCÓN, an-kōn', a Peruvian coast town, of special interest to archaeologists as the site of an ancient necropolis. It is now a seaside resort 30 miles by rail northwest of Callao and has been the scene of several important historical events. Its anchorage was used by Lord Cochrane in 1820 during his attacks on Callao; it was the landing-place of an invading Chilean army in 1838; it was bombarded by the Chileans in 1880; it was the meeting-place of the Chilean and Peruvian commissioners who drew up the Treaty of Ancón, which ended the war between Chile and Peru (see CHILE). One of the noteworthy contributions to our knowledge of the culture and industries of the empire of the Incas was made by Reiss and Stübel as a result of their excavations at this place before 1880. They succeeded in making quite apparent the importance of the discovery of numerous objects which, as industrial products, belong to the domestic economy of the people of the ancient Inca state. "All these objects," they wrote, "have been excellently preserved, a fact due to the scarcely accidental coincidence of two circumstances—climate and worship of the dead. To the dry climate we are primarily indebted for the fact that the rich contents of piously equipped graves have in manifold instances reached us uninjured, and that consequently the picture of a culture speedily swept away by the Spanish conquerors may be reconstructed. Their discoveries "in a single burial place, although one of great extent—the Ancón necropolis"—certainly helped, as they asserted, to "carry us back to the busy life and inner

ANCONA, ån-kô'na, Alessandro d', Italian critic and philologist: b. Pisa, 1835, and from 1860 a professor of literature in the University of Pisa. Among the many works of this distinguished scholar are 'I Precursori di Dante' (1874) 'Origini del Teatro in Italia' (1877); 'La Poesia Popolare Italiana' (1878); 'Varietà Storiche e Letterarie' (1883-85); 'Manuale della letteratura Italiana' (1892-95).

ANCONA, Italian province of the kingdom of Italy, between Pesaro and Urbino on the north, Macerata on the south, and the Apennines and Adriatic on the west and east; area, 736 square miles. It is a mountainous region watered by the rivers Cesano, Esino and Musone, and produces grain, wine, oil, olives, silk and fruit. Capital, Ancona. Pop. about 320,000.

ANCONA, an important Italian port on the Adriatic, the capital of the province of the same name. Its site is an amphitheatre between two headlands, and on its ancient mole, designed by Trajan, is a triumphal arch by Apollodorus, and near it was torn down by a triumphal arch by Vanvitelli. Among important buildings are the cathedral of Saint Cyriac dating from the 11th and 12th centuries, a 13th-century town hall and a museum. Sugar-refining, ship-building and manufactures of silk, paper and gålate were amongst the main industries. A United States consul is stationed here. The city is said to have been founded by Syracusans fleeing from the persecutions of the Elder Dionysius. Pop. about 57,000.

ANCONA, The. Italian liner, sunk in the Mediterranean on 7 Nov. 1915 by a submarine flying the Austrian flag. Bound from Naples for New York, the Ancona was one day out from Messina when she was torpedoed off the coast of Tunis with over 400 passengers on board and a crew of 172. There were 2 American passengers, of whom nine perished. The submarine fired upon the steamer, which, according to Italian report, had to almost instantly after the first shot. The firing continued while the life-boats were being filled and lowered; before the death occurred one of those on board could be got off in the boats a torpedo from the submarine struck and sunk the Ancona, sacrificing over 200 lives. The Austrian Ad- miralty asserted that the Ancona had attempted to escape and had been struck several times before heaving to; that 45 minutes' grace had been allowed by the submarine for those on board to take to the boats; that the cowardice of the crew and the prevailing panic had hampered the life-saving proceedings, and that the steamer had been fired after 30 minutes' delay, and then only because another steamer was approaching. It was denied that the life-boats had been fired on.

An impression at first gained ground that the outage had been committed by a German submarine under the Austrian flag, from the close resemblance between the methods of warfare employed, but the Austrian statement made it clear that that government assumed entire responsibility. The American Amateur Association of the United States telegraphed to the Austrian government a detailed account of the Ancona affair from the Austro-Hungarian government. No reply being forthcoming for three weeks, a peremptory note, dated 6 December, from the American government was presented at Vienna. Admitting that the Ancona had attempted to escape after the first (solid) shot, the note protested that 'the commander violated the principles of international law and of humanity by shelling and torpedoing the Ancona before the persons on board had been put in a place of safety or even given sufficient time to leave the vessel'; that the conduct of the commander could only be characterized as wanton slaughter of defenseless non-combatants, since at the time when the vessel was shelled and torpedoed she was not, it appears, resisting or attempting to escape. The American government was unwilling to credit the Austro-Hungarian government with an intention to permit its submarines to destroy the lives of helpless men, women and children. It prefers to believe that the commander of the submarine committed this outrage without authority and contrary to the general or special instructions which he had received. The United States government demanded a denunciation of the sinking of the Ancona as an illegal and indefensible act; that the leader who perpetrated the deed be punished, and that reparation be made by the payment of an indemnity be made for the citizens of the United States who were killed or injured by the attack on the vessel. From the Austrian Admiralty reply dated 15 Dec. 1915 it appeared that the commander was instructed to prevent the Ancona from escaping in all circumstances, and that his conduct cannot be disapproved. A more lengthy note from the Foreign Minister, Baron Burian, defended the attitude of his government and most sincerely deplored the fate of the innocent victims. The American reply (19 Dec. 1915) found "no other course open" but to hold the Austrian government "responsible for the act of its naval commander and to renew the definite but respectful demands made in the note of 6 December. The incident was closed by a note from Baron Burian dated 29 Dec. 1915, in which he reviewed in detail the circumstances surrounding the Ancona affair. Every American demand had been against the ground that the commander of the submarine had omitted to take adequately into consideration the panic that had broken out among the passengers; that the officer in question had been punished, and that indemnity would be granted.

ANCRE, ån-kir, Concino Concini, Marshal and Marquis d', a Florentine who went to France in 1600, where he obtained rapid promotion, more especially after the assassination of the King (160). Successively governor of Normandy, marshal of France, and last of all Prime Minister, he was thoroughly detested by all. At last a conspiracy was formed against him and he was shot dead on the bridge of the Louvre in 1617.

ANCRE, France, town in the department of the Somme, near Péronne, on the Ancre River. Ancre was a barony in 1563, was raised to a marquisate in 1576, was acquired by Concini in 1610. After his death it passed to the King's favorite, Charles d'Albert, Duke of Louynes. In June 1620 by royal decree the name was changed to Albert. In 1695 the
ANCUD—ANDALUSIA

marquisate was acquired by the Count of Toulouse and in 1769 passed to the house of Orleans, of which a member, the Duke of Penthièvre, was proprietor in 1799. The town has been destroyed several times; at first by fire in 1451, by the Imperialists in 1523, by the Bourguignons in 1553, by the Spaniards in 1637 and by another fire in 1760. It was again destroyed in the Great War, being bombarded by the British and German forces alternately. Its principal manufactures are paper, leather, linen and foundry products. Pop. 5,473. See War, European.

ANCUD, án-kood, Chilean port, capital of the province of Chiloe. It is situated on the island of Chiloe, about 580 miles from Valparaiso, a line of steamships connecting the two. First settled in 1768, it was the last place surrendered by the Spaniards to the Chileans in 1826. Pop. about 3,500.

ANCUS MARCIUS, the fourth King of Rome; b. 638 B.C.; d. 614 B.C. The son of Numia's daughter, he attempted to imitate his grandfather byreviving the neglected observances of religion. His peaceful pursuits were disturbed by the Latins, whom he subdued and caused to be brought to Rome, where he assigned them the Aventine to dwell upon. These conquered Latins, according to Niebuhr, formed the original plebs. He fortified the Janiculum against Etruria, connecting it with the city by the bridge across the Tiber known as the Sublician; dug the ditch of the Quirites; constructed the harbor of Ostia; and built the first Roman prison of which there is any record.

ANCYLOPODA, or ANCYLODACTYLIA, an apparently primitive extinct subordinated group of Ungulata showing certain resemblances to the Perissodactyla, both as regards the cheek-teeth and the skeleton, but broadly distinguished by the feet being of an edentate type, carrying long curved and cleft terminal claws.

ANCYRA. See Angora.

ANDALUSIA, án'dá-ló'śē-ä, Spain (Spanish, Andalucia), a district in the southern part of the country, celebrated for its fertility and picturesque beauty; bounded north by Estremadura and New Castile, east by Murcia, south by the Mediterranean Sea, and west by Portugal and the Atlantic. Length east and west about 310 miles; average breadth about 120; area about 33,650 square miles. It is traversed throughout its extent by ranges of mountains. It is divided into Upper and Lower Andalusia. The Sierra Morena runs along its northern border, and in the southeast rise the mountains of Granada and the Ronda, including numerous sierras, and among them those of the famous Sierra Nevada. Lower Andalusia comprises the province of Moguer, the lower Guadaiquivir, and other sierras. Many mountains of the southern ranges are covered with perpetual snow; the Mulahacen rising 11,678 feet, and the Picacho de Veleta 11,378 feet above the sea. All the mountains abound with mineral wealth, yielding chiefly copper, cinchbar and lead, as well as silver and coal. Some mines have been opened by English companies, especially in the province of Huelva in the west, where the Tharsis and Rio Tinto copper mines are situated. The principal river of Andalusia is the Guadalquivir, which rises in the east part of the province of Jaen, near Carzola, and thence flows west-southwest, and below Seville south-southwest, entering the sea near Sancti Petri. Its principal affluents are the Guadiana, Guadiato and Xenil. The rivers south of the Sierra Nevada are quite insignificant. The basin of the upper Guadalquivir lies at an elevation of from 500 to 1,500 feet, and consists mainly of saline wastes and other sterile tracts. The lower basin presents sharp contrasts; proof of Cordova and Seville luxuriant gardens; on the Xenil a desert without a drop of water; on the left bank of the lower Guadalquivir the extensive marshy district of Marisma; and stretching from the mouth of the Guadalquivir to that of the Rio Tinto, a sandy depression (Arenas Gordas) partially clothed with pine-woods. The lower regions have a very mild climate, but on the Atlantic coast the temperature is much lower, and snow falls frequently. The vegetation is of the character peculiar to the extreme south of Europe and the south of Africa. Wheat, maize, barley, many varieties of fruit, grapes, honey, silk and cochineal form important articles of culture. Many cereals ripen as early as April. A large portion of the soil is in pasture. The horses are the best breed in the Peninsula; the bulls of Andalusia are sought over all Spain for bull-fighting; sheep are reared in vast numbers, and bear an abundance of good but not fine wool; and the hogs reared on the acorns of the mountain forests furnish hams unsurpassed in any part of Europe. Andalusia has been known as the "granary" of Spain since ancient times, and still remains one of the most fertile districts of the country, although famine conditions have prevailed at intervals. The most recent instance was in 1905, when thousands emigrated. The chief manufactures are woolens, silk and leather, and are by no means extensive. The name Andalusia is commonly taken to have been originally Vandalusia, the land of the Vandals. The people are well attired; their language is Spanish with an admixture of Arabic. Pop. (1910), 3,828,916. In the 5th century Andalusia came into the possession of the Vandals, whose name it bears instead of Tartessis, which it bore in classical times. It is probably the Biblical Tarshish. The Carthaginians had acquired it in the 3rd century B.C., and later passed to the Romans, by whom it was called Bética, from the river Betic (Guadalquivir). It became very prosperous and was thoroughly Romanized. It was the home of learning, of art, chivalry and toleration. Cordova has been called the Athens of the West, the seat of the arts and sciences; and when the gnomon of the Dark Ages spread over Europe, Andalusia was perhaps the brightest spot in that continent. Its glory faded with the disruption of Spanish Islam in the 11th century. Granada, it is true, held out for two centuries longer and the gen-
iu of the Moorish race made its home there. In 1429 Granada fell into the hands of Christian Spain. In Spanish times the names of Carbonirillo and Velasquez have shed everlasting lustre on Andalusia. Consult Laine, 'Sur les routes d'Andalousie' in La Nouvelle Revue (No. 115 Paris 1898), and Murray, 'The Cities and Wilds of Andalusia' (London 1883); Wise, 'Spain' (8th ed., London 1904); Poole, S. Lane, 'Moors in Spain' (ib. 1886); Villaescusa, M. H., 'Las Provincias de España' (Barcelona 1905).

**ANDALUSITE**, a native anhydrous silicate of aluminum, first discovered in Andalusia. Its chemical formula is AlSiO₃, and it crystallizes in the orthorhombic system. It usually occurs in coarse crystals, prismatic in form, and nearly square. Its hardness is 7.5, at least on the basal face, and its specific gravity about 3.18. Andalusite is commonly translucent and varies greatly in color. Some specimens are strongly pleochroic; changing from olive green to blood red according to the angle at which the incident light strikes them. A variety known as chalcedonite contains carbonaceous impurities distributed through the prism, according to a definite geometric plan, so that a transverse section of the crystal presents a curious tesselated or cruciform appearance. A variety from eastern Finland has been called 'maltesite,' from the regularity of the Maltese cross it exhibits when seen in section. Andalusite is found in many parts of Europe, usually in schist or gneiss. Fine specimens also come from the province of Minas Geraes, Brazil. In the United States it occurs in Maine, New Hampshire, Vermont, Massachusetts, Connecticut, Pennsylvania, South Dakota and California.

**ANDAMANS**, an-ḍá-man, a chain of volcanic islands in the Bay of Bengal, 590 miles from the mouth of the Hugli, 120 miles from Cape Negrais in Burma, the nearest point on the mainland. Five large islands closely grouped together are called the Great Andaman, and to the south is the island of Little Andaman. There are some 200 islets, the two principal groups being the Andaman Archipelago and the Labyrinth Islands. The total area is 2,292 square miles. The group is about 219 miles long, and at the widest 32 miles broad. The group, densely wooded, contains many valuable trees, the best known of which is the padook or Andaman redwood. The islands are hilly, the highest point, Saddle Peak, being 2,402 feet, and Mount Harriet, 1,996 feet in height. The islands possess a number of harbors and safe anchorages, notably, Port Blair, Port Cornwallis and Stewart Sound, the last being most favorably situated for forest trade. The inhabitants, 1,517 (628 males and 889 females in 1911), are more savage than the islands; they are savages of a low Negro type. The total population in 1915 was 25,732. The climate is tropical, the rainfall irregular and often excessive. In 1914 forest sales, the result of convict labor, amounted to $3,931.59. Tea, the cocoanut, manila hemp and Bahama aloe are successfully cultivated. In 1914 there were 12,233 head of cattle. Wireless telegraphy with Burma was established in 1904. A mail steamer connects Port Blair with Calcutta, Rangoon and Madras. The islands have been used since 1858 by the government of India as a penal settlement for life and long-term convicts. The settlement possesses about 26,600 acres of cleared land and 150 square miles of reserved forest. There were, in 1915, 12,252 convicts (including 570 women) in the place, of whom some 1,730 were on ticket-of-leave in the settlement supporting themselves. Of the women, about half are on ticket-of-leave, and married to convicts.

The Andaman Islands are under the government of India, and the officer in charge is the superintendent of Port Blair. The civil, military and convict population of Port Blair in 1915 was 16,914. For the ethnography of the Andaman aborigines consult Kloss, 'In the Andamans and Nicobars' (1903); Man, 'The Aborigines of the Andaman Islands' (London 1885); Portman, 'Notes on the Languages of the South Andaman Group' (Calcutta 1898); "The Andaman Islands" (in The Indian Antiquary, Vols. XXVIII and XXX, Bombay 1899-1900).

**ANDENNE**, Belgium, a small manufacturing town on the southern bank of the Meuse, eastward of Namur and west of Huy, with a population of nearly 9,000 inhabitants, chiefly engaged in paper-making. For centuries, down to 1785, a female religious community belonging to one of the open orders, i.e., not bound by any vows, had existed here. On the opposite bank of the river lies the town of Sellies, connected with Andenne by a bridge with a single carriageway. During the German invasion of Belgium this light structure was blown up by the Belgian troops at 8 a.m. on 19 Aug. 1914. A few hours later an advanced guard of Ublans entered Andenne, seized the cash at the tax-office and took away with them the burgomaster, an old, corpulent man, who was compelled to keep pace with their horses at a run. By evening a large body of German troops had entered the town without meeting any resistance. On the following afternoon (20 August) shots were fired from the opposite bank of the Meuse, from Sellies, to which the Germans in Andenne replied. Immediately turning upon the inhabitants (of Andenne), the Germans brough in machine guns, and shot them down in large numbers for over two hours. At 7 p.m. a considerable portion of the town was in flames. At 6 on the following morning the Germans began to drag the inhabitants from their houses. Men, women and children were driven into the square, where the sexes were separated. Three men were then shot and a fourth bayoneted. The German colonel in command accused the population of firing on the soldiers; some of the prisoners were picked out, taken to the banks of the Meuse and there shot. "They suffered more than Andenne, but no other Belgian town was the theatre of so many scenes of ferocity and cruelty" (Belgian Report). The Bryce Committee stated in their report that "About 400 people lost their lives in this massacre, some on the banks of the Meuse, where they were shot according to orders given, and some in the cellars of the houses where they had taken refuge." The German reply to the allegations (White Book; see AERCHOT) was that "the demeanor of the in-
ANDERNACH, än'dér-näg, Germany, a town in the Prussian Rhine province, on the left bank of the Rhine, 10 miles northwest of Coblenz. Viewed from the river it makes a glorious, though picturesque, impression, with its parish church (a basilica dating from the 12th century, with four towers), the round watchtower on the Rhine and a famous crane (erected 1554) for lading merchandise. Among other buildings are a Gothic Minorite church (now Protestant), a town hall and a prison, formerly the castle of the archbishops of Cologne. Andernach has considerable industries, brewing and manufactures of chemicals and perfumes, and has also a trade in corn and wine. But its most notable article of commerce is that of mill-stones, made of lava and tufa-stone, a product much used by the Dutch in the construction of their dykes. It was founded by Drusus in the 3d century. In 1109 it received civic rights, and in 1253 joined the confederation of the Rhine cities. In 1794 it passed to France, but in 1815 was ceded to Russia. Pop. about 10,000.

ANDERSEN, än'der-sen, Hans Christian, a Danish novelist, poet and writer of fairy tales: b. in Odense, 2 April 1805; d. Copenhagen, 4 Aug. 1875. He learned to read and write in school, whence he was taken when only nine years old, and was put to work in a manufactory in order that his earnings might assist his widowed mother. In his leisure time he eagerly read national ballads, poetry and plays, and wrote several tragedies which he failed to get accepted. His abilities at last brought him under the notice of Councilor Collin, a man of considerable influence, who procured for him free entrance into a government school at Slagelse. From this school he was transferred to the university and soon became favorably known by his poems. His first considerable work, 'A Journey on Foot from Holmen's Canal to the East Point of Anger,' was published in 1828, the year of his admission to the university. Through the influence of O. T. Sørenson and others he received a royal grant to enable him to travel, and in 1833 he visited Italy, his impressions of which he published in 'The Improvisatore' (1835), a work which rendered his fame European. The scene of his following novel, 'O. T.,' was laid in Denmark. In 1837 he married, and wrote a volume, 'The Story of My Life,' of his early struggles. In 1853 appeared the first volume of his 'Fairy Tales,' of which successive volumes continued to be published year by year at Christmas, and which have been the most popular and widespread of his books. Among his other works are 'Picture-books without Pictures,' 'A Poet's Bazaar,' and a number of dramas. In 1843 he received an annuity from the government. He visited England in 1848 and acquired such a command of the language that his next work, 'The Two Baronesse,' was written in English. In 1853 he published an autobiography under the title, 'My Life in Denmark.' An English translation of which, published in 1871, contained additional chapters by the author, bringing the narrative to 1867. Among his later works are 'In Sweden' (1849); 'To Be or Not to Be' (1857); 'Tales from Jutland' (1859); 'The Sand-hills of Jutland' (1860); 'The Ice Maidens' (1863); 'In Spain' (1863).

ANDERSEN'S FAIRY TALES. See FAIRY TALES.

ANDERSON, David, Canadian clergyman: b. London 1814; d. 1885. He was educated at Edinburgh Academy and Exeter College, Oxford; consecrated bishop of Rupert's Land, 29 May 1849; resigned in 1852 and appointed chancellor of Saint Paul's Cathedral, London, England, and vicar of Clifton. He founded Saint John's College, Winnipeg.

ANDERSON, Edwin Hatfield, American director, New York Public Library: b. Zionsville, Ind., 27 Sept. 1861. He was graduated from Wabash College as A.B. in 1883, later receiving the degree of A.M., and spent a year at New York State Library School, Albany, N. Y., in 1889 and 1891. He was cataloguer for one year at the Newberry Library, Chicago, Ill.; librarian of the Carnegie Free Library at Braddock, Pa., three years and organized and was the first librarian of the Carnegie Library of Pittsburg, Pa., from 1895 until his resignation in December 1904. He was engaged in zinc and lead mining at Carthage, Mo., during 1905; from 1 Jan. 1906 to June 1908 director of New York State Library and Library School; June 1908 to May 1913 assistant director of the New York Public Library; 14 May 1913 to date director of the New York Public Library. President of the Keystone State Library Association in 1901-02; member of the Public Records Commission and of the Historical Archives Commission of Pennsylvania in 1903-04; president of the New York Library Association in 1908, and of the New York Library Club in 1910; president of American Library Association 1913-14; Litt.D. Carnegie Institute of Technology, 1915.

ANDERSON, Elizabeth Garrett, English medical practitioner: b. Aldeburgh, Suffolk, 1836; d. there, 17 Dec. 1917. She was educated at a private school. In 1860 she resolved to study medicine, an unheard-of thing for a woman in those days, and one which was regarded by old-fashioned people as almost indecent. Miss Garrett managed to obtain some more or less irregular instruction at the Middlesex Hospital, London, but was refused admission as a full student both there and at many other schools. Finally she studied anatomy privately at the London Hospital, and with some of the professors of St. Andrew's University and at the Edinburgh Extra-Mural School. She had no
less difficulty in gaining a qualifying diploma to practise medicine. London University, the Royal College of Physicians and Surgeons and many other examining bodies refused to admit her to their examinations; but in the end she was allowed later for the License of Apothecaries' Hall, which she obtained in 1865. In 1870 she obtained the Paris degree of M.D. In 1871 she married J. G. S. Anderson (d. 1907), a London shipowner. She worked steadily at the development of the New Hospital for Women and at the creation of a complete school of medicine in London for women. In 1908 she was elected mayor of Aldeburgh, the first lady mayor in England. The movement for the admission of women to the medical profession, of which she was the indefatigable pioneer in England, has extended to every civilized country except Spain and Turkey.

ANDERSON, George B., an American Confederate soldier: b. Wilmington, N. C., 1831; d. 16 Oct. 1862. He was graduated from West Point in 1852, and in 1853 obtained his commission as first lieutenant in the United States army, and served as regimental adjutant after 1855. Entering the Confederate service in 1861, he was made a brigadier-general and placed in command of the North Carolina coast defenses. While leading a brigade at the battle of Antietam, 17 Sept. 1862, he received the wound which caused his death.

ANDERSON, George Thomas, Confederate general: b. Covington, Ga., 3 Feb. 1824; d. Anniston, Ala., 4 April 1901. He entered Emory College, Oxford, Ga., but on the outbreak of the trouble in Texas, left to join General Kearney's command as lieutenant of cavalry, distinguished himself in various engagements, and on being mustered out received a captain's commission in the regular army. In 1861 he became colonel of a Georgia regiment, fought at the first Manassas or Bull Run, and succeeded to the command of Barton's brigade on the latter's death. He fought throughout the Seven Days' battles (q.v.) about Richmond; was wounded at the second Bull Run; on 1 Nov. 1862 was commissioned brigadier-general for gallantry and skill at Antietam, 16-17 Sept. 1862; fought at Fredericksburg; was wounded at Gettysburg; and upon his recovery was sent with Longstreet to Bragg's assistance in north Georgia. He participated in the battles of Chatanooga, Knoxville, Wilderness, Spottsylvania and Cold Harbor and throughout the protracted struggle around Richmond, and was present at the surrender at Appomattox. After the war he served in several official positions in Georgia, for a short time was freight agent of the Georgia Railroad at Atlanta, was chief of police of that city and later became city clerk and tax collector of Anniston, Ala.

ANDERSON, Henry John, American educator: b. New York, 6 Feb. 1799; d. Lahore, Hindustan, 19 Oct. 1875. He was graduated from Union College, 1818; M.D. College of Physicians and Surgeons, 1823. Professor of mathematics and astronomy at Columbia, 1825-50; trustee 1851, and professor emeritus 1866; geologist to the Dead Sea expedition under Lieutenant Lynch; member of the scientific expedition to the transit of Venus, 1874. He died while exploring the Himalayas. He early became converted to the Catholic faith and was active in promoting its interests in New York city. The United States government publish his 'Geology of the Expedition to the Dead Sea' (1848).

ANDERSON, James, Scottish agricultural economist: b. Hermiston, in Midlothian, Scotland, 1739; d. Isleworth 1808. When scarcely 20 years of age he invented the small two-horse plow without wheels, known as the Scotch plow. Four years later he left Hermiston and rented a large moorland farm of 1,300 acres in Aberdeenshire, where he devoted his leisure hours to writing on agricultural subjects, his first production being a series of essays on planting contributed to the Edinburgh Weekly Magazine. His principal works are, 'Encouragement of the National Fisheries'; 'An Inquiry into the Nature of Corn Laws'; 'Observations on Slavery' and 'Recreations in Agriculture, Natural History, Arts and Miscellaneous Literature' (1799-1802).

ANDERSON, John, Scottish philosopher, founder of Anderson College, Glasgow: b. Roseneath, Dumbartonshire, 1726; d. 1796. He studied at the University of Glasgow, where he was afterward professor of Oriental languages, and later of natural philosophy. In addition to his usual class in physics he instituted one for artisans, which he continued to conduct to the end of his life. In 1786 he appeared his 'Institutes of Physics,' which went through five editions in 20 years. He invented a gun, whose recoil was stopped by air condensation; but having in vain endeavored to attract the attention of the British government to it, he went to Paris in 1791 and presented his model to the National Convention. It was hung up in their hall with this inscription over it, "The Gift of Science to Liberty." When the allies had drawn a military cordon around the frontiers of France Anderson suggested the experiment, which was adopted, of making small paper balloons, to which newspapers and manifestos were fastened and carried to Germany. Anderson by his will directed that his entire effects should be devoted to the establishment of an educational institution in Glasgow for the use of the unacademic classes. This college, opened with a single course of lectures, has now over 20 professors and lecturers; courses of instruction are given in physical and medical science and in chemistry; mathematics, Latin, Greek, Hebrew, French, music, etc., are also taught. As a school of medicine in particular it possesses a high reputation.

ANDERSON, John, Scottish missionary to India: b. in the parish of Kilpatrick-Durham, 23 May 1805; d. Madras, 25 March 1855. He was educated at Divinity Hall, Edinburgh. He was appointed to Madras as a missionary of the Church of Scotland, 28 June 1836, and sailed 13 August. He became at once the principal of Saint Andrew's School; this afterward developed into the Madras Christian College. His fame as an educator spread abroad over all India. Hundreds were educated by him. A splendid hall was erected at Madras to perpetuate the memory of Mr. Anderson.

ANDERSON, John Fisher, American physician and bacteriologist: b. Fredericksburg, Va., 14 March 1873. Having gained his degree of M.D. in the University of Virginia in 1896,
he was appointed assistant surgeon in the United States Public Health and Marine Hospital Service. In 1899 he became sanitary observer at Glasgow, Liverpool and Oporto, and, in 1900, sanitary attaché at the United States consulates at Barcelona, Marseilles and several other European cities. During his service abroad he continued his studies at the Thompson-Yates Laboratory and the School of Tropical Medicine in Liverpool and at the Pathologische Institut in Vienna. In 1902 he was appointed assistant director of the Hygienic Laboratory at Washington, becoming director in 1909. In 1913 he was appointed chairman of the United States commission into the claim of Dr. F. F. Friedmann that he had discovered in his “turtle serum” a cure for tuberculosis. He collaborated with T. B. McClintic on ‘A Method of Standardizing Disinfectants’ (1912).

ANDERSEN, Martin Brewer, American educator: b. Brunswick, Me., 12 Feb. 1815; d. 26 Feb. 1890; was graduated at Watervile College, now Colby University, in 1840; became professor of rhetoric and organized and taught the course in modern history at Watervile; and was president of the University of Rochester, N. Y., 1853 to 1888.

ANDERSEN, Mary Antoinette, American actress: b. Sacramento, Cal., 28 July 1859. She was educated at the Ursuline Convent and the Academy of the Presentation Nuns in Louisville, and when 13 years of age began to study for the stage. She first appeared at Louisville, 27 Nov. 1875, in the character of Juliet. Her success was immediate, and during the following years she played with increasing popularity in the principal cities of the United States in various roles. In 1883 she appeared at the Lyceum Theatre in London and opened the Memorial Theatre at Stratford-on-Avon in the character of Rosalind in ‘As You Like It,’ and speedily became well known in England. At the age of 28 she married Antonio de Navarro and retired from the stage. In 1896 she published a volume entitled, ‘A Few Memories.’ Consult her autobiography ‘A Few Memories’ (1896); Winter, William, ‘Stage Life of Mary Andersen’ (1896).

ANDERSEN, Melville Best, American educator and author: b. Kalamazoo, Mich., 28 March 1851. He was educated at Cornell University (1870-74); the University of Göttingen (1875-76) and at the University of Paris (1876-77). Returning to the United States he occupied several professorships in some of the principal colleges, notably Butler University, Purdue University, the State University of Iowa, and in 1891 became professor of literature in Leland Stanford, Jr. University, and since 1910 professor emeritus. He has translated and edited ‘Paul and Virginia’ (Hug); ‘William Shakespeare’; Boisier’s ‘Mme. de Sévigné’; Caro’s ‘George Sand’; Simon’s ‘Victor Cousin’; Sorel’s ‘Montesquieu’; Say’s ‘Turgot’; Rémusat’s ‘Thiers’; Joutel’s ‘Journal of La Salle’s Last Voyage’ (1896); Tony’s ‘Relation de 1587’ (1898); the ‘Preparation of La Salle’s Manuscripts’ (1898); ‘Cavalier de La Salle’s Discovery of the Mississippi River’ (1901), etc. He also edited ‘French Essays, with Introduction and Notes’ (1890); and wrote ‘Representative Poets of the Nineteenth Century’ (1890); ‘Happy Teacher’ (1910). For 10 years he was engaged upon a translation in triple rime of Dante’s ‘Divina Commedia.’ He has contributed to various literary periodicals.

ANDERSON, Rasmus Bjorn, American author, editor and diplomat: b. Albion, Wis., 12 Jan. 1846. His parents were among the first emigrants from Norway to America, coming in 1836. Rasmus Bjorn was graduated with the first class from Luther College, Decorah, Iowa, in 1866. From 1866 to 1869 he was professor of Greek and modern languages at the University of Wisconsin, and from 1869 to 1875 instructor in languages at the University of Wisconsin. Because of the general interest he developed in Scandinavian studies he was made professor of Scandinavian languages and literature in the University of Wisconsin in 1875, being the first to hold such a chair outside of the Scandinavian countries. In 1889 he was appointed United States Minister to Denmark, serving until 1889. Since 1898 he has been editor and publisher of ‘American’ a weekly Norwegian newspaper published at Madison, Wis. He has also been president of the Wisconsin Life Insurance Company since 1895 and of the Wisconsin Rubber Company since 1904 and served a short term as postmaster of Madison in 1912.

By reason of the intelligent interest he has created in Scandinavian culture Professor Anderson has often been styled the father of Norse literature in America. His first important work appeared in 1874, entitled ‘America Not Discovered by Columbus,’ an historical argument to substantiate the claims of the discovery of America by the Northmen in the 10th and 11th centuries. In 1875 appeared ‘Norse Mythology,’ an exposition of the early mythological system of the north. Both of these works have appeared in several editions and have been translated into German, French, Scandinavian and Italian. Other more prominent works are ‘Viking Tales of the North’ (1877); ‘The Younger Edda’ (1890); ‘First Chapter of Norwegian History’ (1895) and his ‘Autobiography’ (1915). In this work Professor Anderson gives, in connection with a review of his own life, a survey of the Norwegian settlements in America and the activities of the national as well as many hitherto unpublished incidents of statesmen and scholars whose acquaintance he formed as diplomatist and author. Professor Anderson’s translations have been many. In the early eighties he translated the novels of Bjornstjerne Bjornson for an American edition. Other translations that followed were ‘History of Literature’ (from the Danish) (1884); ‘Eminent Authors of the 19th Century’ (Danish, 1886); ‘Teutonic Mythology’ (from the Swedish, 1889); ‘Among Cannibals’ (Swedish, 1889). As literary editor Professor Anderson in 1889 supervised an English revision of Laing’s ‘Sagas of the Kings of Norway,’ supplying also the notes and maps. In 1905-06 he was the editor-in-chief of the preparation of the ‘Norrøna Library,’ a sumptuous edition of 16 volumes containing the most notable productions of Scandinavian literature from earliest times.

Professor Anderson has been a voluminous contributor to the contemporary press and for
ANDERSON

years was a regular contributor to the Dial and the Nation. He has also contributed to the Encyclopedia Americana, and other works of reference.

ANDERSON, Richard Henry, American Confederate soldier: b. South Carolina, 7 Oct., 1821; d. Beaufort, S. C., 20 Feb., 1879. Graduated from West Point in 1842; served in Mexican War. In May, 1861 he resigned from the United States army to join the Confederate service. He assisted in the bombardment of Fort Sumter and distinguished himself for gallantry throughout the war, especially at Fair Oaks, Gaines Mills, Frazier's Farm, Bull Run and Gettysburg. He held the rank of major-general (1862) and lieutenant-general (1864), commanding the 4th corps of Lee's army in the last campaign.

ANDERSON, Robert, American soldier: b. near Louisville, Ky., 11 June, 1805; d. in France, 26 Oct., 1871. Graduating at West Point, 1825, he entered the artillery as second lieutenant. He was on Scott's staff in the Seminole War, 1837-38; in the Mexican War was badly wounded at Molino del Rey. Commissioned major in 1857, in 1860 he was given command of the troops in Charleston harbor, with headquarters at Fort Moultrie. Threatened with attack, the fort untenable and the Buchanan administration making no reply to his appeals for its strengthening or for instructions on 26 December he removed the garrison to Fort Sumter. An attempt of the government to provision it being assumed by the Confederates as a declaration of war, they invested it and compelled its surrender by a bombardment, 12-13 April, 1861; its commander leaving with the honor of a compromise. Appointed brigadier-general, he was assigned to the department of the Cumberland; but his health failing, he was relieved from active duty in October and retired in 1863. Brevetted major-general in 1865, in 1869 he went to Nice, France, for his health. He wrote works on tactics, and was instrumental in organizing the Soldiers' Home at Washington.

ANDERSON, Rufus, American Congregational clergyman, and secretary of the American Board of Foreign Missions: b. North Yarmouth, Me., 17 Aug., 1786; d. Boston, Mass., 30 May, 1880. Having graduated at Bowdoin College in 1818, he studied theology at the Andover Theological Seminary, completing his course in 1822. In 1824 he became assistant secretary to the Board of Foreign Missions, serving as such till 1832, when he became full secretary. In this position he continued for 34 years, till 1866, when owing to his advanced age and failing health he retired. He inspected the missions in the Mediterranean in 1828-29 and again in 1843-44, the results of his tours of these years being chronicled in his Observations on the Peloponnesus and Greek Islands (Boston, 1830). He also visited the Indian Missions in 1854-55, and the Sandwich Islands in 1863. From 1869 to 1869 he was lecturer on Foreign Missions in the Andover Seminary. He with others founded the Mount Holyoke Female Seminary, at South Hadley, Mass., was for several years president of the board of trustees of Bradford Academy, Mass., and a member of the board of trustees of the Andover Theological Seminary. Besides his Observa-

ANDERSON, William Franklin, American clergyman: b. Morgantown, W. Va., 22 April, 1860. He studied at West Virginia University, graduated from Ohio Wesleyan University, 1884; Drew Theological Seminary, 1887; A. M. New York University 1890. He entered the ministry of the Methodist Episcopal Church, joining the New York Conference in 1887. From 1904 to 1908 he was corresponding secretary of the Board of Education of his Church. In 1908 he was elected bishop and is now resident bishop of Cincinnati. He is the author of 'The Compulsion of Love' (1903); editor The Challenge of To-day (1915). He also edited the magazine The Christian Student 1904-08.

ANDERSON, Ind., city and county-seat of Madison County; on the White River, 36 miles northeast of Indianapolis on the New York Central Lines, Pennsylvania and C. I. Railway. It is also the headquarters of the Union Tracton System, one of the most extensive systems of electric traction lines in the middle west. The power-house, costing $1,000,000, is the largest in the State, generating the power which carries the important city in northern and central Indiana. There is also a belt railway for factory service. The city of Anderson lies in the center of a rich agricultural region and is also an important manufacturing centre. Here was established one of the first and largest tin plate mills, introducing that industry into the United States. One hundred and fifteen factories are engaged in industrial enterprises where nearly every commodity known to trade is made. Chief among these are glass, iron, finished metal, steel springs, nails, automobiles, oil and gas engines, street cars, paper boxes, bottles, silos, air-planes, carriages, shovels, files, wind pumps, steel fence posts, magnetos and self-starters for automobiles, vacuum cleaners, rubber tires, bed springs, mattresses, motor trucks, enamel ware, encaustic tiles, etc. The United States census of 1914 recorded 114 manufacturing establishments of factory grade, employing 4,613 persons, of whom 3,905 were wage earners, receiving a total of $2,425,000 annually in wages. The capital employed was $11,757,000, and the yearly output was valued at $12,789,000; of this, $5,578,000 was added by manufacture. Natural gas was discovered in 1867, and while the flow has diminished to some extent it is still sufficient in supply for heating and small manufacturing purposes.

The city has eight banking institutions, with a capitalization of over $700,000, and deposits of $6,000,000; three daily papers; an excellent fire department, and own electric light, sewer, and water works and electric light and power department. The city debt has been paid off by these plants. Electric power can be furnished at one and one-quarter cents per k. w. and light at one and three-quarter cents per k. w. Among the prominent buildings are the court-

ANDERSON 661
ANDERSON—ANDES

house, erected in 1882 at a cost of $200,000, the government building for postal service, a Carnegie library, an orphan's home, a Y. M. C. A. constructed at a cost of $275,000. The prehistoric Mounds Park is located near Anderson, which has several smaller parks and playgrounds. There is an excellent school system with 13 public schools and one parochial, attended by over 6,000 pupils, and a fine new Manual Training High School, costing $380,000, with 700 pupils. Nearly all religious denominations are represented and well housed. The first settlement was in 1822, when, as the home of the Delaware Indians, it was known as Anderson's Town, the chief of the Delaware tribe being known as *Kik-tha-we-mund, or Anderson.* Anderson's Town became a county-seat in 1827. The name was changed to Anderson by act of the legislature in 1838, and in 1865 the city was incorporated. The city government is vested in a mayor elected every four years, a council from three wards, clerk, city comptroller and board of works. The value of taxable property is $11,000,000. Pop. (1910) 22,476; (1910) 30,000.

ANDERSON, S. C., city and county-seat of Anderson County. Three railroads, Blue Ridge Railroad (branch of the Southern Railway) and C & W. C. Railway and electric interurban, Piedmont & Northern, connecting Anderson with Greenville, Greenwood and Spartanburg, S. C. Centre of South Carolina division of the celebrated Piedmont section, also in one of the two asptic zones of the United States, it being a medical fact that wounds heal with twice the rapidity in these zones than elsewhere in the entire country. Fifteen churches representing all denominations. Eight schools, seven for white children and one for colored pupils. Number of pupils enrolled 1 Jan. 1916, white 2,656; colored 1,306. Number of teachers and instructors in the schools, white 55, colored 21. Value of buildings used for school purposes, not including leased property, white $132,000, colored $10,000. School enrolment 1 Jan. 1915, 3,381, increase in 1916, 581 pupils. Anderson College, a seminary for young women, value of buildings and equipment $10,000, employs a faculty of 16 teachers and instructors, attendance 115. Anderson County is second largest in the State in the production of cotton, corn and feed stuff. Ninc cotton mills within a radius of five miles of the courthouse, employing 3,200 operatives, three cotton oil mills and two fertilizer plants, foundry and machine works, two ice plants, two flour mills, three lumber mills, planing mills and variety works, mattress and spring bed factory, horse collar factory, patented steel shingle factory. The United States census of 1914 reports 25 establishments of factory grade, employing 1,254 persons, of whom 1,145 are wage earners, receiving $392,000 annually in wages. The capital employed was $2,575,000, and the value of the year's output was $1,904,000; of this, $1,200,000 was consumed by manufacturers in the state. The city has a gas plant with 16 miles of mains and daily capacity of 165,000 cubic feet; water works and electric lights, 20,000 horsepower plant located on Secoeca River, 35 miles of water mains, 9 miles of street railway, 7½ miles of paved streets, paid fire department, auto engine and two horse-drawn trucks, 1,215 telephones. Taxable property within the city limits, not including six of the city's largest industries, $1,150,000. Aldermanic form of government vested in mayor and six aldermen. Pop. (1900) 5,498; (1910) 9,654, percentage of increase 75 per cent; (1915) 17,500, percentage of increase 81 per cent. Increase for past 25 years of 479 per cent.

ANDERSONVILLE, Ga., a village of Sumter County, 62 miles southwest of Macon, noted as the seat, during the Civil War, of a military prison of the Confederate States. This prison was established in November 1863, and consisted of an unsheltered enclosure containing at first 22 acres, an area subsequently increased to 27. It was commanded by Gen. W. S. Winder, but the superintendent was one Henry Wirz, a Swiss. It has been stated that Andersonville was selected as a suitable site because secure against Federal raiders and generally considered healthful; but it was the laying waste of the fields of the South and the destruction of the means of transportation brought upon the Southern army and people great suffering, in which prisoners of war necessarily shared. It is true that rations were meagre for Confederate soldiers, to whose fate prisoners were legally entitled. But evidence shows that the conditions which prevailed at Andersonville were due to mismanagement and cruelty; such evidence including ample Confederate testimony, as for example that rendered by Dr. G. S. Hopkins and Surgeon H. E. Watkins, constituting a Confederate medical commission (1864), and that by Colonel Chandler of the Confederate War Department in an inspection report (5 July 1864). Into the enclosure as many as 33,000 prisoners were at times crowded, for the most part completely without shelter, and supplied with insufficient and unsuitable food. Between February 1864 and April 1865 there were received at the prison 49,485 prisoners, of whom 26 per cent, or over 12,000, died there. In the autumn of 1864 the Confederate government removed many to Florence, S. C., and Millen, Ga., where they fared decidedly better. Wirz was convicted in 1865 by a military court under an indictment charging him with injuring the health and destroying the lives of prisoners, and was hanged 10 November. The prison burying-ground was made a national cemetery. Consult Stevenson, R. R., 'The Southern Side; or Andersonville Prison' (1876); Chipman, 'The Horrors of Andersonville Rebel Prison' (1891); Schouler, 'History of the United States' (Vol. VI, 1899).

ANDES, ân-dez, the great mountain mass, or, as Humboldt called it, "the largest mountain chain of the globe," extending along the entire western coast of South America and turning toward the east in the regions between the equator and lat. 12° S. Prolongations of the chain still farther eastward and, on the other hand, toward the extreme south, cannot be dismissed contemptuously in the rôle of islands. However, essential to note the deflection below the Caribbean Sea and the interposition of the Antillean continent (compare article CENTRAL AMERICA) between the Andean Cordillera and the quite distinct and separate mountain sys-
tems of western North America. In regard to the derivation of the name Humboldt wrote: "Andez, in the Quechua language (which lacks the consonants d, f and q), Antis, or Ante, appears to me to be made from the Peruvian word "Tawantinsuyu," signifying copper or metal in general."

In the recent work by Professors Pirsson and Schuchert we find a condensed statement that supplies an outline of the geological story of the Andes as a whole:

"From the close of the Cretaceous, the Andes had been elevated and folded throughout the length of South America (4,500 miles), and during most of Tertiary time an extensive peneplain (in places it was a postmatuare surface) was being developed in the central Andes. Vertical uplift began in later Tertiary time, elevating this peneplain from 3,000 to 7,000 feet. This was in turn eroded to mature slopes and then was rapidly warped in Pliocene and early Pleistocene time, so that now the deeply dissected and dissected riding is not at a near elevation of 12,000 feet, though locally it varies between 6,000 and 15,000 feet. Upon it in the west immense lava flows and lofty volcanic cones, some of which attain a height of 21,000 feet above the sea. These are part of a great volcanic field whose development began in the early Tertiary and was completed soon after the Pliocene uplift began. The central Andean plateau is the second highest in the world, being exceeded only by that of western Tibet on the north of the Himalayas of India, where the intermontane plains range from 14,000 to 17,000 feet above the sea."

We shall now endeavor to obtain clear views of the five chief divisions of this great uplifted region, namely, the southern, the south central, the central, the equatorial and the northern.

The mountain region of Argentine Patagonia, which first claims attention in the far southern division, is very different from the Pampa region in topography, climate and vegetation. The rainfall is very much heavier and all the conditions of the country are changed accordingly. Sheep-raising, which is the great industry of the Pampas, is not practicable in this area. The rainfall is not sufficient to support sheep, whereas cattle-raising, which is unsuccessful in the drier part of the Pampas, will always be a principal industry in the Cordillera. Forests, of which there is no vestige in the Pampas, clothe the mountain slopes of the Andes. In the Pampas running streams are rare, but in the Andes they constitute one of the principal natural features and, gathering in beautiful lakes or in great rivers, determine the future of the region to be one of manufacturing industries based on water-power (Compare the extended and excellent study of this region by Mr. Willis, one of the best of recent works in this field. In several of the following paragraphs a few items of permanent interest from the same source are given, with minor modifications.

The mountain chain of the Andes, attaining altitudes of more than 23,300 feet in its highest peaks, has impressed upon the minds of students the idea of an enormous mountain barrier, distinctly separating the lowlands of the Pacific coast from the vast low plains of eastern South America. So fixed is the conception that it has affected the deliberations of statesmen and the relations of nations. The conception of a dividing wall, nowhere easy of passage and in many places impassable, was the fundamental idea according to which the boundary between Argentina and Chile was to have been traced (see CHILE). Throughout the greater part of its extent the conception held true, and the engineers traced a well-defined crest which, following the high summits of the Andes, coincides with the divide of the waters between the Pacific and the Atlantic. But from lat. 38° southward the topographic conditions were found to be very different. In this portion of the Cordillera it spreads out and divides into parallel mountain ranges. Some of the rivers rising in the extreme west of the mountain-belt flow to the Atlantic; others, rising east even of the eastern Cordillera, in the Pampas themselves, flow westward across the entire zone of the Andes to the Pacific. Here was confusion for the treaty-makers, since the numerous mountain peaks encountered, in place of a mountain-wall, a labyrinthish of heights and valleys pierced in many places by rivers which wound in zigzag courses, now toward one ocean, now toward another; and a boundary as far as the highest crest of the Cordillera was found to diverge widely from a boundary traced on the continental divide between the Atlantic and the Pacific. Fortunately for both Argentina and Chile, the treaty-makers had provided that any dispute should be settled by arbitration. In 1902, after 20 years of discussion, the arbitrator, King Edward of England, gave his award in favor of a compromise line. The foregoing statement makes it evident that the Andes of northern Patagonia constitute not a simple mountain ridge but a broad zone, including both mountains and valleys and traversed by large rivers. The summits whose altitudes most closely approach uniformity have been sculptured by erosion from the broad plateau-like mass of the older rocks of the Andes, whereas most of the isolated peaks which rise more than 7,333 feet above sea are volcanic cones built up on the plateau. The most renowned of these is El Tronador ("The Thunderer"), 11,533 feet above sea, which received its name from Friar Menendez, about 1730, who, after seeing it as the mountain that is always thundering. At the foot of this great peak lies the most profound canyon and lake of the region, that of Nahuel Huapi. This southern division of the Andes may be subdivided into two distinct areas, and the distinction may be expressed in the simple statement that in one the valleys extend east and west across the mountain zone, whereas in the other they range longitudinally from north to south within the Cordillera. The former area comprises the stretch of the Andes from lat. 38° to 41°, from Lago Alumine to Lago Nahuel Huapi. All but one of the streams within it rise in the western Cordillera and flow eastward to join their waters in the Rio Colloncurá and the Rio Limay, which flow in the depression that lies along the eastern base of the Andes. Lago Lacar, though its valley once belonged to this Atlantic family, has turned away and now discharges its waters across the western range down the Pacific slope to the Chilean lakes. In this area high transverse ridges extend eastward between the drain-
ANDES

age basins, and some of them attain greater elevations near their eastern extremities than at the western. They divide the area into individual basins and more or less effectively obstruct the passage from one to another within the western part of the Andean plateau. Where the valley floors range from 2,000 to 2,866 feet in altitude above the sea, one must rise to passes that attain 3,333 or 4,000 feet in order to cross from one valley to the next. Each of the deep transverse valleys harbors one or more lakes, which, like the lake of Switzerland and northern Italy, lie in deep basins sculptured by the rock-laden ice of glaciers, descending from the adjacent heights. Their shores are everywhere picturesque and in many places precipitous. About their lower eastern ends are piled the glacial moraines of an ice period which is still represented in the little glaciers that linger about the high summits. In each of these valleys, at a distance of several kilometres below the moraines just mentioned, is a much older glacial terrace which marks the stern northern limit attained by the ice that filled the valleys during a still earlier glacial epoch. Thus these valleys, descending from the western Cordillera to the lowland that intervenes between the Andes and the high plains of the Pampas, range in character westward from deep gorges in the mountains to beautiful lake basins and wide stretches of gravel plains. Their waters flow in the direction of the western winds, in the direction in which the air currents become dryer as they unload their moisture upon the mountains. The vegetation changes accordingly, and the streams, which gather their headwaters from the deep forest shades of the mountain slopes and which linger in the cold rock-bound lakes of the transverse valleys, flow on in the broad sunlight of the treeless grey Pampas. Strong historic interests centre about localities in this area. The paso de Villarica, which crosses the Cordillera in the north, was traversed by Francisco de Villagrán in 1553, the year in which Valdivia, the conqueror of Chile, after 12 years of struggle with the Indians, was defeated by them, taken prisoner and killed. Villagrán was undoubtedly the first European to cross the southern Cordillera. Subsequently Spanish captains, missionaries and embassies dispatched to negotiate with the Indians, sought, prayed or held council in the valleys of Lagos Huichulafquen, Lolog and Lacar.

The section of the Cordillera south of Lago Nahuel Huapi includes a central valley which traverses it north to south, separating the high western and eastern ranges. From Lago Nahuel Huapi itself a deep pass, which is cut nearly to the level of the lakes, leads to Lago Gutierrez, whose waters flow by way of Nahuel Huapi to the Atlantic. East of Gutiérrez is the Sierra de la Ventana, and west of it El Catedral, both prominent summits among the Andean heights, yet between them one may pass from Lago Gutiérrez to Lago Mascardi, over a gravel plain which, although it scarcely separates the two lakes, divides the waters of the eastern and western oceans. Here the continental divide descends from El Catedral, passes across the plain between the two lakes, and ascends again to the summit of the Sierra de la Ventana. El Bolsón and its neighbor, the Hoyo de Epuén, are the deepest valleys in this section of the Andes, lying between 900 and 1,000 feet above the sea and 1,333 feet or more below Lago Mascardi. The temperature naturally changes with the altitude. Frosts, which are common in the northern portion of the central valley, are rare during the summer in El Bolsón, El Boly sometimem characterized as a little paradise in the heart of the snowy mountains. In the south rises the mountain group of Cerro Tres Picos and its attendant heights, stretching clear across the mountain zone as a promontory of the western Cordillera. On the eastern side of this promontory, a valley which follows southward along the summit of the eastern Cordillera, sinks into the Pampas and, swinging eastward outside of the Andes, is marked by the ridge of a glacial moraine surrounding the basin of Cholila. South of the heights of Tres Picos a system of valleys tributary to the Río Fetalafu and thus to the Pacific lies between the snowy western Cordillera and the treeless heights of the Cordón de Leque and the Cordón Esquel, which here represent the stern southern limit of the mountain zone between the ranges is wider here than farther north, the valleys themselves are in general broader, and the western chain is more dominant as compared with the eastern. Communication across this western range is more difficult than it is farther north, and it has been suggested that this circumstance influenced the arbitrator in tracing the boundary upon the western range and giving the valleys of Cholila, Riva Rivadavia, Lago Fetalafuquil and 16 de Octubre to Argentina. These valleys are rich, fertile and, owing to the bracing mountain climate and pure, swiftly flowing streams, healthful. The Bolsón, the Hoyo de Epuén, Cholila and 16 de Octubre will support prosperous communities and play an important part in the future development of the Andes.

The population in this essentially borderland far southern division is composed of the varied elements that usually gather on a frontier and cannot be disregarded in planning for the future occupation of the country by a more stable community. Under the treaty of 1881 defining the international boundary, Chile for 20 years laid claim to nearly all the mountain zone of the Andes, and Chileans were encouraged to claim, settle and cultivate the lands he claimed with the Indians. This it was not difficult for men accustomed to the mountain trails in the forests of southern Chile to cross the passes which lead into the eastern valleys of the Andes. There is along the boundary no conspicuous natural barrier greater than those which the Chilean Indian or half-breed with his active horses and cattle constantly traverses in his own country. Quite naturally, then, the Chilean element is large.

The Andean area which according to Mr. Willis contrasts peculiarly and favorably with other sections of Argentina lies between lat. 38° and lat. 44° and is set apart by such climatic conditions that it may eventually be occupied by energetic people of the temperate zone and become the site of manufacturing industry on a large scale. Within approximately 20,000 square miles, characterized by moderate summer temperatures, cold yet not severe winters, abundant rainfall and such remarkable scenery, that, in brief, it may be called the Argentine Switzerland.

Next, as above promised, we proceed to an
account of the south central division, in which the most interesting region is that extending eastward from the Chilean capital city.

The Cordillera in this part consists of two principal ranges, the passes across which attain respectively an elevation of 13,210 and 14,365 feet. The first great line (consisting, of course, of many subordinate ones) is called Pequén. It divides the waters of Chile and Argentina. To the eastward, a mountainous and elevated region separates it from the second range (called the Portillo) overlooking the Pampas (see article South America—Geology).

The geological structure of the mountains, at this point of observation, is very briefly sketched, and first that of the Pequén or western line; for the constitution of the two ranges is totally different. The lowest stratified rock is a dull red or purple claystone porphyry, of many varieties, alternating with conglomerates, and breccia composed of a similar substance; this formation attains a thickness of more than a mile. Above it there is a thin sandstone, passes into, and is replaced by red sandstone, conglomerates and black calcareous clay-slate. Even at the very crest of the Pequén, at the height of 13,210 feet, the black clay-slate contains numerous marine remains, amongst which a gryphaea is the most abundant, likewise shells, resembling turritella, terebratula and an ammonite. The formation probably is of the age of the central parts of the secondary series of Europe. These great piles of strata have been penetrated, upheaved and overturned, in the most extraordinary manner, by masses of injected rock, equaling mountains in size. On the bare sides of the hills, complicated dikes and wedges of variously-colored porphyries and other stones, are seen traversing the strata in every possible form and direction; proving also, by their intersections, successive periods of violence. The rock which composes the axis of these great lines of dislocation when viewed at a distance resembles granite, and might be termed a granite by those who have not the theory of metamorphism to contain any quartz; and instead of ordinary feldspar, albite. The metamorphic action has been very great, as might have been expected from the close proximity of such grand masses of rock, which were injected when in a liquidified state from heat. When it is known, first, that the stratified porphyry and features in the scenery of the Andes which struck him most were: The flat fringes sometimes expanding into narrow plains on each side,—the valleys,—the bright colors, chiefly red and purple, of the utterly bare, and precipitous hills,—the grand continuous wall-like dikes,—and the strongly marked strata which, when nearly vertical, form the most picturesque and wild pinnacles, but where less inclined, great massive mountains; the latter occupying the outskirts of the range, and the former the central parts:—lastly, the smooth conical piles of fine and bright colored detritus, which slope at a high angle from the flanks of the mountains to their bases, some of the piles having a height of more than 2,000 feet. The quantity of crumbling stone on the Cordillera is very great. Occasionally in the spring masses of such matter slide down the mountains, and cover the snow drifts in the valleys, thus forming natural icehouses the elevation of which may be far below the limit of perpetual snow accumulation.

We now come in these observations made in the south-central division of the Andes to the second range, which is of even greater altitude than the first. Its nucleus in the section seen by Mr. Darwin when crossing the Portillo Pass consists of magnificent pinnacles of coarsely-crystallized red granite. On the eastern flank a few patches of mica slate still adhere to the unstratified mass and at its foot a stream of basaltic lava has burst forth at some remote period,—perhaps when the sea covered the wide surface of the Pampas. On the western side of the axis, between the two ranges, laminated fine sandstone has been penetrated by immense granite dikes proceeding from the central mass, and has thus been converted into granular quartz rock. The sandstone is covered by other sedimentary deposits, and these again by a coarse conglomerate of vast thickness. All these coarse mechanical beds dip from the red granite directly toward the Pequén range, as if they passed beneath it; though such is not the case. Examination of the pebbles composing this conglomerate (which betray no signs of metamorphic action) disclose perfectly rounded masses of the black calcareous clay-slate with organic remains,—the same rock which is found on the Pequén. These phenomena compel us to arrive at the following conclusion: That the Pequén existed as dry land for a long period anterior to the formation of the secondary, and that, during this period, immense quantities of shingle were accumulated at its submarine flank. The action of a disturbing force then commenced: These more modern deposits were injected by dikes, altered by heat, and tilted toward the line whence, in the form of sediment and pebbles, they had originally proceeded,—thus making the offspring at first appear older than its parent. This second, grand and subsequent, of elevation is parallel to the first and more ancient one.

The central division or "Central Andes"—the name proposed by Mr. Bowman for a group of closely related natural regions that lie between 12° and 20° south latitude — may now, in turn, receive brief attention. Here the dominating features are two great plateaus and a central basin between them. These plateaus, trending north and south, are depicted on the physical maps as two roughly-parallel mountain chains, commonly referred to as the eastern and western [central] Andes. In Peru, these eastern-central Andes are variously designated as the Cordillera Oriental, Cordillera of the East, or the Cordillera Real, the latter being an improper
extension of the specific term applied to the high, white, truly "royal and regal" mountain ranges near La Puna, that is terminated on the south by Illimani and on the north by Sorata. The west-central Andes are usually called the Maritime Cordillera, a generic term applied to the aggregations of individual peaks and short volcanic ranges which surmount the western plateau. In addition, specific terms are applied to the culminating ranges. Thus, on the boundary between Chile and Bolivia, lat. 20° S., there is the Cerro de Sillillica, just as in southern Peru the mountain knout at Vilcanote is called the Cerro de Vilcanote. In the eastern plateau the exceptional heights or the crests of the declivities that border basins and valleys are given such specific names as the Tunari de Cochabamba, Cerro de Cliza and Cordillera de Potosí. Between the two great Andine tablelands and their superimposed peaks and ranges is the central basin or plateau of lower altitude than the bordering highlands, separated from the latter by the two great roughly-parallel scarps of marked rectilinear quality often for long distances. This is the altiplano of Bolivia: a broad, interior drainage basin, with its outlet to the sea, and therefore technically a part of the true desert area of the world. On the north the bordering scarps converge in lat. 14° S., enclosing Lake Titicaca, whose waters discharge by way of the Desaguadero River into Lake Poopó, only to be discharged in turn into the Salar de Coipasa and the adjacent salars to the south. Here and there the otherwise flat basin floor is broken by piles of volcanic detritus, lava flows from occasional centres of igneous activity, or by ancient and highly crumpled sediments, as where the upturned edges of slates and quartzites rib the hills back of the port of Desaguadero. East of the central Andes, as indeed along the whole eastern front of the Andine Cordillera, from the Argentine Pampas to the Llanos of Venezuela, the dissection of the adjacent highlands has been accompanied by the formation of extensive piedmont deposits. The western plateau descends by a relatively smooth slope to the coastal deserts and Patagonia. Between these deserts and the Pacific shore are low mountain ranges of complex geologic and physiographic character, the coast ranges of Chile and Peru.

A generalization by Mr. Bowman is to the effect that, in the field of human geography, the central Andes form an exceedingly important group. It is impossible to find elsewhere in South America an area of equal size with so great a variety of life. The density of population ranges from 100 to the square mile in the vicinity of Cochabamba, Bolivia, to one-tenth to the square mile in the Territorio de los Andes, Argentina. Occupations vary between such extremes as, on the one hand, the intensive agriculture of irrigated valleys, and on the other the pastoral nomadism of the pampean meadows: customs are, in one place, those of modern civilized people, but, in another, those that bespeak an unmixed barbarism. It is the extremely wide range in the physical conditions of the central Andes that excites the interest of the geographer. The principles of geographic science rest upon the theory that man is to an important degree the product of the earth. In the varied physical environment of this great tract we should therefore expect climate and relief to exercise a high degree of influence upon the population. A study of its people should demonstrate both the scientific nature of geography and the wide application of its laws.

The fourth division, according to the order we are following from south to north, is the equatorial; and here we notice the points in which this region is sharply differentiated from the other divisions. Edward Wymper, the distinguished explorer, in his 'Travels' wrote: "In a very short time it was found that there were things to be learned as well as discovered in Ecuador. We ascertained that Chimbórazo streamed with glaciers, although high authorities state that it has none; and in course of time it became apparent that the two parallel Cordilleras, which according to geographers are the great feature of the country, do not exist. By an equatorial belt, so to speak, the parallel cordilleras observed hitherto (in this article) are constricted. But these soon diverge above the line, and more than reassert their individualism before yielding to what power exists within the great Cordillera, already mentioned in the first paragraph. The axis of the Andes in Ecuador runs nearly north and south; and toward the western edge of the main chain there is indeed, this author admits, a certain sequence of peaks more or less in a line, East of these summits there is a succession of basins of different dimensions and at various elevations. The nearest mountains on the eastern side occur at irregular distances. There is no such thing as one great valley in the interior of Ecuador. The mountains Pasochoa and Rumiñahui are the only two which lie parallel to the others on the western side, all of the great Andes of the equator rise out of, or upon and above, the main chain, which was created by upheaval at some remote date (compare what has been said above in respect to time). With the exception of Saragua, they are all mountains of volcanic origin, although they may not all have been active volcanoes. It seems probable that there were newer Tampasch and Antisana in one moment. Some that are now extinct have evidently been alive; while others, like Pichincha and Tungurahua, are either dormant or are not perpetually in eruption. Cotopaxi and Sangai alone are in a state of constant activity, and these two mountains seem to be increasing their elevation. Cotopaxi shows no signs of approaching decrepitude, and for many centuries yet to come it may remain the highest active volcano in the world. In general the altitudes here are less by several thousand feet than those of the highest peaks in Chile and Bolivia. Of the extinct volcanoes, Cayambe, Antisana and Chimbórazo are the most important. There are no records of eruptions of Chimbórazo. It must have been an extinct volcano for many ages. The crater, the thickness of the ice-cap at its summit and the large size of its glaciers, the ruin and erosion of its lava-streams and the height vegetation has attained upon its flanks, are all indications that its activity ceased at a remote period. Particularly interesting are the observations of temperatures on summits in Ecuador. On 4 January at 5:15 P.M. the temperature on the summit of Chimbórazo (height 20,498 feet)
was found to be 21° F., while at Guayaquil (6 p.m. on the same day) it was 85° F. On 18 February at 6:20 a.m. the temperature on the summit of Cotopaxi (height 19,613 feet) was 27° F. The course of temperature through the month at 11 a.m. the temperature was 82° F. On 10 March at 10:11:40 a.m. the temperature on the summit of Antisana (19,335 feet) was 44°-46° F., while at Guayaquil on the same day at 11 a.m. it was 80° F. In each case the observations were made at the same time on the summit of the mountain.

The fifth division, the northern, might also be called northern and northeastern. We have already, by anticipation and quite unavoidable, given main facts touching the partition and trend of the Andes in the region between the equator and lat. 12° N. Humboldt described the eastern Cordillera of Colombia—the chain which stretches toward Bogotá; the chain which lies between the Magdalena and the Cauca, which he called the central Cordillera of New Granada (Colombia); and the chain which continues the Cordillera de la Costa from the basin of Almaguer, which he designated the Western Cordillera of this northern division. This tripartition of the Andes (lat. 1 1/4°-2 3/4°) resembles that which takes place in the mountains of the Huanuco and Pasco in lat. 11° S.; but the most western of the three chains that bound the basins of the Amazon and the Huallaga is the least elevated; while that of the shore (the Western Cordillera) is the least elevated of the three chains of the Republic of Colombia. The eastern chain of the Andes of Colombia preserves its parallelism with the other two for a considerable distance; but beyond Tunja, in lat. 5 1/8° N., it inclines more toward the northeast, passing somewhat abruptly from the direction N. 25° E. to that of N. 45° E. It is like a vein that changes its direction. The tripartition of the Cordilleras, and, above all, the spreading of their branches, have a vast influence upon the prosperity of the inhabitants. The diversity of the supposed table-land, and climates gives variety to the agricultural productions as well as to the character of the people.

MARRION WILCOX.

ANDESINE, an-děz-in, a triclinic feldspar, intermediate in composition between albite and anorthite. Albite and anorthite are isomorphous, and andesine includes those mixtures of the two in which the ratio of albite to anorthite ranges from 1:1 to 3:2. Andesine may be described as an anhydrous silicate of sodium, aluminum and calcium. Its hardness is from 5 to 6 and its specific gravity is about 2.68. In color it is white, grey, greenish, yellowish or pink. It was first found in the Andes (whence the name), but has since been observed in Alaska, in Iceland and in other localities. In the United States it occurs at Sanford, Me.

ANDESITE, an-děz-it, a common volcanic rock, consisting of a triclinic feldspar (such as andesine) mixed with hornblende or augite and sometimes also with quartz. It varies in color from green to gray and occasionally has a purplish cast. It is difficult to define andesite accurately because basalt, andesite and trachyte are similar in composition, and intermediate varieties exist, which, with the range of the three classes, form an almost continuous series. Andesite is more fusible than trachyte, but less fusible than basalt.

ANDIRA, an-di-rā, a genus of leguminous typical American trees, with fleshy plum-like fruits. The wood is well fitted for building. The bark of A. inermis, or cabbage-tree, is narcotic, and is used as an anthelmintic under the name of worm bark or cabbage bark. The powdered bark of A. araroba is employed as a remedy in certain skin diseases, as herpes.

ANDIZHAN, an-di-jān, Russia, city and capital of the district of the same name, in the province of Ferghana, Russian Turkestan, 42 miles from Margelan, the provincial capital. Andizhan is the eastern terminus of the Trans-Caucasian Railroad. It is the centre of an immense cotton-raising district, whence Russia received three-fourths of all the cotton used in the empire. It came into the possession of Russia in 1875. In 1902 the city was totally destroyed by an earthquake which killed over 5,000 of the 47,000 inhabitants. In 1916 it had 82,235 inhabitants.
ANDOCIDES, an'ÔdÔs´i-dêz, an Athenian orator: b. 467 B.C.; d. about 393 B.C. Active in public affairs, he was four times exiled; the first time along with Alcibiades, for profaning the Eleusinian mysteries. Three of his orations are extant.

ANDORRA, an'ÔdÔr´râ, a small republic in the eastern Pyrenees between Ariège, a department of France, and Lérida, a province of Spain. It is about 80 miles west from the Mediterranean coast, and 100 miles north of Barcelona. Its area is 173 square miles and the population 5,231. It is under the joint suzerainty of France and the Spanish bishop of Urgel. It is governed by a council of 24 members elected for four years by the heads of families in each of its six parishes. The council elect a first and second syndic to preside; the executive power is vested in the first syndic, while the judicial power is exercised by a civil judge and two magistrates (viguiers). France and the bishop of Urgel appoint each a magistrate and a civil judge alternately. A permanent delegate, the vicar apostolic of the Pyrénées Orientales, moreover, has charge of the interests of France in the republic. The Andorra valley is enclosed by mountains. There is excellent pasture land, on which cattle are raised. FRUIT trees and vineyards flourish, and iron and lead are mined in the mountains. Much of the grain of the republic comes from France. The manufacture of coarse cloth is the chief industry. Wool, ores, cloth, and dairy produce are exported in small quantities. Andorra received its independence from Charlemagne in recognition for its services to him in his campaign against the Moors, and in 1278 was transferred to the Comte de Foix and the bishop of Urgel. During the French Revolution the French declined the annual tribute from Andorra, but in 1806 the former relation with France were resumed and cereals from France were admitted free in consideration of an annual payment of 960 francs. The bishop of Urgel receives an annual sum of 400 francs. Military service is compulsory for all citizens between the ages of 16 and 60. The capital is Andorra with a population of 1,000. Consult Deverell, 'History of the Republic of Andorra' (Bristol 1885); Johnson, V. W., 'Two Quaint Republics, Andorra and San Marino' (Boston 1913); Spender, H., 'Through the High Pyrénées' (London 1898); Tucker, 'The Valley of Andorra' (Cambridge, Mass., 1882).

ANDOVER, England, a market town in Hampshire, on the river Anton, 12 miles west of Winchester. Its large parish church was built about 1850 on the site of a Norman prebendary. The Massachusetts Andover was named in honor of the Hampshire town. It manufactures iron and malleable. There are remains of Roman villas in the neighborhood. Pop. (1911) 7,596.

ANDOVER, Mass., town in Essex County, including several villages south of the Merimack, 22 miles north of Boston, on the Boston & Maine Railroad, and on the Shawsheen River. It is the seat of the Phillips Academy for boys, founded in 1778, and of the Abbot Academy for young ladies. It has a public library. The government is administered through town meetings, at which free selection of officials is made and as executive officers, appropriations made and other civic affairs attended to. Andover was first settled in 1643 and was incorporated three years later. During the witchcraft agitation, in 1692, three citizens of Andover were executed at Salem and several others placed on trial and acquitted. On 5 March 1698 it was attacked by Indians, who slaughtered five of the citizens and set fire to a number of buildings. Andover has manufactories of linen, twine, shoe-thread, woolen goods, ink, brushes, and rubber goods. Pop. (1910) 7,301. Consult Abbot, 'History of Andover' (Andover 1829) and Bailey, 'Historical Sketches of Andover' (Boston 1880).

ANDOVER THEOLOGICAL SEMINARY, Cambridge, Mass., the oldest theological institution in New England, founded in 1807 and opened for instruction the following year, at Andover, Mass. The original founders were Samuel Abbot, Mme. Pheobe Phillips and her son John P. of Andover. The associate founders were William Bartlet and Moses Brown of Newburyport, and John Norris of Salem. The primary aim of the founders was to provide for the professional education of ministers for the orthodox Congregational churches, and, in pursuance of this aim, men of different theological views (Old Calvinists and Hopkinsians) have been trained. Some of the professors have been Leonard Woods, Moses Stuart, Ebenezer Porter, Edward A. Park, Austin Phelps, Joseph Henry Thayer, Egbert C. Smyth, and William J. Tucker. In 1908 the seminary celebrated its centenary with appropriate exercises. At that time it had given instruction to more than 3,500 students and had sent out 2,172 graduates. The same year the seminary was removed to Cambridge and affiliated with Harvard University, although retaining its own faculty and its separate corporate existence. Instruction is given in the two institutions, and the libraries have been combined into one, the Andover-Harvard Theological Library, which contains about 107,000 volumes and 51,000 pamphlets. The total endowment of the two commercial buildings and lands, is about $1,000,000. The seminary is open to all Protestants without discrimination. Only college graduates are eligible for the degree of bachelor of divinity. The annual tuition fee is $150, which entitles the students to admission to Andover and Harvard courses alike. The faculty consists of six professors (1916). For the early history of the seminary consult Leonard Woods' 'History of the Andover Theological Seminary' (Boston 1885).

ANDRADA Y SYLVA, an-drâ´da é sil´âvâ, Bonifacio José D., Brazilian statesman: b. Villa de Santos 1765; d. Niterói 1838. In 1800 he was appointed professor of geology at Coimbra, and soon after inspector-general of the Portuguese mines and in 1812 he was made perpetual secretary of the Academy of Lisbon. Returning to Brazil in 1819, he urged Dom Pedro I to recall the Lisbon court and was appointed one of his ministers in 1821.
When the independence of Brazil was declared Andrady was made Minister of the Interior and of Foreign Affairs; and when it was established he was again elected by the Constituent Assembly, but his democratic principles brought his dismissal from office, July 1823. On the dissolution of the Assembly in November 1823, he was arrested and banished to France, where he lived in exile near Bordeaux till, in 1829, he was permitted to return to Brazil. But being again arrested in 1833, and carried for intriguing on behalf of Dom Pedro I, he passed the rest of his days in retirement.

ANDRADITE (named for the Portuguese mineralogist, d'Andrado), the common or black garnet. See GARNET.

ANDRAL, an'dral', Gabriel, French physician and pathologist: b. Paris, 6 Nov. 1797; d. 13 Feb. 1876. In 1827 he was called to the chair of hygiene, in 1830 to that of pathology in the University of Paris. Andral may be said to have been the first to apply an analytical and inductive method to pathology. His 'Medical Clinic' (1824) established his reputation, and his 'Syllabus of Pathological Anatomy' (1854) was equally successful. Other works of importance are his 'Essay on Pathological Haematology' (1843); 'Course in Pathology — Internes' (1836–37); and 'Investigations into the Modification of the Relative Proportions of Haematogenous Elements' (1845). He was a Traité élémentaire de pathologie et de thérapeutique générale (1843).

ANDRASSY, an-drä-shé, the name of an Hungarian noble family bearing the title of Gróf (German, 'count'), equivalent to 'count or 'earl.' The full name is 'Andrassy von Csek-Szent-Király und Kraszna-Horka.' The family was Andorás, one of the leaders in the Magyar immigration in the 9th century. There are two branches of the family, which received its patent of nobility in 1779. Several Andrassys played more or less important parts in politics and literature. The most distinguished member of the family was Count Julius Andrassy (q.v.), who died in 1890.

ANDRASSY, an-dra-fi, Julius, Count, Hungarian statesman: b. Zempen, 8 March 1823; d. 18 Feb. 1890. He took part in the Revolution of 1848 and was condemned to death, but escaped and went into exile. Appointed Premier when self-government was restored to Hungary in 1867, he became Imperial Minister for Foreign Affairs in 1871; drew up the famous Andrassy note to the Porte in 1876; was a conspicuous member of the Congress of Berlin in 1878; negotiated the German-Austrian alliance with Bismarck in 1879, retiring the same year from public life. The Andrassy 'Note' was a declaration relating to the disturbed condition of Bosnia and Herzegovina, formulated by the governments of Austria, Russia and Germany, with the approval of England and France. It commanded the establishment of religious liberty, the application of local revenues to local purposes, and other reforms, and was formally presented to the Porte, 31 Jan. 1878. As a young man he was attached to the Austro-Hungarian embassies in Berlin and Constantinople, became 'resident officer' in a hussar regiment and was elected to the Hungarian Reichstag in 1884. He was nominated under-secretary in the Department of the Interior in 1892, Minister of Education in 1893, and Minister at the Court of St. James in 1894. On the resignation of the Wekerle Liberal Cabinet in December 1894, Baron Banfi became Premier, and Andrassy retired from office. Banfi's stormy tenure of office ended in February 1897, on which Andrassy returned to the ranks of the Liberal party after having seceded from it the previous year. He supported in turn the Szell, Hedervary and Tisza administrations, the last of which he assisted to wreck in 1905. The Emperor-King (the late Francis Joseph) invited Count Andrassy to form a new ministry, but the sovereign firmly declined to make the concessions which Andrassy considered indispensable, the chief of which was the adoption of the Hungarian language of command in the Hungarian portion of the Dual army. All efforts to form an Andrassy ministry failed; the monarch spent 16 days in Budapest vainly endeavoring to settle the crisis. Count Stephen Tisza, though out of office, was invited to act as Premier till May, begging to be relieved of the duties. Representing the coalition leaders, Count Adrassy visited the Emperor at Vienna to set forth the Hungarian program; being told that further military concessions were impossible, he withdrew from the negotiations, and Baron Fejervary became Premier, but tendered his resignation a few days later. In January 1906 the Emperor and Andrassy met to discuss the claims of the coalition; the terms demanded by the latter were rejected, the Diet was dissolved and the Parliament building cleared by troops. In the end Dr. Wekerle returned to power with a coalition or compromise cabinet in which Andrassy became Minister of the Interior, holding the office till September 1909. He was then offered the premiership, but refused it; in 1911 he went over to the opposition in the Chamber. At the outbreak of the European War Count Stephen Tisza—who with Count Berchtold was largely responsible for Austro-Hungarian policy against Serbia—again held the reins of office. Andrassy, Apponyi and Karolyi, the leaders of the so-called 'Independence Party,' strongly supported Tisza's war policy; in July 1916, however, a section led by Count Karolyi broke away from that policy, the latter having quarreled with Andrassy and Apponyi. This notable movement represented the very first break away from the Teutonic war policy by any non-Socialist party of either of the two dominant Central Powers. President Wilson's reply to the German peace proposals in February 1917 led Andrassy to assert in a newspaper article that Austria and her allies could not accept any demands which would result in a dismemberment of the Dual Monarchy. He and Count Apponyi interposed a determined 'no' when Tisza expressed himself still willing to negotiate for peace with the Allies. In April, Andrassy engineered a movement to boycott Tisza for refusing to consider veiling reforms. He scoffed at the proposal of cabinet posts to members of the opposition. Count Apponyi supported the agitation and when, in May 1917, the Emperor Charles refused his assent to the franchise proposals of
Count Tisza, the latter resigned and Andrassy was entrusted with the formation of a new Hungarian cabinet, 29 May 1917.

Count Andrassy is credited with pro-British sentiments; he speaks excellent English, cares nothing for public opinion, and is deeply en-
grossed in all modern history and constitutional law. Honesty in politics is said to be a passion with him. He has written a great many newspaper and magazine articles in French, German and English, as well as in his own tongue, and published two important works, 'Ungarns Ausgleich mit Oesterreich vom Jahre 1867' (1897), and 'The Development of Hungarian Constitutional Liberty,' of which an English translation appeared in Lon-
don (1908).

**ANDRASSY NOTE.** a memorandum drawn up by Count Andrassy (q.v.) on behalf of Austria, Germany and Russia, and presented to the Turkish government in December 1875. It set out certain reforms, which the Porte accepted with one exception, as a means of checking the revolt of the Sultan's European subjects. The British government supported the note. See BERLIN MEMORANDUM.

ANDRÉ, ân'dra or ân'dri, Charles, French astronomer: b. Chauny 1842. In 1877 he was appointed professor of astronomy at Lyons and director of the observatory in that city, for which he visited the Rocky Mountains and Australia to observe Venus in transit. He is the author of 'L'astronomique pratique et les observations en Europe et Amérique depuis le milieu du XVIIe siècle jusqu'à nos jours' (1874-82).

ANDRÉ, John, British soldier: b. London, of Swiss-French parentage, 1751; executed at Tappan, N. Y., 2 Oct. 1780. His fate is peculiar; failure has given him a monument in Westminster Abbey from his own side, and undying ro-
manitic pity from the other; where success would have loaded him with immortality to the one, and made the other glad to forget him. He entered the English army at 20, and was sent to Canada in 1774; November 1775 he was taken prisoner at Saint John's by Montgomery's expedition and sent to Lancaster, Pa. Ex-
changed, January 1776. In December 1776, he was made cap-
tain in 1777, aide to Gen. Charles Grey, major in 1778, and in 1779 aide to Clinton and adjutant-general of the forces in America. He owed this rapid advancement, as he has owed his enshrinement by posterity, to his extraordi-
nary and somewhat feminine charm of person and manner, which won the hearts not only of his chiefs and associates, but of the very offi-
cers who put him to death. He was full of wit and vivacity, a most entertaining companion, a good amateur musician and artist and a fluen-
tent, pleasing writer, and his literary qualities led to his selection as Clinton's adjutant and secretary. He was also a fair society poet, known in London literary circles; and his cause-sky's in verse, 'The Cow Chase,' 'Yankee Doodle's Expedition to Rhode Island,' 'The Affair Between Generals Howe and Gadsden,' etc., were great favorites in the English army. During that army's winter in Philadelphia, 1777-78, André was the promoter of and a chief actor in all the festal occasions and social events, including the 'Mischianza,' a pageant in honor of Howe on his departure.

In 1780 it fell to his official duty to conduct Clinton's negotiations with Benedict Arnold (q.v.) for the betrayal of West Point, the key of the Hudson, the command of which Arnold had solicited in order to betray it. Both sides were wary and suspicious of each other, and Clinton was uncertain of his correspondent's identity or whether the affair might not be a trap. After various abortive attempts at a secret interview, André, on 19 September, went as 'John Anderson' up the Hudson in the sloop-of-war Vulture, near 'Tory's shanty,' near Fort Montgomery. The plan was to meet under a flag of truce, on pretense of arranging as to the confiscated property of the loyalist Col. Beverley Robinson, whose house was Arnold's headquarters; but this too failed, and finally on the night of 21 September Arnold induced a loyalist farmer, Joshua Smith, to carry a packet from Robinson to 'Anderson' on the Vulture. André returned with Smith, was met on the shore by Arnold, and after a private conference the two generals and eight house, where they spent the night and part of the next day arranging the betrayal, which was fixed for the day of Washington's expected return. Arnold gave him six papers containing drawings of the West Point defenses and full information concerning them, and passes to re-
turn to New York either by land or water. He also sent Smith as escort, charged not to leave André till he had reached the English lines in safety. But in the morning the American bat-
terries had fired on the Vulture and driven her so far down stream that the boatmen would not carry him to her. André, therefore, disguising himself as a civilian, set out on horse-
back, carrying the papers in his boots. Smith, despite Arnold's injunction, left André on the way, probably in fear for himself. About 9 A.M. on the 23d, near Tryrattywn, and almost in sight of the British lines, he was stopped by three patriot militiamen, John Paulding, David Williams and Isaac Van Wart. Supposing them to be Tory 'cowboys,' he told them he was an English officer, and offered them money. Find-
ing that they were not loyalists, he offered more money and his horse in addition, showing also Arnold's pass. Their suspicions thoroughly aroused, he was searched and carried to New York and carried him to one Lieutenant-Colonel Jamison, who, not suspecting treachery on Ar-
old's part, notified him of the capture and proposed to hand the prisoner over to him. This gleam of hope was delusive; and André was finally sent to Washington, while Arnold fled to the Vulture and saved his own life. By military law André was, of course, subject to immediate hanging; but in consideration of his rank, Washington on 29 September convened a military court of six major-generals and eight brigadier-generals, with Gen. Nathanael Greene as president, who unanimously convicted him of being a spy and sentenced him to death on 2 October. Clinton did his best to save André, protesting that he was not a spy because he was under a flag of truce (which was false), and that his movements were in obedience to the directions of Arnold, an American commander, —a grimly humorous defense under the circum-
stances; but Washington replied with firm courtesy that the circumstances justified no ex-
ception to the rules of war. André died like a man and need not be grudged our pity; but he
was treated with a generous humanity curiously in contrast with the treatment accorded to Nathan Hale.

A monument to André was placed in Westminster Abbey, and in 1821 his remains were taken from the tomb near it. Consult Spaight, 'Life of André' (in 'American Biographies'); Sargent, 'Life of André' (1862); Lossing, 'Two Spies' (1886). Lord Mahon in his 'History of England' assumes Clinton's case for André as good both in law and in equity. In 1858 Charles J. Biddle, a Philadelphia editor and ex-soldier, reviewed Mahon's opinions before the Pennsylvania Historical Society. Consult its 'Memoirs,' Vol. VI. For documents consult H. W. Smith's 'Andréana' (1865); Dawson's 'Collection' (1866). André's Journal was printed by the Bibliophile Society in Boston in 1904.

ANDRÉ, Louis Joseph Nicolas, a French military officer: b. Nuits, Burgundy, 29 March 1838; d. Dijon, France, 18 March 1913. He graduated at the Polytechnic School, and in 1862 went to the USA in that capacity throughout the Franco-Prussian War of 1870-71. He was made general of brigade in 1893 and placed in charge of the Polytechnic School. On 29 May 1900 he was appointed Minister of War by President Loubet, succeeding General the Marquis de Gallifet, who held the office during the exciting period of the Dreyfus revision.

ANDRÉ, Saint Jacques d'Albou, Marquis of Fronsac, generally known as Maréchal de Saint André, a French national, gentleman of the bedchamber by Henry II. In 1550 he was deputed to bear the collar of his order to Henry VIII of England, by whom he was invested with that of the Garter. On his return he was appointed to the command of the army in Champagne, where he greatly distinguished himself till taken prisoner at the battle of Saint Quentin. On the death of Henry II he was chosen one of the regency. Killed at the battle of Dreux in 1562. The Huguenots called Saint André 'the Harquebusier of the Weser.'

ANDRÉA, Johann Valentin, a German theologian: b. Waiblingen, 25 March 1528; d. Tübingen, 7 Jan. 1590; became professor of theology and chancellor of the University of Tübingen in 1562, and was the author of over 150 works, nearly all of a polemical character, besides being the chief author of the 'Formula Concordiae.'

ANDREA DEL SARTO, painter. He wrote mainly in Latin, but also in the Suabian dialect. Among the best of his works are his 'Menippus, or a Hundred Satyric Dialogues' (1617), and his 'Spiritual (Clerical) Relaxation' (1619).

ANDREA CHENIER, an opera in four acts by Umberto Giordano; libretto by Luigi Illica; first performance, Milan, 26 March 1896; in New York, 13 Nov. 1896. The scene is laid in Paris during the French Revolution, and the story is woven around a real person, a poet and patriot named Andrea Chenier, born in Constantinople, who was studying in Paris when the revolution broke out. He was guillotined 25 July 1794. The first scene reveals the hall in the castle of the Countess de Coigny (whose daughter, Madeleine, is the heroine of the piece). Among the servants, who are making preparations for a grand ball, is one Gerard, who afterward becomes the leader of the revolution. Chenier, the poet, arrives with the guests, and is requested by Madeleine to improvise a song of love. Instead, however, he preaches to the guests the gospel of liberty against the aristocracy, which naturally displeases the haughty guests. Gerard leads in a crowd of poor, starving people, who look very much out of place amid the gorgeous surroundings. Gerard and the crowd are ordered out, and Chenier exhibits his sympathy by following them. Five years have elapsed between the first and second acts. The latter opens with a café near the Seine. Andrea is seated outside at a table; at another table sit a spy and Madeleine's maid, Bersi. Roucher, a friend, warns Chenier that he is in danger and gives him a pass that will carry him to safety. Bersi, the maid, tells Chenier to wait for a lady, who turns out to be the fair Madeleine. She beseeches Chenier to save her from the dreader power of Gerard, who suddenly appears and attempts to seize the girl. Roucher intervenes and escorts the girl away, leaving Gerard and Chenier to fight a duel, in which Gerard is wounded. Gerard gallantly warns his rival that he is proscribed and implores him to save Madeleine. Chenier hurries away and Gerard disclaims any knowledge of the man who had struck him down. In the third scene, the Tribunal, Gerard is told of Chenier's arrest and is urged to denounce him, which he reluctantly does by signing the warrant. Madeleine offers her own life to save that of Chenier, and Gerard relents. But it is too late; he has signed the paper and Chenier is sentenced to death. Act IV, Chenier is writing verses in his cell, which Madeleine enters through bribing the jailer. Gerard makes a final but ineffective appeal to Robespierre, and in the morning the two lovers go to the guillotine together.

ANDREA DEL SARTO, one of Browning's most famous dramatic monologues, is founded upon the life of the Italian painter as given in Vasari's 'Lives,' and is an attempt to explain the meaning of the portrait that del Sarto painted of himself and his wife, Lucrezia, which now hangs in the Pitti Gallery at Florence. The poem comprises 272 lines of blank verse, and was first printed in the second volume of 'Men and Women' in 1855. Andrea, though called a saint by his contemporaries, lacked some essential quality (according to Browning, elevation of mind,
ANDREANI — ANDREOLITE

aspiration) that enabled such painters as Michelangelo, Raphael, and Leonardo, though inferior in technique, to surpass him. Browning finds in Andrea's infatuation with Lucrezia, which has led to sacrifice of character and artistic ideals, the true theme of the poem. This is brought out as the painter discusses himself and his art in a monologue addressed to his wife, as the two are seated in the dusk at a window of his house looking toward Fiesole. The poem is a three-sided study of character: of an artist who has failed to attain his ideal; who knows why he has failed; of a man who has lost his self-respect; and of a lover who has given his all without return; and yet this artist, man, and lover, through disillusionment and hopelessness, is content. The theory of art implied in the poem grows out of the character portrayal and is incidental to it; and, as is usual with Browning, this philosophic element is rendered human and "dramatic" as the natural utterance of the speaker under the given circumstances. The quiet and restrained style of the monologue, easy and colloquial, reflects the mood of the speaker and seems colored by the autumnal silver-gray of the outer world. Few poems leave so profound and distinct an impression; few are so subtle and so rich in suggestion. As a picture of Renaissance life and character, Andrea del Sarto should be read in connection with its companion piece, Fra Lippo Lippi, to which it forms an utter contrast. In such studies Browning shows himself not only the greatest master of the monologue, but also of all the poets the most profound student of the Renaissance, and the most successful in making poetry out of the subjects with which it provided him. Among the many criticisms of Andrea del Sarto may be mentioned that given by Mrs. Orr in her "Handbook;" by George Willis Cooke, in his "Browning Guide-Book," and by Albert Fleming, "Browning Society Papers" (No. 8, 2-9).

MARIAN TUCKER,
Professor of English Literature, Polytechnic Institute of Brooklyn.

ANDREANI, an'drā-ā'ně, Andrea, Italian wood engraver: b. Mantua about 1560; d. there 1623. He worked in Florence, Sienna and Mantua. He excelled in chiaroscuro engraving, of which he is one of the world's greatest masters. His arrangement of light and shade was remarkable, as also his drawing. His works include "Pavement of Sienna Cathedral;" "The Deluge," and "The Destruction of Pharaoh's Host," both after Titian and Mantegna's "Triumph of Caesar" (10 prints, 1598), which is considered his best work. His monogram is often confounded for that of Albrecht Alt dorfer.

ANDREASBERG, an'drās'-berg, Prussia, a mining town in the province of Hanover, 57 miles southeast of the town of Hanover and 14 miles from Klausthal, on a site 1,800 feet above sea-level, a little to the southwest of the Brocken. The minerals obtained in the mines of the district are silver, copper, cobalt, lead, arsenic, etc. The Samson shaft, 2,950 feet deep, is the deepest mine in the Harz Mountains. Pop. 4,600.

ANDREE, an'drē, Karl, German geographer: b. Brunswick, 20 Oct. 1808; d. Wildungen, 10 Aug. 1875. He was educated at Jena, Götingen and Berlin. After having been implicated in a students' political agitation he became a journalist, and in 1851 founded the Bremer Handelsblatt. From 1855, however, he devoted himself entirely to geography and ethnography, working successively at Leipzig and at Dresden. In 1862 he founded the important geographical periodical Globus. His works include "Nordamerika in Geographischen und Geschichtlichen Umrissen" (1854); "Geographische Wanderungen" (1859); and "Geographie des Welt handels" (1867-72).

ANDREE, an'drē, Richard, German ethnographer and geographer: b. Brunswick 1835; d. 1909. He was educated at Leipzig. In 1859-63 while studying the German-Czech race conflict, he was employed as a foundryman in Bohemia. He edited the Globus from 1891 to 1903. He was appointed professor at the University of Munich in 1902. Among his works are "Nationaleitverhaltnisse und Sprachgrenze in Böhmen" (1870); "Tschechische Gänge" (1872); "Zur Volkskunde der Juden" (1881); "Die Metalle bei den Naturvölkern" (1884); "Die Masken in der Völkerkunde" (1886); "Die Fluitagen" (1891), and "Braunschweiger Volkskunde" (1896).

ANDREE, Salomon Auguste, Swedish aeronaut: b. in Grena, 18 Oct. 1854; date of death unknown. He was educated in Stockholm. In 1882 he took part in a Swedish meteorological expedition to Spitzbergen. In 1884 he was appointed chief of the Patent Office, and from 1886 to 1889 he occupied a professor's chair at Stockholm. In 1892 he received from the Swedish Academy of Sciences a subvention for the purpose of undertaking scientific aerial navigation. From that time he devoted himself to aerial navigation, making his first ascent at Stockholm in the summer of 1893. In 1895 he presented to the Academy of Sciences a well-earned project for exploring the regions of the North Pole with the aid of a balloon at an estimated cost of about $40,000. A national subscription was opened, which was completed in a few days, the King of Sweden contributing the sum of $8,260. With two companions, Dr. S. T. Strindberg and Herr F. Fraenckell, Andree started from Denmark Island, Spitzbergen, 11 July 1897. His balloon was 67 1/2 feet in diameter, with a capacity of 170,000 cubic feet. Its speed was estimated at from 12 to 15 miles an hour, at which rate the Pole should have been reached in six days provided a favorable and constant wind had been blowing. Two days after his departure a message was received from Dr. Andree by carrier pigeon, which stated that at noon, 13 July, they were in lat. 82° 2' and long. 15° 5' E., and making good progress to the east, 10° southerly. Several expeditions sent in search of Andree have returned without obtaining any further intelligence of the explorer.

ANDREINI, an'drē-ne, Giovanni Battista, Italian comedian and poet: b. Florence, 1578; d. Paris, about 1650. From his sacred drama, "Adam" (1613), Milton is by some supposed to have derived the idea of "Paradise Lost."

ANDREOLITE, an'drē-ō-līt (from Andreasberg, in the Harz Mountains), a mineral better known as harmotome (q.v.). The name
androliite should be retained for it according to the law of priority; but mineralogists have preferred to adopt the name harmotome, as given by Hauy, although no good reason can be assigned for so doing.

ANDREOSY, an'drə-o'se', Antoine Françoise, COUNT, French general and statesman: b. Castelnaudary in Languedoc, 6 March 1761; d. Montaubon, 10 Sept. 1828. He entered the artillery in 1781, joined the revolutionists, served under Hauy in Italy and Egypt, and took part in the revolution of the 18th Brumaire. He was Ambassador at London, at Vienna and at Constantinople, from which latter post he was recalled at the restoration. He was raised to the peerage by Napoleon after his return from Elba. After Waterloo he advocated the recall of the Bourbons, but, as deputy, generally took part with the Opposition. He was elected to the Academy in 1826. He was a man of eminent scientific attainments, one of his earliest works being the "Histoire Générale du Canal du Midi" (1800). Besides his many scientific works he wrote several military "Mémoirs."

ANDREW, a Neapolitan king, assassinated with the connivance of his queen in 1345.

ANDREW, James Osgood, American Methodist bishop: b. Wilkes County, Ga., 3 May 1794; d. Mobile, 1 March 1871. He was an itinerant preacher in South Carolina from 1816 till consecrated bishop, 1832. His social relations were the immediate cause of the division of the Methodist Episcopal Church into "North" and "South." His second wife whom he married in 1844 was a slave holder; and the General Conference of that year resolved that he should "desist from the exercise of his office" on the ground that the fact of his wife's owning slaves "would greatly embarrass if not in some places entirely prevent" the exercise of this office. The Southern delegates protesting against this action, the difficulty was settled only by dividing the churches and property into the Northern and Southern jurisdiction. Bishop Andrew adhered to the South, retiring from active work in 1868.

ANDREW, John Albion, American statesman, the "Massachusett" of Massachusetts: b. Windham, Me., 31 May 1818; d. Boston, 30 Oct. 1867. He was graduated from Bowdoin College in 1837, and practised law in Boston 1840–61. He was an earnest anti-slavery advocate and defended the fugitive slaves Shadrach, Burns, and nets. Elected to the State legislature in 1858, was a delegate to the Chicago Convention in 1860, and being nominated governor was elected by an immense majority. He forecast the war, announced in his message the intention to put the State militia on a war footing and privately invited co-operation from other governors. On Lincoln's first call for troops, 15 April 1861, he sent them so promptly that on 19 April the 6th Massachusetts shed the first blood of the war in passing through Brandeis; a week he had dispatched to the front five regiments of infantry, a battalion of riflemen and a battery of artillery. In 1862 he urged the national abolition of slavery and the enrolment of colored troops, and in 1863 sent out the first colored regiment, 154th Massachusetts. He repeatedly interfered to prevent harrying Southern sympathizers by arbitrary arrests, and after the war was foremost in urging conciliation and abstinence from vindictive or humiliating measures. He was re-elected regularly till 1866, when he refused further honors from pecuniary grounds and impaired health, continuing his law practice till death. He was a man of great personal charm and oratorical force, intensely sympathetic and humane, and of simple and frank nature. In religion he was a moderate Unitarian, believing in Christ's supernatural character, and was president of the first Unitarian National Convention in 1865.

ANDREW, Saint, one of the 12 Apostles, and the brother of Peter. There are four important references to him in the gospels, John i, 40, the only account of his introduction to Jesus, in which as a disciple of John the Baptist he follows Jesus on John's word and brings his brother Peter to him; John vi, 8, where he calls attention to the boy with the barley loaves, when the miracle of the loaves and fishes occurs; John xii, 22, where Philip, asked by the Greeks if they may see Jesus, consults Andrew before laying the request before Jesus; and Mark xiii, 3, where he is one of the four who privately asked Jesus the meaning of his utterance about the ruin of the temple. The other two synoptics do not allude to him. John says he was from Bethsaida in Galilee. Tradition early gave him a conspicuous place among the Twelve, and very important acts of the Apostle Andrew were in circulation as early as the middle of the 2d century, but have survived only in later recasting. There were also acts of Matthew and Andrew, and of Peter and Andrew, and a "Martyrdom of Andrew." A gospel of Andrew is mentioned later, but not otherwise known. A tradition of unknown date and no value accredits him with preaching in north Georgia, in the Caspian Sea, and being martyred on a cross shaped like an X at about 70 A.D.

ANDREW I, a king of Hungary, 1046–1061; compelled his subjects to embrace Christianity, exiled his brother Béla and died in battle.

ANDREW II, king of Hungary, 1205–1235, who fought in the crusades, and displayed great valor; granted the Golden Voull, styled the Hungarian Magna Charta.

ANDREW III, king of Hungary, 1290–1301. He was opposed in his claims to the throne, and involved in a civil war during his reign; he died in 1301.

ANDREW, Saint, Cross of, is a white saltille on a blue ground, to represent the X-shaped cross on which the patron saint of Scotland suffered martyrdom, from an early date adopted as the national banner of Scotland. It is combined with the crosses of Saint George and Saint Patrick in the Union Jack. The Scottish Order of the Thistle is sometimes known as the Order of Saint Andrew and Scotland.

ANDREW, Saint, The Russian Order of, the most important of Russian orders, founded by Peter the Great in 1698. It has but one class and is confined to members of the imperial family, princes and persons of the rank of general who already hold two other important orders. The badge of the order displays on the obverse the double-headed eagle crowned, on which is a Saint Andrew's cross.
ANDREW OF CRETE—ANDREWS

e’enamed in blue, with a figure of the saint and bearing in the four corners the letters S. A. P. R. (Sanctus Andreas Patronus Russie).

ANDREW OF CRETE, or JERUSALEM, was so named because he was bishop of the Island of Crete. He was born at Damascus about 660 and early became a monk at Jerusalem; hence his later name. He was a member of the Sixth General Council of Constantinople, 680, where he was ordained deacon. He was made a bishop of Crete by Photius 869, and later by Har- desanes. He was a member of the Pseudo-Synod of Constantinople in 712, which restored the Monothelite heresy. Before he died he renounced his error. He was the author of several hymns, a considerable number of which are included in the Greek Service Books. John Mason Neale has translated several. He died at Mitylene about 714.

ANDREWS, Lancelot, English bishop: b. near Barking, Essex, 1555; d. London, 25 Sept. 1626. Having taken orders he was appointed to the parish of Alton, afterward to that of Chichester, Cripplegate, and in 1589 was made a prebend and canon of Saint Paul’s, and master of Pembroke Hall. Queen Elizabeth, esteeming him highly, appointed him one of her chaplains in ordinary, besides bestowing other preferment upon him; and he was in no less favor with James I. In 1605 he became bishop of Chichester, in 1609 was translated to Ely and appointed one of the King’s privy councilors and in 1618 was translated to Winchester. He was one of the greatest preachers of his time, and was one of those engaged in preparing the authorized version of the Scriptures. He left sermons, lectures and other writings, a manual of private devotions compiled by him in Greek and Latin being well known through several English translations.

ANDREWS, Charles McLean, American historian: b. Wethersfield, Conn., 22 Feb. 1863, Professor of history Bryn Mawr College, 1884–1907; Johns Hopkins University, 1907–10; Farnam professor of American history, Yale University (graduate school), 1910. Author: ‘River Towns of Connecticut’ (1899); ‘The Old English Manor’ (1892); ‘Historical Development of Northern Europe’ (1896); ‘Contemporary Europe, Asia and Africa’ (1871–1901); ‘Colonial Self-Government’ (‘American Nation’ Series V, 1904); two textbooks of English history and a number of papers and monographs on historical subjects. His chief work has been the preparation of a ‘Guide to American History in British Archives’ (2 vols., 1908, with Miss Davenport), and three reports in Reports of the American Historical Association, containing list of documents in the Public Records. His course of lectures, delivered at the University of Wisconsin and the University of Helsingfors, Finland, in 1911, were published as the ‘Colonial Period of American History’ (1912); he has prepared a ‘Bibliography of History’ (with Mr. Gambrill and Miss Tall), and edited and prepared for publication, ‘Original Narratives of American History’ series, entitled ‘Narratives of the Insurrections, 1676–1691’ (1915).

ANDREWS, Christopher Columbus, American diplomat and writer: b. Hillsboro, N. H., 27 Oct. 1829; was brevetted major-general in the Civil War; United States Minister to Sweden 1869 to 1877, and Consul-General to Brazil from 1882–85. Among his many works are ‘Minnesota and Dakota’ (1857); ‘Practical Treatise on the Revenue Laws of the United States’ (1858); ‘History of the Campaign of Mobile’ (1867), and ‘Brazil, Its Condition and Prospects’ (1887, 3d ed., 1895). He served as forestry commissioner of Minnesota (1895–1911) and 16 of his forestry annual reports have been published.

ANDREWS, Edward Gayer, American clergyman: b. New Hartford, N. Y., 7 Aug. 1825; d. Brooklyn, N. Y., 31 Dec. 1907. He was graduated from Amherst College in 1847; entered the Methodist ministry 1848; was principal of Cazenovia Seminary 1854–64; pastor in Stamford, Conn., and Brooklyn, N. Y. 1864–72; elected bishop 24 May 1872. He visited missions in Europe and India 1876–77; Mexico 1881; Japan and China 1884–86; and was delegate to English and Irish Methodist Churches 1894. He delivered the address at the state funeral of President McKinley in Washington, 17 Sept. 1901.

ANDREWS, Elisha Benjamin, American educator: b. Hinsdale, N. H., 10 Jan. 1844; d. 30 Oct. 1917. He served in Connecticut regiments through the Civil War and rose to the rank of second lieutenant. He was graduated from Brown University in 1870, and Newton Theological Institution in 1874. He was prominent both as teacher and pastor 1874–82 and as professor of history and political economy at Brown University 1882–88. In the year last named he was elected president of Brown University and under his administration that institution greatly increased its efficiency. In 1898 he resigned the presidency on account of criticism of his views on the silver question, but complied with the request of his trustees to withdraw his resignation. He was elected superintendent of schools in Chicago 1898, and in July 1900, chancellor of the University of Nebraska, and became chancellor emeritus Jan. 1909. During the years 1909–10 he made a tour of the world. Besides many published addresses he has written ‘Institutes of General History’ (1887); ‘Institutes of Economics’ (1892); ‘An Honest Dollar’ (1894); ‘Wealth and Moral Law’ (1894); ‘History of the Last Quarter Century in the United States’ (1896); ‘Cosmology’ (1900); ‘History of the United States in Our Own Times’ (1904); ‘The Call of the Land’ (1913).

ANDREWS, Ethan Allen, American biologist: b. New York city, 10 Sept. 1859. He was graduated from Yale, then took a postgraduate course in the Johns Hopkins University. He was professor of zoology, and later of comparative and economic zoology at the Johns Hopkins University in 1887, became associate professor in 1892 and
professor of zoology in 1908. In 1904 he was elected president of the Society of American Zoologists.

ANDREWS, George Pierce, American jurist: b. North Bridgeton, Me., 29 Sept. 1835; d. New York, 24 May 1912. He was educated at Yale, studied law and was admitted to the bar in 1861. He was United States district attorney for six years, assistant and corporation counsel, New York, 1872–84, and associate justice of the New York Supreme Court, 1884–1900. He was esteemed a high authority on municipal and corporation law and his opinions in tax cases were especially valued. A very notable event in his career was his conviction of Capt. Nathaniel Gordon in 1860 for slave trading. Gordon was captured with a crew of nearly 900 negroes, was twice tried for piracy and finally convicted as a result of the convincing argument of Andrews. It is generally conceded that the conviction and execution of Gordon ended the slave trade in the United States. It had existed for more than 300 years, and for 42 years after Congress had made it piracy, punishable with death. Thousands of negroes had suffered tortures on the long voyages between African and American ports, and thousands more had died and been cast overboard, but not a person engaged in the nefarious traffic had been punished in this country until Mr. Andrews obtained the conviction and execution of Gordon. Prior to that event 130 vessels had been engaged in the slave trade, and New York was their headquarters. See United States—Slavery in the

ANDREWS, Lorrin, American missionary: b. East Windsor, Conn., 29 April 1795; d. Honolulu, 29 Sept. 1868. He was educated at Jefferson College and Princeton Theological Seminary; missionary in the Hawaiian Islands 1827, until in 1840, from anti-slavery scruples, he resigned connection with the American Board. He became a judge and secretary of the privy council, 1845–55; translated a part of the Bible into Hawaiian and compiled the following works: 'Vocabulary of Words in Hawaiian' (1836); 'Grammar of the Hawaiian Language' (1854); 'Dictionary of the Hawaiian Language' (1865); all published in the island.

ANDREWS, Saint, University of. See Saint Andrews.

ANDREWS, Samuel James, American clergyman: b. Danbury, Conn., 31 July 1817; d. 11 Oct. 1906. He was graduated at Williams College 1839, he was admitted to the bar in Connecticut and Ohio and practised law in those States 1842–44. He then studied at Lane Theological Seminary; ordained in Congregational ministry, 1846; pastor, East Windsor, Conn., 1848–55; adopted the Irvingite doctrines and was in charge of a Catholic and Apostolic Church congregation in Hartford, Conn., from 1868. Author of 'Life of Our Lord upon Earth' (1862); 'God's Revelations of Himself to Men' (1885); 'Christianity and Antichristianity in Their Final Conflict' (1889); 'Wilberforce and Andrews: A Religious Biog-raphy' (1900); 'Man and the Incarnation' (1903).

ANDREWS, Stephen Pearl, American author: b. Templeton, Mass., 22 March 1812; d. New York city, 21 May 1880. He was educated at Amherst; practised law in New Orleans and Texas. His enthusiastic advocacy of the abolition of slavery took him to England in 1843 to raise money to pay for the slaves and make Texas free. He learned in England phonography and became the founder in this country of the present system of phonographic reporting, editing journals devoted to it and publishing numerous instruction books. Early in life he announced the discovery of the universal law of law in the universe, and devoted the last half of his life to developing this philosophy, called by him 'Integralism,' and to the construction of a universal language which he named 'Alwato,' as a part of this system of 'universology.' He spoke several languages and is said to have had a knowledge of 30. In 1882 he instituted the 'Colloquium,' a series of conferences for the exchange of opinions between leading New York clergymen and others of the widest diversity of religious, philosophical and political views. His chief works are 'Discoveries in Chinese' (1854); 'Synopsis of Universology and Alwato' (1871); 'Basic Outline of Universology' (1872); 'Grammar of Alwato' (1877); 'Transactions of the Colloquium' (Vols. I, II, 1882–83); 'The Church and Religion of the Future' (1886).

ANDREWS, Thomas, Irish chemist and physicist: b. Belfast, 19 Dec. 1813; d. there, 26 Nov. 1885. He studied at Belfast and at Glasgow, and later at Trinity College, Dublin. Finally he was graduated as M.D. at Edinburgh in 1835 and settled down to a successful medical practice in his native place, also giving instruction in chemistry at the Academical Institution. In 1845 he was appointed vice-president of the newly established Queen's College, Belfast, and professor of chemistry, and these two offices he held till 1879, when failing health compelled his retirement. Andrews first became known as a scientific investigator by his work on the heat developed in chemical actions; for this work the Royal Society awarded him a medal in 1844. Another important research was devoted to ozone. But the work on which his reputation mainly rests, and which best displayed his skill and resourcefulness in experiment, was concerned with the liquefaction of gases. He carried on a very complete inquiry into the laws expressing the relations of pressure, temperature and volume in carbonic dioxide, in particular establishing the conceptions of critical temperature and critical pressure and showing that the gas passes from the gaseous to the liquid state without any breach of continuity.

ANDREWS, William Draper, American inventor: b. Grafton, Mass., 1818; d. 1896. In 1844 he invented the centrifugal pump which made it possible to save goods not injured by water from abandoned vessels; the pump was manufactured in England as the Gwynne pump; was patented in the United States in 1846. Later he invented and patented the antifriction centrifugal pump; made various modifications of centrifugal pumps and patented a widely-used system of condensing.

ANDREYEV, än-drä'yef, Aleksandr Nikolaeveich, Russian dramatist: b. Government of Pskovskaya, 18 Feb. 1830. After being graduated from an engineering school Andreyev served at first in the Ministry of Ways and
ANDREYEV, â’n-dr’é-yë', Leonid Nikolae-vich, Russian writer; b. Orel 1871. After studying law at the universities of Moscow and St. Petersburg he found himself temperamentally unsuited for the task of making a living, which so depressed him that he attempted suicide when only 23 years of age. He finally found a position as a court reporter for a Moscow paper. This led to his attempting to write short stories, which were published in the daily papers. It was some of these that attracted the attention of Maxim Gorky to him, and this was the beginning of his success. From then until the present time he has been a prolific writer of short stories, essays and dramas. By many he is considered the leading writer of Russia and a brilliant genius. The first collection of his stories was issued in 1901 and a quarter million copies were sold within a short time. His stories have since been published in all European languages. Those that are available in English are: 'The Red Laugh' (1903); 'The Seven Who Were Hanged' (1909); 'Judus Iscariot and the Others' (1910); 'A Diamond' (1910); 'Anathema' (1910); 'Silence and Other Stories' (1910). Besides these many others have appeared in American and English magazines as follows: 'The Burglar', in Current Literature (May 1905); 'His Excellency the Governor', in Harper's Weekly (9 Feb. to 2 March 1907); 'To the Stars' in Poet Lore (Winter 1907); 'Lazarus', in Current Literature (May 1907); 'The Life of Man', in Oxford and Cambridge Review (Midsummer 1908); 'Life is so Beautiful to the Resurrected', in Current Literature (Sept. 1910); 'Love of One's Neighbor' in The Globe (January 1914). Like most of the Russian short story writers there is an abnormal, morbid taint in Andreyev's stories that does not appeal to the American mind. The critic has experienced difficulty in classifying him. He has abandoned the traditional methods so apparent in his earlier work and his eccentricities have increased with the years. His philosophy is that of fatalism; most of his heroes landing in the grave or the madhouse. Andreyev is not a pessimist, however, but rather a mystic with keen analytic power who writes with great originality and brilliancy, yet creates no new types nor delineated real characters. See Anathema (Andreyev's).

ANDRIA, ân-drè’-a, Italy, a town and episcopal see in the province of Bari, 35 miles west of the town of Bari. It was founded about 1046 by Pioberto, Count of Can-pria. There are several fine churches of the 13th century. It is connected with Bari by steam tramway. Pop. about 49,000.

ANDRIEUX, â’n-drë’, François Guillaume Jean Stanislas, French man of letters: b. Strassburg, 6 May 1759; d. Paris, 9 May 1833. He was educated in Paris, and studied law in Paris. He practised at the bar, but his attention was divided between his profession and literature. His plays are of the 18th century style, comedies of intrigue, but they rank among the best of the period next to those of Beaumarchais. 'Les Etourdiss'; his best comedy, was presented in 1788 and won for the author the praise of La Harpe. He hailed the beginning of the Revolution with delight and received a place under the new government. He was later expelled and on his retirement he again turned to write for the stage, producing 'Le TréSOR' and 'Molière avec ses amis' in 1804. He became professor of grammar and literature at the Ecole Polytechnique and eventually at the Collège de France. As a professor he was extraordinarily successful. He was rigidly classical in his taste, and an ardent opponent of romanticism. Among his other plays are 'La Comédienne' (1816) one of his best comedies, and a tragedy, 'Lucius Junius Brutus' (1830). Andrieux was the author of some excellent stories and fables: 'La Promenade de Fénélon'; 'La Bulle d'Alexandre VI' and the 'Meunier de Saint-Souci.' In 1828 he became perpetual secretary to the Academy.

ANDROCONIA, ân-drör-kôn-ë, certain highly modified scent-scales shaped like battle- dores, on the wings of certain butterflies and caddis flies (Trichoptera). In certain butterflies (Thecla, Donas, etc.) they occur on the upper side of the fore wings in limited areas, such as in the discal spots, or they may be scattered in rows or irregularly over the upper surface, or in the folds of the wings. Fritz Müller has shown that these minutes scales function as scent-scales, and are confined to the males. Thomas has proved by sections of the wings of Danais, etc., that the androconia arise from glands situated in a fold of the wing, and that the material elaborated by the local glands, and distributed upon the surface of the wing by the androconia is that which gives to many of the Lepidoptera their characteristic odor. Scudder, who named them, says that they are very capricious in their occurrence. A number of allied genera may possess them, while a single genus, as closely allied, may be quite destitute. They occur in the Nymphalidae, Pieridae, Lycaenidae, Papilionidae and Hesperiidae.

ANDROMACHE, ân-drör-mä’-kë, in Greek legend, the daughter of Eëtion, Prince of Thebes in Mycia, and wife of Hector. She is one of the finest characters in Homer, distinguished by her affection for her husband and child, her misfortune and the resignation with which she endures them. The death of her son Astyanax and the farewell scene between Andromache and Hector (Iliad, VI 323), were represented in ancient works of art, while Andromache her-
ANDROMACHUS, an-dröm-ak-ús, a physician to the Emperor Nero and the inventor of a celebrated compound medicine called theriake, described in Galen's works.

ANDRONICUS I, an-dro-ni-kús (Comnenus), Byzantine emperor: b. 1110; d. 12 Sept. 1185. In his youth he served against the Turks, in 1141 was for some time a prisoner and was afterward appointed to a military command in Cilicia, but was unsuccessful. Engaging in a treacherous correspondence with the King of Hungary, he was thrown into prison by his cousin, the Emperor Manuel; but after 12 years he succeeded in making his escape and reached Kiev, the residence of Prince Jaroslav. He regained the favor of his cousin by persuading Jaroslav to join him in the invasion of Hungary, and by his gallantry in the war; but again incurred his displeasure and was sent in honorable banishment to Cilicia. After a pilgrimage to Jerusalem and his scandalous seduction of Theodora, the widow of Baldwin, King of Jerusalem, he settled among the Turks in Asia Minor on the boundaries of outlaws, making frequent inroads into the province of Trebizond; but at length made his peace with the Emperor and was sent to Chios in Pontus. Upon the death of Manuel in 1182 he was recalled as first guardian, then colleague, of the young Emperor Alexis II. Soon after he caused the Empress-mother to be strangled, and afterward Alexius himself, whose youthful widow he married. His reign, though short, was vigorous, and restored prosperity to the provinces; but tyranny and murder were its characteristics in the capital. At last a destined victim, Isaac Angelus, one of his relatives, having fled to the church of Saint Sophia for sanctuary, a crowd gathered, and a sudden insurrection placed Isaac on the throne, while Andronicus, now 75 years of age, was put to death by the infuriated populace after horrible mutilations and tortures.

ANDRONICUS OF CYRRHUS, Greek astronomer: flourished about 100 B.C. He built a "horologium" at Athens, the so-called "towers of the winds," a considerable portion of which still exists. It is octagonal, with figures carved on each side, representing the eight principal winds. A brazen Triton on the summit, with a rod in his hand turned round by the wind, pointed to the quarter from which it blew. From this model is derived the custom of placing weathercocks on steeples.

ANDRONICUS OF RHODES, a Roman philosopher who interpreted the works of Aristotle (q.v.). He lived in Cicero's time. None of his known works are extant.

ANDROPON, an-dro-pògon, a genus of about 200 species of grasses of very diverse utility, distributed widely, especially over dry plains throughout the temperate and tropical zones. The species are usually characterized by long, narrow leaves; terminal and axillary spikes; sessile perfect spikelets paired with pedicellate empty ones or sessile; and straight or twisted awns. A. halepensis, or Sorghum halepense of some authors, Johnson grass, attains a height of from three to six feet from stout, perennial creeping rootstocks, which being difficult to eradicate make the plant a troublesome weed where not needed for pasture or hay, for which it is largely grown in South America, Australia and the southern United States, where it was introduced about 1830. It makes quick growth, yields abundantly and may be cut several times in a season. It is not fully hardy in the North, where, as in Europe, it is often grown for ornament. A. schananthius, lemon grass, and A. nardus, citronella grass, are handsome tropical species cultivated in India and Ceylon for the fragrant oils they contain, and which are used in perfumery, soap-making and in the former case for the adulteration of certain perfumes, notably attar of roses. A. sorghum, or Sorghum vulgare of some authors, is of wide economic importance, its numerous varieties or sub-species being cultivated for fodder, sugar, alcohol, brushes, brooms and its seeds, which last are used for jute, stock, and human food (see SORGHUM). A. provincialis, A. scoparius and various other species known as blue-stem grass, are valued as fodder grasses in arid regions where they are native.

ANDROS, Sir Edmund, an American colonial governor; b. in London, England, 6 Dec. 1637; d. there, 27 Feb. 1714. His father was master of ceremonies to Charles II. He earned the favor of the Stuarts by steady and laborious service, unwavering loyalty and military and executive ability. In 1666 he was made major of an infantry regiment and sent to America, where he won laurels against the Dutch. In 1672, after his return to England, he became titular commander of the British forces in Barbados, and in the same year was made major in a regiment of dragoons raised for Prince Rupert; also a "landgrave" in Carolina, two years later succeeding his father as bailiff of Guernsey.

In 1674 Andros was made lieutenant and governor of "all the Duke of York's territories in America," including New York (just restored by the Dutch, who had retained it the year before), New Jersey and Delaware, Martha's Vineyard and parts of Maine, and a claim to all the Connecticut west of that river. He arrived in November, and the next year began to push the Connecticut claim; but the Duke did not desire an appeal to force, and after making formal declarations at Saybrook, Andros retired. During the next two years the Indian troubles were acute; and in settling these he proved himself one of the ablest and most useful of Indian managers, winning the good will of the Iroquois at a critical time, and not only keeping his own colony protected, but sending help to the outlying points in Rhode Island, Massachusetts and Maine. He spent a few months in England in 1677–78, and was knighted. In 1678–80 there was increasing friction, religious and otherwise. He was an Episcopalian, and one of his appointees to a coadjutorship in an Albany church was tried for heresy but acquitted; Andros, however, tactfully quieted the disturbance and contributed to build a Reformed church in New York. Then the merchants charged him with unfairness in trade matters, and with suppressing part of his receipts in his public accounts, with the object of inducing the Duke to sell some of them the right to farm the New York revenues. At this period Philip Carteret was acting as gov-
umor of East Jersey under the Duke of York's grant to his brother and Berkeley; there were complications inherited from previous changes which forced Andros to keep interfering, under his superior commission, and at last he sent a body of soldiers to seize Carteret and bring him to New York to be tried for exercising illegal jurisdiction. Andros acted as judge, but the jury acquitted Carteret, who was triumphantly reinstated. Lady Carteret complained to the Duke of York, who recalled Andros, and sent him as a commissioner to investigate this and the other charges: he reported that Andros was not in fault, but the latter was retained at home, made gentleman of the privy chamber to Charles II, and received a 96-years' grant of the island of Alderney and other favors.

The accession of the Duke of York as James II (February 1685) was followed by the return of Andros to New England, as the agent in an unpopular scheme of consolidation, and in consequence his memory has been loaded with unjustifiable abuse. The Massachusetts charter had been revoked in October 1684, and Charles II had appointed the notorious Col. Pierry Kirke governor; but as he never entered on his duties, Andros was commissioned governor of all New England as one centralized colony on 3 June 1686. Andros has done injustice to this statesmanlike scheme, distasteful though it was to the New Englanders. The intention was to create, out of the several weak and mutually contending colonies, one strong confederated colony with a militia powerful enough to resist French and Indian aggression, and under one command. Andros can only be blamed for needless harshness or blundering or corruption in obeying his instructions; and despite the current opinion there was none of this, but rather the reverse. On arriving at Boston, 19 Dec. 1686, he organized his new government, which, as the people had no longer the right to tax themselves, levied a new tax, the exact counterpart of the old. Ipswich refused to pay, and the ringleaders were fined and imprisoned. This must happen under any law. Andros was ordered to proclaim all land titles invalid unless confirmed by the Crown for a quitrent. Outrageous as this may seem, it was held to be sound law, and he enforced it in the most humane way by bringing test suits against a few of the wealthiest citizens before proceeding further. As a fact, only a part had yielded when the Revolution interrupted it. He granted waste common-lands to individuals who would improve them; a venial crime. Heavy fees were charged by the public officials; but he neither fixed the rates, received the proceeds nor appointed the officers who did. He had Episcopal services held in the Old South Church, but only when its regular congregation was not using it; this sacrilege, however, has blackened his memory more than anything else. He was sometimes sharp in speech; but when some wickedly foolish people charged him with secretly fomenting an Indian war, he only laughed at them and left the courts to attack this himself. In a word, there was neither a political nor a religious reign of terror set up; no one was persecuted for non-conformity or executed or whipped for political offenses. Andros behaved like a statesman, an honest man and a humane one. He early extended his authority over Plymouth, New Hampshire and Rhode Island, as well as Maine and Massachusetts. In October 1687 he visited Hartford, to take up the Connecticut charter: the story of its being hidden in the Charter Oak is classic, and it is certain enough that one copy was hidden and was efficient in restoring the charter rights of the colony long before there was another copy, and the event was regarded as of no significance at the time. Andros, on returning to Boston in 1688, received the news that he was made governor also of all the British provinces in America except Pennsylvania, Delaware, Maryland and Virginia. While making a tour of his northern provinces he was checked by the information that the Penobscot Indians, stirred up by Castine (q.v.), whose property had been taken, were about to go on the war-path. He collected 700 troops, and in November 1688 sailed to Horace to depose Andros and appoint several posts. On 4 April 1689 news was received of the deposition of James II; on the 18th the citizens of Boston rose and captured Andros, and kept him prisoner till 2 August, when he was released. He was arrested and brought back, and was released still 2 February 1690. He returned to England to face a trial, with a committee of his accusers, but the charges fell through. William III needed officials as able and upright as he, and in 1692 made him governor of Virginia. He carried with him the charter of William and Mary College, and till 1698 remained in Virginia, a most public-spirited, hard-working, excellent ruler, doing much for the progress of the colony and esteemed by its people. His removal was caused by a quarrel with the commissary of the bishop of London and president of the college, who quarreled with all the governor. He was governor of Jersey 1704-06. He had been governor of every mainland English province in North America, and won the confidence of four successive monarchs on hostile lines. Even for New England, his departure was not an unmixed good, for it was followed by one of her bloodiest and most disastrous Indian wars, which his presence might have averted. See Brodhead, 'Governorship of Sir Edmund Andros' (1897); New Netherland to New England (1691); Andros Tracts, with Notes and a Memoir (Prince Society, Boston 1868-74).

ANEMOMETER, an-e-mom'e-ter, an instrument for measuring the velocity of moving air or other gaseous substance. It is almost always combined with a recording device and thus becomes strictly speaking an anemograph, though it is popularly known by the former name. The instruments in use as anemometers are of five distinct types: (1) The pendulum or Brooke anemometer; (2) the cup or Robinson anemometer; (3) the "windmill" anemometer; (4) the U-tube or Dines anemometer; and (5) the electrical anemometer. The first consists essentially of a flat plate of definite area, usually one square foot, arranged so as to swing after the manner of a pendulum, in a wind that is to be measured. It is used chiefly in the determination of wind pressure upon buildings, bridges and other structures, although this pressure is translated into velocity by a suitable scale. The Robinson anemometer is described at length below. The "windmill" type is simply a minia-
ture windmill very lightly built, with small *sails* at the end of comparatively long arms, and held in a position to face the wind by a yane. This instrument is much more accurate in registering sudden gusts and lulls than the cup anemometer, but has the disadvantage of having to shift its position with a change of direction in the wind, and this occupies an appreciable length of time in which the record is incorrect. The U-tube anemometer is regarded as the most accurate one in common use. Its basic feature is a U-shaped tube containing a mobile liquid in the bend of the U. One of the top ends of the tube is bent so that the opening faces the draught whose velocity is to be measured; the other end is turned so that at the same time the passing draught exerts a sucking effect upon it. Under the influence of these two forces the liquid moves in the tube on which a scale is fastened. In a modification of this instrument called the Seger anemometer, two non-miscible liquids are used, generally paraffin oil and tinted alcohol. The Fletcher anemometer is also of this type, for use under trying conditions, like measuring the velocity of draughts in industrial chimneys. The liquid used in the Fletcher anemometer is ether. The instrument is at some distance from the chimney, and the arms of the U-tube are greatly extended. The electrical anemometer, also known as the Linear Hot-Wire anemometer, depends for its action upon the cooling by the passing draught of a hot platinum wire. The wire is heated to a dull red phase by its resistance to an electric current passing through it. As the draught cools the wire its resistance is increased, thus disturbing the electrical balance in a Wheatstone bridge. The additional current necessary to restore this balance measures the velocity of the current blowing upon the platinum wire. This instrument is extremely sensitive to low velocities, and may be used for velocities between two feet per second and 35 feet per second.

In commercial use anemometers are employed in measuring the velocities of gas or steam flowing through pipes; the delivery of hot air in heating schoolrooms and other public apartments, and also of cool air in ventilating them; the regulation of the flow of gases in some industries—as in the manufacture of sulphuric acid from pyrites; and in by far the larger numbers in determining and recording the velocity and direction of winds in meteorological and climatological observations.

The Robinson cup anemometer is used by the United States Weather Bureau. In this apparatus the hollow cups are made of thin aluminum or copper and are as nearly hemispherical as possible. These are securely fastened to small square steel arms set with their diagonals horizontal and vertical, respectively, so as to offer the greatest resistance to the bending action of the wind pressure upon the cups and as little resistance as possible to the wind itself. Copper cups should always be used for exposures where the aluminum does not well withstand the corrosive action of salt air or the acid fumes from smokestacks, etc. In the American standard instrument the cups are four inches in diameter and the arms 6.72 inches long from the axis to the centre of the cups.

The most prejudicial resistance in any part of the anemometer, when in good condition, is that occurring in the top bearing of the spindle. This bearing should first be made very smooth and polished and afterward kept clean and freely lubricated, if good results are to be expected. When well made and properly cared for the anemometer will show only a very little wear after years of exposure, even with comparatively high winds. The small bright spot upon the lower end of the steel spindle, where it wears against the steel plate, should never be larger than a pin head. If this portion becomes dry of oil by neglect, as sometimes happens, it will quickly wear flat and introduce a very great amount of friction. The
instrument can then be restored to good condition only by recutting and polishing the pivot end, also the small plate, so as to conform to the above specifications.

Certain advantages result from the use of ball-bearings in anemometers, chiefly in increasing the service to be obtained and in reducing the attention necessary to maintain the bearings in proper lubrication. The reduction in friction is not such an important gain as might be supposed, unless the instrument is used in very slight winds. The slight friction in an anemometer is quite inconsequential in light and fresh winds, such as usually prevail at practically every station.

The ideal anemometer exposure is secured when the instrument is placed where the movement of the wind is unobstructed from any direction, such for example, as would be obtained in the centre of a large open expanse or plain. Only an approximation to the ideal exposure is possible in most places, but every effort should be made to better anemometer exposure in order that the records from the several stations may be comparable. Usually, with an anemometer exposed in a city or town, the great interference offered by buildings and other natural obstructions to the free movement of the wind causes the velocity to be much less in the vicinity of these obstructions than beyond such influence; therefore, in selecting the location for an anemometer preference should be given to the more elevated points in the vicinity of the station, and some rigid support should be used to raise the instrument as far as practicable above the immediate influence of the office building itself.

The Robinson anemometer has the fault of "slurring" its records of gusts and lulls of the wind, due to a certain amount of inertia which cannot be overcome. Moreover, in very light winds it is not dependable, and it is customary to check its record with that of a U-tube instrument placed beside it. The anemometer must be regarded as an instrument of convenience rather than of precision, the difficulty lying in the fact that there is no fixed constant for moving gases, except within narrow limits. Elaborate scales have been devised for ease and rapidity of calculation, but the results, from the windgauge, are at best approximate. Consult report of the director of the meteorological office of Great Britain (London 1906). See Wind Vane.

RICHARD FERRIS.

ANEMONE, an-né'm-ó-né, wind-flower, a genus of plants belonging to the Buttercup family (Ranunculaceae) containing many species found in temperate regions. Many of them occur in the United States. Several Old World species are common in cultivation. See Sea-Anemone.

ANEMOSCOPE. An instrument for showing the course or direction of the wind. It may be combined with the anemometer, thus indicating both the direction and velocity of the wind. Lately the anemoscope has been made self-recording, and now in most observatories needs no watching, every movement of the wind being written down, the force or pressure and the velocity in miles per hour being also recorded. This is done by pencils which press lightly upon a cylinder covered with a sheet of paper divided into horizontal hour-lines, the lines moving at the rate of half an inch an hour, a complete revolution of the cylinder occupying 24 hours. Lines marked by the pencils show by their relation to the graduated lines the direction of the wind at any moment of the day.

ANERIO, Felice, Italian composer: b. Rome 1500; d. Rome, 28 Sept. 1614. At the age of 15 he entered the choir at Saint Peter's as a soprano and became a pupil of G. M. Nanini. On the death of Palestrina (q.v.) in 1594, Anerio was appointed his successor as composer to the Papal Chapel, whilst Ruggiero Giovannelli was made conductor. Together with Fr. Sartorio, Anerio edited the so-called Edizione Medicea of the Graduale of 1614. For many years several compositions of Anerio have been attributed to the great Palestrina himself, e.g., "Adoramus te Christe" and "Stabat Mater." A great number of his hymns, masses and madrigals are still preserved in his own handwriting.

ANERIO, Giovanni Francesco, Italian composer, probably a brother of the preceding: b. and d. Rome about 1567-1620, respectively. He was a choir boy under Palestrina, and in 1609 received an appointment at the court of King Sigismund III of Poland. In the following year he became conductor in the cathedral of Verona; in 1611, prefect of the Jesuit College in Rome, and was ordained priest in 1616. He composed a great number of church pieces.

ANEROID BAROMETER, a species of barometer in which no fluid is employed, an ingenious and delicate instrument invented by M. Vidi of France in 1844. Its mechanism consists of a hollow metal cylinder, with thin and corrugated ends, which contract or expand according to the pressure of the atmosphere, the air within having been previously exhausted by the air-pump. The motion of the ends of the cylinder acts upon a principal lever attached to it, and connected with two smaller levers, to one of which a chain is attached, working upon a roller, and to the axis of the roller a hand is fixed, exhibiting the variation of the barometer by means of an index on the face of the barometer. A pocket aneroid is very useful for measuring small heights. See Barometer.

ANEURISMS, a circumscribed tumor of an artery composed of a sac, the cavity of which communicates with the artery and contains liquid or coagulated blood. So-called "false" aneurisms are everywhere composed of all of the coats of the artery, and are rare and always small. Aneurisms are usually of the class anatomically designated as "false," in which only one of the coats of the artery takes part in the formation of the walls of the sac. Condensed adjoining tissues may also enter into the formation of the wall. A more common classification divides aneurisms into (1) common or encysted aneurisms, (2) arteriovenous aneurisms, (3) of the forceps of aneurisms. The first division includes aneurismal dilatation or fusiform dilatation which extends for some distance, with the three arterial coats preserved; true aneurism, mentioned above, limited to one point; false aneurism at one point in which one coat has disappeared; and consecutive or diffused aneurism in which the condensed
ANGLFISH—ANGELICO

Adjoining tissues take part. Arteriovenous aneurism denotes an abnormal communication between artery and vein with or without an intermedia sac. Avid aneurism is the general dilatation of an artery and its branches and dissecting aneurism is formed by the effusion of blood between the coats of an artery. Internal aneurism are those situated within the thoracic or abdominal cavities, external aneurism those in other parts of the body.

Aneurisms are also known as spontaneous or traumatic according to their origin. The latter occurs in consequence of sudden division or injury of the walls of an artery through some external agent or a splinter from a fractured bone. A spontaneous aneurism is due to a degenerative change in the wall of the artery by which its elasticity and resistance to strain are diminished. The degenerative change may be due to a lodgment of an embolus, overstretching pressure of a ligature or some other mechanical cause. Anatomical factors in the production of an aneurism are those changes in the artery, change of direction, enlargement, bifurcation, and so on. Occupation of exertion, alcoholic excess, the presence of rheumatic diathesis, syphilis, are also causative factors. An aneurism may terminate spontaneously by coagulation of the blood within it. Absolute rest and low diet are the most essential medical means of treatment, but the treatment is large, surgical, its details depending upon the variation and situation of the aneurismal swelling.

ANGELFISH. See Monk-fish.

ANGLOF THE BATTLEFIELD. See Anthony, Sister.

ANGELICA, a genus of herbs of the family Apiaceae, consisting of 60 species, occurring in north temperate regions and in New Zealand, several species being natives of North America. The name angelica, however, is popularly applied to various other members of the same family, Aralia, of which the most common is A. officinalis, to which it is often erroneously given. It is a tall herb with much divided leaves and small white flowers in umbels, native of Europe. The leaf-stalks were formerly blanched and eaten like celery. Candied in sugar they are much used in Europe as a sweetmeat.

ANGELICO, Fra, ön'jä le-co, Florentine painter: b. Vicchio, in the province of Mugello, 1387; d. Rome 1455. Il Beato Fra Giovanni Angelico da Fiesole is the name given to this celebrated painter-friar. In English it runs—the Beatihe Friar John the Angelic of Fiesole. His real name was Guido, but on becoming a brother in the Dominican Order at Fiesole he took the name of Giovanni, the name of Angelico by which he is always called in art circles being a surname that came to him later because of the quality of his work. We find him referred to as Angelico already in 15th century. The history of his early years is extremely obscure. We know that he became a Dominican in 1407 and that he shared the vicissitudes of his brethren of the convent, wandering to various cities, notably Cortona, where there are a number of his works. His first paintings as an artist were probably before 1407 and it seems likely he had been in the school of Masolino, and that he began as a miniaturist. Another artist of the previous generation, who influenced him is Orcagna. It is probable that Fra Angelico returned with the Dominicans to Fiesole in 1418 when they resumed their former residence. He remained there for 18 years. Under the protection of Cosimo de Medici, the brotherhood was installed in the monastery of San Marco in Florence in 1436. The decoration of this edifice, including several large frescoes and a large number of small ones in the individual cells, is one of the principal monuments of the Beato Angelico's long and unusually prolific career. We find here the great 'Crucifixion,' possibly unfinished, and certainly restored, which is one of the friar's best impressionist works. Here also is the 'Annunciation' which is generally regarded as his most beautiful version of a subject to which he loved to return. No single institution more fully embodies the spirit of mediaeval piety at the dawn of the Renaissance. Pope Eugenius IV, who had presided at the installation of the convent, was so impressed with Fra Angelico's achievement that he first offered him the archbishopric of Florence, and on his declining it, invited him to Rome to execute frescoes in the Vatican. Vasari, the authority for the story, says it lacks authentication though credible enough in view of the humility of Fra Angelico. Fra Angelico was in Rome most of the time from 1445 until his death. In 1447 he worked for some time in the Duomo of Orvieto. He was moreover busy on easel pictures for numerous cities, now scattered to Florence (the very important 'Descent from the Cross,' the 'Last Judgment' and the 'Coronation of the Virgin'), Paris, London, Munich, New York, etc., but the great work of his old age was the decoration of the chapel of Nicholas V, that pontiff having succeeded Eugenius while the work was in progress. The frescoes portray eight scenes from the lives of Saint Stephen and Saint Lawrence. While we may note certain changes in his style, as we take Fra Angelico's works in chronological order, a remarkable uniformity of ideal pervades them throughout. The almost unearthly purity of the artist's spirit, its sweetness —which never falls into weakness—and the restful faith in the divine life whichcombine to sweep away all obstacles of a material nature and produce in us the conviction that his art is sublime. Its modest exterior conceals immense gifts and inexhaustible resources which renew themselves afresh throughout his life. Attempting neither the emotional nor the technical scope of Giotto, Masaccio or Michelangelo, he so concentrates his spirit on his own problems that his work attains a Christian perfection even as a Greek master reaches a perfection in his sphere. In some respects he was even an innovator, being one of the first to paint the Christ Child as a real infant, and the very first to paint a landscape that can be identified. According to all accounts which have reached us, few men have deserved more nobly the distinction of having chosen as their model Fra Giovanni Angelico. He led a holy and self-denying life, shining all advancement, and was a brother to the poor. He painted with unceasing diligence, and treated none but sacred subjects. Consult Langton Douglas, 'Fra Angelico,' (London 1909); other studies by Supino (Florence 1898; Eng. trans. 1902); Sortais (Lille 1905); Newnes (London 1906).
ANGELL, George Thomâke, American reformer; b. Southbridge, Mass., 1823; d. 16 March 1909. He was graduated at Dartmouth College in 1846, and admitted to the bar in 1851. He was a leader in promoting measures for the prevention of crime, cruelties and the adulteration of food. He founded the American Humane Educational Society.

ANGELL, James Burrill, American educator; b. Scituate, R. I., 7 Jan. 1829; d. Ann Arbor, Mich., 14 April 1916. He was graduated from Brown University in 1849; and was professor of modern languages and literature there, 1853-60; editor Providence Journal, 1860-66; first president of the University of Vermont, 1866-71; became president of the University of Michigan in 1871 and held that position until 1899 when he became president emeritus, after conferring degrees on 2,500 graduates, of whom 200 were women. He was fortunate in being able to secure the loyalty of all his students, a d it was said regarding him that the real capital of Michigan was at Ann Arbor. He served at United States Minister to China (1880-81); and as Minister to Turkey (1897-98). He was also one of three commissioners appointed to negotiate a new treaty with China, and was subsequently chairman of the Canadian Commission for Deep Waterways (1896). In November 1900 the Emperor of Japan conferred on him the first decoration of the Imperial Order of the Sacred Treasure in token of his regard for the eminent American diplomat. Beside numerous addresses and articles in periodicals he was the author of 'Manual of French Literature' (1857); 'Progress in International Law' (1875); 'Reminiscences' (1912); 'Selected Addresses' (1912).

ANGELL, Joseph Kinnicutt, American legal writer; b. Providence, R. I., 30 April 1874; d. Boston, Mass., 1 May 1857. Graduated at Brown University, 1813. Edited the Law Intelligencer and Review, 1829-31, and prepared the first published law reports of Rhode Island. Alone or in collaboration he produced a number of valuable and much-used legal textbooks, chief of which are, 'Treatise on Corporations' (4th ed., 1858), highly commended by Chancellor Kent; 'Common Law in Relation to Watercourses' (4th ed., 1850); 'Liabilities and Rights of Common Carriers' (2d ed., 1845); 'Law of Fire and Life Insurance.'

ANGELICUM, Michael. See MICHELANGELO.

ANGELS. A creation of higher order than man mentioned in the Bible. They are often represented as the messengers of God and are frequently pictured as ministering to man. There are degrees among the angels for there are seven archangels, four of whom are mentioned in Scripture. All are mentioned in the book of Rev. The idea of guardian angels was early adopted in the church. It was thought that each individual is under the care of his own particular angel. The Jews and Mohammedans hold the same belief.

ANGELUS, the Catholic prayer and practice by which the mystery of the Incarnation is recalled to mind. The custom of saying the Angelus at noon and evening. It forms the subject of a famous painting by Millet (q.v.).

ANGERS, an-zhâr', Srz Auguste Râal, Canadian statesman; b. 4 Oct. 1838. He was called to the bar, and became a Q.C. in 1880, in which year he was elected to the Dominion House of Commons. He was a judge of the Superior Court of Quebec, 1880, and lieutenant-governor of the province, 1887-92, in which position he dismissed the Mercier ministry on account of the Baie des Chaleurs Railway scandal. From 1895-1915 he was a Dominion Minister of Agriculture, and president of the council, 1896. He was knighted in 1913.

ANGERS, Felicite ('Laure Conan'), French-Canadian novelist; b. Malbaie, Que. She is the author of a number of works which have had a wide circulation, among them 'Angeline de Montrevin' (1884); 'Si les Canadiens le voulaient'; 'Elisabeth Seton' (1903).

ANGERS, France, city, capital of the department of Maine-et-Loire, 191 miles southwest of Paris. It occupies a rising ground on both banks of the Maine, which is here crossed by three bridges. Of its several buildings the most important is the Cathedral of Saint Maurice, dating from the 12th century. The palais de justice, the institute, a fine theatre and a hospital are the more remarkable of the modern buildings of the town. Its educational institutions include ecclesiastical seminaries, a lycée, a preparatory school of medicine and surgery, a university with free faculties of theology, law, letters and science, a higher school of agriculture, training colleges and a school of fine art. The prosperity of the city is largely due to the great slate quarries of the vicinity, but the distillation of liquors, cable, rope and thread-making, and the manufacture of boots and shoes, umbrellas and parasols are leading industries. Machine construction, wire-drawing and the manufacture of sparkling wines and preserved fruits are also carried on. The chief articles of commerce, besides slate and manufactured goods, are hemp, early vegetables, fruit, flowers and live-stock. In animal husbandry the Angers and Juliomagus. It suffered severely from the invasions of the Northmen in the 9th century; the Huguenots took it in 1585 and the Vendean royalists were repulsed near here in 1793. Till the Revolution, Angers was the seat of a celebrated university founded in the 14th century. Pop. 84,000.

ANGINA PECTORIS is a name given to a symptomatic condition characterized by attacks of pain often very severe associated with an oppressive, tightening sensation and sense of impending death. The pain may begin in remote organs or in the precordial region and from this point radiate usually to the left shoulder and arm even to the extremities of the fingers. Sometimes it attacks the right arm or both arms simultaneously.

There are two main varieties of angina pectoris, the so-called true and the false. True angina pectoris is rare, at least in this country. For this form there is an anatomical basis in the heart itself. It may be explained as a vascular cramp, the pain occurring in the vessels through the heart, nerves and muscles. The condition is associated with sclerosis of the coronary arteries. The attacks may last
from fifteen minutes to an hour or two. Sometimes they prove directly fatal. Precipitating causes of attack are bodily exertion, marked mental excitement and errors in diet. The condition is probably due to coronary disease combined with disease of the heart muscle, so that death is actually caused by failure of the latter to perform its function.

False angina pectoris is comparatively frequent and must be classed as a neuralgia of the heart. It simulates that of true angina pectoris but is less severe and never fatal. The two forms, however, may be combined and are at all times difficult to differentiate. The latter belongs probably to the class of cardiac neuroses largely of psychogenic origin.

ANGLE, strictly, the degree of inclination to one another of two lines which meet, or of two or more surfaces which meet. The same term is incorrectly used for the point in which lines meet, and for the line in which two surfaces meet or such line is the vertex of the angle. The lines in the first case and the surfaces in the second case are known as the sides of the angle.

An angle made by two lines is called a plane angle; that made by two planes, a dihedral angle; that made by three or more planes, a solid angle, or a polyhedral angle. Angles may again be subdivided into rectilinear, curvilinear and mixed angles. A plane rectilinear angle is the inclination to each other of two straight lines which meet but are not in the same straight line. A curvilinear angle is the inclination to each other of two curved lines which meet in a point, and is equal to the inclination of the tangents to the curves at their intersection. A mixed angle is one formed by the meeting of a curve and a straight line, and is measured as the angle between the straight line and the tangent to the curve at the point of intersection.

Plane rectilinear angles are generally divided into right, obtuse, or into right, acute and acute. When a straight line standing upon another straight line makes the two adjacent angles (those on the right and left of it) equal to one another, each of them is called a right angle and the direction at which the two straight lines stand is called a right angle. An obtuse angle is that which is greater than one right angle, but less than two. An acute angle is that which is less than a right angle; both are obtuse. A spherical angle is one formed by the intersection or the meeting of two great circles of a sphere.

The inclination of any two lines which form the sides of an angle is measured by the length of the arc they cut out on the circumference of a circle struck from the vertex of the angle as a center. The radius of this circle is obviously a matter of convenience, as the arcs will be the same for any radius. Angles are expressed, therefore, in degrees, minutes and seconds and decimals of a second: as, for example, an angle of 90°, or an angle of 3° 14′ 17.298″. In mathematical nomenclature an angle upon a diagram is usually designated by three letters, one on each side and one at the vertex, the vertex letter being the middle one of the triad. as, the angle BCD, in which C is the vertex at the vertex. In some cases where no ambiguity could arise, the same angle might be named by its vertex letter: as, the angle C.

The complement of an angle is that length of arc by which it falls short of 90°: that is, the complement of an angle of 32° is 58°. The supplement of an angle is that length of arc by which it falls short of 180°: that is, the supplement of 75° is 105°.

In astronomy angles are considered between lines which never meet. These angles are measured as between parallels to the original lines, so drawn or projected that they do meet.

ANGLE IRON. See Rails and Structural Shapes.

ANGLE OF SITE. In indirect fire, when the gun and target are at different levels, it is necessary to set the gun at an elevation corresponding to the height of the target. The angular measurement of this difference, expressed in mils, is the angle of site. Practically speaking, it is such that when set off on the quadrant, the axis of the bore will point directly at the target. Having set off the angle of site, the gun is given the additional elevation corresponding to the range. If the target can be seen at the gun, the angle of site may be measured directly. To find the angle of site it is necessary to determine the difference in level between the gun and the target in yards, and to convert the yards into mils. For convenience the vertical scales of all artillery instruments are graduated from 0 to 600, and the centre of the reading, 300, corresponds to horizontal.

ANGLE OF TRACTION. In draught, the angle which the plane of the traces makes with the road on which the carriage is moving. Artillery carriages having sometimes to move over the worst description of roads, the angle of traction must be slightly inclined upward, as the vertical component of the pull will then assist the wheels to surmount obstacles; the weight being transferred to the shoulders of the horse, increasing the pressure of its feet upon the ground, thus giving greater hold and enabling him to exert with ease a stronger pull, while the resistance against which he contends is at the same time diminished.

ANGLER. See Goosepig.

ANGLES, a German tribe who probably lived originally on the east side of the Elbe, between the Saale and Ohre rivers, whence they moved to what is now the district of Angeln in Schleswig-Holstein, lying between the territories of the Jutes and Saxons. They never approached the Rhine and the Roman frontiers, hence we do not find their name mentioned by the Roman authors, who comprehended them with many others, under the general name of Chauci and Germani, till the conquest of Britain made them better known as a separate nation. In the 5th century they joined their powerful northern neighbors, the Saxons, and took part in the conquest of Britain, which from them derived its future name of England. A part remained in their continental homes and gave their name also to the district of Angeln.

ANGLESEY, [ŋˈɡlɛ-ˌsi]. Henry William Paget, Marquis of, English soldier and statesman: b. 1768; d. 1854. He was educated at Oxford, and in 1790 entered Parliament as member for the Carnarvon boroughs. In 1794 he took part in the campaign in Flanders under
the Duke of York, and in 1808 was sent into Spain with two brigades of cavalry to join Sir John Moore, and in the retreat to Corunna commanded the rear guard. In 1812 he became, by his father’s death, Earl of Exeter, and at the battle of Waterloo overthrew the Imperial Guard. For his services he was created Marquis of Anglesey. In 1828 he became lord-lieutenant of Ireland and made himself extremely popular, but was recalled in consequence of favoring Catholic emancipation. He was again lord-lieutenant in 1830; but lost his popularity by opposition to O’Connell and his instrumentality in the passing of the Irish coercion acts, and he quitted office in 1833.

ANGLESEY, ân’gle’sè, or ANGLESEA, an island and county of north Wales, in the Irish Sea, separated from the mainland by the Menai Strait. It is about 20 miles long and 17 miles broad, with an area of 175,886 acres, of which 59,352 are arable land. The crops and permanent pasture, exclusive of mountain and heath land used for pasturage (about 7,600 acres). It is divided into three cantrefs, and each of these into two cumuduws, equivalent to the English hundreds. The surface of the island, with the exception of Holyhead, Parys and Bodafon Mountains, is comparatively flat, and the climate, though milder than that of the adjoining coast, is not so favorable to the growth of trees. There are no streams of any importance, but the coast affords some natural harbors, the principal of which are Holyhead and Beaumaris. The principal crops are oats, barley, turnips and potatoes. Cattle and sheep are the staple productions of the island, and large numbers of both are annually exported. Of minerals, Anglesey contains copper, lead and silver ore, limestone, marble, asbestos and marl, but the copper mines at Parys and Mona, once so celebrated and productive, have much decreased in value. The Menai Strait is crossed by a magnificent suspension-bridge, 580 feet between the piers and 100 feet above high-water mark, allowing the largest vessels which navigate the strait to sail under it; and also by the Great Clifton Bridge, for the conveyance of railway trains, Holyhead being the point of departure for the Irish mails. The market towns are Holyhead, Beaumaris, Llangefni and Amlwch, the first-named by far the largest. The county itself returns a member to Parliament. On the coast are several small islands, the chief being Holyhead and Puffin Island.

ANGLESITE, ân’gle-sit (from the island of Anglesea, where it was first observed, a native sulphate of lead, PbSO₄. It crystallizes in the orthorhombic system and has a hardness of from 2.75 to 3, and a specific gravity varying from 6.1 to 6.4. It may be transparent or opaque, and in color white, greenish, yellowish or gray. It occurs in many localities, usually in connection with galena, whence it is apparently derived by oxidation. A beautiful transparent variety of several inches in diameter are known. Anglesite, in a massive form, is extensively mined as an ore of lead (q.v.).

ANGLEWORM. See EARTHWORM.

ANGLIA, East, an English kingdom founded by the Angles (q.v.) in the 6th century in the eastern part of England in what now forms the present counties of Norfolk and Suffolk. It was conquered by the Danes in 878, and became part of the English kingdom in 921, under Edward, son and successor of Alfred. The modern see of Norwich corresponds in extent to the East Anglian kingdom, and the name East Anglia is still frequently employed to denote these two shires.

ANGLICAN CHURCH. See CHURCH OF ENGLAND.

ANGLING, Margaret Mary, American actress: b. Ottawa, Ont., 3 April 1876. Her father, the Hon. T. W. Anglin, was speaker of the Canadian House of Commons. She was educated at Loretto Abbey, Toronto, and at the Sacred Heart Convent, Montreal. In June 1911 she married Howard Hull of New York. In 1894 she was graduated from the Empire School of Dramatic Acting, New York, and made her first appearance in that city, in ‘Shenan doah’; an injury sustained in riding laid her up for a year; she made her first appearance as the leading lady with James O’Neill and toured with him in the United States and Canada, playing with much success in ‘The Girl I Left Behind Me,’ ‘Dr. Jekyll and Mr. Hyde,’ ‘The Courier of Lyons,’ ‘Virginibus,’ ‘Hamlet’ and ‘Monte Cristo.’ Subsequently she played with the Southern Company and scored heavily as Lady Ursula; it was not till 1898 that as Roxane, with the late Richard Mansfield, in ‘Cyrano de Bergerac,’ she gave evidence of her great future as an actress. Her next appearance was in ‘The Echo’ with Charles Frohman in California 1899, she gathered fresh laurels, which were afterward sustained, and added to, in the same capacity with the Empire Theatre Company, New York. Later she starred with Henry Miller, producing such plays as ‘Mrs. Dane’s Defence,’ ‘Macbeth,’ ‘The Only Way,’ ‘Zira,’ ‘The Aftermath,’ ‘Young Fernald,’ ‘The Great Divide,’ the latter causing a veiy real sensation in the dramatic world. In 1909 she produced ‘The Awakening of Helena Ritchie,’ having made a successful tour of Australia in Shakespearean repertoire not long before, afterward she went to Egypt. In 1910 she produced Sophocles’ ‘Antigone’ at the Greek Theatre, Berkeley, Cal., and ‘Electra’ in 1911, when she also toured Canada in the comedy, ‘Green Stockings.’ She produced Euripides’ ‘Iphigenia in Aulis’ and ‘Medea’ at the Greek Theatre in California during the Pan American Exposition of 1915. A Boston writer, speaking of her rendition of ‘Zira,’ said that in a generation there had only been Bernhardt’s to match it, and Mme. Bernhardt has stated her to be ‘one of the few dramatic geniuses of the day.’

ANGLING, the sport of fishing with hook and line. Some authorities have insisted that a rod is an essential concomitant. There is, however, on record of a court proceeding the decision that a rod is not necessary to the practice of angling, but that the personal manipulation of the tackle as sport creates the distinction between angling and ordinary commercial fishing.

By its devotees angling in its highest development is claimed to be both an art and a science, as well as the sport of sports—especially to the ‘Contemplative Man’ as Izaak Walton styled him nearly three centuries ago.
The requirements of a peculiarly cultivated judgment and skill, and equanimity of temper, together with the fascination of the picturesque in nature's water courses and water levels, to be followed in solitude, stealthily and in silence, are what engage the attention and charm to which no other sport may lay equal claim.

The literature of angling has been prodigious, more than 3,000 volumes on the subject having been published since the first, "The Treatise of Fyshinge with an Angle," appeared in 1507—besides an innumerable essays, papers and magazine articles.

Angling divides naturally into sweet water or fresh water angling, and salt water or sea angling.

The game fish most sought by fresh water anglers in America are, first of all, the Atlantic salmon and the brook trout, with the black bass a strong rival for the reputation of either as to the quality of piscatorial sport they afford. The favorite salmon haunts are the rivers of Canada, and the brook trout, generally distributed all over the country, thanks to the activities of the United States Bureau of Fisheries, and there are a few sections north of Georgia where they may not be found. In this organized distribution of game fishes the brown trout of Europe and the rainbow trout of the Pacific coast streams have shared with the common brook or speckled trout, and from year to year are to be found in increasing numbers and in an ever-widening area. Other sweet-water fish which attract the attention of discriminating sportsmen are the muscalunge, pike and pickerel, and the lake trout and salmon trout. By many anglers the world over the docile perch would be mentioned among sport fishes, and with good reason if the fact that it has contributed a myriad hours of gentle sport to multitudes of its species.

Sea angling is sport of sterner and often strenuous quality. Its captures are large and powerful fish with whom angling becomes in some instances a battle rather than a sport. The value of the bass in salt waters is much larger than that which lures the fresh water angler. Bluefish, striped bass, weakfish and sea bass are well known to the shore and off-shore anglers of the north Atlantic and north Pacific coasts. The sporting grounds for big fish are the semi-tropical waters of Florida and the Gulf, and of southern California. Here the tarpon, tuna, yellowtail, shark, swordfish and the ray invite the absorbed attention of the most vigorous sportsman, and it must be said that the combat with a big fish on light tackle is not one for the delection of the "Contemplative Man" for whom the immortal Izaak recorded his peaceful observations.

The culmination of the angler's art is, by commonly, the conquest of fish with the artificial "fly." The special skill required in casting the fly accurately to the spot decided upon, whether it be near or far, and whatever the difficulties which nature presents, calls for devoted practice and persisted patience. A very few rods need to pass into the hands of the great majority it must be acquired.

There are two schools of fly-casters among anglers, the old-fashioned wet caster, who did not restrict himself to any number of flies, and who moved up or down the stream casting frequently as he went, his fly sinking below the surface of the water, and the modern school of dry casters who restrict themselves to a single artificial fly, made very small, dressed with upstanding wings, so as to ensure its floating on the surface, and sometimes anointed with an odorless oil to keep it dry. To distinguish this far from being a rigid order of flycasters being quite ready to substitute a wet fly for a dry one when the fish refuse the latter. Some anglers of the ultra type do not indulge in promiscuous fishing but await the rise of a fish, and then devote their energies to the capture of that particular specimen.

In either school the casts are divided into six classes: the overhead, the underhand, the spray cast, the wind cast, the flip cast and the switch cast. The object of them all is to cause the fly to drop upon the water toward the angler's feet, and then, lowering his rod by a quick downward movement, the line is sent forward rolling over and over itself in curves. When all the curves are unwound the fly falls back into the water at the extreme end of the line. The first movements in the wind cast are just like those of the switch cast: the difference is in the thrash by which the line is made to travel up against the wind. The flip cast is made by taking the fly between the thumb and finger, pulling the top of the rod downward until it is a bow, and then letting it slip back. The force will carry the fly to the desired spot. The spray cast is used now when a great length of line is out. The fly is then drawn up to the feet of the angler and the pole thrown forward up stream, not, as in the overhead cast, swished behind the line of the shoulders.

For the experienced angler there is nothing to be said—he knows it all. But for him of little experience or none, it is advised that he read freely among the books written on the subject before essaying the adventure in the open. Careful study of the habits of the fish to be hunted will be well repaid in the weight of the creel on the homeward stretch; and fishermen's lore should be absorbed without stint. It is an old saying that "good luck is half the battle." It is a common mistake to start in with
a very cheap and hence unresponsive outfit. It is
unwise also to select the most refined and
delicate tackle before appreciative skill is ac-
quired. In the selection of tackle the personal
equipment of the angler and the weighty factor.
Tackle which best suits the angler is that which
will eventually bring him the most fish. But
fishing tackle is a subject so diverse and ex-
tended as to demand a separate article, and to
that the reader is referred for detailed informa-

ANGLO-AMERICAN COMMISSION, a joint international commission appointed in 1898 by the United States and Great Britain for the negotiation of a plan for the settlement of all controversial matters between the United States and Canada. The subjects submitted for the consideration of the commission were officially determined as follows: *The Behring Sea sealing question, reciprocal mining regulations, the preservation of the fisheries of the Great Lakes, the north Atlantic fishery question, the boundary question, the alien labor laws, and reciprocity of trade.* Lord Herschell, Sir Wilfred Laurier, Sir Richard Cartwright, Sir Louis H. Davies and Mr. J. Charlton, a member of the Dominion Congress, were appointed British commissioners. The American commissioners were United States Senators Fairbanks and Gray, Congressman Dingley, Reciprocity Commissioner Kasson and ex-Secretary of State Foster. The commission met at Quebec, 23 August, Lord Herschell being chosen chairman; W. C. Cartwright, of the Foreign Office, and H. Bourassa, member of Parliament for La-
Belle County, Quebec, were chosen British secre-
A TREATY is a formal compact or agreement between two or more states. It is a legally binding document that sets out the rights and obligations of the parties involved. Treaties are often used to establish or modify relationships between nations, such as trade, military, or cultural cooperation. They can also address issues like territorial boundaries, diplomatic relations, and international law.

remain binding until the expiration of one year from the day on which either of the High Contracting Parties shall have denounced it. But if, when the date fixed for its expiration arrives, either ally is actually engaged in war, the alliance shall, ipso facto, continue until peace is concluded.

The second treaty was signed at London 12 Aug. 1905. The following letter explains its objects and purposes.

Despatch to his Majesty's Ambassador at Saint Petersburg, forwarding a copy of the Agreement between the United Kingdom and Japan, signed at London, 12 Aug. 1905.

The MARQUIS OF LANDSDOWNE to SIR C. HARDINGE

Foreign Office, Sept. 6, 1905.

Sir,—I inclose, for your Excellency's information, a copy of a new Agreement concluded between his Majesty's Government and that of Japan on Jan. 30, 1902. You will take an early opportunity of communicating the new Agreement to the Russian Government.

It was signed on Aug. 12, and you will explain it would have been immediately made public but for the fact that negotiations had at that time already commenced between Russia and Japan, and that the publication of such a document whilst those negotiations were still in progress would obviously have been improper and inopportune.

The Russian Government will, I trust, recognize that the new Agreement is an international instrument, to which no exception can be taken by any of the Powers interested in the affairs of the Far East. You should call special attention to the objects mentioned in the preamble as those by which the policy of the contracting parties is inspired. His Majesty's Government believe that they may count upon the goodwill and support of all the Powers in endeavoring to maintain peace in Eastern Asia, and in seeking to uphold the integrity and independence of the Chinese Empire and the principle of equal opportunities for the commerce and industry of all nations in that country.

On the other hand, the special interests of the contracting parties are of a kind upon which they are fully entitled to insist, and the announcement that those interests must be safeguarded is one which can create no surprise and need give rise to no misgivings.

I call your especial attention to the wording of Article II, which lays down distinctly that it is only in the case of an unprovoked attack made on one of the contracting parties by another Power or Powers, and when that party is maintaining its territorial rights and special interests from aggressive action, that the other party is bound to come to its assistance.

Article III, dealing with the question of Korea, is deserving of especial attention. It recognizes in the clearest terms the paramount position which Japan at this moment occupies and must henceforth occupy in Korea, and her right to take any measures which she may find necessary for the protection of her political, military, and economic interests in that country. It is, however, expressly provided that such measures must not be contrary to the principle of equal opportunities for the commerce and industry of other nations. The new Treaty no doubt differs at this point conspicuously from that of 1902. It has, however, become evident that Korea, owing to its close proximity to the Japanese Empire and its inability to stand alone, must fall under the control and tutelage of Japan.

His Majesty's Government observe with satisfaction that this point was readily conceded by Russia in the Treaty of Peace recently concluded with Japan, and they have every reason to believe that similar views are held by other Powers with regard to the relations which should subsist between Japan and Korea.

His Majesty's Government venture to anticipate that the alliance thus concluded, designed as it is with objects which are purely peaceful and for the protection of rights and interests the validity of which cannot be contested, will be regarded with approval by the Government to which you are accredited. They are justified in believing that its conclusion may not have been without effect in facilitating the settlement by which the war has been so happily brought to an end, and they earnestly trust that it may, for many years to come, be instrumental in securing the peace of the world in those regions which come within its scope. — I am, &c.,

(Signed) LANDSDOWNE

The text is as follows:

**Inclosure.** Agreement between the United Kingdom and Japan, signed at London, Aug. 12, 1905.

**Preamble.** The Governments of Great Britain and Japan, being desirous of replacing the Agreement concluded between them on Jan. 30, 1902, by fresh stipulations, have agreed upon the following articles, which have for their object:

(a) The consolidation and maintenance of the general peace in the regions of Eastern Asia and of India;

(b) The preservation of the common interests of all Powers in China by insuring the independence and integrity of the Chinese Empire and the principle of equal opportunities for the commerce and industry of all nations in China;

(c) The maintenance of the territorial rights of the High Contracting Parties in the regions of Eastern Asia and of India and the defence of their special interests in the said regions.

**Article 1.** It is agreed that whenever, in the opinion of either Great Britain or Japan, any of the rights and interests referred to in the preamble of this Agreement are in jeopardy, the two Governments will communicate with one another fully and frankly and will consider in common the measures which should be taken to safeguard those menaced rights or interests.

**Art. 2.** If by reason of unprovoked attack or aggressive action, wherever arising, on the part of any other Power or Powers, any contracting party should be involved in war in defence of its territorial rights or special interests mentioned in the preamble of this Agreement, the other contracting party will at once come to the assistance of its ally, and will conduct the war in common, and make peace in mutual agreement with it.
ANGLOMANIA—ANGLO-SAXON

Art. 3. Japan possessing paramount political, military and economic interests in Korea, Great Britain recognizes the right of Japan to take such measures of guidance, control and protection in Korea as she may deem proper and necessary to safeguard and advance those interests, provided always that such measures are not contrary to the principle of equal opportunities for the commerce and industry of all nations.

Art. 4. Great Britain having a special interest in all that concerns the security of the Indian frontier, Japan recognizes her right to take such measures in the proximity of that frontier as she may find necessary for safeguarding her Indian possessions.

Art. 5. The High Contracting Parties agree that neither of them will, without consulting the other, enter into separate arrangements with another Power to the prejudice of the objects described in the preamble of this Agreement.

Art. 6. As regards the present war between Japan and Russia, Great Britain will continue to maintain strict neutrality unless some other Power or Powers should join in hostilities against Japan, in which case Great Britain will confer with the assistance of Japan, and will conduct the war in common and make peace in mutual agreement with Japan.

Art. 7. The conditions under which armed assistance shall be afforded by either Power to the other in the circumstances mentioned in the present Agreement, and the means by which such assistance is to be made available, will be arranged by the naval and military authorities of the contracting parties, who will from time to time consult one another fully and freely upon all questions of mutual interest.

Art. 8. The present Agreement shall, subject to the provisions of Article VI, come into effect immediately after the date of its signature, and remain in force for ten years from that date.

In case neither of the High Contracting Parties should have notified twelve months before the expiration of the said ten years the intention of terminating it, it shall remain binding until the expiration of one year from the day on which either of the High Contracting Parties shall have denounced it. But, when the date fixed for its expiration arrives, either ally is actually engaged in war, the alliance shall, ipso facto, continue until peace is concluded.

In faith whereof, the undersigned, duly authorized by their respective Governments, have signed this Agreement, and have affixed thereto their seals.

Done in duplicate at London, the 12th day of August, 1905.

LANDISDOWNE,
His Britannic Majesty's Principal Secretary of State for Foreign Affairs.

TADASU HAYASHI,
Envoy Extraordinary and Minister Plenipotentiary of His Majesty the Emperor of Japan at the Court of St. James.

Thus it will be seen that whereas the first treaty referred to China and Korea exclusively, and only became operative upon the intervention of a third Power, the treaty which is superseded applies also to the regions of eastern Asia and of India, and becomes operative when either party to the agreement becomes the object of wanton attack or aggression with respect to the special interests in the regions coming within the scope of the agreement. In effect this new treaty guarantees the status quo for very nearly the entire continent of Asia, of course omitting Turkey. England will have Japan's support to withstand any foreign aggression in Persia and Afghanistan or against India, while Japan has the offensive and defensive backing of England in the new relations which she occupies toward Asiatic countries. The terms of this treaty are eminently satisfactory to neutral nations and practically give the "open-door" to all and present vast permanent commercial opportunities. Many of the principles agreed upon and incorporated in the agreement were known before the Battle of the Sea of Japan.

ANGLOMANIA, a term denoting undiscriminating imitation of everything English on the part of persons of other nationalities. In the United States it was formerly applied to a fad of fashionable society.

ANGLO-SAXON, the name given by modern historians to the Angles, Jutes and Saxons who migrated to Britain from Germany in the 5th and 6th centuries A.D. They emigrated from the districts about the mouths of the Elbe and Weser, and the first body of them who gained a footing in England are said to have landed in 449, and to have been led by Hengist and Horsa. The Jutes settled chiefly in Kent, the Saxons in the southern and middle country, and theAngles in the northern. Among the various Anglo-Saxon states that afterward arose those founded by the Angles first gained the preponderance, and gave to the whole country the name of Engla-land, that is, the land of the Angles.

Among the Anglo-Saxons we find the English constitution already existing in all its essentials, but its origin is not to be attributed to Alfred, though he brought it to a greater pitch of completeness. In a rudimentary form it was the common property of the Germanic peoples before the emigration of the Saxons and Angles from the Continent. It developed itself more independently, however, among the Anglo-Saxons than among those Teutonic races who came into closer connection with the Romans, and afterward the Frank. The Anglo-Saxon community was frequently spoken of as consisting of the eorls and the ceorls, or the nobles and common freemen. The former were the men of property and position, and were themselves divided into different ranks; the latter were the small landholders, handycraftsmen, etc., who generally placed themselves under the protection of some nobleman, who was hence termed their hlaford or lord. Besides these there was the class of the serfs or slaves (thorfas), who might be either born slaves or freemen who had forfeited their liberty by their crimes, or whom poverty or the fortune of war had brought into this position. They served as agricultural laborers on their masters' estates, and though mere chattels, as absolutely the property of their masters, cattle, their lot does not appear to have been very uncomfortable. They were frequently manumitted by the will of their master at his death, and were also allowed to accumulate savings of their own, so as to be able to purchase their freedom or that of their children.
One of the peculiar features of Anglo-Saxon society was the wergild, or life-price, established for the settling of feuds. A sum, paid either in kind or in money where money existed, was placed upon the life of every freeman according to his rank in the state, his birth, or his office. A corresponding sum was settled for every wound that could be inflicted upon his person; for nearly every injury that could be done to his civil rights, his honor, or his domestic peace; and further fines were appointed according to the peculiar adventitious circumstances that might occur to aggravate or extenuate the offense. From the operation of this principle no one was exempt, and the king as well as the peasant was protected by a wergild, payable to his kinsmen and his people (Kemble, 'Saxons in England').

The king (cyning, cynge) was at the head of the state; he was the highest of the nobles and the chief magistrate. He was not looked upon as ruling by any divine right, but by the will of the people, represented by the witan, or Great Council. The notion is the same in the Latin monarchia, where we find that the new king was not always the direct and nearest heir of the late king, but one of the royal family whose abilities and character recommended him for the office. The king was invested with certain honors and privileges in order that he might maintain his position with becoming dignity. Besides his wergild as an exeheling or person of royal blood, his life was further guarded by a sum of equal amount, called cynedbót, or price of royalty, and the former sum was to be paid to his relatives, the latter to the people. As king he held possession of the Crown lands, which were national property, distinct from any private estates he might himself purchase. Among other privilages he was entitled to a portion of the fines and confiscations laid upon offenders; he had the right of maintaining a standing army of household troops, the duty of calling together the Council of the Witan, and of laying before them measures which concerned the welfare of the state, with certain qualifications of degrees of dwelling, etc., all his privileges being possessed and exercised by the advice and consent of the witenagemót, or Parliament.

The queen also was held in high honor. She had her own gatherings, and she possessed a separate establishment from that of the king though on a smaller scale. Next in rank and dignity to the king were the ealdormen. These were at the head of the administration of justice in the shires, possessing both judicial and executive authority, and had as their officers the scir-gerefa, or sheriffs. One of their most important functions was the leading of the armed force of the county, a duty which often fell to their share during the period of the Danish invasions. The ealdorman, as such, held possession of certain lands attached to the office, and he was also entitled to a share of fines and other moneys levied for the king's use and passing through his hands. Thus the position which his nobility, his power, and his importance gave him was a brilliant one. In fact, the whole executive government may be considered as a great aristocratic association, of which the ealdormen were the members, and the king little more than the president. They were in nearly every respect his equals, and possessed the right-of

intermarriage with him; it was solely with their consent that he could be elected or appointed to the Crown, and by their support, co-operation, and alliance that he was maintained there. Without their concurrence and assent, their license and permission, he could not make, abrogate, or alter laws; they were the principal witan or counsellors, the leaders of the great gamót or national inquest, the guardians, upholders and regulators of that aristocratical power of which he was the ultimate representative and head* (Kemble, Vol. II, p. 142).

Under the Danish kings the earl or ealdorman fell into a subordinate position, the eorl or earl taking his place in the county. The ealdorman and the king were both surrounded by a number of followers called thegns or thanes, bound by close ties to their superior. The king's thanes were the higher in rank, and formed a kind of nobility by themselves. They possessed a certain quantity of land smaller in amount than that of an ealdorman, and filled offices connected with the personal service of the king, of which the Earl of Wessex is an example. According to Leppenberg they were in all respects the predecesors of the Norman barons. We frequently hear of a class of functionaries called gerefa or reeves, such as the scir-gerefa (shire-reeve or sheriff), the tun-gerefa (farm-reeve or bailiff; Scotch, grieve). These, of course, had different duties to perform, those of the shire-reeve being the most important. He presided at the county court along with the ealdorman and bishop, or alone in their absence; and had to carry out the decisions of the court, to levy fines, collect taxes, etc. In virtue of his office he had a portion of land allotted to him, hence called reeveland. The shires were divided into hundreds and tithings, the former being equal to 10 of the latter. The tithing consisted of 10 heads of families, jointly responsible to the state for the good conduct of any member of their body. For the trial and settlement of minor causes there was a hundred court held once a month at the place of the modern market that was being by the witenagemót, the representative council of the nation. Its members, who were not elected, comprised the æthelings or princes of the blood royal, the bishops and abbots, the ealdormen, the thanes, the sheriffs, etc.

Agriculture, including especially the raising of cattle, sheep and swine, was the chief occupation of the Anglo-Saxons. Large tracts of the marshy land in the east of England were embanked and drained by them and brought into cultivation. Gardens and orchards are frequently mentioned, and vineyards were common in the southern counties. The forests were extensive, and valuable both from the mast they produced for the swine and from the beasts of the chase which they harbored. Hunting was a favorite recreation among the higher ranks, both lay and clerical. Fishing was largely carried on, herrings and salmon being the principal fish caught. The whale fishery was also pursued, when the Anglo-Saxon vessels used to go as far as Iceland. The production of iron was naturally of small moment. Iron was made to some extent, and some cloth, and salt works were numerous. In embroidery and working in gold, however, the English were famous over the continent, and very elegant specimens of gold work have come down to our times. There
was already a considerable trade at London, which was frequented by Normans, French, Flemings and the merchants of the Hanse towns. The Anglo-Saxon forefathers were notorious for their excessive fondness for eating and drinking, and in this respect formed a strong contrast to the Normans who invaded the country. Ale, mead and cider were the common beverages, wine being limited to the higher classes. Pork was a favorite article of food, and so were eels, which were kept and fattened in eel ponds and sometimes paid as rent. The houses were of wattle and daub or brick, mostly of wood and without proper chimneys, but were often richly furnished and hung with fine tapestry. The dress of the Anglo-Saxons was loose and flowing, the materials being linen, woollen and also silk; and their garments were often adorned with embroidery. The men looked upon the hair as one of their chief ornaments, and wore it long and flowing over their shoulders, while they also usually wore beards.

Christianity was introduced among the Anglo-Saxons in the end of the 6th century by Augustine, who was sent by Pope Gregory the Great and became the first archbishop of Canterbury. Kent, then under King Ethelred, was the first place where it took root, and thence it soon spread over the rest of the country. It must, of course, be remembered that the Britons and Scots had already embraced Christianity, and missionaries from these lands were instrumental in the conversion of the Anglo-Saxons. Monasteries were founded at an early period and became numerous. For a time the Anglo-Saxon Church maintained customs different in discipline from Rome, but uniformity was established in 670 by Theodore, the archbishop of Canterbury.

**ANGLO-SAXON LANGUAGE AND LITERATURE.** (a) Anglo-Saxon or Old English is the period of the English language extending from the end of the 5th to the end of the 11th century, the traditional story of the coming of Hengest and Horsa to England in 449, and the Norman Conquest in 1066 being convenient but arbitrary limiting dates. In its origins it is the language brought to Britain by the Teutonic conquerors of Roman and Celtic Britain in the 5th and 6th centuries. The Teutonic invaders were of three north German tribes, the Jutes, who settled mainly in Kent and on the Isle of Wight; the Angles, who settled the country north of the Thames; and the Saxons, who settled the regions south of the Thames except those occupied by the Jutes.

The language of these three tribes was a branch of the West Germanic group of languages, its closest relationships being to Frisian and Low German. Following the lines of the tribal settlement in Britain, the language of the Anglo-Saxon period falls into three main dialects: (1) the Anglian, which subdivides into the Northumbrian, spoken north of the Humber, and the Mercian, spoken by the Angles occupying the Midland counties between the Thames and the Humber; (2) the West-Saxon, spoken by the Saxons who settled in the regions south of the Thames; (3) the Kentish, spoken by the Jutes in Kent and the Isle of Wight. In time the Kentish speech was assimilated by the West-Saxon. Kentish and West-Saxon combined, thus constituting a southern dialect, Mercian and Northumbrian a northern or Anglian dialect. As the dialect in which a literature was first produced and as the speech of originally the most powerful of the various kingdoms established by the invaders, the Angles gave the name to the speech of the country as a whole, *Englisc or Englisc sprae*, and to the country itself, *Englond*, land of the Angles. The term Anglo-Saxon was rarely used in the Anglo-Saxon period and then only as the collective name of the people, not as the name of the language or of the country. At no time, however, in the Anglo-Saxon period was a single "standard" literary or colloquial speech established for all sections of the country, although an appearance of considerable uniformity is presented to us now by the fact that most of the extant monuments of the Anglo-Saxon period are preserved only in the West-Saxon dialect. This is due to the important unifying position which the West-Saxon royal house took under Egbert (802-39) and his successors Alfred (871-900) and Alfred's son Eadward (900-24), Winchester, the capital of Wessex, thus becoming the literary as well as the political capital of the country. The literature of the period, chiefly poetic and written in the Anglian dialect, was at this time translated into West-Saxon, the West-Saxon versions replacing the more original ones, which were thus largely lost. Since the body of Anglo-Saxon literature is preserved only in the West-Saxon dialect, it is that dialect which is commonly understood by the term Anglo-Saxon and which is usually made the basis of systematic presentations of the grammar of the language.

Besides the natural changes in the vowel and consonant system to which language is always subject, Anglo-Saxon differs from later periods of English in two main respects. First, the inflectional system of Anglo-Saxon is relatively a full one. Nouns are inflected for four cases, nominative, genitive, dative and accusative, and for three grammatical genders, masculine, feminine and neuter. The definite article and the adjective are inflected in all the forms of the noun to agree with it. Adjectives are also inflected strong and weak, as they are in Modern German, according to the grammatical position. The verbal system, in its main outlines the same as that of Modern English, differs from the latter in the greater number of forms which it possesses, the subjunctive mood, for example, being still clearly distinguished both in form and use. Owing to its more complicated inflectional system in general, the rules of concord play a much more important part in Anglo-Saxon than they do in Modern English.

The second main distinguishing characteristic of Anglo-Saxon as compared with the English of the Middle and Modern English periods relates to its vocabulary. The Anglo-Saxon vocabulary is practically a uni-lingual one, whereas the tremendous transforming influence of the 13th and 14th centuries, and of the Renaissance in the 15th and 16th centuries, upon English, have changed the language of the later periods into a bi-lingual tongue. Aside from an insignificant Celtic element, the greater but still comparatively slight influence of Latin learning and Latin
Christianity on literary Anglo-Saxon, and toward the end of the Anglo-Saxon period, a small Scandinavian loan element, taken from the Danish and Norse conquerors of England, the vocabulary of Anglo-Saxon is an etymologically pure one. New ideas imported into the life of the people were usually expressed by means of native words giving the language, to the historical student, an appearance of homogeneity and simplicity possessed by no later period of English.

Anglo-Saxon literature is rarely preserved in contemporary documents, the main reason being that, in a method of manuscript transmission, early monuments are gradually altered to fit the contemporary conditions and tastes of successive later generations, with the consequence that the originals are either lost or destroyed. Since most Anglo-Saxon literature is also anonymous, it becomes necessary to determine its date and authorship, so far as this can be done, by the internal evidence of the work and slight help as may be afforded by occasional allusions in contemporary historical documents. Chronologically we may divide the literature of the whole period into three main groups: (1) the chiefly poetical works composed in the latter half of the 7th and in the 8th century; (2) the Early West-Saxon period, comprising chiefly prose works written in the time of Alfred the Great; (3) the Late West-Saxon period, centering about the name of Aelfric, in the late 10th and the early 11th centuries, comprising mainly works in prose but also a few attempts at a revival of the earlier poetry. The body of this literature may be most conveniently reviewed under the two general heads of poetry and prose.

Anglo-Saxon poetry has been preserved to modern times in several different manuscripts of miscellaneous content, the most important being the 'Vercelli Book,' or 'Codex Vercellensis,' so called because the volume is now contained in the cathedral library at Vercelli in northern Italy; the 'Exeter Book,' or 'Codex Exonensis,' still in the possession of Exeter Cathedral in England to the library of which it probably was given about the year 1050 by Bishop Leofric; the 'Jesup manuscript' (Jesuit XI), in the Bodleian Library at Oxford; and the 'Cotton Manuscript' (Cotton Vitellius A XV), in the British Museum, which contains the unique copy of the 'Beowulf.' These manuscripts were all written in the late 10th and early 11th centuries, although the period of the original composition of the works which they contain is of course much earlier. As to metrical form, however, the whole body of this poetry is remarkably homogeneous, and a single description will answer for all of it. The normal line of Anglo-Saxon verse consists of two halves, bound together by alliteration, alliteration consisting in the identity of initial consonants, or in the case of vocalic alliteration, the repetition of a single vowel. Each half line contains at least one alliterating syllable, although one may contain two and the other one, or both may contain two. Normally the number of alliterating syllables in a full line cannot be more than four and is usually less. Each half line contains at least two feet, the principle of the structure of the foot being accentual. Each half line contains at least two and no more heavily stressed syllables, the metrical stress coinciding with the logical stress of the words, and at least two unstressed syllables, although the number of the unstressed syllable may vary within the limits. According to the order of the stressed and unstressed syllables the half lines fall into a limited number of types, consecutive passages being made up of half lines of the various types arranged in whatever order the poet pleases. Within the limits of its own content the scansion of Anglo-Saxon poetry is rigid and exact. The use of stanzas forms, except in one or two sporadic instances, was unknown to the Anglo-Saxon poets. Not only in metrical form, but also in its use of the various devices of poetical ornament, the body of Anglo-Saxon verse is fairly constant for all periods. The simile is very rarely used, its place being taken by the metaphor of *kenning.* Specially characteristic of the poetic style is the device of *wring,* by which the person or object about to be expressed is repeated in several different forms by the use of synonymous terms. This gives to the poetry a retarding effect which is often particularly noticeable, and, to our modern taste, particularly unpleasant in the earlier verse. The diction and tone of the poetry is elevated and dignified throughout, the poetic convention apparently not tolerating anything that approached *doggerel* in tone.

As to its content, Anglo-Saxon poetry is best considered in two groups, according as it follows the heroic or native tradition, or the Christian or literary tradition. Anglo-Saxon poetry of the native tradition goes back in its origins to the earliest historical periods of the race. The most primitive pieces are such poems as the 'Widsith,' 'The Complaint of Deor,' bits of popular lore such as the 'Charms' and 'Riddles,' and above all the 'Beowulf.' Although given a Christian coloring here and there by the interpolations of later transcribers and redactors, this poetry is essentially heathen, or, at least, non-Christian, in spirit. The 'Beowulf,' the most important single monument of the Anglo-Saxon period, is an heroic or epic poem of 3,182 full lines, telling the legendary and mythical deeds of a hero, Beowulf. Although its manuscript first appears in the 8th century, the poem was probably composed in England in the 8th century, by an unknown author or compiler, from a group of more or less loosely connected lays which had grown up in popular oral tradition, its tone is that of a much earlier period. The action of the poem, which falls into two parts, is altogether legendary and mythical. It takes place not in England nor are any of the characters Anglo-Saxons. In the first part, Beowulf, a Geat from the Scandianavian peninsula, comes to the court of Hrothgar, the royal residence of the Danish King Hrothgar, probably on the island of Zealand, to save it from the ravages of the moor-dwelling monster Grendel. He destroys Grendel and also Grendel's mother, who may be interpreted in the terms of nature myth as symbolizing the destructive power of nature in certain phases, and then returns to his own country. In the second part, Beowulf who is now an old man and has for many years been King of the Geats, fights with a terrible fire-drake that has been devastating his land; but
the hero himself is mortally wounded in the combat, and the poem closes with the account of his death and burial. Beside the main character Beowulf, and the mythological characters Grendel, Grendel's mother and the fire-drake, numerous minor characters are introduced and several longer episodes of great interest and beauty are developed. Despite the mythological character of the main action, the poem is given a strong human interest. The tone of the narrative throughout is epic and warlike and the action is always upon an extremely noble and dignified plane. The ideal of character presented in the hero Beowulf is one of valor and power directed by a self-sacrificing zeal for the welfare of others. Aside from the "Beowulf," native Anglo-Saxon epic poetry is limited to a fragment (48 lines) of what in its complete form probably was a poem on the same scale as "Beowulf," the fragment of the "Battle of Finnsburgh." In the Late West-Saxon period a revival of interest in the earlier heroic poetry took place, the principal results being the "Battle of Brunanburgh," descriptive of a battle between the English and the Danes in 937, and the spirited and technically admirable "Battle of Maldon," descriptive of a battle which took place in 991. With these poems expressive of the native or heroic spirit should be grouped a small number of shorter lyric pieces, also non-Christian in origin and feeling, "The Wanderer," "The Husband's Message," "The Wife's Lament," "The Seafarer" and a group of some 90 poetical riddles. These poems are generally elegiac in tone and are often characterized by that imaginative beauty and charm of expression.

Anglo-Saxon poetry of the Christian tradition consists chiefly of the poetry of the Cædmonian and the Cynwulfian schools. It is Christian in subject-matter, but in method and style it resembles closely the native heroic poetry, a resemblance due to the conscious maintenance of the national and traditional poetic style. The only early authority for the existence of a poet Cædmon is Bede ("Historia Ecclesiastica," Book IV, Chapter 24) who tells us that C. Imo was an illiterate lay-brother of the monastery at Whitby (then known as Streoneshalh), who received miraculously the gift of song and who versified certain stories from the Old and New Testaments. The date at which Cædmon lived, according to Bede, was several generations before himself, that is about 650. Answering in part to Bede's description, we have still extant long versified narratives based on the story of Genesis, of Exodus, of Daniel and of Judith. That all of these, however, are by the same author and that poet the one that Bede mentions, the internal evidence of the poems themselves forbids us to believe. It is probable that the only actual extant specimen of the work of Cædmon is a short poem of nine lines known as "Cædmon's Hymn." The other Cædmonian poems, although they have features in common, particularly as to style and subject-matter, which justify holding them together in a group, are undoubtedly the work of various authors. Our information concerning a poet Cynwulf is derived altogether from certain poems to which the author has appended his signature in runic letters woven into the context of his verse. These signed poems are the "Christ," "Juliana," "Elene" and the "Fates of the Apostles." The period at which Cynwulf lived and wrote was probably the last half of the 8th century, and the region in which he lived was probably Northumberland. Various attempts have been made to identify the poet with persons mentioned in contemporary historical animals, but all the name Cynwulf is of not infrequent occurrence, none of these attempts has so far proved convincing. The remaining important poems of the Cynwulfian group, some of which may have been composed by Cynwulf, although in no instance do the proofs permit a positive assertion, are "Andreas," based on the apocryphal legend of Saint Andrew; "Guthlac," in praise of the English saint of that name; the "Dream of the Cross"; "Phoenix," a Christian allegorical poem, "Harrowing of Hell" and a number of shorter hymnic poems. The characteristics which distinguish the Cynwulfian from the Cædmonian poems are sharply marked. The subject-matter of the latter is chiefly Old Testament story, of the former, New Testament story, as in "Christ," and Christian legend, as in "Elese." The poems of Cynwulf are of the influence of the "Cross" by Saint Helena, the story of Saint Juliana, of Saint Andrew and of Saint Guthlac. The Cædmonian poetry is characterized in general by severity and simplicity of style, whereas the Cynwulfian poetry is highly colored and romantic in tone. Particularly noticeable in the Cynwulfian poetry is the free and often extravagant use of phrases and themes borrowed from the "Beowulf." These differences in style, however, are relatively not great, and in a general review of Anglo-Saxon poetry is struck by the remarkable similarity of treatment which characterizes it throughout. There is but one metrical form, sporadic instances of attempts at stanzaic structure, as in "Deor," merely serving to emphasize the fixed character of the metre. Aside also from a few pieces written under the influence of the church hymns, the basis of all Anglo-Saxon poetical composition is narrative. Moreover the authority acquired by the poet of "The Dream of the Cross" is high. In imposing an established and conventional standard of style which remained constant throughout the period. In its respect for rule and convention, in its uniform and "classical" quality, Anglo-Saxon poetry is paralleled by only one other period of English Literature, the Augustan age of the 18th century.
ments, the originals were lost or destroyed. The chief extant prose monuments of patriotic or national interest are the codes of laws, which were got together and revised at various periods, and under the direction of various kings, one of the most notable forms being that known as the Legal Code of Alfred, and the Anglo-Saxon Chronicle (consult 'English Chronicles'), in its final form written under the direction of Alfred the Great and perhaps in part actually by him, but to some degree also based on pre-existing Anglo-Saxon and Latin documents. The prose of educational and religious interest may be considered in two groups, that centring about the name of Alfred (849–901) or Early West-Saxon prose, and that centring about the name of Ælfric (955–1025?) or Late West-Saxon prose. Early West-Saxon prose consists almost altogether of translations of Latin works. Those which there is reason to believe issued directly from the pen of King Alfred are translations of Pope Gregory's 'Cura Pastoralis,' Bede's 'Historia Ecclesiastica Gentium Anglorum,' Orosius' 'Cursus Chronologicus,' Gregory the Great's 'De Senectute,' and 'De Consolatione Philosophiae' and a combination from the writings of Gregory and Augustine known as the 'Bloom's' (i.e., 'Anthology') of Alfred. A translation of the 'Dialogues' of Gregory was made, probably by Bishop Werferth of Worcester, for which Alfred wrote a preface. These works differ in the degree of fidelity with which they follow their originals, some, as for example the 'Cura Pastoralis,' being close but always idiomatic translations, whereas others, for example the versions of Orosius and Boethius, are fairly free and contain extensive original additions. The style of this prose of the Early West-Saxon period, of both the religious and the patriotic interest, is generally clear and simple, but is utterly without literary quality, its highest attainment being a certain naive directness and vigor of expression.

The prose of the Late West-Saxon period consists in part of translations of Latin theological writings and of parts of the Bible, but owing to the renewed interest in preaching rising out of the Benedictine reform of the latter half of the 10th century, also of a considerable body of sermon literature reflective of contemporary conditions in England. The chief collections are the 'Blickling Homilies,' so called because the manuscript in which they are preserved is kept at Blickling Hall, Norfolk; the sermons of Wulfstan, and the 'Fremmo Catholice' or 'Catholic Homilies' of Ælfric. The 'Blickling Homilies' and the sermons of Wulfstan are popular in tone, frequently rising, especially in the sermons of Wulfstan, to passages of considerable oratorical power and effectiveness. Ælfric's homilies are more literary, both in themes and in style. They are written easily and lightly and represent the highest development of Anglo-Saxon in the direction of a literary artistic prose. Ælfric's taste is not pure, his style not always falls into the error of a too elaborate and conscious use of ornament and figure. Very characteristic of his method is a half-verse, half-prose style, which he made use of in his 'Saints Lives.'

A fragment of a translation of the Greek romance of Apollonius of Tyre, made from a Latin version in the Late West-Saxon period by an unknown translator, should be mentioned as the sole example in Anglo-Saxon of the literature of the imagination in prose.

Bibliography.—The standard Anglo-Saxon grammars are Siever, 'Angelsachsische Grammatik' (3d ed., 1898, translated into English by A. S. Cook); Buehringer, 'Das angelsächsische Elementarbuch' (unfinished, the first part appearing in 1902); and Kaluza, 'Historische Grammatik der englischen Sprache' (Pt. 1, 2d ed., 1906). More elementary presentations of the grammar will be found in the beginners' books by Sweet, 'An Anglo-Saxon Reader' (4th ed., 1881) and Bright, 'An Anglo-Saxon Reader' (3d ed., 1899). The dictionaries are Bosworth-Toller, 'Anglo-Saxon Dictionary' (1882); Grein, 'Sprachschatz der angelsächsischen Dichter' (1861–64), a dictionary of only the verse texts but an invaluable aid in the study of them; Sweet, 'Students' Dictionary of Anglo-Saxon' (1897); and Clark Hall, 'A Concise Anglo-Saxon Dictionary' (1894). Practically all Anglo-Saxon poetical texts are contained in Grein-Wuelker, 'Bibliothek der angelsächsichen Poesie,' and a good part of the prose in the 'Bibliothek der angelsächsischen Prosas,' by the same general editors. Separate editions of most texts have been made, for which and for the bibliography of Anglo-Saxon General, consult Wuelker, 'Grundriss der Geschichte der angelsächsischen Litteratur' (Leipzig 1885), and Koerting, 'Grundriss der Geschichte der englischen Litteratur' (4th ed., Muenster 1905). For Anglo-Saxon metre consult Schiper, 'Grundriss der englischen Metrik' (1895), and Siever, 'Altgermanische Metrik' (1893). The history of Anglo-Saxon literature is treated by Brooke, 'The History of Early English Literature' (1892) and 'English Literature from the Beginning to the Norman Conquest' (1888); Ten Brink, 'Geschichte der englischen Litteratur' (Vol. I, 1899), translation by Kennedy; Gomme, 'Translation of the Anglo-Saxon Chronicle' (1910).

GEORGE P. KRAPP,
Instructor in English, Columbia University.

ANGOLA, Ind., city and county-seat of Steuben County, 40 miles northeast of Fort Wayne, on the Lake Shore and Michigan Southern and the Saint Joseph Valley railroads. Tri-State College is located here. Angola was settled in 1834, incorporated as a town in 1866 and a city in 1906. Pop. 2,800.

ANGOLA (Portuguese West Africa), west Africa, a Portuguese dependency on the Atlantic coast. It has a coast-line of over 1,000 miles, is bounded on the north and northeast by the Belgian Congo, on the east by British South Africa and on the south by German Southwest Africa. It has an area of about 500,000 square miles and has belonged to the Portuguese since 1575, with the exception of the years 1641–48, when it was held by the Dutch. It is watered by the Coanza and other rivers and its climate, though excessively hot, is greatly tempered by the trade-winds. There are large tracts of amazing fertility in the interior. It is under a governor-general, who resides at Loanda. It is divided into six districts: Kongo, Loanda, Benguela, Mossamedes, Huila and
ANGORA — ANGUIDAE

Lunda. The capital is South Paolo de Loanda, other important towns being Cabinda, Ambizi, Novo Redondo, Benguela, Mossamedes and Port Alexander. The estimated population is about 4,000,000. There are 52 government schools, and seven municipal and two private schools, with altogether about 2,410 pupils. Various missions are at work in the country. The chief products are coffee, rubber, wax, sugar for rum distilleries, vegetable oils, cocoa-nuts, ivory and fish. Rubber supplies are now becoming exhausted; cotton-growing, formerly remunerative, has been neglected but is now increasing; tobacco is grown and manufactured for local consumption; petroleum and asphalt are worked by a British syndicate. The province contains large quantities of malachite and copper, iron, petroleum and salt. Gold has also been found. The imports in 1914 reached an aggregate value of $4,171,574 and the exports $3,477,789. The chief imports are textiles, chiefly British prints, hardware, machetes, tools, cutlery, musical instruments and drugs. The chief exports are coffee, rice and tropical fruits. Dried fish are exported in considerable quantities. The trade is largely with Portugal, the export trade being exclusively by sea. In 1914 there entered the port of Loanda 195 vessels of 293,531 tons and cleared 187 of 270,917 tons. The Portuguese National Navigation Company has most of the carrying trade to and from Europe; the steamers of three British lines and one German line touch at ports of the colony. There are 818 miles of railway in operation and 2,688 miles of telegraph line with 69 telegraph offices. Angola is connected by cable with east, west and south African telegraph systems.

ANGORA, or ENGOUR, Asiatic Turkey. (the ancient ANCYRA), a town 215 miles east of Constantinople, with which there is now railway communication. It is the capital of the vilayet of the same name. It has ruinous walls, and there are some remains of Byzantine architecture belonging to the ancient city, and a few relics of earlier times, both Greek and Roman. Among the latter are the remnants of the Monumentum Ancyranum, raised in honor of the Emperor Augustus, who much embellished the ancient city. Ancyra was the centre of the Tectosages, a Gallic tribe who settled in Galatia in the 3d century B.C., and was the capital of the Roman province of Galatia after 25 B.C. In the Byzantine period it was a place of great importance, was captured by Persians and Arabs; next fell under the sway of the Seljuk Turks, was held by the Crusaders for 18 years, and passed to the Ottoman Turks in 1360. A great battle between the Turks and Tatars was fought near Angora in 1402, in which the latter were victorious. It was reconquered by the Turks in 1415, and has since remained in their possession. It was taken by the Egyptians under Ibrahim Pasha in 1832. Angora is celebrated for the long-haired goats bred in its vicinity called by the Arabs the chamal goat, meaning "silky or soft." The fineness of the hair seems to depend on some peculiarity of the atmosphere, for it is remarked that the cats, dogs and other animals of the country have exceedingly long and fine hair, and that they all lose much of their distinctive characteristic when taken from their native haunts. Goat's hair forms an important export; other exports being goats' skins, mohair, grain, dye-stuffs, principally madder, and yellow berries; mastic, tragacanth and other gums; also honey and wax. Mohair cloth is manufactured. British manufacture are imported to some extent. Estimated pop. 35,000, of whom 18,000 are Moslems, 9,400 Roman Catholic Armenians and 400 Jews. Consult Wright, 'Cities of Paul' (Boston 1905).

ANGORA CAT. See CAT.

ANGORA GOAT. See GOAT.

ANGOSTURA. See CIUDAD BOLIVAR.

ANGOSTURA, or ANGUSTURA, ãn-gãs-tur'ã, BARK, the bark of a shrub or small tree of the Orinoco River Valley, Galipea cuspara, family Rutaceae. It comes into the market in the form of broken quills, the outer surface being yellowish-gray and covered with small warty, corky growths. The taste is very bitter and aromatic. Its active constituents are volatile oil, hence its aromatic nature; angusturin, a bitter principle, and four alkaloids; cusparin, C24H18NaO5; galipein, C24H16NaO6; galipin, C26H20NaO6; and galipedin, C24H18NaO9. The action of these principles has not been thoroughly investigated. The bark is used as an antimalarial remedy and as an aromatic bitter for the stimulation of the intestines. It is also a laxative. It is a common ingredient of many potent medicines and liqueurs.

ANGOULEMÉ, ãn-goo-lam', France, city, capital of the department of Charente, and formerly of the province of Angoumois, on the left bank of the Charente, 60 miles north-northeast of Bordeaux. It stands on the summit of an isolated rocky hill, at the foot of which are the suburban quarters. There is a handsome modern town-house on the site of the old castle of the ancient counts of Angoulême. The cathedral is a Romanesque building, dating from the 12th century. Angoulême possesses a lyceum, theological seminary, normal school, two hospitals, a lunatic asylum, theatre, etc.; besides a public library and a museum of natural history. The staple manufacture is paper made in numerous mills in the neighboring valleys. There are also manufacturing of carpets, linen, earthenware, woolen stuffs, fire-arms, gunpowder, wire, brandy, distilleries, etc. A considerable trade is carried on. Angoulême represents the ancient Icutilisma, destroyed by the Normans in the 9th century. The bishopric was founded in 379. Clovis erected the first cathedral in 507. Pop. (1911) 38,211. Consult Cabinet de Rencogne, 'L'Histoire du commerce et de l'industrie en Angoumois' (Angoulême 1879); Castaigne, 'La Cathédrale d'Angoulême' (ib. 1834); Nanglard, 'Fouille historique du diocèse d'Angoulême' (ib. 1897).

ANGSTROM, ång'trêm, Anders Jons, a Swedish scientist: b. 1814; d. 1874. From 1867 to his death the secretary to the Royal Society of Sciences at Upsala. He was a recognized authority upon optics, and among his writings are 'Optiska Undersökningar' (1853); his best known work, 'Recherches sur les Rayons Solaire' (1869); 'Sur les Spectres des Gas Simples' (1871); and 'Mémoire sur la Température de la Terre' (1871).

ANGUIDAE, a family of vermiform, terrestrial lizards, including the glass-snake of
ANHYDRIC, a mineral having the composition of calcium sulphate, CaSO₄, and differing from gypsum in its lack of water. In its common white, massive form it much resembles the snow-white gypsum (q.v.), but is readily distinguished by its superior hardness, 3 to 3.5. Anhydrite also occurs in orthorhombic crystals and in cleavable-lamellar and fibrous masses. Its colors are very varied, white or gray being the most common, but blue and even brick-red not being uncommon. It is brittle, breaking with an uneven or splintery fracture, or when crystallized, cleaving with ease into rectangular chips. Its lustre is also very varied, the crystals appearing pearly, greasy or vitreous according to the faces examined.

ANHYDROUS AMMONIA. See GASES, COMPRESSED.

ANI, ā'ne, a bird of the subfamily Crotophaginae of the cuckoo family, characterized by uniformly greenish-black or purplish-black plumage, a long, spreading tail and a high, keel-like projection on the top of the beak. Several species of these aberrant cuckoos inhabit South and Central America, one (Crotophaga Ani) occurring in Florida and the West Indies, where it is known as Savanna blackbird, black witch, and rain-bird. Bold but wary, the ani flies from bush to bush, uttering a mewing sound or a sharper double cry. Flocks gather in swarmy woods, especially among mangrove thickets, and feed on insects, lizards, berries, etc., and accompany feeding cattle, picking ticks from their hides. These birds in most cases build huge community nests, many pairs nesting in niches in a great structure of sticks, etc., placed in some low tree; but this subject is not very well understood. An exception exists in one South American species, the "white ani" (Guira purpurea), which is brown, buff and white in color, and puts its pale blue eggs in individual nests.

ANILINE is an oily organic liquid classified as a base. Its formula is C₆H₅NH₂. It is commonly known as a derivative of coal-tar, but that substance contains only from ½ to ¼ of 1 per cent of aniline, and the difficulties of separating it are so formidable that it is never derived from coal tar directly. Aniline is colorless, but commercial aniline turns gradually brownish on exposure to air and light, due to a small admixture of thiophene. Aniline solidifies at 18° F., and boils at 330°. Its vapor is inflammable, burning above the liquid with a large, smoky flame. Aniline is an actively corrosive poison. It has a peculiar nauseating odor, and its fumes exert decided, poisonous effects upon workmen handling it.

Aniline was first discovered by Unverdorben in 1826. He found it among the products of the destructive distillation of indigo. In 1834 it was identified by Runge in coal-tar. With the discovery of the first aniline color, "mauveine," by Perkin, in 1856, aniline became a valuable commercial product. It is now prepared from nitrobenzene with the aid of clean borings of soft cast iron in an acid solution. Into a still fitted with an agitator are placed a part of the nitrobenzene and a small quantity of the iron borings with water and hydrochloric acid. Steam is turned in and the contents are thus boiled and constantly stirred. The distillate is turned back into the still and the remaining nitrobenzene and iron borings are fed in at intervals. When the distillate ceases to contain nitrobenzene the operation is at an end, and the still will contain only aniline oil, water and iron chloride and oxide. A charge of 1,000 pounds of nitrobenzene requires about 1,000 pounds of iron borings and yields about 765 pounds of aniline oil in about 10 hours' operation. The final purification of the crude aniline oil is conducted in a vacuum still.

Commercially, three forms of aniline oil are recognized: (1) aniline oil for blue, which is unmixed aniline; (2) aniline oil for red, which is a mixture of aniline with ortho-toluene and para-toluene, and (3) aniline oil for safranine, which is a mixture containing aniline and orthotoluidine. See COAL-TAR COLORS.

With chlorates, in the presence of metallic salts, aniline gives the indispensable dyestuff Aniline Black. It is also extensively used as raw material for many other colors used in dyeing. In the manufacture of drugs aniline is used as the starting point for the production of acetanilide, antipyrine, antifebrin, etc. Nitrated aniline has been experimented with as an explosive. It is claimed to be particularly adapted for use in detonators, primers, etc., and for mines and torpedoes. It is estimated that the output of aniline in the United States for the calendar year 1916 was 11,000 tons.

ANILINE POISONING. The use of the anilines, and particularly of the new synthetic drugs derived from this product, has become so universal that many instances of poisoning, both acute and chronic, are observed. In acute aniline poisoning the chief effects are on the blood. It prevents the oxidation of hemoglobin in the red blood-cells, forms methemoglobin, causes the destruction of red blood-cells (hemolysis) and thus results in death. The chief symptoms are headache, vertigo, weakness and stumbling walk, blue color of defective blood oxidation (cyanosis), disturbances of respiration, increase of urine, which is frequently colored reddish to dark brown from the broken-down blood-cells, depression of temperature, chills, dilated pupils and death from asphyxia. The fatal dose is about ½ drams. In non-fatal cases recovery may be much protracted. Treatment consists in withdrawal of all of the poison, washing the stomach, fresh air, artificial respiration and infusion of normal salt solution. The aniline
derivations mostly used are acetanilid (antifebrin), phenacetin, exalgen, lactophenin, methacetin, malakin, phenocol, citrophen, apolyisin, cosaprin, malarin, etc. Several aniline dyes are also used in medicine, of which the principal are methylene blue as a urinary antiseptic, scarlet red as an ointment on granulating surfaces, fluorescin, eosin and fuchsin. These dyes are also used to give an agreeable color to medicines, but they always have the same general effect. Chronic aniline poisoning, found chiefly among workers in color factories, is of much the same character, but the symptoms develop slowly. There are skin symptoms, urinary changes and various nervous attacks, with headache, tremors, changes in sensation, anaesthesia, etc. The treatment should involve the ventilation of the factories, thus getting rid of the color-dust floating in the moisture of the rooms.

ANIMA MUNDI, anv-t’ma mən’di (‘soul of the world’), an ethereal essence considered by ancient philosophers as the informing principle of the universe or matter and bearing the same relation to it that the human mind does to the body. The conception originated in the East and was held by the Egyptians. Anaxagoras (q.v.), one of its earliest Western exponents, believed that it gave form to the universe; Plato treats of it at large in his ‘Timaeus’; Aristotle considered the world a living entity, but informed by an external spirit. Nearly all philosophical sects dallied with the idea. The Stoics thought it the sole vital principle of the universe, but not the universe itself in a different shape, as the doctrine of pantheism imputed to them would imply. In modern times it appears in the works of Cornelius Agrippa (who calls it spiritus mundi), Paracelsus, Van Helmont, Giordano Bruno, Sebastian Franck, Jacob Boehme, etc., in More and Cudworth, in the later Platonists, and in the philosophy of Schelling, who has incorporated it into his whole system. See Animism; Pantheism.

ANIMAL. The word *animal* being derived from *anima*, breath, soul, suggests the distinction popularly accorded to animals as contrasted with plants. Linnaeus said that plants grow and animals feel, to that another matters not. As will be seen below, however, animals do not fundamentally and in their simplest forms differ from the simplest plants, as both are constituted of protoplasm, which is equally contractile in both kingdoms, and we are coming more and more to speak of living beings as organisms. All organized beings agree in being formed of protoplasm, “the physical basis of life.” Strictly speaking, however, an animal is a living organism, the protoplasm of which does not secrete a cellulose cell-wall, and the existence of which requires proteid material obtained from the living or dead bodies of existing plants or animals.

Differences between Plants and Animals.

— It is difficult, when we consider the simplest forms of the vegetable kingdom, to define what an animal is as distinguished from a plant, for it is impossible to draw hard and fast lines between them. In defining the limits between the animal and vegetable kingdoms our ordinary conceptions of what a thing is will be of little use in dealing with the lowest forms of either kingdom. A horse, fish or worm differs from an elm-tree, a lily, or a fern in having organs of sight, of hearing, of smell, of locomotion and special organs of digestion, circulation and respiration, but these plants also take in and absorb, the transfer of the sap is not confined to any one portion or set of organs as such. It is always easy to distinguish one of the higher plants from one of the higher animals. But when we descend to animals like the sea-anemones and coral-polyps, formerly called “zoophytes,” so striking is the external similarity between the two kinds of organisms that early observers regarded them as “animal flowers.” Sponges until a very late day were regarded as plants. So-called plants, as Bac terium or Bacillus and their allies, and so-called animals, as Protamaba, or certain monads, which are simple specks of protoplasms without genuine organs, may be referred to either kingdom. Indeed, a number of naturalists, notably Haeckel, number to a name (Protista, q.v.), certain lowest plants and animals. Even the germs (zoospores) of monads like Uvella and those of other flagellate infusoria may be mistaken for the spores of plants; and there are certain flagellate infusoria so much like low plants (such as the red-snow or Protococcus), and the slime molds (Mysomyces) in the form, deportment, mode of reproduction and appearance of the spores, that even now it is possible that certain organisms placed among them are plants. It is only by a study of the connecting links between the nearly lowest organisms, leading up to what are undoubtedly animals or plants, that we are enabled to refer these beings to their proper kingdom.

As a rule, plants have no special organs of digestion or circulation and nothing approaching to a nervous system. They differ from animals in their metabolic processes. Most plants absorb inorganic food, such as carbonic acid gas, water, nitrate of ammonia, and some phosphates, silica, etc., all of these substances being taken up and stored away, and then used, either on dead animal matter and promote the process of putrefaction and decay, but the food of these organisms is inorganic particles. The slime molds, however, envelop the plant or low animals much as an amoeba throws itself around some of the living plant and absorbs its protoplasm; but Myxomyces, in their manner of taking food, are an exception to other molds and are now regarded as animals. The lowest animals swallow other living animals whole or in pieces; certain forms, like the Low Protozoa (bore into minute algae and absorb their protoplasm; others engulf silicious-shelled plants (diatoms), absorbing their protoplasm. No animal swallows silica, lime, ammonia or any of the phosphates as food. On the other hand, plants manufacture or produce from inorganic matter starch, sugar and nitrogenous substances which constitute the food of animals. During assimilation plants absorb carbonic acid and in sunlight exhale oxygen; during growth and work they, like animals, consume oxygen and exhale carbonic acid.
Animals move and have special organs of locomotion; few plants move, though some climb, and minute forms have thread-like processes or vibratile lashes (cilia) resembling the flagella of monads, and flowers open and shut; but these motions of the higher plants are purely mechanical and the perpetual local ororganic rhythm controlled by nerves. The mode of reproduction of plants and animals, however, is fundamentally identical, and in this respect the two kingdoms unite more closely than in any other. Plants also, like animals, are formed of cells; the latter in the higher forms combine into tissues.

Physiological Distinctions and Resemblances.—As has been said, the bodies of the lowest plants and animals are plainly enough made up of protoplasm. The irritability, contractility, and metabolism of a plant-cell or a living, free unicellular plant do not differ from those of a unicellular animal (Protozoa) of the same morphological grade. The movements of the lowest algae, the sensitiveness of the leaves of the sun-dew and other insectivorous plants, are due to the same primary cause as the movements of animals at all grades, as the power of lifting one’s arm is fundamentally due to the contractility of the protoplasm forming the cells of the muscles. The movements of the highest animals are not fundamental, those moulds which do not contain chlorophyll and bacteria performing the same metabolic functions as regards carbon dioxide as animals. Animals are also subject to the same general tropisms as plants; they are geotropic, heliotropic, thermodromic, hydrotropic, chemotropic, etc. (See Tropisms.) To a much greater extent than formerly supposed even insects so highly developed as ants are subject to the influences of the primary factors of growth, morphogenesis, and of the conduct of life, and the instincts of animals in general are more dependent on these agents, on external stimuli, than was previously thought to be the case.

Plants Fixed Organisms; Animals as a Rule Free-moving Organisms. Various algae, the lowest plants (Protophytes) are, as entire organisms, often motile, free-swimming, closely resembling monads, the higher or more specialized forms, comprising the great majority of the vegetable world, are fixed and have always remained so. It is this fixed condition of life which, so to speak, has held the plant world in an iron grasp and kept it within its natural limits. On the other hand, animals as a rule are active, free to move, restless. Whenever animals, though born free-swimming germs or larvae, are constrained by change of circumstances to become attached or fixed to the sea-bottom or solid objects, they degenerate and become more and more subject to the influence during growth of those cosmic and physical forces, such as gravity, temperature, of which two, or of which three, determine the shapes and morphology of plants. Fixed animals, like the polyps, sea-anemones, sponges, Polychaeta, etc., which lead a purely vegetative life, tend to assume plant-like shapes. Even echinoderms, as the fixed crinoids, are plant-like, hence their name, sea-lilies. It is freedom of motion, greater activity, which have led to the vastly more complex and higher types of life in animals, to the development of a nervous system, and to the origin of mind and intelligence.

Plants Not the Primitive Basis of Animal Life.—As the lowest plants and animals are scarcely distinguishable, it is probable that plants and animals first appeared contemporaneously; and while plants are generally said to form the basis of animal life, this is only partially true; a large number of fungi are dependent on decaying animal matter; and most of the Protozoa (q.v.) live on animal food, as do a large proportion of the higher animals. The two kingdoms supplement each other, are mutually dependent and probably appeared simultaneously in the beginning of things. It should be observed, however, that the animal kingdom greatly overtops the vegetable kingdom, culminating in man. (See Zoology.) Consult ‘Cambridge Natural History’ (London 1911); Bergson, ‘Creative Evolution’ (New York 1911); Morgan, ‘Evolution and Adaptation’ (New York 1903).

ANIMAL ALKALOIDS. Ptomaines (q.v.) was the name originally given to a large class of products resulting from the putrefactive process occurring in animal substances. These possessed many of the characteristic actions of the vegetable alkaloids and have been termed animal alkaloids. Similar products formed in the human body, as the result of normal metabolism chiefly of lecithin, or proteids, are termed leucornas. Many of these leucornas and leucocains are highly poisonous toxins. See ALKALOIDS; METABOLISM; PTO- MAINES; TOXICOLOGY.

ANIMAL CHARCOAL. See Charcoal.

ANIMAL CHEMISTRY. The department of organic chemistry which investigates the composition of the fluids and the solids of animals, and the chemical action that takes place in animal bodies. There are four elements, sometimes distinctively named organic elements, which are invariably found in living bodies, namely, carbon, hydrogen, oxygen and nitrogen. To these may be added, as frequent constituents of the human body, sulphur, phosphorus, lime, sodium, potassium, chlorine, iron and iodine. The four organic elements are found in all the fluids and solids of the body. Sulphur occurs in blood and in many of the secretions. Phosphorus is also common, being found in nerves, in the teeth and in fluids. Chlorine occurs almost universally throughout the body; lime is found in bone, in the teeth and in the secretions; iron occurs in the blood, in urine, and in bile; and sodium, like chlorine, is of almost universal occurrence. Potassium occurs in muscles, in nerves, and in the blood corpuscles. Minute quantities of copper, silicon, manganese, lead and lithium are also found in the human body. The compounds formed in the human organisms are divisible into the organic and inorganic. The most frequent of the latter is water, of which two, or of which three, determine the shapes and morphology of plants. The organic compounds may, like the foods from which they are formed, be divided into the nitrogenous and non-nitrogenous. Of the former the chief are the albumens (found in blood, lymph, and chyle), casein (found in milk), myosin (in muscle), gelatin (obtained from bone), and others. The non-nitrogenous compounds are represented by organic acids, such as formic, acetic, butyric, stearic, etc.; by animal starches, sugars; by fats and oils, as stearin and olein, and by
ANIMAL COLORS—ANIMAL HEAT

alcohols (two compounds, cholesterin and glycogen) from.

ANIMAL COLORS. See COCHINEAL; KERMES; PURPLE SHELL.

ANIMAL ELECTRICITY, electricity which certain species of animals, particularly those inhabiting the water, have the power of producing. The amount which they can produce varies with different animals. The electric eel or torpedo can give a severe shock. Contact between the nerve and muscle of a frog will produce a feeble current of electricity.

ANIMAL EXPERIMENTATION. A method of studying disease by the use of low animals in order to alleviate human suffering. The ancient Greeks practised it, even primitive tribes learned somewhat about human disease by observing lower animals and many human superstitions had their origin from such observations. Harvey's celebrated discoveries concerning the circulation of the blood rested upon animal experimentation, and were it not for the large increase in knowledge made possible by its methods, much of our modern civilization would have been impossible. Animal experimentation, moreover, has benefited all those animals which are useful to man, and most of the opposition to the application of its methods is founded upon very superficial and illogical reasoning.

The chief impetus to modern methods came after the introduction of general and local anaesthetics, such as ether, chloroform and cocaine. These substances banished all pain to the animal and permitted the delicate manipulations which were so essential to the developments of correct methods of technique.

Animal experimentation has supplanted a great deal of guessing about disease by direct methods of proving cause and effect. To give up the knowledge acquired would be to slip back into an era of barbarism, so far as medicine is concerned. No essay could be written which could possibly exhaust the innumerable benefits which every member of an enlightened community enjoys. The chief advances have been made along so many different lines that it becomes difficult to single out those of most importance. Although disease itself in the human being is nature's great vivisection, nature's methods are so ruthless and widespread that without animal experimentation the processes which we call disease could not be minutely analyzed. The insight obtained concerning the physiological processes of every kind of human activity would be impossible without animal experimentation. Harvey's monumental study and his discovery of the circulation of the blood is but one of a million discoveries which have established a true physiology. Without a sound physiology there can be no rational medicine. The knowledge of the circulation, of the digestive system, of the formation of the blood, of the ductless glands, of the kidneys, the movements of the intestines, and above all the vast and intricate workings of the nervous system—all of these have been made possible by animal experimentation.

The successful attack upon disease is no less a result of the studies on animals. Pasteur's early studies in infectious diseases were made upon lower animals. Our knowledge of every disease of infectious origin has been vastly advanced. Tuberculosis, typhoid fever, syphilis, gonorrhea, diphtheria, all pus infections, meningitis, poliomyelitis, and one might go on indefinitely, have all been better understood and hence nearer cure by the methods of experimentation. It is less than a score of years since the secret of syphilis was unravelled by its methods—and syphilis kills more people every year than 10 world wars will ever kill. The excessive prudery of the human being who would rather indulge his infantile sexuality than understand it keeps this disease alive as a sort of policeman to aid in the attack upon man's essential sexual immorality. Gonorrhoea is the most widespread of all diseases, scattering the sufferings of disease wherever man goes. It is still permitted to undermine the health of a nation, because of this same prudery which calls itself morality but is a hideous mask which conceals man's immorality and lust power.

Whenever large bodies of men are assembled, as in large contract enterprises, in the manœuvres of war or similar mass actions, typhoid fever has often been a veritable scourge. Animal experimentation laid the solid foundations of anti-typhoid inoculations which have been eminently successful. The conquest of the scourge of smallpox which entered the palace as well as the hovel in Shakespeare's time has been practically eradicated through Jenner's original animal experimentation. To treat of all of the vast benefits to the farmer in the treatment of hog cholera, chicken cholera and the innumerable diseases of farm animals, which have come through animal experimentation, would alone fill a volume. Consult Cannon, 'Reference Handbook of Medical Sciences' (1913).

SMITH ELY JELLIFFE.

ANIMAL FLOWER, a term applied to sea-anemones or similar polyps on account of the resemblance which their expanded tentacles bear to flower petals.

ANIMAL HEAT, nearly all animals possess a heat-regulating mechanism by which they maintain a temperature necessary for the continuation of life processes. In many cold-blooded animals this sustains a temperature only slightly above that of the surrounding media, and thus in winter they relapse into a torpid state. Some few, however—bees being an example—have a higher temperature and are not
torpid. In warm-blooded animals, especially those high in the evolutionary scale, a high constant temperature is usually sustained. Some warm-blooded animals occupy an intermediary position. In summer the temperature is high and constant, in winter they hibernate and the temperature is low and dependent upon that of the surrounding medium. Some cold-blooded animals living in the tropics may really show very high degrees of temperature, thus the terms warm-blooded and cold-blooded are relative only. The mean average temperature in man is 36.7°C (98.4°F) in the mouth, 36.98°C (98.5°F) in the axilla, and 37.2°C (99°F) in the rectum. There are slight daily variations, the lowest temperature usually being between midnight and early morning during sleep. Certain warm-blooded animals show interesting average temperatures. Thus, the horse is 99-100°F, ox 100-101°F, cow 101-102°F, sheep 104-105°F, dog 100-101°F, cat 101°F, pig 101-103°F, rabbit 101-107°F, rhinoceros, monkey 101°F, duck platypus 76°F, hen 107°F, duck 107.4°F, spaniel 110°F. The higher the standard of heat, the less able is the animal to bear a reduced temperature. A 30°F drop causes vital changes in a bird or animal, and death finally ensues. Fish and frogs, however, have been found to survive after having been encased in ice. In cold-blooded animals the temperature, as has been noted, varies widely. The study of the temperature of bees is of much interest in this connection.

Several conditions modify the regulation of the animal heat; day and night, age, muscular work, sleep, sex, race, pregnancy, idiosyncrasies, surrounding temperature, season of the year, baths and certain drugs, all have a distinct influence on the heat regulatory apparatus. The variations in temperature in man compatible with life are wide; a range of less than 2°F is normal, but variations from 75° to 112°F have been recorded and the patients recovered. Temperatures below 80°F and above 106°F are dangerous.

The chief sources of animal heat are the chemical processes of the body and they are dependent on the food supply. Every kind of food has its definite percentage of heat-production measured in units or calories. Thus 1 gm. (15 grains) of the white of egg has 4,896 calories; the same amount of cow's milk, 5,733 calories, of fat 9,600 calories, etc. These are purely physical values, but they have their physiological equivalents. The chief sources of heat production in the human body are the muscles, the heart contraction being a very important one, and the glands (intestines, liver, etc.). Loss of heat takes place through the skin by radiation and conduction, by evaporation, from the respiration, and from the defecation.

Regulation of these many factors is in the province of the nervous system. The vasomotor system controls the heat loss by regulating the amount of blood in the deep and superficial portions of the body, the respiratory center regulates the amount of respiration and the cerebral cortex regulates the amount of muscular activity that is the main source of the heat production (see FEVER). Consult Kirkes, 'Textbook of Physiology' (Philadelphia 1907).

ANIMAL MAGNETISM. See HYPONOTISM.

ANIMAL PSYCHOLOGY. Definition. That portion of the general science of psychology which concerns itself especially with a study of mind in animals other than man is generally designated either as animal psychology or as comparative psychology. Obviously, it would be more logical as well as scientifically more profitable to designate as animal psychology the study of mind in animals as contrasted with the study of mind in plants. In this definition animals should be used as inclusive of man. In this article the popular usage has been accepted, and the discussion will treat of the psychology of infrahuman animals.

History.—For many centuries, the human race has exhibited keen interest in the instincts, habits, experiences, and life-history of animals, as well as in their structures, bodily functions, and development. Animal psychology existed for Aristotle, who, at considerable pains and great expense, accumulated a vast and heterogeneous assemblage of facts concerning animal behavior. Modern science finds little value in this ancient record, for the observations were uncritically made and carelessly recorded. In the Middle Ages and later the animal soul became a bone of contention, and men sought heatedly to prove or to disprove its existence. One camp gathered facts to prove that animals are purely instinctive mechanisms, endowed by the Creator with the necessary powers to meet life's demands, and lacking will, purpose, insight and reasoning ability. The other camp quite assiduously, albeit not so religiously, enshrined evidences that intelligence, even to thought and reasoning as well as instinct, is common to brute and man.

Not until the last century did inquiry into the nature of the animal mind become fruitful of relatively disinterested and reliable results. The work of Darwin, Wallace, and their contemporaries stirred an interest in the origin, development or natural history of things biological, which shortly came to include mind. In fact, Darwin himself clearly indicated the possibility of learning much concerning the evolution of mind in animals and its growth in individuals.

In the latter half of the 19th century, especially from 1860 on, the science of animal psychology was born and vigorously advanced. England and the continent shared in this scientific achievement; but to the former belongs the credit of having produced a small group of gifted and devoted students of animal behavior. Romanes, Lubbock, and Morgan did more to create a valuable body of knowledge than had all their precursors from Aristotle onward. Their methods, like those of earlier observers, were crude, but in a measure they abandoned the use of anecdotal materials in favor of direct experimental observation and systematic inquiry.

With the present century came another notable change. The experimental method began to be applied systematically to specific problems of animal psychology. Early observers experimented more or less profitably, but usually with scant control of their materials and for ill-defined purposes. It remained for an American psychologist, Thorndike, to demonstrate the significant applicability of the
method of experimentation to the study of various important problems of animal behavior. His discussion, in 'Animal Intelligence,' of the associative processes of chicks, cats and dogs, at once brought the new science to the attention of scientists.

Presuppositions and Tendencies.—The old problem of instinct versus intelligence in animals has nearly disappeared. It is generally admitted that many animals in addition to man possess intelligence as well as instinct. To prove the existence of mind in animals, or even the existence of intelligence, is not the task of the animal psychologist. Instead, he strives to describe mind in various organisms and to formulate its laws. Certain psychologists assume that mind in some form is coextensive with life. Others believe that it appears at certain undetermined stages in organic evolution. For the one group of observers the chief task is that of discovering the forms and functions of mind in different organisms; for the other it is the existence of consciousness. Again, it is assumed by certain observers that mind, as psychic energy, is a factor in behavior, and by others that forms of physical energy are the sole and sufficient conditions of behavior. In behavior, the mental phenomenon being, as Huxley put it, merely an epiphenomenon. Still other animal psychologists make no assumption in this matter, but patiently work toward definite knowledge of the role of mind in individual life and in organic evolution.

Methods.—The history of animal psychology and its present status alike indicate the prevalence of two methods and resulting kinds of psychological description,—the naturalistic and the experimental. By naturalistic observation is meant the study of animals under natural and uncontrolled conditions, usually, in a free state; by experimental observation, the study of animals under definitely controlled conditions for the solution of specific problems. Experimental work is usually done in the prearranged conditions of a laboratory.

Prior to 1900, almost all of the materials of animal psychology were naturalistic or anecdotal. They were gathered without systematic or thorough effort to control or even to describe the conditions of the most part, are the contributions of Aristotle, Pliny, Buffon, Huber, Hudson, Wallace, Brehm, Fabre, Burroughs, Seton. These writers have presented valuable accounts, as a result of field observations, of what animals do. The daily life activities of animals, their habits, instincts, education, free play, are the natural objects of interest. Specific problems are not necessarily in the mind of the naturalist. He seeks a kind of natural history of behavior and mind, and this he more or less satisfactorily attains.

Modern experimental work is directed toward definite problems for the solution of which animal and environment are alike commanded and controlled. Whereas the naturalist seeks wood and field and any patient, persistent watching satisfies himself that the young of the cat tribe instinctively captures and kills its prey, the experimentalist places his animal subject in an environment which calls forth whatever capacity it may have to respond to prey. The one observer gains intimate and valuable acquaintance with the nature of his animal and becomes sympathetically familiar with it; the other proceeds directly to the solution of his problem, often ignoring materials of extreme interest and value.

Naturalist and experimentalist are alike necessary to the progress of animal psychology. But most to be desired, perhaps, is the combination of qualifications and interest in a single individual.

Problems.—Originally, so far as human records go, the instinctive and habits of adjustment to environment fascinated observers. Thus we find the ancient literature filled with descriptions of individual and race preservative activities. With the birth of a more truly scientific animal psychology, evolutionary problems came to the fore. The development of various functions now commands attention. To-day several fairly well-defined lines of research are conspicuously furthered in important centers. Of these, six seem worthy of special mention and brief consideration as indicating characteristics of the animal psychologist's interest. (1) Sensory functions; (2) the role of the senses, as in orientation; (3) instinctive and hereditary modes of response; (4) emotional experience and expression; (5) modifications of behavior; (6) ideation and thought processes, together with modes of expression thereof.

Naturally, with these are bound up many problems concerning the functions of the nervous system, on the one hand, and the characteristics of consciousness on the other. But in the main, the present-day student of animal psychology is concerned with behavior and its conditions. If he is deeply interested in mind as a factor, he may be called a psychologist; if not, he should be called a physiologist.

Each of the six varieties of problem mentioned above may now be commented upon in order that the achievements of the science of animal psychology may be indicated.

Sensory Functions.—In no field of inquiry has more notable progress been made than in the study of the senses and their role in behavior. The few and crude methods of research employed by the pioneers of the last century have been replaced by varied and refined methods. Nowhere is the contrast in the nature and the extent of progress more evident than in the study of color vision.

For several decades, and up to about 10 years ago, it had been customary to test the color sense of animals by noting their responses to colored objects in nature or by arranging colored surfaces so that one color should be sought, another avoided. Food was usually associated with the color to be chosen. The older naturalists and experimentalists unhappily attributed color vision of some sort to many insects and to all vertebrates.

Critical consideration of color stimuli and of the nature of animal response has indicated, during the past few years, that colored objects may be responded to specifically for various reasons, important among which are (1) color; (2) lightness or intensity of visual stimulation; (3) pattern or texture of the stimulating surface; (4) apparent distance from the eye; (5) size; (6) form or shape; (7) odor or taste; (8) temperature or electrical condition; (9) tactile qualities, and so on.

Only if the possibility of response to all
other sensory factors is eliminated or controlled can the observer be certain of color vision.

To-day, instead of using two colored balls or bits of colored paper, the skilled and cautious animal psychologist demands for his study of color vision adequate physical means of obtaining pure color stimuli, of controlling them in their various aspects and of measuring both stimuli and response.

Modern experiments indicate that color vision is less widely distributed among animals than has been supposed. Mice and rats, if not also other rodents, possess little or no ability to distinguish colors. Cats and dogs, if not color blind, possess color senses radically different from the human. The color vision of bees, wasps and ants is very imperfectly known. In certain bats, color sensitivity is highly developed. This is true, likewise, of monkeys, anthropoid apes and probably of several other mammals.

What has happened in the case of color vision is happening also for other senses. The thorough study of the senses that a particular animal requires infinite time and patience. Sight, hearing, smell, taste, touch, internal senses must be studied before the life of an animal can be adequately described—indeed, before certain of the most important and interesting problems of habit formation can be solved. The psychology of the senses is the foundation of the modern science of animal psychology. It is difficult to exaggerate its importance.

The Rôle of the Senses: Orientation.—When it is asked, how an animal can recognize and satisfactorily respond to a particular object or situation, the senses immediately come to mind, for it is their chief rôle to supply the guiding factors of response. So apparently simple a reaction as orientation with respect to a source of light is controlled, doubtless, by sensory processes. In fact, all forms of orientation to near and distant objects would appear to be conditioned by the various senses. Thus, the courtship behavior of many insects; the horse, dog, or cat finds its way home; the flock of birds migrates over a long distance; the nesting bird, insect or mammal locates its home spot, and each presumably because few or all of the senses are guiding it. It therefore appears that the careful study of the senses is essential to an understanding of many of the most interesting and puzzling things that animals do.

The problem of animal orientation, especially distance orientation, has been attacked experimentally by none so successfully as by the American psychologist, Watson, who has worked chiefly with white rats and cats. What Thorndike did for animal psychology in general by his pioneer study of the senses is what Watson has done for the important problem of orientation.

Instinct: Hereditary Response.—Scientific progress has definitely settled the quarrel concerning instinct and intelligence, for it has been proved that intelligence is possessed by other animals than man and that instinct is widely distributed in the animal kingdom. Human intelligence differs importantly from that of any other animal, but so does the intelligence of the chimpanzee from that of the cat.

Experiments have further demonstrated that instincts are not perfect and invariable from their first appearance, but instead become modified and perfected with use. They are intimately related to habits, and in most animals form the basis for systems of habits which are developed through experience.

Studies in the heredity of mental traits and modes of response have been initiated by animal psychologists, and there are indications that the heretofore baffling problem of the origin and mode of development of instincts may shortly be solved. The modern experimental literature on instinct contrasts sharply with the older literature, for it presents definite facts in place of speculative imaginations, endless discussions, a priori definitions and theological disputes.

A single example from modern experimental work must suffice to illustrate its characteristics. By Breed, the instinctive feeding behavior of young chicks has been observed, and on the basis of controlled experiments, he is able to affirm that the pecking reaction improves in definite fashion with use, and indeed becomes the basis for complicated feeding habits. Instinct is being brought into closer and closer relation to habit. It no longer stands apart as something mysterious, God given, unmodifiable, but instead as the hereditary or innate factor in a complex system of responses.

Emotions and Their Expression.—Pain, anger, astonishment, joy, are being studied today in other animals as they have been studied for years in man. The animal psychologist evidently realizes that he must discover new methods to supplement those of human physiology and psychology.

Most promising among the innovations is the so-called reflex method, by which the variations of some particular reflex response in connection with emotion-evoking situations are measured. Heart-beat, respiration, salivary secretion and the functioning of various other glands are being used by this method. The brilliant Russian physiologist, Pawlow, has perfected a method of using the salivary reflex in the study of the functions of the nervous system, and the method is now being adapted by animal psychologists to inquiry into the emotional or affective responses of various animals.

Modifiability of Behavior or Habit Formation.—Loeb and other physiologists and psychologists have held that the ability of organisms to profit by experience is evidence of the existence of consciousness. This criterion or test of consciousness is no longer widely accepted because of certain obvious weaknesses, but the suggestion of it stimulated observation. It appears from the results which have been accumulated that the behavior of all living beings can be modified more or less markedly and lastingly. It also appears that the nature of the modification as well as the rapidity with which it develops varies from organism to organism. Thus, whereas a single stimulation by a hot object may establish in the human infant relatively permanent avoiding reactions, the less highly organized creature, such as fish or frog, guinea pig or rat, may come to avoid the dangerous stimulus only after a number of repetitions.

Again, experimental results indicate that there are many important kinds of habits in the animal kingdom. Some involve adjustment only to present conditions; others to conditions
which are temporarily or spatially more or less removed. Some are dependent upon the initiative of the animal; others upon social stimuli. Some are evidently influenced by the results of activity; others seemingly are not.

There is no single field of inquiry, not excepting the senses, in which animal psychology has made more, or more widely influential progress than in that of the modifiability of animal behavior, habit formation, memory, imagination, the learning processes. Many new types of method have been devised, and results of obvious importance to education, to medicine, as well as to physiology and psychology, have been recorded.

The maze method, a contribution of animal psychology to biology, offers the possibility of analyzing the learning process. The sensory discrimination method enables an observer to isolate and measure the values of various important factors in habit formation. The importance of the number and frequency of repetitions of an act, the value of punishments and rewards, the mutual relations of habits and the tendency of training is facilitative or interfering with effects of other kinds of training are being persistently and successfully investigated.

_Imagination and Reasoning._—The study of ideational associative processes, thoughts, reasoning, is regarded as difficult. Thorndike undertook the task and achieved remarkably interesting results, but his lead was not directly followed. Instead, interest turned to the study of the senses and of habit formation. Only recently have the problems of complex behavior of the ideational sort been once more brought to the forefront.

Various forms of animal behavior, some doubtless ideational, others probably not, have been observed, and initial attempts are being made to analyze them. The methods of search are of considerable interest and may be briefly described.

Cole, working with raccoons, used a simple apparatus in which a number of levers served to present a color stimulus. The color, the order, or the number of visual stimuli presented indicated food. The animals learned to expect food as a reward on presentation of a certain visual stimulus or series of such stimuli. They even discovered how to work the levers for themselves in order to cause the desired stimuli to appear. Cole considers their behavior as imaginative, that is, indicating the functioning of ideas.

For the purpose of exhibiting the reactive tendencies or capacities of different kinds of animal, Hamilton devised an ingenious method and apparatus. He places his subject, animal or man, in a room on one side of which there are four doors, all closed. According to a predetermined scheme, one of these doors will open when approached by the animal and allow it to escape to food and freedom. In that particular trial, all of the other doors are locked. In the next trial, the door which previously was unlocked is locked, and some one of the other three doors will open when approached. In each of 100 trials, each door is unlocked 25 times. The question is: How will any animal meet this practical situation, ideationally or otherwise, effectively or ineffectively? As Hamilton has shown, there are various degrees of adequacy or effectiveness of response possible. These may be spoken of as types of reactive tendency.

The method of Hamilton may be used systematically to obtain knowledge of the reactive tendencies, that is, ability to solve a particular type of problem in various types of animal (he has studied cats, dogs, horses, monkeys, gophers, rats and human subjects), the same type of animal at various stages of development, as for example, in infancy, childhood, adoescence, and so on, or in various conditions of disease or defectiveness.

By Hunter, yet another ingenious means of testing for ideas has been devised and applied. It is called the delayed reaction method. The apparatus is so arranged that an animal may escape from confinement in a box and obtain the reward of food by selecting and passing through a certain exit passage. The particular passage to be selected from among others in a given trial is indicated by a light. Many animals, such as mice, cats, rats, raccoons, quickly learn to go directly to the passage which is illuminated. This habit has been determined, the experimenter, before permitting the animal to make definite choice of a particular passageway, turns off the light. It then becomes necessary for the animal to choose its path in the absence of the indicating stimulus. The question in the mind of the experimenter in this method is, Can a given animal correctly choose its way of escape on the basis of a signal which no longer exists, unless it be in its own consciousness or brain? If so, how long after disappearance of the indicating light is correct response possible, and what is the nature of the process by which choice is made?

It has been found that rats can make their choice correctly after being forced to wait for 10 seconds; raccoons, after a delay of 25 seconds; dogs, after 30 seconds; children, after 25 minutes. And it is conceivable that the human adult might respond properly even after an interval of many months, were the matter of extreme importance.

This ability to respond appropriately to stimuli or situations remote in time or space is indicative of what the psychologist terms images or ideas, the representative conscious process. Thus, the method of delayed reactions tends to throw light on the ideational character of animal behavior.

Yet another method of studying the associative and ideational behavior of animals involves the presentation of problems of various sorts which demand ingenuity and initiative. This is called the problem or puzzle box method. It was first extensively and systematically used by Thorndike.

The animal is placed in a box from which it may escape to food, which is visible outside, by operating some simple mechanism as, for example, a latch, bolt, lever or pedal. It is the observer's purview to learn from the animal how he can discover the relation of means to ends, or having accidentally happened upon the correct act or series of acts, can skillfully and with apparent insight perform the necessary act when next required to.

Thorndike's discussion of how cats and dogs learn to solve simple and novel problems and Kinnaman's similar studies on monkeys indicate that these animals learn very largely by a
process of trial and error. They give slight ground for the assumption that free ideas exist and are the cause of behavior.

Those with a penchant for ideation in animals will take greater satisfaction in the experiments of Hobhouse, since he finds varied evidence of what he considers animal ideas. As a last example of current methods of investigating ideational behavior, one devised by Yerkes may be briefly described. It, too, is a problem method. As used for human subjects, the apparatus consists of a series of 12 similar keys, any number of which may be used in a given experiment. For lower animals, a series of boxes, each with an entrance door and an exit door, takes the place of the keys.

The animal's task is to select from any group of boxes whose entrance doors are open that one which bears a particular spatial relation to the remaining members of the group, the relation having been determined in advance by the experimenter. Thus, the right box might, in one series of observations, be defined as the middle one of the group. The animal would be rewarded when it entered the middle box by presentation of food and punished by confinement in a given box each time it chose incorrectly. It, therefore, tries to make only correct choices. This is possible only if it can perceive the relation of middleness and react to it sensitively. Problems varying in difficulty from the extremely simple and easy to those practically insoluble by human beings can be presented by means of the multiple choice apparatus. The method promises to be fruitful of important results in animal psychology, psychopathology, and to contribute abundantly to the materials of genetic psychology.

Animal psychology is an infant science, or part-science. It has tremendous advantage over human psychology in the greater controllability of its subjects, for lower animals can be used in experiments which are either extremely difficult or impracticable in the case of human subjects. So vigorous has the new science become that its methods and results are of farreaching interest in the development of the general science of psychology and contributing abundantly to the advancement of genetic psychology. See Genetics; Comparative Psychology; Genetic Psychology; Psychology.

Animal WORSHIP, a practice found to prevail or to have prevailed in the most widely distant parts of the world: in India, where it is a consequence of the belief in the transmigration of souls, according to which the soul of a god may pass into the body of an animal in the heart of Africa, where it is still in life; in South America, where very remarkable instances of it were met with by the earliest Spanish visitors; but its most extraordinary developments were in ancient Egypt. Nearly all the more important animals found in the country were regarded as sacred in some part of Egypt. Some animals were held sacred throughout the whole land, but in many cases the animals enjoyed a local reverence only; an animal that was worshipped in one place might be an object of aversion in the next and destroyed at every opportunity. The degree of reverence paid to the sacred animals was such that the voluntary killing of one was punishable with death, and if any one killed an animal involuntarily in his path, he was held sacred if he was punished by a fine. Throughout Egypt the killing of a hawk or an ibis, whether voluntary or not, was punished with death. So strong was the feeling of the people on this point that when it was of the utmost importance to the Egyptians that they should conciliate the Romans, even the intercession of the king was impotent to save from the fury of the people a Roman soldier who had killed a cat. The animals were regarded as sacred to the deities, and the worship paid them was symbolic. The Egyptian idols always bore on a human body the head of the animal sacred to the god represented by the idol. Only in three cases were certain animals believed to be incarnations of the deities themselves. These were at Memphis, where the bull Apis was worshipped as an incarnation of Ptah; at Heliopolis, where the bull Mnevis was reverenced as an incarnation of Osiris; and at Mendes, where a goat received worship as an incarnation of Khem.
ANIMALCULE, the diminutive of animal; an old name applied to animals of microscopic size, and now frequently used for many Protzoa, such as the Amaba and various Infusoria. The term is not now used in zoology in any strict significance, nor employed in classification.

ANIMALS, Chemical Sense in. Almost all animals exhibit specific responses to chemical stimulation. In Amaba proteus food-particles are ingested by the formation of a sort of invagination that surrounds them, whereas this is not true of bits of inedible material. In many species of Coleterete we find that touch with an inedible body produces a reaction of aversion, contact with food is followed by motions leading to its ingestion. In other cases, as with Carminaria hastata, though the reactions to chemical and mechanical stimulation are qualitatively similar, the local sensitivity to chemical stimulation is independent of that to mechanical stimulation. In planarians the general evidence for the chemical sense resembles that in Coleteretes. According to Lehner, a land planarian, Geodermis bilineata, is able to perceive the existence of food with which it is not in contact. This is the chemical sense in the animal scale where we have evidence of any sense analogous to smell, which perceives chemical substances in the form of vapor, as apart from taste, the sensitivity of which is limited to substances in solution. This distinction, be it noted, has only meaning in land-animals. In most planarians, however, chemical stimulants only act on contact.

With the earthworm, the evidence for the existence of a specific chemical sense is very slight. Responses to chemical stimuli exist, and even to stimuli at a distance, but they are o.: the same nature as the responses to mechanical stimuli. The only reason for regarding the chemical sense as distinct is to be found in the different speeds of the reactions to different chemical excitants.

There is good evidence for the existence of a rather sensitive chemical sense in the echinoderms and in many molluscs. In the snail, smell is apparently most acute at the ends of the tentacles, but is not confined to them. An analogous distribution of chemical sensitivity is found in many crustaceans, where the antennule and the mouth-parts constitute its chief, but not its sole, organ.

The first place where we find evidence of a varied and sensitive set of chemical reactions is in the insects, and more particularly in the higher hymenoptera. The marvelous powers which are possessed by bees and ants of finding their way to their hive or nest and to their food, of recognizing whether an individual belongs to their colony or not and of taking care of their young, are to be attributed in a large measure, at least, to the acuity of their sense of smell. Though the mechanism of all these actions is still a matter of the gravest uncertainty and dispute, there is evidence that in the ant the perception of different sorts of odors is located in different segments of the antennae, which are the principal olfactory organs in all insects. The individual odor of an ant is perceived by means of the tenth segment of the antennae, the race odor by the eleventh and the nest odor by the twelfth.

In the lancelet, there is not much evidence for the separate existence of a specifically chemical sense. While fishes, reptiles and amphibians possess organs structurally and historically similar to the smell and taste organs of man, little is known about their function. The so-called terminal buds of fishes, resembling the taste-buds of man, are found not only in the mouth but sometimes over the whole surface of the body, but it is not completely established that they exercise a gustatory function. The existence of taste has been established in birds but little is known about their sense of smell. The taste and smell sensations of mammals would seem to bear a great resemblance to our own, though they are often far more sensitive, as in the dog. See TASTE AND SMELL.

Norbert Wiener.

ANIMALS, Classification of. Classification is simply sorting out — arranging different things according to their likeness, putting them into groups. To these groups names are given for convenience in referring to them, and thus arises the terminology of this department of knowledge which is the systematic basis of all science broadly considered. In the present article, however, the writer purposes to confine himself to organic nature, and chiefly to zoology.

The sorting out of animals into groups is, as above is indicated, very simple and easy at first. The child undertakes it in the kindergarten when he separates blue papers from red, square blocks from round ones, the long sticks from the short. But presently something combining more than one quality is encountered, and the question arises: Shall I put this on one pile or on that? An infant in a kindergarten who picked up a red ball might well hesitate whether to place it with the red things by virtue of its color, or on the spherical pile by virtue of its shape. This illustrates the cardinal difficulty that has embarrassed all classifiers, and has caused so great a diversity of schemes for the orderly arrangement of natural objects. Probably the only perfect classifier is nature herself, in the form of that noetic and marvelous selector, chemical affinity. Human intelligence is less well informed as to the real constitution and affinities of the objects, animate and inanimate, that man's senses perceive, and, for the present, his arrangements of them must be imperfect and tentative. Hence classifications of the various groups, or even the limits of the groups themselves, may and do vary in at least two directions — first in the selection of a standard of comparisons, and second in knowledge or opinion of relationships.

At first, as was natural, superficial resemblances sufficed to group seemingly like objects. This brought worms, spiders and insects into one lot, classed bats with birds, whales with fishes and so on. But a closer examination soon revealed these and other congruences. It was ascertained that every known bird was clothed in feathers and reproduced itself by eggs. The bat, although it flew in the air, was covered with hair, brought forth its young alive and suckled them; those were the most conspicuous and universal characteristics of
mammals. So the bat was a mammal that flew. Fishes were found to be always covered with a more or less scaly skin and breathed the air within the water by means of gills. The whales were found to breathe only atmospheric air, brought forth living young and suckled them. Plainly it was wrong to keep them among the fishes, although they lived in the water—they were mammals. Thus arose the concept that fundamental structure was a better criterion by which to classify than external likeness.

Artificial Schemes.—In the earlier days the knowledge of animal structure was very limited. Comparative anatomy had hardly been thought of, and, indeed, arose into a definite science largely because of curiosity as to classification. Meanwhile naturalists wanted to group their facts, pigeon-hole and label their increasing information, which more and more was falling into coincidences and suggesting new comparisons and contrasts. Hence the early attempts at classification were frankly for convenience, as a scaffolding for study, pigeon-holes in a clerk's desk. The crowning example of this, probably, is the "system" by which Linné (Linnaeus) arranged the plants of the world.

The makers of all these "artificial" arrangements, as they were called, were ever seeking for the best, the most comprehensive features by which to work. Some were fantastic, as the "circle" theory of Maclay and Vigors; others sensible and useful. An arrangement of birds long in vogue was by the form of their feet, by which all birds were separated into several "orders" according as they were seizers, runners, climbers, etc. This was utilizing function as a criterion, and only hinted at structure.

But the untruth of this method was early perceived by some systematists who insisted that structure was the true foundation on which to erect what they styled a "natural" classification. Hence arose a classifying of classifications into two categories—the "artificial," for convenience, as a scaffolding for study; and the "natural" as an expression of real truth.

To some extent these lines of thought and work still exist, but the former has been nearly abandoned.

Seekers after truth of relationship by study of structure—forms of organs, morphology—increased in number from the early 17th century onward, and their accumulated information, published in various partial schemes, together with his own extensive investigations, gave material for the first grand generalization in zoology—that by Georges Cuvier (1769-1832), whose fame was popularized in this country by the most talented of all his pupils, Louis Agassiz, himself a great investigator and the author of a remarkable "Essay on Classification."

Cuvier's "Plans of Structure."—Cuvier thought himself able to separate animals into four groups, distinguished by four "plans of structure" which had been assigned by the divinity of each animate or inanimate rank. These were: (1) Vertebrata, characterized by an internal skeleton, an essential part of which was a backbone; it comprised mammals, birds, reptiles (including batrachians) and fishes. (2) Molusca, characterized by a passive type of body without bones; the mollusks, brachiopods, tunicates, etc. (3) Articulata, with bodies composed of ring-like segments; the insects, crustaceans, annelids and spiders. (4) Radiata, characterized by a radial arrangement of all the parts around a vital focus; star-fishes, polyps, worms, and animals.

Those four "plans of structure," ordained from the beginning of things, Cuvier regarded as great facts; and Agassiz objected to all those like Leuckart, Vogt and others, who criticized or modified this arrangement, that they were considering too much complex structure and losing sight of "plan" or "type." Agassiz pointed out that Cuvier's divisions combined their various subdivisions; and that this was a great step forward, even if he had not the correct measures for all his groups. "For we must remember," said Agassiz, "that at the time he wrote naturalists were bent upon establishing one continuous, uniform series to embrace all animals, between the links of which it was supposed there were no unequal intervals." The watchword of their school was "Nature makes no leaps;" they called their system the "Chain of Being."

Nevertheless these views were not accepted by all investigators. One after another the leaders in biological nomenclature, especially as to the Radiata. Ehrenberg in 1836 departed altogether from the Cuvierian notion, and laid down the principle that the type of development is one and the same in all animals from nomad to man; that is, he set aside the idea of "plan," and erected a classification on purely anatomical grounds. That of Owen, a few years later, had a similar basis. Both assembled in their schemes groups that were heterogeneous, and gave varying rank to similar aggregations. The result was that neither was much accepted. Von Siebold, in 1845, added to Cuvier's four plans or types of structure two more— Zoophyta and Vermes—asserting that they had equal rank with the others, and Leuckart accepted them. Later Von Baer, the great embryologist, offered a classification based on mode of development from an egg to maturity, and other embryological systems were made by Van Beneden, Rolliker and Vogt. All these men multiplied facts, cleared up subordinate relationships, and, by the different angles from which the subject was looked at, broadened knowledge immensely. The effort of all was to find a standard that could be applied uniformly, and would necessarily reveal the true place in nature of every living thing. If a perfect order in organic nature existed, then approaches from the point of view of the embryologist and from the point of view of the anatomist ought to arrive at the same result—the real condition—the truth. Thus far it had not done so except in favorable cases. One method would logically assign an animal or a plant to a well-defined group to a certain place in the system which would be quite negatived by other considerations.

Search for "Natural" Scheme.—Facts of biology accumulated, but nothing new organized systems for "natural" classification of them eluded all searchers. That this should be the case is not surprising when one recalls that it was believed by all the older zoologists, except a few advanced thinkers, whose views were usually scouted, that the individuals of each kind of animal were descended from their own peculiar
ancestor; that this original pair was totally
unconnected with the ancestor of any other
line, having, as Buffon asserted, 'participated
in the grace of a distinct creation'; that a
species so created was forever unchangeable.

Classifiers sought to perfect their apprecia-
tion of resemblances, and constantly used the
word relationship, but this term, when em-
ployed with reference to two kinds of animals
having a wholly independent origin, was of
course used in a purely metaphorical sense. It
was not until the prevalent idea outlined above
was discarded that relationship took on its real
significance and became the key-word in clas-
sification; and this came about only when the
discipline and facts of organic evolution—that
is, transmutation of forms of life through vari-
ation in descent—destroyed the earlier concep-
tion of the origin and history of living things
on the globe. Then it was that all the avenues
of inquiry (anatomy, embryology, geographical
and geological distribution, adaptations to
habits, etc.) led to the same point, indicated
the true place in nature of each animal or
group—true because it had become so by de-
velopmental necessity. Instead of species or
certain or other number of parallel "plans" of
immutable structure, it became plain that ani-
mal life and plant life represented only one
progressive, enlarging, and ever-varying
scheme of adaptive and fruitful beings.

This compelled the discarding of another old
assumption, one on which, in fact, all previous
schemes of classification had rested, namely,
the existence and fixity of "species." This
word came into use in zoology and botany at
the beginning of the 18th century, when John
Ray applied it to indicate a group of animals
and plants with common characteristics that
would interbreed freely. (This last test has
been popularly considered definite, although not
universally true.)

"Linnaeus," says Prof. William B. Scott
in his 'History of Land Mammals' (1913),
"regarded species as objective realities, con-
crete and actual things, which it was the na-
turalist's business to discover and name, and
had not that they were until then had been
separately created. This belief in the
fixity and objective reality of species was al-
most universally held until the publication of
Darwin's 'Origin of Species' (1859) converted
the biological world to the evolutionary faith,
which declares that the only objective reality
among living things is the individual animal
or plant.

Descent the Test of Relationship.—This
conception upset completely all previous
methods of determining relationship—"the
basis now, as always, of classification; and
gave to that word a new and proper definition,
namely, association by blood-connection de-
rived through descent from the same stock.
The term had been so used with reference
to organisms, and this meaning was now
extended to all living things, as was right
and natural. A man's relatives are those who
belong to the same family-stock; the relation-
ship between them is one of blood and inher-
ance. The same is true of horses, or sparrows,
or fishes, or snails. Any recognizable relation-
ships are those produced by common descent;
and when these are unrecognizable the search
for them must be along lines of ancestry.

Hence the vast service of paleontology has ren-
dered to classification of living things—the
same kind of service for the brute world that
the study of genealogy has rendered to human
history. Paleontology reveals the genealogy of
the animal world so far as its materials permit.

Genealogy, then, is the guide to the classifi-
cation of the individual, whether human, quad-
ruped, bird or lowly worm; and the old-fash-
iioned "plans of structure" are merely helpful
indications of probable community of descent.
They exhibit the groups that have resulted
from the more or less gradual variations, pre-
historic divergencies, and frequent extinct-
ions of intermediate lines, that have affected
the descent of animal life from some original
source. Biological classification is the expres-
sion of heredity.

The matter is commonly symbolized by a
tree growing from seed and root to trunk,
splitting into limbs that spread out in various
directions, putting forth lesser divergent
branches and finally innumerable twigs. Many
branches flourish to the very tip; others remain
short; others produce twigs; others die and
disappear. Instead of species or genera or
lesser branches from which they spring may
represent genera, families, orders, and classes,
until at last the root-trunk is reached. The
figure is incomplete and inadequate, but is
helpful.

The newest, that is the most modern and
simple manifestation of arrangement in the
living world, is the species, which we may now
define as an assemblage of individuals more
closely related by common descent to one
another than to anything outside their class.
All the members of a species will interbreed,
and, as a rule, will not interbreed with any
other species, or at least will not produce fer-
tile offspring. Some species are very distinct
in their characteristics, others vague; some
are exceedingly numerous, others contain few
individuals; some are strictly local in their habi-
at, others exist over an immense area; some
appear modern in their origin, others may be
traced far back in the zoological record; some
are remarkable which have been so
so that systematists create "sub-species" or
g "geographical races" to mark their variations,
which some regard as "nascent" species.

The species, then, is the unit of classifica-
tion, and its characteristics are mainly external
peculiarities of contour and color, which, by
their very nature are impermanent. Let us take
as an example of a species our common cat,
which is, in the main, simply a domesticated
form of the Egyptian wildcat, known in zo-
ology as Felis libycus.

The earliest naturalists gave long descrip-
tive names to animals and plants. Ray, Lin-
næus, and students after them have reduced
these to two, and have used Latin (or Latin-
ized) terms in order to identify the subject in
d all languages and make the study the same
inaccuracy of vernacular names, which often
are applied ignorantly or carelessly to very dif-
ferent creatures. Our Canadian moose is vir-
tually the same animal as the elk of north-
ern Europe; but the "Felix" of this country is not
that at all but a deer closely related to the red
der of the Old World. A Japanese has no
trouble in distinguishing them, however, when
he reads of Alces malchis (the European elk)
animals

and Cerus canadensis (the American "elk"). This is called the binomial system of nomenclature; and sometimes geographical varieties are designated by a third (trimomial) name, as Succo magna argutius, our Western meadow-lark.

After this digression on the form of specific names let us resume our account of the development of the scheme of arrangement of animal life.

Relative Rank in Classification.—As one surveys the world he finds two or more species with a certain close resemblance that separates them from others, and these he unites into a secondary group called a genus.

For instance, kinds of cats, different in habitat, size, coloring, etc., have the same general features of a comparatively elongated body, long tail, and small, plain ears; they are united in the genus Felis, with different specific names, as Felis ibyca, Felis cats, Felis leo, etc.—the binomial being the generic and the specific name used together like Smith, John; Smith, George, and the like. But there are other kinds of cats that agree in having heavy bodies, short tails and tufted ears. These are recognized as forming another genus Lynx, and we have of these several species, as Lynx canadensis, Lynx pardalina, etc.

These several genera may now be united by common characteristics into a higher group called a family, the name of which in zoology always ends in the suffix ide, and is likely to be taken from the name of the most prominent genus as Felidea, the cat family. (Large families are often subdivided into sections or sub-families designated by the termination ine.)

This family group is based on a combination of the features that ally all its constituents, and at the same time separate it from other groups of equal rank, and these are usually features of structure, rather than of form or appearance, such as the form and number of the teeth, adaptations of limbs to a special mode of life, etc., which are well marked. For example, the family of the cats differs from that of the dogs or bears or weasels in having claws that may be withdrawn into a sheath—a distinction of family rank. The cattle family (Bovidae) comprises a wide variety of forms, neat cattle, sheep, goats, and antelopes—but is separated from the deer family (Cervidae) by the fact that all have hollow but permanent horns, while the deer have solid, deciduous horns (antlers). It is such broad characteristics that make family rank; and now and then families represent divergencies from their allies so great that only a single genus, perhaps containing but one species, is given family rank. This is the case with our American pronghorn.

The fourth rank is the order, containing a collection of families believed to have consanguinity or descent from a common stock. To determine this by the detection of a common characteristic, usually of intimate structure, is sometimes easy, as in the case of the order Carnivora, or beasts of prey, whose sign is the character of the teeth, and particularly the presence of the prominent canine tooth, so strongly developed in the cats, which are highly representative of that order. Orders are usually large and comprehensive groups, and often may be divided into well-marked sub-orders, as, in this instance, the Pinnipedia, or fin-footed carnivora (seals and walruses) and the Fissipedia, or toed carnivora (land beasts of prey); and most orders include several extinct families. It is probable, also, that the families and certain others ought to form a super-order Cresetonta, ancestral to them. When one is dealing with groups as large and widely separated as orders, it is possible to discover any features possessed by all that will enable us to collect them into a still higher group? It seems doubtful, when one recalls the diversity in the one group alone chosen for our illustration. Here are 11 orders (not counting 'extinct ones) represented by animals so diverse as the duckbill, kangaroo, sloth, ox, manatee, whale, cat, mouse, mole, bat, and man. Have they anything in common? Much; and particularly two prominent features that separate them from all other animals— their covering of hair, and their nourishing their newly-born young on mother's milk. Hence they go together into a still larger group called a class— the class of mammals (Mammalia). In this class are two sub-classes, Prototheria (duckbill and the echidnas), and Eutheria (all other mammals).

The mammals are equal in rank with the classes Birds, Reptiles, Amphibia, Fishes, Round-mouths, and several others formerly regarded as worms or mollusks, all of which possess one feature of prime importance—a notochord, the prototype of the spinal cord and backbone of the more highly developed forms. This unites these otherwise so varied classes into a still broader aggregation or "phylum," the Chordata. Beyond this are only two words—Animal and Plant, indicating the two grand kingdoms of life in the world. Even these, however, are so essentially alike in their simplest form, the monad, that they are doubtfully distinguishable at that point of contact, and may be combined under the term organism.

Here, then, ends our inquiry into the place in nature of our example. This animal organism called "cat" is a chordate, eutherian, carnivorous mammal of the family Felidae, genus Felis, and species Ibyca.

Such is the schematic history of a single animal, and it represents not only its place in nature, but its phylogeny, that is, the line of evolution from a primitive monad to the complexity and finish of an animal highly adapted to a certain manner of life.

Biological classification is now, therefore, on a sure, philosophical, scientific basis. It has but one principle—that of descent—blood affinity. The problems are those of perception: to detect the evidence of genetic relationship. To this every fact of investigation, from the embryologist's microscope and the anatomist's scalpel to the geologist's hammer and the field-naturalist's notebook, contributes; and no longer is any artificial grouping possible, except on account of an ignorance that study will correct, or as a theoretical suggestion that must be proved before it is acceptable.

In the present article only a single kind of animal has been considered. The process is the same for all others, but different criteria must be employed in the various groupings, and even different terms used, or the same term with different limits. Thus "family" is a far more comprehensive and important group in
ANIMALS

Poisoning is a serious source of loss. There are a number of poisonous plants which occasionally cause the death of animals that eat them. Cattle are very susceptible to lead and not infrequently they are poisoned by licking an emptied lead pail or a newly painted fence or barn. Other poisons such as arsenic and corrosive sublimate are occasionally the cause of death among animals.

Animals suffer to a considerable extent from tumors. Cancers, epitheliomas, sarcomas and leukemia are quite common. Melanoses are more numerous in the horse and leukemia or the so-called lympho-sarcoma in fowls. Benign tumors, especially those arising in the connective tissues, are also frequently encountered.

The specific infectious diseases are those caused by definite pathogenic bacteria, fungi, protozoa and the filterable viruses. Each disease is produced by its specific organism and by no other cause. For example, anthrax is caused by Bacillus anthracis, Texas, or Southern, cattle fever is caused by Piroplasma bigeminum, foot and mouth disease by a filterable virus, that is, a specific substance that will pass through filters (Berkefeld) that keep back ordinary bacteria. The specific infectious diseases are sometimes confused with dietary disorders. They can be readily differentiated by taking into account the following:

Cause.—An infectious disease is produced by a specific virus. This necessitates as the first requisite an exposure to and an infection with the specific organism. Ordinarily a few animals in a herd are infected simultaneously.

Period of Incubation.—The infection must be followed by a certain time required by the invading micro-organisms to become established in the body and to bring about the first symptoms of the disease. According to Vaughn it is the time required for the infecting organism to sensitize the tissues. The incubation period varies in different diseases, and, to a certain degree, in the same disease, according to the mode of infection, the virulence of the organism and the resistance of the individual. Usually, however, it is practically the same for all individuals of the same species when subjected to the same mode of infection.

Lesions.—The tissue changes in an infectious disease are usually nearly the same in all the animals affected in the outbreak. Each pathogenic organism brings about tissue changes more or less peculiar to itself. They may, however, vary within rather definite limits. They may also be acute or chronic in nature. The cause for the changes in the body is the action upon the tissues of exogenous and endogenous toxins (bacterial proteins), or the mechanical blocking of the vessels by the organisms. In many epizootics, the disease appears in an acute form in the first animals attacked while those infected later suffer from a chronic or modified form of the affection. In other outbreaks the noed was abundant and the latter ones acute. It is important to distinguish between the lesions due to the virus and secondary tissue changes that may be present.

Duration.—In animals, as in man, most of the infectious diseases are self-limiting. After they run a certain time the animals either die.
or fully recover. As a rule, the percentage of fatal cases in an outbreak is larger among animals than with people.

Transmission by Inoculation.—Finally, in making a positive diagnosis it is necessary to find the specific organism, or to prove the transmissibility of the disease from the sick or dead animals to healthy ones. The extent to which the disease spreads will also aid in determining its infectious or non-infectious nature. In diagnosing an epizootic disease, investigations have shown that too much reliance cannot be placed on the period of incubation, or the morbid anatomy. There are many possibilities, therefore, that an erroneous diagnosis may be made when the symptoms or tissue changes are alone considered.

Diagnosis.—The accurate diagnosis of a specific infectious disease is made by taking into account one or more of the following: (1) The symptoms; (2) the lesions or morbid anatomy; (3) the specific cause; and (4) specific reactions. The value of symptoms in making a positive diagnosis varies with the disease and often with the individual case. While each disease exhibits a somewhat constant chain of symptoms it is also true that there is a striking similarity between the symptoms exhibited in many different diseases. As a rule it is difficult to make a positive diagnosis from the symptoms alone.

The changes produced in the tissues by a specific micro-organism are usually constant in their nature. They represent the result of the reaction of the body tissues to the particular invading organism. In some diseases, like rabies, the characteristic tissue changes are microscopic and cannot be determined from the gross examination of the organs. It is very important in making a diagnosis from the lesions that the specific tissue changes be recognized and that they be accurately differentiated from other tissue changes that often accompany such diseases.

The positive diagnosis is made when the micro-organism that caused the disease is demonstrated in the morbid tissues. In some diseases, such as anthrax, this can be done by very simple bacteriological methods. With others, it requires special methods to isolate, cultivate or even to demonstrate the specific organism. There are, however, several epizootic diseases, such as foot and mouth disease, for which a specific organism has not been isolated.

It has been found that animals suffering from certain infectious diseases will react to the injection into the body of the specific protein of the organism with which they are infected. Thus, if mallein is injected into a horse suffering from glanders, a definite reaction will occur which can be determined specifically for glanders. There are also certain substances given off by the tissues into the blood that have a specific affinity for the antigen or species of organisms that cause the infection. There are a number of these so-called specific reactions employed in diagnosis. The more important are the reactions caused by mallein, tuberculin and other like substances, the agglutination test and the complement fixation test. When a reaction occurs with these tests it is generally considered positive evidence that the disease is present.

Control.—The control or eradication of the}

Infectious diseases is of the greatest importance. This can be accomplished by (1) preventing the spread of the germs which cause them, or (2) immunizing susceptible animals against them.

The checking of the spread of infectious diseases involves an intimate knowledge of the organisms that cause them. It requires that one should know: (1) When in the course of the disease the virus is eliminated from the body and the channels through which it escapes. (2) What happens to the virus after it leaves the body and how long it will resist the action of external influences such as drying and sunlight. (3) By what means and through what channels it gains entrance to the body of the uninfected animal. When the facts regarding these points are ascertained it is not difficult to determine what should be done to prevent the virus from spreading from the animals in one herd to those in another, or from a sick individual to a well one in the same herd.

Immunization.—The immunizing of animals against either sporadic or epizootic infectious diseases has been found to be practicable with certain animals such as black leg, hog cholera and possibly a few others. This method is valuable in those diseases where it is possible to establish an artificial immunity. It cannot be employed satisfactorily with others. The danger in this method is, that where it is employed, precautions against infection are usually minimized and consequently if the protection is not complete it gives a false security. The immunizing processes for the control of infectious diseases are based upon the principles of immunity and the methods for its production.

Parasitic Diseases.—These are morbid changes brought about by animal parasites that are large enough to be recognized without the aid of a microscope, although diseases caused by the protozoa and even bacteria may be considered parasitic. Animal parasites cause a number of disorders that are serious and some of which, such as the nodular disease of sheep and taeniasis of fowls, are frequently mistaken for tuberculosis. There are many parasites and a discussion of their classification is beyond the scope of this chapter. The disorders they produce would be at all adequate would require many pages. Some of the parasites attack the exterior of the body; others live in the digestive tract; others occur in the lungs; others find their way into the organs; and a very few appear in the blood. Many of these have a serious effect upon the animal and the losses occasioned by them are heavy. In addition to the direct injury to their hosts, a few parasites of animals are transmitted to the human family. Among these may be mentioned certain of the tapeworms and trichinae or the worm which causes trichinosis in rats, swine and people.

To summarize, the bodies of living animals are subject to a great variety of deviations from their normal condition due to unsuitable conditions of living, to internal and external causes and to the irritation of animal parasites. These may produce changes ranging from the slightest possible irritation to the destruction of the host. See also CATTLE, DISEASES OF.

ANIMALS, Domesticated. A very large part of man's success upon the earth and of his achievements in supremacy are due to the animals that he has been able to draft into his service through domestication. They have fed him, clothed him, carried him and his burdens, cultivated his fields, drawn his machinery and have in every way surrendered their lives to him and his purposes.

 Originally from the Wild.—Like the crops of the orchard, garden and field, the domesticated animals all came originally from the wild. Choosing for his purposes such of the wild animals about him as could in his opinion assist in his enterprises and as were sufficiently docile to lend themselves to his mastery without too much difficulty and danger, man while yet in the primitive state took absolute possession of certain species, although one of his first attempts was with the wildest of the wild, the horse.

Sources of Material.—The dog is the direct descendant of the wolf, found in the wild the world over, with possibly a dash of the fox in certain breeds. The horse is the direct descendant of the wild stock of central Asia. The ass comes also directly from the wild in western Asia and northern Africa. Common sheep are undoubtedly descended from the native stock of northern Africa and southern Europe, and the fat-tailed variety from that of western Asia. Almost every country of the earth had its wild variety that might have been developed into the domestic pig, but strangely enough we owe our present stock to a foundation developed in southeastern Asia, improved by a later dash of the wild boar of northern Europe.

In general our poultry came from southeastern Asia, except the guinea from western Africa, the goose from northern Europe, the duck which is cosmopolitan from the subarctic regions, and the turkey which is a truly American bird — our only contribution to the domesticated animals — from the New England woods or the jungles of Mexico.

The elephant of India and Africa, the camel of Asia and Africa, the buffalo of Asia and Africa, the humped cattle of India and the yak of Tibet are all developed from native stock, and in general every country has drawn upon its own resources for domestication except that America, being suddenly settled and at a comparatively late date, was stocked by importation, the supply coming largely from western Europe.

Degrees of Domestication.—Species differ greatly in their response to the ameliorating effects of domestication. Probably no animal is so thoroughly under the influence of its master as the dog, completely responsive to his master as the dog, and none less responsive than the cat, though both have been long attached to the domiciles of man.

Most domestic animals will come at call, but few have the homing instinct sufficiently developed to offset their native wanderlust or their natural disposition to forage for food. The result is that most animals must needs be kept in more or less strict confinement. The pig, if unrestrained, will wander wherever food is to be found. Sheep will go in flocks or bands and follow a self-appointed leader anywhere. Though every cow knows her stall in the barn, she will wander aimlessly across country and, except in rare cases, stop with perfect satisfaction wherever night overtakes her. Some horses know the way home; others are absolutely lost and indifferent as to their whereabouts. Even the trusted saddle horse responds to the call whenever a band of wild horses comes his way. The cat with all her lazy luxury goes wherever she is fed, and even the dog, most faithful of all servants to his personal master, easily turns tramp, making friends with everybody, and responsible to nobody, clearly demonstrating how strong after all is the call of the wild.

Domestication is at best a relative term, some species responding much more freely than others, the whole process shading off into that border land, where song birds are bred in cages and gold fish in bowls, and where the response of the animal is exceedingly problematical.

Quite aside from true domestication is that voluntary association of rats and mice with the habitations or rather the storehouses of man, not from any instinct for human society but purely from an attraction to food and warmth not far removed from the blind principles that bring weeds into the crops or parasites upon the body.

Purposes of Domestication.—Domestication means responsibility for food and whatever shelter, restraint or attendant care may be necessary. This all takes money and time and money, so that the domesticated animal, while exceedingly serviceable, is at the same time extremely expensive, as will be seen when we compute the value of the hay, oats and corn crops, practically all of which go to the support of animals. Considering this fact, it is evident that man has domesticated for strictly personal reasons, never for the welfare of the animal.

Animals Domesticated for Hunting.—The primitive man, in constant distress for food, hunting animals that were in every way his superiors except as to wits and a serviceable hand, must have early noted the habit of the wolf to hunt in packs. He was not long in finding that a litter of young pups brought up in camp became extremely loyal and still retained their hunting instinct. In this way the hunter obtained his dog. To the dog were early added the horse, the elephant, the cheetah or hunting leopard, the falcon or hunting hawk and last of all the ferret.
ANIMALS

Animals Domesticated for Their Meat.— Here must be counted the ox—excepting the humped cattle of India not used for food—the sheep, the pig, the goat, the rabbit and a horde of birds—the chicken, the guinea, the goose, the duck, the swan, the pheasant, the peacock, the pigeon, and greatest of all the turkey. Rarely, except in war, has horse meat been offered for sale. In general it is coarse and of poor quality, while sentiment is against its use for food.

Animals Domesticated for Their Milk.— Though the milk of all domesticated animals is sometimes used, yet it would be fair to say that probably the only animals domesticated mainly or even largely on account of their milk are the cattle, both plain and humped, the goat and the ass.

Animals Domesticated for Their Labor.— Though the horse like the ass was domesticated for riding, he has been put to all kinds of work in Europe and in North America, seldom in other parts of the world, where he is held superior to menial tasks. The ox, both plain and humped, the ass and his hybrid progeny the mule, the water buffalo, the elephant and the camel, the reindeer and the dog, all have been commonly put to hard labor, and up in Tibet the yak is no exception to the rule that man under almost any conditions will contrive to find some animal to bear his burdens and perform his hardest labor—even drafting in the llama.

Animals Domesticated for Their Body Covering.— The skin of most animals is valuable for tents, for clothing, and for the thousand and one occasions in which leather is desirable. The horse, the ox, the sheep, the pig, the goat, the dog and the rabbit all yield valuable skins, especially the ox and the goat. Modern methods of tanning make even the tender sheepskin extremely useful for many purposes. One of the original objects in domesticating the sheep was its wool, first as attached to the skin, afterward for spinning into yarn and cloth. The same principle governs the semi-domestication of the vicuña and the alpaca; indeed, one of the marvels of early civilization was the skill developed in weaving. Latterly with the decreasing supply of fur-bearing animals, both the fox and the skunk are artificially produced under conditions of semi-domestication.

Animals Domesticated for Their Eggs.— Eggs have long been in standard demand for food, and however much our poultry may have been domesticated for its meat, the egg supply doubtless played no secondary part in the reasons for dealing with so troublesome a lot of animals. Preferable as are the eggs of the chicken, those of all domesticated varieties of poultry are sometimes used, and even so the supply is not sufficient to meet the demand, which is very largely satisfied by drawing upon the domestic fowl.

Miscellaneous Objects of Domestication.— Aside from the ordinary and more obvious reasons for domestication there are certain secondary objects such as feathers from the goose, the swan and especially the ostrich; honey and wax from bees; and last of all should be mentioned the raising of the guinea pig for purposes of experimentation especially along pathological and physiological lines, as well as in tracing the principles of descent.

Animals Domesticated for Pelt.— It is doubtful if ever an animal was domesticated primarily for other than strictly utilitarian purposes, but once domesticated the response was often so instant and pronounced as to lead to real affection between master and servant. This explains the hold of the dog and the cat upon popular favor, even when their natural value is not needed. Horses are quite commonly kept primarily as pets, and no other impulse can explain the present day use of the swan, the parrot, the peacock, the pheasant and certain strains of the rabbit, the dog and the cat, not to mention gold fish and canaries.

Native Characteristics of Domesticated Animals.— What might be called the psychology of wild species would make an interesting study; for example, the two most faithful of all domestic species are the dog and the horse, yet in the wild state the dog is more cowardly than the wolf, and none more ferocious than the horse. Cattle for the most part are indifferent to man, while sheep will follow him anywhere. The response of the cat to domestication is apparent rather than real. She enjoys warmth and soft places on which to lie, but it is a question whether in general the domestic cat has acquired much response to man, particularly when we remember that as large and savage a cat as the puma is creditably reported as never under any circumstances attacking a human being. The manner in which the rat and the pig respond to training is as unaccountable as is the limited intelligence of the sheep and the cow, or the substantially opposite reaction of the horse and the ass to objects of fright, the one tending to run away and the other to investigate.

Improvement under Domestication.— Quite naturally man selected for domestication those species that served him best. Not only that, he picked the particular strains and varieties that fitted his needs the closest. He followed the same principle when he asked, what meat he desired? He bred from the heaviest fleshed individuals. Was it milk? He chose those of the heaviest flow. Was it wool? He bred from the specimens of the longest and finest fibre. Was it labor? He bred from the strongest, or if for speed from the fleetest. So it is that the domesticated animals have, generation by generation, become constantly a little more completely adapted to the needs of man, and favorite species like the dog, the horse and the ox have been broken up into numerous breeds of all sorts and sizes, each adapted to serve the particular need or whim of a group of men sufficiently large to create a demand. Thus was laid the foundation of the science of breeding by which the domesticated species will be yet more closely adapted to the needs of man, and yet more completely freed from certain accidental but unwelcome characteristics, such as weakness of constitution, tendency to sterility, bad temper and lack of intelligence.

Unused Materials.— If the world had all been settled at once, undoubtedly every section would have developed out of its own material
its proper domesticated races. But America lagged behind. Her excellent start toward a horse had come to an end in Montana at the four-toed stage, and she had nothing to take its place; hence the backward state of the Indian, and hence the certainty of importation. She had the bison which might have been domesticated, but already the European cow had been neglected for its better compatriot, the ancestor of our common cattle. She had a pig, but she could not afford to stop to build it up in competition with what had been gained by long years in Asia and Europe. She had the turkey, and nothing under domestication was its equal for the feast, and consequently the peacock and the swan have been neglected at modern banquet boards. The prairie hen or the partridge of the woods might have afforded a domestic strain, but the chicken was better and so the natural supply was unused. The bear might have been domesticated to advantage, and no doubt he may yet follow the fox and the skunk as a denizen of the fur farm.

Thus, as it may, a wealth of material was left over and neglected, not only here but in that great storehouse of raw material, central Asia, only because man had already all he could use to advantage.

EUGENE DAVENPORT,
Dean and Director, University of Illinois College of Agriculture.

ANIMALS, Mind in the Brute. Like other phases of psychology, that which concerns itself with the minds of non-human animals has broadened considerably in the few years just gone—so far at least as actual research-reports are concerned. How far a questionary investigation would show the acceptance of the new liberalism among psychologists in general it is difficult indeed to be sure, since (as we see in regard to the subconscious aspect of mind) many scientific men when asked will admit the existence and even the importance of a thing which yet they wholly ignore in their own spontaneous work. Specialization is overdone in psychology as elsewhere, and few academic psychologists venture to attempt the correlation between the human and the brutes.

Whatever may have been the motive of René Descartes for seriously declaring that of all the animals only man was conscious (perhaps it was due to his predominant ecclesiastical or to his mathematical interests) no one, perhaps not even himself, ever believed the dictum any more than that his will is not free, however loud, or even however good, his arguments.

The twin-principles of analogy and of continuity teach everyone, who is not prejudiced by some underlying system of belief, that the "lower" animals are conscious like ourselves; in proportion, however, to their complexity, both of environmental relationship and of functional internal relationship. The sceptic who admits consciousness in himself but denies it in the dog and elephant and lion has one resource which he is bound to make use of continually. He can deny the principle of continuity in organic evolution and claim that the protoplasm of man is essential different from that of all other animals and that the difference is such that conscious-ness may inhere in it and not at all in the brutal organism, the consciousness accruing to it suddenly as if out of Pandora's box. So arbitrary, however, is this supposition, so gratuitous in the biology of protoplasm, that it may be disregarded, the burden of proof resting wholly on its claimants. So far as every evidence goes, structural and functional, the two classes of animals compared, built on the one same plan, live in the light of the same consciousness, save probably for ratiocination, which has perhaps developed the vast complicating of the connections of the fibres of the brain and the consequent development of abstract symbols of speech and language. The burden of proof in this matter rests with those that deny the analogic probability.

Now going along the multitude of animal forms toward the simplest animal from the most human, where can a line be drawn beyond which consciousness may be denied? With wonderful morphologic variety there is striking biologic uniformity, the same use of the same mechanical principles and of chemical reactions and assuredly of nature generally, so that even in Amoeba, the simplest, indeed the logical limit of animal structure, we find the same events in type and the same means for producing these events—metabolism in irritable living protoplasm. Even in Amoeba there is that same amazing complex protoplasm whose chemophysical interactions science is only beginning to unravel. Co-ordination in Amoeba is poor and we find him sometimes trying to crawl in opposite directions for a brief space, for there is of course no nervous matter. For the same reason the animal's adjustment to external conditions is imperfect, although in the main protective of its life.

Notwithstanding all this, the whole varied metabolism is there, giving rise to the same sort of heat, motion and activity, the same nutritive from the same protoplasmic life, supplied by the same nutrients and giving off the same katabolic waste as does a nerve cell or any other cell of a human body. Without a single nerve-fibril the naked protoplasmic impulses, as one may quickly see when the whole animal nearly at once contracts after stimulation, and co-ordination and even adjustments occur without anything which can be called nerve. Without muscle contraction takes place. Without separate gland-tissue secretion goes on. Without reproductive cells the marvelous so-called simple division of the animal occurs whenever its overgrowth demands, a process compared with which even mitosis is easy to understand. In Amoeba then, the logical limit of animal simplicity, a minute drop of uncolored streaming protoplasm, the matter is organized as forces which interact and are mutually and self sustaining. The adjustment of relations which is its life is nearly as perfect as in other animals and because the chemical process at the basis of this series of adjustments is perhaps even more complex than elsewhere (since every function nearly inhere in every part), a modicum, a trace, a sample of consciousness must be supposed to be concerned.

What can be supposed as to the nature of
this requisite consciousness of Amaba? Shall we imagine it like our own? Of course not. Can we imagine it at all? Scarcely so, it must be allowed, and yet, *the dim crawling life* is part and parcel of a system of uniformities in which we ourselves and our own consciousness partake and within these limits we can imagine much. It is customary for descriptive psychology to say that the most prominent aspects of mind as we know it are feeling, will and thought. The first, feeling, is based wholly on sensations, on modifications of consciousness which seem to have to do with that protoplasm, which in man and his congener is made up as sense-organs. Amaba's protoplasm and that of other unicells is universally sensitive to irritating stimuli, and its irritation causes reactions exactly comparable to those of protoplasm elsewhere under the influences coming from sense-organs. A dim and simple sensation-mass would seem then to be a reasonable basis and substance of Amaba's consciousness. Besides this there are obviously elements of which we all or at least this involves that something else, that certain pluses, not to be defined but representing perhaps in its last analysis the life itself, action, active purposiveness, that quality by which the interaction of Amaba's molecule is ordered in complexity and in self-adjustment those of other self-regulating materials—if indeed any such besides bioplasm exists. Another word for will is conscious spontaneity and possessing this the animal may still be as much the slave of its environment. Its spine is extreme. Sensation-mass and will, conscious spontaneity, such we may imagine, are present in Amaba's consciousness. In these nerves are unnecessary, and their physical basis is adequately enough the universally complex, irritable and active protoplasm of which the whole body is composed. So much for this logical type of animal, a speck of undifferentiated bioplasm. In this form we are interested only for these very reasons—that it is the logical type and it is undifferentiated protoplasm only.

In the series of animals from Amaba "up" (no scale save a very indistinct one can be made out), we find at once development in the whole organism of the concepts in the various organisms begin to take on distinctly the qualities and uses of nervous tissue, the first token of this being assumption by certain cells of a new vigor and promptness of reacting to stimulation, it being therefore the sense-organ part of the nervous system which appears first in the phylogenetic development. In this simple plan these sensitive cells are also means of defense. In animals a little more complicated we find the rudiments of an entire nervous system, the first form being a mere line or lines of fibrils, with the necessary nerve-cells connecting parts required to work in unison for some reason or other, or, where adjustment of any sort is necessary. Functional condition, where adjustment of any sort is necessary, is always the business of these fibrils. In forms of life more and more complicated, the nervous system's reticulum of fibrils shows corresponding development, not only in actual intricacy, but in relative mass. This is the way the nervous system comes to be a rough general index of the complexity of any animal's life, of relations more and more involved, not only between cells and organs within the limits of the animal, but with numberless conditions outside the individual which are yet part of its environment and in a biologic sense inseparable from itself. Conduction, co-ordination, adjustment, appreciation, become more and more complete as the vital conditions demand. Small portions of the protoplasm develop into sense organs and the corresponding sensation-mass of the animal we may suppose because of his richer with involutions of feeling in its nature. In very simple forms muscular tissue of a simple sort has already developed, so that actions are made more promptly and in a more perfectly adjusted way. Thus the will has developed also in richness and in strength, as represented by what the various animals variously do.

But if sensation and violation constitute by far the larger part of the brute's consciousness (as of man's) what of cognition, the faculty of knowing, an analytic distinct abstracting from the mental continuum? We have scarcely yet escaped the exaggeration which the associationists forced into psychology. Man's pride is reluctant to admit how small is the proportion of cognition and especially of constructive conception in his own mental process minute by minute. If he ordinarily overestimates his own intellectualism in the determination of behavior, it is equally certain that he has somewhat underestimated the practical function of the brutes. Researches made of late, especially by Yerkes of Harvard, suggest beyond much doubt that the brutes conduct the rudiments of the processes of ideation (the formation of ideas) and of reasoning (with inference as its essence) much as do humans, but always in far closer connection with actual motor behavior than is the case with ourselves. E. M. Smith of Cambridge University said in 1915: "It is by no means disproved that animals are intelligent and have ideas. All the point that clearly emerges is the need for new methods of inquiry."

It is plain that one of the most pressing needs of animal psychology is definite information in regard to the relative functions of the various classes of brain in the more higher vertebrates. Parker of Harvard, as well as Yerkes and many others, have set about this task more or less systematically, but curiously enough this particular line of work on the more intelligent of our poor relations has been mostly neglected. Yet, before we can study intelligently the chimpanzee, the dog, the cat, the pig, we must certainly know just what their senses are like, for sensation is the "beginning" of the reflex nerve-circuits on which all their behavior depends to a greater or less extent. There is where new methods (often necessarily of great ingenuity), will yield most productive observations. So far most animal psychologists have begun to study the wrong end, so to say, of the reflex *arc*, the actual result of behavior involves a manifold of the sensibility and the children need, above all things else, sense-training and for a like reason psychologists need precise facts as to the perceptual powers of the brute animals. On these data the work of proving that mind is everywhere attested with for the most part only quantitative differences
will perhaps be gratifyingly accelerated. This at least seems to me the present psychologistic indication.

GEORGE VAN NESS DEARBORN,
Professor of Physiology, Tufts College.

ANIMALS, Superstitions in Regard to. See AMERICAN MYTHOLOGY.

ANIME, ă-nē-mə, a resin supposed to be obtained from the trunk of an American tree (Hymenaea courbaril). It is of a transparent amber color, has a light, agreeable smell, and is soluble in alcohol. It strongly resembles copal, and, like it, is used in making varnishes. Specific gravity is 1.028 to 1.054.

ANIMIKEAN, a term used largely by Canadian geologists for what the United States Geological Survey calls Upper Huronian. See HURONIAN SERIES.

ANIMISM, the system of philosophy propounded by Stahl, and based on the idea that the soul (anima) is the seat of life. In modern usage a term applied to express the general doctrine of souls and other spiritual beings, and especially to the tendency, common among savage races, to explain all the phenomena in nature not due to obvious natural causes by attributing them to spiritual agency. Among the beliefs most characteristic of animism is that of a human appurtenance of the form and the life of the body, and living after death a sort of semi-human life.

ANIMUCCIA, ă-nē-moo’chā, Giovanni, Italian musician: b. 1500; d. 1571. He was appointed chapel master of the Vatican in 1555, and composed the Laude, to be sung at the conclusion of the regular office, and from which the oratorio is said to have developed. Hence he is often called the Father of the Oratorio. He composed a number of masses, motets, madrigals, etc. His most noteworthy works are ‘Il primo libro di madrigali, etc.’ (Rome 1593); ‘Anuus Animucciae Magistri Capellae Superioris Basilicae Vaticane Missarum Libri’ (ib. 1567); ‘Magnificat ad Omnes Modos’ (ib. 1568) ‘Il secondo libro delle laudi ove si contengono motetti’ (ib. 1570).

ANIO, ă-nē-ō, ANIENE, or TEVER-ONE, an Italian river tributary to the Tiber, which it enters from the east a short distance above Rome.

ANISE, ă-nīz, an annual plant of the family Umbelliferae. It is a native of Egypt and the Mediterranean regions. The stem is about two feet in height, and divides into several slender branches. The leaves are wedge-shaped. It is extensively cultivated in southern Europe, Germany, India, etc. It is used as a condiment in the preparation of liqueurs, and as a stomachic stimulant in medicine, to relieve flatulence, etc., especially in infants. It contains a volatile oil, called oil of anise, which is used for purposes similar to the seed. The oil is procured either from the seeds or from the stems and leaves.

ANISOPOILLY, ă-nīsō-pō’lī, the phenomenon of the production of two sorts of leaves on the same shoot. It is due to the unequal action of several factors, principally gravity and light. For illustrations of this phenomenon in various species consult Bosch, K., ‘Beiträge zur Kenntniss der Blatta-
symmetric und Exotrophie’ (1911); and Figdor, W., ‘Die Erscheinung der Anisophillie’ (1909).

ANKERITE, a carbonate belonging to the calcite group of minerals. It is intermediate between calcite, magnesite and siderite, the normal mineral being a carbonate of calcium, magnesium and iron, having the formula 2CaCO₃·MgCO₃·FeCO₃. It occurs in rhombohedral cleavage, a hardness of 3.5 to 4, specific gravity of about 3, vitreous to pearly lustre, and usually white color. It also occurs in granular, crystalline and compact masses.

ANKYLOSIS, ă-ni-kī lö’sis, a stiffening of the joints, a term used by surgeons to denote fixation of a joint not dependent on rigidity of the muscles. It is caused by injury or disease, resulting in a deposit of new bone between the articular surfaces or in the formation of fibrous adhesions. In the latter case the stiff joint may be forcibly bent and the bond of union ruptured, so as to restore mobility. Passive movement, massage, and friction are all the phenocleum depends on. Sometimes, however, an anesthetic is administered and the joints are moved by force. See JOINT, DISEASES OF.

ANN ARBOR, Mich., city and county-seat of Washtenaw County, on the Huron River, and the Michigan Central, the Ann Arbor and Toledo railroads and the Detroit United Railway. It is situated among the southern part of southern Michigan, 38 miles from Detroit, and is regarded as one of the most desirable residential cities in the Middle West. Here is the seat of a famous school of learning, the University of Michigan (see MICHIGAN, UNIVERSITY OF). Ann Arbor has, among prominent buildings, an auditorium with seating capacity of 5,000; a university hospital, a homoeopathic and four other hospitals, county courthouse, post-office building, high school and numerous churches and public and private schools, two schools of music, two libraries. It is the business centre of a large agricultural and fruit-growing region and an important shipping point. It has extensive manufactures of agricultural implements, furniture, pumps, engines, automobile accessories, laces and curtains, steel ballbearings, boilers, lumber products, organs, pianos, flour, wagons, etc. The United States census of 1914 reported 75 manufacturing establishments of factory grade, employing 1,079 persons, of whom 842 were wage earners, receiving a total of $516,000 annually. The capital employed was $2,888,000, and the value of the year's output was $2,603,000; of this, $1,301,000 was added by manufacture. The Barton Dam furnishes water power, producing electric energy sufficient for the city and surrounding territory. The city has an extensive electric light system, waterworks plant and electric traction lines connecting with Jackson, Kalamazoo, Battle Creek, Detroit and other cities. The waterworks are owned by the city. It has daily and weekly newspapers and one national bank, three savings banks and two branch banks. It was originally settled in 1824 and was incorporated as a city in 1851. Pop. (1890) 9,431; (1900) 14,509; (1910) 14,817; (1914) 14,500, besides 7,000 students.
ANNA — ANNALS OF A SPORTSMAN

ANNA, Ill., city in Union County, 35 miles northwest of Cairo, on the Illinois Central Railroad. It contains a public library and the State Hospital for the Insane. It has a large trade in the agricultural products of the district, which produces corn, fruit, hay, vegetables and flax. Pop. 2,809.

ANNA IVANOVNA, Anná É-vá'nov'-na, Empress of Russia: b. 1693; d. 28 Oct. 1740. She was the second daughter of Ivan, brother of Peter the Great. In 1710 she was married to the Duke of Courland, who died the following year, thus ending her line. On the death of Peter II in 1730 the Supreme Council offered her the throne, under certain conditions restricting the power of the monarchy. Ostermann, her former preceptor, and in 1730 Chancellor of the Empire, furthered her cause before the Council, but was rebuffed, finding her less amenable to his wishes than he had hoped. During the earlier portion of her reign Russia was engaged in the War of the Polish Succession and also in war with Turkey in the Crimea in 1735–39. At home her administration under the influence of Biron was a very cruel one. Thousands were exiled to Siberia and other thousands were tortured at home. Among the victims were Prince Basil Dolgoruki and members of his family. The Emperor’s health broke down in 1740, and she died in the autumn of that year, leaving the throne to her grand nephew Ivan, under the regency of Biron. See RUSSIA.

ANNA KARENINA. The world has come to regard Tolstói’s novel, ‘Anna Karenina’ as one of its greatest masterpieces; but the author himself, also in the character of Levin depicted his own vain efforts to discover the secret of happiness, began to detest it before it was half finished. He called it “ordinary and empty,” “incoherent, neither fish-nor-flesh stuff,” he even wanted to destroy it. He slightly characterized it as “a novel, showing how an officer fell in love with a married woman.” The immediate incentive to its composition was his chancing on the commencement of a story by Pushkin. He cried out: “That is the way to begin a book,” and on 19 March 1872 began ‘Anna Karenina’ with the sentence, “All happy families resemble one another; every unhappy family is unhappy in its own way.” Its publication in the Russky Vestnik (Russian Messenger), edited by Katkov, immediately aroused the greatest enthusiasm in Russia. Tolstói was amazed at its popularity, but soon lost interest in it and allowed months to elapse without furnishing the expected copy or even correcting the proofs. When the Turco-Russian War broke out in 1876, he brought it to a conclusion with a chapter showing his disapproval of the volunteer movement. Katkov refused to publish it, returned the manuscript, and printed a brief note to the effect that the logical end of the novel was in the third act. The extra section was included in the definitive edition in three volumes aggregating 1,381 pages. The novel is panoramic: it gives a multitude of episodes of high life in Moscow and Saint Petersburg and of country life in the district of Levin. Its main purpose is to contrast the rather frivolous existence of a public official mingling in corrupt social circles with the serious endeavors of an idealistic landowner bent on carrying out reforms among the peasantry. It also contrasts the homely “family happiness” of the conventionally married couple with the irregular relationship of a married woman and a wealthy count, logically ending in despair and death. It is really two stories in one. The unexpected love-affair of Prince Stepan Oblonsky and of his sister Anna bring into relief the pure and delicate romance of the Princess Oblonskaya’s youngest sister, the Princess Kitty Scherbáktskaya with Konstantin Levin, a landed proprietor, a bashful, erratic idealist, uncertain of himself, making all kinds of experiments, dissatisfied, but high-minded. In Levin Tolstói undoubtedly depicted his own nature and it gave him an opportunity to introduce his own observations on philosophy, agriculture and religion. The account of Levin’s proposal was taken directly from Tolstói’s wooing of Miss Sophia Beers. Indeed the author frequently drew his details from his own experiences and his characterizations from his keen study of his relatives and friends. He painted from real life the gambling scenes, the horse-racing of Levin’s disreputable brother, the hunting episodes, the quaint and often amusing naïvetés of the peasantry. The tragic suicide of Anna Karevna was probably the echo of a tragedy which took place on the railway near Tolstói’s country estate, Yasnaya Poljana. ‘Anna Karevna’ is often careless in style and contains strange incongruities, but taken all in all it seems like a veridical history rather than fiction. It belongs to world-literature. The first English translation, somewhat expurgated, was made by Nathan Haskell Dole in 1886, but revised and rendered complete in 1899. There are also translations by Leo Wiener, Mrs. Constance Garnett and Aylmer and Louise Maude.

NATHAN HASKELL DOLE.

ANNA KARLOVNA, Anna kár'l'ov'-na, Regent of Russia during the minority of her son Ivan: b. 1718; d. 1746. She was the daughter of Charles Leopold, Duke of Mecklenburg, and of Catharine, sister of the Empress Anna Ivanovna. She married Anthony Ulric, Duke of Brunswick-Wolfenbüttel in 1739. A son Ivan was born to them 24 Aug. 1740, and was appointed her successor by the Empress Anna Ivanovna. The latter died in October 1740, and Biron, whom she had appointed regent, was soon overthrown. Anna Karlovna thereupon proclaimed herself Grand Duchess and Regent of Russia, but showed little capacity for administration and soon fell under the influence of Julia Mengden, one of the ladies of her court. A conspiracy to place Elizabeth, daughter of Peter the Great, on the throne was successful and Elizabeth was proclaimed Empress 6 Dec. 1741. Ivan was soon afterward murdered at the castle of Schlüsselburg; Anna and her husband were condemned to prison for life and confined at Kholmogory on the White Sea, where she died in 1746. Her husband survived her 34 years, and died in prison in 1780.

ANNA LEOPOLDOVNA. See ANNA KARLOVNA.

ANNALS OF A SPORTSMAN. A work by Ivan Turgenieff, consists of 22 short sketches of Russian peasant life, appearing in book form.
in 1852 and establishing the author's reputation as a writer of realistic fiction. Turgeneff represents himself as on a hunting trip through the country districts, noting the local life and social conditions, and giving truthful studies of the people. He was the liberator of Alexander II; his book being one of the agencies that brought about that reform.

**ANANAM, ān'nam**. See ANAM.

**ANAMABOE, āná-má'-bó**, Africa, seaport town, with a fort, on the Gold Coast, 10 miles east of Cape Coast Castle. It was at one time a principal mart for slaves, in trafficking in which many of its inhabitants became wealthy, and is still a place of considerable trade. Pop. about 5,000.

**ANANN**, Scottish seaport and parliamentary borough in Dumfriesshire, on the Annan River. It has railroad connection with Glasgow, Carlisle and Edinburgh, and water connection with Liverpool and Whitehaven. The important manufactures are tanning, rope-making, and cotton-spinning.

**ANAN**, a river of Scotland, having a course of about 50 miles, flowing from north to south through the centre of Dumfriesshire to the Solway Firth, its sources being not far from those of the Tweed and Clyde.

**ANAPOLIS, Md.,** the capital and port of entry of Maryland and county-seat of Anne Arundel County; on the Severn River, two miles from Chesapeake Bay, on the Maryland and the Annapolis, Baltimore and Washington electric railroads. It is 26 miles southeast of Baltimore and 30 miles northeast of Washington, D. C. It is also connected by boat with Baltimore and other cities on the bay. It is in a fruit and berry-growing region; has oyster-packing plants, marine railway, glass factory, two banks, daily, weekly and other periodicals, and a property valuation of $3,000,000. Annapolis is widely known as the seat of the United States Naval Academy (q.v.), with its beautiful new buildings and grounds on which the government has expended $15,000,000. The marine barracks and naval experiment stations are also situated here. Saint John's College, the first free school in America, was established in Annapolis in 1696; there are good schools, a fine new high school and a preparatory school for the naval academy. The State buildings include the Colonial State House dating from 1772, recently rebuilt, and the little treasury building. There are Catholic and Presbyterian churches and the historic Episcopal Church of Saint Anne first erected in 1695. A convent, a house of Redemptorists, Fathers, formerly the Carroll residence, and some of the finest colonial mansions in the country are among other points of interest, as well as the bronze statues of Gen. John de Kalb and Chief Justice Roger B. Taney. The city was founded in 1649 and was first named Providence. It received its present name in honor of Queen Anne and was made the capital of the province in 1694; in 1708 it was given a charter by the Queen. Annapolis played an important part in early American history. On 19 Oct. 1774, the Brig Peggy Vixart laden with tea was burned in the harbor in protest against the taxation of the colonies by Great Britain; the first Federal Constitutional Convention was held here in 1786, and in 1783 Washington surrendered his commission in the senate room of the State House where a year later the treaty of peace with England was signed. Pop. (1910) 8,609; (1914) 8,643. Consult Ridegley, 'Annals of Annapolis' (Baltimore, 1841) and Cos. 146. Symposium of the Southern States' (New York 1900).

**ANNAPOLIS CONVENTION.** This small gathering was held 11 Sept. 1786, to discuss proposed changes in the Articles of Confederation. By the time it met, the Confederation had utterly broken down: Congress could not find means to carry on the government and the Annapolis Convention was anxiously looked to as the last hope by the business interests. Only five States were actually represented,—New York, New Jersey, Pennsylvania, Delaware and Virginia. These, however, were precisely the ones which wished the entire Confederation remodeled. New Jersey had instructed its delegates to accept nothing but a new Federal government; and the New York group, headed by Alexander Hamilton, was equally zealous for a stronger system. John Dickinson, one of the chief authors of the Constitution, was made chairman; and a committee was appointed to prepare a report, which was drafted by Hamilton, though he was not on the committee. This report recommended that the States they represented should agree, and try to induce the others to agree, to meet at Philadelphia on the second Monday of the next May, to consider the situation of the United States and devise such further provisions as should appear necessary to render the Constitution adequate to the exigencies of the nation; and to report to Congress such an act as, when agreed to by them and confirmed by the legislatures of every State, should effectually provide for the same. They then adjourned; but this call led to the convention of 1787, where the Constitution was adopted.

**ANNAS** (Hebrew, "merciful"), a Jewish high priest; appointed high priest by Quirinus, proconsul of Syria, about 7 A.D., and deposed by Valerius Gratus, procurator of Judea, in 14 A.D. His family was wealthy and he was evidently very influential, as the office of high priest was held by five of his sons, by Gamaliel, by Caiaphas, before 36 A.D. In the New Testament (Luke iii, 2; John xviii, 13; Acts iv, 6) Annas is mentioned as high priest conjointly with Caiaphas. The first hearing of Jesus was before Annas, who sent him bound to Caiaphas. The tributes or taxes were frequently a cause of contention between ecclesiastical and civil authorities. An effort was made to put an end to these contentions in the paples of Pisa and Constance, and gradually all the minor tributes were abolished. In the Council of Basel it was decided to abolish every tribute of this kind, but to raise revenues for the anti-
pope Felix excations doubly severe were im-
posed on his adherents. In Germany the
payment was satisfactorily regulated in the
Concordat of Vienna (1448) and after several
modifications it was finally abolished in 1803.
In France the payment was stipulated in a Con-
cordat between Innocent X and Francis I; it
was finally refused entirely in 1789, and its
abolition recognized in the Concordat of 1801.
In England such sums were first paid to the
archbishop of Canterbury, later to the Pope,
and transferred to the Crown in 1534, the sov-
ereign at present retaining only those derived
from bishops and Crown livings, the rest,
since Queen Anne's time (see Queen Anne's
Bounty), going to increase the poorer livings.
The Pope used them to support himself, the
Cardinals and other papal officials; to defray
expenses of nuncios, legates, bishops exiled
from their sees, princes deprived of their
thrones, envoys and vicars apostolic to mis-
ionary countries. As this source of revenue
has a thick, constantly falling off during the past
century, the deficit is made up by the voluntary
contributions of Catholics, known as "Peter's
Pence" (q.v.). Consult Ferraris, 'Prompta
Biblica'. See First Fruits.

ANATTO, ān-nät'ō, ANATTO, or AR-
NOTTO, a small tree which grows in Central
and South America. The seeds are surrounded
with a thin coating of waxy pulp, which is sep-
parated from them by washing in water, pass-
ing the liquid through a sieve and allowing
the suspended pulp to deposit. The water is
then drained away and the paste dried, till it is
a thick, stiff insipid mass. In this state
it has a dark orange-red color and is known as
"roll" or "flag" arnotto, according to the form
in which it is put up, but when further dried it
is called "cake" arnotto. It is much used by
South American Indians for painting their
bodies; among civilized communities its prin-
cipal use is for coloring butter, cheese and var-
nishes. It yields a fugitive bright orange color,
and is to some extent used alone, or in conjunc-
tion with other dyes, in the dyeing of silks and
in calico printing.

ANNE, ān, Queen of Great Britain and
Ireland b. at Twickenham near London, 6 Feb.
1665 d. at White Hall 1714. She was the second
daughter of James II, then Duke of York, and
Anne, his wife, daughter of the Earl of Clarence-
don, and was educated according to the princi-
ples of the English Church. In 1683 she was
married to Prince George, brother to King
Christian V of Denmark. On the arrival of
the Prince of Orange in 1688 Anne desired to
remain with her father; but was prevailed upon
by Lord Churchill, afterward Duke of Marl-
borough, and his wife, to join the triumphal
party. After the death of William III in 1702
she ascended the English throne. Her character
was amiable but lacking in firmness, and she
was influenced first by Marlborough and his
wife and afterward by her favorite, Mrs. Mas-
burrow. Most of the principal events of her
reign are connected with the war of the Spanish
Succession. The only important acquisition
that England made by it was Gibraltar, captured
in 1704. Another very important event of this
reign was the union of England and Scotland,
under the name of Great Britain, which was ac-
complished in 1707. She seems to have long
cherished a wish to secure the succession to her
brother James, but this was frustrated by the
internal dissensions of the Cabinet. Grieved
at the disappointment of her secret wishes, she
fell into a state of weakness and lethargy and
died. The reign of Anne was distinguished by
the brilliant successes of the British arms.
Consult Oldmixon, 'Life of Queen Anne'
(1716); Ashton, 'Social Life in the Reign of
Queen Anne' (1882).

ANNE, Saint, wife of Joachim and mother
of the Virgin Mary. The Catholic Church cel-
brates her feast day on 26 July.

ANNE, Sister, the sister of Fatima in the
tale of 'Bluebeard.' From the top of the
castle tower she awaits the arrival of their
brothers to rescue them.

ANNEALING, a process to which metals
and glass are subjected in order to increase
their ductility, or lessen their liability to frac-
ture under sudden stress. It is usually effected
by heating the substance to be annealed until it
approaches softness, and then allowing it to
cool very slowly. Copper, however, is best an-
nealed by heating it to a high temperature and
then plunging it immediately into water. Met-
als that are to be annealed should be heated in
close vessels, so that they may not be dis-
credited by direct contact with the fuel. It is not
uncommon to anneal large masses of metal or
glass by allowing the fires in the heating fur-
nace to go out, and permitting the furnace and
its contents to cool together. The articles to be
annealed are also often buried, while still hot,
in lime, ashes or some other poor conductor of
heat and left until cold. Metals that are to be
drawn into wire or rolled into sheets, or pressed
into complicated shapes, usually require an-
nealing during the process, as otherwise they
are likely to become brittle and crack or break.
Zinc, however, grows strong and flexible as it
is drawn into wire, though it loses its flexibil-
ity and retains its crystalline structure if kept in
boiling water for a time. It is usually taught
that the object of annealing is to soften the
material sufficiently to allow molecules to move
slightly among themselves, and thus relieve the
strains previously introduced by sudden cooling,
or by the violent stresses to which the material
has been subjected in the process of working.
This theory is very possibly true to a certain
extent, but the anomalous cases of copper and
zinc, cited above, show that it can be regarded
only as a first approximation to the ideal theory
of annealing, which has yet to be discovered.

ANNECY, ān-sā, town of eastern France,
situated in the central part of the department
of Haute Savoie at the northwest end of Lake
Annecy. It has manufactures of silk, cotton,
wool and steel, and contains many buildings of
historical interest, including a cathedral and
the old castle of the Counts of Genevois. Pop.
about 15,000.

ANNENSKI, Nikolai Feodorovich,
ā-něn'skē, Russian publicist and social worker:
b. 1843. He spent his childhood in Siberia,
where his father was engaged in military serv-
vice. He took the degree of bachelor of law at
the University of Saint Petersburg in 1867 and
the bachelor's degree in history and philology in
1873. In 1897 he entered the civil service, tak-
ANNEXATION

ANNEXATION, politically, the formal incorporation by a state with itself of territory previously under another government; usually territory contiguous to itself or its colonial possessions, or an insular neighbor, but only because other annexations are not from any principle of international law. The annexation may be by purchase, peaceful cession or conquest. Existing laws and local authorities do not lose their binding force and title to obedience till the formal act of annexation is passed by the new power, or treaty or proclamation validates it, even after cession by the old; though that cession cancels all legal relation to the former sovereign power.

Annexations to the United States.—(1) The Louisiana Purchase (q.v.) from Napoleon, 1803; 1,171,931 square miles, including Alabama and Mississippi south of lat. 31° S.; the whole of Louisiana, Arkansas, Missouri, Iowa, Nebraska, North and South Dakota, Idaho, Montana, Oregon, Washington and Indian Territory; Colorado and Wyoming lying east of the Rocky Mountains; Kansas, except the southwest portion south of the Arkansas River, and Minnesota west of the Mississippi. This was bought by Jefferson's administration for $15,000,000, $3,750,000 of it in assumption of claims of American citizens against France. The preliminary convention was signed by Livingston and Monroe 30 April 1803, and was confirmed by the Senate in special session 19 Oct. 1803, and by the House the 25th,—the extreme Federalists opposing it as unconstitutional, and the President acknowledging it to be so, but necessary.

(2) Florida (q.v.), 1819—21, from Spain: 59,268 square miles; price $5,000,000, entirely in assumption by the United States of claims of its citizens against Spain, and the relinquishment by it of claim to Texas and the boundary of the Rio Grande. The treaty was signed by the Spanish Minister at Washington, 22 Feb. 1819; Spain refused to ratify it till after two years of vain insistence that the United States should refuse to recognize the independence of the South American States.

(3) Texas (q.v.), 1845: 376,133 square miles. Texas, originally part of the Mexican province of Coahuila, obtained its de facto independence in the War of 1836 against Mexico, was acknowledged by the other powers in 1837, and at once began the attempts for admission into the United States which had been the ultimate object of its first colonization by Southern settlers. In the previous April a treaty of annexation with Texas had been concluded, but was rejected by the Senate. President Tyler on the last day of his term sent a special messenger to secure the consent of the Texas Congress to annexation; it acceded unanimously, a popular convention of 4 July ratified the action, and the annexation was completed by a joint resolution of the United States House 16 Dec. 1845, and of the Senate on the 25th. It extended west to the Rio Grande, taking in all the immemorial Spanish province of Coahuila, a circumstance which led to the Mexican War.

(4) New Mexico and Upper California, seized from Mexico in the War of 1846, and annexed by an ordinance of the Guadalupe-Hidalgo, 2 Feb. 1848: 545,783 square miles. Besides the
present State of California it included Utah and Nevada, the most of Arizona and New Mexico and Colorado west of the Rocky Mountains. Price, $15,000,000, and the assumption by the United States of $3,250,000 in claims of its citizens against Mexico. The portion of New Mexico east of the Rio Grande was claimed by Texas, which afterward received $10,000,000 from the United States in release. The capital engaged aggregated $3,810,000, and the year's output was valued at $4,365,000: of this, $1,819,000 was added by manufacture. Anniston is the seat of the Southern Female College, the Noble Female Institute and the Alabama Presbyterian College for young men; has three national banks, numerous fine churches and other public buildings. It was founded by the Woodstock Iron Company in 1872 and received a city charter in 1879. Pop (1910) 12,794; (1916) 15,000.

ANNONACEAE, än-ô-nash-é, the custard-apple family, a group of trees and shrubs with simple, alternate leaves, destitute of stipules, by which character they are distinguished from the Magnoliaceae, to which they are otherwise closely allied. Their flowers are commonly axillary, sometimes terminal. The calyx is persistent, with three deep divisions. The corolla is formed of six petals, disposed in two series; the stamens are very numerous, forming several series; their filament short, their anthers almost sessile. The carpels, generally aggregated in great numbers in the centre of the flower, are sometimes divided; each of them has a single cell which contains one or more ovules attached to the inner suture, and often forming as many distinct fruits (rarely one only in consequence of abortion); sometimes they are united together and form a kind of fleshy, scaly cone. The seeds have a horny endosperm deeply grooved, and this is another character which distinguishes them from the Magnoliaceae. The Annonaceae are mostly tropical plants belonging both to the Old and New Worlds, the pawpaw (Asimina triloba) being the best-known American species. They are generally aromatic, a quality found chiefly in the bark, but also in the leaves and flowers, and to some extent in the fruit, all of which parts are consequently employed in the countries of which the plants are native as remedies and for seasoning. Many of them yield likewise an edible and nutritious fruit, extremely agreeable to the taste.

ANNIHILATION is the name of a doctrine held at different periods in the history of the Church. It means the exaltation of the righteous and the annihilation of the wicked. Brahmanism holds a periodic annihilation. It is said that the Siamese hold annihilation as the crowning reward of virtue. There are some traces of a belief in the theory in the writings of the early Church fathers. Jonathan Edwards had a long controversy with Dr. Chauncey on the subject. Later Archbishop Whately held the same view regarding the wicked. From 1850 to 1860 the question was much discussed. It is now a dead question in theological circles.

ANNISTON, än-nis-tön, Ala., city, capital of Calhoun County; on the Lowisville & N. & Southern railroads, 62 miles northeast of Birmingham. It is one of the most important coal- and iron-mining regions of the country; is a trade centre for cotton and agricultural products; and is noted for its manufactures of iron and steel, cast-iron piping, cotton goods, bricks, cordage and other articles. The United States census of 1914 reported 40 manufacturing establishments of factory grade, employing 2,491 persons, of whom 2,327 were wage earners, receiving annually $1,023,000 in wages.

ANNUAL, in botany, a plant which germinates, grows and produces its seed in a single growing season, after which it dies. Plants which are annuals in temperate regions may, in tropical countries, live for several years. Annuals are plants which germinate in autumn, persist through the winter, then flower, produce seed and die.

ANNUALS, in literature, the name given to a class of publications enjoying at one time an immense yearly circulation, and distinguished by great magnificence both in binding and illustration, which render them much sought after as Christmas and New Year presents. Their contents were chiefly prose tales and ballads, lyrics and other verse. The earliest was the 'Forget-me-not,' started in 1822, and followed the next year by the 'Friendship's Offering.' The 'Literary Souvenir' was begun in 1824 and the 'Keepsake' in 1827. Among the names of the editors occur those of Alaric A. Watts, Mrs. S. C. Hall, Harrison Ainsworth, Lady Blessington and Mary Howitt. The popularity of the annuals reached its zenith about 1829, when no less than 17 made their appearance; in 1856 the 'Keepsake,' the last of the series, ceased to exist.
