COLT, Samuel, American inventor: b. Hartford, Conn., 19 July 1814; d. there, 10 Jan. 1862. He had a common school education and was employed in his father's textile mill, but went to sea as a sailor when 15. His attention being drawn to firearms while at sea, he began to perfect a revolver and patented it in 1835. Its great success led to the erection by him at Hartford of one of the most extensive weapon factories in the world. Among his other inventions are a battery for submarine harbor defense, and the first submarine telegraph cable.

COLTMAN, Robert, Jr., American physician: b. Hartford, Conn., 19 Aug. 1862. He was graduated at the Jefferson Medical College, Philadelphia, in 1881 and began the practice of medicine in the same year. In 1896 he became professor of anatomy at the Tung Wen College, Peking, and in 1898 professor of surgery at the Imperial University of the same city. He was appointed foreign correspondent of the Chicago Record in 1900, to which he sent out during the siege of Peking by the Boxers the first message that reached the outside world. He is now the representative of the Standard Oil Company of New York at Peking, China. He published 'The Chinese, their Present and Future: Medical, Political and Social' (1891), and 'Yellow Crime, or Belatedness in Peking' (1901).

COLTON, Arthur Willis, American writer: b. Washington, Conn., 22 May 1868. He was graduated at Yale in 1890, held the Poole scholarship there 1890-93, and was instructor in English literature 1893-95. Since 1895 he has devoted himself to writing, and his stories, essays and verse have appeared in the Atlantic Monthly, Scribner's, Harper's and other magazines. In book form he has published 'Bennie Ben Cree' (1900); 'The Debatable Land' (1901); 'The Delectable Mountains' (1901); 'Tioba, and Other Tales'
(1903); 'Post Argent' (1904); 'Belted Seas' (1905); 'The Cruise of the Violetta' (1906); 'Harps Hung Up in Babylon' (1907). In 1906 he became librarian of the University Club, New York.

**COLTON, Charles Henry**, American Roman Catholic prelate. b. New York, N. Y., 15 Oct. 1848; d. Buffalo, 9 May 1915. In the schools of that city he pursued his elementary studies, later attended the Latin school connected with Saint Stephen's Church, and in 1869 began a theological course at Saint Francis Xavier's College. After three years he repaired to Saint Joseph's Diocesan Seminary, Troy, N. Y., where he was ordained priest 10 June 1876. He was then made assistant pastor of Saint Stephen's Church, New York, and, in 1886, assumed charge of the church of Our Lady Abbey, Chestertown, N. Y. In 1897 he was recalled to New York to aid the Rev. A. J. Donnelly of Saint Stephen's. Father Colton was named administrator of the parish, and subsequently appointed rector. In 1896 Archbishop Corrigan appointed him chancellor of the New York diocese and upon Bishop Quigley's promotion to the archbishopric of Chicago, Ill., the Holy See chose Father Colton to succeed him as bishop of Buffalo. He was consecrated by Archbishop (now Cardinal) Farley, 24 Aug. 1903.

**COLTON, Gardner Quincy**, American scientist. b. Georgia, Vt., 7 Feb. 1814; d. Rotterdam, Holland, 11 Aug. 1898. He discovered the anaesthetic properties of nitrous oxide, or laughing gas, in 1844 for which he is also given to Dr. Horace Wells. He perfected an electric motor in 1847.

**COLTON, George Radcliffe**, American public official. b. Galesburg, Ill., 10 April 1866. He was educated at Knox College, was a ranchman in New Mexico in 1881-86, member of the Nebraska House of Representatives 1889-90 and national bank examiner for the district of Nebraska in 1897. He went to the Philippine Islands as lieutenant-colonel of the First Nebraska Volunteer Infantry, organized the customs service at Manila, and served the American occupation and served with it until 1905, when he went to the Dominican Republic and organized the Dominican customs receivership under the modus vivendi between the United States and the Dominican Republic. In 1907-09 he was insular collector of customs for the Philippine Islands. He drafted and presented to Congress the tariff for the Philippines, enacted by special session of Congress 1909, and also took part in drafting provisions of the Payne Bill relating to free trade between the United States and Philippines. In 1909-13 he was governor of Porto Rico.

**COLTON, Walter**, American writer. b. Rutland, Vt., 9 May 1797; d. Philadelphia, Pa., 22 Jan. 1851. He became professor of moral philosophy and belles lettres at Middletown Academy, Conn. (1825); in 1828-30 he was editor of the American Spectator, Washington. In 1845 he went to California, and in Monterey established the first newspaper of the State, called the Californian. He wrote several books of interest, including 'Ship and Shore in Madeira, Lisbon and the Mediterranean' (1835); 'Visit to Athens and Constantinople' (1836); 'Three Years in California' (1850); 'Deck and Port' (1850); 'The Sea and Sailor' (1851).

**COLTON, kōlt’n**, Cal., city in San Bernardino County, 58 miles east of Los Angeles, on the Atchison, Topeka and Santa Fé, the Southern Pacific and other railroads. Great quantities of fruits and vegetables are shipped from here and the city has railroad repair shops, canneries and packing-houses, cement works, flour mills and fertilizer works. The city owns the waterworks and electric-lighting plant. Fop. 3,560.

**COLUMBIDE, kō-lü’bri-dē**, a family of snakes, typified by the limited genus Columber of Linneaus, which comprises nine-tenths of all living snakes. As arranged by Cope the family contains non-venomous snakes (Aglypha) only, but under Boulenger's more approved system it embraces both the Opisthoglyphus and Proteroglypha, which include all the poisonous snakes except the vipers and pit-vipers (Gloydiidae). Even in the limited sense, a vast majority of snakes, not less than 1,000 species, fall within the family. All are of relatively small size, only a few giants attaining a length of 10 feet, and all have continuous rows of small teeth in both jaws, and none enlarged to serve as poison fangs. The head scales are large non-imbricate plates, but the body scales usually overlap, tile-like. They are oviparous or ovoviviparous and feed on insects, small mammals, birds, etc., though a few, as the king-snake, habitually devour poisonous serpents. Most of them are terrestrial, but some are aquatic and others arboreal. Nearly cosmopolitan in their distribution, but very sensitive to the influence of cold, they are absent from the polar regions, and in temperate climes hibernate during the winter. Many species are found in North America. (See Blacmsnake; Cornsnake; Gartersnake; Pinesnake; Watersnake; etc.). Consult books mentioned under Snake, especially Cope, 'Snakes of North America' (Ann. Rept. Smith's Inst. 1898, Washington 1900); and Gadow, Amphibia and Reptiles (New York 1901); 'Catalogue of Snakes of the U. S. National Museum,' where full references will be found.

**COLUGO, kō-loo’go, COBEGO, kō-hā’go, or KAGUAN, kág’wan, an East Indian insectivore of the only genus of the family Galeopithecidae, as yet imperfectly known. It is a slender creature about 18 inches long, its body covered with peculiarly sleek fur and provided with a parachute of membrane furred on both sides and extending from the neck nearly to the tip of the tail, which is enabled to make long sailing leaps like a flying-squirrel, a feature which gives it its technical name, Galeopithecus volitans. Like the bat, which the colugo resembles in various actions, it is a creature of twilight, hanging suspended by its hind legs from branches during the glare of day and seldom venturing forth in the complete darkness of night. It feeds upon leaves, fruit and insects. Consult Moseley, 'Notes by a Naturalist on H. M. S. Challenger' (New York 1866).

**COLUMBA, Saint**, apostle of the northern Picts of Caledonia and founder of numerous monasteries in the Hebrides and the Scottish mainland. b. 7 Dec. 521 in the territory of the Kinel-Conal, modern Donegal. He was a scion
of the illustrious race of Conal and was thus of kin to the northern princes of Ireland and of the Gaelic princes of Scotland. Whether his name, or surname, Columbia, is Latin or a Latinized form of a Gaelic name cannot be determined; it appears also in the form Colm (whence the name Malcolm, servant or devotee of Columbia); and the saint is also known as Columkille (Columbia of the churches, or celiae, the c in Gaelic being equal to k); because of the great number of churches and monasteries he founded both in Ireland and in Scotland and the isles. He became a monk in his youth in the monastery of Moville in Downetl, and at the age of 30 was a priest. Among the monastic establishments founded by him in Ireland are those of Daire-Calgaich (Calgach's oak grove), the site of the famous city of Derry or Londonderry; and Dair-mach (oak of the plain) where now is Darrow. This was the greatest of all his Irish monasteries. It is worthy of note that after his migration to Scotland, he and his immediate successors in Iona exercised jurisdiction over these Irish monasteries. About the year 563, being then under excommunication, and for the part he had taken in the bloody battle of Cooldrevyn, he set sail for North Britain with a band of his monks to preach the Christian religion to the still pagan Picts of northern Caledonia. He was entertained hospitably by his kinsman, Conal, king of the Scots in Argyll (Aner-Gadhill, land of the Gae) who gave him for his residence the island in the Hebrides later called I, or Iona and I-Colm-kile. Having established in Iona a monastery and training-school for the monks, he crossed over to the country of the northern Picts—the southern Picts had already been converted to Christianity—and to them preached the gospel with such effect that their king Brude and the whole people embraced the faith. Before Columba's death all northern Caledonia was Christian and monasteries were very numerous whether on the mainland or in the islands. Iona was the mother house, and thence Columbia and his successors, abbots of Iona, governed not only the monastic houses but the churches also; and though there were bishops for the special functions of the episcopate—the ordering of priests, for example, the administering of confirmation, the consecrating of churches and the like—those bishops were subject to the authority of the abbot of Iona, though he was never more than a presbyter in ecclesiastical order. Time was at his disposal amid the many cares of his station, Columbia devoted to study and to transcription of the Scriptures. On 8 June 597 he was employed in this labor, transcribing the psalm Benedictam Domino (the 33d in the Septuagint and the Vulgate, but the 34th in the authorized English version); after penning the words "Inquirentos autem Dominum non minuentur omni bono"—they who seek the Lord shall want no manner of thing that is good. "Here," he said, "I must stop; what follows let Baithen write," and laid down the pen. At the midnight hour he was in choir for the office of Compline, when, coming to the church unaided and knelt at the altar; through sleep he in a few moments passed to death. Three Latin hymns are attributed to him, and, in addition, some Celtic poems. The story of his life and miracles was told first by Cuimine Ailbe, who was also abbot at Iona (printed at London 1789 and at Paisley 1889). Based on this account Adamnan, the ninth abbot, wrote another, 'Vita Sancti Columbiae' (Dublin 1664; ed. by Reeves, Dublin 1857; J. T. Fowler, London 1894-95). Consult Troup, 'Saint Columbia; the Lord's Song in a Strange Land' (London 1913).

COLUMBA, or COLUMBA NOACHI, nó-Á'ki (Lat. "Noah's dove"), a small constellation of stars south of Lepus and Canis Major, about the time of whose discovery there are different statements. It is generally believed that it was first named by Royer in 1679 or 1680. This is easily disproved by the fact, seldom noted, that Bayer in his 'Uranometria,' published in 1603, on the 37th map, just below Canis Major, pictures the dove flying with the olive-branch in its mouth. Dr. Gould states that it was mentioned by Petrus Plancius, an eminent Dutch geographer and teacher of Petrus Theodori. The latter died in 1596. The constellation is known to-day by the name of Columbia, and is situated between Puppis, Pictor, Calum, Lepus and Canis Major.

COLUMBÆ, a sub-order of charadiiform birds containing the pigeons, fruit-eating pigeons, sand-grouse, etc. The typical family is Columbidae, or true pigeons and doves. See Pigeon.

COLUMBANUS, kól-úm-bá'nûs, missionary and foundress of a monastic order, that of the Columban monks, was born in Ireland about 543; died in his monastery of Bobbio, in the Apennines, Italy, 21 Nov. 615. The order founded by him was for a while hardly inferior to the order of Saint Benedict in number of monasteries or in the services it rendered to the Church. He was an alumnus of the great monastery of Benchor or Bangor, in Ulster, and thence in his 45th year he went to France as a missioner, accompanied by 12 young disciples. In France he founded the monasteries of Luxeuil, Arnoglay and Fontenay, giving to the monks a rule identical with that of the Celtic monasteries of Ireland. He gave offense to the French bishops by the fashion of his tonsure and by his observance of Easter in accordance with the calculation of the Eastern churches. And his apostolic zeal in rebuking the vices of the Burgundian court, the king (Thierry II) and the queen mother (Brunehaut) led to his expulsion from that country. He now decided to cross the Alps and labor as a missioner in Italy, with his route thither he tarried a while among the Swiss, preaching the gospel on the shore of Lake Constance. One of his 12 companions, named Gallus, falling sick, was left behind when the missionary party resumed their travel; this Gallus afterward laid the foundations in Switzerland of a monastic institute which later was called by his name, Saint Gall (Sankt Gallen) and which was one of the notable centres of monasticism in Europe. Columbanus, in 612, founded the first monastery of Bobbio in the Apennines, giving to the monks of that house, which soon was recognized as the mother-house of a multitude of abbeys and monasteries, a rule of great austerity. The keynote of it is implicit, unquestioning obedience in all things to the abbot or su-
perior. It prescribes perpetual silence save where speech is absolutely necessary. The use of animal food of all sorts is interdicted. The monks are allowed one meal daily, taken at eventide, and it consists of vegetables and bread. The monks of his monasteries, called Columbans, came under the Benedictine rule in the 8th century and the Columban order was merged in the Benedictine. Columbanus was a man of learning, acquainted not only with the Latin language current in his time, but with the classic Latin authors, as also with the Hebrew and Greek languages. He left a few writings, all in Latin; they have all been published more than once. They comprise his Monastic Rule (Regula Cenobialis); a few poems of considerable merit; 16 brief sermons and several letters of value for ecclesiastical history. A town in Lombardy, San Colombano, perpetuates the memory of this Celtic missionary to Italy.

COLUMBIA, the popular name of the United States; derived from Columbus and applied to the greatest nation of the New World from a feeling of poetic justice to the memory of its great discoverer.

COLUMBIA, British. See British Columbia.

COLUMBIA, District of. See District of Columbia.

COLUMBIA, Mo., county-seat of Boone County, situated 10 miles north of the Missouri River, on the Wabash and the Missouri, Kansas and Texas railroads. It was first settled in 1815 by Kentuckians and is governed by a mayor and a council of eight members, who are elected semi-annually. The city has four banks with a combined capital of $370,000. Columbia has many public and educational institutions, including Missouri University, Missouri State Farm and Experiment Station, Parker Memorial Hospital, Stephens Baptist College for Women, Christian College for Women, Columbia Normal Academy, Columbia Business College, University Military Academy and high school. Its industries include flour and planing mills, grain elevators, a packing plant and a shoe factory. Pop. 9,662.

COLUMBIA, Pa., borough, in Lancaster County, on the Susquehanna River and on the Pennsylvania and the Philadelphia and Reading railroads, about 26 miles southeast of Harrisburg and 80 miles from Philadelphia. The place, originally called Wright's Ferry, was founded in 1726 by Quakers from Chester County. Columbia was one of the places proposed, in 1789, for the capital of the United States. The bridge, which connected Columbia with Wrightsville, was burned in 1863, to prevent the Confederate forces from proceeding to Philadelphia. A fine bridge, one of the longest in the United States, has taken the place of the old one. Columbia is an industrial and trade centre of considerable importance. The chief manufactures are: machine and tool shop products, boilers and engines, flour, beer, wagons, glass, automobiles, shirts, silk, lace and lumber. The United States census of manufactures for 1914 showed 61 industrial establishments, employing 2,315 persons, of whom 2,140 were wage earners, receiving annually a total of $824,000 in wages. The capital invested aggregated $3,313,000, and the yearly output was valued at $3,341,000: of this, $1,486,000 was the value added by manufacture. It has three national banks, a high school, a state armory and the value of its taxable property is about $3,000,000. Pop. 11,454.

COLUMBIA, S. C., State capital, and county-seat of Richland County, situated in the centre of the State, on the east bank of the Congaree River, at the head of navigation, two miles below the junction of the Congaree and Saluda. It is on the Atlantic Coast Line, the Seaboard Air Line, the Southern and the Columbia, N. and L. railroads, 129 miles north-west of Charleston, 82 miles northeast of Augusta, Ga., and 153 miles north of Savannah.

Topography.—Columbia is one of the handsomest cities of its size in the country and in a district noted for sanatoria. It is built on a sand-hill plateau which forms a bluff 100 feet high at the river and sloping away on all sides, giving excellent drainage. The streets are 100 feet wide at right angles to each other, and there are four avenues 150 feet wide radiating from the capitol. All the chief streets are boulevards, with handsome shade-trees not only along the sides but in the centre. There is also a fine park.

Public Buildings.—The business buildings are rapidly increasing in size and architectural beauty. The granite State-house, costing $4,000,000 and modeled on the capitol at Washington, is one of the most imposing in the South and one of the handsomest in the country. Spacious grounds surround the capitol, and among the city's attractions are the monuments, which include a "Palmetto Tree" in bronze. The executive mansion, the government building, the county courthouse, the city hall, the State insane asylum and State penitentiary are also noteworthy. The city is rich for its size in important educational institutions: South Carolina College, now the University of South Carolina, founded 1801; the Presbyterian Theological Seminary, also very old; Lutheran Theological Seminary; Columbia Female College (Methodist Episcopal Church South), founded 1859; Allen University (African Methodist Episcopal Church), founded 1818; the College for Women (Presbyterian) 1890; and Benedict College (colored). It has also a well-attended public school system and two high schools.

Municipal Conditions.—The principal streets are asphalt; the roads are chiefly of sand and clay and are excellent. The city owns its waterworks and has gas, electric light and power and an electric railway system. Columbia was the first city in South Carolina, and one of the first in the Union, to adopt the commission plan of government.

Business Interests.—The city affords one of the most remarkable instances of manufacturing development in the country. It is in the heart of a fertile cotton district and near forests of pine, oak, walnut and maple; but its site is the key to an important future. A rocky shelf projecting for four miles from the junction of the Broad and Saluda forms the bed of the Congaree, 500 feet wide, which plunges down it in rapid, alternating immense falls which is made available by a canal 2½ miles
long, 110 feet wide at bottom and 150 at top, with 31 feet fall, furnishing 14,000 horse power, and steam dynamos which create electricity for manufacturing power, light and street railways. But the greatest establishments are independent of this except as a resource, using steam dynamos—for all Columbia’s industries are run by electricity. In 1892, there was one cotton mill factory employing 125 men. Now the great Whaley system of cotton mills includes four in Columbia, with 197,000 spindles, 4,840 looms and $1,100,000 invested capital. The Olympia mill, with 9 to 10 acres of floor space and over 100,000 spindles, is the largest in the world operating under one roof; the Granby and Richland are also large and well-equipped mills; and the three, owned by one company and employing almost 3,000 hands, are the nucleus of a large village of 500 acres owned by the company, with sewerage, fire department, electric street lighting, cottages wired and plumbed, churches, schools, etc. The Columbia Mills Company is also a great organization, capitalizing at $1,500,000, and turning out over 20,000 bales of cotton duck a year. Besides this predominant industry, there are growing hosiery works, glass works which utilize the fine sand found nearby, four quarries of fine granite, large lumber and smoke stack furnishing and small miscellaneous industries. The vast beds of kaolin in the vicinity now supply outside potters, but local works are contemplated. The United States census of manufactures for 1914 reported 71 industrial establishments of factory grade, employing 2,571 persons, of whom 2,228 are wage earners receiving $1,091,000 annually in wages. The capital invested aggregated $7,348,000 and the year’s output was valued at $6,765,000. Had this, $2,540,000 was the value added by manufacture. The rock ledge before mentioned extends two miles below the city with only four feet of water over it, dropping off to 10 feet or more at Granby. Deep water is now brought up to Columbia by a floating dam 15 feet high, costing $250,000, which enables vessels of 10 feet draft to come up to the city instead of unloading and trucking up from Granby as heretofore. Two steel steamers run from Columbia to Georgetown and will ultimately go to Charleston. This improvement makes Columbia the great distributing point for central and northern South Carolina.

History.—The town was settled about 1700, but remained farm land till 1786, when the people of the State demanded a capital more centrally located than Charleston, and Columbia village was laid out. The legislature first met there in 1790. In the Civil War it shared the general fortunes of the State, till Sherman’s army entered it 17 Feb. 1865. The following night a fire broke out which lasted all the next day and laid over half the city in ashes, including a number of business blocks, private residences, schools, the railroad station, several churches and a convent, and destroyed a great quantity of cotton. Its development since is part of the general industrial awakening of the South. Pop. (1860) 8,052; (1870) 9,298; (1880) 10,036; (1890) 15,353; (1900) 21,108; (1910) 26,319; (1914) 33,500, not including the mill villages, chiefly that of the W. Carolina dynamos, which contain just outside the old city limits though close by. Since that time several suburbs have been annexed, giving Columbia a population (1915) 56,992.

RAWLEY W. HOLCOMBE,
Secretary of Columbia Chamber of Commerce.

COLUMBIA, Tenn., county-seat of Maury County, situated on the Duck River and on the Louisville and N. and the Nashville, C. and Saint L. railroads. It is the trade centre of a fertile agricultural region, and has a stock yard, a grain elevator and cotton and flouring mills. It is the seat of Jackson College, two seminaries for young women and a military academy. It also has a United States arsenal. Pop. 5,754.

COLUMBIA, or OREGON, after the Yukon, the largest river on the western side of America. It rises in the Kootenay District of British Columbia, on the western slope of the Rocky Mountains, near mounts Brown and Hooker, in about lat. 50° N. Its course, which is very irregular, is generally southwest through British Columbia and Washington. It forms the northern boundary of Oregon for about 350 miles and enters the Pacific by an estuary 35 miles long and from 3 to 7 wide. Its estimated length is 1,400 miles, and the area drained by it and its tributaries, of which the largest are Clarke’s Fork (with the Missoula, 700 miles long), and the Snake River (940 miles in length) along which are very remarkable canyons, has been computed to be 229,000 square miles. The river is broken by falls and rapids into separate portions, and formerly a bar across its mouth obstructed navigation. The construction of a jetty two and one-half miles long has provided a good harbor, but the water level of the river has fallen and rapids have increased. Sea-going vessels ascend the Columbia for 100 miles to the Willamette from the junction with the latter to Portland (10 miles), while steamboats reached the Cascades (160 miles), where there was a portage of 6 miles which was bridged by a railroad; and beyond this another navigable stretch of 50 miles to the Dalles. In November 1896 the government completed a canal and locks at the Cascades, at an expense of nearly $4,000,000, and thus opened the Columbia to the Dalles, where a 14-mile railroad passes round the Great Dalles channel to the next section above (185 miles), beyond which there is a final part navigable for 250 miles by steamboats. The Columbia and its branches have 2,132 miles of navigable waters. The extraordinary abundance of salmon in the river has developed numerous fisheries which have been well exploited. Near the mouth are a number of canneries. Captain Gray of Boston entered the river in 1792, and Lewis and Clark explored it in 1805.

COLUMBIA CITY, Ind., county-seat of Whiteley County, in the northeastern part of the State, situated on Blue Creek and on the Wabash and on the Pittsburgh, Fort W. and Ch. railroads. It has lumber mills, sawmills, manufactures furniture, wagon, etc. Pop. 3,448.

COLUMBIA PLATEAU, a broad upland region lying in Washington, Oregon and Idaho. It averages about 3,500 feet in elevation, but is deeply trenched by Columbia and Snake River Canyons. The plateau is bounded between the Rocky Mountains and the Cascades, consists of broad level expanses of Tertiary
lava flows. The southern part is a desert. In the north, particularly in the Big Bend country, considerable wheat is raised. The mineral wealth is very limited.

**COLUMBIA RIVER HIGHWAY**

**COLUMBIA RIVER HIGHWAY**, a 60-mile scenic highway leading out of the city of Portland, Ore., to Hood River, and traversing the notably picturesque scenery along the Columbia River. The engineering work has been done with the most careful observance of artistic possibilities and effects, and the results are hailed as a model for similar enterprises. The roadway is 18 feet in width, of bitulithic pavement, and the steepest grade does not exceed 5 per cent. The highway joins the Lincoln Highway at Cheyenne and forms a link in the route through Yellowstone Park.

**COLUMBIA SALMON.** See QUINNAT.

**COLUMBIA UNIVERSITY**, a seat of learning in New York. The idea of establishing a college in New York was more than 50 years in contemplation before it was carried into effect. In 1746 provision was made by law for raising money by public lotteries. Five years later the proceeds of these lotteries amounted to about $1,700 and were given to trustees. The fact that two-thirds of these trustees were in communion with the Church of England and that some of them were vestrymen of Trinity Church excited opposition to the proposal as a scheme to strengthen the Established Church and delayed the procurement of a royal charter. Friends of the enterprise proceeded, however, with the arrangement for opening the college and elected for their first president the Rev. Dr. Samuel Johnson of Stratford, Conn., who assumed the office 17 July 1754, in the schoolhouse belonging to Trinity Church. There was a class of eight students.

The cosmopolitan character of the governing body of the college is due to its charter. To meet the objections that had been made, it was so drawn as to include in its boards of governors, besides other ex officio representatives, not only the rector of Trinity Church, but the senior minister of the Reformed Protestant Dutch, Ancient Lutheran, French and Presby- terian churches. This is due to this circumstance that Columbia almost alone of all the pre-Revolutionary colleges in the United States has never had a theological faculty connected with it. The trustees, at present, are members of the Episcopal Church, and also of the Reformed, Presbyterian and Roman Catholic churches, showing that this cosmopolitan character has never been lost. A prominent He- brew rabbi was at one time a member of its councils.

The charter of King's College, the original name of Columbia, was granted by George II, and finally passed the seals on 31 Oct. 1754, from which day the college dates its existence. It received from Trinity Church, according to a promise previously given, a portion of a grant of land known as "the King's Farm," upon the site of which its first building was erected. It was stipulated in the royal charter that its president should be a communicant of the Episcopal Church and that proper selections from the liturgy of that church should be used in the religious services of the college. This caused much angry controversy, and after the Revolution it was stricken out of the charter, but remains as the condition of the deed of gift from Trinity Church. The college played a conspicuous part in securing and confirming the independence of the United States. The Revolutionary War caused a suspension of the activities of the college, and in 1776 the college building was used as a military hospital. After eight years the college was reestablished by act of the legislature, 1 May 1784, under the name of Columbia College. On 13 April 1787 the legislature revived the original charter with amendments, which abolished ex officio membership of its governing body, canceled the requirement that the president should hold a certain form of religious belief or that a certain form of prayer should be used in the services of the college, and named a body of 29 trustees, which, when reduced to 24 members, was made a self-perpetuating body, under which government the college has remained. The medical faculty was organized in 1792 and a professorship of law was established in 1793.

The original site of the college was in what became later the block bounded by College Place, Barclay, Church and Murray streets. In 1857 the college was moved to 49th and 50th streets and Madison avenue, where it remained until 1897. In 1892, for $2,000,000, purchase was made of 17½ acres of land lying between 110th and 120th streets, Amsterdam avenue and the boulevard. Here in 1897 the college was reorganized on the basis of a university. Columbia University, in a technical sense, consists of the faculty of law, the first professor of which (1792), James Kent, during the period of his second appointment in 1823 delivered the courses of lectures which developed into the first two volumes of his famous "Commentaries"; the faculties of medicine; philosophy, political science; pure science and applied science. The College of Physicians and Surgeons, the outcome of the medical faculty, established in King's College in 1798, in June 1860 became the Medical College of Columbia. In 1891 it surrendered its separate charter and became an integral part of Columbia College. A peculiarity of the Columbia organization is the system by which seniors in Columbia College have entered the college not later than the beginning of the junior year, are allowed to select part or all of the courses necessary for the bachelor's degree from among those designated by the university faculties, professional or non-professional, as open to them. The object of this arrangement is to shorten the time necessary to the attainment of the higher, particularly of the professional, degrees. The degree of master of arts is conferred for advanced work in law done under the faculties of law and political science together. The faculties of law, medicine and applied science conduct respectively the schools of law, medicine and mines, chemistry, engineering and architecture, to which students are admitted on a professional degree on terms prescribed by the faculties concerned. The school of mines was due to the exertions of Thomas Egleston, who was made professor of mineralogy and metallurgy in 1864, and who opened the school of mines the same year in the basement of the old college building in 49th street. There is also the school of chemistry, engineering and architec-
ture, set off from the school of mines in 1896. Out of the school of mines grew the school of pure science, established in 1892. In 1912 a school of journalism was established and in 1916 a school of business. Under President Barnard’s influence, the trustees in 1889, the trustees gave their official approval to the plan for founding Barnard College for women studying for Columbia degrees. It is financially a separate corporation, but educationally it is part of the system of Columbia. Teachers’ College, a professional school for teachers, is also financially a separate corporation and educationally a part of the university. It was founded in 1888, chartered in 1889 and included in the university in 1892. (See Colleges for Teachers). Some of these courses are accepted by Columbia University, and may be taken without extra charge, by students of the university in partial fulfilment of the requirements for the degrees of Bachelor of Arts, Master of Arts and Doctor of Philosophy. In 1914-15 the university had a total of 11,876 resident students in all departments, 3,305 extension students and 1,833 special students in Teachers’ College, and its library comprised 550,000 books and periodicals. The library building is a gift from ex-President Low, and cost over $1,000,000.

The Presidents of the University have been: Samuel Johnson (1754–63); Myles Cooper (1763–75); the Rev. Benjamin Moore (1775–76); William S. Johnson (1787–1800); Charles H. Wharton (1801); the Rt. Rev. Benjamin M. Moore (1801–11); William Harris (1811–29); William A. Duer (1829–42); Nathaniel Moore (1842–49); Charles King (1849–64); Frederick A. P. Barnard (1864–89); Henry Driscoll, acting (1889–90); Seth Low (1890–1901); and Nicholas Murray Butler (inaugurated 1902).

COLUMBIA UNIVERSITY SCHOOL OF MINES. See Columbia University.

COLUMBIA COLLEGE. See George Washington University, New York.

COLUMBIA FORMATION, a series of gravels, sands and clays of Pleistocene Age covering the coastal plain of the Atlantic slope from New Jersey southward and typically developed in the District of Columbia. The formation in the north covers the plain up to elevations of 400 feet, and in the south up to 100 feet. It includes marls, marly sandstones, and delta deposits, and the fossils are recent marine and terrestrial species, indicating a very slight submergence and re-elevation of the coast. The formation may correspond to the Champlain stage of the glaciated portion of the continent. See CHAMPLAIN STAGE: GLACIAL PERIOD.

COLUMBIAN UNIVERSITY. See George Washington University, New York.

COLUMBIAN WORLD’S FAIR. See World’s Columbian Exposition.

COLUMBIÆ, kò-lüm’bi-dè, the family of true pigeons, the typical one of the order Columbæ, of which it embraces the bulk of the known species, more than 300 belonging to this family of true pigeons and doves. Over half of them are found in the Malay and Austro-Malayan Archipelago, and 75 in South and Central America, while all other parts of the world, except the polar regions, have their representative species in smaller numbers. Although our native species give but a faint idea of the richness of color and other peculiarities of adornment of the tropical pigeons, the structural features are remarkably constant and well exemplified in the domestic pigeon and its domesticated and interbred varieties. The wings are rather long and exceptionally powerful; the plumage generally compact and the feathers without after shafts. One of the most variable features is the tail, which may be short and square or long and pointed, and its rectrices from 12 to 16. Although classed by Cuvier with the gallinaceous birds, the Columbës differ from them in structure and especially in habits, being monogamous and good flyers. Besides they are unlike the domestic fowl which is the type of the Gallinæa in that the males assist in nest-building and the incubation and the young are not able to walk, and are nourished by the parent birds, which secrete in the double crop a milky fluid utilized to soften their food. Moreover the Columbës drink at a single draught. They feed on seeds, but also on fruit and more rarely on insects. See Doves; Pigions; etc.

COLUMBINE, a popular name for Aquilegia vulgaris or other species of the genus Aquilegia. The common columbine has dropping purplish-blue flowers with five flat sepals; five petals, with long often curved; five follicles; the root-leaves twice or thrice terete, the others once terete. Numerous species of the genus occur in North America. A. caerulea, the Rocky Mountain columbine, with very large, sky-blue flowers, the showiest plant of the genus, is the State flower of Colorado.

COLUMBITE, a mineral of variable composition, consisting of a compound niobate (columbate) and tantalate of iron and manganese. When niobium is present in large amount relatively to the tantalum, the mineral is called "columbite" and when the reverse is the case, it is called "tantalite"; the two minerals passing into each other, in nature, by insensible gradations. Typical columbite has a hardness of 6, 7, and a specific gravity of 5.2, the specific gravity increasing with the proportion of tantalum present. The crystals are short and prismatic, often tabular and belong to the orthorhombic system. The mineral is black or brownish-black in color and is often iridescent. In the United States columbite is known to occur in most of the States lying near the Appalachian Mountain system and also in Colorado, South Dakota and California. One crystalline mass of it, found in the Black Hills region, is said to have weighed about a ton. The existence of columbite in the United States was first made known through a specimen sent by Governor Winthrop of Connecticut to Sir Hans Sloane, president of the Royal Society of Great Britain.

COLUMBIUM, a metallic element, better known as niobium. It was discovered by Hatchett in 1801 and named columbium and rediscovered by H. Ross in 1846 who named it niobium. It is found in small quantities in various minerals; but principally in columbite and tantalite. Columbium has been found in various parts of the United States, Sweden,
Mexico and other Central and South American countries. It is a very hard metal, especially when combined with carbon, its normal condition. It was called niobium on account of its resemblance to niobium, which grows in great profusion in the island of Mozambique. It is also called columba. The root, sliced transversely into discs, is dried and used in medicine in the form of an infusion as an appetizer and tonic. It contains a bitter alkaloid, berberine, and another bitter principle, columbin. It is free from tannic acid, so, unlike most bitters, it may be mixed with the preparations of iron. It was formerly employed for diarrhoea, dysentery and gas in the bowels, being carried to India, whence it is exported.

COLUMBUS, Bartholomew (Sp. Bartolomeo Colón; It. Bartolommeo Colombo, his real name), Italian navigator, the discoverer of America: b. Genoa before 1455; d. San Domingo, 12 Aug. 1514. The events of his early years are not on record. In 1470 we find him established at Lisbon as a mariner and constructor of maps— one of those adventurous navigators whom the patronage of the Portuguese princes had drawn to their capital. About 1486 he visited the Cape of Good Hope, probably with Barthelemi Diaz. His brother sent him to England to seek the aid of Henry VII in 1486, but it appears certain that Christopher was ignorant of his fate, further than that he was captured by pirates. He did, however, attain the ear of the English monarch and presented him with a map of the world, but it does not appear that he succeeded in securing English aid. On his return to France, where he became cartographer to Anne de Bourbon (de Beaujeu), he learned that his brother had already discovered the new world and had sailed on a second voyage (1493). Hastening to the Spanish court, he was received as captain of the admiral. Queen Isabella sent him in command of three store ships to the new colony of Hispaniola (1494) where Christopher received him with joy and appointed him adelantado or lieutenant-governor of the Indies. In this position Bartolommeo showed great bravery and decision. He shared his brother's imprisonment, and with him was liberated on reaching Spain, where the Spanish monarchs confirmed his title and gave him the lordship of the small island of Mona near San Domingo, with 200 Indians as his personal body-guard. The fierce energy of his character, however, made them jealous of giving him too much latitude in public affairs.

COLUMBUS, Christopher (Sp. Cristóbal Colón; It. Cristoforo Colombo, his real name), Italian navigator, the discoverer of America: b. Genoa, 15 Oct. 1451; d. Españoles, 20 May 1506. His father, Domenico Colombo, a poor weaver, gave him a careful education in that trade—better characterized as an industrial art or handicraft, highly regarded in Italy during the 15th century, and indeed with good reason esteemed long before and long after the very noble Quattrocento. (See Professor Venturi's account of the Quattrocento or 14th century, in the article ITALY—Historical Synopsis of Italian Art.) The tails of his early life are confused and unsatisfactory. The date of his birth has never been definitely established; different historians range between 1430 and 1456, those most often given being 1435 and 1446. Judging from the ages of his younger brother (b. 1438), and his younger sister, the year 1451 given above seems the most likely estimate. He is shown by documents cited by Henry Vignaud to have sailed to Chios when about 23 or 24 years of age. Again, in 1476, he sailed for England, and about one year later engaged in commerce at Lisbon. There he married Felipa Moniz Perestrello, a daughter of a distinguished navigator who had founded a colony in Porto Santo, an island recently belonging to the Madeira group, and had left many charts and nautical instruments. Columbus made use of these materials, and his opinion that the other side of the globe contained land, belonging to eastern Asia and connected with India, was, at first, largely ignored, but as he became more and more fixed. While the Portuguese were seeking to reach India by a southeast course round Africa, he was convinced that there must be a shorter way by the west. He applied in vain to Genoa for assistance, and equally fruitless were his endeavors to interest John II of Portugal in the enterprise. He also sent letters on the subject to Henry VII of England, with the same ill success. He then determined to apply to the Spanish court, Ferdinand and Isabella being at this time the sovereigns of Spain, and after an eight years' struggle with the obstacles thrown in his way by ignorance and malice, he received three small vessels. These were named the Pinta, the Niña and the Santa Maria; and the documents show the complement of men to have been, for the crews 90, officers and all others, 30, total 120. The Capitulations of Granada provided that, after successful accomplishment and conclusion of the aforesaid enterprise—its leader should be advanced to the dignities and offices of peer, admiral and viceroy of such regions as he should or might discover and take possession of—"certain islands in the sea of whose existence Columbus knew." No reference to the Indies appears in records of the negotiations for this great voyage.

It was early in the morning of Friday, on 3 Aug. 1492, that Columbus set sail from the port of Palos. Eighteen years had elapsed since he had first conceived the idea of this enterprise. The most of that time had been passed in almost hopeless solicitation, amidst poverty, neglect and ridicule; the prime of his life wasted in the struggle. Nor should it be forgotten that it was to Isabella alone that he was finally indebted for the means of executing his project, which had been coldly rejected by the prudent Ferdinand. Having provided himself at the Canary Islands with fresh water, he sailed at first due South off the Spanish coast, and then turned into an ocean never before navigated. But when 21 days had elapsed without the sight of any land, the courage of his men began to sink. It was certain, they said, that they should perish, and their visionary commander ought to
be forced to return. Some of them even proposed to throw him overboard; and Columbus had to exert all the powers of his daring and commanding spirit to quell the mutiny. It seems clear that this crisis in the ship was due partly to Pinzón’s able and loyal assistance. A phenomenon, which surprised even him, filled his pilots with consternation: the needle deviated a whole degree. But the sea appeared suddenly covered with grass, and again showed signs of shoals in the neighborhood of the island. The birds were also seen. Columbus sailed in the direction from which they flew. For some days the voyage was continued with revived courage, until at last the dissatisfaction of the crews began again to break out into open violence; but Columbus, after endeavoring in vain to pacify his men by promises, finally assumed a different tone, and told them it was useless to murmur; that he was determined to persevere. Fully convinced that he must be near the land, he promised a reward to the man who should first catch sight of it. On the night of 11 and 12 October Columbus himself descried a light which sometimes flickered in the distance and sometimes disappeared. At two o’clock in the morning of the 12th a cannon shot from the Pinta announced that a sailor belonging to that vessel had sighted land. That sailor was Rodrigo de Triana.

It was the island of Guanahani, which Columbus believed to belong to eastern Asia, the Indies or India, a belief which he carried with him to his grave. Hence the mistaken names of Indians applied to the natives of America, and that of West Indies applied to the group of islands of which Guanahani forms one. On landing Columbus threw himself upon his knees and kissed the earth, returning thanks to God. The natives collected round him in silent astonishment, and his men, ashamed of their disobedience and distrust, threw themselves at his feet, begging his forgiveness. Columbus, drawing his sword, planted the royal standard, and in the name of his sovereigns took possession of the country, which, in memory of his preservation, he called San Salvador. He then received the homage of his followers, as admiral and viceroy, and representative of the sovereigns. Being informed by the natives that there was a rich gold country toward the south, Columbus directed his course toward that region, and reached Cuba on 26 October, and Española (Hisp aniola, Haiti), on 6 December; but as one of his vessels was wrecked and the other separated from him, he resolved to carry the news of his success to Spain. Having built a wooden fort from the wreck of his vessel, he left in it 39 volunteers, and set out on his return, 4 Jan. 1493. The day after he left the island he met the Pinta, which had been missing. Both vessels were afterward nearly wrecked in a terrible storm. Columbus, more interested for his discovery than for himself, wrote an account of his voyage on a piece of parchment, which he secured in a case, and threw the whole overboard, in the hope that it might be carried ashore. He had hardly finished his work when the vessel had been removed from Isabella, according to his orders, to the other side of the island, and a new fortress erected called San Domingo. Columbus found the colony in a state of confusion. After having restored tranquillity by his prudent words, he ordered the deficiency of laborers he distributed the land and the inhabitants, subjecting the latter to the arbitrary will of their masters, and thus laying the foundation of that system of slavery which has lasted down to our time. His enemies, in
the meantime, endeavored to convince his sov-
ereigns that he had abused his power, and that his
safety was not the government independent, till
at last even Isabella yielded to the wishes of
Ferdinand, who had previously become con-
vinced of the truth of the slanders. Francisco
de Bobadilla was sent to Hispaniola with exten-
sive powers to alter the government. As soon as
he reached the island he summoned Columbus to
appear before him and put him in irons. His brothers were treated in the same
manner. All three were sent to Spain, accom-
panied by a number of wranglers, drawn up
from the statements of the bitterest enemies
of Columbus. Columbus endured this outrage
with noble equanimity, and wrote, as soon as he
had arrived in Cadiz, 25 Nov. 1500, to a lady of
the court vindicating his conduct, and de-
scribing in eloquent and touching language the
way he had received the fetters with which he
had been bound, and where he was kept in jail
till his death, and his son Hernando states that he
even ordered that they should be enclosed with
him in conflagration, as a way of setting
himself free. But when he found himself no
longer a prisoner, he showed himself in public,
and was reinstated in his dignities. Ferdinand even consented to
the removal of Bobadilla, which was intended for the
first step toward the promised restoration of the
great discoverer to his dignities. But these dis-
positions in the monarchs were very soon changed.

There was much talk of great expeditions, and
in the meantime Nicolas de Ovando y Larens was
sent as governor to Hispaniola. Columbus still
urged the fulfilment of the promises solemnly
made to him; but after two years of delay he
became convinced that there was no intention
to do him justice.

But he had now learned to suffer, and he
was principally desirous of completing his work.

Supposing the continent which he had seen to
be Asia, he did not doubt that he should find,
through the Isthmus of Darien, a way to the
Spanish possessions, which the Portuguese had recently reached. In four slender vessels supplied by the crown for
this purpose Columbus sailed from Cadiz on
his fourth and last voyage, 9 May 1502, with his
brother Bartolommeo and his son Hernando:

He arrived in the harbor of Jamaica, where he
was scarcely able to save himself and his companions. Here the severest
trials awaited the constancy of Columbus. Sep-
Arat from the other part of the world, his
destruction seemed to be certain. But he suc-
ceeded in procuring a few canoes from the
natives, and prevailed on some of his boldest
and best men to attempt a voyage to Hispaniola,
in two canoes, in order to inform the natives of his situation. Several months elapsed with-
out a glimpse of hope. Part of his companions,
reduced to despair, rebelled, repeatedly threat-
ened his life, separated from him and settled
on another part of the island. Here they alien-
ated the minds of the natives by such cruel
 treatment, that the latter ceased to bring them
supplies. The death of all seemed inevitable;
but Columbus, whose courage rose with the
danger, preserved his head. He had ascertained that a total eclipse of
the moon was about to take place, and threatened
the natives with the vengeance of his God if they
should persist in their enmity. As a proof of
his assertion the moon, he said, would lose
its light, in token of the chastisement which
awaited them. When they beheld his threats
come true, they hastened to bring him provisions,
and implore his intercession with the Deity.

But hostilities now broke out between him and
the rebels, in which many of his companions
were killed, and their leader was taken prisoner.

After remaining a year on the island, relief at
last appeared. The two canoes had reached
Hispaniola in safety, but the messengers could
not prevail on the governor to undertake the
deliverance of the admiral. They finally bought
a vessel themselves, and it was on board this
ship that Columbus left Jamaica, 28 June 1504.

He went to San Domingo, but only to repair
his vessel, and then hastened back to Spain.

He arrived in Spain ill and exhausted. The
death of the queen soon followed, and he urged
in vain on Ferdinand the fulfilment of his con-
tract. After two years of illness, humiliations
and despondency, Columbus died at Valladolid.

His remains were transported, according to his
will, to the city of San Domingo, but the
cession of Hispaniola to the French they were
removed in January 1796, with great pomp, to
the cathedral of Havana in Cuba. A splendid
monument was erected to him, in a convent at
Seville, where his body lay before being trans-
ferred to San Domingo. In 1898 his remains
were again removed to Spain, Cuba being no
longer a Spanish possession since the war with
the United States.

In the vigor of manhood Columbus was, ac-

According to tradition, of an engaging presence,
tall, well formed and muscular, and of an ele-
vated and dignified demeanor. His visage (here also we can be guided only by tradition
and relatively late portraits, inasmuch as an
authentic contemporary portrait probably
does not exist) was long, his nose aquiline,
his eyes light gray and apt to kindle. His
whole countenance had an air of authority.

Care and trouble had turned his hair white at
30 years of age. He was moderate and simple
in diet and apparel, eloquent in discourse, en-
gaging and affable with strangers, and of great amiability and suavity in domestic life. His
temper was naturally irritable, but he subdued
it by the benevolence and generosity of his
heart. Throughout all he maintained a strict attention to the offices of religion; nor
did his piety consist in mere forms, but par-
took of that lofty and solemn enthusiasm with
which his whole character was strongly tinct-
ured. Of a great and inventive genius, a
lofty and noble ambition, his conduct was char-
COLUMBUS

connected with the grandeur of his views and the
magnitude of his spirit.

COLUMBUS, Diego, or Giacomo (It. Giacomo Colombo), Italian voyager: b. Genoa about 1446; d. at Seville, 21 Feb. 1515. He was a brother of Christopher Columbus, whom he accompanied on the second voyage to America in 1493. He was sometimes left in command at the settlements of Isabella and San Domingo and returning to Spain in 1500, subsequently entered the priesthood.

COLUMBUS, Diego (Sp. Colón, kó-lón'): b. probably of Lisha, about 1475; d. Madrid, Spain near Toledo, Spain, 21 Feb. 1526. He was a son of Christopher Columbus (q.v.) and from 1492 to 1504 was a page at the Spanish court. In 1508 he married into the famous and influence he was confirmed admiral of the Indies and governor of Hispaniola in 1509, where he ruled with great pomp and splendour. Through- out his life he continued his claim to the office of viceroy of the Indies which had been conferred upon his father; and this kept him in a constant legal battle in which his opponents generally went to the wall; but at last, in 1520, when he finally won the contest; on his death, to hold his hard-won prize until 1523, when he was summoned back to Spain, where he died three years later.

COLUMBUS, Ferdinand (Sp. Ferdinando Colón, férdin-and o-lón'), Spanish navigator: b. Cordova, Spain, 15 Aug. 1488; d. Seville, 12 July 1539. He was a son of Christopher Columbus, whom he accompanied on his fourth voyage 1502-04. His library of 20,000 books was bequeathed to the cathedral chapter of Seville and was afterwards the basis of the majority of the 'Lives' of Columbus. COLUMBUS, Luis, loo-es' (Sp. Colón), Spanish noble: b. San Domingo 1521 or 1522; d. Oran, Africa, 3 Feb. 1572. He was a son of Diego Columbus 2d (q.v.), and a grandson of Christopher Columbus. He was given the title of admiral of the Indies, but in 1530 was obliged to relinquish the title of viceroy, receiving in exchange the island of Jamaica, an estate 25 leagues square in Veragua, a pension of 10,000 ducats and the titles of Duke of Veragua and Marquis of Jamaica. He was captain general of Hispaniola 1542-51. Arrested in 1559 for having three wives, he was imprisoned for three years and then banished to Africa. Felipa, his daughter, married her cousin, Diego, who then became Duke of Veragua, but dying childless in 1518 the family of Columbus then became extinct in the male line. The present Duke of Veragua (b. 1857) traces his descent from Columbus through Diego, Cristoval, Diego's son, and Francesca, the daughter of Cristoval and sister of Diego Columbus, who died in 1578.

COLUMBUS, Ga., city and county-seat of Muscogee County, 95 miles southwest of Atlanta, on the Chattahoochee River and on the Seiboard Air Line, the Southern and the Central of Georgia railroads. It is at the head of navigation on the river and steamboat service is maintained with Apalachicola, Fla. Columbus is the centre of a rural territory which is a large producer of beef and dairy cattle, live stock and hogs, peanuts, corn, oats, wheat, etc. The city's manufacturing industries have earned for it the title of the "Lowell of the South" and are operated mostly by hydro-electric power, of which the river at this point is capable of furnishing about 60,000 horse-power, 20,000 of which has been developed. The city has cotton and hosiery mills, lumber and building material plants, agricultural implement plants, iron and steel mills, bottling plants, fertilizer factories, flour and grist mills, cotton-seed oil mills, peanut factories, showcase and fixture manufactories, brick and sewer-pipe works, and barrel factories. About $20,000,000 is invested in the city's industries and the value of the output is approximately $16,000,000 annually. The city
COLUMBUS contains an industrial school, three national banks, two exclusive savings banks and fine State banking institutions, and in addition the usual quota of churches, clubs, libraries, etc. The waterworks are controlled by the city. Columbus was settled in 1826 and incorporated the year following. In the Civil War the city was Union grain suppliers, not of the Confederates and a vast quantity of supplies for the Southern armies was manufactured here. On 16 April 1865, the city fell into the hands of the Federals. Pop. (1910) 20,554; (1917) about 25,000.

COLUMBUS, Ind., county-seat of Bartholomew County, in the southern central part of the State, situated on a fork of the White River and on the Cleveland, C., Ch. & Saint Louis and the Pittsburgh, C., Ch. & Saint Louis railroads. It has large manufactories of cerea-line, agricultural implements and furniture, starch, and flour mills and gasoline engines. Pop. 8,419.

COLUMBUS, Kans., city and county-seat of Chautauqua County, 55 miles south of Fort Scott, on the Missouri, Kansas and Texas, the Saint Louis and San Francisco and the Joplin and Pittsburgh railroads. The region is rich in coal, lead, zinc and farm products, in all of which the city has large interests. It contains flour mills, grain elevators, a cigar factory, bottle works, canning factory, machine shops and large brickyards. Natural gas also is found in the district. The city has a high school, a public library and owns the waterworks. Pop. 3,064.

COLUMBUS, Miss., county-seat of Lowndes County, situated on the Tombigbee River, 150 miles southeast of Memphis and the same distance northeast of Jackson. It is the farming trade centre of the country, and has a large cottonmill, machine shops and lumber mills. The United States census of manufactures for 1914 reported 27 industrial establishments of factory grade, employing 636 persons; of whom 21 were wage earners. The capital invested aggregated $984,000, and the year’s output was valued at $1,240,000. Of this, $502,000 was the value added by manufacture. It is the seat of the State Industrial Institute and College for girls and of Franklin Academy. The value of its taxable property is about $7,800,000. Pop. 10,053.

COLUMBUS, Neb., county-seat of Plattsmouth County, in the eastern part of the State, situated on the Loup River, near the Platte and on the Union Pacific and the Burlington & M. railroads. It is the seat of a Roman Catholic academy and has flour mills, a brewery, a wooden-shoe factory and a roller mill. In the vicinity are some Indian mounds of scientific interest. Pop. 5014.

COLUMBUS, Ohio, the capital of the State and the county-seat of Franklin County, is located on a plateau about 800 feet above sea-level, in the geographical centre of the State, and practically in the centre of the area of the population of the United States, in lat. 39° 57' 41" N. and long. 82° 59' 46" W. It is 120 miles northeast of Cincinnati and 135 miles southwest of Cleveland, at the junction of the Scioto and the Olentangy rivers. Eighteen steam railroads, including the C. H. V. & T. and the P. C. & Saint L., radiate from Columbus to all parts of the State, intersecting all lines running East, West, Northeast, Northwest and South, and there are besides eight electric interurban traction lines in the city. Pop. 47,842.

Area, Parks, Streets and Squares.—The area of the present city is 22.362 square miles. It is laid out on the same scale and plan as Washington, and in general outline resembles a Maltese cross. It has an area of 280 acres in public parks, 100 acres in other parks and 952 acres in public grounds, and the fine system of parks and boulevards is being steadily enlarged. The Ohio State fair grounds of over 100 acres are just outside the city limits. There are 252 miles of paved streets, about 65 miles of which are asphalt, within the city confines, the main thoroughfares lighted by a system of electric cluster standards. The longest streets are High street and Broad street, which run north and south and east and west respectively. The uniform width of the former is 100 feet, its length about eight miles; the breadth of the latter is 120 feet; its length 7.13 miles. Broad street is planted with four rows of shade trees for its entire length east of the Capitol Square, where it penetrates the fashionable residence district. Here are many beautiful homes and fine mansions. High street is the leading business thoroughfare, and on this and on the other business streets are situated the state, brick and stone office buildings from 8 to 16 stories high. Capitol Square, a miniature park of 10 acres, is situated at the intersection of High and Broad streets, two squares east of the Scioto River. At the main entrance is the McKinley Memorial (modeled by H. A. McNeill), and northwest of the Capitol buildings is a group of statues of famous men known as "Ohio's Jewels.

Public Buildings.—The first State House was of brick and cost $85,000; the present massive buildings and additions are of dressed native gray limestone, in the Doric style of architecture. They cover nearly three acres and their total cost has been $2,500,000. Among other public buildings of importance are: Federal Building, Memorial Hall and Auditorium, the Athenaeum, city hall, post-office, chamber of commerce, union station, Y. M. C. A. building, the opera house, athletic club and Elks club. There are 59 hotels, including the new Deshler Hotel erected at a cost of $2,000,000, six theatres and five auditoriums with a combined seating capacity of 40,000.

Public Institutions.—Columbus is the location of the State Hospital for the Insane, of State institutions for deaf-mutes, blind and imbecile youth, and has 12 general hospitals besides a number of private sanatoria. The Ohio State Penitentiary, in which Morgan and his raiders were imprisoned during the Civil War, is one of the oldest and largest in the country. A United States pension office and the Columbus barracks, the largest interior military recruiting station in the United States, are also situated at Columbus.

Schools and Colleges.—There are 59 public school buildings in the city, six being devoted to high school purposes, with an average attendance of 29,000, the high schools having
2,300. The churches number 175, with an active church membership of about 75,000.

Educational Institutions.—Chief among the institutions for higher education is the Ohio State University, with a campus of 440 acres, 38 buildings valued at $6,500,000, and a student body of nearly 7,000. There are, besides, the Capital City University, the Josephinum College and Saint Mary of the Springs (both Catholic), and a number of other religious and private educational institutions. The professional schools include one dental and two medical colleges, a law school, a school of oratory and music, school of art and the Bliss Business College. The city has also seven public libraries with over 3,000,000 volumes.

Trade and Industry.—Prominent business interests of the city are represented by 7 national and 20 private banks, trust companies, savings and building and loan associations, with clearings amounting in 1917 to $525,641,400. Besides its other important commercial and manufacturing interests, Columbus is a great distributing centre for hot-house fruits, vegetables, lumber, coal, iron and steel. It has 90 manufactories (including those just outside the city limits), with an approximate annual product of $95,000,000. Seven of these are the largest industrial concerns of their kind in the world, and produce mine and mill machinery, electrical machinery, trucks, wheelbarrows, shoes, butterine, regalias, uniforms, dental supplies, drugs and patent medicines, agricultural implements and vehicles. There are also steel plants, blast-furnaces, malleable iron works and manufactories of steel, iron and wood products, beer and liquors, cash registers, watches, furniture, agricultural implements, mine, mill and farm supplies, cloth fabrics, gloves, hosiery, clothing, automobiles, novelties, specialties and general merchandise. The United States census of manufactures for 1914 reported 643 industrial establishments of factory grade within the city limits, employing 21,323 persons; of whom 17,236 were wage earners receiving a total of $11,177,000 annually in wages. The capital invested aggregated $52,988,000, and the plant valued at $37,698,000: of this, $26,972,000 was the value added by manufacture.

Finances.—In 1917 the assessed property valuation was $305,423,900; the revenue from taxation for the city was $2,001,635; for schools, $1,878,623.

Newspapers, etc.—The newspapers and periodicals include four English and one German daily papers, and about 20 papers and periodicals devoted to special interests.

Sewerage, Waterworks, etc.—The city has over 358 miles of sewers and owns a sewage disposal plant costing $1,200,000, and a garbage disposal plant costing $500,000. There is a model waterworks system, costing $1,500,000, which includes a storage dam establishing a reservoir 15 miles in length, and a purification and softening plant. The electric light plants are also owned by the municipality. Natural gas is the principal fuel for domestic use, and bituminous coal is found in unlimited quantities a few miles south of Columbus.

Government.—Under a new charter submitted in May 1914, and which became effective 1 Jan. 1916, the government of the city is vested in a mayor and council of seven members, elected at large every four years. It is a modified federal form and contains several progressive features, such as non-partisan ballot, preferential voting, referendum and recall.

History.—Columbus was made the capital by the legislature in 1812 and became the permanent capital in 1815, the original Territorial and State capital having been Chillicothe. In the same year it was incorporated as a village, and was chartered as a city in 1834.

Population.—Three-fourths of the population are native born. The largest foreign elements are German, Irish, Welsh, English and Italian. Since 1880, when it had 32,194 inhabitants, Columbus has grown rapidly. In 1910 it had a population of 125,650; in 1910, 181,511; in 1916, it was estimated at 211,021, inside the city limits. Metropolitan Columbus, including contiguous suburbs, in 1917 had over 260,000 inhabitants.

C. E. Dittmer,
Editor of City Bulletin.

COLUMBUS, Tex., county-seat of Colorado County, situated on the Colorado River and on the Southern P. Railway. Its chief industry is its cotton trade. It is the seat of Colorado College. Pop. about 1,800.

COLUMBUS, Wis., city of Columbia County, 65 miles southeast of Milwaukee, on the Little Crawfish River, and on the Chicago, Milwaukee and St. Paul Railroad. It contains a public library, Saint Mary's Hospital and a county normal school. It has a flour mill, canning factories, carriage and wagon works and has a good trade in agricultural products and live stock. Pop. 2,660.

COLUMBUS, Knights of. See Knights of Columbus.

COLUMBUS BARRACKS. See Columbus, Ohio.

COLUMELLA, Lucius Junius Moderatus, Roman practical writer on agriculture: b. Cadiz, Spain. He flourished about the middle of the 1st century, and wrote 12 books on gardening ('De Re Rustica'), one of which was a metrical combination of the Georgics of Virgil. He treats in this work of all the branches of agriculture. The earlier editions of this work contain also his treatise 'De Arboribus,' in one book. According to Pliny, Columella wrote a work on ancient sacrifices for obtaining the fruits of the earth, but this is lost. The editio princeps, printed in folio by Jenson at Venice, in 1472, and forming part of a collection of 'Rei Rusticae Scriptores varii,' is very rare. The most complete edition is contained in the 'Scriptores Rei Rusticae' of Schneider (1794-97). Consult Barbare, 'De Columellae Vita et Scriptis' (Nancy 1888); Becher, 'De Columellae Vita et Scriptis' (Leipzig 1897).

COLUMN (Latin, column), in architecture, a supporting pillar, usually round. In the earliest times the column was merely a tree-trunk, or its imitation in stone, used to support the roof. The original sense of the word is something that is high or rises in height. The root of the word survives in "Colonel" and the French "colonne," hill. The gods of nature were originally worshiped in places they were supposed to haunt, in the woods. The first temples were rude shelters in which the trunks of the trees of the forest, the "high things," were imitated. Hence, the first columns
were of wood, being merely trunks of trees, and nearly all the existing primitive columns are round. The parts of a complete column are its base, on which it rests; its body, called the shaft; and its head, called the capital. Columns are used to support the entablature of an order, which has also its peculiar division. In ancient Egypt, where timber fit for construction is scarce and stone abundant, the latter became the principal material for columns, and those of Egypt are remarkable for the beauty of their workmanship and the durability of their materials. The Egyptian columns were numerous, close, short and very large. They were generally without bases, and had a great variety of capitals, from a simple square block ornamented with hieroglyphics, or faces, to an elaborate composition of palm leaves, not unlike the Corinthian capital. The Greeks, for their columns, used marble of the finest kind, with which their country abounded; and other nations the stone or material of their country. The Greeks considered the column as the soul of the temple, and never used it as a mere decoration. In fact the primitive Greek temples were little else than roofed columns, thus showing clearly their origin.

The manner of constructing the columns of all the orders rests on similar principles. They are all divided into three primary parts or divisions, the base, the shaft and the capital, except the Doric order, which has no base. The lowest or thick part of the shaft is used by architects as the universal scale or standard whence all the measures which regulate and determine heights and projections are taken; and this standard or scale must be understood before any architectural design can be commenced. The universal architectural scale is called a diameter, and is the diameter of the lowest or the largest part of the column; and, unlike the foot, inch or yard, is as various as the size of columns. By the diameter, of course, is meant that of the column at the bottom of the column. Half of this diameter, or the length of the radius which forms the circle, is called a module, and is used as well as the diameter as a primary standard and universal measure of architecture. These measures of length are subdivided as follows: namely: the diameter into 60 parts, and the module into 30 parts, called a minute. The Ionic column has a base peculiar to itself called the Attic, which, with that of the Corinthian order, is described under ARCHITECTURE.

The shafts of the orders differ in height and even in various examples of the same order. The capitals also are as various. Columns are either plain or fluted, and the flutes and manner of dividing them are different in the Doric and Corinthian orders. The Ionic flutes much resemble the Corinthian, and in many instances are exactly similar. Columns of all the orders taper from the middle to the upper part of the column, and in the middle there is sometimes a slight swelling called an entasis. Roman architecture being derived from the Greek, Roman columns were either exactly similar to Greek or modifications of the column made by the Romans were that form of the Ionic capital in which there were four pairs of diagonal volutes instead of two pairs of parallel ones, and that peculiar to the Composite order, in which the capital of the Corinthian column was combined with that of the diagonal or modern Ionic.

Columns are also often used for commemorative purposes as well as for architectural supports; and pictures of Egyptian and Antonine columns in Rome, and the Monument in London, erected in commemoration of the great confagration of 1666, one of the loftiest, best constructed and most beautiful in existence. It is a Doric fluted column, 202 feet high from the bottom of the pedestal, which is ornamented with bas-reliefs of Charles II and his court giving protection to the fallen city, and various inscriptions, to the top of the vase of flames, by which it is surmounted.

COLUMN, in military tactics, a formation in which the units (soldiers, squad sections, platoons, companies, troops, squadrons or battalions) are arranged from front to rear, or in general any formation with relatively great depth and a narrow front. Columns are found in different forms in close order and extended order. In close order they may be divided into those that are purely drill formations and those that are march formations. The drill-formation columns may be open, when the distance between two successive units permits wheeling or turning into line, or close, when this is not possible. The units of which close columns are formed are companies in America, platoons in Great Britain. Double columns are used by several countries.

The marching formation of infantry in America is the column of squads, in which the change from line into column is made by the bodily turning of the squad, a body two men deep and four men wide, under the command of a corporal. Germany has a similar formation, but provides for a place for the officers, sergeants and other file-closers in the column, and not merely beside it. Great Britain and most other countries form the column from the line and vice-versa without any oddity which is strict architecture. The change from line to column is accomplished in Great Britain by the command "Form-Fours!", on which odd numbers front and rear stand fast, and even numbers step to the rear and up to the left. In France the minor units of the column of route are drawn up side by side; the section, under the command of a subaltern or adjutant, consists of four parallel squads in single file, which open up fan-wise in deploying into line. Column of twos or fours is the universal cavalry marching formation; column of sections is that of artillery.

In open order lines of small columns are used by infantry to gain ease moving through brush and security from fire, especially on reverse slopes. They are also far easier to manoeuvre than lines. In the American army, these columns are either squad columns, in single file, under a corporal, or platoon columns, in double file, under a sergeant or subaltern. In the French army, a section deploys into squad columns by the mere lateral separation of its squads. The French often arrange their squad columns in two echelons.

The principle of the echelon formation, that of echelonment in depth, is emphasized strongly by the French in actual fighting tactics. It enables one to secure that the reinforcement of
a depleted body of troops shall come from its own organization, and that as little confusion of command as possible shall result.

The term "column" is also used of the supply, ammunition, engineer and sanitary trains in the line of communication. These start from a rail-head or water-head, and turn over their supplies, etc., to the trains proper or take up wounded at refilling or distributing points.

Consult Balck, 'Tactics' (tr. Fort Leavenworth 1915); United States Small Arms Firing Manual; Infantry Drill Regulations; Cavalry Drill Regulations; Field Artillery Drill Regulations; Field Service Regulations. See also Artillery; Cavalry; Infantry; Line; Tactics.

COLUMN OF JULY. a monument erected in Paris in 1840, on the site of the old Bastile in honor of the citizens killed in the revolution of 1830. It is a shaft of bronze on a marble base, capped with a gilded statue of the Genius of Liberty. It is 154 feet high and 13 feet in diameter.

COLUMN OF SAINT MARK. See Venice.

COLUMN OF TRajan, a monument erected in Rome in 114 A.D. in honor of the emperor. It is a Roman Doric column of white marble of 34 blocks, 23 composing the shaft, on which are carved representations of various scenes in Trajan's campaigns, containing 2,500 figures of men, each about two feet in height. The quadripartite pedestal bears an inscription which can easily be read. It is 127½ feet high, exclusive of the statue of Saint Peter, which now stands on the apex of the column, having taken the place of the colossal figure of Trajan in 1857.

COLUMN VENDOME, vohn-doom, a monument erected in the Place Vendome, Paris, by Napoleon I, to commemorate the victories of the Grand Army over the Russians and Austrians in 1805. It is similar in design and ornamentation to the Column of Trajan, but is built of masonry encased in bronze taken from 1,200 captured guns, and capped by the statue of Napoleon. It is 142 feet high and 13 feet in diameter. It was overthrown in 1871 during the Commune but was restored in 1875.

COLUMNAR JOINTING, and COLUMNAR BASALTS. In lava flows (q.v.) and sills (q.v.) there is often manifested a peculiar structure consisting of five or six sided prisms or columns, separated by narrow cracks. These are usually at right angles to the cooling surface of the igneous mass. The cause is supposed to be contraction during cooling. Such columnar jointing is well displayed in the Giants Causeway (q.v.), at Fingals Cave (q.v.), along the Palises of the Hudson (q.v.), in Yellowstone Park (q.v.) and at numerous other points.

COLURE, kō-lūr, one of two imaginary great circles of the celestial sphere passing through the celestial poles; one passing through the equinoctial point of Aries and Libra and the pole of the equator; and the other through the solstitial points of Cancer and Capricorn, and the poles both of the ecliptic and equator. For this reason the first is called the equinoctial, and the second the solstitial colure. The name, meaning "dock-looked" or "dock-tailed," is now rarely used; it was originally applied because a portion of these circles is always concealed under the horizon.

COLVILLE, Sir Edwin Henry, English general: b. 10 July 1852; d. 1907. He was educated at Eton and entered the grenadier service in 1870. He served in Egypt, the Sudan, Uganda and South Africa, where his failures led to his recall. He has published 'A Ride in Petticoats and Slippers' (1879); 'The Accursed Land' (1884); 'History of the Sudan Campaign' (1887); 'The Land of the Nile Springs' (1895); 'The Work of the Ninth Division' (1901). He was created K.C.M.G. in 1895.

COLVILLE, Wash., town and county-seat of Stevens County, 85 miles north of Spokane, on the Colville River and the Great Northern Railroad. It has extensive lumbering and agricultural interests and a number of small industries. Near here was established a Jesuit mission in 1846, for the christianizing of the Salishan Indians. In 1872 a reservation was established, the Indian population of which in 1910 was 785. Pop. of Colville 1,600.

COLVIN, Sir Sidney, English critic: b. Norwood, England, 18 June 1863. He was Slade professor of fine arts at Cambridge 1873-85 and keeper of prints and drawings at the British Museum 1884-1912. His writings include 'Children in Italian and English Design' (1878); 'Life of Walter Savage Landor' (1881); 'Life of Keats' (1887); 'A Florentine Picture-Chronicle' (1898); 'Early History of Engraving in England' (1905). He edited the Edinburgh edition of the works of Robert Louis Stevenson (1894-97), and also his letters. He was knighted in 1911.

CLOVOCORESSES, George Partridge, American naval officer: b. Norwich, Vt., 3 April 1847. During the Civil War he served two years on the ships Supply and Saratoga and then entered the United States Naval Academy from which he was graduated in 1869. He was advanced through all grades, becoming captain in 1905 and retiring, at his own request, as rear-admiral in 1907. He was present with Dewey at Manila Bay in 1898 and was advanced five numbers in grade for eminent and conspicuous conduct there. He served in nearly all the ports of the world, was instructor at the Naval Academy 1886-90 and again in 1893-96. In 1905-07 he was commandant of midshipmen and served at the War College and in command of the Key West Naval Station.

COLWELL, Stephen, American lawyer and writer: b. Brooke County, Va., 25 March 1800; d. Philadelphia, 15 Jan. 1872. He was graduated at Jefferson College, studied law, was admitted to the bar and practised for some years in Pittsburgh. About 1830 he removed to Philadelphia, became an iron merchant and amassed a fortune. He early developed a fondness for the study of finance, political economy and social science, and frequently published the results of his studies on questions of current interest or debate. During the Civil War he aided the administration with pen, purse and voice, and was a liberal supporter of the work of the sanitary commiss. He was appointed by the government one
of the commissioners to examine the internal revenue system and suggest improvements. He left his large and valuable library for the use of students, and his name is associated with the development of political and social science at the University of Pennsylvania, where he also endowed a professorship of social science. Of his writings the following may be mentioned: 'Relative Positions in Our Industry System' (1841); 'Domestic Commerce, Domestic Production, and Internal Trade' (1850); 'New Themes for the Protestant Clergy' (1851); 'The South... Effects of Disunion on Slavery' (1856); 'Ways and Means of Commercial Payment' (1858), his last and most important work.

COLY, a bird of the African family Coliidae. See Mouse-bird.

COLYMBIFORMES, an order of archaic birds, all aquatic, with webbed or lobed toes, the metatarsi extraordinarily flattened, and having great power in swimming and diving. There are two suborders: (1) Colymbi, the least; and (2) dicypedes, the grebes (q.v.). See Ornithology.

COLZA OIL, COLESEED, or RAPE OIL, an oil, familiar from its use as an illuminating agent in the moderator and other lamps, expressed from the seeds of several plants of the cabbage and turnip genus, the name being originally apollozad (Dutch), that is kail- or cabbage-seed. It is yellowish brown, has a specific gravity of 0.92, and little or no smell, and dissolves in hot alcohol and in ether. It becomes thick and solid only at very low temperatures, has hestted it volatileizes, but not completely, undergoing partial decomposition. It is purified for use by continued agita tion with sulphuric acid, which destroys mucilaginous matter from the seed, and washing with water to remove all trace of the acid. The oil is used in Great Britain and on the Continent in soap-making, tanning, fulling of cloth, lubricating machinery and for burning. For the last it is so well adapted that it was specially recommended for lighthouse purposes. It is a clear liquid, steady, is managed with very little attention and is cheap. In these respects it is said to be superior to spermaceti.

COMA, in medicine, a state of complete or almost complete unconsciousness, resulting from various diseases, as apoplexy; from poisons, as opium, uræmia, diabetes, alcohol; from accident or injury to the brain; or from excessive cold. In cases of coma the pulse is usually slow and soft, but sometimes quick, the breathing is rarely stertorous, the pupils of the eyes are commonly more or less dilated and the face is often swollen and livid. The patient is either altogether unconscious and incapable of replying to any question, or he makes incoherent and rambling statements. Stimulating agencies and blistering are sometimes used in the treatment of comatose cases, but generally the disease or injury producing the condition determines the remedy.

COMA BERENICES, bær-ë-nil'sëz ("The Hair of Berenice"), a northern constellation, the name of which is due to the flattery of Alexandrine astronomers, who professed to see in it a portrait of the beautiful hair of Berenice, wife of Ptolemy Euergetes. Callimachus in Greek and Catullus in Latin wrote poems descriptive of the apotheosis of the curl. Ptolemy did not introduce it into the Almagest as a distinct constellation, but called it Phleumoz (Or. "hair," or "ether"). Tycho Brahe restored it as a distinct constellation in his catalogue of 1602. It is formed of rather faint stars, none being brighter than the fourth magnitude. Baily, in the "B. A. C." in 1845, attached the first three letters of the Greek alphabet to three of the brighter stars. The constellation is surrounded by Ursa Major, Canes Venatici, Bootes, Virgo and Leo.

COMACCHIO, kô-mä-chë'o (ancient Co manctium), Italy, town in the province of Ferrara, in Emilia, about 20 miles north of Ravenna and 30 miles south of the plains of Ferrara. The town is built on 13 islands which are connected by bridges. The chief industries are fishing and manufacturing salt.

COMAN, Katherine, American teacher; b. Newark, Ohio, 23 Nov. 1857; d. Wellesley, Mass., 11 Jan. 1915. She was graduated with the degree of Ph.B. at the University of Michigan 1880, and at once joined the faculty of Wellesley College, remaining there until her death. She was professor of economics there from 1900 to 1914. She went abroad in 1913-14, and made a special study of social insurance, as worked out in England, Spain, Belgium and the Scandinavian countries. This study, which was to have included France, Germany and other countries of Europe, was interrupted by the illness which brought her home to die. She published "Growth of the English School" (1895); "History of England" (1899); "History of England for Beginners" (1901), and in collaboration with her colleague Katherine Lee Bates, "English History Told by English Poets" (1902); "Industrial History of the United States" (1905); and "Economic Beginnings of the Far West" (2 vols., 1911).

COMANA, kô-mä-nä. (1) An ancient city of Cappadocia, supposed to be the modern Elbostan, on the river Sarus, celebrated in antiquity for its temple of Artemis Tauropolis, and for the great devotion of its inhabitants to the worship of that goddess. Over 14,000 persons were engaged in the service of the temple. The city was governed by the high priest, who was always a member of the reigning family, and took rank next to the king. (2) A city of Pontus, now Tokat, on the river Iris, and almost as famous for its devotion to Artemis as the other city of the same name. There is evidence to show that this worship to Artemis or Ma, as the goddess was generally called in both the cities of the same name. There is evidence to show that this worship to Artemis or Ma, as the goddess was generally called in both the cities of the same name. There is evidence to show that this worship to Artemis or Ma, as the goddess was generally called in both the cities of the same name. There is evidence to show that this worship to Artemis or Ma, as the goddess was generally called in both the cities of the same name.

COMANCHE, kô-män'chë, CAMANCHE, CHOUMAN, COMANDE. Their own name is Num, "people"; the Sioux gave them one which the French turned into Fadoouca, a powerful and fierce tribe of the widely distributed Shoshonean stock, speaking the same language as the Shoshones of Wyoming, and traditionally their neighbors. When first made known to the whites by the French under Duteiné, they were located in eastern Colorado. They had already obtained horses from the Spaniards and become nomads and expert horsemen, and a powerful and fierce tribe of the widely distributed Shoshonean stock, speaking the same language as the Shoshones of Wyoming, and traditionally their neighbors. When first made known to the whites by the French under Duteiné, they were located in eastern Colorado. They had already obtained horses from the Spaniards and become nomads and expert horsemen, and a powerful and fierce tribe of the widely distributed Shoshonean stock, speaking the same language as the Shoshones of Wyoming, and traditionally their neighbors. horses from them. In 1724 another French expedition made a treaty with them. They seem shortly after to have been pushed southward by the Sioux, and we find them later roving the plains of northwestern Texas, making plundering raids into Southern New Mexico, deep into Mexico, and westward to Santa Fé. They lived in skin wigwams, with few or no fixed villages except near the Spaniards, and were in eight bands, with a very loose organization. They probably numbered 5,000 warriors, and 25,000 in all, at their best estimation. One village near the Spaniards had 800 warriors, and over 4,000 in all. They were at constant war, both with the Spaniards and the other Indian tribes, and in 1783 engaged in a wholesale war with the former; but Anza inflicted a crushing defeat on them, killing 30 of their chiefs, and there was peace for a time. In 1816 they are said to have lost 4,000 of their number by an epidemic of smallpox; but they were still estimated at 9,000; and in 1847 at 10,000 or 12,000, one-third in warriors. They recruited their numbers by kidnapping and adopting Mexican children, boys or girls. For all the years of immigration into those regions, down to 1875, they were the bloody and relentless scourge of the white settlers, and furnished a good part of the Indian horrors of the Southwest. They were once placed on a reservation in Texas, but were driven off. In 1868 the bulk of them agreed to go on a reservation in western Oklahoma; but the Quahada or Staked Plain band refused, and kept up their murderous forays. They were sharply punished by Colonel McKenzie at McClellan's Creek in 1872, in which year they were estimated at 3,218 on the reservation, with 1,000 more in roving bands. The last of these surrendered in 1875. In 1901 their reservation in Oklahoma was thrown open to settlement. At present they number about 2,000. Consult Hodge, W. H., 'Handbook of American Indians' (Washington 1907).

COMANCHE, Tex., city and county-seat of Comanche County, 110 miles southwest of Fort Worth, on the Fort Worth and Rio Grande and the Saint Louis and Southwestern railroads. It is an agricultural centre, has a number of brickyards, cotton gins and stockyards. Comanche was settled in 1857 and is governed under a charter of 1876 which provides for a mayor, elected for two years, and a council. The waterworks are municipally owned. Pop. 2,756.

COMANCHIAN. See CRETACEOUS.

COMAYAGUA, kō-mā-yā'gwā, or VALLAGOLID LA NUEVA, Honduras, C. A., a town, capital of the department of the same name, situated on the southern border of the plain of Comayagua, on the Humuya River, 220 miles east of Guatemala. It is the seat of a bishopric, has a large and handsome cathedral, a richly endowed hospital, several convents and a college. It was founded by Alonzo Caceres in 1540, and up to 1827 was a thriving place, with about 18,000 inhabitants. In that year, however, it was burned by the monarchical faction of Guatemala, and has never recovered. Pop. 3,100.

COMB (A.S. camb), an instrument to separate and adjust the hair, too well known to need description. We have no certain authority that either the Greek or the Etruscan women applied this useful article regularly to their hair in the operations of the toilet, although it was used by the Greek women, at least, to arrange their hair. The combs used by the Greeks were of boxwood, and had teeth on both sides, while those used by the Egyptians had teeth only on one side. The Romans also had combs of boxwood, and at a later time probably of ivory and other materials. In the work of Guasco Della Ormatrici there are several representatives of ancient Roman combs. One of them is a long one of box, of which the handle is overlaid with ivory, and appears to have been ornamented with a small meander in gold. It has two rows of fine teeth, delicately wrought and well proportioned. Modern combs are generally made of tortoise shell, ivory, horn, wood, bone, metal, india rubber and celluloid. Machinery has been perfected for their production. In making combs the material is first cut to the form which the comb is to have, and the teeth are then made at once by means of circular saws mounted on the same axle and placed at a suitable distance from one another. Large combs in horn or shell, with wide teeth, are sometimes made with a punch, which cuts in the piece the teeth of two combs by the same operation. The teeth are afterward finished with the file. Combs made of vulcanized india-rubber, which are now so common, are made by pressing the caoutchouc while soft into molds, and then bringing them to the desired degree of hardness by the process of vulcanization. Canova and other modern sculptors have made great use of the comb, placed in the heads of their women, to which they add much grace and elegance.

COMB, the wax cavities in which bees lodge their honey. The comb of a bee is composed of hexagonal cells, of which there are two tiers, the cells of which are placed end to end, so that the three plates of wax, which serve as the bottom of the cell in the one tier, constitute also that of the corresponding one in the other. The mathematical problem in "maxima and minima," how to construct the greatest number of boxybricks, cotton gins and stockyards. Comanche was settled in 1857 and is governed under a charter of 1876 which provides for a mayor, elected for two years, and a council. The waterworks are municipally owned. Pop. 2,756.

COMBA, kō'mà, Emillo, Italian author: b. San Germano Chisone 1839. He became a professor at the Istituto Valdese at Florence; there he founded in 1873 the review entitled Rivista Cristiana, devoted to the discussion of religious problems and topics. He is the historian of the religious reform in Italy. His works include 'Introduzione alla storia della riforma in Italia' (1881); 'I nostri protestanti' (1897); 'Storia dei Valdesi' (latest ed., 1901; Eng. trans., London 1889).

COMBACKUM, Madras, British India, town in the district of Tanjore, 194 miles from Madras. It is regarded by the Hindus as a place of peculiar sanctity, and is inhabited largely by the Brahmans. It contains numerous pagodas and tanks with water, supposed to come from the Ganges River. One of the oldest places in southern India, it is one of the strongholds of Brahmanism and Brahmanical culture. Pop. about 64,000.
COMBASOU, the trade name of an African weaver-bird (Hypochera chalybeata), kept in aviarieds for its pretty plumage and manner. The male is black with a bluish gloss, bill white and legs pink; the female is brownish.

COMBAT, in its general sense signifies a fight. The noun form is derived from the verb and the preposition from the French of the same form. Owing to the prevalence of single combats in Normandy and England in early Norman times, the word combat, in England, where it was not altogether at home, came to be restricted in sense generally to a fight between two individuals or between two parties, each chosen to uphold the honor of its own party or faction. Trial by combat and the ordinary single combat encounter have both the same origin, which goes back to the dim ages long before formal history began. Originally single combat was frequently made use of to adjudge the guilt or innocence of the contending parties, and it was itself the same in import and origin as the trial by combat in all its various forms whether by ball or by water, when she was popularly supposed to hate. In India women accused of unfaithfulness to marriage vows were subject to trial by fire to test their innocence or guilt. The single combat, early in the organization of society, came to be a union of two social inclinations, that of the tendency of two disputants to fight out their quarrel, and that of the potent influence of magic in which all primitive tribes believed and which was supposed to help the more powerful contendant. Later on this magic idea was the basis of the barbarian races and the savages gradually surrounded itself with a moral atmosphere, the result of attributing the magic itself to the influence of the gods and their interference in behalf of one of the contendants, generally the one in the right. Later the idea of a divine guardianship of every human being came to lend still more pronounced moral atmosphere to the single combat fought to decide a question of right or wrong. Gradually, however, this idea lost ground in ordinary single combat encounters, as the age of chivalry advanced, without a weakening of influence in its own particular sphere of trial by ordeal, into the service of which the trial by single combat still continued frequently to be pressed to the end of the age of chivalry. Very ancient usage was evidenced by Goliath (1 Sam. xvii), and by Ajax in the 'Iliad,' and by many of the characters in the mythologies of various nations. Among the Scotch clans the combat was sometimes between individuals; but just as often between a certain picked number on each side. Then again not infrequently one clan defied another to combat. The Norse practice of principals going alone to a small holm or island, to be free from disturbance while settling their quarrels by strength and skill, gave rise to the Saxon term Holm-Gang. In the days of chivalry the single combat received the strong support of law and custom, and was resorted to both in civil and in criminal cases. The great accuser of plaintiff swore to the truth of his tale, the other gave him the lie, a gage of battle was thrown down and taken up, and they fought it out under rules before an assembly, the suppositions being that God would give victory to the right. The barbarous practice survives in European countries, without its excuse of superstition, in the modern duel, which is legally prohibited in the United States. In England it was still a legal method of trial well into the 19th century, but was abolished by statute 59 George III, cap. 48.

COMBAT TRAINS. See AMMUNITION.

COMBE, kôm or koom, Andrew, Scottish physiologist: b. Edinburgh, 27 Oct. 1797; d. there, 9 Aug. 1847. He was educated for the medical profession, and in 1822 he commenced practice at Edinburgh, and had considerable success. In 1838 he was appointed one of the physicians extraordinary to the queen in Scotland. His chief works are 'Observations on Mental Derangement' (1831); 'Principles of Physiology' (1834); 'Physiology of Digestion' (1836); 'A Treatise on the Physiological and Moral Management of Infancy' (1840). Like his brother George (q.v.), he was a zealous phrenologist.

COMBE, George, Scottish phrenologist: b. Edinburgh, 21 Oct. 1788; d. Married to Miss Berruy, 14 Aug. 1838. He was a brother of Andrew Combe (q.v.), was bred to the law, and in 1812 admitted a member of the Society of Writers to the Signet. He was the first to introduce the doctrines of phrenology into Great Britain; and visited Germany and America lecturing on his favorite science. He was also a zealous promoter of the cause of popular education and social progress; and was among the first to advocate compulsory education and the establishment of a board of education. He was a frequent and important contributor to the 'Phrenological Journal' and he wrote for other publications, and in his own works, on education, theology, politics, economics and other subjects and matters of general interest. He had a way of presenting his subject that made him an immensely popular writer. Besides the 'Constitution of Man' (1828), which has had an enormous circulation, he was the author of 'A System of Phrenology' (1825); 'Lectures on Popular Education' (1833); 'Philosophy' (1840); 'The Life and Correspondence of Dr. Andrew Combe' (1850); 'Principles of Criminal Legislation and Prison Discipline Investigated' (1854); 'Relation Between Science and Religion' (1857).

COMBE, William, English writer: b. Bristol 1741; d. Lambeth, 19 June 1823. His 'Tour of Dr. Syntax in Search of the Picturesque' (1812) was once very popular. Other works by him are 'The Diabolion,' a poem (1776); 'The Devil Upon Two Sticks in England' (1790). After 43 years within the rules of a debtors' prison, and previous vicissitudes of fortune from army officer to cook, he died in Lambeth.

COMBERMERE, kôm'bér-mér, Sn Stapleton Cotton, Viscount, English general: b. Denbighshire, 17 Nov. 1773; d. Clifton, 21 Feb. 1865. He entered the army in 1790, served in Flanders and India, and with the rank of major-general accompanied the Duke of Wellington to the Peninsula in 1808. In 1809 he succeeded to the family baronetcy. At Salamanca, in 1812, he headed the brilliant cavalry charge which greatly contributed to the decisiveness of that victory, and was subsequently present at the battles of the Pyrenees,
COMBES — COMBINATION

Orthez and Toulouse. Shortly after the last battle he was raised to the peerage with the title of Baron Combermere. From 1817 to 1825 he was commander-in-chief of the army in Ireland, and in 1825 was sent to India as commander-in-chief of the forces there, to put down the usurper Doorjun Sal. After a siege of less than two months, Blurrpore, the chief city of Doorjun, was taken by storm on 8 Feb. 1826, for which Combermere was raised to the rank of viscount. The remainder of his life was passed in England. In 1852 he was appointed constable of the Tower; and in 1855 made a field-marshal.

COMBES, koomz, Justin Louis Emile, French statesman: b. Roquecourbe, Tarn, France, 6 Sept. 1835. He was educated in a Roman Catholic seminary for the priesthood, but subsequently studied medicine, and began practice in Pons, where he filled various posts of responsibility, such as those of mayor and town councilor. In 1865 he was elected to the Senate, of which he was vice-president 1893-94, becoming Minister of Public Instruction in 1895. He has been active in the reorganization of primary and secondary education. In July 1902 he succeeded Waldeck Rousseau as President du Conseil des Ministres. In this capacity he has enforced the Association Act, abolishing liberty of teaching in France and aimed at the clergy. The law against the religious orders was enforced with great severity, and over 500 teaching, preaching and commercial orders were suppressed under the Combes régime. His opponents have claimed that this has been done with needless severity. It has caused widespread disturbances throughout the country. On his becoming Prime Minister, M. Combes announced his intention to reduce the period of military service to two years, and to establish a general income tax. Steps were also taken during his ministry which were to lead later to the separation of church and State. In spite of the fact that M. Combes was upheld by the Chamber in all his acts, he resigned in 1905 because of the intense bitterness which these acts aroused among the Conservatives. M. Combes is a latter-day Voltaire, with all of his master's hatred of clericalism in all its forms. To him the Catholic Church appears as the sworn enemy of modern life and culture and particularly of the Republic of France. Personally he is what is called in France an "austere Republican," a man simple, in his private life and rigid in his adherence to the principles of the French Revolution.

COMBINATION, in mathematics, the selection, from a given set of objects, of a stated number without regard to their arrangement. Each combination can, by varying the arrangement of the constituent objects, be made to give rise to a permutation. Thus, in the four letters, a, b, c, d, four combinations, three at a time, are possible; namely, abc, abd, acd, bcd. Each of these combinations, however, produces six permutations, according to the order of the letters. For example, the combination abc yields the six permutations abc, acb, bac, bca, cab, cba. Thus, of the four letters, a, b, c, d, the number of permutations three at a time is 24. It is easy to prove that the number of permutations of n objects two at a time is n (n - 1); three at a time n (n - 1) (n - 2); four at a time n (n - 1) (n - 2) (n - 3); and so on, the number when r at a time are taken being n (n - 1) (n - 2) ... (n - r + 1). The number of permutations of n things n at a time is therefore n (n - 1) (n - 2) ... 2. A product usually represented by n! or n!, and read as "factorial." The theory of permutations and combinations is of very great importance in higher mathematics, and may be studied in any textbook of algebra, such as those by Chrystal, Todhunter and Smith.

COMBINATION, Industrial, in law, a union of individuals, companies or corporations formed for the purpose of accomplishing a particular object or purpose. In the United States a combination is not unlawful in itself, though it becomes so if it seeks to obtain its ends in an unlawful manner, or by unlawful acts. Combinations may be divided into two general classes, those formed by employees or labor, and those formed by employers or capital. Combinations formed by employees, or labor, generally bear the designation of unions. The purpose of a union is to better the condition of its members in relation to the work in which they are engaged, by securing higher wages, less working hours, different methods of doing the work and similar changes. A union generally tries to enforce its demands by striking, or threatening to strike. A strike is a combination effected by employees whereby at a prearranged time they all stop working unless their demands are granted. A strike is usually organized through a union.

A boycott is a combination to cause a loss to a particular person by restraining others from doing business with that person. It is often so conducted that the person is affected socially as well as in his business. When a boycott has been declared against a person, any one having either business or social relations with that person is also boycotted.

When the objects of such combinations are effected in a peaceful and lawful manner there is no legal means by which they can be interfered with; but it generally happens that when a number of working-people strike there is a breach of contract, or a conspiracy, in which case there is a legal redress. The usual action is for the injured party to proceed in equity and ask for an injunction restraining the former employees from committing certain acts. Sometimes damages are asked for, and it makes no difference what the status is when the cause is heard, as damages can be recovered for acts committed during a strike, the strike may have ended long before the demand for damages.

Combinations formed by employers, or capital, are usually known as trusts. Trusts are generally formed with the object of regulating the supply or price of a product, or both, for the purpose of reducing expenses or competition.

It has been found very difficult to frame a law which will be effective against all the different arrangements under which a trust can be carried on. The State courts have no jurisdiction outside the limits of the State to which they
belong, and it is very seldom that a trust would be formed whose business would be confined to any one State. The Federal government has passed several anti-trust laws, and up to the present time the most effective way of dealing with this class of combinations is by laws passed under the clause in the Federal Constitution (Art. I, §8, cl. 3), which provides that Congress shall have power to regulate commerce with foreign nations, and among the several States, and with the Indian tribes. See Boycott; Strikes and Lockouts; Trust Companies. Consult Jenks, T., 'Trusts and Industrial Combinations' (in Bulletin of Department of Labor, No. 29, July 1900).

COMBINATIONS AND PERMUTATIONS. Combinations and permutations deal with the arrangement and grouping of objects. They arose out of problems such as these: How many numbers can be thrown with two dice? How many striped flags can be made with three colors? How many whist hands of the total can be dealt from a pack of 52 cards, the cards being put back and shuffled after each deal? Although games of chance furnished most of the problems in the beginning, the modern aspect of the subject finds applications in statistics, probabilities and the theories of numbers, finite group, and algebraic forms. Aside from isolated references to single questions in the works of the Greek mathematicians, the earliest attempt at organized treatment of combinations and permutations occurs in the treatise of the Hindu astronomer Bhaskara Acharya in the 12th century. The subject received no further attention until the time of Cardan (1501-76) and another century elapsed before Pascal (1623-62) succeeded in building it into a science, as yet, however, in its infancy. Hindenburg (1741-1808) is regarded as the founder of the modern theory, but his school, known as the "combinatory school," held aloof from the rest of mathematics. Since then the researches of Jacobi, De Morgan, Sylvester, Cayley, Franklin, Mathews and MacMahon have shown its use in the general theories of arithmetic and algebra. We shall take up only elementary combinations and permutations; for a complete treatment of combinatorial analysis consult MacMahon, 'Combinatory Analysis' (1915), and Netto, 'Kombinatorik' (1901).

Permutations. A permutation of $n$ elements taken $r$ at a time is a linear arrangement, as in a row, of $r$ of those $n$ things with regard to the order in which they may be placed; e.g., $a b c$ and $a c b$ are permutations of $a$, $b$, and $c$. This name was given by Jacob Bernoulli ('Ars Conjectandi,' 1713). The number of permutations will be denoted by $P_n, r$, $n$ being the total number of elements and $r$ the number in a group; the notation $(n\ r)$ or $(n\ r)$, is often used. To find $P_n, r$, observe that the first one of the $r$ objects may be selected in $n$ ways and for each selection there are $n-1$ things left from which to choose the second object; both may thus be chosen in $(n-1)$ ways. By continuing the argument we find:

$$P_n, r = n(n-1)(n-2)\ldots(n-(r-1))$$

there being $r$ factors. The following table gives numerical values of $P_n, r$ from $n=4$ to 10 and $r=2$ to 10. The table $P_n, 2=6720$ and is found under $n=8$ and opposite $r=5$.

$$P_n, r = P_n, s = 6; P_n, 2 = 2. S_p$$

will be explained later.

$S_p = n! \sum_{r=1}^{n} \frac{P_n, r}{n!}$

When $r = n$

$P_n, n = n\ (n-1)\ (n-2)\ \ldots\ \pm 2\ n$ factors.

This product of the integers from 1 to $n$ is represented by

$$n! [n-1][n-2]\ \ldots\ 1$$

and is read factorial $n$; it is due to Kramp ('Elémens d'arithmétique universelle,' 1808).

The number of $r$ permutations is therefore written

$$P_n, r = \frac{n!}{(n-r)!}$$

Now when $r = n$, $P_n, n = n!$ hence $(n-n)!$ or $0!$ must equal unity. That is, if Kramp's notation is to be carried out consistently we must regard $0!$ as a symbol for unity although according to the strict meaning of $n!$ factorial 1 is 1 and factorial 0 is 0. But as both 1! and 0! must be taken as unity

$$P_n, n = P_n - n - 1$$

the table shows this to be so.

When $n$ is large as in the theory of probabilities, $n!$ can be computed from the series due to Laplace ('Théorie des probabilités'):

$$n! = n^n e^{-n} \sqrt{2\pi n} \left(1 + \frac{1}{12n} + \frac{1}{288n^2} + \ldots\right)$$

which as $n$ increases indefinitely approaches

$$n! = n^n e^{-n} \sqrt{2\pi n}, \text{ approx.}$$

this is Stirling's formula ('Methodus Differentialis,' 1730). For example, when $n = 10$ this approximation gives 3,598,700 which differs from the correct value in the table by 0.33 per cent. For $n = 20$ the error is less than one-half per cent.

The number of permutations often runs astonishingly high; the number of whist hands in the problem stated at the beginning of this article is $P_{10, 5}$, 635,013,559,600 so that the probability of a player getting the same hand twice in a lifetime is remote to say the least.

The sum of the permutations of $n$ things successively one at a time, two at a time, and so on up to all at a time is

$$\sum_{m=1}^{n} P_n, m = S_p$$

where $S_p$ is given in the last row of the table.

Since

$$P_n, m = \frac{n!}{(n-m)!} \text{ and } P_n, n - n$$

Then when $n$ is large the parenthesis approaches the
COMBUSTION

is chemically the rapid oxidation of a substance with the evolution of light and heat. It is generally accompanied by flame and the production of carbon dioxide, carbon monoxide and the vapor of water. The substances which are consumed are popularly termed combustibles. Chemically, the substances oxidized are the carbon and hydrogen components of the combustibles. The heat in combustion is a result of the chemical changes which take place during oxidation. The light is emitted by incandescent particles of carbon in the flame. The temperature to which any particular substance must be raised in order that it shall take fire is called the "ignition point" of that substance. Ignition points vary with the different combustibles. They may even be below the temperatures which ordinarily prevail. In such case the substance will burst into flame when that temperature is reached, and this phenomenon is called "spontaneous combustion." Some kinds of vegetable and animal oils when spread out thinly, as on a rag, may oxidize so rapidly as to become very hot, and if in a confined place will eventually take fire spontaneously.

In combustion two classes of combustibles are recognized: (1) Those which in the process generate heat sufficient to continue the combustion until the whole of the combustible is consumed; (2) those in which the combustion can only be kept continuous by the constant application of external heat. When the processes of combustion take place instantaneously the combustion is called an explosion. Acetylene may be mentioned as an example in this connection. It has a tendency, especially when under pressure, to decompose, with the evolution of so great a degree of heat as to expand enormously and result in explosion. The economic use made of combustion is chiefly for the generation of power, but also in cooking and the heating of houses and the production of all artificial lights but electric light. The combustibles utilized in this way are called fuels. See EXPLOSION; FUELS; FURNACE; GAS; HEAT; LIGHT; OXYGEN; PHLOGISTON. Consult Hayes, J. W., 'Combustion and Smokeless Furnaces' (Chicago 1915).

COMBUSTION, Spontaneous, the ignition of bodies by the internal development of heat without the application of an external flame. It not infrequently occurs in the case of certain rags, soot, paper, woolens, cotton and other substances strongly lubricated with oil, when, if the oil is freshly made, it is very ready to combine with the oxygen of the atmosphere and give out carbon and water. This development, diffusing itself through a mass of highly inflammable substances, will in certain circumstances be sufficient to set them on fire. A remarkable instance of spontaneous combustion among hemp was that of General Sin, 1861, being the cause of the terrible conflagration at Tooley street, London. Bituminous coal, piled
up in heaps, is apt to ignite by the decomposition of the sulphuret of iron which it contains. In ships laden with coal impregnated with sulphur and iron in the form of bar-sulphuret of iron (pyrites), decomposition of this substance is sometimes occasioned by the access of moisture, and heat is evolved to such a degree as to cause the combustion of the coal, especially if air is admitted freely. Water poured upon the burning mass only adds to the intensity of the action. Charcoal and green hay are liable to spontaneous combustion. A somewhat unusual case of spontaneous combustion occurred in 1916, when an explosion in a flour mill was found to be due to accidental spark ignition of an intimate mixture of flour dust and air. Legends and tales exist of spontaneous combustion of human bodies; but no authenticated case has been recorded, and it is regarded as impossible.

**COMBUSTION. Velocity of.** It can be shown by direct experiment that the burning of a grain of powder in a fire-arm is progressive, and that the size of the grain exerts a great influence on the velocity of the projectile. For instance: if one piece of the press cake were placed in a small mortar and fired, little or no motion would be given to the projectile. If this piece be divided into seven or eight parts, the projectile will be thrown a short distance; and by increasing the number of parts or grains, so will the effect of the powder on the projectile also increase. The progressive burning of powder is further confirmed by the fact that burning grains are sometimes projected from the gun with sufficient force to perforate screens of paper and wood at considerable distance. It is even found that they are set on fire in the gun and afterward extinguished in the air before they are completely consumed. The velocity of combustion of powder varies with the purity, proportions, triturative, density and condition of the ingredients, also with the pressure under which the powder is burned. By varying the proportions and increasing the sulphur there is a tendency to produce a more violent explosion and a more quickly build-up of the mixture. A general formula may be deduced to show the amount of gas developed and the quantity of powder burned at any instant of the combustion of a grain or charge of powder. For this purpose take a spherical grain of powder and consider it inflated over its entire surface. Let \( t \) represent the time of burning, from the instant of ignition to the moment under consideration; \( R \), the radius of the grain. Since the combustion of the grain passes over the radius \( R \) in the time \( t \), the velocity of combustion is equal \( \frac{R}{t} \) and for the time, \( t \), it will pass over the space \( \frac{R^2}{2t} \), the radius of the decreasing sphere will therefore be \( R \left(1 - \frac{t}{R}\right) \). The volume of the grain of powder and that of the decreasing sphere are \( \frac{4}{3} R^3 \) and \( \frac{4}{3} \pi R^3 \left(1 - \frac{t}{R}\right)^3 \) respectively; and their difference \( \pi \) or the quantity of powder burned, will be equal to \( \frac{4}{3} \pi R^3 \left(1 - \frac{t}{R}\right)^3 \).

The first factor of this expression represents the primitive volume of a grain of powder, and the other expresses the relation of the volume burned to the primitive volume.

The same expression will answer for all of the grains of a charge of powder, if they are of the same size and composition; consequently, if we let \( A \) represent the primitive volume of the grains composing a charge of powder, the quantity remaining unburned after the time, \( t \), will be represented by \( A \left(1 - \frac{t}{R}\right)^3 \); and the quantity burned by \( A \left(1 - \frac{t}{R}\right)^3 \). Although the grains of powder are not spherical, their sharp angles are partially worn away by rubbing against each other in glazing and in transportation, and the mode of fortification and inspection reduces the variation in size within narrow limits; therefore, if we examine the influence which the actual form and size of the grains exercise over the phenomenon of combustion of powder, we shall find that the effect varies but slightly from that due to the spherical form. If we consider the velocity of the projectile on leaving a gun and the time necessary to overcome its inertia in the first period of its movement, we shall see that a very large part of each grain is burned up before the projectile leaves the gun. If the size of the grain be increased, the effect will be to diminish the amount of gas evolved in the first instant of time, and to diminish the pressure on the breech. This principle has been made use of to increase the endurance of large cannon.

**COMBUSTION ENGINE. See Internal Combustion Engine.**

**COMÉDIE FRANÇAISE,** kō'mā-dē frān'-sä', the official name of the national theatre of France which is supported by public funds for the purpose of advancing dramatic art. It was long known popularly as "La Maison de Molière," or Molière's Theatre, even after it had become, by royal decree in 1680, a national institution; and the two great bodies of actors then in Paris, those acting at the Hotel de Bourgogne Theatre and those at the Géne- gaud Theatre, had been united and fused into one body. The former, which was Molière's dramatic institution, had originally been an old theatre where miracle plays had been presented as early as 1543. Thus the Comédie Française may be said to have an unbroken tradition reaching back to the days of Molière, and to have had theatre connections for more than a century previous to the date of its founding in 1673. Two years after the amalgamation of the dramatic companies they received a royal grant of 12,000 livres ($2,400) per year; and seven years later they took, for their first, their present designation of players of the "Comédie Française." From 1770 to 1782 the "Comédie" had quarters in the royal palace of the Tuileries. But the Revolution of 1789 divided the players of the "Comédie Française" into two strongly antagonistic political parties and disrupted the organization to such an extent that all public performances were suspended. Each party reorganized, some months later, as an independent theatrical organization, the Royalists taking the name "Théâtre de la Nation" and the Republicans that of "Théâtre de la République." In 1793 the former theatre closed its doors and its players were arrested by the Committee of Public Safety; but they were subsequently released and allowed to again open their theatre. Napoleon, in 1812, issued regulations for the government
of the national theatre, which are still, with some subsequent modifications, in force. The government appoints a general manager of the theatre, the members of the stock company of which divide the profits according to laws and regulations prescribed by the articles of incorporation of the organization. The "Comédie Française" receives from the French government an annual pension of 240,000 francs. Its membership is divided into "sociétaires" and "pensionnaires." The former are regular members of the organization and are entitled to a pension of 4,000 francs a year after 20 years of service, while the latter are paid actors who may, after a certain length of service, become "sociétaires.

The building of the "Comédie Française" was so badly damaged by fire in 1900 that it had to be practically rebuilt. This resulted in making the edifice much more modern in every way. The names of nearly all the great actors and dramatists of France have, at some time in their career, been associated with that of the "Comédie."

W., "The French Stage in the Eighteenth Century" (London 1888); Joannides, "La Comédie Française 1680 à 1900" (Paris 1901); Lucas, "Histoire philosophique et littéraire du Théâtre Français" (Paris 1862); Pougin, A., "Dictionnaire historique et pittoresque du théâtre" (Paris 1888); Rigal, Eugène, "Les Théâtres de Paris 1548 à 1635" (Paris 1890); Soubies, A., "Almanach des Spectacles" (1890); Weiss, "Autour de la Comédie Française" (Paris 1892).

COMÉDIE HUMAINE, ú-mán, La, a series of novels by Balzac, so designated by their author, and intended to form a picture of the manners and morals of the period. The first volume of the "Comédie Humaine" appeared in 1829; but it was not until 1842 that Balzac adopted the general title. The author intended to present a panorama of his time in France, and he wrote nearly 100 novels without completing the herculean task he had set himself.

COMÉDIETTA, kó-má-dé-ťa (It. diminutive of comédie), a dramatic composition of the comic class, but not so much elaborated as a regular comedy, and generally consisting of one or at most two acts.

COMÉDONES, kóm-ë-dóns, a name applied to the little cylinders of sebaceous and epithelial substances which are apt to accumulate in the follicles of the skin and to appear on the surface as small round black spots. When squeezed out they have the appearance of minute maggots or grubs with black heads, and these have derived their name. They are generally associated with a weak state of the skin as well as of the individual. Generous diet and tonic treatment with soap-and-water cleansing and friction will be useful; as an astringent to invigorate a debilitated skin, a lotion of corrosive sublimate (two grains) in emulsion of bitter almonds (one ounce) and dilute alcohol will be effective. See ACNE.

COMEDY, a dramatic representation of a light and amusing nature, in which are satirized pleasantly the weaknesses or manners of society and the ludicrous incidents of life. Comedy took its origin in the Dionysian festivals, with those who led the phallic songs of the band of revelers (Gr. kômôs) who, at the vintage festivals, gave expression to the exuberant joy and merriment by parading about, dressed up, and singing jovial songs in honor of Dionysus. These songs were frequently interspersed with extempore jokes at the expense of the bystanders. Comedy first assumed a regular shape among the Dorians. The first attempts at it among the Athenians were made by Susarion, a native of Megara, about 578 B.C. Epicharmus first gave comedy a new form and introduced a regular plot. That branch of the comic drama known as the Old Comedy begins properly with Cratinus. It lasted from 458 B.C. to 404 B.C. The later pieces of Aristophanes belong to the Middle Comedy. The chorus in a comedy consisted of 24. The Middle Comedy lasted from 404 to 340, and the New Comedy till 260 B.C. Middle Comedy found its materials in satirizing classes of people instead of individuals. New Comedy answers to the comedy of the present day. The most distinguished of Roman comic writers were Plautus and Terence, whose plots were mainly derived from the Greek. See DRAMA; LITERARY FORMS.

COMEDY OF ERRORS, The, This, Shakespeare's shortest play, is certainly one of his earliest. Conservative modern critics are inclined to fix upon 1591 as the probable date of composition and to place it second only to 'Love's Labour's Lost' in the order of the poet's independent works. To the general reader the comedy is chiefly known as Shakespeare's solitary effort at direct imitation of a classic model; and the neglect it suffers may be due to the mistaken notion that it is no more than a free rendering of the 'Menæchmi' of Plautus. The idea of the indistinguishable Antipholus twins and the rough pattern of their adventures is to be sure derived from the 'Menæchmi,' and certain other points from a second Plautine play, the 'Amphitruo'—notably the situation in Act III, scene 1, where the true master and his slave are shut out of their house while their doubles play the part in plot, however, and in development the Shakespearean play invents more than it borrows, and it deserves respect as an instance of the same kind of treatment of sources which marks the poet's maturest work. Short as it is, 'The Comedy of Errors' is vastly richer and more varied than the 'Menæchmi.' The clever notion of duplicating the twin Antipholi by twin servants (the Dromios) tebiles the opportunity for mirthful misunderstandings, while the creation of the pathetic figures of the old father and mother and the charming sister-in-law, Luciana, introduces a depth of human feeling and a romantic atmosphere entirely alien to Plautus. The reader of 'The Comedy of Errors' will find many suggestions of later plays. Compare the old father Aëgeon with Egeus in 'A Midsummer Night's Dream'; the business of the chain with the trouble over the ring in 'The Merchant of Venice'; and note particularly the forecast of 'The Winter's Tale' in the story of the escape of the shipwrecked twins, their subsequent confusion and the episode of the supposed madman bound and laid...
in a dark room. An English translation of the 'Menechmi' was printed in 1595 and may conceivably have been accessible to Shakespeare in manuscript at an earlier date. It is quite likely that he got his general knowledge of this play as well as of the untranslated 'Amphitruo' while at school, where Plautus was often a regular subject of study. For the influence of Plautus on Shakespeare in his classical period, consult the introduction to M. W. Wallace's edition of 'The Birth of Hercules' (Chicago 1903). The 1595 translation of the 'Menechmi', with parallel Latin text and introduction, has been edited by W. H. D. Rouse in the 'Shakespeare Classics Series' (New York 1912).

TUCKER BROOKES, Assistant Professor of English, Yale University.

COMENIUS, kō-měn'sē-ē, or, KOMENSKY, Johann Amos, Moravian educational reformer; b. probably at Nitrnitz, Moravia, 28 March 1592; d. Amsterdam, 15 Oct. 1671. His family belonged to the sect of Moravian brethren. He studied at Hebron in Nassau and at Heidelberg. He became rector of a school at Hradec Králové, a position which he held till 1632. When the Church of the sect of his parents, accepted the position of pastor and rector at Fulnek. The plunder of that town by the Spaniards after the battle of Prague in 1620 cost him all his possessions and writings. He fled to Poland, where in 1632 he was elected bishop of his communion at Lissa. Here in 1630 was published his 'Pansophic prodomus', a work on education which attempted to organize all human knowledge within the reach of the minds of everyone. In 1631 there appeared his 'Janua Linguarum reserata', which outlined his method of teaching languages through the vernacular and by means of illustrations and object lessons. This work obtained widespread popularity and was translated into many European languages as well as into Persian, Arabic and Mongolian. His 'Orbis pictus' was an abridgment of the 'Janua' with many illustrated cuts for use by children, and was the first textbook of its kind. In 1635 he went to Sweden to plan a system of education for that country. In 1641 he visited England on a similar mission which was unsuccessful because the political upheaval made the time unsuited for reform of that sort. He therefore sailed for Amsterdam in 1642, and, with the assistance of Oxenstjerna, worked on plans for the curricula and management of the Swedish schools. At Elbing, in West Prussia, whither he went in the same year, he worked on further elaborations of his schemes; and then continued both this and his religious duties at Lissa (1654). In the war which followed, he again lost all his manuscripts, and was obliged to flee. He went to Amsterdam, where he remained for the rest of his life.

His educational theories were remarkably broad and inclusive. His system of schools has not yet been superseded in practice. His efforts were directed toward arousing the interest of the whole people in education. In addition to the arts and sciences, economy, politics, world history and science were included. Education was to him a means of interpreting and enlarging every-day experience by use of its own terms as well as by use of the classics. His writings on education are numerous. 'Didactica Magna', the most comprehensive of his publications, reveals his attempt to make a science of education by approaching it by the same method as that employed by the physical sciences. At the celebration of his tercentenary, a society was formed for the publication of his works. His place in the history of educational reform is well merited in spite of the weaknesses of his scientific basis.

As a theologian he was mystical, a believer in prophecies, dreams and revelations. Among his works in this field are 'Synopsis physica ad lumen divinum reformata'; and 'Lux in tenebris', a prophetic work. Comenius, Laurie, 'John Amos Comenius' (1881); Keatinge, 'The Great Didactic of Comenius' (London 1896), and Monroe, 'Comenius and the Beginning of Educational Reform' (New York 1903).

COMET (Greek, șhair, alluding to the luminous appendage or tail with which the brighter comets are always associated, and which formerly won for them the name of śhairy stars*). Comets may for convenience be divided into two classes, periodic and unperiodic. From the former one can find, from 3 to 4 of the latter, appear on the average every year, but the number varies greatly. In 1898 as many as 10 were discovered, 5 being found in 12 days. Of the 10, 7 were unexpected. Every comet, no matter how magnificent it may subsequently be, when first discovered, if remote from the sun, appears as a small, very faint, hazy ball. As it comes nearer it becomes brighter, and generally larger, although sometimes it contracts in size. If it is going to be a fine comet it gradually lengthens out, and develops a short tail. The tail rapidly brightens and lengthens as the comet approaches perihelion, as the point in its orbit is called where it is nearest the sun. If the earth is favorably situated the comet appears at its best a few days after the passage of perihelion, and then gradually fades out and disappears as it came. About one unexpected comet in eight is said to be an comet. The periodic comets move in elliptical orbits about the sun in planes not in general greatly inclined to the ecliptic. The longest period so far definitely known, that of Halley's comet, is 76 years. The unperiodic comets have no larger orbits, lying in all planes, with much longer periods. Many of them have a retrograde motion, and occasionally one visits the sun never again to return to it. When an unexpected comet arrives, its orbit is first computed from three observations made on different nights, on the assumption that it is moving in a parabolic orbit. If we are able to observe it through a long period we frequently find that its path differs slightly from a parabola. It is not likely that any comet moves in an exact parabola. If it moves a little slower than the parabolic velocity, its orbit is an ellipse, and the comet really becomes periodic, although it is not classified as such until it has been certainly idled, at another return. If it moves a little faster than the parabolic velocity, its orbit is a hyperbola, and the comet will recede into space never to return.

Shudul, comet happen to pass near one of the larger planets, the orbit may be somewhat changed by the approach and its speed may be
either increased or diminished. In this manner new members of the periodic class of comets are from time to time added to the list. On the other hand, its velocity may be so far accelerated as to change its orbit, or even drive it out of our system, never to return to it. In this way some of the members of our periodic family of comets are subject to change; others, however, have been permanently added to the solar system. Out of 33 well-known periodic comets 24 have, or did have, periods lying between five and nine years. Many of these were doubtless brought into our system by the giant planet Jupiter. Some of them have already disappeared, owing to a change in their orbits, while some have lost a large part of their gaseous constituents and thus become invisible.

This last statement naturally brings us to the question, What is a comet? In early times comets were supposed to be objects within our own atmosphere, presaging famines, wars and the death of kings. It was first shown by Ptolemy that they are bodies independent of the earth, and Newton proved that, excepting their tails, they were bodies subject to the law of gravitation. In the middle of the last century it was shown by H. A. Newton, Schiaparelli and others that our comets move with such great velocity as to make the moon's orbit and 14 November, were due to great swarms of meteoric bodies moving in elliptical orbits, practically coincident with the orbits of two well-known periodic comets, 1862, III (Tuttle's), and 1866, I (Tempel's).

In several instances two or more comets are known to be following practically the same path, and it was but a step from this to see that the head of a comet was only a concentrated swarm of meteorites. It is only within the last few years, however, that we have begun to understand the nature of a comet's tail. That it is matter in a state of extreme tenuity is obvious, since, when millions of miles of it is interposed between us and the faintest stars, they are still visible and practically undimmed. What has puzzled astronomers since the time of Newton, however, is the fact that while all other bodies in the sidereal universe, as far as we are aware, obey the law of gravitation, comets are not subject to it. It is this repulsive force, which drives the matter composing them away from the sun with enormous high velocities. The tail, therefore, always lies outside of the comet's orbit, being somewhat behind the comet when the latter is approaching the sun, and somewhat in advance of it when the comet is receding.

That the tail is gaseous is proved conclusively by the spectroscopic method; also that it is in an extremely rarified condition; but why the external atmosphere should act in any way differently under the law of gravitation from the larger meteoric masses which constitute the head of the comet is not at first sight obvious. If, however, we consider the matter carefully, we shall see that if all objects are attracted to the sun in proportion to their mass, and repelled from it in proportion to their surface, then the attraction will vary as the cube of the diameter of the objects and with the square as the mass. For objects of ordinary size the repulsion is so slight that we cannot detect it; but if the object becomes gradually smaller, the attraction of the mass will diminish much more rapidly than the repulsion on the surface, and a time will come when they will be equal, and if the particle becomes still smaller, the repulsion must exceed the attractive force. It therefore becomes evident that if such a repulsive force existed, and if the gaseous molecules were sufficiently small, we should have an effect exactly like that which we observe.

It has been shown by J. J. Thomson (Proceeding of the Royal Society, 1890, No. 350) that if hydrogen gas is electrified positively, the green line in its spectrum will be brighter than the red, and, on the other hand, if negatively charged, the red will be brighter than the green. In the case of the sun the red is the brighter line, so that we may infer that the solar surface is charged negatively.

It is a well-known fact that if the ultraviolet rays of the spectrum be allowed to fall upon a metallic body little corpuscles or electrons leave the atoms forming the metallic body and fly away at the same velocity. These corpuscles either carry a negative charge of electricity, or what is perhaps more probable, constitute the negative electricity itself. The atoms lacking these corpuscles are as we usually express it positively charged.

Surrounding the head of a comet are a cloud of gases and dust, and a tail pointing away from the sun. The sun is the source of the gases, which form the comet's head as a mass of gas. When a flying corpuscle comes in contact with a molecule of this gas the two unite, the molecule becomes negatively charged, and both being repelled by the negatively charged sun, recede from it. The subject will be found treated in more detail by R. A. Fessenden, Astrophysical Journal, III, 36. He there computes the potential of the sun's surface at about 15,000 volts. According to Arrhenius and Thomson the corpuscles which constantly deliver a negative charge to the earth, and would therefore also deliver it to a comet, proceed directly from the sun. The tail probably receives a charge from both these sources, but the latter would seem to be much the more effective of the two.

The question may now naturally be asked, since there is an abundance of extremely rarefied gas at an altitude of a few hundred miles above to some strong electrical field, why are we too are exposed to the flying corpuscles, why is not the earth itself provided with a comet-like tail? In answer we reply that at certain times it is. Annals of Harvard Observatory, XXXII, 288. Our great auroras are indeed nothing else than the appearance of a small cometary tail. These great auroras, which exist at an altitude of several hundred miles, and envelope the whole earth, must not be confounded with the small but intensely brilliant local auroras always existing at low altitudes in the polar regions.

The reason that these great auroras only reach an altitude of a few hundred miles, instead of several millions, like the tail of a comet, is on account of the great mass of the earth, which does not permit the electrified gases to escape from it. The great auroras exhibit two notable characteristics. They appear only when the electro-magnetic condition of the sun is greatly perturbed, and they are most conspicuous at those times when the sun is approaching or receding most rapidly from it; that is, at the end of March and September.
COMET

The same appears to be true of comets. The longest tails belong to those comets that approach the earth at an acute angle; and these tails are the most luminous. If the comet’s tail consists of a more or less continuous stream of meteors enveloped in gas and dust and that the tail is a current of gas and sometimes dust proceeding from the head, being most pronounced when the comet crosses the greatest number of electro-magnetic equipotential surfaces, then the elongation of the comet’s tail may be explained. We may therefore say that the most probable explanation of a comet-like tail is the great elongation of the comet’s tail. The shape and size of the tail enable us to compute the intensity of the repulsive force causing the tail to recede from the sun. This was done by Bredichin, who divided all comets’ tails into three classes according to the sharpness of their curvature, and suggested that the sharpness of the curve indicated the atomic weight and therefore the general chemical constitution of the matter forming the tail. This last suggestion is open to doubt.

More recently, by means of photography, we have been enabled to detect condensed areas in the tails of certain comets, and by comparing the photographs upon successive nights we have measured directly the speed of recession of the particles forming the comet’s tail. The comet’s tail is the most luminous part of the comet. Two comets so far have been measured in this manner that of 1892 I (Swift’s), by the writer, and that of 1893 II (Rordam’s), by Hussey. The comet of 1892 the repulsive force was 39.5 times that of gravity. In the case of the comet of 1893, the repulsive force was 86 times as great. (Pub. Astron. Soc. Pac., VII, 150, 185, portions of the tail at times receding with a velocity exceeding 150,000 miles an hour. A remarkable behavior of a part of the material composing the tail was observed in the bright comet Moorhouse, during the month of October 1906. Two great cloudlike knots appeared, an approximately normal, fan-shaped tail extending outward from the first knot, and the second being merely connected to the comet’s head by a narrow band of luminous matter. It was evident that for some cause the great repulsion of matter had almost ceased for a short time; the matter already in the condensation had receded some distance when a second active repulsion took place, thus pushing away the second condensation. The latter was found to be receding with a speed of 95,000 miles an hour, which was 10,000 miles greater than the rate of recession of the first. It was this fact, combined with the forward motion of the comet itself in its orbit, that caused the two clouds of material to be seen later side by side in the interrupted tail. It has become evident from this and from several other anomalous cases that comets’ tails are not due to simple light pressure, or to the comets passing steadily into regions of higher or lower electric potential, and for that the tail must be of a very complicated nature.

Since the gaseous particles receding from a comet’s head can never again return to it and since a comet is visible to us chiefly, and generally, by the electrical illumination of this gaseous medium, it is very probable that the tail we shall hardly expect to distinguish the solar lines, but a distribution of photographic intensity in the spectrum similar to that which we find in the sun might be accepted as very close to the sun’s surface, and the head. Such a distribution was found in the case of the bright comet of 1811 III.
by the tail, which neutralizes the gravitation—or pull of the various portions of the comet's head for one another—and therefore permits those portions of the meteoric swarm which are nearest to the sun to move at a higher speed than those portions which are more remote. In cases, like those of the distribution extends throughout the orbit, with but one luminous condensation, known as the comet of 1862 III. In other cases there are two or more condensations. Thus Biela's comet was seen to split into two parts. Four distinct comets were found following in the track of the great comet of 1668.

We must now discuss the important question of the origin of comets. It is known that the sun, with its attendant planets, is traversing space in the direction of the constellation Lyra at a speed of about 11 miles per second. If comets come from remote interstellar space, or from the other stars, it is obvious that we should meet more comets coming from Lyra than would overtake us coming from the opposite direction. Also that those comets we met would have a greater velocity relative to the sun than would those that might overtake us. Nothing of the sort is found, however, in the distribution of its uniform in all directions. There is but one conclusion to be drawn from this, and that is that all the comets that we have observed possess the same common speed as the sun, omitting relative motion, and travel in the same direction. In short, they are all of them parts of the same original gaseous mass from which the solar system condensed, being merely those portions which were originally left on the outside, before the great common rotation was established, and which now occasionally drop in toward the centre, and then fly back again to their original position on the outskirts of the system. The normal path of every comet is therefore an ellipse. If the paths of some comets have become slightly hyperbolic through the action of some outside body, they can never again visit the sun. As we have just seen, a comet not belonging to our system would be most likely to approach us from the general direction of the constellation Lyra. We come out of it with a much greater velocity. We are acquainted with the orbits of about 400 comets, but no such body is certainly found among them.

From this point of view it is interesting to determine of what chemical elements comets are composed. To this the spectroscope gives a ready answer, and shows that by far the most common elements are hydrogen and carbon in chemical combination. This answer, however, is only a partial one, because most comets do not approach sufficiently near to the sun to enable their more refractory elements to be volatilized. The bright small comet of 1882 I (Wells') approached so close to the solar surface that the distance at perihelion amounted to only about 3,000,000 miles. Only one of its metallic constituents were accordingly vaporized, the most prominent of them being sodium. The great comet of 1882 III approached within 300,000 miles of the sun's surface. This was so near that not only the sodium but even some of the iron lines appeared in its spectrum. This is what we should have expected, judging by the chemical composition of most of the meteors that reach the earth's surface. We thus see that incidentally comets are able to give us information regarding the temperature that bodies would attain at different distances from the sun. When the metallic lines are present in the spectra of these comets the carbon bands vanish. This is precisely the effect that is produced in our laboratories when the cause of the illumination is an electric current. The current by preference selects the molecules which are the best conductors. If the illumination of the comet were due merely to heat, there is no doubt that the carbon bands should have disappeared.

Few persons now living remember distinctly the great comet of 1843. It appeared suddenly in the northern hemisphere about the middle of March, and was not long visible. It was notable for the great length of its tail and its small perihelion distance,—the smallest on record. This amounted to only 511,000 miles. Its centre therefore came within 78,000, and the nearer side of its head within 32,000, miles of the sun's surface.

The great comet of 1858, known generally at Donati's, was a magnificent object. Not only was it a fine comet in itself, but it seems as if everything conspired to enable it to be well seen from the earth. The comet, from its unique position in the northern sky during the early evenings in October, and was nearest us shortly after the passage of perihelion. Its tail reached a length of 60 degrees and swept as a broad curved plume across the heavens. It was visible for several months, which enabled it to be carefully observed, and there is no doubt but that it moves in an elliptic orbit. Its period is about 2,000 years.

The great comet of 1861 was discovered by Tabbott in Australia. It appeared suddenly in the northern hemisphere at the end of June and, according to Sir John Herschel, was the brightest comet of the century up to that time. It was not long visible.

The great comet of 1882 was remarkable on many accounts. In the first place it was shown to be one of a group of five comets all following nearly in the same orbit. The four others were those of 1668, 1843, 1880 and 1887. The last was one of the highest hyperbolic velocity. The others were all notable. The nucleus of the comet of 1882 moreover showed a tendency to fall apart, five different condensations in it being visible at once. Schmidt, Barnard and Brooks all noticed small companion nebulous in the immediate vicinity of the comet and moving with it. It was visible for about nine months—an unusually long interval, and in this time it traversed 340 degrees of its orbit. It clearly follows an elliptical path with a period which lies between 772 and 1,000 years. The tail was very extraordinary. It measured about 200,000,000 miles in length, and was strongly forked at the end. Moreover it was accompanied by a clearly seen but filmy sheath of light, extending three or four degrees toward the sun. The whole comet was surrounded by an elliptical envelope of enormous dimensions and of a still more filmy nature. That this most remarkable object was not more generally observed is probably due to a combination of the fact that it was visible only in the early morning hours. It was certainly the brightest comet of the century, and it was so bright that it was watched in perihelion passage until in
contact with the sun's limb, when it suddenly disappeared, being too filmy a nature to be detected on the sun's surface. For three days it was visible to the naked eye with the sun above the horizon. There have been so far 14 different comets placed on record which were bright enough to be seen under these circumstances. Turning now to the periodic comets; by far the finest is Halley's. Our first record of it is chief reason for its relative faintness in 1835 is that the material which formed the tail has been largely used up by the frequent visits to the sun, and that it will thus never again present the brilliancy of its past appearances. An account of its last appearance is given below. The following table of the elements of the orbits of the periodic comets has been condensed and brought up to date from Holm's tables of periodic comets:

</table>

The question is often asked the astronomer, what would happen if the earth should come into collision with a comet? As far as the tail is concerned, that is probably a frequent occurrence. It happened twice during the last century, in the case of the comets of 1819 II and 1861 II, and it probably occurred also during the apparition of Halley's comet in 1910, but in no case were any particular effects observed. Should we come into contact with the head of a small comet there would undoubtedly be a fine meteoric display. That is in fact what probably happened in 1833, and also on a number of previous occasions, notably in 472, 902, 1029, 1302 and 1799, although the comet itself was not luminous. If the comet were moving rapidly with regard to the earth, as in these cases, the meteor would be consumed at a great altitude in our atmosphere, and no harm would be done. If the comet were moving in the same direction as ourselves, however, and at about the same speed, the matter would then become more serious, as many of the meteors might reach the earth's surface.

The self-luminous, and therefore visible comet, which has escaped the earth, as far as we are aware, was that of 1770 I (Lexell's). It approached within 1,400,000 miles, or six times the distance of the moon. Its head appeared about four times the diameter of the moon, but its mass was imperceptibly small. Should the earth strike the nucleus of a
COMET — COMETS

great comet, like that, for instance, of 1858, it is impossible to foretell what would happen, but possibly the temperature and shock would be such that all life within several thousand miles of the point of contact would become extinct. Considering the vast recesses of celestial space, lighter than the tiniest speck of dust, the probability of such an encounter is almost infinitely small.

For a more detailed account of the individual peculiarities of the more interesting comets, see Clerke's 'History of Astronomy'; Chambers' 'Story of the Comets' (1910).

WILLIAM H. PICKERING.
Harvard College Observatory.

COMET, in ornithology, one of a group of humming-birds with long forked tails. One of the most imposing of all humming-birds is the Sappho, or Cotes Sappho, or bar-tailed humming-bird, native to Bolivia, but migratory, and in the winter generally visiting eastern Peru. Specimens are secured only with great difficulty, owing to the rapidity of the complex evolutions of the bird when on the wing. The mounted examples, gorgeous as they are, do not convey an adequate idea of the brilliancy of the plumage. The Phaon comet (Cometes Phaon) is equally magnificent, but larger. It also inhabits Peru and Bolivia. It is distinguished from the Sappho comet by the fact that the tail is wholly crimson red, while that of the Sappho comet is ruddy brown at the base and tipped with a black band. See HUMMING-BIRDS.

COMETAS, called SCHOLASTICUS, Greek author, generally assigned to the 9th century A.D., although his time is doubtful. There are extant of his works a paraphrase of part of the 11th chapter of Saint John's Gospel, in 57 hexameter verses, and six epigrams in the Greek Anthology. It appears from some of these epigrams that he made a new recension of the Homeric poems, effecting radical changes for the better in the punctuation. Clemens Alexandrinus refers to a Cometas of Crete as a commentator on Homer. By some he has been identified with the Cometas who was made professor of grammar at Constantinople in 850.

COMETS, 1910A and Halley's.—During the year 1910 two brilliant comets appeared which excited world-wide popular interest — the first being a new comet known as 1910A, the second the celebrated comet of Halley. We shall add a brief account of these remarkable objects. Comet 1910A belonged to the group of great southern comets, and was discovered in South Africa about 15 January. On 16 January the startling news that a comet visible to the naked eye was near the sun was cabled to Europe by Director Innes of the Transit Circle Observatory in Johannesburg, and thence telegraphed to all observatories. Wherever the weather was clear astronomers scanned the region about the sun with eager interest, as this was the first naked-eye comet to appear so suddenly since the great comet of 1882, which was also a southern comet, announced in the same way. At Lick Observatory, California, the comet was promptly observed by Aitken and Wright, the latter working with the spectroheliograph and finding a abundance of sodium vapor in the brilliant head, which rivaled Venus in splendor. It was also observed at the Lowell and Harvard observatories; and at the Yerkes Observatory by Barnard, as well as at several observatories in Europe. In a few days an orbit was computed by Kobold, editor of the Astronomische Nachrichten, in Kiel, Germany. This showed that the comet had passed perihelion on 17 January, at a distance of some 4,000,000 miles from the sun's centre, and would rapidly decrease in brightness. The passage so near to the sun had exposed the comet to a terrific radiation and produced the brilliant tail with sodium vapor in the head. During the latter part of January and early part of February the comet hung in the western sky in the form of a great plume, with curved tail some 30 degrees long; and it was observed by all classes of people on sea and land. As Halley's comet was expected and had been much talked of, 1910A was at first taken to be this celebrated historical object; but the confusion of thought was soon removed, and the new comet popularly described as a "tramp" comet which had unexpectedly come along, and occupied the centre of the stage. In the stage was the comet hove in sight to the ordinary citizen watchet of the skies.

The question may be asked: Why did not astronomers detect 1910A till it got so near the sun? To this we answer that the comet had approached the sun from behind, and thus it had been constantly obscured by the sun's rays, and only became visible when its head had attained splendor comparable to that of the planet Venus. Comets which approach the sun from the further side usually are invisible unless they are quite brilliant. On more than one occasion astronomers have been astonished at noticing a small comet near the sun during a total eclipse; but where it is not brilliant enough to observe by daylight, even with the telescope, such an object is again lost as soon as the eclipse is over, and thus the orbit of such eclipse comets cannot be determined.

The apparition of Halley's comet during 1910 had long been looked forward to by astronomers. Some three years before the expected return, astronomers Cowell and Cromelin of the Greenwich Observatory took up the problem of laboriously calculating the effect of the perturbations of other planets on the last appearance of this comet in 1835. These skillful mathematicians calculated an ephemera which enabled the astronomer to point his telescope toward the region where the comet was known to be long before it got near enough to the sun to become visible even with the most powerful of modern instruments. Finally, on 11 Sept. 1909, Dr. Max Wolf, of the Heidelberg Observatory, photographed the predicted region for Halley's comet, using a wide field, and sensitive plates, and found no comet. On developing the plate he found on it a small blotch, the first such record ever made of Halley's comet, photography having been invented since the last appearance of the comet in 1835. The comet was found to be very near the place predicted by Cowell and Cromelin, with an outstanding error not exceeding 4 minutes of arc, or one-eighth of the diameter of the moon. This was a splendid triumph for mathematical astronomy.

The plate of the comet being thus detected by photography, Prof. S. W. Burnham was able to see it a few days later with the 40-inch
refractor of the Yerkes Observatory, Chicago, and it was soon under the scrutiny of hundreds of telescopes in all parts of the world. When first detected Halley's comet was about half way to the orbit of Jupiter; at this great distance both from the sun and from the earth it appeared Time and this was due to perihelion 20 April 1910, and astronomers made extensive preparations to observe it over as long a period as possible. Special calculations on the perturbative effects of Mars, the Earth and Venus were made by Professors Leuschner and Crawford, of the University of California, in order to determine the exact time of the expected transit of the comet's head over the sun's disc, 18 May 1910.

The transit of a comet over the sun is a very extraordinary phenomenon—only one other, that of the great comet of 1882, having ever been observed—and as such a thing is not likely to happen more than once in a century, it was felt that every effort should be made, in the hope of finding out whether there is any solid matter in the head of a comet. The calculations of Leuschner and Crawford showed that the transit would begin a little before 8 P.M. of 18 May, Pacific Standard Time, and thus after the sun had set on the Pacific Coast of the United States; so that the transit could be observed only from the islands of the Pacific and the East Indies and Australia. Mr. Ellermann of the Mount Wilson Solar Observatory was sent to Honolulu to observe the transit; and it was subsequently looked for also by Father Aigue at Manila, and by several observers in Australia. None of these observers, however, could detect any trace of the comet passing over the sun. In transit Halley's comet must have totally disappeared, just as happened also when the great comet of 17 Sept. 1882 was noticed by astronomers at the Cape of Good Hope to vanish the instant it entered upon the sun's disc, so that they thought it had gone behind the sun. The conclusion to be drawn from the failure of these two comets to become visible on the sun's disc is that the heads of the comets are such rare, unsubstantial masses that they do not sensibly obstruct the sun's light, and that if solid nuclei exist, they must be too small to be noticed. This confirms our general experience that comets are very unsubstantial bodies.

One other result of considerable interest was the detection by Lowell of hydrogen monoxide as the chief constituent of the tail of Halley's comet. Hydrocarbons, cyanogen and other gases were found in the head.

Just before the transit the earth was expected to pass through the tail, and popular alarm existed lest some harmful results might ensue. The length of the tail was at the maximum from 100 degrees to 120 degrees in length. It stretched across the morning sky, from Pisces to Ophiuchus, like a great searchlight, having an extreme width of perhaps 10 degrees. After the transit of 18 May it was still visible for a day or two in the morning sky, which was explained by the usual backward curvature of the tail.

No sensible effect from the passage of the earth through the edge of the tail could be detected, though it was watched for by astronomers throughout the world. Innens of Johannesburg has made it probable that a slight electric charge borne by the earth's atmosphere tended to scatter the tail as it neared our planet, so that hereafter comet's tails will have less terror for the people than heretofore. No harmful effects of any kind from the appearance of Halley's comet could be observed, and the popular excitement rapidly died away. Altogether Halley's comet proved to be the most interesting object of this kind which has appeared since Donati's great comet of 1858.

T. J. J. See, Professor of Mathematics, Naval Observatory, Mare Island, Cal.

COMETTANT, kö-mêt-tän', Oscar, French musician, composer and author: b. Bordeaux, 18 April 1819; d. Montivilliers 1898. He was a pupil of Elwart and Carafa at the Conservatoire, and first became known as a pianist; he also wrote several works for the piano, duets for violin and piano, and choruses and songs. Among the piano compositions were 'Robert Bruce' and 'Le jui f errant'; the vocal included 'L'Alboni' and 'L'Inde révoltée.' For many years he was musical director at the Opéra, and he was also a contributor to the Ménestrel, the Gazette Musicale, and other journals of music. A great traveler, he visited the United States and wrote a book of impressions, 'Trois Ans aux Etats-Unis' (1857). Among his further works, most of which are marked by a humorous and brilliant style, are 'Les civilisations inconnues' (1863); 'Le Danemark tel qu'il est' (1865); 'La musique, les musiciens, et les instruments de musique' (1870); and 'Francis Plante' (1874).

COMFORT, George Fisk, American scholar and educator: b. Berkshire, Tompkins County, N. Y., 20 Sept. 1833; d. Syracuse, N. Y., 1910. Graduated from Wesleyan University in 1857, he studied archaeology and the history of the fine arts in Europe, in 1865-66 was professor of modern languages and aesthetics in Allegheny College (Meadville, Pa.), and in 1868-72 lecturer on Christian art and archaeology in the Drew Theological Seminary (Madinon, N. J.). In 1872 he was appointed professor of modern languages and art history in the newly established Syracuse University, where he organized the college of fine arts, of which he was dean from 1873 to 1893. In the latter year he became president of the Southern College of Fine Arts, at La Porte, Tex. He organized the Syracuse Museum of Fine Arts in 1866, and became its director. He was also one of the chief organizers of the American Philological Association, and from 1869 to 1874 its secretary. From 1872 to 1893 he was editor of the art department of the Northern Christian Advocate. He also contributed extensively to periodicals, and published 'Art Museums in America' (1869); 'Modern Languages in Education' (1866); 'Woman's Education and Woman's Health' (1894); 'The Land Tenures in Ireland' (1898), and a series of German textbooks.

COMPREY, köm'prä, the common name of the genus symphytum of the natural order Boraginaceae or Borage family. There are about 20 species, all natives of the Old World, where many of them are used in household medicine or for forage plants. Attempts have been made to naturalize them in America for commercial purposes, but the experiments have not given
much promise of success. There is but one known American species growing wild, S. officinale, naturalized from Europe or Asia. It is a coarse perennial weed, from two to three feet high, with yellow flowers. The thick roots are mucilaginous, and are supposed to have medicinal virtues as a cure for diarrhea. It is known also as blackwort, bruisewort and boneset. In England the leaves, gathered while young, are sometimes used as a substitute for spinach, and some people of unrefined taste eat the young shoots after blanching them by forcing them to grow through heaps of earth. Comfrey stews in sugar, with a small amount of paregoric added, makes a highly prized domestic remedy for coughs and bronchial irritations.

COMINES, kō-mēn, Commines, or COMYNES, Philippe de, French statesman and historian: b. Comines near Lille 1445; d. Argenton, 18 Oct. 1509. He stood high in the favor of Charles of Burgundy, afterward Charles the Bold, and on occasion of Louis XI's imprisonment by Charles at Péronne, succeeded in bringing about a treaty of peace between them. In 1472 he forsook the cause of the Duke of Burgundy and became councillor and chamberlain of Louis XI, who compensated him so amply for the loss of his property, which had been confiscated by Charles, that he soon became one of the most wealthy and influential noblemen in France. The death of Louis, however, proved fatal to his fortunes. He was no favorite with Anne de Beaujeu, the regent, and was imprisoned on a charge of conspiracy against her. On the accession of Charles VIII, however, he was again employed in the public service, but went into retirement after the advent of Louis XII, who seemed reluctant to favor him, although he left him in possession of a pension. The fame of Comines rests not only upon his astuteness as a statesman, but still more upon his Mémoires, which give a complete view of the political affairs of his time, and present a vivid picture of the character of Louis XI. They have been frequently printed. Lenglet-Dufresnoy's edition (London 1747) is still sought for, especially on account of its annotations; but the best are those published by Mlle. Dupin (Paris 1840-47), and Chantelauze (1881). Comines figures in Sir Walter Scott's romance of 'Quentin Durward.'

COMING RACE, The, a story by Edward Bulwer-Lytton, published in 1871. It was a skit at certain assumptions of science; but its clever invention and brilliant treatment, added to the craving wonder of humanity as to what its evolution is to be toward, gave it a large popularity.

COMITAT, kōm·tət (L. comitatus), that which went with or accompanied the name given to administrative districts of some size into which Hungary and Transylvania are divided. In old English law comitat, of which comitat is a contraction, was a county or shire. The comitatus were the personal followers of the king or earl, and the county or shire was the land of the comitatus or comitat. Hence the present use of the term in various European countries in the sense of a division of land.

COMITIA, kō-mish·tə (Lat. assemblies), with the Romans, the assemblies of the people in which the public business was transacted, and measures taken in conformity with the will of the majority. They existed even under the kings. In the time of the republic they were convoked by the dictator, the tribunes, and in extraordinary cases even by the pontifex maximus. There were three comitia among the Romans, which were called comitia curiata, comitia centuriata and comitia tributa. (1) The oldest of these was the comitia curiata, so called because in it the people voted by curiae or wards. It consisted exclusively of the patricians, the original ruling class at Rome, and the class to which the name of populus was at first restricted. They were divided into the three tribes, the Luceres, Ramnes and Tities, each of which was divided into io curiae, so that there were 30 curiae who voted in the comitia curiata. (2) The comitia centuriata was a mixed assembly of the patricians and plebeians, in which the people voted by centuries, as these had been formed by Servius Tullius. On the institution of this comitia the principal privileges of the comitia curiata were transferred to it, and in course of time the functions of the latter became a formality, so that even before the time of Cicero these were not performed by the curiae themselves, but by 30 lectors representing them. The rights of the comitia centuriata were thus very important, comprising the right of electing the higher magistrates, the right of passing or rejecting laws proposed to them, the right of deciding upon war on the ground of a senatus consultum or decree of the Senate, and the highest judicial power. This comitia could be held only on certain days, and it must be summoned 17 days before the day of meeting. On the day of the comitia itself the presiding magistrate, with an augur, went into a tent before the city in order to observe the auspices. If the augur declared them unexceptionable, the comitia was held; if not, it was postponed to another day. Before sunrise and after sunset no business was transacted in the comitia. The presiding magistrate, on his curule chair, opened the assembly by a prayer which was repeated after the words of the augur. In earlier times, first the equites, then the centuries of the first class, etc., were called upon to vote. In later times lots were cast for the order of voting. The opinion of the centuries which first voted was usually followed by all the rest. In the earliest times every century voted verbally; in later times by ballot. What was concluded in each century by the majority was proclaimed by the herald as the vote of the century. The comitia was interrupted if any one in the assembly was attacked by a fit of epilepsy (which was called for this reason morbus comitis), or if a tribune of the people pronounced his veto, and under some other circumstances. (3) The other comitia, the comitia tributa, was also an institution of Servius Tullius, was essentially plebeian in its nature, for if the patricians were not, as some think, entirely excluded from it, they were in so small a minority that their influence was scarcely felt. It was based upon the division which Servius Tullius made of the whole Roman territory into 30 local tribes, which were afterward increased to 35. Its power was at first very limited, being merely local, but it gradually increased, so that it in the end came to possess the right of exercis-
COMITIUM—COMMANDER OF THE FAITHFUL

ing electoral, legislative and judicial functions, though not so extensive as those of the comitia centuriiata; it had the right of electing only the inferior magistrates; legislatively, it was merely entitled to pass resolutions proposed by the tribunes, which before becoming law had to be sanctioned by the Senate; judicially, it had the right of trying only those who had committed offenses against the majesty of the people, and the only punishment it could inflict was a fine. It might assemble either within or without the walls of the city, but not at a greater distance than 1,000 paces, which was the limit of the power of the tribunes. The comitia centuriiata, on the other hand, always met in the Campus Martius. Sometimes the comitia centuriiata was mixed with the comitia tributa, but in what manner it is not known. The emperors retained these assemblies for the sake of appearance, but used them only as instruments for the accomplishment of their purposes. Con- sult Greenidge, 'Roman Public Life' (London 1901); Botsford, 'The Roman Assemblies' (New York 1909); Mommsen, 'Römische Forschungen' (Berlin 1879).

COMITIUM (Lat. "place of assembly"), a square in the ancient city of Rome between the Curia and the Forum, where the comitia curiata (q.v.) met. It contained the original rostrum or speakers' platform.

COMITLAN, kö-mē-šān, or COMITAN, kö-mē-ān, town in the state of Chia- pas, on the Grijalva River, 35 miles southeast of San Cristóbal. It has a magnificent church and is a place of considerable trade. The town is largely engaged in agriculture and cattle raising, but has manufactures of cotton and woolen goods, liquors, etc. It is supported chiefly by contraband trade with Guatemala and British Honduras, as the duties on foreign goods are excessive. Comitlán suffered considerably from the raids of Juan Ortega in 1853-64. Pop. 10,196.

COMITY OF NATIONS (very frequently mentioned by its Latin equivalent, comitas gentium), the international courtesy by which effect is given to the laws of one state within the territory and against the citizens of another state, in the silence of any positive rule, says Story, "affirming, or denying, or restraining the operation of foreign laws, courts of justice presume the tacit adoption of them by their own government, unless they are repugnant to its policy or prejudicial to its interests." The comity of nations rests upon common consent of the nations themselves and not upon positive law. In the United States the provisions of the constitution cover explicitly the question of comity between the States of the Union, in Art. IV, Sec. 1, which reads as follows: "Full faith and credit shall be given in each State to the public acts, records and judicial proceedings of every other State. This, however, only applies where a State has a right to act or render judgment for the federation. Consult Story, 'Conflict of Laws.'

COMLY, Samuel Pancost, American naval officer: b. Woodbury, N. J., 13 July 1849. He was graduated at the United States Naval Academy in 1869. He was promoted through the various grades, became captain in 1900, and rear-admiral in 1909. He was the

Juniata in the Polaris search expedition of 1874. During the Spanish-American War he was in action at San Juan, P. R., and at the destruction of Cervera's fleet, 3 July 1898. In 1905-07 he commanded the Alabama and in 1910 commanded a division of the Atlantic fleet. In 1910-11 he was on cruises on martial duty and was retired the latter year.

COMMA, the stroke or mark used in writing and printing to separate from each other phrases and clauses in a sentence. The word is of Greek origin and is the noun of the verb kópto, to cut; hence literally comma is section, and in grammatical works written in Greek and Latin comma or its diminutive kómmation means a clause in a period as well as the punctuation mark, and in prosody the casura. In German typography the punctuation mark comma is a downward short stroke from right to left (/).

COMMA BACILLUS. See CHOLERA.

COMMAGENE, köm-a-jē-ān, in ancient times a district in the north of Syria, bounded on the east by the Euphrates, on the north by Mount Amanus and on the west by Cilicia, for some time attached to the kingdom of the Seleucids, but afterward for more than 100 years an independent state. It seems to have become independent about 100 B.C., and on the death of its fifth king, Antiochus III, in 17 A.D., it was made a Roman province. It was again for a time allowed by the Romans to hold a position of nominal independence, but was reduced to a Roman province by Vespasian, 73 A.D.

COMMANDER-IN-CHIEF, the supreme commander of the united forces of any country. In the United States the President is commander-in-chief of the army and navy, and of the militia of the several States when the latter is in the national service and forms part of the national provisional army. In all other cases the governor of each State is the commander-in-chief of the State troops. In England he is officially called the officer commanding-in-chief. He is the head of a department of the military administration. He acts, under the Secretary of State for War, as the head of the army, and when military operations are undertaken on a sufficiently large scale to require his presence, is charged with the duty of commanding the army in the field, though, as a matter of fact, this very rarely occurs. In Germany the emperor is the supreme commander-in-chief of the army and navy. The British sovereign, while he talks of "my army and my navy," has little or nothing to do with the chief command of military or naval matters, which are in the hands of a war council. Even the title of commander-in-chief of his majesty's forces was abolished in 1904, since which date there has been no holder, in deputy, of the once regal title of commander of the forces on land and sea of the nation. The Secretary of State, as head of the war council, is now responsible to the Crown and Parliament for the conduct of military affairs.

COMMANDER OF THE FAITHFUL, a title assumed by the Caliph Omar, father-in-law ofMohammed and retained by his successors. See CAHIF.
COMMENDAM ISLANDS—COMMENEMATION ODE

COMMENDAM ISLANDS, two islands belonging to Russia lying east of Kamchatka in Bering Sea. The larger, Bering Island (q.v.), lies nearest the coast; the other island of the group, Miedni, is nearly 30 miles long but narrow; it is sometimes called Copper Island, because copper is found there in small quantities. The climate is mild and there are few inhabitants.

COMMANDERY. (1) Among the Knights Templar, Hospitallers, etc., a district under the administration and control of a member of the order, called the commander or preceptor, who received the income of the estates within that district, expending part for his own use and accounting for the rest. In England more especially applied to a manor belonging to the Knights Hospitallers or Knights of Saint John of Jerusalem. These establishments formed at the same time branches. On the first creation of these (branch) establishments they were extinction. A commander, the superior being called the preceptor; but eventually the name became changed to that of commander by which they were always afterward known. The council reserved to themselves the power of at any time recalling a commander from his post and substituting another in his place, he being merely considered as the steward of their property. Time, however, gradually wrought a great change in the relative position which the commanders held to the council; and, eventually, a nomination to a commander came to be considered in the light of a legal acquisition, subject only to the payment of a certain amount of annual tribute to the public treasury, which tribute received the name of Responsions. (2) A regular assembly of Knights Templar, which confers certain degrees. Consult "History of Knights of Malta."

COMMANDING OFFICER. (1) In military service, the senior officer of a regiment, corps, post or detachment, where there is no higher local authority, is regarded as the commanding officer. (2) The officer in actual command of a vessel of war. He is an officer of the executive corps and is usually addressed by the courtesy title of "captain" without regard to actual rank, provided he is permanently in command and not in charge temporarily during the absence of a senior. The commanding officer of a modern battleship is responsible for the safety of ship and crew and for the proper care of batteries, engines and other machinery.

COMMENDITE, kóm-món-dét', En, a term used in France, primarily for a partnership or firm, in which one advances the funds, while another devotes his skill and assiduity; but by extension, a partnership in commandite often means a company for manufacturing or trading, "with limited liability." In terms of French commercial law, those whom we would call the sleeping partners or silent partners in such associations are denominated commanditaires. Their names do not appear in the nominal title of the firm; they may assist it with their counsel, but they cannot order or sign for its benefit, nor act overtly for it in any way; on the other hand, they are not bound to incur a final loss in case of its failure beyond that of the entire sum they have advanced, should indeed such be needed to satisfy the claims of agents and creditors. For all details on the rights and obligations of commanditaires, consult the French 'Code de Commerce,' articles 23-28.

COMMELIN, kóm-lín', Hieronymus, hi-ér-ón-mús. See COMMELIN, JEROME.

COMMELIN, Isaac, Dutch historian: b. Amsterdam 1598; d. there 1676. Among his works the history and description of Amsterdam is still much valued.

COMMELIN, Jan, yán, Dutch botanist: b. Amsterdam 1629; d. 1692. He was for many years a professor of botany in the university of his native city, where with his nephew, Casper, he founded the botanical gardens renowned throughout Europe. He wrote much on horticultural subjects in Latin, the inspiration in some cases being his interest in these gardens over which he exercised a fatherly care.

COMMELIN, Jerome, Flemish printer: b. Douay; d. Heidelberg 1598. He was distinguished by his excellent editions of Greek and Latin classics. His emblem is the figure of Truth, and on many editions the words Ex Officina Sanct. Andreae.

COMMELINA, kóm-mě-lí-nà, or dayflower, is a genus of the spiderwort family (Commelinaceae). It contains about 100 species widely distributed in warm and temperate zones. There are about eight species found in the United States, along streams and in waste places, from Massachusetts to Missouri, southward to Florida and Arizona. The fleshy rhizomes of some species may be eaten when cooked, as they contain much starch and mucilage. In Asiatic countries some are used for medicinal purposes. The plant receives its name from Jan and Casper Commelin, two noted Dutch botanists.

COMMENEMATION ODE. The 'Ode Recited at the Harvard Commemoration' was delivered by James Russell Lowell, 21 July 1865, at the laying of the cornerstone of Memorial Hall, Harvard, and the exercises in honor of the sons of the college who had died in the war for the Union. The choice of a poet for the occasion was a fitting one, for Lowell was a devoted Harvard man, and had suffered serious personal bereavements as a result of the war. In its present form the 'Ode' consists of 12 strophes, but the sixth strophe, on Lincoln, was written after the rest of the poem had been delivered. It sustains a high tone throughout, though there is a certain unevenness which may in part be accounted for by the author's habits of work. While by no means intellectually indolent Lowell was accustomed to postpone the task of actual composition as long as possible, and he was never very successful in revision. In this case he did not begin to write until within 48 hours before the poem was to be delivered, and, except for the addition of the strophe referred to, later changes were not important. From its nature the 'Ode' could show none of the rollicking humor of the 'Fable for Critics' and none of the clever satire of the 'Biglow Papers,' and it lacks something of the youthful energy and enthusiasm that accompanies the idealism of the 'Present Crisis' ('Vision of Sir Launfal'). But if it does not show these distinctive characteristics of the author, it is the best expression of Lowell, the
dignified scholar and patriot, and as such some of his admirers have ranked it as his best work. Among the finer passages are the tribute to Lincoln, and the third strophe, beginning "Many loved Truth."

WILLIAM B. CAIENS.

COMMENCEMENT. In the colleges of the United States this term denotes the day when the students are made bachelors of arts. The degree of master of arts and the degree of doctors in the professions are also conferred at this time. The term is given also to the closing exercises of secondary and even elementary schools. The commencement custom is a very old one. Originally it was really a commencement or inauguration, for the term meant, not the beginning or commencement of a school or term, but the inception of the pupil graduate as a teacher and his recognition as such by his master and other members of the profession. He at once entered upon the duties of his new work; so in this sense the ceremony signifies a conclusion.

COMMENDAM, kōm-mén'dám (Lat. commendare, that is, to intrust), used in ecclesiastic law to denote the administrative or provisional management of a benefice during a vacancy. The person entrusted with the management is called commendator. The grant or benefice was afterward conveyed into a regular gift and was then said to be in perpetuum commendam. The practice gave rise to great abuses, and is now almost unknown.

COMMENSALISM, the intimate connection or partnership between animals of quite different affinities; thus commensals, messmates, or fellow-boarders take up their abode together for their mutual benefit. A good example is a large sponge, whose canals and passages shelter innumerable worms, crustaceas, etc., which lodge there without expense to their host. Floating jellyfish shelter certain pelagic crustaceans (Hypenerima) and little fishes. The oyster-crab (Pinnotheres) is a typical case of commensalism; it does no harm to the oyster or mussel in whose shell it lives, and which protects it from danger; while, as the result of its sheltered life, its shell is soft and thin. The pearl-oyster, besides taking in a Pinnotheres as a boarder, admits a kind of shrimp. Certain small slender, eel-like fishes (Fierasfer) insinuate themselves into the body of bivalvia, which also keeps open house for Pinnotheres and shrimps; hence a holothurian has been compared to a hotel with its table d'hôte. Other crustaceans board in different animals; thus a little crab (Pachycheles) lodges in the end of the tube of a sea-urchin; another (Porcellana) lives on the Brazilian coast in a starfish. Polyplps and corals shelter various species of crabs, snails, etc., all being of the same color, while a crinoid (Comatula) takes in as a permanent lodger a decapod crustacean (Galathea). Hermit crabs, taking up their abode in an empty snail-shell, are obliged to admit a variety of intruders who come to stay. Certain mollusks live in starfishes and other echinoderms and, as the result of their semi-parasitic life, are more or less modified and degenerate. Thus Styliina lives on a crinoid (Comatula); a species of Stilifer becomes encysted on the rays of a starfish (Linckia), and on the underside of the arms of the same Linckia lives a limpet-like snail (Thycho), while S. astericola lives in the body of a Bornean starfish, and so on with a number of similar cases. Ascidians throw their "front hall" (atrium) wide open to a variety of forms, such as small worms, mollusks, crustaceans of different orders, spiders, brittle-stars. The "Venus flower-basket," a silicious sponge of the Philippine Islands, gives shelter to three different kinds of crustaceans: a prawn, a Pinnotheres and an isopod.

Rising to the higher animals there occurs on an island off the New Zealand coast the case of the interesting lizard "tuatara," which shares its deep burrows with a petrel, though the latter may at times be the work of the bird. Each builds its nest on opposite sides of the chamber, the lizard almost invariably choosing the right and the petrel the left side. The former sits with its head close to the entrance ready for any attack; it feeds partly on worms and beetles, and in part on the remains of fishes and crustaceans brought to their common table by the petrel.

By far the most numerous assemblage of messmates are the different kinds of beetles and other insects which live in ants' nests, the number of kinds of which has been set at over 1,500. See ANT; COCKROACH; SYMBIOSIS.

COMMENSURABLE, among geométricians, an appellation given to such quantities or magnitudes as can be measured by one and the same common measure. Commensurable numbers, whether integers or fractions, are such as can be measured or divided by some other number without any remainder; such are 12 and 18, as being measured by six or three. Magnitudes having no common measure are said to be incommensurable. Thus the diameter and the circumference of a circle are incommensurable as are also the diagonal and side of a square. The word commensurable is also used in a slightly different sense. Numbers like √2 which are not commensurable with ordinary rational numbers are said to be incommensurable.

COMMENTARY, a term used (1) in the same sense as memoirs, for a narrative of particular transactions or events, as the Commentaries of Caesar. (2) A series or collection of comments or annotations. These may either be in the form of detached notes, or may be embodied in a series of remarks written and printed in a connected form.

COMMENTRY, kō-mán-трé, a town in central France, in the department of Allier, eight miles southeast of Montluçon, in the midst of a vast coal field, to which the town owes its prosperity. There are important iron works in the vicinity. Pop. of commune 10,112.

COMMERCE, Tex., city in Hunt County, 90 miles northeast of Dallas, on the Saint Louis Southwestern and the Texas Midland railroads. East Texas Normal College is located here. The city has considerable trade in live stock, cotton and grain, and manufactures flour, cottonseed oil and lumber. It contains also planing mills, railroad repair shops, bottling works and machine shops. The waterworks are the property of the municipality. Pop. 3,000.
COMMERCe, a card game in which each player contributes an equal sum to the pool, and a full pack of cards is dealt to the players. The dealer, who is the one who receives the first card on the left of the dealer, then exchanges one of his cards with his left hand player, who, in turn, exchanges one with his right hand player, and so on, until some one finds that his hand consists entirely of cards of one suit. Then both play "Mark Spectre." Aces count 11, court cards 10, the rest according to "Pips." Each player, through all the exchanges, is aiming to hold a tricon, three cards alike; a sequence, three following each other in the same suit, or a point, the smallest number of pips on three cards. The winner of the pool is the player who has the highest tricon, or, if none is displayed, the highest sequence, or in its place the holder of the best point. Consult Cassell, 'Book of Pastimes.'

COMMERCe, Chambers of. See ChAmBeRs oF COMMERCe.

COMMERCe, Department of. One of the main divisions in the executive branch of the government of the United States. We shall here describe its origin and organization and the duties assigned to the officers of its several branches.

In the year following the adoption of the Constitution of the United States three of the executive branches of the government with secretaries were established. First, the Department of Foreign Affairs, by act approved 27 July 1789 (the name of which was changed to Department of State by act approved 15 September of the same year); second, the War Department, created by act of 7 Aug. 1789 (then embracing naval affairs); and third, the Treasury Department, established by act of 26 Sept. 1789. Until the Department of Commerce (and Labor) was organized, in 1903, the Treasury Department was the principal agency of government through which a limited supervision of the commerce and industrial life of the nation was administered, and the designation sought to be given to its chief officer in the Constitutional Convention was that of "secretary of commerce and finance."

For Establishment.—Commercial conventions at Detroit in 1865 and at Boston in 1868 and the National Board of Trade in 1874 memorialized the Congress for the establishment of a Department of Commerce, in order that the rapidly increasing volume of capital invested in commerce and manufactures might be the subject of governmental aid and supervision. Many similar petitions were subsequently presented to Congress, and the subject was referred to in political platforms and annual messages of the President. These petitions, and the representations of commercial organizations before the committees of Congress, stated that the twelfth census showed the aggregate value of the products of the manufacturing establishments of the United States, during the census year ended 1 June 1900, to exceed $13,000,000,000, which was probably almost four times the aggregate value of all the products of agriculture during the same year; that the earning interests in the United States exceeded in volume and importance the industrial interests of any nation in the world, and yet there was no government office specially charged with any duties relating directly to them, and that in this respect the United States was almost alone among the nations of the world.

The Department Established.—In the 57th Congress, in the interests of the organization of a Department of Commerce was enacted. On 4 Dec. 1901 Senator Nelson introduced in the Senate a bill "To establish the Department of Commerce." That bill passed the Senate with a number of amendments, including one charging the new office "Department of Commerce and Labor," on 28 Jan. 1902. (A separate Department of Labor was created 4 March 1913.) The act was received in the House 30 Jan. 1902, and nearly a year later (17 Jan. 1903) was passed with amendments. In due course the bill was sent to a committee of conference; the conference report was agreed to in the House on 10 Feb. 1903 and in the Senate the following day; and the bill was signed by the President 14 Feb. 1903.

Organization.—The department, as at present constituted, in addition to the offices and divisions in the immediate office of the Secretary, consists of the bureau of the census, the coast and geodetic survey, the bureau of fisheries, the bureau of foreign commerce (which has among its duties the direction of the work of commercial attachés at foreign capitals and of commercial agents at home and abroad), the bureau of lighthouses and the lighthouse service, the bureau of navigation, the bureau of standards and the steamboat inspection service.

Duties of the Secretary's Office.—The organic act of 14 Feb. 1903, creating the department, as modified by the act of 4 March 1913, creating the Department of Labor, provides for a Secretary of Commerce whose term of office shall be the same as that of other Cabinet officers. It is the duty of the department, under its organic act, to foster, promote and develop the foreign and domestic commerce, the mining, manufacturing, shipping and fishery industries, and the transportation facilities of the United States; and the Secretary of Commerce is charged with the responsibility of carrying out the purpose of the department as thus broadly outlined. In addition, however, the powers and duties of the Secretary may be summarized as follows: The administration of the lighthouse service, including the establishment and maintenance of aids to navigation; the taking of the census; the making of coast and geodetic surveys; the collection and publication of statistics of foreign and domestic commerce, and the promotion and development of the foreign and domestic commerce of the United States; the investigation of the cost of production of the Price-fund investigations; the inspection of steamboats and the enforcement of laws pertaining thereto for the protection of life and property; the propagation and distribution of useful food fishes and the supervising of Alaskan fur-seal and salmon fisheries; jurisdiction over merchant vessels; the standardization of weights and measures; the formulation (in conjunction with the secretaries of the Treasury and Agriculture) of regulations for the enforcement of the Food and Drugs Act and the Insecticide Act. It is the further duty of the Secretary to make such special investigations and furnish such information to the President or Congress as may be required by them on
the foregoing subject matters and to make annual reports to Congress upon the work of his department. The organization includes an assistant secretary, solicitor, engineer, treasurer, disbursing clerk, the appointment division, the division of publications and the division of supplies. During the fiscal year which ended 30 June 1915 the organization of the department was changed by the creation of the Federal Trade Commission into which the Bureau of Corporations was merged on 16 March 1915.

COMMERC, History of.—Commerce is a division of labor among the people of the world. By it man assigns, unconsciously perhaps, the production of certain articles to certain areas in which they can be most conveniently produced, and other articles to other areas or groups of people. Some of these articles may be food, others manufacturing material, such as vessels and railways, and each article or group of articles is in each case the class most natural to the circumstances surrounding the groups of people who respectively produce them. Manufactures are the natural product of certain areas and peoples, while foodstuffs or manufacturing material are natural to others. The community whose population is greater than is required to cultivate the soil and work the mines and fisheries of the area which it occupies naturally develops a manufacturing industry, and the surplus of its manufactures is gladly exchanged for the food and manufacturing material of other communities. The inhabitants of the less densely populated areas naturally give their attention to the production of those articles of food or manufacturing material which the conditions of their soil and climate most readily supply and gladly exchange their surplus for the manufactures of the more densely populated areas. Thus commerce is the exchange of the products most natural to the conditions surrounding the various peoples and climatic areas of the world, and is thus a division of labor among men. These exchanges of the products of different people and climatic areas have become more general with the cheapening of transportation and the multiplicity of the facilities for distribution of natural as well as manufactured products. The exchange of these exchange the products of the respective areas and groups of people has become a convenient division of labor, the principle which underlies all successful business and industrial activities of civilization.

The history of commerce divides itself into three great periods. The first is that in which merchandise was transported by men and animals, followed by vessels sailing along the coasts and seldom venturing out of sight of land; the second began when man learned the use of the compass and traversed the great ocean, but by sailing vessels only. The third began when he applied steam power to the movement of vessels on the ocean and vehicles on land, and this period was simultaneous with that of the establishment of instantaneous communication by the use of electricity.

These three periods vary greatly in length. The first period, that of the sailing vessel creeping along the shores or crossing narrow seas by the observation of the heavens, extends from the earliest period of history down to about the year 1300. The second, that of the sailing vessel guided by the compass, extends from about 1300 to 1819, when the first steam vessel crossed the sea. The third, that of the steam vessel on the ocean, steam transportation on land and instantaneous intercommunication by electricity are all included within the last 100 years. These three periods, of course, greatly overlap one another. The period of the sailing vessel, guided by the observation of the compass or the sun and stars, merged almost insensibly into that in which vessels were guided by the use of the compass, and no exact date can be named as that of the transfer. The compass was known as early as the year 1300, but it took more than a century to so develop its practical use as to lead man to the exploration of the great oceans which he had always looked upon as a barrier to travel or exploration; nor can it be said that the transition from the sailing to the steam vessel occurred at a fixed date, for it took 20 years after the first steam vessel crossed the ocean to establish even a limited trans-Atlantic service, and for many years thereafter a large part of the commerce was carried by sailing vessels. The invention of railways, a part of the third period, occupied many years of time and experimental work. The telegraph and ocean cable, the telephone and wireless telegraphy, which are important factors in the third period, were a gradual development but multiplied enormously the commerce demanding the services of the steamship and railways.

In the first period commerce centred in the Mediterranean and extended over western Europe, northern Africa and western Asia. In the second period, when the use of the compass encouraged man to explore the oceans, the Atlantic was crossed in 1492, India reached in 1496, China in 1516, and the first voyage around the world made in the period 1519-22. Yet with these long experiences of the sailing vessel, 3,000 years of the first period and 500 years of the second, the entire international trade of the world when the period of steam began 100 years ago was but $1,500,000,000, and to-day is $45,000,000,000. The traffic of the sailing vessel on the oceans and animal transportation on land had developed but $1,500,000,000 of international trade, then, with the advent of steam and electricity 100 years brought the total to $45,000,000,000, or 30 times as much in 100 years as had been developed in 3,500 years without steam and electricity.

The exchanges between nations and peoples have always been governed by certain great natural laws. Tropical products have always been wanted by peoples living in temperate zones, and temperate zone products are wanted by the people of the tropics. Also, the people of the older and more densely populated areas demand the food and other natural products of the more recently developed regions and the newly developed areas demand the manufactures and luxuries of the older communities. Densely populated Europe buys the foodstuffs and manufacturing materials of the more newly developed continents, North America, South America, Asia and Oceania, and the more developed areas take the manufactures of Europe in exchange for their natural products. This is the division of labor among the world population, accomplished by commerce.
The earliest records of commerce between great groups of people relate to the exchanges between Egypt and Mesopotamia 4,000 years ago. The Egyptians were chiefly an agricultural people, while those of the Mesopotamia Valley, particularly the Sumerians, had developed certain manufacturing industries, and drew other manufactures from India, and perhaps China, and also certain temperate zone products from the upper waters of the Tigris and Euphrates. So, there grew up limited trading between the two valleys, carried across the desert by the caravans of the Arabs, chiefly the silks, precious stones, spices and gems of the Orient, exchanged for the cotton and flax and cattle and food grains of Egypt. The Phoenicians, a Semitic race closely allied to the Hebrews, removed about this time from the Persian Gulf to the eastern end of the Mediterranean, and slowly built up a carrying trade along its shores, their vessels first propelled by oars, but later by sails. Gradually they extended their operations along the shores of the Mediterranean, passing through the Bosphorus into the Black Sea, and also pushing westward along the northern shore of Africa, and even in a limited way along the western coast of Europe as far north as the British Isles and the Baltic. They built great cities, Tyre, Sidon and Carthage, established manufacturing industries and became the great traders of the world during a very long period, bringing the temperate zone products of the Baltic Sea region and of northeastern Europe, wool, furs, grain, tin and copper and silver, and exchanging them for the semi-tropical products of the Mediterranean countries and Euphrates Valley and the manufactures of their own great cities. Of course it took hundreds of years to develop these cities and their manufacturing industries and build up the commerce with the great frontage stretching from the Baltic Sea along both sides of the Mediterranean and the western coast of Europe, and the Phoenicians were the great trading people of the world for more than 1,000 years.

Gradually, however, the Greeks, who from their homes nearby witnessed the successes of the Phoenicians, followed in their footsteps. Athens became the manufacturers and commercial cities, and Greek vessels and merchants entered upon the trade of the same area in which the Phoenicians had been so successful. The conquests of Alexander, which extended to Persia and India, also aided Greek commerce by the views which they disclosed of Oriental civilization and the increased use of money in commerce, just as the experiences of the Crusaders in the same area did for Western Europe many generations later. The Greeks, however, did not develop as successful commercial qualities as did the Phoenicians, and the period of their control of world commerce was much shorter. The Romans succeeded the Greeks, as they extended their political power over the Mediterranean Valley nearly as great as the present United States, and with a population nearly as big as our own at the present time, stretching from the Euphrates valley on the east to northern Europe, and including both frontages of the Mediterranean. They built up great fleets of commercial vessels, developed roads and commercial routes throughout their colonies, and Rome became the great centre of their enormous area. The natural products of northern and western Europe and the manufactures and luxuries of the Orient supplied the demands of that great and luxurious city of more than 1,000,000 inhabitants. The decline of the Roman power reduced this commerce very greatly, though that with the East was somewhat revived by the transfer by Constantine of the seat of government to Byzantium, since called Constantinople. The development of the Mohammedan Empire in the 7th century in India, brought great changes in the commercial world. The Mohammedan religion favored commerce, and as its followers occupied most of the Mediterranean shore the effect upon commerce and industries was very great. Damascus, Bagdad, Alexandria, Cairo and the cities of Spain became great centres of industry and trade, and the people of the Christian world learned from the Mohammedans many important lessons of industry and traffic. Even the Crusades, which were organized military movements of the Mohammedans in the Holy Land, taught the people of western Europe many valuable lessons in manufacturing through the opportunities thus offered to the Europeans of observing the superior industries of the Eastern world, in manner similar to that resulting from Alexander's invasions of the Orient, and these lessons resulted in the development of manufacturing industries in western Europe.

During the long period following from the fall of the Western Roman Empire to the application of the compass to ocean navigation, the period which is usually designated as the Middle Ages, new trade routes and commercial centres were developed. Venice and other Italian cities became great trading and manufacturing centres, sending their ships to the eastern end of the Mediterranean and the Baltic Sea for the Oriental products of tropical Asia and the grains and wool of the Baltic Sea frontage, redistributing them with their own manufactures to northern and western Europe by land routes and coasting vessels and bringing back the woolens and linens and leather and other products of France and Great Britain and Germany and other countries. Again it was the exchange of the products of different climatic areas and different civilizations. Venice became a great manufacturing, commercial and financial centre and sent its manufactures to Asia Minor, northern Africa and northern and western Europe. Its vessels were numbered by thousands, yet their operations were confined to the inland seas and the Atlantic Coast. It sent its consuls to report upon conditions of the countries with which it traded, built up a great banking and credit system with branch banks in these countries, and its example was followed by other Italian cities, especially Genoa and Florence. These commercial activities of the Italian cities developed trading stations and cities in northern Europe. Antwerp, Amsterdam, London, Cologne, Hamburg and Lubeck became active commercial centres, while fairs and markets were built up along the routes over which this merchandise was carried, developing into trading towns and cities.

Commerce during this period of the Middle Ages was, however, subject to constant attack by brigands and petty feudal lords, and as a
result the great trading cities and stations of northern Europe built up organized leagues for the protection of their trade. They supplied armed guards to protect the commerce against the natives and colonists, and this led to the establishment of new trading stations which developed into towns and cities. The Hanseatic and Rhenish leagues, organized in Germany, included nearly 100 towns in each, and their influence in the protection to and development of trade in the area had an important influence in developing orderly government and new political governments. Their activities extended over a term of nearly 250 years, and only ended when the use of the compass turned the activities of trade to the oceans, greatly reducing the importance of the Italian cities and the trade systems which they had built up. The commercial and financial activities of this long period, however, developed great commercial, financial, banking and credit systems, as well as organized governments, and fitted western Europe to begin trade with the Americas and eastern Asia when the application of the compass to ocean navigation revolutionized trade routes and commercial methods.

The period of the practical application of the compass to ocean navigation began about 1400, although its use was begun in a limited way about the year 1300. The eastern frontiers of the Atlantic were explored and the islands off the coast of Africa occupied. Columbus, convinced that the earth was a globe, and that India could be reached by sailing westward, ventured boldly out on the Atlantic, discovering America in 1492. The circumnavigation of Africa and the opening of the route to India occurred in 1498, the extension of the route to China in 1516 and the circumnavigation of the globe 1519–22. This developed new routes of commerce and also the true functions of commerce, the interchange of the products of different climatic areas and different types of civilization, the division of labor among the people of the world. The great masses of Oriental population were found possessed of certain products, such as spices, which they who were able to offer in exchange their own manufactures and the precious metals which they had begun to receive from America. Commerce then became truly international and intercontinental, exchanges between different climatic areas and civilizations. To develop this new form of commerce, the interchange of the products of the various quarters of the entire globe, new facilities were required, and large sums of money demanded, both in the transportation of merchandise and in the financial operations of the exchange. The governments of Europe, stimulated by the prospects of gaining additional territory as well as commercial profits, entered the field. The Spanish, Portuguese, Danish, English and French governments charted commercial companies for the development of trade and exploration and granted them liberal aid, and at the same time encouraged colonization, especially in America, where the Spanish and the Portuguese sent their trading ships around Africa and established a trading station at Goa, on the coast of India, and the commerce was conducted under the direction of the government, but open to all Portuguese. Spain explored and conquered Mexico and the western coast of South America, and established commerce with those areas, with squadrons escorted by ships of war. Merchandise was sold to the natives and the colonists, and this greatly increased the gold and silver transferred to Europe, stimulating manufactures and proving extremely useful in the trade with the Orient. The English, who had been buying quantities of Oriental merchandise from the Portuguese, were excluded from that market and were forced to find a new market and a new way to trade in the Orient, taking possession of Java and developing a very large business in Oriental products, especially spices which were extremely popular in Europe at that time. Their business was highly successful and Holland became a great commercial, financial and banking country. The French government also established an East India trading company, also one for the West Indies, but they were less successful than those of Great Britain and Holland.

These great commercial companies, chartered by their respective governments, were not only traders but explorers and colonizers as well, especially those operating in America, while those operating in the Orient established trading stations and by obtaining concessions from the native governments gained control of important areas. The colonies and trading stations thus established contributed greatly to the advantage of the mother country, both by their contributions of needed supplies and by the market they furnished for manufactures. As a result of the desire to develop the production of the tropical areas, especially in America, the African slave trade was built up, multiplying the production of the colonies, in the New World, and only during the American Civil War. The application of the compass to navigation had a profound effect upon world commerce. Prior to that time most of the international trade was the exchange of products of the near East and the subtropical Mediterranean area for those of northern and western Europe, a limited exchange of the products of the different climatic products and civilizations. But with the extension of the transportation and trade to every part of the world, and the development of the producing power of the new countries the exchanges between different civilizations, climatic areas and manufacturing communities was greatly enlarged, and commerce became more than ever a division of labor among great groups of people and great sections of the world.

The transition from the sail on the ocean and animal power on land to steam vessels and railways was not accomplished in a single year or decade. The first steam vessel crossed the ocean in 1819, and another from England to India in 1825, but it was not until 1838 that successful trans-Atlantic steam service was established.
All of these vessels were propelled by the paddle wheel, which proved unsatisfactory for ocean service, and in about 1845 the screw propeller was introduced and soon displaced the paddle wheel. Iron began to be substituted for wood for the construction of vessels about 1850, and steel for iron about 1865. The engines used by the vessels were at first very simple and unsatisfactory, and it was not until 1864 that the compound engine was adapted to marine use, and the steam-expansion engine in 1874, and other equally important changes later. By these improvements the speed and carrying power of vessels was quadrupled. A single steamship of to-day will carry 600 modern carloads of ordinary merchandise. The result of this development of the steamship was the tonnage of the sailing vessels of the world is now but about one-fourth of that of 1860, while that of the steamships is 16 times as great as in that year, and when we remember that the average steamship will, by reason of its greater speed and more complete control in all kinds of weather, make four times as many trips over a given course in a year as the sailing vessel we begin to realize the enormous expansion of the carrying power which came with the ocean steamer. The growth of the railway on land was an equally important factor in the development of the third period, and so was that of the telegraph. The railways of the world were but 24,000 miles in 1850, now they are 725,000 miles, or 30 times as much, and their carrying capacity per mile is probably four times as much as then, due to the improvement of roadbeds, the change from iron to heavy steel rails, double and quadruple tracks, stronger, larger and faster engines and larger and better cars. They have made possible the transportation of merchandise from the interior of the continents to the water's edge, and this fact has stimulated the development of population in the interior. The population of the interior of the United States, for instance, has trebled since 1870, and the value of its products increased from $2,000,000,000 to $20,000,000,000. World population, which was but 650,000,000 in 1818, grew to 1,690,000,000 in 1918, due in part to the opening of new areas to population, and in part to the practicability of increasing the density of population at any point and transporting from other parts of the world the food which is required.

Instantaneous communication has also contributed greatly to the growth of commerce in the latest period. The land and ocean telegraphs in 1850 aggregated but 5,000 miles and to-day are more than 2,000,000 miles, with greatly increased facility of transmission per mile, and even this wonderful system has been greatly intensified by the telephone and wireless telegraph. The fact that the business man or producer in any part of the world can now speak instantly to the business man in any other part of the world, on the other side of the globe, in the interior of the continent and even to the vessels in the midst of the oceans, and may also transmit funds by the same instantaneous process, if desired, adds enormously to the convenience and activity of commerce.

Finance has also participated largely in this growth of commerce in recent years. The world's production of gold prior to 1850 was less than $10,000,000 a year; now it is $460,000,000 per year, or 50 times as much. The quantity of gold mined in the short period since 1870 is twice as much as in the 400 years prior to 1870. This enormous increase in the quantity of the world's accepted medium of exchange has greatly aided the growth of commerce, while the development of the banking and credit systems has been quite as important. The banking power of the world, by which we of course

1 For 1917 figures of the previous year are repeated for those countries from which no returns were received.
2 The figures are those of the Director of the Mint, but do not represent the findings of the respective columns, as data official, for the period from 1871 to 1885, employs Sotheber's averages upon a somewhat different basis from that used in this table.
3 The value of gold production of the world from the discovery of America (1492) to the celebrated silver campaign in the United States (1896) was $8,780,000,000, and from 1896 to the end of 1918, $8,680,000,000 (1918 estimate based on 1917 production).

Transportation, intercommunication and finance. International commerce has grown from approximately $8,000,000,000 in 1870 to $80,000,000,000 at the present time, and credits have expanded with an equal rapidity.

It is for these reasons that the third period of world commerce, that of steam, electricity and finance, has been one of unparalleled developments. In the first period, extending over thousands of years of the sailing vessel without the compass, in which the oceans were considered a barrier to commerce or exploration, the world trade in an entire year was less than that of a single day at the present time. In the second period, that of the sailing vessel and compass, covering about 500 years, in which man traversed the globe by sailing vessels only, he built up world commerce to $1,500,000,000 a year. In the third period, which has covered but 100 years, he has developed a trade of $45,000,000,000 per annum, or 30 times as great as he had been able to create in 500 years without the aid of steam, electricity and modern finance. International commerce at the beginning of the third period averaged about $2 per capita for the entire world population; in 1913 it was about $24 per capita for the greatly increased population. In this last period of growth, some principles of a division of labor among the people of the earth, the exchange of the products of certain peoples and areas and climates for the different products of other areas and peoples and climates stand more clearly than in the earlier periods. Manufacturing Europe buys food and manufacturing materials from the other continents and pays for them in manufactures; the United States draws upon the tropics and Orient for manufacturing material and certain foodstuffs and pays for them with the product of her factories; Asia exports her silk and tea and fibres to Europe and sells manufactures and takes manufactures in exchange; South America and Oceania sell their foodstuffs and raw material to the United States and Europe and take the product of their factories; and Africa sells gold and diamonds and ostrich feathers and high grade cotton and buys manufactures from Europe and America. Everywhere it is the exchange of the products natural to the area in which they are produced for the natural products of some other area and people, and thus the division of labor becomes more and more sharply defined with the enlargement of transportation, intercommunication and finance.

Commerce, Internal, of the United States. The internal commerce of a country is the exchange of merchandise among its own people. Studies of the internal commerce of a country are valuable, especially from the economic standpoint, in determining the industrial and commercial activity of the people, at stated intervals and also in comparison with that of other groups of people.

To fully determine the internal commerce of a country would require a knowledge (1) of the original value of the merchandise exchanged; (2) the number of times that each article was bought and sold between the original producer and consumer; (3) the cost added by transportation from the producer to the consumer; and (4) the cost added by the expenses and profits of the dealers or "middlemen" who handled and rehandled it in its passage from producer to consumer.

Obviously it is impossible to determine with accuracy the costs added by these processes through which the product passes on its way from production to consumption. In some cases they involve short and in other cases long distance transportation; in some cases a small number of transfers from hand to hand, and in other cases many; in some cases the cost of the product is greatly increased by the processes required to fit it for consumption, and in certain articles the charges added for "expenses and profits" form a much higher percentage of the original value than in others. Fruits from the Pacific coast cross the continent and after numerous handlings by dealers are consumed in the Atlantic coast cities and our foreign trade, or to the total international commerce of the world.

The principal articles forming the internal commerce of a country are (a) products of agriculture; (b) products of the mines; (c) products of forests and fisheries; (d) manufactures produced within the country; and (e) articles imported and sold among the people. All these are measured in a single unit of measurement, the dollar, at the place of production. While the manufactures are of course made from the products of the other industries, agriculture, mining and forestry and from certain foreign products, and their use as a basis thus involves a second sale of a part of the already recorded product, the fact that the manufactured article presents this material in an entirely new form seems to justify the inclusion of all manufactures among the five great groups of articles forming the internal commerce of a country, agricultural products,

* Manufactures and agricultural products reduced to gold basis.  † Includes estimate for hand trades and neighborhood industries.  § Estimated.

minerals, forest and fishery products, manufactures, and imported merchandise.

The acceptance of these five great groups as the articles forming the internal exchanges of a given countable custum of households, the internal commerce of the United States at various dates and its average value per capita of the entire population, and also to determine how our own internal trade compares with that of other countries when estimated on the per capita basis. To measure the value of the merchandise forming the internal commerce of the countries we must also utilize the official or other acceptable valuations of these five great groups of articles. The Census of 1915 put the value of the factory products of the United States in 1914 at $24,246,000,000, and we know from the reports of earlier censuses, that the value of the manufactures produced by the hand trades and neighborhood industries is nearly $2,000,000,000 which must be added to the value of the factory products in an effort to obtain the true value of all manufactures produced in the country. So we may set down the value of the manufactures turned out in the United States in 1914 at fully $26,000,000,000. The Secretary of Agriculture estimates the value of the farm products of the United States in 1914 at approximately $10,000,000,000, though it is estimated that about one-tenth of this, or say $1,000,000,000, was consumed on the farm and did not therefore enter internal trade, leaving the amount of agricultural products entering internal commerce at approximately $9,000,000,000. The Geological Survey of the United States estimates the value of the mineral products of the country in 1914 at over $2,000,000,000, and to this we must add at least $1,000,000,000 for the products of the forests and fisheries and others of a miscellaneous character. The merchandise imported in 1914, all of which entered internal commerce after passing through the customs houses, was valued at nearly $2,000,000,000 on its arrival at the ports, and of course the tariff duties were added to this cost before it entered trade.

These great groups of merchandise, the manufactures, the agricultural products, the minerals, the products of the forests and fisheries and the merchandise imported, form the internal commerce of the United States, the merchandise exchange between its people, for even that which is finally exported is a part of the internal commerce before exportation. The value of the manufactures in 1914 was $26,000,000,000; agricultural products exclusive of those consumed on the farm, $9,000,000,000; minerals, $2,000,000,000; and imports, $1,000,000,000; imports, $2,000,000,000, making an aggregate of $40,000,000,000 as the value at the place of production of all the articles exchanged among our own people, and forming the internal commerce of the country in the year 1914.

This grand total of $40,000,000,000, the estimated value of the merchandise forming the internal commerce of the country, represents the products in question at the place of production, and does not make any allowance for the cost added by transportation or the profits of various dealers who handle it between the producer and consumer. Nor does this total of $40,000,000,000 represent more than one sale of the merchandise in question, the original sale by which it passed from the hands of the producer to the markets of the country. How many times it is handled and resold before it reaches the consumer and how much advance he pays upon the price received by the producer is a matter of conjecture rather than of possible statistical measurement. There are no accepted standards, governmental or otherwise, by which we may determine the average number of times that the merchandise is handled or the percentage added to the price at which it is sold by the producer.

With this basis of measurement of the value at the place of production of the merchandise forming the internal commerce of the United States, it is possible to measure the growth of the merchandise exchanged among her own people from year to year or decade to decade, though the fact that this must be expressed in a single unit of measurement, the dollar, reduces the value of the comparisons since general advances or reductions in prices would show greater fluctuations in the value figures than those in quantities. For purpose of general comparison in measuring the growth of the grand total of all products forming the internal commerce of the country, it is, however, necessary to have some single standard applicable to all, the dollar. Accepting the above discussed standards of measurement of the internal commerce of the country, a single measurement at the place of production of all
COMMERCE, INTERNAL

articles forming the internal commerce of the country, we find that the internal commerce of the United States grew from $2,500,000,000 in 1850 to $4,000,000,000 in 1860; $6,000,000,000 in 1870; $9,000,000,000 in 1880; $14,000,000,000 in 1890; is, in fact, greater than the $34,680,000,000 of 1910 and $40,000,000,000 in 1914, a per capita average of $112 in 1850, $128 in 1860, $153 in 1870, $179 in 1880, $222 in 1890, $276 in 1900, $371 in 1910 and $400 in 1914, all of these figures being in very round numbers.

It is interesting at this point in the study of the internal commerce of the United States to compare it with that of other countries. This comparison can be only in very general terms, because of the fact that no other country has as complete facilities for such study as has the United States, since no complete and periodical census of manufactures is taken in the European countries. Utilizing, however, the partial censuses which have been made from time to time and supplementing these with estimates of the statisticians and economists of the respective countries, the comparison of the value of merchandise forming the internal commerce of the United States, Great Britain, Germany and France in 1913 is shown by the following table. The estimates for the European countries are upon a basis similar to that used in the above discussion of the United States, namely, products of agriculture, mining, fisheries, forests, manufacture and imported merchandise. It will be seen that the per capita value of the internal commerce of the United States is much larger than that of the other countries enumerated.

### ESTIMATED VALUE OF MERCHANDISE FORMING THE INTERNAL COMMERCE OF GERMANY, FRANCE, UNITED KINGDOM AND THE UNITED STATES, 1913:

The causes of the greater interchange of merchandise among the people of the United States than in other countries lies in part in the large area and great diversity of production in the United States. With an area practically equal to that of Europe great mountain regions and long sea frontages the United States has varying climatic conditions from temperate to sub-tropical, and consequently a greater variety of products than the smaller countries of Europe with which comparison is made in one of the above tables. It is in this fact, that our own country by its very bigness and diversity of climate produces such a great variety of products, and has exceptional facilities for their interchange, that we have applied in the United States is more fully than anywhere else the great law of economic of a division of labor among men and thus made our interchanges greater in proportion to population than is natural to other and smaller countries.

When we compare the value of the merchandise forming the internal commerce of the United States with that forming the international commerce of the world that we begin to fully realize the great volume of our own internal trade. International commerce, as it is usually stated, consists of an aggregation of the imports and exports of all countries of the world, but as every article exported is again counted when it becomes an import at destination, it is apparent that the aggregation of all the exports and imports of all countries of the world really counts the merchandise twice; first, when exported from the country of production, and again, when imported into the country of consumption, and that, therefore, the real value of the merchandise forming international trade of the world is but about one-half that of the customary statement of international trade. For example, the international trade of the world in 1913, the year preceding the European War, which may be accepted as a normal year of international trade, aggregated $40,000,000,000. But as this aggregation included all exports plus all imports, it is apparent that the real value of the merchandise, counted when exported and again counted when imported, is in fact but $20,000,000,000, or one-half of the usual statement of international trade in 1913, $40,000,000,000.

The table which follows shows the aggregate value of exports and imports of all countries of the world, the value of the merchandise forming the international trade, and the value of the merchandise forming the internal commerce of the United States, from 1850 to 1914.

*1913

The fact that the internal commerce of the United States grew more rapidly than the international commerce of the world is accounted for in part by the fact that our population increased practically 100 per cent in the period in question, while that of the world as a whole increased but 15 per cent in the same time.

There are no gateways through which the internal commerce of a country must pass and therefore no governmental or other machinery by which it may be measured in detail. We know that Congress passes laws for the regulation and control of the commerce between the States and that we have an Interstate Commerce Commission yet there is no record, financial or otherwise, of the value of the merchandise passing between the respective States or other divisions of the country, and billions of dollars worth of merchandise cross and recross State and municipal boundary lines without a record of any sort as to their character, value, the place of production or final destination.

By one process, however, it is possible to estimate the value of the merchandise forming the internal commerce of the United States.
Necessarily, the merchandise exchanged among our own people consists chiefly of the products of our own industries, and while it is not possible to measure the actual movement of merchandise between the States, it is practicable to obtain a general view of the interchanges between the various portions of the country. Nature and man in conjunction have divided the United States into four pretty distinct sections. These four great sections are (1) the North Atlantic area usually designated as the New England and Middle States; (2) the upper Mississippi Valley; (3) the South; (4) the mountain regions of the West. These four sections differ radically in their products and as a result, the interchanges between them are very large and form a large part of the internal commerce of the country. They are in fact an application of that great economic law of division and labor among great groups of people and the interchanges of their respective products. It is the operation of this great economic law that lies at the root of the prosperity of the world which has developed the international trade of the globe and it has become equally effective in producing the great interchanges of merchandise between certain sections of the country which we designate as our internal commerce.

In the North Atlantic area which occupies all of the New England and Middle States, there is a long ocean frontage, rivers furnishing power for manufacturing purposes, a comparatively light soil in most of the area, a dense population, great industrial and trade centres, plentiful supplies of fuel and plentiful transportation facilities. These conditions have made it the great manufacturing section of the United States. The second mentioned area, the upper Mississippi Valley stretching from the eastern boundary of Ohio to the western edge of Kansas, Nebraska and the Dakotas, is the great temperate zone producing area of the United States with a rich deep soil, producing most of the wheat and corn and meats of the country, and while it has a population slightly larger than the North Atlantic section, the density of population is much less since it is hilly which gives it the third section, the South, including everything south of the Potomac and Ohio rivers as far west as the western boundaries of Oklahoma and Texas, has in a part of the area a sub-tropical climate and its most important products are cotton, rice, tobacco, cane sugar, and other subtropical growths, timber, live stock, petroleum and limited quantities of cereals. The fourth section, the mountainous area stretching from the western borders of Texas, Nebraska, Kansas and the Dakotas to the Pacific has a larger area and smaller population than any of the other sections mentioned and produces materials of a radically different character, minerals, precious metals, wool, lumber, but little in the way of foodstuffs. To sum up, the sentence, the North Atlantic area produces the bulk of the manufactures of the country; the upper Mississippi area produces most of the foodstuffs; the South produces manufacturing material and tropical foodstuffs; the West manufactures wool, but little in the way of foodstuffs; and these four great areas freely interchange their products, thus forming a large part of the internal commerce of the country.

The North Atlantic Section which is composed of the New England and Middle States, has a comparatively small area, only about as much as that of the State of California, yet its population is 30 per cent of the entire country, the area being 160,000 square miles, and its population 30,000,000. If dependent upon half the last census year, over $11,000,000,000 worth of factory-made manufactures out of a total of less than $24,000,000,000, or practically one-half of the factory products the entire United States when measured by value invested in its manufacturing industries was $11,000,000,000 out of a total of $23,000,000,000 invested in the entire manufacturing industries of the United States.

Yet this North Atlantic area with 30 per cent of the population and one-half of the manufactures of the country produces but a small proportion of the food or manufacturing material which its people and industries require. With 30 per cent of the population of the country, it produced per cent of the cotton, 3 per cent of the corn, 9 per cent of the cattle, 4 per cent of the swine, 4 per cent of the sheep, none of the sugar and but 9 per cent of the value of all foodstuffs produced in the country. Clearly, it is dependent upon the other sections of the country for most of the food and manufacturing material required, for its 30,000,000 people engaged chiefly in manufacturing. For manufacturing material this great manufacturing area is also dependent upon other sections of the country. It produces no cotton although manufacturing 60 per cent of the cotton goods of the country, little wool, although turning out 90 per cent of the woolen manufactures of the United States, has but 6 per cent of the animals supplying hides for leather although it produces 70 per cent of the boots and shoes manufactured in the country, has comparatively little timber for manufacturing uses, no copper and but 4 per cent of the iron ore mined in the country although turning out about 50 per cent of the pig iron and of the iron and steel manufactures as a whole. It produced in 1909 but about 7 per cent of the raw manufacturing material of the country although it turned out approximately 50 per cent of the manufactures. Clearly, it was generally dependent upon the other sections of the country for most of the $6,500,000,000 worth of manufacturing material which its factories used in 1909, the year covered by the latest detailed census reports, those of 1910. The cotton it brought from the South, the iron ore from the upper Mississippi, the copper from the mountain region, the timber from the South and the upper Mississippi and most of the foodstuffs which it consumed were from the upper Mississippi Valley. For these, it paid chiefly with its manufactures.

The Upper Mississippi Section is equally distinctive in its products and equally dependent upon other sections of the country for certain of its requirements. This section includes the States of Ohio, Indiana, Illinois, Michigan, Wisconsin, Minnesota, Missouri, Iowa, Kansas, Nebraska and the Dakotas. With an area forming about 25 per cent of the entire United States exclusive of Alaska; it has 22 per cent of the population of the country. It is clearly the great grain and meat producing section of the United States. It produces about 75 per cent
of the wheat of the country, 70 per cent of the corn, 50 per cent of the potatoes, 50 per cent of the butter, 45 per cent of the food animals and turns out 35 per cent of the flour and 70 per cent of the products of slaughtering and packing. It produces 38 per cent of the value of all foodstuffs turned out in the United States and the value of its farms is 57 per cent of that of the entire country. Of manufacturing material, it produces about 20 per cent of the entire value, of the entire manufacturing material of the country. The total of its manufactures in 1914 was nominally about 33 per cent of those of the entire country, though a very considerable part of these so-called manufactures consisted merely of meats and flour which the census classes as manufactures, though in fact foodstuffs. Having 45 per cent of the food animals of the country, it turned out in 1914 75 per cent of the products of slaughtering, having plentiful timber supplies, it manufactures 80 per cent of the agricultural implements, 70 per cent of the automobiles and 50 per cent of the furniture, and producing 75 per cent of the wheat of the country, it turns out 60 per cent of the flour. Producing 85 per cent of the iron ore of the country and about 25 per cent of the coal, it turns out 33 per cent of the pig iron and 30 per cent of the manufactures of iron and steel. Producing no cotton, little wool or other fibres for industrial purposes, it relies almost exclusively upon the North Atlantic section for its manufactures of cotton and wool and silk and fibres, also for its chemical industry and other high grade manufactures and those of a miscellaneous character. For these, it exchanges its wheat and flour and food animals and meats and furniture and automobiles, while it also pays with like products for the minerals and sugar and fruits and live stock which it brings from the southern and western sections of the country.

The Southern Section which includes all of the States south of the Potomac and Ohio rivers and extending to the western boundaries of Texas and Oklahoma has 30 per cent of the area of the country and 32 per cent of the population. Its industries are chiefly agricultural and forestry, as an agricultural and mining. It produces practically all of the cotton of the country, about 18 per cent of the cereals, 28 per cent of the food animals, over 50 per cent of the petroleum and has 40 per cent of the farm acreage of the country. It turns out about 30 per cent of the value of farm products of the country, and 24 per cent of the value of the foodstuffs of the United States. With its monopoly of cotton production, and its valuable minerals and forests, it supplies about 50 per cent of the raw material required for manufacturing. It supplies 26 per cent of the coal, over 50 per cent of the petroleum, all of the raw cotton and practically all of the sulphur produced in the United States. Producing 50 per cent of the country's raw material for manufacturing, it turns out but 14 per cent of the total value of manufactures produced in the United States, and the capital invested in its factories is but about 12 per cent of the total manufacturing capital of the country. The demand for its manufactures is great but the capital invested in its factories is less than that of the cotton and farm machinery industries.

The Mountain Section covers the entire area from the western boundary of Texas, Kansas, Nebraska and the Dakotas to the waters of the Pacific. It has a larger area than any of the others, about 40 per cent of the entire country exclusive of Alaska, but only 7 per cent of its population against 32 per cent in the Southern Section, 32 per cent in the Upper Mississippi Section and 29 per cent in the North Atlantic Section. It produces but 6 per cent of the manufactures of the country, 8 per cent of the cereals, 9 per cent of the foodstuffs, has but 12 per cent of the acres in farms, 3 per cent of the swine, 15 per cent of the cattle, but 55 per cent of the sheep of the country. Clearly it is not a manufacturing section, though it is large in agricultural or manufacturing section, though it does supply most of the beet sugar produced in the country, over one-half of the wool, and large quantities of fruits. Its chief products are minerals. It produces 80 per cent of the copper and practically all of the gold and silver produced in the United States, about 33 per cent of the petroleum, 25 per cent of the minerals of the country as a whole and about 20 per cent of the entire manufacturing material produced in the United States. Its sheep produce 65 per cent of the value of the wool product of the country and its forests 20 per cent of the lumber. Its natural products it must exchange for the food and manufactures of other parts of the country. While it turns out about 6 per cent of the total manufactures of the country, and its total population is about 7 per cent of that of the entire United States, it does not follow that it is self-sufficient in manufactures, for the output of its factories is composed of few articles, such as lumber, iron and steel, sugar and the products of slaughtering and packing leaving its population dependent upon the manufacturing sections, the North Atlantic and the Upper Mississippi Section for its cotton, woolen and silk goods, its clothing, agricultural implements, cars, carriages and high grade manufactures of iron and steel and miscellaneous products.

For these it exchanges its minerals, wool, fruits and sugar.

The four great requirements of man are food, fuel, manufacturing material and manufactures. The North Atlantic Section with 6 per cent of the area of the United States and 29 per cent of its population produces 50 per cent of the manufactures and 33 per cent of the fuel but only 9 per cent of the food and 7 per cent of the manufacturing material of the entire country. The Upper Mississippi Section with 13 per cent of the population produces 60 per cent of the food, 33 per cent of the fuel, 21 per cent of the manufacturing material and 33 per cent of the manufactures though about one-fourth
COMMERCe, INTERSTATE

of its so-called manufactures are merely the products of slaughtering and milling which are scarcely entitled to be classed manufactures. The Southern Section with 30 per cent of the area and 32 per cent of the population produces 23 per cent of the food, 28 per cent of the fuel, 30 per cent of the manufacturing material and 6 per cent of the manufactures. The Western Section with 40 per cent of the area and 7 per cent of the population produces 20 per cent of the manufacturing material, 13 per cent of the fuel, 9 per cent of the food and 7 per cent of the manufactures of the country.

Thus the great economic principle of a division of labor among men, which had been unconsciously but consistently developed in the North Atlantic and Upper Mississippi Sections and the sub-tropical products of the Southern Section,

These exchanges between these great areas of the United States having products with distinctly varying characteristics form the bulk of the international commerce of the country in which the value of the merchandise is twice as great as that found in the entire international commerce of the world.

The table which follows shows the principal products of the four great industrial sections of the United States: the North Atlantic Section, whose chief industries are manufactures; the Upper Mississippi Section, the chief producer of foodstuffs; the Southern Section, the prov-\[\text{Table: Principal Products of the Four Great Industrial Sections of the United States, Also Area and Population}\]

Note—The North Atlantic Section includes the New England and Middle States. The Upper Mississippi Section: Ohio, Indiana, Illinois, Michigan, Wisconsin, Minnesota, Missouri, Kansas, Nebraska, and Dakota. The Southern Section: All States south of the Potomac and Ohio rivers extending to the western boundary of Texas and Oklahoma. The Western Section: All States west of Texas, Oklahoma, Kansas, Nebraska and the Dakota.

Oscar P. Austin, Statistician, National City Bank of New York.

COMMERCe, Interstate. Complete freedom of trade among the States was established by the Federal Constitution. The States were forbidden to lay any duties on imports or exports or to lay any duty of tonnage. Congress itself was denied the power to levy taxes or duties on articles "exported from any State," so that the flow of commodities from State to State was freed of any danger of interruption through customs, or other charges, imposed by Federal authority and to be collected at State boundaries or ports of entry. At the time of the adoption of the Constitution the commerce...
with foreign nations and among the several States, which Congress was empowered to regulate, was almost exclusively water-borne. Overland traffic was practically non-existent; the cost of transportation of heavy commodities, in large quantities and for long distances, was prohibitive. Interstate commerce was slow and long after, meant trade conducted by schooners, sloops and "yankies" on the bays, sounds and estuaries skirting the Atlantic shore; and there was little thought of exercising the regulative powers of Congress over any other. The only national legislation on the subject for half a century after the foundation of the government was that contained in the Navigation laws, whereby the coasting trade between ports of the United States was required to be conducted in vessels of American registry, American-owned and American-built. When steam-propelled vessels had come into general use, and laws for the inspection of steamboats and the licensing of masters and engineers were enacted by Congress, the trade on all steam vessels, including those engaged in traffic on rivers and lakes wholly within the territorial limits of a single State. With respect to overland traffic on the other hand, there are no laws on record where States and incorporated transportation companies, with exclusive rights of running their stage coaches and wagons over roads in other States. The earliest Federal activity with respect to overland communication, which might inferentially be called a regulation of commerce, was the establishment of the pre-existing postal service as a governmental service. The next in time and importance was the construction of the Cumberland Road, or "National Pike," from Cumberland, Md., through Wheeling and Columbus. This highway, begun in 1806, finally reached Vandalia, on the Kaskaskia River, in 1827. It had been intended to project this road to Jefferson, Mo., but long before its construction had progressed to the Mississippi River line the superiority of the railroad had made long-distance overland traffic had been demonstrated. As early as 1772 George Washington had directed attention to the need of improving the means of inland communication by roads, railroads and canals. Prior to its completion, a through route from the seaboard to the region west of the Alleghany Mountains; but this was not realized until, 26 years after the death of Washington, a connection between the Great Lakes and the Hudson River was established by the completion of the Erie Canal. The first direct assertion by Congress of the right to regulate overland commerce among the States was the act of 15 June 1866 (31 Statutes at Large, 1446, chap. 866) which provided as follows: "Every railroad company in the United States is authorized to carry...all passengers, troops, government supplies, mails, freight and property on the way from State to State, and connect with the roads of other States, so as to form continuous lines of transportation from the boundary to the place of destination." This has been called, not inappropriately, the "Magna Charta" of the interstate railways.

Long before this, however, the potentialities later to be secured by Congress had been disclosed by the courts. The epochal case of Gibbons v. Ogden (9 Wheaton 1) turned on the interpretation of the word "commerce." The State of New York had granted an exclusive right of navigation over its territorial waters; but the court decided that commerce includes navigation, so that, in making a grant of the character described, the State had exceeded its powers and encroached upon those of the United States. In the written opinions of Chief Justice Marshall and his associates on the Supreme Bench the superior and exclusive authority of Congress is declared with the greatest emphasis. The power of Congress to regulate commerce is complete in itself, and may be exercised to its utmost extent, acknowledging no limits other than are prescribed in the Constitution. The power is plenary, because it is vested in Congress "as absolutely as it would be in a single government"; it may be exercised "whenever the subjects exist." If there was any object fiding over every other in the adoption of the Constitution, it was to keep commercial intercourse uniform, free from restraint and particular restraints. In all commercial regulations we are one and the same people. In the ensuing years the scope of the Federal authority was determined mainly by decisions of the Supreme Court. The power of the enforcement of State regulations, or the collection by the States of tolls and taxes, deemed to be obstructive of or burdensome on interstate commerce. With the opening of the railroad era overland traffic steadily gained in navigation in relative importance; but the idea of the "Commerce Clause" as a check upon hindering legislation by the States, rather than as an invitation to Federal regulation, persisted. As late as 1859, in the State Freight Tax case (15 Wallace 232) Justice Strong still adhered, and gave expression to, this idea—saying, that when this clause was framed, a power to prevent embarrassing restrictions by a State was the thing desired. Pennsylvania had placed a tax on all charges made by railroads for the transportation of freight within the State and, though the impost was on earnings and not, directly, on the commodities carried, and though no discrimination was made in favor of local traffic, it was declared to be a toll on interstate commerce and was not allowed. In the Covington Bridge case the establishment of toll rates on the bridge from Cincinnati to Covington was declared to be a regulation of interstate commerce and, therefore, not within the legislative power of a State. And this notwithstanding the fact that the regulation of ferries, even when operated across rivers forming State boundaries, had always been regarded an exclusive function of the adjacent local authorities. The right of a State to prohibit the entry of intoxicating beverages was denied, when the goods were imported in the "original packages" as articles of interstate commerce. The law on this subject has been recently changed, however, and such shipments are now excluded by act of Congress from States with which prohibitory entry. The imposition of license fees on persons or employments, even though not discriminatory, have been declared unlawful when they were, in effect, regulations of interstate commerce; for instance, when fixing rates or orders for goods or freight to be shipped into or out of a State or to or from another State.
Several years ago the United States Circuit Court sitting at Minneapolis forbade the execution of a state law on the ground that the Minnesota system of grain inspection had become practically an interstate system by custom of the trade.

Laws passed by States in the exercise of their police powers, however, are valid, though they may incidentally affect interstate commerce. The States may exclude persons or goods by quarantine; regulate or restrict the sale of merchandise by pure food laws or other legislation in the interest of public health or morals; regulate the use of highways; impose conditions on the conduct of business by foreign corporations within their limits, and oust corporations or associations which have been declared monopolies. In a few cases which involve direct regulations of interstate commerce—for instance, the transportation, or storage for transshipment, of explosives—State laws have been held operative in the absence of Federal regulations on the subject. But it is the elementary and long-settled rule that the exercise of this divided authority over interstate commerce, and that regulations of Congress are supreme. In cases where, from the particular nature of the subject, the State may exert authority until Congress acts, it is under the assumption that Congress by inaction has tacitly authorized the State to do so. Action by Congress, though not expressly inhibiting, destroys the possibility of such assumption, since such action covers the whole field and removes the State limitation. Southern Railway Co. v. Reid (1912), 222 U. S. 424; Railway Co. v. Hardwicke Farmers' Elevator Co. (1913), 226 U. S. 426.

The gigantic extension of the railroads of the country in the decade following the Civil War resulted in a complete change in the aspect of our commercial problems. Not interstate commerce, but the most important instrumentality thereof, appeared to be in urgent need of regulation. The authority given by the act of Congress of 15 June 1866 had facilitated railroad connections and the establishment of continuous lines, overleaping the boundaries of States and defying their control. The railroads thus connected were consolidated by merger, or by lease, into great interstate systems, competition among which was stifled by pooling agreements. New lines projected as competitors to existing ones were bought out, or frozen out by means of stock jobbery or legal and political scalduggage. Of the many evils growing out of uncontrolled railroad operation the greatest of all was the practice of discriminating in service and rates between individual shippers and localities. Favored shippers were enriched at the expense, and often by the ruin, of businesses, who had to go more for service, if they got it at all. The prosperity of towns and whole sections, with the farms, mines and industries they contained, were dependent upon the good will of those who commanded the means of communication and transportation. Railway rates had started about 1870, resulted in the enactment of stringent regulative laws in the States of the Northwest and Middle West. Local legislation, however, was of little avail. More than two-thirds of the railroad traffic was interstate and lay wholly outside of State control. Nearly all of the grain and other produce that went into the elevators and became law under the act was for transshipment to other States, or for export to foreign countries. Neither could terminal services be effectively regulated, nor could unfair and discriminatory through rates be prevented. The only limitation on charges was 'what the traffic would bear.' The first attempt at regulation by Congress was made in 1873, when a bill was introduced to forbid any railroad company to charge more per mile for a short, than for a long, haul. This crude measure, which took no account of the rule of diminishing cost, was very properly defeated. Judge Reagan, of Texas, introduced into the House of Representatives in 1878 a series of bills covering the whole subject, some provisions of which ultimately found their way into the Cullom bill. Not until nine years later, however, was this bill finally passed as the Interstate Commerce act of 4 Feb. 1887. The principal objects of this law, as defined by the Supreme Court, are: to establish uniformity of rates and reasonable charges for transportation; prohibit unjust discrimination in the rendition of like services under similar circumstances and conditions; to prevent undue preferences to persons, corporations or localities; to inhibit greater compensation for shorter than for longer distances over the same lines; and to abolish combinations for the pooling of freights. Interstate Commerce Commission v. Baltimore (1892), 145 U. S. 263.

The law at first was made applicable to carriers wholly by rail or partly by rail and water, and to the instrumentalties of shipment and carriage. Transportation on water routes, by navigation companies or individual owners, operating their lines or vessels independently and not under direction of a railroad as components of a combined rail and water route, was not in the purview of the law. The Hepburn act of 29 June 1906 extended the act to pipe lines and specified with great particularity the services required in connection with the receipt, delivery and transfer in transit, ventilation, refrigeration, elevation, storage or handling of property transported; the Mann-Elkins law of 18 June 1910 included telegraphs, telephones (wire or wireless) and cables, also express companies, sleeping car companies, bridges and ferries. The pooling of freights having been absolutely prohibited by the Interstate Commerce law efforts were at first made to secure a uniformity of rates by agreement among the member railroads in each of the several regional traffic associations. Such agreements, however, were declared by the Interstate Commerce Commission, which had been created to administer the law, and by the courts, to be in violation of the Sherman Anti-Trust law, being contracts in restraint of trade. But inasmuch as the whole spirit of the law was the principle of equality, and preferences among localities similarly situated were expressly forbidden by the act, the inevitable consequence was a practical elimination of rates and classifications of freights in each of the regions covered by the traffic associations. Regulation had superseded competition as the means of adjustment. Nevertheless, mergers or combinations of parallel and competing lines
and systems are prevented by State laws, which have been declared valid by the United States Supreme Court; and the same court unscrambled the Northern Pacific and Great Northern merger, and dissolved the combination, through stock ownership, between the Union Pacific and Southern Pacific systems. The prohibition in the original act of lower rates for a long haul than for a shorter haul was unconditional; but the commission, with the concurrence of the courts, applied the qualification that it be in competition to other provisions of the law so that, where a railroad between two given terminals is in competition with an all water route, or a foreign overland route out of the jurisdiction of the commission, it was decided that there was "a substantial difference in the circumstances" such as would warrant the establishment of a lower through rate for the longer haul from terminal to terminal than for a shorter haul to intermediate points on the same line. By the Hepburn act amending this character of the law, it was finally and definitely authorized. The same law also abolished the right to a judicial review of the commission's order, making the rates established by it unappealable except on constitutional grounds — as being an exercise of the equal protection of the law, or involving the taking of property without compensation. The requirement to construct and operate switch connections by request of any lateral or branch line or shipper, if practicable and justified by the business furnished, and the "commodities clause," which forbade railroads to haul coal from mines owned or controlled by them, were other features of the Hepburn law.

It was found necessary several times to increase the severity of the penalties provided by the original law for discriminations in rates and services. The Elkins act of 4 Feb. 1903 made the giving of rebates, or the granting of any special favors which were differentials in effect, punishable by imprisonment of the agents or officers responsible for the wrong, as well as by the imposition of a fine on the bodyless and soulless corporation. But the principle of selling cheaper at wholesale than at retail has been acted upon in the sale of transportation, just the same as in the sale of other services or of commodities. The existence of "large shippers under single control, sending continuous quantities at stated and regular intervals, also weight and bulk, convenience or inconvenience, may be considered in rate making."—Interstate Commerce Commission v. Chicago & Great Western Railroad Company (1908), 209 U. S. 108.

In determining the reasonableness of a charge the interests of the carrier, the shipper and the public must all be considered; the cost of service to the carrier would be an ideal basis, but is impracticable; the value of the service to the shipper is a factor; also the density of traffic, or ability of some traffic to bear a greater charge than some other, having regard for the character of the commodities and the locality or other circumstances of production; and rates may be unreasonable because too low. As a general basis for the determination of sufficiency of the rates to produce 6 per cent on capital, over and above operating cost and fixed charges. Pursuant to this suggestion the Interstate Commerce Commission, by the act of 1 March 1913, was directed to make a physical valuation of all railroad property in the United States, the assumption being that the value so found would be less than the nominal value of the stock in the hands of shareholders, and copious illustrations of "water" could be squeezed out of the nominal capitalization.

The Panama Canal act of 24 Aug. 1912 made it unlawful for any railroad to own, lease, operate, control or have any interest (by stock ownership directly, or indirectly through a holding company) in any carrier by water or any vessel carrying freight or passengers operated on any water route with which it (the railroad) does or may compete. By this act also the Interstate Commerce Commission was authorized to require the establishment of physical connection between the lines of carriers by rail and the docks of carriers by water by means of spur tracks. The connection must be reasonably practicable, and the amount of business must justify the outlay; the commission must apportion the cost of installation and determine the conditions and charges of operation. The law applies even when the dock belongs to neither carrier, so that piers owned by municipalities or independent wharves have been subjected to Federal regulation. The commission may determine through-routes and maximum joint rates; establish maximum proportional rates by rail to and from ports, to and from which traffic is carried by water. Any carrier by rail entering into engagemens with a carrier by water for handling through business may be required to enter into similar arrangements with any or all lines of steamships operating from the same port. By this law of Federal regulation of rates, authority was still held at the water fronts; moreover, ferries unconnected with transportation by rail appear to be still under exclusive State jurisdiction. This is so even when the "ferry boats" have to go 20 miles across the high sea as do not infrequently the Peden & Cal. to Santa Catalina Island. Consult Wilmington Transportation Co. v. California R.R. Commission (1915), 236 U. S. 151. The Sherman Anti-Trust law of 2 July 1890, though it purports to be an antitrust law, has been used to break up unlawful restraints and monopolies was at first declared inapplicable to a monopoly in the production of a necessary of life, which is transported to, and sold in, every corner of the land. But the sugar trust decision has long since become obsolete and the prohibition of the Sherman law of trading in trust products makes it a most effective regulative of interstate commerce. The power of Congress to prohibit, as well as to regulate, trade is invoked also in the Federal Meat Inspection and the Food and Drug laws. But the act of Congress prohibiting interstate commerce in the products of child labor has been declared unconstitutional by the United States Supreme Court, though by a bare majority. The Interstate Commerce Commission has nothing to do with the administration of these laws and the regulation of transportation and rates on salt water routes, which the government has at last assumed and has thrown the hands of the United States Shipping Board.

The regulative powers of the Interstate Commerce Commission have been practically suspended by the establishment, as a war meas-
COMMERCIAL INTERCHANGE OF THE WORLD

Stephen Pyne

COMMERCIAL INTERCHANGE OF THE WORLD, International. World commerce is primarily the interchange of the products of its great natural divisions. Nature gave to the world three great natural divisions: the broad tropical belt stretching around the globe at the equator, and on either side of this a temperate zone. Between these two lines lies the tropics, a belt of latitude which runs through New Orleans, Cairo and Shanghai, and the 30th parallel of south latitude, which runs through Southern Brazil, the southern tip of Africa and the southern part of Australia, the products of which are chiefly tropical. North and south of these lines the products are chiefly temperate. Curiously, the area between these two lines, the 30th degree north and the 30th south, is about one-half of the land surface of the globe, exclusive of the Arctic and Antarctic regions. That tropical Africa has, today, about one-half of the world's population. Its products—cotton, silk, hemp, sisal, jute, rubber, hides, sugar, tea, coffee, cocoa and fruits—are demanded by the people of the temperate zone for food and clothing and for use in manufacturing. The temperate zones, with one-half of the world's area and population, produce the cereals, meats and other foodstuffs, and are the great manufacturing section of the world. These two zones are demanded by the people of the tropics, for food, clothing and the requirements of their domestic and industrial life. So there are great and perfectly natural interchanges of the raw and manufactured products of these two great climatic zones of the globe, the temperate zones and the tropics.

Nature, however, not content with these climatic divisions of the earth's surface, also subdivided them by the creation of continents and islands, separating them by great oceans, across which the various products of these climatic divisions must be transported by vessels. To add to this complication of interchanges, certain of these natural sections were populated and their producing powers developed long before others of them. Western and southern Europe, northern Africa, India, China and the Euphrates valley, were the seats of a busy population long before America, central and southern Africa, Australia, or the islands in the Pacific, and even the arctic regions, are populated. They contribute their products to the requirements of the world.

It is the interchanges between these great sections of the globe and the various countries and whale with which we are concerned in this discussion of international commerce. The exchanges began in a small way, with commercial caravans passing between Egypt and the Orient, and coasting vessels creeping along the waterways of southern and western Europe. But these exchanges were of comparatively little value, and it was not until the introduction of the compass when men learned that the oceans were a highway and not a barrier to commerce that trade between the great natural divisions and subdivisions really began.

It is not surprising, then, to find that the international trade of the world in 1700 was about $50,000,000, of which about $200,000,000 was conducted by Europe and the remainder by Asia and America. Great Britain was then, as she has been ever since, the leader of commerce, her trade amounting in 1700 to about $50,000,000 a year, Spain $40,000,000, France and the area which we now call Germany about $25,000,000 each, Spanish America and the East Indies $40,000,000 each, and the British colonies $10,000,000. By 1750 world commerce had doubled, amounting to about $750,000,000, and by 1800 it doubled again, reaching $1,500,000,000 at that date. These figures are as good a gauge of the imports and exports of all the countries of the world at that time.

In the next half century, however, a series of events changed entirely the commercial movements of the world and greatly stimulated world commerce, multiplying the interchanges and stimulating development and the producing powers of the hitherto undeveloped regions of the globe. In 1819 a little vessel of 300 tons, the Savannah, crossed the ocean from the United States to Great Britain by steam power, and gave to the astonished world a lesson in multiplying the usefulness of the oceans in commerce, and at the same time reducing greatly the cost of interchange between the great natural divisions. About the same time man learned to transport merchandise and people on land by the use of steam power, the railway. The result of these two great contributions to transportation and commerce was that in the year 1850 there were 15,000 miles of railroads in the world, and by 1880 the number had increased a hundredfold, there being over 1,000,000 miles of railways in 1880. This vast increase in railway mileage brought about a rapid increase in the quantity of goods transported by railways, and the cost of transportation fell until it was cheaper than by any means of transportation until then known. The product of the railroads amounted in that year to about $3,000,000,000,000, or nearly three times as much as in 1800.

From that time international trade grew by leaps and bounds. By 1870 it was $10,000,000,000, and by 1900 $20,000,000,000. Even this rapid increase, however, was outdone in the opening years of the present century, for in 1913, the year before the opening of the great European War, the international trade of the world was $40,000,000,000, having actually doubled in the short period 1900-1913.

The causes of this rapid growth following the application of steam to transportation were the opening of new areas to population and production, a reduction in the cost of transportation by which many articles were added to the list of international exchanges, the increased facility of intercommunication by the mails, the telegraph, the telephone and the wireless telegraphy, the development of banking power, and the development of great manufacturing systems, which supplied their products to all the world and took in exchange the manufacturing material from all sections of the globe. Steam vessels of the ocean grew from 1,000,000 tons in 1850 to 30,000,000 in 1913; railways from 25,000 miles
Commerce of the World

to 700,000, and telegraphs and ocean cables from 5,000 miles to about 2,000,000. World currency enormously increased and the banking power of the world grew from $3,000,000,000 in 1813 to $50,000,000,000 in 1850, and 1,600,000,000 in 1913, and the producing and purchasing power of each man greatly increased. North America, which had in 1800 but about 7,000,000 people had in 1900 about 140,000,000, and in many other areas the development of population and producing power was phenomenal.

With the increase of transportation there came a great reduction in the cost of moving merchandise between the continents and climatic sections. The wheat and corn and meats, and cotton and other manufacturing material of North America were transported to Europe and the manufactures of that continent sent in exchange; the meats and wool and hides of South America crossed the equator to Europe, and were also paid for in manufactures; and the tea and coffee and cacao and spices and sugar and fruits and manufacturing materials of the tropics were sent to the north temperate zone in great quantities, and paid for in the products of the farms and factories of the temperate zones, upon which the tropics rely for their flour and meat as well as clothing and other manufactured articles.

The wonderful growth of the world's commerce is pictured in tables presented herewith. One of these shows the total world trade and the trade of each grand division at 25-year intervals from 1800 to 1900, and also in 1913 and 1916, showing not only the total commerce at each period, but the population and the average per capita commerce at each of the dates, both for the entire world and for each grand division. Another table shows the commerce of each of the principal countries of the world, by years and export separately, at intervals from 1850 down to 1916, though in certain of the countries at war the commerce of 1916 can only be estimated by reason of the absence of official figures. Care has been exercised in the preparation of these tables to include only the domestic exports of merchandise of the various countries, omitting the precious metals and the foreign merchandise re-exported, though in certain of the smaller and newer countries this has been impracticable.

An examination of these tables of imports and exports of the various countries will disclose the fact that in many of the older countries, notably those of Europe, the imports constantly exceed the exports, while in the newer countries exports are greater than imports. This excess of imports by the European countries is due to the fact that they are compelled to draw upon other parts of the world for a large proportion of their food and manufacturing material, and that manufactures to offer in exchange their imports in most cases exceed their exports, the difference being made up by the earnings of their steamships, the earnings of their capital invested abroad, the profits upon the merchandise imported and re-exported. Many of the countries of Europe have, however, considerable quantities of natural products to export, which is in 1913 degenerated to the general fact that manufactures are the chief exportable material of that part of the world. Great Britain, for example, exported prior to the European War large quantities of coal, which she sent to all parts of the world largely as ballast for her ships carrying their lighter products, manufactures, and scouring the world for foodstuffs and manufacturing material as the return cargo. Some of the coal she supplied to the adjacent countries of Europe, taking in exchange the beet sugar of Germany, Russia and Austria; the iron of Spain and Sweden; the lumber and timber and wood pulp of Norway, Sweden and Russia; the copper of Spain, and the cork of Portugal, though much of this she paid for in certain manufactures. The imports of Europe as a whole, as shown elsewhere, are normally less than those of the exports, while in America, Africa and Oceania the exports exceed the imports. In the case of the United States, however, the imports have exceeded the imports by from $300,000,000 to $600,000,000 per annum, and in most of the South American countries and Australia the exports also exceed the imports, and this is also true of most of Africa. Tables presented here with show the total imports and exports of the countries forming each continent, and also the excess of imports or exports, also the total imports and exports of certain principal countries of the world for a series of years. It will be noted that the aggregate trade of the countries of each grand division other than Europe shows larger exports than imports, while in Europe the imports exceed exports by $2,700,000,000 in 1913, the latest normal year.

The table showing the imports and exports of the countries forming each continent and therefore the aggregate of the international commerce of the world shows for the year 1913, the latest normal year, $2,400,000,000 of imports and $1,400,000,000 of exports, and indicates that the stated value of the world imports therefore exceeded that of exports by $1,850,000,000. When we reflect that all the exports necessarily become imports in some other part of the world (except any part which may have been lost en route) we might expect that the stated value of the imports would equal that of the same articles when exported from the country of their production. But it is a fact that the stated total of imports is in most instances greater than the stated value of the same merchandise when exported. It is not unusual for the grand totals of world imports to exceed the grand total of exports by about 10 per cent. This discrepancy between the stated value of the merchandise when exported and again imported is accounted for in part by the value added by cost of transportation, and in part by the fact that the countries importing the merchandise are likely to give it a slightly higher valuation than did the countries that exported it. By reason of the fact that much of the merchandise when imported pays an ad valorem rate of duty, and the authorities are on the alert to give to it as high a valuation as cir-
COMMERCE OF THE WORLD

Circumstances will justify, while as few countries have an export tax the merchandise when exported is not subjected to so close scrutiny in determining its full value. The suggestion that the cost of transportation is added to the valuation of the merchandise when imported, does not however apply to the United States which, by law, accepts as the value of its imports the valuation declared before the United States consul when it is sent to the United States.

It will be seen from the above discussion of the valuation of the merchandise when leaving the country of origin and again when imported, and that the real value of the merchandise forming the international commerce of the world is therefore but about one-half of the usual figures of "world commerce." Records of world international trade are formed by aggregating the imports and exports of all countries of the world, and while we can only determine the value of the merchandise of any given country by aggregating its imports and exports, it must be remembered that the aggregation of the imports and exports of all the countries of the world necessarily counts the merchandise twice, once when it leaves the country of production as an export and again when it enters some other country as an import, and that when we say that the international commerce of the world in 1913 was $40,000,000,000 we therefore mean that the value of the merchandise forming that trade was only $20,000,000,000, since its value was counted twice, once as it left the country of production as an export and again when it entered the country of its destination as an import.

The intra-continental trade of the world is much less than is usually supposed. Much of the trade of the various countries occurs with adjacent or neighboring countries, on the same continent. The trade of the United States with Canada, for example, which now amounts to over a billion dollars a year, is properly considered international commerce, yet none of it leaves the continent, and our trade with all of the North American countries in 1917 was nearly $2,000,000,000. In fact, only 64 per cent of the imports of all the North American countries in 1913, the latest year of normal commercial interchanges, was drawn from other continents, and only 67 per cent went to other continents. Thus about one-third of the international trade of the North American countries in 1913 was intra-continental, or trade within the continent, while about two-thirds was inter-continental, or trade with other continents. During the war period, 1914 to 1918, with the lack of inter-continental transportation, the proportion of the intra-continental trade increased. In the case of Europe the intra-continental trade formed in normal years a larger share of the total than was the case with our own continent. Of the world's imports by all the European countries in 1913, the latest year for which complete figures are available, only 44 per cent were drawn from other continents, and of their exports only 36 per cent was sent to other continents, the remainder in each case being intra-continental, or trade between the countries of Europe. Of the total international trade of the countries forming the continent of Europe, aggregating in 1913 in round terms $25,000,000,000, only $10,000,000,000 was trade of any given country by aggregating its imports and exports, it must be remembered that the aggregation of the imports and exports of all the countries of the world necessarily counts the merchandise twice, once when it leaves the country of production as an export and again when it entered the country of its destination as an import.

The inter-continental trade of the world is much less than is usually supposed. Much of the trade of the various countries occurs with adjacent or neighboring countries, on the same continent. COMMERCE OF THE WORLD

ments. This, however, cannot yet be determined for the entire world, or indeed for many of the countries, because of the fact that the facilities of measuring the value of all the primary and manufactured products of the countries are insufficient to render available accurate figures as to the total value of the produce and thus determine the share entering international or inter-continental commerce. In the case of the United States, however, it is estimated from statistical data that the exports of the various classes of articles, agricultural, manufactures, mines, forests, fisheries, etc., that the value of the total products in 1913, the latest normal year, was about $40,000,000,000, of which a little more than 6 per cent was exported, and of this but about two-thirds, or approximately 4 per cent of the total passed to other continents.

Attention has been called to the fact that a considerable part of the international commerce of the world is the interchange between the climatic sections, the temperate zones and the tropics. The strictly tropical sections now export about $3,500,000,000 worth of merchandise annually, and import about an equal quantity, and most of this is inter-continental trade. Their chief exports are sugar, rice, coffee, tea, cacao, rubber, silk, cotton, jute, hemp, sisal, hides, gums, tobacco and fruits, and it happens that certain of the important minerals of the world, notably tin, nitrates and much of the gold, silver, lead and copper are also mined in that section. Practically all of these go to the northern temperate zone. This tropical belt could produce and supply much more of these important articles, all of which are demanded by the temperate zones for food and manufacturing, if they had railroad facilities to bring their their products to the water's edge, where the temperate zone countries gladly send their vessels to get whatever the tropics have to offer. Thus about $3,500,000,000 worth of the $20,000,000,000 worth of merchandise entering international trade is now produced in the tropical belt, and most of it sent to the temperate zones, a large part of that trade being in products while all of this tropical production exported is for the manufactures, breadstuffs and meats of the northern temperate zone, and is thus chiefly inter-continental.

The remainder of the inter-continental trade, and from that of the tropics is the interchange of the foodstuffs and manufacturing material of the newly-developed areas for the manufactures of those which have great manufacturing systems, Europe, the United States and Japan. The countries of Europe and Japan, and the south temperate zone send their fresh meats in refrigerating vessels across the equator to the markets of Europe, where they arrive in perfect condition for consumption, also their wool and grains and hides and fibres and coffee and tea and sugar and fruits and metals, and most of these are received by the north temperate zone and paid for in manufactures, chiefly the products of Europe and the United States, for practically all the factory products of the world are produced in the temperate zone, and chiefly in Europe, the United States and Japan. The total value of the manufactures produced by the factories of the world is normally about $70,000,000,000 per annum, of which approximately $7,000,000,000 or 10 per cent enters international trade, the other 90 per cent being consumed in the countries of production. Of this $7,000,000,000 worth of manufactures entering the international trade of the world the United States, in normal years, supplies about $1,000,000,000 worth, though the great increase in our exports of manufactures under the stimulus of the war gives reason to hope that we may permanently retain a larger share of the world's trade in manufactures after a return to peace conditions.

(a) No figures are available for 1916 commerce of Central Powers of Europe. Totals and per capita for Europe and entire world cannot therefore be stated for 1916.

Note.—Figures are as far as possible those of imports for consumption and exports of domestic merchandise. In some cases, however, gold and silver are necessarily excluded with figures of commerce, notably in earlier years in America and in later years in Africa and Oceania. Early figures are estimates of Mulhall and Malte-Brun.

Oscar P. Austin, Statistician, National City Bank of New York.
COMMERCIAL ASSOCIATIONS.

Early Organizations.—There were but few commercial associations in the United States before the Civil War. As a rule, only the larger cities possessed them. The functions of these early merchant organizations were to hold annual meetings to elect officers and to have occasional banquets where local politicians spoke. The strictly commercial organizations frequently aimed to maintain a produce exchange and provide room-trading facilities in such staples as grain, tobacco, and cotton. The larger of these associations compiled and published trade statistics in their annual reports. These early statistics are very interesting to the historian.

The volumes of the New York Chamber of Commerce give statistics of the movement of freight by the Erie Canal. The Cincinnati reports chronicle the rise and fall of the Ohio River trade and give the figures for Western pork packing. The Saint Louis volumes contain an account of the lumber rafts of the Mississippi River, of the Galena lead trade, of the furs and gold brought down from the upper waters of the Missouri River, of the buffalo skins shipped East from the plains and of the merchandise which entered and left the Southwest by wagon over the Santa Fe trail.

Trade Associations.—After the Civil War there began to be formed in various parts of the country organizations of men engaged in the same line of trade. The wagon makers united; the window glass blowers got together; the hotel keepers began to consider their problems, etc. These various organizations, planned along trade lines, were local, state, or national in scope.

Among the important functions which they attempted were to standardize commercial usages, to exchange craft knowledge between the members and to control prices more or less directly. Some of these associations have done good work. The Society for Testing Materials (an organization of purchasing agents) has formulated many scientifically complete buyers’ specifications. The Association of Railway Master Mechanics called attention, some years ago, to the dearness of the freight rates charged to the railroads, and the Cleveland Government for apprenticeship courses and shop schools, which has accomplished so much in the hands of American railroads. Some of the trade associations have brought their members upon a more or less uniform plane of efficiency by prescribing a standard system of cost accounting suited to the industry. The majority of the associations formed along trade lines are of wholesalers. If an organization be of wholesalers it is very likely to plan trade-getting trips, to make special arrangements for buyers’ weeks either by securing railway transportation of members at reduced rates or by giving free transportation to those who buy a specified amount of merchandise, and to organize credit and buying bureaus. The majority of retailers often make arrangement for style shows, draw up rules to prevent unprofitable advertising, operate a co-operative delivery system or establish a local credit bureau to aid them in collecting debts.

The Civic Basis of the Modern Movement.—The recent rapid growth of commercial associations in this country may be attributed to a revival of local civic life and to a new understanding of the basis of local business prosperity. The civic motive is about equal in importance with the economic one in the typical modern board of trade or chamber of commerce. There is coming to exist a more vivid civic consciousness. People now travel about so much that they get into the habit of appraising towns and cities as communities and of comparing them with their home town. Young businesses now look about more diligently for an advantageous location than was once the case, and less frequently grow up where the original idea happened to strike the founder. In other words, there is now a competition not only of individuals and firms but of neighborhoods for social, civic and economic prestige.

So long as the primitive communities had mud roads, oil lamps at the street corners, individual wells in the back yards; so long as locomotion was on foot or on horseback and there was plenty of space between the structures, the administration of local government was a routine affair. But when it became necessary to provide waterworks, grant franchises to a variety of public utility corporations, undertake such matters as street paving and the building of streets and bridges, maintain an efficient fire department, administer a complicated building ordinance, provide parks and technical schools and consider comprehensive schemes of city planning, it began to be realized by business men that the administration of a city was very much like that of a large business. And so there came a demand for “a business administration.”

In relation to this demand commercial associations have proved to be a convenient means for free and informal discussion. They have provided a centre where the progressive elements of the community could gather. They may be called the “planning departments” of the city government, to borrow a term from “Scientific Management.” They are training schools for a new type of citizenship. This function has been defined by Pres. H. A. Garfield of Williams College, in an address before the Cleveland Government for apprenticeship courses and shop schools, which has accomplished so much in the hands of American railroads. Some of the trade associations have brought their members upon a more or less uniform plane of efficiency by prescribing a standard system of cost accounting suited to the industry. The majority of the associations formed along trade lines are of wholesalers. If an organization be of wholesalers it is very likely to plan trade-getting trips, to make special arrangements for buyers’ weeks either by securing railway transportation of members at reduced rates or by giving free transportation to those who buy a specified amount of merchandise, and to organize credit and buying bureaus. The majority of retailers often make arrangement for style shows, draw up rules to prevent unprofitable advertising, operate a co-operative delivery system or establish a local credit bureau to aid them in collecting debts.

The Economic Basis.—Membership committees of commercial associations have often to deal with the manager who says, “How can I feel it in my business?” “What is there in it for me?” This brings up a critical economic point, the answer to which is, in brief, that business has been rapidly-changing in character, and changing in such a way as to produce a more intimate local solidarity in economic matters. Business units have grown larger, margins of profit have grown smaller, more care is needed in buying, delays in local traffic are more hurtful, competition for labor is ad-
vancing to a higher plane, a wider and more even market is demanded, more science is available and more is needed. Of the local solidarity of business upon its select phases only,—namely, that which pertains to the equipment of a place as a market. How does a city become a good buying and selling centre? Merchandising involves measurement of quantities (systems of weights and measures), measurement of qualities (systems of grades), means of protecting merchandise while it is being held (warehouses and warehousing law) and an adequate assortment for the buyer. A sufficient assortment can only be ensured for out-of-town trade buyers by a systematic survey of the merchandise requirements of the tributary territory. A market also requires fair prices. The formula for fair prices is to bring to bear upon each transaction all possible elements of supply and demand. This means to bring past and future supply and demand to bear upon the present by providing adequate warehousing and cold storage. It means to bring to bear upon the market of one commodity the realities of the market in its analogies which are either its raw materials or its manufactured derivatives; a thing which can be done by having the converting or manufacturing interests actively represented. It involves bringing the price of money to bear upon the price of goods by taking such steps as will interest the banks actively in commercial transactions and will make out of goods in storage an acceptable collateral for loans. It means, also, to bring different markets to bear promptly upon each other, by adequate market reports. A perfect market must have flexible credit for persons of ability and character. It must have efficient local trucking. It requires prompt railway transportation, which means not only the presence of railways but proper rates, frequent train service, a minimum of delay, convenient package car accommodations and a low percentage of loss and damage. A market is completed by an adequate information service of trade and general papers, and by a wide range of service industries to facilitate each item of trading transactions. From this bare enumeration it can be seen that a market is a complex thing. A large market is, indeed, about the most complex thing the mind of man has devised. Markets, well organized and of high efficiency, are still rare in the United States. Such a market does not merely happen; it does not grow like Topay, nor emerge Phoenix-like from the fires of competitive hatred, nor blossom from the narrow stem of policy known as "every man minding his own business." It is the result of persevering joint effort. The economic activities of commercial associations cannot be measured more than suggested by means of a few illustrations. The Commercial Association of Bridgeport (Conn.) maintains a trade school. At Grand Rapids vocational guidance for boys over 15 years of age is provided. The Lynchburg (Va.) Chamber of Commerce erected a new hotel, and finally a municipal public market. Atlanta (Ga.) manages a buyer's convention twice a year. The New Orleans Merchants' and Manufacturers' Bureau publishes a Spanish magazine, Mercure, twice a month; the Saint Louis Manufacturers' and Exporters' Association also publishes a monthly journal in Spanish. The Galveston (Tex.) Commercial Association sent a party of merchandisers to Guatemala, Honduras, Costa Rica, and Panama in 1913. The San Francisco Chamber of Commerce helped to found the Remedial Loan Association. The Spokane Chamber of Commerce has aided the North Pacific Fruit Distributors to organize. The Minneapolis Civic and Commercial Association took a census of factories and transportation lines on good roads. The Houston (Tex.) Chamber of Commerce maintains a bureau which chronicles all freight delays in and out of the city. Hannibal (Mo.) has a Commercial Club which bought a large tract of land between the tracks of three railways and sold it to new plants. A number of associations, including those of Davenport, Iowa, Williamsport, Pa., Rockford, Ill., Jackson, Mich., and Boston, Mass., have loaned credit to new business concerns. It is now estimated that there are over 3,000 paid secretaries of commercial associations in this country. In 1912, President Taft, through Secretary Nagel of the Department of Commerce and for other commercial concerns, organized the of the country to attend a national conference. The result was the formation of the Chamber of Commerce of the United States. This organization serves as a means of formulating the opinion of the business men of the country upon such economic questions as require a certain national co-ordination in action, or which rise into the domain of practical politics and require legislation or the attention of the administrative departments of government. The organ of this Chamber is The Nation's Business. See CHAMBERS OF COMMERCE.

COMMERCIAL COURTS. Tribunals distinct from the ordinary civil courts, in some countries are established in various commercial towns, or within certain districts, to settle disputes with regard to rights and obli-
COMMERCIAL EDUCATION — COMMERCIAL GEOGRAPHY

notifications between persons engaged in trade, with the assistance of experienced merchants, by a brief process, according to equitable principles. The general introduction of tribunals of this sort began in the Middle Ages. The first was that at Genoa in the 11th century, and the basis of its decisions was the code of maritime laws of Pisa, confirmed by Pope Gregory VII in 1075. At first the commercial tribunals were not so much established by grants of the government as by agreements of disputes, freely chosen by the merchants and confirmed by the governments. Under the name of commercial consuls such committees of arbitration were appointed in all the great commercial cities of Europe; and in the course of time they really became tribunals of justice, and were, in part at least, administered by men of legal learning and experience. Pope Paul III confirmed the commercial consuls in Rome. Francis II in 1560 granted to the Parisian merchants particular arbitrers for the adjustment of commercial disputes; and in 1563 was established the Parisian Court of Commerce, consisting of a judge and four consuls. The same thing soon followed in all the important commercial towns of France. In London Henry VII appointed particular commercial judges. The president of the commercial tribunal for the Hanse towns, established in 1447, bore the name of alderman. At Nuremberg, in 1621, a similar tribunal was instituted under the name of inspectors of the markets. The diets of the empire even called upon the German princes and commercial cities to follow this example, as the decrees of the empire in 1664 and 1668, and the decree of the Imperial Commission of 10 October 1663, show. In many of these cities, as in Frankfort-on-the-Main, and in Leipzig, they were not so much independent authorities as delegates from the city councils. When commercial courts take cognizance particularly or solely of disputes relating to maritime affairs, they may be called courts of admiralty. Such a court was erected in Hamburg in 1623. The internal regulations of commercial courts commonly require that a part of the members, or at least one of them, be lawyers; the rest are for the most part experienced merchants, who are better adapted than regular judges to give counsel on commercial affairs, with which they are more acquainted, and which very often are not to be reduced to simple principles of law, but are to be decided according to commercial practice. Their jurisdiction commonly extends over all commercial disputes, matters of exchange, insurance, freight, bottomry, average, etc.; and further, over bankrupts, the hiring of shops and stores, clerks and apprentices; the debts of those who receive goods from merchants upon credit; and all natives and foreigners who traffic in the place and are found there, all shipowners, contractors for transporting goods, brokers, factors, etc., are obliged to submit to their decisions. They do as much as possible by oral investigation; and the intention of their institution is that they shall avoid the long and tedious process. But when the difficulty and confusion of the matters in dispute occasion the necessity of an investigation in writing recourse is had thereto. The greater dispatch of these courts consists principally in this—that the defendant is orally summoned, once or several times, to appear before them at an early day, and if he fails to come, he can be brought by force. The complaint is then made orally, both parties are heard and sentence is given, if possible, immediately after. But this is not always done, and most cases require reference to written documents, a day not far distant is appointed for the answer to the complaint and for the evidence on both sides, and the time is seldom or never prolonged by granting a recess. A sentence must be sought from the same judges and are not easily obtained. Appeals are only allowed in very important cases, and upon the deposit of a large sum as a pledge that the final decision shall be obeyed without delay. The principal features of this process form the basis of most commercial codes. From the sentence of these tribunals appeal is made to the court of appeal within whose jurisdiction they happen to be. The courts country whose these tribunals exist are Belgium, Spain, Portugal and Italy. See COMMERCIAL LAW; UNITED STATES COMMERCE COURT.

COMMERCIAL FERTILIZER. See AGRICULTURAL CHEMISTRY; FERTILIZERS.

COMMERCIAL GEOGRAPHY. Commercial geography is the study of the exchanges of merchandise between the geographic sections of the world. Nature has greatly diversified the productions of the globe. Tropical growths for example differ in quality from those of the temperate zones and those of the mountain regions differ from those of the plains. Certain areas are especially fitted to produce foodstuffs, others manufacturing materials and in still others, the circumstances of population, transportation and supplies of raw material and fuel have developed great manufacturing industries. Commercial geography studies these conditions and notes the production of each area, and the interchanges present and possible. It is in fact a study of the geography of commerce.

The great improvement in facilities of transportation, communication and production which have characterized recent years, has stimulated the study of commercial geography. World international commerce has made its chief growth in the life time of the present generation. It was but $4,000,000,000 in 1850, $10,000,000,000 in 1870, $20,000,000,000 in 1900 and then jumped to $40,000,000,000 in 1913, the year preceding the great European War, which disarranged the commerce of the entire world and especially that of the great European countries, the world's largest importers and exporters. International trade quintupled in the half century, 1850 to 1900, and then doubled again in the 13 years 1900-13. The per capita of international commerce taking the entire world population, averaged in 1850 $4 per capita, in 1900 $13 per capita, and in 1913 $24 per capita.

This growth in international trade is, of course, very unevenly divided amongst the various countries and geographical sections of the world. The United States for example doubled its sales to Europe from 1900 to 1915, and doubled its purchases from that continent from 1900 to 1914, and this is true in a general
way of its trade with Asia, Africa and South America. Equally striking is the fact that the United States' imports of tropical and sub-tropical products, including those from island possessions, grew from $355,000,000 in 1900 to $1,000,000,000 in 1910. This actually trebled in value in the short 16-year period, and this is a mere illustration of the growing demand of the temperate zones upon the tropical world. The international trade of the United States averaged $15 per capita in 1850, and $43 per capita in 1913. The international trade of all the countries forming the continent of Europe averaged $10 per capita in 1850, and $54 in 1913; that of the countries of the North American continent averaged $11 per capita in 1850, and $45 in 1913; that of the countries forming the continent of Asia 69 cents per capita in 1850, and $4.64 per capita in 1913. The contrast in commercial conditions in the different countries is illustrated by the fact that the commerce of China in 1916 averaged $1.63 per capita of its population, and that of Japan, which lies just alongside $11.20 per capita in the same year.

Commercial geography studies these currents and circulating currents of air and water, and seeks to determine the underlying causes of the contrasts and changes which these studies disclose.

Nature divided the land area of the globe into two great land masses stretching from the Arctic regions on the north to the Antarctic at the south. Then she cross-sectioned these by climatic belts, thus multiplying the exchangeable qualities of the products of their respective areas. America stretches in a continuous land mass from above the Arctic circle at the north to within a comparatively short distance of the Antarctic circle at the south. The continent of Eurasia, which we improperly divide into Europe and Asia, stretches in a continuous land mass from above the Arctic circle well into the tropics, and then by one southern extension, Africa, extends well into the south temperate zone, while its eastern limb, the Malayan Peninsula, with the co-operation of the chain of islands extending to Australia, stretches almost to the north temperate zone. These two great masses, America on the one hand and Eurasia with its southern extensions on the other, are separated by two great oceans, the Atlantic and Pacific, thousands of miles in width, while climatic conditions cross-section each into a half dozen distinct belts, Arctic and Antarctic, north temperate, south temperate, tropical and sub-tropical. Local conditions within the continents also affect production and producing possibilities. The great elevations which criss-cross mountains and the tablelands adjacent to them lift their producing surfaces into temperatures radically different from those lying alongside on a lower level. Certain areas in tropical America for example, while lying above the ocean level, enjoy a temperate zone climate although distinctly within the area designated as the tropics, while the adjacent areas lying but a few feet above the ocean level swelter in the fiercest tropical heat and their crops ripen in like proportions. On the other hand, certain land masses in the far interior of the continents are so distant from the ocean that they receive little if any rain, for, as is well known, all the water which the land receives is carried to it by the currents of air which have obtained their moisture from the evaporation of the ocean. Air which has been so charged in passing over the ocean begins to lose its moisture in the form of rain as soon as it passes over the land and is forced upward, and so may lose practically all of its moisture before reaching the far interior of the continent, especially if it crosses high mountain ranges in its passage. As a result, we have two great desert areas in central and southwest Asia, North Africa, in the western part of the United States, the interior of Australia and certain sections of South America. Thus certain areas which lie within the tropics may have a temperate zone climate and certain other countries in the temperate zone or tropics may be absolutely unproductive by lack of moisture, which, is plentiful in the same latitude a few hundred miles away.

Air currents and the currents of water which they have formed in the ocean have also a marked influence upon the productive conditions of the land, especially in the vicinity of the ocean. The trade winds, so-called or air currents of the north, flow toward the equator to fill the partial vacuum caused by the upward movement of the intensely heated air of that region blow more and more toward the west as they approach the equator, on account of the fact that the surface of the earth at that point is traveling toward the east more rapidly than that part over which they passed in their movement from the north or south. This continuous flow of air toward the west during untold ages has set up currents of water in the ocean over which it passes, which also move toward the west in the vicinity of the equator, and when these currents of water come in contact with the land of the continent, they are forced to the north or south as circumstances may dictate, and carrying the great masses of water heated by their long passage through the tropics affect, to a greater or less degree, the climate of the land masses with which they come in contact. The temperate zone, which flows west across the Pacific Ocean from the Panama Canal to the Philippine Islands and the Asiatic coast is deflected northward along the eastern frontage of Asia and thence eastward to the northwest coast of North America, carrying some of the heat which it received in the tropics and materially modifying the climate of Japan and also that of the west coast of North America from Alaska to the southern part of the United States. Not only does it modify their climatic conditions but also gives to those areas much greater supplies of moisture than they would otherwise receive. The similar currents of air and water crossing the Atlantic Ocean just above the line or two or three miles above the ocean level, enjoy a temperate zone climate although distinctly within the area designated as the tropics, while the adjacent areas lying but a few feet above the ocean level swelter in the fiercest tropical heat and their crops ripen in like proportions. On the other hand, certain land masses in the far interior of the continents are so distant from the ocean that they receive little if any rain, for, as is well known, all the water which the land receives is carried to it by the currents of air which have obtained their moisture from the evaporation of the ocean. Air which has been so charged in passing over the ocean begins to lose its moisture in the form of rain as soon as it passes over the land and is forced upward, and so may lose practically all of its moisture before reaching the far interior of the continent, especially if it crosses high mountain ranges in its passage.
in their production and contribution to commerce.

By these various conditions, the temperate and tropical climates, the differences of elevation, and the modification of climate due to air movements, has greatly diversified the production of the earth's surface, while she has also by other processes distributed beneath the surface the minerals which man has learned to utilize in the manufacturing industries of transportation, and the various natural products now so freely interconnected the world over. Within the last century man has learned to apply the power of steam and that of the waterfall in the form of electricity to the transportation of the great natural products of these various sections of the globe, and also to utilize these powers in transforming the natural products into the form required to make them useful to man. One hundred years ago there was not in all the world a steamship on the ocean or a mile of railway or telegraph on land. Now steamships seek their landing place at the frontage of every continent, and 700,000 miles of railway bring the products of the interior to the water's edge or receive them at the coast. In the steamship has brought across the ocean and distribute it to the interior. One hundred years ago the world had less than 800,000,000 people; now it has over 1,600,000,000 with vastly greater producing and consuming power per capita than those of a century ago, and their vastly greater commerce, $40,000,000,000 per annum at the present time against $4,500,000,000 a century ago. Thus geography and geographic conditions, coupled with the power of transportation between the geographic sections and areas produce commerce, and in studying commerce we must study the geographic conditions which bring it into existence.

The value of the merchandise forming international trade was in the latest normal year, 1913, about $40,000,000,000 or one-half of the usual statement of $40,000,000,000, which is obtained by counting the merchandise when exported from the various countries of the world and counting it again when it becomes an import in some other country. If we assume that the cost of transportation is about 5 per cent of the value of the merchandise transported we shall find that the world is paying $2,000,000,000 a year for mere carriage of the merchandise which it exchanges between the countries or continents, while the profits, legitimate or otherwise, of the millions of "middlemen" who handle the products in the passage from producer to the consumer thousands of miles from the place of production, are of course several times as much as the mere cost of transportation. Yet the people of the world ungrumingly bear these billions of dollars every year for the sake of obtaining the manufactured materials and manufactures accumulated from any and every part of the globe.

Trade between the climatic belts is very large irrespective of continental relationship. The tropical and sub-tropical areas of the world with the 30th parallel of north latitude which runs through New Orleans, Cairo and Shanghai and the 30th parallel of south latitude which falls a little north of Buenos Aires, Cape Town and Sydney, Aus- tralia. This tropical and sub-tropical belt around the world lying between the 30th parallel of north latitude and the 30th parallel of south latitude has one-half of the land area of the globe and half the world's population and it sells to the temperate areas at the north and south about $3,500,000,000 worth of its annual products.

Attention is especially called to the fact that only about one-half of the international trade of the world consists of exchanges of merchandise between countries lying alongside each other or at least within the same continent. For example, the trade between the United States and the other countries of North America is, in normal years, one-third as much as that with all the other grand divisions of the world and the total interchanges of merchandise among the countries of North America are one-half as much as their trade with the other continents. In Europe, the interchanges among the countries forming that continent are actually greater than their trade with all the other grand divisions of the world. The aggregate of the imports of all the countries of Europe in 1913 was $14,000,000,000, but the aggregate of the exports was $6,000,000,000 worth was drawn from other grand divisions, the remaining $8,000,000,000 being trade between the countries forming that continent; and of the $11,000,000,000 of exports of all the European countries, only $4,000,000,000 passed "overseas" or out of that grand division, Europe, the remainder being exchanges between the countries of Europe and therefore intra-continental. The share of the aggregate trade of the European countries which occurs with other continents is about 40 per cent, in the case of Asia about 50 per cent, North America 66 per cent, South America, Africa and Oceania 90 per cent. North America sells to the other grand divisions $2,250,000,000 worth of her products annually, and buys from the other continents $1,750,000,000 worth. South American exports to the other grand divisions are over $1,000,000,000 a year, and her purchases from them range about $750,000,000, and in others much as $1,000,000,000. Asia sends $2,250,000,000 worth of merchandise to the other grand divisions, and takes from them $1,000,000,000 worth of their products. Slightly more than one-half of the entire international trade of the world is intercontinental or exchanges between the continents or grand divisions, the remainder is intra-continental or exchanges between the countries of the continent in which the merchandise originates.

What are the principal articles which form the exchanges between the great geographic and climatic divisions of the world? Food, manufacturing material and manufactures. Man must have food, he must have manufactures and therefore he must have manufacturing materials. The countries having a dense population produce less food than their own people require and must import the remainder. The countries having a sparse population produce more food than their own people require and can export the surplus. The country having the surplus is willing to sell its surplus to the country having the shortage, if the latter has something with which to pay for it, and it usually happens that the country which must
buy food has a surplus of manufactures to sell, and as the new and less densely populated countries are not manufacturers, they are willing to take manufactures in exchange for their surplus food. If it is not convenient to make the exchange in the direct process, the purchasing country pays for the foodstuff in cash and the selling country takes the cash and buys its manufactures from a more convenient market. The manufacturing countries must also have manufactures in exchange for the tropical produce which they cannot conveniently produce, and these they usually get from America, Africa, and Australia. The tropical countries are not manufacturers, they gladly accept manufactures in exchange for their natural products. They have also certain foodstuffs peculiar to the tropics, such as rice, sugar, coffee, cocoa, spices, fruits and nuts, which the temperate zones want and pay for in manufactures in certain kinds of food which the tropics can not conveniently produce, especially flour and meat. In studying these natural exchanges and the exchanges of commerce between climactic as well as continental sections, we therefore develop the study of commercial geography.

What have the respective geographic divisions to offer the other parts of the world, and what do they respectively take in exchange? Europe has a population of 465,000,000 and an average of 120 persons per square mile; Asia, 80 per square mile; North America, 16 per square mile; Africa, 12 per square mile; South America, 7 per square mile, and Australia, 5 per square mile. Not only is the population of Europe much more dense than that of any other continent, but its people are much larger consumers per capita than those of certain other continents, notably Asia and Africa. So, it is quite apparent that Europe, densely populated as she is and having a population with a large consuming power, must draw large quantities of food from other parts of the world. That continent is also the largest manufacturer of the world, and with its dense population and closely occupied acres must draw much of its manufacturing materials from the other grand divisions. Europe as a whole produces in manufacturing materials about $45,000,000,000 worth of manufactures per annum out of a world total of about $80,000,000,000,000 of factory products, and supplies about $7,000,000,000 out of the $8,000,000,000,000 worth of manufactures entering international trade. For the food and manufacturing material which she requires, she draws chiefly upon North and South America, Australia and South Africa, and pays in manufactures and in the earnings of her ships and invested capital. North America, with a population of but 16 per square mile, has more food and certain classes of manufacturing material than she requires; and although the United States is a large manufacturer and supplies nearly a half billion dollars worth of manufactures to her neighbors, the continent as a whole takes nearly a billion dollars worth of manufactures from Europe. South America, with a population of but seven per square mile, has a billion dollars worth of food and manufacturing material to spare, and Europe gladly takes most of it and pays for it with a half billion dollars worth of manufactures and the remainder in the services of her shipping and the earnings of her invested capital in that continent. This does not mean that all of the merchandise of South America goes to Europe, for parts of its wool and rubber and coffee go to North America, especially the United States. In Asia, with a population of 80 per square mile, the exportable surplus is small, and consists chiefly of silk fibres, rubber, tea, coffee, tin, and certain other minerals, and for these she takes manufactures, chiefly from Europe, but in smaller quantities from the United States. In Africa and Oceania, the chief surplus is in tropical products and precious metals, though Australia and New Zealand supply large quantities of wool, meats and wheat, and all of Africa and Oceania take manufactures chiefly from Europe in exchange for the natural products above noted.

The tropical and sub-tropical world, while not a continent or grand division in the ordinary sense of the term, is in fact, a climatic division—a broad belt stretching around the world between the 30th parallel of north and south latitude already described. It supplies to the world about $3,500,000,000 worth of its products per annum, chiefly fibres, hides, rubber, coffee, tea, sugar and fruits, and takes manufactures in exchange, chiefly from Europe, but in limited amounts from the United States. Practically all of the surplus of the tropics is consumed in the temperate zone—chiefly in the United States and the manufacturing countries of Europe. The imports of tropical and sub-tropical products by the United States, including those from island possessions, increased from $335,000,000 in 1900 to over $1,000,000,000 in 1916.

While it is not practicable to indicate in the limits of a discussion of this character the exact commercial relation of the various countries of the world to the various geographical sections, the broad extent of distribution, especially by the great industrial countries, is illustrated by the fact that the United States draws certain of its imports, especially manufacturing materials, from more than 75 different geographical or political divisions of the globe—continents, islands or countries and colonies, and sends certain of its products to more than 100 geographical and political divisions, extending to every part of the world.

Oscar P. Austin, Statistician, National City Bank of New York.

COMMERCIAL LAW. This term is rather loosely applied to a body of laws of the greatest diversity in their origin and character, but which have this in common, that they have arisen out of the usages of merchants that the legislation and judicial pronouncements thereon have taken note of and embodied these usages. There is no better way of indicating what Commercial Law, or the Law Merchant, is than to enumerate the chief topics which it comprises. These are: Agency, arbitration and award, auctioneers, bailments, bankruptcy, common carriers, composition with creditors, corporations, factors and brokers, guaranty and suretyship, insurance, monopolies and restraints of trade, negotiable instruments, partnerships, patents, sales, trademarks. The classification of Commercial Law here given is in substantial accord with that adopted in the French 'Code de Commerce' and in the German 'Handelsrecht,' although the French codification is more inclusive and
covers also the whole field of maritime law. The Law Merchant was regarded a distinct department of the common law and the word "merchant" had once a technical meaning in English jurisprudence, being defined as "a person subject to the lex mercatoria." Inferentially thereby from the Roman Concept, a merchant subject to this law, and in the provisions of the English and American bankruptcy acts, limiting their applicability to merchants and traders, one may see a survival of the distinctiveness above referred to. As a subject, a merchant, however, was not an outgrowth of the unaided Anglo-Saxon genius.

Commercial law was well developed among the civilized nations, which lived and flourished in Mesopotamia and the Euphrates delta from a period prior to 4000 B.C., and the Jewish bankers of Babylon and Nineveh had learned to deal in foreign exchange, their primitive drafts being inscribed in cuneiform letters on clay tablets. The commercial usages of remote antiquity, assimilated and added to by the发育 trade, was the beginning and basis of other trading communities of the Mediterranean during the period of the Middle Ages. A goodly part of the Law Merchant was absorbed into the common law of England directly from the Law Merchant, though not without the other modern usages of the Mediterranean. A goodly part of the laws of the Hanseatic League, or some of the modern developments thereof, for example, cold storage and bonded warehouses, grain elevators and coal ports, are the intended destination of shipments ab initio. A warehouse receipt, unless it is specifically stipulated to the contrary on the face of the same, is a negotiable instrument.

The four main forms of commercial paper are the bill of exchange and its derivative, the bank check, the promissory note and its derivative the banker's note, the bill of lading and the warehouse receipt. Local usages have caused slight divergences in the law of negotiable instruments in the various States of the Union and other political subdivisions of the English-speaking world. Thanks to the efforts of the American Bank Association in propounding uniform State laws on this and related subjects, the inconveniences resulting from diversity are in the way of being remedied. From the latest Report of the proceedings of the Association (1917) it appears that the uniform Negotiable Instruments Act has become a law in 40 States (Georgia and Texas being the exceptions) as well as in the territories of Alaska and Hawaii, the District of Columbia, Philippine Islands; the uniform Warehouse Receipts Act has been accepted by 29 States, and the Bills of Lading Act by 20 States.

The greatest addition made to commercial law at one stroke by judicial authority was the statement of the law of Baiments by Lord Holt in the celebrated case of Coggs vs. Bernard, which is reported in 2 Ld. Raym., page 909. What a large block of law this is will appear from a consideration of the fact that carriers, depositories (including banks), factors and brokers, innkeepers, pledgors, warehousemen and all other persons who borrow, hire or receive goods and chattels for selling, transporting or safekeeping, or for performing some work on or with the same, are bailees with respect to the property thus put into or left in their possession. The commission merchant, who receives a consignment of goods to sell is a bailee, so is a banker who receives a note for collection; so is one who hires a team by the hour, day or week and, also, the peddler, who makes "pants" for "gents" from their own cloth or makes furs for ladies "from their own skins." The word "bailing" is derived from the
Norman French, baillor, to deliver. Whatever is delivered by the owner to another person, in any of the ways or for any of the purposes above indicated, is bailed to him; and the law of Bailments compiles the rules and usages whereby the rights and duties of the parties in relation to the property and to each other are determined. Justice Holt, however, borrowed most of his principles, perhaps all of them, from the 'Debuitis' of Justinian and the 'Corpus Juris Civilis.'

Under the subhead Arbitration and Award are embraced the rules of law and usages whereby merchants may obtain decisions of controversies between themselves without resort to the regular courts of law. An arbitrator is appointed by the parties on each side of the controversy and the two arbitrators select an umpire; whereupon the tribunal thus constituted proceeds with the hearing of evidence and the making of an award. The proceedings are informal and, while nobody can be compelled to arbitrate, when the parties have once submitted a case the submission is irrevocable, and the award made is enforceable just the same as is the judgment of a court of law. Some commercial exchanges, under special legislative authority, maintain courts of arbitration, presided over by permanent judges, who act either alone or as umpires in association with arbitrators appointed by the parties. Latterly efforts have been made to extend this method of adjudicating disputes among merchants internationally, and notable progress has been made toward an agreement between the Chamber of Commerce of the United States and the corresponding Argentine body at Buenos Aires. Composition with creditors is a common law method for the discharge of an insolvent debtor from his obligations. Usually the composition is preceded by an assignment of the debtor's property for the benefit of all of his creditors, with the object of preventing any creditor from obtaining a preference. All of the creditors must agree to the composition and the terms of settlement must be equal for all. If a single creditor, no matter how small his claim, refuses to sign the composition deed, or if by secret arrangement any discrimination whatsoever be made in favor of one or more creditors, the settlement is a nullity. To all intents and purposes compositions with creditors have been superseded by proceedings in bankruptcy (q.v.). Originally the law terms guaranty and warranty were of identical meaning. In time, however, warranty became employed exclusively as a term of assurance of the title, quality or quantity of a thing sold. Guaranty is an undertaking on the part of the guarantor to pay the debt or perform the obligation of another in the event of the latter making default. A guaranty, generally speaking, is not negotiable; nor is it transferable in such a way as to enable anybody except the party with whom the contract was originally made to maintain an action thereon. Regarding marine insurance as a subdivision of maritime law, the form of indemnity contract with which commercial law is now concerned insurance. This kind of insurance is sometimes made to indemnify against loss by fire of ships in port; more often this form of insurance is made to cover warehouses and mercantile property therein contained, or goods and chattels in stores and factories. The general principles of the law of contracts will answer most questions raised by fire insurance policies; but the analogies with marine insurance are many. A debtor, however, may insure his life for the benefit of his creditor. The law of agency rests on two fundamental principles: (1) The agent is a mere instrument, though a living and intelligent one; for, whether a man signs his name with a pen which he takes from the table, or by another man whom he requests or authorizes to sign for him, in either case the act is that of the principal; (2) as between the principal and a third party, the former is responsible for all the acts of the agent, if there was no colorable reason for the belief of the third party that he was dealing with a principal or that the agent was duly authorized. Like the law of agency, the law of partnership and its modern outgrowths, the law of joint-stock associations is founded on the principle of making the parties too large for cursory treatment under the general head of commercial law. The modern law against monopolies and restraints of trade, though the same has become the subject of voluminous statutory regulations and judicial opinions, is a mere amplification of a few principles of the common law on the subject. The epochal opinion of Chief Justice White in the Standard Oil case was little more than a restatement of old and familiar legal maxims embodying commercial usages. The codification of the law of sales has been accomplished in England, but the Sales Act submitted to the National Conferences of the Commissioners on Uniform State Laws has, thus far, been ratified by only 18 States and Alaska Territory. The two controlling principles of the law of sales are: (1) That, where goods are sold by sample or according to description, there is an implied warranty that they correspond to the sample or description; (2) that in the absence of an express warranty the purchaser, having an opportunity to examine the goods, must be on his guard against defects.

In default of codification the Commercial Law as it exists in the United States must be sought under the titles of the subjects which it comprises. Even such a subject as 'warranty' is of little service to layman inexpert in the interpretation and construction of statutes. The hodge-podge published under such names as 'Business Laws' or 'Every Man his own Lawyer' are to be shunned as traps for the unwary. The saying that 'a man who is his own lawyer has a fool for a client' is as true as ever. There are no short cuts to a knowledge of the law any more than there are to the knowledge of other sciences. Consult 'On Contracts' (9th ed., 1909) or any other of the standard textbooks used by law students, which fairly cover the ground. An excellent English work is Smith, John William, 'Mercantile Law' (11th ed., London 1905).

STEPHEN PFEIL

COMMERCIAL LIFE INSURANCE.

The primary purpose of life insurance is the protection of one's family in case of the death of the provider of the family's income. The proceeds of a life policy may serve at the same time to protect the insured's business interests when these are unexpectedly deprived of his directing hand and brain; but in recent years the agency of life insurance has been more
directly and broadly applied to commercial affairs. After providing suitably for the family by means of a policy made in their favor, an individual may provide guaranty for business credit beyond his tangible assets by means of a policy made payable to his estate; and co-partners may provide against disturbance of their joint capital and prospects by policies made in favor of the firm or of each other; while corporations may provide against loss through the untimely removal of experienced executive heads or of peculiar and essential talent by means of policies covering the lives of those on whom the company's prospects for the time depend. Owing to the immense development to-day of combined commercial interests and the consequent weight of responsibility resting on single lives, insurance running often to hundreds of thousands of dollars, and in some cases to millions, is now placed to safeguard the financial stability of corporate concerns or to indemnify them in case of the loss of service difficult or impossible to replace. The simplicity and economic organization of a generation past called not often for such protection, but such is the peculiar genius, talent or experience involved to-day in many large enterprises that untoward removals in their personnel would cause serious if not irretrievable loss. Thus, on the one hand, commercial life insurance serves to aid in the development and stability of business by affording an additional guaranty for credit or for emergency loans, and on the other hand conserves business interests that might otherwise suffer from the loss of lives essential to their prosperity. The prediction is ventured by an authority that the life insurance policy will soon be an integral part of every considerable business arrangement. All the common forms of life policy are in use for commercial purposes, and the premium is considered an expense charge.

COMMERCIAL PAPER. A general name for checks, drafts, notes, bills of lading, bills of exchange, warehouse receipts, warehouse warrants, orders for delivery of goods, certificates of stocks and bonds, and securities loosely applied also to contracts and agreements. The term is intended to cover all that class of documents which are used commercially in place of money, and is therefore sometimes restricted to checks, drafts and notes.

Checks.—A check is an order on a bank, trust company or broker connected with a clearing house, calling for the payment of a specified amount of cash, from the funds of the maker on deposit, made out in the name of some one named, or to “Cash” or “Bearer.” It is frequently numbered, and written on a printed form blank, which may be on paper with a printed tint to prevent erasures. It is usually filled in with ink, and often the figures are also punched out of the paper or embossed so as to prevent alteration. It is good, however, if written in lead pencil, on any sort of paper. Its payment depends on the bank official's recognition of the signature, or his knowledge of, and confidence in the party presenting the check. Check or payment houses seldom cash their checks, but deposit them as received, and draw their own checks for the payment of their bills. The check after payment is punched or canceled and eventually returned to the signer or maker, who thus secures a receipt which is positive evidence of the payment of the sum named, as the party receiving a check has to put his name on the back before it will be cashed or credited to his account. A check is payable whether dated or not, but if dated ahead is not payable until the date stated. To give a check dated ahead is sometimes necessary for a conditional transaction, but it is an improper proceeding unless the cash is in the bank. When a bank is asked to certify a check, it will do so, if the funds are there to the credit of the maker, and it then becomes primarily liable, and the sum no longer remains to the credit of the signer of the check. Checks are usually printed in quantities in blank and bound in books with stubs, on which may be kept a record of the transactions. Banks have to pay all the checks they handle or make themselves liable for them, but they turn the checks over daily to a clearing house which figures out the balances due to or receivable from each bank, and settles only the balances in cash. This system relieves each bank of the immense detail of collecting each individual check.

Drafts.—A draft is very similar in form to a check, but it is an order from one bank to another bank to pay a sum stated to the party in whose favor it is made. A small merchant in a small town, who is not known, desiring to send a payment to a large city house and secure immediate shipment of the goods he orders, gets from his local bank a draft on a city bank, and uses this instead of his own check. The city merchant receiving such draft can cash it at once, knows that it is good, and has no hesitation in shipping the goods. A sight draft is an order drawn by a party to whom money is due, for the payment of money by another party at a bank named, and sent through the bank for collection. If the payment to whom it is addressed through the bank pays it, it is said to be accepted.

Bills of Lading, etc.—A bill of lading or a warehouse receipt is a receipt from a transportation company, stating that the goods specified have been delivered to them. Such bills are often commercially important, being frequently used as a basis for borrowing money. Wholesale merchants sometimes handle goods vastly in excess of their capital, but through borrowing on such receipts secure funds for transacting a large business.

Notes.—A promissory note is a promise to pay a specified sum on demand or at a future date. (See Promissory Note). The signer of a note, draft or check is the drawer or maker. The one to whom payment is to be made is the payee. One who signs on the back is an endorser, and he thus guarantees the payment. To hold an endorser liable for the non-payment of a note, he must receive prompt notice. There may be several endorsers. A release by the holder of a note to one endorser releases all other endorsers.

Money Orders, etc.—In the United States these are issued at nearly all post-offices by the postmaster for amounts up to $50 on payment of a fee of 3 cents for $2.50 or less and up to 30 cents. They are payable at the post-office named or can be banked for collection for $100.
COMMERIAL POTASH — COMMERCIAL TERMS

Express orders are also issued by express companies for moderate amounts and are payable at any office of the company, or can be banked like ordinary checks.

Certificates of stocks and bonds that have reached maturity must be deposited with banks as collateral security for loans. See NEGOTIABLE PAPER; BANKS AND BANKING (Article 17).

COMMERCIAL POTASH. See Potash, COMMERCIAL

COMMERCIAL REVOLUTION AND DEMOCRACY. See Democracy, History of.

COMMERCIAL TERMS. The following list is practically a short dictionary of the terms used in commercial or business life. As it is manifestly impossible to include all the terms applied in this relation, care has been taken as far as possible to omit those that may be ordinarily regarded as self-explanatory. Some of the more important terms are defined more fully under their respective headings.

ABANDONMENT. — Used in the customs when an importer asks the warehouse company to stop charging the goods in his account.

ACCEPTANCE. — An engagement to make a draft or bill of exchange payable at a future date, as a condition of its being paid. It is also called acceptance of a draft, or acceptance of a bill of exchange. It is also used in law for the acceptance of a bill of for goods.

ACCOUNT. — See ACCOUNTING.

ACCOUNTING. — The act of controlling the market by means of the book of accounts.

ACCOUNTS PAYABLE. — The sum charged against stockholders to pay debts of a corporation.

ACCOUNTS RECEIVABLE. — The entire property, both real and personal, that may be devised to pay the debts of the person, estate, or corporation.

ACCOUNTS RENDERED. — The transfer of title or interest in property, chiefly used when the transfer is made for the benefit of creditors. The term is applied both to the action and to the document making said transfer.

ACCOUNTS SETTLED. — A legal process directing that the person or estate of a person be taken and held by an officer of the court to secure a debt, or demand, etc.

ACCOUNTS TOTAL. — Official verification of accounts and claims made to prevent fraud on the part of the person keeping the books.

ACCOUNTS. — (1) As applied to a series of accounts, the date at which the whole sum due may be regarded as payable; (2) The charges, over and above freight charges, paid to the master of a ship for his personal attention to the care of the goods. The small charges paid by the master for piloting, towage, etc., are specified as "petty average."

ACCOUNTS AVERAGE. — A person who, while not a party to a bill of exchange which has been protested, consented to pay it if the drawer does not.

ACCESSORY CONTRACT. — An engagement made to secure the observance of a prior contract; sometimes by the same parties; sometimes by others, as in the case of suretyship, etc.

ACCESSORY OBLIGATION. — An obligation that is subordinate to another obligation, as when a mortgage is made to secure the payment of a bond.

ACCESSORY SECURITY. — A term usually used to denote pecuniary aid in time of emergency.

ACCOUNT SELLER. — An account rendered by a broker or commission merchant to his principal, specifying the goods sold, prices obtained and the net result after the deduction of commissions, expenses, etc.

ACCOUNTABLE RECEIPT. — The form of receipt given when the money or goods received are to be accounted for.

ACCOUNT DIVIDEND. — The proportion of dividend not yet due, computed to a date prior to the time set for payment, or the elapsed time since the last payment.

ACCOUNT INTEREST. — The amount of interest not yet due computed to a date prior to the date of payment.

ACCOUNT DISCOUNTED. — Dividend or interest past due and unpaid.

ACCOUNTS. — An acknowledgment in writing that a debt has been paid.

ACTIVE. — A term used to denote brisk, or lively trading, as on an active market.

ADULTERATION. — The act of debasing goods by admixture with other substances. It is often performed to meet the tastes and demands of the public. It is called "conventional" adulteration; when done with intent to deceive it is "artificial" or "false." When silver, in a mold, but still untried, careless adulteration is known as "accidental" adulteration.

AD VALOREM. — According to value. Usually applied to future delivery in the expectation that he will be able to buy them, in the meantime, at a lower price.

ADVANCE MARKET. — A condition of the stock market in which prices are tending downward.

BILL. — A written statement of goods delivered or services rendered with the amount of money due thereon.

BILL-BOOK. — A book in which the merchant keeps the detailed record of promissory notes, bills of exchange, etc.

AGAINST. — In commerce in reference to a balance, as when an exporter draws against the merchantise he has shipped.

ALL-ROUND PRICE. — A price which includes all charges and commissions.

ALLOTMENT. — Allocation, as of stocks or bonds to bidders.

ALONG. — Sometimes called a rider. A paper attached to a note, or bill of exchange to receive endorsements for which there may be no room on the back of the bill.

ALLOTMENT. — The act of delivering a ship's cargo into separate portions that they may be assigned to different purchasers.

ALLOTMENT CERTIFICATE. — The memorandum issued to an applicant for stock, showing the number of shares allotted, etc., as well as the dates on which the payments are to be made.

ALONGSIDE. — Delivery of goods at the side of the vessel on which they are to be loaded.

AMORTIZATION. — A term used chiefly to denote the extinction of a debt by a sinking fund.

ANNUAL. — Chieflly used to denote the value placed upon special articles by disinterested person.

APPRaisal. — An increase in the value of property — as of real estate.

ARBITRATION. — A branch of the stock exchange business, its transactions being based upon the temporary difference in the price of securities in two markets, the purchases being made in the cheaper, the sales simultaneously in the dearer market. As applied to exchange it is called arbitration.

ARTICLES OF ASSOCIATION. — The document containing the internal regulations of an incorporated company with all the laws by which its affairs are conducted.

ASSESSMENT. — The transfer of title or interest in property, chiefly used when the transfer is made for the benefit of creditors. The term is applied both to the action and to the document making said transfer.

ATTACHMENT. — A legal process directing that the person or estate of a person be taken and held by an officer of the court to secure a debt, or demand, etc.

AUDIT. — Official verification of accounts and claims made to prevent fraud on the part of the person keeping the books.

AVERAGE. — (1) As applied to a series of accounts, the date at which the whole sum due may be regarded as payable; (2) The charges, over and above freight charges, paid to the master of a ship for his personal attention to the care of the goods. The small charges paid by the master for piloting, towage, etc., are specified as "petty average."

AVERAGE ADJUSTER. — When a loss is to be divided between several interested parties the expert accountant who ascertains and states the sum to be paid by each person is called the average-adjuster, or average-staker.

BACK SPREAD. — An arbitration in which the price in either market is less than the price in the other plus the transportation charges.

BALANCE. — The sum required to equalize the debit and credit sides of an account. If added to the balance of a credit balance, and vice-versa.

BALANCE OF PAYMENT. — A comparison of the difference shown between the total value of a country's annual exports and imports.

BANK NOTE. — A promissory note by which the bank of issue agrees to pay its face value to bearer on demand. In the United States and Canada, where these notes are issued only by banks authorized by law, such paper passes as currency.

BANK RATE. — The rate of discount established by the banks. The term is used generally in reference to the rate established in foreign countries by the government of a country.

BANKRUPT. — A person who, having become insolvent, or unable to pay his debts in full, is adjudged a bankrupt by the court, either upon his own application or on that of his creditors.

BARN. — Commercially a barn is an outhouse, hump or gold of cattle, or silver, run in a mold, but still untried. Carelessness in it is known as "accidental" adulteration.

BID. — In the stock exchange the term denotes a person who sells stocks or shares that he does not own in the expectation that he will be able to buy them, in the meantime, at a lower price.

BILL MARKET. — A condition of the stock market in which prices are tending downward.
COMMERCIAL TERMS

BILL OF ADVENTURE.—A document by which a master or ship-owner shows that the goods shipped on a vessel are at the request of another person, he being responsible only for their delivery.

BILL OR LETTER OF CREDIT.—A letter requesting that credit be given to the bearer.

BILL OF ENTRY.—A written statement of goods entered at the customs house.

BILL OF EXCHANGE.—A written order to pay, demand, or deliver goods at a future date.

BILL OF HEALTH.—An official certificate showing the condition of a ship's company at the time of her clearing port. Bills are acceptable according to conditions prevailing, both on the ship and at the port, at which the goods are delivered.

BILL OF LADING.—A receipt for goods delivered to a common carrier for transportation. Usually applied to goods delivered to a railroad or on board ship.

BILL OF SALE.—A contract by which an absolute or conditional transferee of goods is made; often given as a security for debt.

BILL OF SIGHT.—A custom-house entry which permits the importer to buy the goods against the consignor's order.

BILL OF STORES.—A receipt granted by customs officials by which merchant vessels are permitted to carry stores and provisions for their voyage free of duty.

BILL OF SUFFRAGE.—A license authorizing coasting vessels to trade in the ports free of customs duties. Under such license all goods must be loaded and laded at suffrage wharfs.

BILL OF EXCHANGE PAYABLE AND RECEIVABLE.—A bill of exchange, promissory note or other commercial paper. The person who is to pay it terms it a "bill payable," the person who is to receive it a "bill receivable." The term "blakend endorsement" is applied to money actually in hand.

BLANK ENDORSEMENT.—An endorsement without direction as to the transferee of money funds are to be paid: the bearer then becomes the owner.

BLIND POOL.—A fund contributed by several persons and paid over to one for secret investment.

BLOTTER.—Called also the day-book: the running record of business.

BOARDING-OFFICER.—A custom-house official whose duty it is to board ships upon their arrival, to examine papers and prevent smuggling.

BOND.—(a) An instrument by which the maker binds himself to perform a specified act; (b) a surety; (c) goods or merchandise left in charge of custom-house or excise officers.

BOUND DEBT.—An obligation contracted under and secured by a bond.

BOUND WAREHOUSE.—Often called "public" or "bonded stores." A building in which goods or merchandise is stored pending the payment of customs duties or excise tax.

BONUS.—(a) A premium for a loan; (b) an extra-dividend or allowance paid out of accumulated profits; (c) an honorarium, or extra sum paid voluntarily as a reward for some service or accomplishment.

BOOK-ACCOUNT.—In double-entry bookkeeping, an account stated in terms of dollars, commodities, or certain characteristics without reference to the individual with whom they may have been effected.

BOOK VALUE.—The value of stock as based on the records of the company as distinguished from the market price.

BOOKKEEPING.—The sum charged for the right to erect booths at fairs or in market places.

BOTTLENEY.—The mortgage of a vessel to secure a loan.

BORDER.—A contract issued between brokers at the conclusion of arrangements for sales or purchases. Also called "Contract notes."

BONDS.—A premium or reward offered by a government to encourage some particular branch of industry.

BOURSE.—The name applied to the stock exchanges, or money markets of Continental Europe.

BROKER.—The middleman who negotiates the purchase or sale of stocks, commodities, etc., for others, accepting a commission, called "brokerage," in return for his efforts.

BUCHEK.—There are many classes of brokers, the following being examples: Buckers, brokers who buy and sell stocks, exchange brokers, cotton brokers, stock exchange brokers, curf brokers, ship brokers, etc.

BUCKET SHOE.—While nominally established for the conduct of business, in fact there are neither transfers nor deliveries of the stocks or commodities dealt in has led the courts to determine that its transactions are nothing more than gambling wagers.

BILL.—On the stock exchange, one who purchases stock for others expecting to sell at a higher price before the time of settlement.

BULLION.—Chiefly used to denote uncoined gold and silver in the hands of the public; another term for bullion is the value of the metal in coins as metal.

BUYER.—Purchased stock in the hands of another person, he being responsible only for their delivery.

BUYER'S BILL.—A bill made out to a stockholder who elect to demand its delivery upon 24 hours notice. The period may not be less than 4 days nor more than 60 (New York Stock Exchange). Buyer the Year is permitted on some exchanges.

BID-BIDER.—A person employed to make fictitious bids upon goods sold at auction, to secure higher prices for the owner.

CALL.—(a) A privilege secured by contract and a consideration, of claiming and receiving either a certain number of shares of some particular stock at a given price at a given time; (b) a given period, or the difference in value between the date of the demand and the date of the contract. (c) A notice of withdrawal of bonds or notes receivable which the holder must present them and receive payment of the principal and whatever interest may be due. (d) An assessment upon stockholders to pay in liquidation.

CALL MONEY.—Money loaned on condition that it may be recalled at any time.

CALL ON.—A call for the purpose of payment. A bond ceases to earn interest when it is called.

CAMERAGE.—The rental paid for a storage house.

CARRY.—A bill, or bond becomes void when the word "CANCELED" has been written across it, or the signatures punched out or cut.

CARRIERS.—One who conveys goods or persons for hire. A "common" carrier carries as a business; a "private" or "special" carrier, by special arrangement.

CARRYING CHARGES.—Interest paid by purchasers of stocks on margin, on the difference between the market price of the stock bought and the amount of margin deposited to hold ownership in it.

CASH.—Any term ordinarily applied to coin, and other currency, although readily negotiable securities are sometimes included. The term "hard cash" is also frequently applied to money actually in hand.

CASH ACCOUNT.—An account of money transactions; a ledger, as and balance on hand; (b) a term used in banking to denote the credit given to depositors on receipt of a properly secured bond for the repayment of the amount advanced with interest.

CERTIFICATE OF DEPOSIT.—A negotiable receipt issued by a bank upon deposit of money. The legal possession of the certificate carries with it the ownership of the money deposited.

CHARGE.—(a) To fix as a price; (b) to set down at a price; (c) to enter on the debt account.

CHARGES FORWARD.—The accumulated expenses of goods in transit to be paid on delivery. They may include the purchase price also.

CERTIFICATE.—A document given in evidence of a government grant conferring privileges on the fulfillment of specified conditions; (b) the hiring of a ship by special contract.

CERTIFICATE OF TITLE.—The written agreement under which a vessel is leased.

CHECK.—To all intents a check is practically a bill of exchange, payable on demand, being a written order for money previously deposited, with a banker. When a check has been endorsed by the payee, and paid to a third party it loses its claim against the endorser, not deposited by the drawee. A letter for collection, or mail a collection by the day after its receipt by the holder.

CHIP.—An exporter's brand, representing a certain definite quality of goods.

C.I.F.—Cost, insurance and freight (c.i.f.).

CIRCULAR NOTE.—A letter of credit issued on foreign firms by bankers to travelers.

CIRCULATING MEDIUM.—The recognized means of making payments.

CLEAR.—A business day intervening between the day a transaction is entered upon and the day it is concluded.

CLOSING.—An official document certifying that a vessel leaving for a foreign country has complied with the laws of the port sailed from.

CLEARING.—The term used in several branches of trade, and usually to denote different actions. A vessel is "cleared" when it has furnished all particulars about its crew and cargo when about to leave port. In importations goods are "cleared" when all duties and dues have been paid. In banking, "clearing" is a term applied to a plan by which checks and bills are exchanged.

CLEARING HOUSE.—An institution where local banks meet daily to settle their mutual claims. Its certificates of deposit are negotiable only by members of the association.

COLLATERAL SECURITY.—Any property given to secure the performance of a contract and that is to be surrendered upon the performance of the latter.

COMMERCIAL PAPER.—Drafts, bills of exchange and other negotiable paper given in the course of business.

COMMUTATIVE CONTRACT.—A contract in which each of the parties interested gives and receives an equivalent.

COMPOSITION.—The sum, or rate agreed upon in compound-
ing with creditors. When a contract for composition is made the creditors agree not to molest their debtor the document is termed a "composition deed."

COMPAND INTEREST.—Interest paid not only on the principal but on the interest that accumulates thereon, the latter being added to the original amount.
COMMERCIAL TERMS

CONCESSION.—A grant or privilege made by governments to individuals to encourage them in carrying on undertakings that promise to be mutually beneficial.

CONFIRMATION.—A document remedying a defect or supplying a missing or omitted condition.

CONDITION OF SALE.—A written statement of the particular terms under which property may be sold at auction.

CONSIGNMENT.—Goods sent for sale or delivery according to agreement. The sender is called the "Consignor;" the other party the "Consignee."

CONTENT.—A term used in the customs to denote the paper given by the master of a vessel before she clears outward. It describes the vessels, describes goods shipped, etc.

CONTRABAND.—Goods exported or imported contrary to the laws of the country concerned.

COOKED.—A term used to stigmatize a report or account as having been tampered with in any manner, to make it more deceptive.

CORNER.—Commercially the term is used to denote the fact that some person or clique has purchased so largely of a certain stock or commodity for immediate and future delivery that nearly the whole available supply had been absorbed.

CORPORATION.—A company of individuals whose acts are recognized by law as those of a single person. A corporation which fills its own vacancies is known as a "close" corporation.

COST, INSURANCE AND FREIGHT.—Items of expense sometimes grouped to make the purchase price of goods—said to be sold c.i.f. In such case the carrier becomes the agent of the buyer and delivers goods to carrier's order.

CREDIT.—A warrant for the payment of interest or dividends that may be detached from bonds and presented for collection when such payments fall due. The expression "over-

DEBT.—That which is entered upon an account as a debit. Debtors and Creditors.—Bonds on which the payment of interest does not begin till some future date. Holders of "Deferred shares" do not participate in the profits until the expiration of a specified time.

DEBTOR.—A person who has obtained credit.

DEBT.—A term used in banking to denote a non-negotiable letter employed by banks in transferring a debt; also, a third person substituted for the original debtor in a transaction.

DEBT.—A charge made as compensation for the deterioration of a freight given by a corporation as an evidence of debt which may be negotiated like any other investment paper; (b) in the customs the term is used to denote the letter of credit which, to the extent to which it is taken, indicates that the holder is entitled to a refunding from the government on the re-exportation of goods upon which the duties have been paid.

DEBT.—A term used in banking to denote a non-negotiable letter employed by bankers in transferring a debt; also, a third person substituted for the original debtor in a transaction.

DEBT.—A charge made as compensation for the deterioration of a freight given by a corporation as an evidence of debt which may be negotiated like any other investment paper; (b) in the customs the term is used to denote the letter of credit which, to the extent to which it is taken, indicates that the holder is entitled to a refunding from the government on the re-exportation of goods upon which the duties have been paid.

DEBT.—A term used in banking to denote a non-negotiable letter employed by bankers in transferring a debt; also, a third person substituted for the original debtor in a transaction.

DEBT.—A charge made as compensation for the deterioration of a freight given by a corporation as an evidence of debt which may be negotiated like any other investment paper; (b) in the customs the term is used to denote the letter of credit which, to the extent to which it is taken, indicates that the holder is entitled to a refunding from the government on the re-exportation of goods upon which the duties have been paid.

DEBT.—A term used in banking to denote a non-negotiable letter employed by bankers in transferring a debt; also, a third person substituted for the original debtor in a transaction.

DEBT.—A charge made as compensation for the deterioration of a freight given by a corporation as an evidence of debt which may be negotiated like any other investment paper; (b) in the customs the term is used to denote the letter of credit which, to the extent to which it is taken, indicates that the holder is entitled to a refunding from the government on the re-exportation of goods upon which the duties have been paid.

DEBT.—A term used in banking to denote a non-negotiable letter employed by bankers in transferring a debt; also, a third person substituted for the original debtor in a transaction.

DEBT.—A charge made as compensation for the deterioration of a freight given by a corporation as an evidence of debt which may be negotiated like any other investment paper; (b) in the customs the term is used to denote the letter of credit which, to the extent to which it is taken, indicates that the holder is entitled to a refunding from the government on the re-exportation of goods upon which the duties have been paid.

DEBT.—A term used in banking to denote a non-negotiable letter employed by bankers in transferring a debt; also, a third person substituted for the original debtor in a transaction.

DEBT.—A charge made as compensation for the deterioration of a freight given by a corporation as an evidence of debt which may be negotiated like any other investment paper; (b) in the customs the term is used to denote the letter of credit which, to the extent to which it is taken, indicates that the holder is entitled to a refunding from the government on the re-exportation of goods upon which the duties have been paid.

DEBT.—A term used in banking to denote a non-negotiable letter employed by bankers in transferring a debt; also, a third person substituted for the original debtor in a transaction.

DEBT.—A charge made as compensation for the deterioration of a freight given by a corporation as an evidence of debt which may be negotiated like any other investment paper; (b) in the customs the term is used to denote the letter of credit which, to the extent to which it is taken, indicates that the holder is entitled to a refunding from the government on the re-exportation of goods upon which the duties have been paid.

DEBT.—A term used in banking to denote a non-negotiable letter employed by bankers in transferring a debt; also, a third person substituted for the original debtor in a transaction.

DEBT.—A charge made as compensation for the deterioration of a freight given by a corporation as an evidence of debt which may be negotiated like any other investment paper; (b) in the customs the term is used to denote the letter of credit which, to the extent to which it is taken, indicates that the holder is entitled to a refunding from the government on the re-exportation of goods upon which the duties have been paid.
UNEXPECTED INCREDENCE.—The increase in the value of land resulting from such general causes as the increase of population, etc., is distinguished from the increase due to the efforts of its individual owner.

Unfair Prices.—The lowest figure at which bids for property will be accepted at auction sales or other competitive buying.

Unlawful.—The time allowed for the payment of bills of exchange drawn on foreign countries. The term is also used as a verb, and for incomplete, unfinished, or unproved.

Voucher.—A written document in proof of money transactions.

Warning.—The practice of buying and selling the same stock by a combination of brokers for the sole purpose of recording the quotations, and making it appear active. See Manipulation.

With Exchange.—As included in a draft, signifies that the cost of carriage is to be assessed on the face of the draft.

COMMERCIAL TREATIES. Definition.

Treaties of commerce and navigation are agreements between nations relative to the privileges and immunities which may be enjoyed by the commerce and by the citizens or subjects of each party to the treaty within the territory of the other. In general treaties of this character treat of specified foreign countries, treaties, conventions or agreements define the terms under which the citizens or subjects of each of the contracting governments may reside and pursue their industries and occupations within the territories of the other government, and under which the vessels and commerce of each may enter the ports, etc., of the other for trade and transportation. The object of such treaties is to procure the greatest possible freedom from discrimination in the pursuit of trade and the expansion of industries, and to this end they are reciprocal in terms.

In Case of War.—Permanent rights and general arrangements made between countries by treaty do not cease on the occurrence of war, but are, at the most, only suspended while the war lasts. (U. S. Supreme Court 1823—8 Wheat. 464, 494—Moore, Vol. V).

Modern Policy.—A policy of discrimination in favor of one foreign nation as against others is repugnant to the modern spirit of commerce. The application of the principle that a favor granted by one nation to another must be equally extended to all other nations for like consideration is now almost universal. Usually nations entering into a treaty of commerce and navigation agree to reciprocate in the protection of the citizens or subjects and to the commerce of the other within its territories the same privileges that are enjoyed by natives, under the laws of the nation within whose territories such privileges are granted.

Great Britain, France and Germany.—Great Britain, France and Germany has each a distinct policy as to concessions for trade expansion, each applying a form of discrimination in its own favor without violation of the principle of equality of foreign nations. Great Britain, as a free trade nation, opposes the employment of discriminating customs duties and places the broadest possible construction upon the "most favored nation" principle. The policy of France has been that of specific reservations favorable to her own citizens, but is tending toward greater liberality. In 1882 she terminated all her European tariff treaties, and in 1892 adopted a minimum tariff for all nations with whom she had a most favored nation agreement and a minimum for all others. The Entente Cordiale convention between France and Great Britain (1904) made provision for equality of import, customs dues,
COMMERCIAL TREATIES

etc., as to trade, commerce and navigation facilities of each with Morocco and Egypt; with reference to the Suez Canal and Gibraltar and as to fisheries in certain portions of the territorial waters of the other. In 1907 a reciprocal treaty was entered into between the two governments as to Canada, dealing with specific schedules, later (1909) enlarged in scope.

Germany in 1902 adopted a tariff system which was put into effect in 1906, making an increase in tariff rates, but providing lesser or "conventional" rates to be made effective by commercial treaties. The most favored nation clause in existing treaties of the empire was terminated and in 1905 treaties were made with Austria-Hungary, Russia, Italy, Switzerland, Belgium, Rumania and Serbia, by which these countries get the benefit of the "conventional" rates.

United States.—In the enactment of the 1909 tariff the United States adopted the maximum and minimum system effecting commercial agreements, but preserved the most favored nation principle as interpreted by this government. A concession of the kind was accorded to countries not unduly discriminating against the United States, and all countries now enjoy this concession.

Most Favored Nation.—The most favored nation clause, contained in nearly all treaties, may be declared in a few words with respect to each provision of a treaty, or be made the subject of a separate article. The form approved by the United States is: "Except as otherwise expressly provided in this treaty, the High Contracting Parties agree that, in all that concerns commerce and navigation, any privilege, favor or immunity which either contracting party has actually granted, or may hereafter grant, to the citizens or subjects of any other State shall be extended to the citizens or subjects of the other contracting party gratuitously if the concession in favor of that other State shall have been gratuitous, and on the same or equivalent conditions, if the concession shall have been conditional."

The United States construes the most favored nation clause to imply a reservation as to favors granted gratuitously, as expressed in the above article, whether so stated in exact terms or not. (Adams, 1817; and adhered to by United States State Department). Great Britain and some others contend that there is no such reservation unless expressed in terms.

Form and Scope of Commercial Treaties.

—The most recent commercial treaty of the United States is that made with Japan and proclaimed in 1911, superseding that of 1894. In express terms, this treaty provides:

"The citizens or subjects of each of the High Contracting Parties shall have liberty to enter, travel and reside in the territories of the other, to carry on trade, wholesale or retail, to own or lease and occupy houses, manufactures, warehouses and shops, to employ agents of their own choice, to lease land for residential and commercial purposes, and generally to do any and all incidental business necessary for trade upon the same terms as native citizens or subjects, submitting themselves to the laws and regulations there established.

"They shall not be compelled, under any pretext whatever, to pay any charges or taxes other or higher than those that are or may be paid by native citizens or subjects.

"The citizens or subjects of each of the High Contracting Parties shall receive, in the territories of the other, the same protection and security for their persons and property, and shall enjoy in this respect the same rights and privileges as are or may be granted to native citizens or subjects, on their submitting themselves to the conditions imposed upon the native citizens or subjects.

"They shall, however, be exempt in the territories of the other from compulsory military service, either on land or sea, in the regular forces or the national guard, or in the militia; from all contributions imposed in lieu of personal service, and from all forced loans or military exactions or conditions."

Other articles of the treaty provide that the dwellings, manufactures and shops of the citizens or subjects of one country in the territories of the other, and all premises appertaining thereto shall be respected. That there shall be no domiciliary search of premises nor examination of books, papers or accounts, except rates of excise and in the law for the natives. Provide for the appointment of consular officers, with all the authority and immunity accorded those of any nation, in all ports, cities or places opened to commerce to any nation. That there shall be freedom of commerce, reciprocally between the two countries, the citizens of each, equally with those of the most favored nation, having liberty to come with their ships and cargoes to all places, ports and rivers opened to foreign commerce, subject to the laws of the country into which they come. That the import on articles imported shall be regulated by treaty or internal legislation. That no export duties or charges shall be made nor prohibition of export or import imposed, except such as apply to all foreign nations, this not to apply, however, to prohibitions imposed as sanitary measures or to protect animals and useful plants. Reciprocal enjoyment upon equal terms is accorded to the people of both countries in the territories of the other in exemptions from transit dues and privileges relative to warehousing, bounties, facilities and drawbacks.

Limited liability and other companies and associations, commercial, industrial and financial, already or hereafter to be organized in accordance with the laws of either country and domiciled in the territories of such country, are authorized, in the territories of the other country, to exercise their rights and appear in the courts either as plaintiffs or defendants, subject to the laws of such other country. This stipulation has no bearing upon the question of whether a company or association organized in one of the two countries will or will not be permitted to transact its business or industry in the other, this permission remaining always subject to the laws and regulations enacted or established in the respective countries or in any part thereof.

No discrimination is permitted by either country against the vessels of the other in the matter of import charges, reciprocal equality of treatment being accorded whether articles of import come directly from the place of origin or from any other foreign place. No
discrimination of any sort as to either import or export is permitted. No duties of tonnage, harbor, pilotage, quarantine or other similar or corresponding duties, and be levied except as applied to vessels of the most favored nation. Coasting trade is to be regulated by the laws of the respective countries, but each is to have the same treatment as that accorded the most favored nation, so as to allow, marks, designs and patents are reciprocally the same as those accorded to natives; and the general declaration as to most favored nation is incorporated as a separate article of the treaty.

This treaty illustrated the general scope and purpose of such compacts between nations for reciprocal treatment of commerce and navigation. Local laws, habits and conditions require variations in form, and national policies determine how far such engagements may be extended to the colonies of a nation, or what ports may be closed to all foreign commerce.

Open Ports.—The United States, by an act of Congress approved 24 May 1828 opened all ports of this country to the vessels of all nations on the same terms as our own vessels in return for reciprocal treatment, without discrimination as to the nature of the merchandise carried or the ports where laden. In general, throughout the world, ports that are open to foreign commerce are open to all foreign nations on equal terms.

Retaliation and Embargo.—The application of the principle of retaliation and embargo has in recent years been generally recognized to be detrimental to expansion of commerce and unprofitable to the nation applying it. Any departure from the most favored nation principle reciprocally applied meets with disfavor among nations engaged in commerce. Attempts by various nations to apply such discriminations, for profit or in resentment, have not been beneficial to their own commerce.

Treaty Tariffs.—Reciprocal benefits from reductions in tariff dues are resorted to for the encouragement of better commercial relations between the United States and the native nations, but customarily the most favored nation principle is observed, at least in theory. Reciprocal tariff treaties with South and Central American republics by the United States under the provisions of the McKinley treaty that failed of ratification. Similar treaties made with leading foreign countries under a provision of the treaty act of 1897 were terminated on account of the constitutional objection to tariff negotiations not approved by legislative enactment, and in the place of these the maximum and minimum system adopted by the treaty act of 1909 was applied to our commercial relations. This act provided that the minimum rates (a reduction of 25 per cent) might be collected from countries which do not unduly discriminate against the United States, the higher rates to apply to all others. President Taft proclaimed the lower rates to all countries, after the adjustment of some differences with Germany and France (1910). France and Germany also have maximum and minimum systems under which (in their practice) discriminations occur.

The Open Door.—At the instance of the United States in 1899-1905, agreements were entered into between the United States and France, Germany, Great Britain, Italy, Japan and Russia, extending the enjoyment of perfect equality of treatment for their commerce and navigation within the "spheres of influence" over which they were considered the most favored nation, within China, the most favored nation provision being the ruling principle.

The treaty between Great Britain and Japan (1905) provided for the preservation of the common interests of all Powers in China, by insuring the independence and integrity of the Chinese Empire, and the principle of equal opportunity for the commerce and industry of all nations in China. It also recognized the paramount right of Japan to take measures of guidance and control over Korea, and to respect always that such measures are not contrary to the principle of equal opportunity for the commerce and industries of all nations.

Special Features of United States Treaties.

—By notice of the United States, the "most favored nation" clause in the (1850) treaty with Switzerland was arrested in 1899 together with some other articles, the general features of the treaty remaining in force.

The American treaty (1854) provides that in case of war between the two countries, the citizens of either of them residing in the territory of the other shall have the privilege of remaining and continuing their trade or occupation therein without any manner of interruption so long as they behave peaceably and commit no offense against the law; and their effects and property, whether entrusted to individuals or to the state, shall not be liable to seizure or sequestration, or any other demands than those which may be made upon the like effects or property belonging to the native inhabitants of the state in which such citizens may reside. Provision is made also for religious liberty and the right of burial in grounds owned by aliens.

The Belgian treaty (1875) reserves the right on the part of Belgium to grant special importation privileges to products of her national fisheries, and provides for the termination of the most favored nation clause by either party by one year's notice, without affecting the other provisions of the treaty.

The Bolivian treaty (1858, proclaimed 1863) makes reservation of waterways artificially rendered navigable, while opening freely all others under former treaty, free from obligation. This treaty also grants, reciprocally, the right of refuge or asylum to vessels of either country, "whether merchant or of war," from stress of weather, pursuit of pirates or enemies . . . giving them all favor and protection for repairing their ships and placing themselves in a situation to continue their voyage without obstacle or hindrance of any kind. All the provisions of this article apply to private or private vessels of war, as well as to public until the two countries relinquish this right in consideration of the general relinquishment of the right of capture of private property upon the high seas.

Free Ships and Free Goods.—In the Bolivian treaty system, or treaties of about that period, some of which, like that of Bolivia, are still in force, the following broad principle of international law is made: The two High Contracting Parties recognize as permanent and immutable the following principles, to wit:

1. That free ships make free goods, that is
to say, that the effects or goods belonging to the subjects or citizens of a Power or State at war are free from capture or confiscation when found on board a neutral vessel, with the exception of articles contraband of war. (2) That the property of neutrals on board an enemy's vessel is not subject to confiscation unless the same be contraband of war. The like neutrality shall be extended to persons who are on board a neutral ship with this effect, that although they may be in enemy's ports, property of their ships is not to be taken out of that ship unless they are officers or soldiers, and in the actual service of the enemies. The contracting parties engage to apply these principles to the commerce and navigation of all such Powers and States as shall consent to adopt them as permanent and immutable.

The treaty enumerates articles which shall be regarded as contraband of war, limiting these to arms, munitions, uniforms, horses and actual military equipment, and extending liberty of navigation to all merchandise other than the character of articles enumerated.

In case of war between the two countries, the merchants of either doing business within the territory of the other must return within three months if on the coast or within one year if in the interior. All of other occupation may remain.

The Brazilian treaty (1828), of similar character, was abrogated in 1841, except as to the most favored nation clause and general provisions for freedom of commerce and navigation. A reciprocity treaty made in 1906 was terminated under provisions of the United States Tariff Act of 1909.

The Chilean treaty (1832), similar to that with Bolivia, was abrogated in 1850.

The Chinese treaty of 1903 re-enacts provisions of treaties then in force except in so far as they are modified by other treaties to which the United States is a party. The broadest most favored nation clause is provided by this treaty. The "spheres of influence" open door is provided by agreement of the Powers.

The Congo treaty (1885) contains the "Free ships make free goods" article of the Bolivian treaty, to which it is similar.

The Cuban relations (1902) are exceptional, articles from the Island being admitted to the United States at a reduction of 20 per cent and articles to Cuba at a reduction of from 20 to 40 per cent.

The treaty with Denmark omits the most favored nation clause.

The Dominican treaty was abrogated in 1898. Now the United States supervises the collection and application of Dominican revenues.

The Ecuadorian treaty (1839) was terminated in 1892.

In treaties with Egypt and Ethiopia the most favored nation clause is incorporated.

The "temporary convention" entered into with France in 1822, for two years, or "until the conclusion of a definite treaty," is still in force. It provides discriminating duties during a period of 16 years only: so that now it provides that the duties of tonnage, lighter-money, pilotage, port charges, brokerage and all other duties on foreign shipping shall not exceed in France, for vessels of the United States, five francs per ton of the vessel's American register; nor for vessels of France in the United States, ninety-four cents per ton of the vessel's French passport; and that no discriminating duties shall be levied by either country on goods transported in vessels of the other.

Germany renounced her reciprocity treaty with the United States in 1906—before all similar treaties were legislated out of existence by the United States Tariff Act of 1909. Treaties with all German parties prior to the formation of the German Empire in 1871, not conflicting with the Prussian treaty, were assumed by the empire. The United States does not stand in "most favored nation" relations with Germany, so as to enjoy the minimum tariff rates of that country, but an arrangement was entered into in 1910 satisfying the requirements of the United States for the extension of the minimum United States tariff rates to Germany.

The treaty with Great Britain made in 1815 was indefinitely extended in 1827. It applied the favored nation clause to British East Indies as well as to England, but prohibits commerce by American vessels with India and Cape of Good Hope. Within six months if on the coast or within one year if in the interior. All of other occupation may remain.

The Italian treaty (1871) contains the "Free ships make free goods" declaration and agrees "that a state of war between one of them and a third Power shall not, except in the case of blockade and contraband of war, affect neutral commerce of the other," defining an effective blockade in terms, so that there shall be no misunderstanding.

The Korean treaty (1882), the execution of which was assumed by Japan in 1905, with the proviso that Korea should make no more treaties except through Japan, contains the most favored nation clause; temporarily recognized extraterritorial jurisdiction of the United States and confined commerce to the coast, prohibiting interior trading.

The Mexican commercial reciprocity treaty of 1884 lapsed in 1887, because of a failure on the part of the United States Congress to enact tariff legislation essential to its operation.

The Netherlands treaty (1852) regards trade between the East Indies of the Netherlands as coast trade and reserves the right to discriminate in import and export duties in favor of direct trade between Holland and her colonies, but grants to American vessels the same privileges as those under the Dutch flag.

The Serbian treaty (1881) excepts local traffic with neighboring states in the application of the most favored nation clause.

The Russian convention (1832) was terminated by a resolution of the United States Congress in 1911 because "no longer responsive in various respects to the political principles and commercial needs of the two countries"; and because "the considerations that led the respective contracting parties differ upon matters of fundamental importance and interest to each." The United States has no commercial treaty with any of the following nations, but they have treaties with other nations as follows:
Brasilia has commercial treaties with France (1900), Italy (1900) and Japan (1895).
Chile has a commercial treaty with Japan (1897).

Ecuador has treaties with France (1898) and Italy (1900).
Guatemala made a treaty with Germany in 1887 until 1911.

Mexico has treaties with France (1888), Germany (1882), Great Britain (1888), Italy (1900) and Japan (1888).
Nicaragua has treaties with France (1900), Germany (1896), Great Britain (1905) and Italy (1906).

Peru has treaties with Great Britain (1850), Italy (1874) and Japan (1895).

Salvador has a treaty with France (1901).

Uruguay has treaties with France (1892), Germany (1892) and Great Britain (1885).
Venezuela has treaties with France (1902), Great Britain (1825) and Italy (1861).

John Pierce Miller.

COMMERCY, kō'mär-se', France, town in northeastern France, in the department of the Meuse, on the left bank of the Meuse River, about 180 miles east of Paris. In its ancient castle the Cardinal de Retz wrote his memoirs. Today this city is largely modern, with buildings of red brick and chimneys. It is the headquarters of several small industries, including the manufacture of boots and shoes. The city is also known for its high quality of life, with numerous parks and green spaces.

COMMERCY, kō-mär-so-n, Philibert, French botanist, b. Chatillon-les-Dombes, 18 May, 1677; d. Mauritius, 1733. At the request of Linnaeus he composed a treatise on the 'Fishes of the Mediterranean,' the most important ichthyological work that has yet appeared. In 1767, at the command of the king of France, he accompanied Bougainville on his voyage around the world. He died on the Isle de France (Mauritius), after residing there for about four years, which he spent in gathering and correlating and studying a vast amount of material, much of which he used greatly the study of biology. He wrote, among other things, a botanical martyrology—a biography of those who have fallen victims to their efforts in the cause of botany. He left his plants, drawings and papers to the royal cabinet at Paris. Commersonia, a genus of the family Sterculiaceae, was named in his honor.

COMMINATION, an office in the liturgy of the Church of England, appointed to be read on Ash Wednesday (the first day of Lent), containing a recital of God's anger and threatenings toward sinners.

COMMINES, kō-mēnz, or COMINES, France and Belgium, towns on opposite sides of the Lys, eight miles north of Lille. The one on the right bank is in the department of the Nord, France, and communicates by a drawbridge with the other, which is in the province of West Flanders, Belgium. Ancestrally they formed a single town, which was fortified and had a castle, in which the celebrated historian, Philippe de Commines, was born. The manufactures are chiefly ribbons and cotton goods, tanning and cutlery. Pop. of French Commines, 8,572; Belgian Commines, 6,641.

COMMISSARIAT, kōm-mis-sār'iat, that department of an army which provides provisions, forage, camp equipage and all the daily necessaries, other than those connected with actual fighting. Up till 1912 the provisioning of the United States army was in the care of the Department of Subsistence; but in that year this department was united with the quartermaster's and pay departments into one of supply under the title of the Quartermaster's Corps, and charged with the provision of subsistence, pay, transportation, clothing and wages. In the British army the duties of the commissariat have been managed by different bodies at different times, and at present there is no department so named. The commissariat duties now partly fall on the Army Service Corps, while there is also an ordnance store department for the supply of war provisions. It is only in the latter body that there are officers designated commissaries.

COMMISSARY (L. commissus, pp. of committere, commit, Fr. commissaire, one entrusted with a task, duty or office). In a general sense a commissary is, as its root implies, one to whom some charge, duty or office is committed by a superior power; hence one who is sent, with delegated power, to execute some official duty in a certain place. Here it has the sense of commissioner. An officer of a bishop who exercises spiritual jurisdiction in parts of a diocese, or one entrusted with the performance of duties in the bishop's absence. In Scotts law a commissary is a judge in a Commissary Court (q.v.). For this term in its military sense, see COMMISARIAT.

COMMISSARY COURT, in Scotts law, was a Supreme or High Court established in Edinburgh in the 16th century which took to itself the duties formerly incumbent upon and performed by the bishops' commissaries. It had jurisdiction over actions for divorce, declarator of marriage and nullity of the same and all matters related thereto. This court, which was abolished in 1836, is embodied in the powers of the Court of Sessions. A second meaning of this term is that of a Sheriff's Court or County Court having the power to decree and confirm executors to deceased persons and leaving property in Scotland. See COMMISARY.

COMMISSION. (1) Formal act of trust; a warrant by which any trust is held or authority exercised. (2) A written document investing a person with an office or certain authority. (3) A certificate issued by authority by which a military officer is constituted; as, a captain's commission. (4) A body of persons joined in an office or trust, or their appointment; as, a building commission. (5) Brokerage, allowance or compensation made to a factor, agent, etc., for transacting the business of another; as one per cent commission on a sale. (6) Ship is said to be "in commission" when she is fitted out for service and her commanding officer has taken charge under his commission (see definition (3), above). (7) In an official sense, a commission is a legally created body of persons invested with limited but well-defined jurisdiction, as the Interstate Commerce Commission, the Civil Service Commission, the Anthracite Coal Commission, etc.

Commission of Bankruptcy. A commission appointed to investigate the facts relative to an alleged bankruptcy and to secure all
arms as the engineers and artillery and in a few other organizations. This system, initiated in the time of Charles II, continually became more expensive, until in 1854, during the Crimean War, the prices ranged from £430 for the commission of an ensign in the line to £7250 for the commission of a lieutenant-colonel of footguards. Under the present system in times of peace, besides the regular course of training as cadet and the examinations given to highly recommended non-commissioned officers, the avenues of approach to commissions in the British army are the officers training corps of the universities, the special reserve of officers and the territorial force. In the United States army, besides West Point and promotion from the ranks, commissions may be obtained on examination and appointment from civil life, by specially recommended men from various training corps at educational institutions where army officers are stationed, and in the Officers Reserve Corps, by the methods explained in the article on that corps. In the European War, special training courses for aspirants to commissions were initiated at Plattsburg and elsewhere. Of course, in all armies, the bars to commissions—which are the most conspicuous— are greatly let down in times of war, and it is possible for a qualified enlisted man or civilian to get a commission without going through the course of training or the highly technical examinations necessary in times of peace. See RANK.

COMMISSION FORM OR GOVERNMENT. Definition and Origin.—The commission form of government is that system of city administration in which all legislative and executive powers are vested in a single body of five elective commissioners or councilmen. The plan originated in Galveston, Tex., in 1901. Prior to that time all American cities were governed by a mayor and various administrative boards exercising the executive functions of government and by a city council of one or two chambers exercising the legislative power. The Galveston experiment accordingly marked a departure from the traditional principle of division of powers in American municipal affairs. Its adoption in Galveston was induced as a temporary measure to carry the city through the grave financial emergency caused by a tidal inundation which had destroyed a great deal of private and municipal property in September 1900. But the commission plan proved successful in its workings and soon attracted the attention of other communities.

Outline of the Galveston Plan.—As originally framed, the commission plan in Galveston provided that all powers formerly vested in the mayor, the various administrative boards and the city council should be vested in a body of five citizens of whom three were to be appointed by the governor of Texas and two elected at large by the voters of Galveston. The provision for the appointment of three commissioners by the governor was decided by the courts to be unconstitutional, however, and the scheme was amended to provide for the election of all five commissioners. At the ensuing election the five being allotted to the successful candidates as commissioners who had been already appointed by the governor. Under the terms of the charter of 1901, as thus amended in 1903, the members of the commission were to serve for a two-
year term and one of the commissioners was given the title of mayor-president but with no special functions save that of acting as chairman at meetings of the commission. It was provided that the commission should hold regular sessions, open to the public, and that by a majority vote of its members it should enact municipal ordinances, make the appropriations, award all contracts for public work and determine all appointments to positions in the city's service. It was timed that the commissioners should, by majority vote, apportion among themselves the headships of the four main departments of civic administration: namely, finance and revenue, waterworks and sewerage, police and fire protection, and streets and public property. The mayor-president was not to be assigned to the headship of any department but to exert a co-ordinating influence upon them all. These were the essentials of the Galveston Plan.

Extension to Other Texan Cities.—Although it had been prepared hastily, with little or no experience elsewhere to serve as a guide, the Galveston experiment soon demonstrated its success. All over, when the commissioners took over the duties of the city, the city had already defaulted on the payment of interest upon its debt; its bonds were selling at 40 per cent below par and it had a large floating debt which could not be funded. Within a few years, however, this situation had been enormously improved. The city was once again able to pay its way in spite of the great burdens due to the cost of reconstructing the inundated sections. Accordingly, what had been designed as a makeshift to tide over a serious emergency not only became a permanent scheme of government for Galveston but was within a few years adopted by the other cities of Texas.

The Des Moines Plan.—In due course this Galveston system found its advocates in other States of the Union. Its progress was slow, however, because of the feeling that the plan concentrated too much power in the hands of a small group of men. While retaining its main principles, therefore, some cities sought to make its practice more democratic. Most important among these was Des Moines, Iowa, which in 1907 adopted a new charter providing for a commission of five men nominated at a non-partisan, open primary and elected at large with additional provision for the use of the initiative and referendum by the voters of the city as well as (see INITIATIVE AND REFERENDUM) for the recall of one or more of the commissioners at any time after three months' tenure of office (see RECALL). The Des Moines plan further provided that no franchise giving rights in the city's streets should be valid until confirmed by popular vote. In general it aimed to establish what the Galveston plan did not seem to provide, namely, some adequate safeguards against the abuse of the large powers entrusted to the five commissioners.

Spread of the System.—With the new safeguards which the Des Moines plan added to the original scheme, the commission plan of city government began to spread. During the next few years it found adoption, without any change except as regards minor details, by many American cities, large and small, in nearly all the States of the Union. At the present time more than 300 municipalities of all sizes are governed by commissions. The majority of these are small communities with populations not exceeding 10,000; but some of the largest cities of the United States, notably Buffalo, Minn., Jersey City, Portland, Saint Paul and Oakland are included in the list. Among commission governed cities there are now six with populations exceeding 200,000 and 13 with more than 100,000. Of the larger municipalities which once adopted the plan only two, Denver, Colo., and Salem, Mass., have since abandoned it.

The Commission-Manager Plan.—A further development of the original plan soon took place in the adoption by many cities of an arrangement which, while retaining the commission, established a new administrative post known as that of city manager. Under this plan the commission retains all its legislative and policy-determining powers but devolves responsibility for the actual administrative work upon a highly-paid, professional official who makes the subordinate appointments and is accountable for securing efficiency in the various departments. This variation of the original scheme is now used by more cities in addition to many others which have adopted the city manager plan in conjunction with a larger city council instead of a small commission. See CITY MANAGER.

Merits of the Commission Plan.—The chief advantages of the commission form of government are first of all the concentration of power in definite hands thus avoiding the delays, friction and evasion of responsibility which characterized the old system of government by a mayor, various boards and a double-chambered council. In the second place, by reducing the number of elective offices it has raised the plane of officeholding, securing for the commission citizens of a better type than those ordinarily elected to municipal positions. It has not wholly succeeded in ousting the professional office-seeker, but it has given the man of business ability a better opportunity to serve the city in an official capacity. In the third place, the commission plan has made possible the introduction of improved methods of budget-making and accounting, the extension of the civil service system, publicity in the award of contracts, the development of new sources of city revenue, and the adoption of a pay-as-you-go policy in municipal finance. It has facilitated the introduction, in many cities, of the so-called new agencies of democracy such as the initiative and referendum, the recall, preferential voting, proportional representation, the short ballot and the open primary. Finally, it has had an educative value, awakening the interest of the citizens in their public affairs, making the government of the city simple and intelligible which is the first necessary step in making it responsible to them. More has been claimed for the plan, however, than it or any system of local government could of itself be expected to accomplish, but its substantial achievements are beyond question.

The Defects of Commission Government.—The chief objections to the commission form of city government, on the other hand, are that it may place a dangerously large amount of power in the hands of a few men and enable
COMMISSION MANAGER — COMMITTEE

them, by collusion, to carry corruption or dishonesty a long way without detection. It is furthermore urged that the plan violates a cardinal principle of American government by vesting both the appropriating and the spending powers in the same hands, something that is not permitted in national or State government. There the tradition of checks and balances is still powerful. It is contended, however, that a legislative body ought to be fairly representative of all interests in the community and that a body whose membership is limited to five men cannot be adequately representative. Finally, there is the allegation which experience seems to support, that it divides among five men the responsibility which was formerly concentrated in one man, the mayor. In other words, the plan goes too far in one direction and not far enough in another. The commission is too small to be adequately representative as a legislative body and too large to be efficient as an administrative organ. The adoption of the city manager plan, with provision for a city council, is a recognition of this defect in the commission form of government.

Financial Results.—The financial results of the commission plan have been shown to be good as the result of a careful investigation made in 1916 by the United States Bureau of the Census. Comparing cities which have remained under the mayor and council framework with those which have had some years of experience with commission government the balance of advantage appears to rest with the latter in such matters as lowered tax rates, more efficient checks upon expenditure, better budget methods and a reduction on municipal debts. See MUNICIPAL GOVERNMENT; CITY MANAGER.

WILLIAM BENNETT MUNRO,
Professor of Municipal Government, Harvard University.

COMMISSION MANAGER. See City Manager.

COMMISSION ON SOUTHERN RACE QUESTIONS. See UNIVERSITY COMMISSION ON SOUTHERN RACE QUESTIONS.

COMMISSIONNAIRE, kom-mi-syô-nâr̥', the attendant attached to European hotels, who awaits the arrival of the trains to secure customers, to look after their luggage, etc. He may also be employed as guide or otherwise. In London, Edinburgh and elsewhere bodies of commissionnaires have been established, the men being drawn from the ranks of military pensioners of undoubted character. In a secondary sense a commissionnaire is in general a kind of light porter or messenger.

COMMISSIONER, a member of a commission. See COMMISSION.

COMMISSURE, an anatomical term applied to nervous connections between adjacent parts of the nervous system. Though it is not always used in quite the same way, the general signification of the term, and the physiological import of the structure, is that of a bridge. It has the sense of a suture, seam, joint or closure, the places where two bodies or parts of a body meet or unite. In architecture the commissure is the joint between two stones formed by the application of the one to the other; in botany it signifies the face by which one carpel coheres to another; in anatomy it is the name for certain bands of nerve tissue which connect the right and left parts of the brain with the spinal cord; while in zoology it is a nerve cord connecting the larger ganglia of the nerve system.

COMMITMENT, in law, a written warrant for the arrest of a person named or described therein; also, the placing of a person in jail, as by warrant, for crime, contempt or the like. The word is applied usually when the detention is for a short period, so as to secure hold for trial. A commitment is made only after the person to be committed has made his appearance or has been summoned, in which particular it differs materially from a warrant. Commitments may be made by civil courts, although they are more commonly made by criminal courts.

COMMITTEE, one or more persons elected or deputed from among a larger body to examine, consider and report on any matter of business.

Large deliberative assemblies, with a great variety of business coming before them from time to time, are unable, when sitting as a whole, sufficiently to discuss and investigate many subjects on which they are obliged to act. Committees, therefore, are appointed to examine and report to the assembly from which they are selected. In the legislative bodies of the United States and in the British Parliament—in fact, in all legislative bodies in representative governments—there are committees for various purposes. What are known as "standing committees" and "grand committees" are regularly appointed at the beginning of every session, and have a definite class of subjects with which to deal, the object being to divide the work of the assembly among several bodies, and so facilitate the progress of legislation. In the British Parliament there were formerly four grand committees—of Religion, of Grievances, of Courts of Justice and of Trade, but they fell into disuse and were discontinued in 1832. Another ancient committee is that of Privileges, which is still appointed at the beginning of every session, but has seldom any work to do, questions of privilege being generally laid before a select committee specially appointed. In the United States Congress there are numerous standing committees. Among the most important of them in both Senate and House (though each House has not the same committees) are those on Appropriations, Commerce, Elections, Foreign Affairs, Judiciary, Military Affairs, Rules and Ways and Means. (See CONGRESS, UNITED STATES). "Select committees" are appointed by both Houses of the British Parliament and of the United States Congress to take
up special questions and investigate them pre-
vious to legislation. In these witnesses may be
examined upon oath, and evidence of all kinds
brought forward, the proceedings being such as
could not be carried on before the whole House.
When their reports are given in, measures may
be based upon them and passed into law. What
is known as a Committee of the Whole House
is regarded as distinct from the regular com-
mittee in so far as its procedure is concerned, since it consists
of all the members who are present. Matters
of great concernment (as supply, ways and
means, etc.) are usually referred to a commit-
tee of the whole House, in which bills, resolu-
tions, etc., are debated and amended till they
take a shape which meets the approbation of
the majority. The sense of the whole assembly
is better taken in this way, because in all com-
mittees the member is permitted to speak as
often as he pleases. When in the British Par-
lament, the House is in committee, the chair
is regularly taken by the chairman of commit-
tees, a member who receives a salary and holds
the post during the duration of the Parliament, subject to indemnity.
(See PARLIAMENT.)
When the House is desirous of forming itself
into committee, the speaker, on motion, puts
the question whether the House will resolve
itself into a committee of the whole, to take
into consideration such a matter, naming it.
The previous question cannot be put in com-
mittee; nor can the House in committee ad-
journ, as ordinary committees may, but if the business is unfinished, must hold an entirely
new sitting. If the business is finished, the
chairman reports, either immediately, or if the
House wish, at a later period. The committee
stage of a bill takes place between the second
and third reading, when the measure is dis-
cussed clause by clause. Private bills are
reported on by select committees.
In law, a committee is a guardian appointed
to take charge of the person or estate of one
who has been found to be of unsound mind, or
who is laboring under some other disability.
The next of kin is usually selected, but the
appointment rests in the discretion of the court.
It is the duty of the person appointed to take
care of the incompetent.

COMMITTEE OF PUBLIC SAFETY
(Comité du Salut Public), a body elected by
the French Convention, 6 April 1793, from
among its own members, at first having lim-
ited power conferred upon it—that of super-
vising the executive and of accelerating its ac-
tions. Later, its powers became extended; all
the executive authority passed into its hands,
and the ministers became merely its scribes.
At first composed of nine, it was increased to 12
members—Robespierre, Danton, Couthon, Saint-
Just, Prieur, Robert-Linett, Hérald de Séchelles,
Jean-Bon Saint André, Barrère, Carnot, Col-
lot d'Herbois and Billaud-Varennes. In the
term of the sessions the members should
have been elected only for one month, but all
the above-mentioned held their seats for a
whole year. The prevailing party acted on
the ground that France, threatened from within and
without, had to be prevented from falling, but
could only be saved by desperate measures,
as in times of the greatest danger. But after
the downfall of the Girondists, 1 and 2 June
1793, when the Mountain, on the recommenda-
tion of the Committee of Safety, declared that
the population of France consisted of but two
parties—patriots and enemies of the Revolu-
tion—and consigned the latter to the persecu-
tion of all kinds, the constitution of the state
was la vertu et la terreur! Carnot confined
himself to the direction of the armies, and left
to his colleagues the affairs of the interior. At
the motion of these men the new constitution
was suspended for a time, and the revolutionary
government conferred on the Committee of
Safety by a decree of the Convention of 4 Dec
1793. The committee now instituted in all the
communes of the republic, as judges of the sus-
ppected, revolutionary committees, composed of
the most furious zealots: the number of these
new tribunals was as great as 20,000. The last
remaining forms of regular process were abol-
ished; their place was supplied by violence, and
often by avarice and folly. In this time of
internal severity, the system of bloodshed;
and Robespierre himself acquiesced in the condemnation of the ring
leaders of the Paris mob (24 March 1794),
among whom was Hébert; but soon after (5
April) Danton and de Séchelles was himself
overthrown by Robespierre. Till 28 July 1794 the latter now remained master of the
lives of 30,000,000 of men. He appointed Fou-
quier-Tinville public accuser. Prisons were
multiplied and crowded; the prisoners were
ruelly treated, betrayed by spies and con-
demned without being allowed the privilege
of defense; the property of all imprisoned
was confiscated, and the guillotine remained en permanence. The same violence
was practised in the provinces by some of the
delegates of the committee. Among the num-
berless victims of the system were the noble
Malesherbes and the celebrated Lavoisier.
The members of the Committee of Public Safety
and of the comité de sûreté générale at last
disagreed among themselves. Each committee
contained three parties. These, and not Tallien,
were the real causes of the 9th Thermidor (27
July). In the Committee of Public Safety
Robespierre, Couthon and Saint-Just (gens de
la haute main) formed one party; Barrère, Bil-
laud and Collot d'Herbois (les gens révolution-
naires) another, and Carnot, Prieur and Linet-
d (les gens d'examen) a third. In the comité de
sûreté générale one party comprised Vadier,
Amor, Jaget, Louis (du bas Rihn) and Voill-
land (les gens d'expédition); to the second be-
longed Danton and Lebas (écouteurs); to the
third Moise Bayle, Lavicomterie, Elie Lacoste,
Dubarran (les gens de centrepoids). Robes-
pierre attempted to remove the unyielding Car-
not from among the majority. On the other hand Billaud-Varennes labored to effect
Robespierre's downfall. Couthon, Saint-Just,
the Jacobins and the commune of Paris alone
adhered to Robespierre. But when Saint-Just
actually proposed in the committee a dictator-
ship for the safety of the state an opposition was raised against Robespierre in the National Convention by Vadier, Colin d’Herbois, Billaud-Varennes, and especially by Tallien and Frère; the dictator and his faction were proscribed, and the victory of Barras (q.v.) on the 9th Thermidor brought Robespierre, his brother, Saint-Just, Couton and others, 105 in all, to the scaffold, 28 July. The Convention now recovered its authority; the Jacobins and the partisans of terrorism (le gave de Robespierre) were completely overthrown; and at the same time the Convention gave the Committee of Safety and the revolutionary tribunal a more limited power and jurisdiction. The bloody despotism ceased; and when a new constitution introduced, in 1793, a new government (see DIRECTORY), the Convention was dissolved, and with it sank into its grave the revolutionary government, the reign of terror and the Committee of Public Safety.

COMMITTEES OF CORRESPONDENCE, in American Revolutionary history, public committees of a type first appearing in England, created by the parliamentary party of the 17th century in their struggles with the Stuarts. In 1763, when the English government attempted to enforce the trade and navigation acts in America after the Peace of Paris, the colonial leaders advised the merchants to hold meetings and appoint committees to memorialize the legislature and correspond with each other to forward a union of interests. This was done in Massachusetts, Rhode Island and New York 1763-64. On 13 June 1764 the Massachusetts General Court appointed a committee to communicate to other colonial governments its instructions to its agent in London, to protest against the Sugar Act and the proposed Stamp Act. When the latter was passed in 1765, the Sons of Liberty formed committees of correspondence to organize resistance. Samuel Adams, during the decade 1764-74, constantly urged the adoption of this plan by the patriots of the colonies. He moved the general court to that effect in 1770-71. A few public bodies in the country appointed such committees, but there was no general concert. The payment of judges’ salaries by the royal government in 1772 was seized upon by Adams as a fresh incitement, at first with scant effect, but on 21 November a slender town meeting at Faneuil Hall, Boston, appointed a correspondence committee of 21 to communicate with other Massachusetts towns concerning infringements of popular rights. It consisted of the foremost popular leaders—Adams, Otis, Warren, Quincy, etc.—and until late in 1774 (see COMMITTEES OF SAFETY) remained the real executive of the town and largely of the province. A report of its first meeting was printed and sent to all the towns and to other provinces, and in a few weeks 80 Massachusetts towns had appointed similar committees, many more doing so in a short time. No fresh places in other colonies joined, though the report was printed in their newspapers. But the royal commission to investigate the burning of the Gaspee in Rhode Island and send the culprits to England for trial expired without result, not in Rhode Island itself, but in Virginia, where the House of Burgesses, on 12 March 1773, appointed a committee of 11 to communicate with other colonies on the doings of the administration, especially in Rhode Island, and report. The plans were characteristically different, the Massachusetts being by the town voters, the Virginia by the legislature, but the latter was immediately effecting its eliciting response. Committees were appointed by Rhode Island 7 May, Connecticut 21 May, New Hampshire 27 May, Massachusetts 28 May, South Carolina 8 July. This threat of united opposition daunted the government; the Gaspee prosecutions were not pressed, and the commissioners found adversely to its commander. There being nothing more to do, the legislative committees stopped for the time, after exchanging proceedings. The Boston committee alone continued its political activities, and the tea question (see BOSTON TEA PARTY) soon revived the others. The Boston committee, followed by that of Connecticut, sent out circulars urging the defeat of British purposes; and the former, by legal town-meeting was made the executive of Boston. It called the committees of five surrounding towns into consultation, and sat like a little Senate,8 Hutchinson said. Under its direction the tea was thrown into the harbor. The Tea Act roused the remaining colonies: Georgia in September, Maryland in October, North Carolina in December, New York and New Jersey in February, chose legislative committees of correspondence; and new municipalities joined the movement—several in New Hampshire and Rhode Island and the city of New York. After the Boston Port Bill came into effect the Boston committee invited those of eight other towns to meet in Faneuil Hall, and the meeting sent circulars to the other colonies recommending suspension of trade with Great Britain, while the legislative committee was directed by the House to send copies of the Port Bill to other colonies and call attention to it as an attempt to suppress American liberty. The organization of the committees was at once enormously extended; almost every town, city or county had one, though a few dismissed theirs in fear of the coming storm. The Boston opposition attempted this, but were crushingly defeated. In the middle and southern colonies the committees met by the terms of their appointment, to elect deputies to meet with those of other committees, to consult on measures for the public good. The history of the committees from this time on is the history of the preliminaries of the Revolution. Consult Frothingham, ‘Rise of the Republic’ (1872); Howard, ‘Preliminaries of the Revolution’ (1905).

COMMITTEES OF SAFETY, in American Revolutionary history, these were a later outcome of the committees of correspondence (q.v.). An Massachusetts committee faced a crisis and, toward a crisis, it became usual for towns to appoint three committees, of correspondence, of inspection and of safety. The first was to keep the community informed of dangers either legislative or executive, the second to protect the fruit of public good; the second to watch for violations of non-importation agreements, or attempts of loyalists to evade them; the third to act as general executive while the legal authority was in abeyance. In February 1776 these were regularly legalized by the General Court; but consolidated into one, called the Committee of Correspondence, Inspection and,
Safety, to be elected annually by the towns. This possessed all the powers of the other three, but in addition was empowered to notify the provincial authorities of all violation of any of the acts, resolve or recommendations of the legislature; also to send for persons and papers, call out the militia, take charge of confiscated property and prisoners of war, and carry out the laws against Tories. An appeal from them to the legislature, but was not often judged. Previous to this, however, in October 1774, the first Provisional Congress of Massachusetts had appointed a provincial committee of safety, with 11 members, to act as the executive of the province; and in the next few weeks it made arrangements to raise and support an army. On 9 Feb. 1775 the second Provincial Congress constituted five members a permanent executive, and instructed it to call a general muster and cause to be assembled with the utmost expedition, and completely armed, accoutred, and supplied, such and so many of the militia of the province as they shall judge necessary, such levy to be made when the committee shall be notified that a force is about to be made to carry out the Boston Fort Bill. It was this committee's decision to take possession of Charlestown and Dorchester Heights, on the rumor that Gage was to have heavy reinforcements and occupy them, which led to the battle of Bunker Hill. New York had also a committee of safety of 100 men, but it is characteristic of the undeveloped politics of the time that several of these were conservatives who afterward joined the British side. Partly from this, and partly from the unwieldy size of the committee, an inner committee was formed consisting entirely of Sons of Liberty, and directed its operations. At the news of the battle of Lexington, they called a public meeting in New York at the city hall, and secured the arms and ammunition in the arsenals. John Lamb and Isaac Sears led the action, arrested all British vessels about to sail for Boston, locked up the custom-house, and discharged the cargo of a vessel detained by British authorities as loaded with supplies for the patriots, formed a military company, armed it from the arsenal, surprised and captured the chief depot of British stores at Turtle Bay, and when the British commander ordered his men to join the army in Boston, refused to allow them to take any arms but those in their hands. Otherwise they were to be allowed to embark unmolested. The more ardent members were displeased at this, but kept the letter of the promise and no more. The muskets being carried in wagons, they confiscated them as not "in the hands," the soldiers declaring that they should not be used against their brethren in Boston. Consult for the functions of the committees, Sparks, Life of Gouverneur Morris,' (Vol. I., Chap. 2), and Hunt, A., Provincial Committees of Safety (1904).

COMMODORE, in the United States navy, formerly an officer ranking next above a captain and commanding a few ships when they were detailed for a particular purpose of the fleet. The grade was abolished by Congress in 1899, when all commodores became rear admirals. While there is no actual grade of commodore in the British navy, it is by courtesy applied to the commander of a flotilla of submarines, or to the captain in command of a squadron. The word is also a title given in courtesy to the president of a yacht club, or to the senior captain of a line of steamers.

COMMODOUS, kōm' mō-dōs, Lucius Aurelius, Roman emperor: b. 161 A.D.; d. 31 Dec. 192. He was the son of Marcus Aurelius Antoninus and gave early proofs of his cruel and voluptuous character. On the death of Marcus Aurelius, 17 March 180 A.D., Commodus ascended the throne. A conspiracy against his life in which his sister Lucilla played a prominent part, having been discovered in 183, he showed himself a more execrable monster than even Caligula, Nero or Domitian. For his amusement he cut asunder persons, put out their eyes, mutilated their noses, ears, etc. His brutal character made him jealous of all those who had risen to prominence during his father's reign, and most of them were put out of the way. He was endowed with extraordinary strength, and often appeared in the arena, having demonstrated his strength and skill in arms he appeared publicly in the amphitheatre. He is said to have fought in this way 735 times, and as his opponents were armed with weapons of tin or lead, while he was encased in impenetrable armor, he had naturally an easy victory on every occasion. In his combats with wild beasts he was securely protected by a screen of net work, through which he hurled his darts or shot his arrows. A part of the city having been consumed by fire, and the people reduced to despair by famine, disturbances broke out, and the Emperor was obliged to consent to the death of his minister, Cleander, who was charged with being the author of these calamities. He demanded that he be himself worshipped as a god under the title of Hercules Romanus. Commodus was strangled by the gladiator Narcissus, who was hired to commit the deed by Marcia, the mistress of Commodus, who had plotted with Lactus, the prefect, and Eclectus, the imperial chamberlain, to put him out of the way, and on the news of his death, which was reported to be the consequence of an apoplexy, the Senate declared him an enemy of the state, ordered his statues to be broken to pieces, and his name to be erased from all public inscriptions. Rome was indebted to him for her handsomest baths—the Thermæ Antonianae. He established also an African fleet, in addition to the Egyptian one, for the purpose of supplying the city with corn.

COMMON, that which belongs as a privilege or right equally to more than one, to many, or to the public at large; free to all; general; universal; public; having no separate owner; as, the common weal. In Scotts Law, common good, taken in its widest sense, signified all the properties of a corporation over which the magistrates had a power of administration and dispose of. In the sense of that which is for the general public, the Court of Common Pleas is often called the "Common Bench." In common has the legal sense of equal...
COMMON ACCIDENT—COMMON LAND

with another or with others, or for equal use or participation by two or more. Hence the old expression "tenants in common" which is still in use.

The word is also applied to an open and (generally) unenclosed space, the use of which is in the hands of the public or to a certain number. In most of the cities and towns in the United States there are considerable tracts of land appropriated to public use. These commons were generally laid out with the cities and towns where they are found, either by the original proprietors or by the early inhabitants.

In logic the word is applied to terms or names, in opposition to individual, singular or proper. 4 Common terms, therefore, are called "predicables" (namely, affirmatively predicables), from their capability of being affirmed of others; a singular term, on the contrary, may be the subject of a proposition, but never the predicate unless it be of a negative proposition (as for example, the first-born of Isaac was not Jacob); or, unless the subject and predicate be only two expressions for the same individual object, as in some of the above instances. 5

COMMON ACCIDENT, a term in logic used to denote a character or predicate which is nearly always or, it may be, always found in a certain kind of subject. See Logic.

COMMON ASSURANCES, in law, the legal evidence of the transfer of the title to property, as deeds or wills. In most countries such evidences must be registered in conformity with the provisions of the law in order to become operative and effective.

COMMON BENCH, the Court of Common Pleas. See Common.

COMMON-BUD, a term used in botany to indicate a bud which is, at one and the same time, a leaf-bud and a flower-bud.

COMMON CARRIERS, such as carry goods for hire indifferently for all persons. The term includes carriers by land and by water and is sometimes applied to those who handle goods as a matter of business convey messages. On the one hand they comprise stage-coach proprietors, railway companies, truckmen, wagoners and teamsters, car-men, porters and express companies, whether such persons undertake to convey goods from one portion of the same city to another, or through the whole extent of the country, or even from one country to another; and on the other hand they include the owners and masters of every kind of vessel or water-craft, who undertake to carry freight of any kind for all who choose to employ them, whether the extent of their navigation be from one continent to another or only in the coasting trade, or whether employed in lading or unlading goods or in ferrying, with whatever motive they may adopt. (Story, Bailments, §§ 484-496). Common carriers are liable for all damage or loss during the transportation from any cause, except the act of God or the public enemy. Common carriers, with land or water, when they undertake to carry freight of any kind for all who choose to employ them, are obliged to carry all which offer, and if they refuse without just excuse, they are liable to an action. Common carriers may qualify their common-law responsibility by special contract. The bill of lading is usually the written evidence of the contract between the parties. The responsibility of the carrier begins on receipt of the goods from the owner. Carriers of passengers are not held responsible as insurers of the safety of those whom they transport, as common carriers of goods are. They are, however, bound to a high degree of care in the selection of appliances, employees, etc., in order to secure the safety of their passengers. Extensive powers over carriers, especially in regard to the fixing of rates, are possessed by the Interstate Commerce Commission, appointed by the act of 1887. Consult Fetter, "The Law of Carriers of Passengers" (Saint Paul 1897); Hutchinson, "Treatise on the Law of Carriers" (Chicago 1891); Judson, "The Law of Interstate Commerce" (Chicago 1905). See Commerce, Interstate.

COMMON COUNCIL, the council of a city or corporate town, empowered to make by-laws for the government of the citizens. In American cities the city council is generally composed of but one chamber, but may be, and sometimes is, applied to a body consisting of two cameras. They are elected by the people.

COMMON DIALECT, a name given to the common tongue of the educated classes in Greece and other countries after the death of Alexander the Great. This "dialect" which was both written and spoken was also known as the "Hellenic dialect," a form of the Greek tongue much like pure Attic, which, with the writings of Aristotle, begins to change into the "common dialect." The latter had pretty well changed into Byzantine Greek at the beginning of the 5th century.

COMMON DIVISOR, or COMMON MEASURE, in mathematics, a number that divides each of two or more given numbers exactly, that is, without leaving a remainder in the form of a whole number, fraction or decimal. The theory of divisors is that part or section of the theory of numbers relating to their divisibility; while the method of divisors is the means of finding the commensurable roots of an equation. This method is rendered integral, after which they are sought for among the factors of the absolute term.

COMMON FIELD, a term generally used in the plural to denote the arable land of a village community in ancient times. These, lands were divided into three long, narrow strips and were cultivated in co-operation though the land was allotted to several owners. In French Canada and those parts of the south of the United States which formerly belonged to France small tracts of land, usually quite narrow and long, fenced in and cultivated by the inhabitants in general, were long known by the name of the common land or common field.

COMMON LAND, a term loosely used to indicate that land is held in severalty but used in common. It also has the signification of land owned by the community and used as a waste or open land for common pastureage. Such land has not been appropriated to cultivation by an individual. There was a great deal of such land in all the Latin-American countries less than half a century ago; and in certain retired communities considerable of it.
still exists, more especially in the Latin-American countries. It was a common manner of holding land among all primitive peoples given to the cultivation of the soil on a scale extensive enough to make the provision of land a consideration in the life of the community or of the individual.

COMMON LAW, the great body of unwritten law in England and the United States as distinguished from the written or statutory law. The ultimate sources of the common law of England are the usages and customs which were observed by the barbarous ancestors of the Saxon and Norman conquerors, and administered in their rude forest courts long before the beginning of their historic records. This origin is not peculiar to Teutonic law. Custom is law," said Cicero. Usage, or rather the spontaneous evolution by the popular mind of rules, the existence of which is proved by their general observance, is the oldest form of law making. The criminal law was a major part of the early English as of every other rudimentary central system. All law was penal at its beginning, and the licensed revenge of injured parties, next to popular opinion, was the most powerful means of enforcing customary rules of conduct in loosely organized primitive communities. Indeed, compounding for injury was the beginning of criminal and, also, of civil procedure; the privilege of paying *wergild* to buy off the avenger passed by almost imperceptible stages into the obligation to pay damages for breaches of contract as well as for injurious res MR from distinctively tortious acts. Oliver Wendell Holmes, Jr., now justice of the United States Supreme Court, in his "Common Law," published nearly 40 years ago, illustrated this evolution, and also the almost perfect parallel in the development of the Roman and Teutonic systems. A few examples of the early law of liability drawn from each of these systems may be useful as well as interesting. In the Twelve Tables (a.c. 451) it was provided that if an animal had done damage it must be surrendered to the injured party or his personal representatives, or compensation paid for the damage done. The same rule was applied (consult Gaius, "Institutes") to the torts of children or slaves. The underlying idea in all these cases was to make the owner answerable for the acts or things over which he had, or claimed, a proprietary right. Failure to observe a contractual obligation might not be considered a wrong that would excite a desire for vengeance; still, it is provided in the Twelve Tables that an insolvent debtor should be compelled to sell his goods and lands in observance of certain formalities, obtained the right to cut up the bankrupt's body and divide the parts among themselves. Now as to the Teutonic parallels: According to the Salic Law, if a man was killed by a domestic animal, the owner was required to pay one-half the compensation (wergild) which he would have had to pay to buy off the blood feud if he himself had killed the man; for the other half he was required to surrender the animal to the complainant. The origin of payment of one-half the customary wergild where the slave was a slave, and for the surrender of the latter to the vengeance of the blood kindred of the slain. In more primitive Teutonic law, as in the Twelve Tables, injuries done by persons were atoned for by their surrender alone. The "Lex Saxonica" made the master responsible for wrongs done by his bondmen at his command, and according to the Thuringian law, the master was required to pay damages for all injuries resulting from the acts of his slaves. In the Kentish laws of Hlothaire and Eadric (A.D. 680) it is provided that if a slave slay a freeman, let the owner pay with 100 shillings and save up the slave. According to the laws of Ine, "if a Wealas slave slay an Englishman, then shall he who owns him deliver him up to the lord and the kindred, or give 60 shillings for his life." (Consult Thorpe, "Ancient Laws," 1, pp. 27, 29 and 149). In the laws of King Alfred (A.D. 871) it is stated that a man "if a man with a naked sword a man slay (cattle) be delivered up or compounded for." (Thorpe, "Ancient Laws," 1, p. 79). Here we have the successive and almost identical stages through which the law of an owner's liability passed in both the Roman and Teutonic systems, from the requirement to surrender the cause of injury to the payment of compensatory damages. In Alfred's laws may be found even a compulsion to inanimate objects of the injured party's right of vengeance. It is there declared that a tree by which a man is slain, though without fault of the owner, shall be given to the kindred; which is not unlike the custom of the Kukis, a savage tribe in southern Asia, recorded by Tyler in his "Primitive Culture," that, if a man be killed by falling from a tree, his relatives take revenge by felling the tree and scattering it in chips. And the idea of avenging a death on the instrument which caused it among the English jurisprudence up to relatively modern times. A "deodand," the thing with which a homicide was committed, was regarded as accursed and was forfeited to the Crown, although the owner had nothing to do with the slaying. From a record ("tempus Edward I") we learn "if a man fall from a tree, the tree is deodand; if he be drowned in a well, the well shall be filled up," while from the days of Elizabeth down ward law students have been made familiar with the proposition: "If my horse strikes a man, and afterward I sell my horse, and after that the man dies, the horse shall be forfeited." The curse follows the deodand and nobody can acquire property therein. There is nothing in Teutonic law quite comparable in ferocity to the division of an insolvent debtor's body among his creditors, as authorized in the Twelve Tables; yet the early Teutonic law of suretyship was very severe. Down to the times of Charlemagne, who, after a man had incurred a debt, was taken as a hostage and his life was forfeited if his principal defaulted in the performance of an obligation. Bail is a prisoner's keeper and shall he charged for an escape, some say the ball shall be charged in the piece; the same opinion of Shard, a justice of the time of

The distinction is very properly made by American and English jurists between *written* and *unwritten* law. Even before the time of Chief Justice Coke the term *written* was applied almost exclusively to statutory law; but there was a written law in England before Parliament came into existence, as the collections of laws going under the names of Alfred, Canute and other kings of the pre-Norman period indicate. William the Conqueror in the fourth year of his reign (1070) promulgated the so-called *Laws of Edward the Confessor,* his immediate predecessor and the last of the Saxon kings. These laws were collected by a grand committee of wise and noble English (not Normans) learned in their laws and customs, whom William had caused to be summoned from all parts of the country. The method adopted in this case bears a distant resemblance to the enactment of laws by a legislative body; but the legislation of the Norman monarchs, who governed without parliaments, usually took the form of a *charta* or charter. The *Great Charter* or *Magna Charta* is the only legal rights motto exemplar. The *Laws of Edward the Confessor* are little more, however, than a collation of the laws of liability and compensation, whereof several examples are given in the foregoing paragraphs. More instructive, though less authentic, than the collection just mentioned, is one bearing the name of the *Laws of Henry I.* a son of the Conqueror, who reigned from 1100 A.D. The work is a compilation, made by an unknown hand, of many things to be found in the earlier enactments, though some parts are extracted from the civil and canon law and there are several express references to the laws of the Salic as well as of the Ruparian Franks. Notwithstanding its defects it provides better means of forming an opinion of the nature of law among the early English than does any other extant document. The impression given is, that there was a body of laws and customs sufficiently well known to be of service, but that when anything in the nature of a legal principle or definition was required they were at the mercy of any person whom they suspected as a learned man, and who was prepared to lay down a rule on his own or any other authority or no authority at all. Roman law must have been the source of many such legal principles, for none other was then in existence. The extent to which the civil law was drawn upon, probably, will never be clearly ascertained. The compilation of the *Laws and customs of England,* which bears the name of Glanville, Chief Justiciar in the reign of Henry II (1154–89), does not anywhere cite or refer to the Roman law as authority. It would need to be seen to buy and sell, borrow and lend, hire and let, and is in the nature of things and, in an even indifferently well-ordered community, customs and usages, whereby men will regulate the conduct of their affairs. From the Roman Glanville commentary on these transactions of ordinary life is in complete accord, however, with the Roman law. The principle of the *jus civilis* respecting "real contracts," that the delivery of the object of an agreement created an obliga-

*COMMON LAW* 411

The distinction is very properly made by American and English jurists between *written* and *unwritten* law. Even before the time of Chief Justice Coke the term *written* was applied almost exclusively to statutory law; but there was a written law in England before Parliament came into existence, as the collections of laws going under the names of Alfred, Canute and other kings of the pre-Norman period indicate. William the Conqueror in the fourth year of his reign (1070) promulgated the so-called *Laws of Edward the Confessor,* his immediate predecessor and the last of the Saxon kings. These laws were collected by a grand committee of wise and noble English (not Normans) learned in their laws and customs, whom William had caused to be summoned from all parts of the country. The method adopted in this case bears a distant resemblance to the enactment of laws by a legislative body; but the legislation of the Norman monarchs, who governed without parliaments, usually took the form of a *charta* or charter. The *Great Charter* or *Magna Charta* is the only legal rights motto exemplar. The *Laws of Edward the Confessor* are little more, however, than a collation of the laws of liability and compensation, whereof several examples are given in the foregoing paragraphs. More instructive, though less authentic, than the collection just mentioned, is one bearing the name of the *Laws of Henry I.* a son of the Conqueror, who reigned from 1100 A.D. The work is a compilation, made by an unknown hand, of many things to be found in the earlier enactments, though some parts are extracted from the civil and canon law and there are several express references to the laws of the Salic as well as of the Ruparian Franks. Notwithstanding its defects it provides better means of forming an opinion of the nature of law among the early English than does any other extant document. The impression given is, that there was a body of laws and customs sufficiently well known to be of service, but that when anything in the nature of a legal principle or definition was required they were at the mercy of any person whom they suspected as a learned man, and who was prepared to lay down a rule on his own or any other authority or no authority at all. Roman law must have been the source of many such legal principles, for none other was then in existence. The extent to which the civil law was drawn upon, probably, will never be clearly ascertained. The compilation of the *Laws and customs of England,* which bears the name of Glanville, Chief Justiciar in the reign of Henry II (1154–89), does not anywhere cite or refer to the Roman law as authority. It would need to be seen to buy and sell, borrow and lend, hire and let, and is in the nature of things and, in an even indifferently well-ordered community, customs and usages, whereby men will regulate the conduct of their affairs. From the Roman Glanville commentary on these transactions of ordinary life is in complete accord, however, with the Roman law. The principle of the *jus civilis* respecting "real contracts," that the delivery of the object of an agreement created an obliga-
devoted to the law of "Actions." From this time forth the law reports, the issue of which increases in volume from year to year, became the province of their industrious and industrious compilers. The reports of Chancery, in the "Year Books" the report of a case generally consists of a statement of the form of action, the plea, a summary of the facts and the judgment of the court, whether for the plaintiff or defendant; the rule of law involved must usually be inferred. From the time of Coke judicial opinions became more and more elaborate and, nowadays, they are frequently of inordinate length even in cases involving no point of particular novelty or importance, while the reporters follow no discoverable principle of selection in making up their volumes. The Roman system of laws begins and ends with a code. The theoretical descent of this body of law from the Twelve Tables and the theoretical ascension of the common law to immemorial unwritten tradition were the chief reasons for the difference in the development of the two systems.

The early Teutonic law scarcely recognized individual property. A man might own his spear, his sword, his shield and other weapons of offense or defense; but the alod, or domain of each household, was incapable of being disposed of by sale or testament, being strictly reserved to the kin. Even chattels were regarded as common possessions, the family partaking somewhat of the character of a corporation, of which the pater-familias was the trustee, and the members of which were clothed with certain inalienable rights. Under the feudal system a new viewpoint was taken with regard to property in land. The Gothic, Frankish and Saxon chieftains, who conquered the domain of the decadent Roman Empire, parceled out their conquests among their retainers in fiefs. But the land thus distributed was not owned by the person in possession. It was merely held in tenure by way of reward for prospective, as well as past, military service. When the holder of a tenure died or failed in his loyalty the property, which had theoretically remained vested in the sovereign, reverted absolutely to the latter. The succession to land was in the disposition of the overlord, who could not transmit the fee simple from the successor as conditions of investiture, and who would also see to it that the latter was a person capable of fulfilling his military obligations. The preference of males in the line of descent and the practical disinheritance of all but the first-born were natural outgrowths of feudal institutions. The privilege of conveying land without regard to these limitations and the view of a will, which regards it as conferring power to divert property as the fancy of the testator may dictate, are not older than the later portion of the Middle Ages. The modification of the strict feudal rules of inheritance in England was an achievement of the courts and lawyers, which was not obtained without conflict with the landed interests represented in Parliament. For instance, where a conveyance or devise of land was made to a person "and his heirs," the courts held this condition to be satisfied when an heir was born to the grantee or descended from the heir in whose favor the feu was thereby indirectly created, and the right to dispose of the land by sale or will was complete. The statute 'De Donis' reversed this rule of the lawyers and declared that in the event of the non-existence of an heir in the holder of the feu the title reverts to the grantor. The feudal law recognized entails, but the lawyers invented the process of "fine and recovery" whereby an entail could be defeated. Finally, by the rule in "Shelley's case," the word "heirs" in a conveyance of land was held not to be a word of limitation curtailing the grantee's right of disposition, unless so qualified that another interpretation would necessarily have to be given to it. Another legal fiction, whereby the alienation of estates in land was facilitated, was introduced by the equity jurisdiction. The holder of a fee simple was permitted to create a "use" by conveying the legal title to another, with the understanding that the grantee was to retain an equitable estate therein. The court of chancery would enforce this understanding against the grantee, who held the legal title, and a "use" was capable of testamentary disposition. In the event of intestacy the "use" descended to the owner. Finally Parliament made a statute declaring the beneficiary of a "use" to be the real owner and permitting the disposal of estates in land by will. In this roundabout manner were "tenures" converted into absolute rights of ownership. In theory the holder of a tenure continued to owe homage to his immediate lord, though by Coke's time the obligation to perform military service as a condition of holding had become in the main a legal fiction. A tenancy in fee was tantamount to ownership, and there were lesser estates, as copyholds, in the creation of which the possibility of the tenant trailing a pike in the service of his liege was never thought of. A copyholder was simply a lessee who paid rent, and a lease had become simply a contract. The provision made by law for the widow was attributable to the exertions of the Church, which achieved one of its greatest triumphs when the express promise exacted from the husband at marriage to endow his wife was converted into a legal right and the principle of "dower" was grafted upon the customary law of all western Europe. A milestone in the history of the common law was the publication of Thomas Littleton's famous treatise on "Tenures" (about 1481). This work, written in Norman French, was the first really systematic exposition of the English law of real property. It contained not merely a clear and accurate account of the great variety of tenures then known in England, but of the rules with respect to the alienation and inheritance of land, including the law of primogeniture and entailment, as well as the rights incidental to land holding, as easements, the husband's usufruct. Also the property rights growing out of personal relations between the parties, for instance, a husband's estates by curtesy and a wife's right of dower. Also the absence of rights of alienation of the holder of a fee in social order, as, for example, villeinage. Also the law of actions on 'Covenant' and of 'Fine and Recovery.' In fact, for a community which was just emerging from the feudal stage of organization, and in which the law, literally and subliterally, considered real property, the law of tenures contained a practically complete
system of rules for the governance of society in its commercial and civil relations. It was this that moved Camden, in his 'Britannica,' to speak of Littleton as the famous lawyer, to whose 'Treatise on Tenures' the students of common law are no less beholden than are the civilians to Justinian's Institutes. Coke called the book the ornament of the common law, the most absolute and perfect work that ever was written in any human science—and, when he had drown original rivulet of text in an inky flood of commentary, he put forth the product (in 1628) as the 'First Institute of the Law of England.' In this form the work for nearly two centuries remained an authoritative textbook on the common law and, though now almost wholly obsolete, it still has undeniable historic value.

The legislative or statutory contributions to the common law have been massive in quantity and of transcendent importance in their subject matter. It is impossible to even mention more than a few, which stand out above the domain of changes subsequently exerted. The statutes of Mortmain and Charitable Uses were designed to prevent perpetuities. They marked the growth of the right to alienate land and the gradual undermining of the feudal system. Frequent additions and amendments were required to overcome the ingenuity exercised by the lawyers to evade the statutes related to the formation of ecclesiastical and other latifundia. Of equal importance, though in a quite different direction, was the Statute of Frauds. A distant progenitor of this was the provision of Magna Carta which required seaca (witness proofs) for parol debts, and set a limit to contentious and vexatious litigation by forbidding suit for such debts except within the traditional limits of the seaca. The statute of Charles II (1677) for the Prevention of Frauds and Perjuries requires written instruments as proof in many classes of contracts and in all contracts not to be performed within a year. The imperfection and danger of verbal evidence as proof of past transactions make this one of the most salutary legislative measures in English jurisprudence. The Statute of Limitations, passed during the reign of James I, should also be mentioned. The provision for extinguishing from litigation after long lapse of years, when oral and other evidence concerning the transaction was no longer procurable, is the only effective means of quieting titles and assuring the members of society from provocative interferences with other long enjoyed rights and promoting the peace. Other sources of the common law, which may here be conveniently mentioned, are the charters granted to municipalities and trading companies, many of the liberties granted in these having become general rules of law. The 'Law Merchant' was a body of usages common to traders in all parts of Europe relating mainly, of course, to mercantile transactions. The law was laid down by the merchants themselves. The traders of the later Middle Ages were cosmopolites and their established customs and legal rules were observed by all alike, irrespective of nationality. The law was administered by special tribunals—England had the 'Shires,' and continental countries the 'Courts de Poids et Measures.' It was administered as distinct from the Common Law even after Coke, in whose time the ordinary law courts had begun to take jurisdiction of controversies between traders. The customs had to be proven as facts in each case. During the presidency of Lord Mansfield over the King's Bench, the Law Merchant was finally incorporated with the common law (see COMMERCIAL LAW). Finally, the equity jurisdiction assumed by the lord chancellors at the end of the 17th and continuously broadened, yielded a tremendous influence on the matter, form and practice of the common law; more particularly with regard to women, children and other persons of imperfect legal capacity. This department of law reached its full development in the 18th century under Lord Eldon (see EQUITY). The laws of marriage and the family, of consanguinity and testamentary succession had their origin in the civil and canon law and until modern times (in England) they were administered by the ecclesiastical courts. The title 'Surrogate,' quite common in the United States, was originally that of the officer who presided over the probate of wills in the Ordinary's Court.

In the domain of pure common law the common law has drawn its tenants from a variety of sources; but all of them are purely English. The right of freemen to representation in their own government is traditional, and the Saxon 'witenagemot' and Norman 'folke things' were the prototypes of Parliament and Congress and all other later legislative assemblies. Immemorial usage also is the basis of the right to trial by jury, though this is also confirmed by Magna Carta. The English Bills of Rights, as their names import, were acts of Parliament, though in America they have generally been embodied in written constitutions, State and Federal. The independence of the judiciary of royal prerogative and the answerability of judges to God and their own conscience, and to no other authority whatsoever, were pronounced in a deh of King James I by Lord Chief Justice Coke. The latter also anticipated the United States Supreme Court by nearly 200 years in passing upon the constitutionality of statutes, saying that 'the common law doth control acts of Parliament and adjudge them void when against common right and reason.' The fiction that English sovereigns can lay no claim to the crown, that they can be divested of that honor and allegiance, is a fiction shattered at least four times, when reigning monarchs were deposed and it was shown that kings in England ruled only by grace of the law and of Parliament. This was the complexity of political liberties and public and private rights, known as the common law, which the English colonists carried with them to America as a cherished heritage. It may suffer in the estimation of precissians because of its lack of form; its nomenclature, as has been truly said, is 'a mosaic of many languages'—and the law itself, 'except so far as it has been deduced with much logical pellucidness from the theory of feudal tenure,' is little more than a collection of rules strung together on a slender thread of analogy, through which the practitioner must be content to find his way by the help of indices, abridgments or so-called Digests arranged in alphabetical order. On the other hand the case against the embodiment of the law in single codes is that the law would be restated in the language of the codifier, is a strong one. A code, being inflexible in its character, prevents true growth.
in the law. Discussions in court would turn on the interpretation of words employed in the codification instead of the examination of legal principles. Moreover, an uncodified system of law can be mastered by the student without any reference to earlier enactments, or cut his own path through the tangled growth of enactment and precedent and, so, to codify for his own purposes. The common law as it existed at the time of the Declaration of Independence, including the acts of Parliament in so far as they were not repugnant to the rights and liberties contained in their respective constitutions, was formally adopted in all the original States of the Union and by most of the commonwealths subsequently admitted as States. Louisiana, where the 'Code Napoleon' prevailed at the time of its admission to statehood, is an exception. Feudal tenures, the right of primogeniture and entail were abolished in all the original States, and were never recognized by the common law in America. Though the Constitution of the United States in no words adopts the common law, its provisions no less recognize the existence and continuance thereof as the law of the land, with which the courts might not interfere. But even statutes are to be construed with reference to the common law, for it is not to be presumed that the legislature intended to make any innovation upon the common law further than the case absolutely required. This rule of construction has been held applicable to acts of Congress. The Federal courts have no jurisdiction over common law crimes; however, in the trial of actions between citizens of different States involving ordinary legal rights these courts necessarily take cognizance of the laws of the States and of the principles of the common law governing the cases thus brought before them. The Constitution of the United States, together with foreign treaties and acts of Congress made under its authority, are the supreme law of the land. In the States their constitutions, statutes and the common law rank in authority in the order given. When the American colonies had achieved their independence, Blackstone's 'Commentaries on the Laws of England,' which Horne Tooke called 'a good gentleman's law-book, clear but not deep,' had not long been off the press. In it the emphasis is still laid on the rights pertaining to land ownership, under the titles 'Rights of Persons,' 'Rights of Things' and 'Private Wrongs;' he classified, not very scientifically, the law of possession and ownership, contract and succession to property by sale, assignment of rents, and the law of trespass, negligence and fraud. Bentham criticised the commentators' overstrained, courtly praise of his subject and the obscurity and confusion of his fundamental ideas with irresistible point and vigor and a racy sense of humor. Admitting all these defects, the fact remains that Blackstone first rescued the common law from chaos and did exceedingly well, for the end of the 18th century, what Coke tried to do, and did exceedingly ill 150 years before. He gave and left a law that had been, or was being studied, not only without disgust, but with interest and profit. Another rich mine of the common law was laid open to the young American commonwealth in the decisions of Lord Mansfield, who during his 30 years' incumbency of the office of Chief Justice of England (1756-88) reduced the mercantile law to a systematic and harmonious form. The rise of the United States early in the 19th century to the position of a maritime power second only to Great Britain, and the long-continued state of war on the high seas during that period, naturally produced litigation pertaining to shipping and commerce. Accordingly, the early American law turns a notable page for the large proportion of judicial opinions they contain on bills of exchange, bills of affreightment, charter party and, particularly, marine insurance. Little was left for succeeding courts to add to the law on the last named topic. The growth of trade and industry made a form of association desirable, to which many could subscribe capital, with liability limited to the amount of their subscription; therefore, the adaptation to the requirements of manufacturing, trading and other business enterprises of the corporation, which had heretofore served mainly for the administration of charitable, ecclesiastical and educational foundations, of municipalities and such politico-commercial entities as the East India Company, the government of Ceylon, and the government of the business corporation are to be counted among the great achievements of American jurisprudence. The partial emancipation of married women from the disabilities of coverture was begun by legislative enactments in the States in the 40's of the last century. In the systematization or codification of the substantive law no great progress has been made in the United States. The law on such topics as negotiable instruments, bills of lading and sales has been reduced to the form of proposed statutes, which have been recommended to the States for adoption—and the first mentioned has been almost unanimously adopted, so that the law on this subject is practically uniform throughout the country. New York led the way in the codification of the rules of civil procedure, with incidental simplification and the abolition of the distinction between common law and equity pleadings. The example has been pretty generally followed, and in a law and criminal procedure have likewise been codified in many States. See COMMERCIAL LAW; CRIMINAL LAW; EQUITY; FAMILY LAW; HUSBAND AND WIFE; JURISPRUDENCE; MARITIME LAW.

STEPHEN PFEIL.

COMMON LIFE, Brethren of the, or THE COMMON LOT, a religious institute founded about 1376 by Geert or Gerhart Groot at Deventer in the Low Countries. Groot on a visit to the noted mystic Ruysbroek was so impressed by the spectacle of peace and joyful co-operation shown in the community of Austin friars over which Ruysbroek presided that he resolved to form a society embracing both clerics and laity that, without taking the monastic vows, should lead an austere Christian life in common. One of the aims of the brotherhood was to conduct schools for the religious and moral education of children, and their labors in that field were so successful and so highly appreciated that their school at Heringenbosch had 1,200 pupils and another school even a larger number. Establishments of the brotherhood were founded in Italy, Sicily and Portugal, and in 1430 there were in existence 130 societies of the institute. At the same time there was formed a similar institute for women: here the superior of each society was styled the Martha. Among the eminent characters who were members of the brotherhood or alumni of their schools were Thomas a Kempis, Nicolaus Cusanus and Erasmus. Many of the **obscenatist** letters in the ‘Epistola Obscurorum Viroorum’ purported to be written by members of the Deventer Brotherhood, who are made to appear as irredeemable blockheads.

COMMON METRE, a term used in psalmody to indicate a special form of iambic stanza, consisting generally of four lines, with eight and six syllables alternately to the line. It received its name because it was actually the *common metre* in use in the metrical version of the psalms. Common long metre, in psalmody, consists of a six-line stanza, combining a common-metre stanza with half a long-metre stanza; while common particular meter, consisting also of a six-line stanza, has six syllables in the third and sixth lines and eight syllables in the remaining lines.

COMMON PLEAS, Court of. See COURT.

COMMON PRAYER, Book of. See BOOK OF COMMON PRAYER.

COMMON RECOVERY, in law, a collection suit instituted by the intended grantee of land against the intended grantor in which the land is suffered to be recovered by the grantee. This device, which was once in common use to avoid legal restraint on alienation by conveyance, is now gone out of use, as additional provisions of the law have made its employment impracticable.

COMMON SCHOOLS, schools for the common people or the people in general. It is only in modern times that education has spread to the masses. In ancient times education was generally confined to a limited class and it was only after the Reformation that common schools came into being. All were directed by the Church, ecclesiastical direction, but were gradually secularized and placed under the control of the state. Most of the American colonies established common schools and by 1825–30 the free school system developed. The system has extended to all the States and the scheme of instruction has been greatly enlarged. In the United States, therefore, the term means schools to which all persons within certain ages, except criminals and those with contagious diseases, may attend and implies, moreover, that such schools are supported and controlled by the people and charge no tuition. At first the term was confined to elementary and secondary schools, but there is a growing tendency to include in the common schools of the United States all grades and degrees from the kindergarten to the university. There were in 1917 enrolled in the elementary and secondary common schools 19,153,786 persons or 73.66 per cent of the school population. The average daily attendance in the same year was 14,216,459 or 74.2 per cent of the pupils enrolled. There are 580,058 teachers employed in the common schools, of which number 19.8 per cent are males. The average monthly salary of teachers was $60.07, and the estimated value of all public property used for school purposes was $1,444,066,859. A total of $555,077,146 was expended on the common schools, or $3.62 per capita of total population and at a cost of $39.04 per capita of average attendance. The common school system in general use in the United States has been extended into Porto Rico, Hawaii and the Philippine Islands. Cuba has adopted the same system. See EDUCATION, HISTORY OF; EDUCATION IN THE UNITED STATES; EDUCATION, ELEMENTARY, SECONDARY, etc. See also PUBLIC SCHOOLS; PARISH SCHOOLS.

COMMON SENSE, the philosophy of the so-called Scotch school of philosophy founded by Thomas Reid (1710–96), who aimed to establish a series of fundamental truths indubitable as primitive facts of consciousness. He taught that the general consent of mankind as to the existence of an external world, as to the difference between substance and qualities, between thought and the mind that thinks, is sufficient to establish the reality of a permanent world apart from ourselves; and he maintained that sensations are not the objects of our perception, but signs which introduce us to the knowledge of real objects. The name is applied in colloquial language to that power of mind which arrives at correct conclusions. The thinker has no knowledge of laws of thought.

COMMON-TIME, time with two beats in a bar or any multiple of two beats in a bar. The beats may be of the value of any note or rest or compound of notes and rests, providing the sum required by the time sign be exactly contained in each bar. Common time is divided into various kinds, simple and compound. Simple common-time is that which includes four beats in a bar, or any division of that number, or square of the number of the divisions. The signs used
to express simple common-time are the following: †, ‡, §, ‡, †, and the characters C and C. In these signs the upper figure denotes the quantity of notes required in the bar, and the lower figure the quality of the notes. Compound common-time is expressed by the signs †, ‡, §, ‡, such signs meaning two or four beats of three crotchets or quavers to each beat.

**COMMONS, John Rogers.** American economist: b. Hollandsburg, Ohio, 13 Oct. 1862. He was graduated at Oberlin College with the degree of A.B. in 1883 and received the degree of LL.D. from the same institution in 1915. He studied at Johns Hopkins University 1888–90 and became professor of economics and sociology at Oberlin College 1891, at Indiana University 1892–95, Syracuse University 1895–99, and at the University of Wisconsin since 1904. He was director of the Bureau of Economic Research 1899–1901, and is director of the American Bureau of Industrial Research since 1904. He was investigator for the United States Industrial Commission 1901–02. In 1911 he was appointed a member of the Wisconsin Industrial Commission; and in 1913 he published a report of the work of the Milwaukee Bureau of Economy and Efficiency. He is the author of articles on wealth, labor, representation, etc., in scientific and other journals, and of *The Distribution of Wealth* (1893); *Social Reform and the Church* (1894); *Proportional Representation* (1895, rev. 1907); *Trade Unions and Labor Problems* (1905); *Races and Immigrants in America* (1907); *Labor and Administration* (1913); *Labor Legislation* (with John B. Andrews, 1916). He edited *Restriction of Output by Employers and Employees* (the 7th special report of the United States Commissioner of Labor, 1904). He was also one of the editors of *A Documentary History of American Industrial Society* (1910); *History of Labor in the United States* (1917); and wrote *Principles of Labor Legislation* (with John Andrews, 1917).

**COMMONS**. The commons of Great Britain, in a general sense regarded as comprising all such men in the kingdom as had not seats in the House of Lords, and every one of whom had a voice in Parliament, either personally or by his representatives. With the women now (1917) enrolled in the parliamentary franchise, the Commons must be regarded as including both sexes. Commons in Parliament is the lower House, the third estate of the realm, and consist of representatives elected by the counties or divisions of counties, and by the cities and boroughs. In the election of representatives anciently all the people had votes; but in the 8th and 9th of King Henry VI, for avoiding tumults, it was enacted that in counties the vote should be given by persons of freehold, did reside in the county, and had 40s yearly revenue, equivalent to nearly £20 a year of the present money; the persons elected for counties to be *milites notabiles*, at least esquires or gentlemen by knighthood; native Englishmen, or at least naturalized and 21 years of age; no judge, sheriff or ecclesiastical person to sit in the House for county, city or borough. The House of Commons, in Fortescue's time, who wrote during the reign of Henry VI, consisted of upward of 300 members: in Sir Edward Coke's time their number amounted to 493. At the time of the union with Scotland, in 1707, there were 513 members for England and Wales, to which 45 representatives for Scotland were added, so that the whole number of members amounted to 558. In consequence of the union with Ireland, in 1801, 100 members were added for that country; and the whole House of Commons therefore consisted of 658 members. By the reform bill of 1832 the number of members was reduced as follows: 500 for England and Wales, 53 for Scotland and 105 for Ireland; by the act of 1885 they became respectively 495, 72 and 103. See PARLIAMENT; GREAT BRITAIN—PARLIAMENT.

**COMMONWEALTH**, the state or prosperity of a country without any reference to the form of government under which it may be at the time. Owing to the unsettled position of the States of the American Union the term commonwealth is of frequent application to the various members of the great Federal government, which itself is spoken of as the National or Federal Commonwealth in contradistinction from its constituent autonomies. In many of the States the legal proceedings against criminals, etc., are instituted in the name of the *(for example) Commonweal th of*...

The word is also applied to the period in the history of England during which the parliamentary army and the Protector, Oliver Cromwell, exercised the power of government. King Charles I was beheaded on 30 Jan. 1649, but if the beginning of the commonwealth be deferred to the time when Oliver Cromwell became Protector, then its beginning was not till 16 Dec. 1653. It received an all but fatal blow by the death of its great chief, 3 Sept. 1658. On 22 April 1659, Richard Cromwell, his incompetent son and successor, resigned, and on 29 May 1660, Charles II was restored to the throne. The Commonwealth of Australia, embracing the states of New South Wales, Victoria, Queensland, South Australia and Tasmania, was established by act of Parliament passed 9 July 1900, and proclaimed at Sydney, 1 Jan. 1901.

**COMMUNALISM**, the theory of government by communes or corporations of towns and districts, adopted by the advanced republicans of France and elsewhere. The doctrine is that every commune, or at least every important city commune, as Paris, Marseilles, Lyons, etc., should be a kind of independent state in itself, and France merely a federation of such states. This system must not be confused with "Communism" (q.v.), with which, however, it is naturally and historically allied, though the two are perfectly distinct in principle.

**COMMUNE**, köm'mn, the unit or lowest division in the administration of France, corresponding in the rural districts to the English parish or tenement, and in the English municipality. In France there are about 36,000 communes, with a considerable measure of self-government, with the power of holding property, etc. Each commune has a council elected by universal suffrage, and the council is pre-
COMMUNICATIO — COMMUNISM

417

sided over by a maire and one or more adjoints or assistants. In the larger communes the maire is selected by the central government out of the members of the council; in others he is appointed by the prefect of the department. The central government, through its officials, exercises generally a very large control over the affairs of the commune.

The rising of the Commune of Paris in 1871 should not be confused with "Communism" (q.v.). It was a revolutionary assertion of the autonomy of Paris; that is, of the right of self-government through its commune or municipality. The theory of the rising was that every commune should have a right to autarchy, the central government being merely a federation of communes. The movement was based on discontent at Paris, where the people found themselves in possession of arms after the siege of the Germans. The rising began on 18 March 1871, and was only suppressed 10 weeks later after long and bloody fighting between the forces of the commune and a large army of the central government; 6,500 Communists having fallen during May, and 38,787 being taken prisoners. Consul Du Camp, 'Les convulsions de Paris' (4 vols., Paris 1878-79); Lessagaray, 'Histoire de la Commune' (Paris 1866); March, 'History of the Commune of 1871' (London 1896).

COMMUNICA TIO, kəm-mí-nə-kuh-shə-o, or COMMUNIO, idiomata, is the term or phrase hardly capable of translation into English, which is used to signify the appropriation mutually of divine attributes to Christ as man, and of human attributes or human affections to Christ as God because of the hypostatic union of the two natures and the human nature in Christ; thus, we say "God died for us," and the mother of Jesus is theotokos, deipara, mother of God. Idiomata, plur. idiomata, is Greek equivalent to Latin proprietas, and means that which belongs to one, an attribute. The theological phrase in Greek is antidosis idiomaton.

COMMUNION, the reception of the Eucharist. In the Roman Catholic Church the Eucharist is administered to the faithful only in the species of bread. Only the priest who performs the act of consecration receives the sacrament in both kinds. In the Protestant churches the laity receive the sacrament in both kinds, and the usage of the Greek and Oriental churches is the same. The withholding of the cup from the laity was not required by the laws of the Latin Church till the Council of Constance ordered it in 1414, though by that time usage had made it an almost universal custom. Yet down to the 11th century communion under both species was universal, and as late as the middle of the 13th century Saint Thomas Aquinas notes the communion under one kind as the usage only of "some churches." As it is purely a Church regulation, the Church can and does dispense from it, or the Church can abrogate it and bring back the original usage of communion in both kinds. Even in the earliest times communion under one kind was the rule when the sick was to be administered to the sick and infirm in their last illness; in that case the one kind was under the species of bread, but in the same early period it was customary to administer the Eucharist to infants immediately after baptism, but only under the one species of wine. See LORD'S SUPPER.

COMMUNISM. Although aiming at the abolition of private property, communism must not be understood as including at all times an equal division of all property. In its limited application it may mean the common management of industry and the sharing of the fruits of some of these in common. Socialism is not communism, though some socialist schools are communist, that of Edward Bellamy's 'Looking Backward' being purely so.

Communism, or the sharing of things in common, is, in a limited form, practised by every civilized community. There is to-day common management of parks, schools and other utilities, and practical communism in water, which is supplied free to the poorest inhabitant of our cities. In the case of commodities which are plentiful and cheap, as, for example, matches, there is a kind of communism prevailing among individuals. But perfect communism as a social theory finds few adherents, and practical experiments in the past in such directions have been, save for limited periods, unsuccessful. Even the communism of certain societies or settlements has succeeded temporarily it has been done so largely by their trading with or manufacturing for the greater world of capital and labor that touches them from without. Even communities that have remained entirely isolated have attained even a measurable degree of success.

COMMUNISM in the Christian Church.— It is not too much to say that in primitive times property was in common, and that individual ownership arose as a natural development out of communism. The Cretans and the Spartans possessed communist societies, and there seems to be little doubt that communism as a supernatural ideal was practised among the early Christians. That it was successful for a time in the primitive state of society then prevailing among the disciples of Jesus also seems highly probable. The communist societies that have since been formed have been successful in the measure of that inspired sacrifice, and have declined as this religious ardor subsided or became corrupted by other elements. But whatever their temporary success may have been among the early Christians, the experiments were soon utterly abandoned, and the principle of individual ownership of property finally and fully asserted itself. That even the early Christians adopted without qualification the theory of communism may be doubted. Certainly authorities are disagreed, so that even here we go without the necessary data to conclude that perfect communism was temporarily successful. During the Middle Ages many of the religious orders, notably those that strove to preserve the apostolic simplicity of the early Church, the Franciscans, the Brothers of the Common Lot and others, taught and practised communism.

COMMUNISM in the United States.— Fourierism.—The communities that have been formed in the United States, mostly in New England and the Western States, have all died out, or exist in a moribund condition. We need not speculate upon the reasons, though
it would seem that the desire of individual ownership, with the incentive to action which such ownership inspires, is indestructible and therefore fatal to perfect communism. The most famous of all American Communist or semi-communist societies that arose as a result of the teachings of Charles Fourier (q.v.), was that of Brook Farm (q.v.) because of the intellectual and literary eminence of its founders. Horace Greeley (q.v.) was a warm friend of the circle, the favorite member of the favorite group, and he advocated it powerfully in the New York Tribune and was vice-president of the North American Phalanx, in Mommouth County, N. J., one of the most successful of the Fourrierite communities, for it lasted over 12 years, dying in 1856. It was intended as the model of its kind, and at the beginning it prospered. Perhaps no similar movement has ever received anything like the influential support accorded to Fourierism. The teachings of this remarkable man, the insight and value of much that he wrote, as well as the warmth that suffused his prophecies, enlisted the enthusiasm and aid of some of the most eminent men of the time. But faults and dissatisfaction set in, and slowly the experiment began to disintegrate. The noble dreams of Fourierism were either founded upon mistaken generalizations, or were too early anticipations of the industrial and social development of mankind. It was only at a later period of its career that Brook Farm came to be modeled on the Fourier plan, and its simple life became perhaps too systematized. Work was in common, and at the most menial occupations men who became the glory of American letters, and women of the highest New England culture, cheerfully took their turn. But with the ebbing of the tide of Fourierism the Brook Farm experiment came to an end. The North American Phalanx outlived it for a short period; but with the death of that settlement a movement which embodied one of the most pretentious and sweeping philosophies of social regeneration perished from the American continent. Fourierism, which in France had lived for lack of soil of frutition, visited this country and founded a number of communities, the best known of which was that of New Harmony Ind. Most of the others were short-lived, and that of New Harmony, born in 1825, expired in 1827.

The Shakers.—Among the communities that owe their origin to religious fervor, and which flourished for a short period, but could not escape the persecution which had followed her bold assertion of divine revelation. The Shakers are celibates, and thus their communities have not grown very rapidly, yet 15 are said to exist to-day.

Oenieda Community. The Oenieda Community, another of the very few survivals of that communist spirit which swept over the country in the middle forties, was established in 1848. It ignored the regulation of marriage, founding the union of the sexes purely on the mutual concomitant. For the first time it was observed that the Oenieda Community fell into evil repute, and this reputation extended in many cases to communities less deserving of the stigma. The union of one man with one woman the community expressly discouraged as an "exclusive and idolatrous attachment." When a man and woman were brought together, and showed a tendency to "fall in love," everything was done by the society to discourage such relationship, even to the extent of forcing them apart by publicly expressed condemnation. A more extraordinary view of sex relationship has probably never suggested itself among all the confused and eccentric beliefs of mankind. The Oenieda Community was founded by John Humphrey Noyes, in Madison County, N. Y. They practised communism and a change of occupation (a Fourrierite principle). They have, it is said, forbidden the admission of new members, the New Harmony Society, which was succeeded in 1825 by New Harmony, Robert Owen having purchased the land of that settlement from George Rapp (q.v.) and his followers, was a notable experiment. Rapp's notions were queer enough, but he had great influence with his followers, who regarded him as possessed of supernatural powers. They practised communism and celibacy from 1805, the date of the founding of the community in Butler County, Pa., where they remained until 1814, when they changed their location to the Wabash Valley. Here the settlement flourished until the purchase of the lands by Robert Owen.

The Amana Community. The Amana Community, still surviving, was formed in 1842 by emigrants from Germany and Switzerland, who originally belonged to the peasant class. They settled in New York State, near Buffalo, and later removed to Iowa. They were spiritualists who regarded themselves as the subjects of special revelation. This religious-communist settlement is probably the earliest in origin in this country, for it traces the beginnings of its creed as far back as the early part of the 18th century. Their rules of life are rigid and forbidding; amusements are prohibited; and much that ministers to innocent pleasure is banished as sinful.

The Icarian Community. To mention even the name of all the communities that exist or have existed in the United States would take more space than can be given to the subject. The appended bibliography will guide to all the information of which the reader may be in search. But special mention ought to be made of the Icarian Community, remarkable as owing its origin to a book, 'A Voyage to Icaria,' by Etienne Cabot (born 1788), who had been a member of the French legislature and a leader of the Carbonari. He sailed in 1838 with a number of his followers from France,
COMMUNISTIC SOCIETIES — COMMUNITY DRAMA

and established the community in Illinois in accordance with the ideas contained in his work. They numbered as many as 1,500 at one time, but they were compelled to seek other settlement in Iowa. This community was peculiar in that it came nearer to the ideal of democratic communism; the rigid regulations of other communities were absent, the point aimed at being to let every one do as he pleased.

A settlement in which no community of property save that of land obtains, and in which the government is nearly as purely democratic, is that of Fairhope, Ala., founded a few years ago by a handful of disciples of Henry George. It is organized as a corporation, by which its real estate is administered. The annual value of the land is taken for communal purposes. It numbers about 300 members, and up to the present time is prosperous.

Significance of Communism.—All these experiments which have been reviewed have failed to demonstrate the feasibility of communal life. Existence within its confines is, for the most part, meagre and unsatisfying. Though the individuals sometimes grow rich, progress in its finer sense there is none; they do not rise in culture and intelligence above their original level. Yet some things they have demonstrated, among which are the possibilities of a more peaceful industry, more unselfish lives, together with a fuller leisure, and freedom from the harassing fear of want. Abnormal as they seem, they are really protests against what in our civilization is abnormal. Clothed, as the most successful of them are, in religious guise, the fact that they are impulses, even when most eccentric, of the more profound and imperishable nature of man, is vastly significant.

JOSEPH DANA MILLER.

COMMUNISTIC SOCIETIES. See COMMUNISM.

COMMUNITY CHRISTMAS TREE MOVEMENT. The Community Christmas Tree Movement, which was initiated in New York with festivities for the children at Madison Square, in 1912, has very rapidly developed in popularity. The tree is set up at Christmas Eve till the midnight of 31 December, when thousands of children welcome in the New Year with music. Even before 1912, at San Francisco, the public singing of carols led by Madame Schumann-Heink and other distinguished artists was an eagerly watched event. Other cities all over the land have promoted the Christmas tree celebrations. The American Pageant Association Bulletin 41, 15 Oct. 1916, entitled "Some Suggestions for Community Christmas Celebrations," gives lists of Christmas mysteries and plays and music with much other valuable information. Bulletin No. 42, 15 Nov. 1916, "The Possibilities of the Christmas Masque," by William Chauncey Langdon, should also be consulted.

COMMUNITY DRAMA, or CIVIC DRAMA. This is a term that has recently sprung into widespread use to embrace various kinds of performances, generally more or less dramatic in form, but sometimes merely professional and picturesque, presented by large bodies of people (marching, singing, dancing, acting and so forth) in co-operation with writers, designers and others. The differences in kind are denoted by the use of the names: pageant, masque, festival; and, somewhat loosely, the rural play, the school play and the outdoor play. Mr. William Chauncey Langdon, the well-known pageant master, has cleared away much of the difficulty of classification by pointing out that the essential characteristics of these forms may be differentiated as follows: The pageant is historical; the masque is philosophical; the outdoor drama like the regular drama is individual; and all these are objective in their character. On the other hand, while the festival is lyrical, it is subjective in character. The school play is educational and subjective. These forms are all treated separately under special headings.

The history of the community festival, all that may be written with reasonable certainty, covers the long stretches of the past, under many a ritual, back to the immemorial religious cults. There can be little doubt that all theatres had their rude beginnings when human beings first began to dwell together in communities, and to hunt, feast, play and worship in common. For a fuller account of the primitive drama consult Grosse, E., 'Beginnings of Art,' and Frazer, J. G., 'The Golden Bough.' Mr. L. Havemeyer's 'The Drama of Savage Peoples' (Yale 1916) contains the new material in accessible form. The first chapter of Prof. Brander Matthews' 'Development of the Drama' gives an excellent summary of the broad facts.

The archetypal of the Greek theatre itself, the apex and crown of all prævalent culture, may be seen in active existence at the present day in the islands of Melanesia. There, in the rustic dancing circle, we have the perfect example of the Greek orchestra, in embryo; and in the little robing hut of these simple islanders of the south seas we are in at the birth of the magnificent Skene of the theatre of Athens; the word skene originally meaning a booth or tent, and then a stage, projecting our English word scene. These two extreme cases of the Greek theatre and the Melanesian circle provide us with exemplars of sites as suitable to-day as ever for either the community drama or festival.

In mediæval times, when first the Church and later the guilds set the religious and assisted in the performances of the mystery and morality plays, all that existed by way of a theatre was distinctly communal. The passion plays, still performed in Oberammergau, Bavaria, and in Selsach, Switzerland, and elsewhere, are survivals of the mysteries and miracles of the old communities. In the spreading liturgy of the mediæval Church we mark the beginnings of the long slow rise toward the compact drama of the most modern playwright. Following the ecclesiastical period of play-making and play-going and entering upon the secu-
COMMUNITY MUSIC

lar period of folk drama, the culmination was reached in the works of members of the trade guilds, of whom the wise old cobbler Hans Sachs (1494–1576), and merry John Heywood (1497–1590), are the classic types. Thereafter came the development of the regular theatre and the farcical form of the expression of the dramatic instinct of the folk to the usual calendar festivals, games, etc., described with droll particularity in such compilations as Chambers's Book of Days. In the 19th century the growth of machinery and the effects of industrialism, when men discussed the humanities more than they practised humanity, men and women and children, too, well-nigh forgot even these simple festive joys of the open air. They, however, remained in literature and in tradition for a new and more democratic practice in this present century.

The civic theatre idea, as a distinctive issue, implies the conscious awakening of a people to self-government in the activities of its leisure. The civic theatre is an expression of the arts of the theatre, participation by the people in these arts (not mere spectatorship), a new resulting technique, leadership by means of a permanent staff of artists (not of merchants in art), eliminating the profit motive by endowment and public support, dedication in service to the whole community; these are chief among its essentials, and these imply a new and nobler scope for the art of the theatre itself. Mr. Percy Mackaye, author of 'The Civic Theatre', from which the above lines are taken, deplores the severance of joy from labor under modern commercial conditions, and conceives the one answer to the workers' protests to be in "Art, the recreative labor of leisure." His favorite phrase, his slogan and the subtitle of his book is, "the redemption of leisure." To the now swiftly increasing body represented by Mr. Mackaye the reorganization of leisure is not alone a fine aim in itself, but the real goal, the focus, of all the striving of the age, the fulfillment of the deepest instinct of humanity, the need for happiness. In the spirit of his illustrious British prototype, William Morris, he pleads for a theatre endowed as the public schools, communities, churches and libraries are already endowed.

On the other hand, the opponents of the community festival movement, while acknowledging the fine disinterestedness of its leaders, do not recognize any pulsing life in the paysantry of to-day, so far as it relates to America; they deny real interest on the part of the people, and maintain that we have no traditions upon which to found a vital community theatre comparable to the same in Europe. For an able expression of this view, consult "Modern Pagans not Spontaneous" (in 'The Nation', Vol. XCV, p. 245, New York 1912).

The supporters meet these disavowals by reminders of our native Indian, Spanish, French, Colonial and Post-Revolutionary lore, and partly admitting a tincture of artificiality and crudeness incidental to the early stages of the cultivation of the form, point to the amazing growth of the movement among all classes over all the States. Particularly have the life and growth of the community movement been slow, vitality can be reached in any concern touching the genius of the mass, in the co-operation of the industrial and rural folk, as well as in that of the children. In point of fact no country or district in Europe, or any other part of the world, can show wider or more enthusiastic interest in community drama, especially on the part of the young people and educationists of all grades, than has been demonstrated by the United States. Indeed, in this form of the art of drama, and in this alone, can the United States show herself more forward than Europe. This holds good not only in respect to organization and scope but also to actual performance. See also: THE COLLEGE DRAMATIC; CIVILIZATION, DRAMATIC; CHILDREN'S THEATRES; FESTIVAL; MASQUES; OUTDOOR THEATRES; PAGEANT; RURAL THEATRES.

DUNCAN MACDOUGALL.

COMMUNITY MUSIC, a term recently brought into wide currency through the characteristic interest of the day along lines of social administration; and, in general, somewhat loosely embracing both old and new forms of organized musical practice. More strictly, however, it describes the newer, popular expressions of the love of music by way of recreational, ameliorative, and educational settlements, as well as through countless neighborhood and municipal centres, both rural and urban, that have had their origin in the peculiar industrial, social and political conditions of recent times; many of these organizations corresponding to the more spontaneous outgrowths of merrymaking in olden days. See Festivals.

In the social consciousness of our day music has come to be regarded as a tremendous force in expansion, where alone vitality can be reached in any concern touching the genius of the mass, in the co-operation of the industrial and rural folk, as well as in that
COMMUNITY MUSIC

and simple melodies they know well, the people are also moved intensely by even the difficult and unfamiliar classics, provided they are played with feeling and intelligence. Great music greatly performed, says Professor Dykema, is able to overlap seemingly impossible barriers of lack of culture; the majestic strains of a Beethoven symphony played by a fine orchestra carrying every listener before them. Then, much more intense is the influence of music in the case of the active performer, however humble. In concerted music the social side is carried to its highest point. There are few social forces comparable to the power of a large group of people singing a grand chorus. The continually rising standards of municipal concerts, the organization of community choruses, Christmas Tree celebrations, pageants and masques with music, school and community orchestras and popular symphony concerts all over the Western World, point to the general hunger for musical expression, more especially in the community sense.

Domestic and Industrial Circles.—No one can fail to make observation of the almost universal distribution of various modern mechanical inventions for the rendering of both instrumental and vocal music; the pianolas, phonographs, etc.—which, while retarding individual technical development in some circles, have in others encouraged group singing and playing to a point of enthusiasm and excellence in districts where the greatest performers of the day would otherwise, in all probability, have remained unheard. This applies most pointedly to a legion of large and small communities of factory, shop, studio, agricultural and mining workers, who, till a few years ago, would play most of their musical recreation on the violin, the guitar, the tambourine, the drum, etc. Now, these new mechanisms, were often musically strangled, both in town and in country, to an extent that is only now being realized. Innumerable industrial groups have from such beginnings organized themselves until their trained bands, choirs, etc., have become of wide importance in musical affairs. Nevertheless it is regrettable that the antique custom of both solo and concerted singing at actual labor has well-nigh passed into oblivion in the greater part of both hemispheres. In America our own aboriginal people, the Indians, to whom song is the very consecration of the spirit of life, rarely undertake even the most menial tasks without an appropriate song. Like all real folk music, the most of the folks songs, whether they be most earnest expression of the soul of a people, and of all music the most distinctively American. Old tradition, tribal history, the counsels and warnings of every day, the mighty deeds and the wise and the brave, the unchallengeable verities, the customs and to the feast, all are expressed in the rhythm of song and poetry.

Schools and Colleges.—Within the last decade a great change in musical instruction in the schools has resulted from the recognition by educationists throughout the country that music in the schools must be more than another type of disciplinary study; above all, in the insistence by the pedagogic leaders of the movement on the use of better musical material and a larger number of songs before beginning technical drill. They also point out the possibility of cultivating original art power among gifted pupils by allowing scope for individuality, and of developing the more conscious sympathetic aspects of the children's singing by allowing them to take part in musical festivals and concerts for the general community. In most of the larger communities throughout these States it has become customary to hear good music, ranging from simple unison songs, light operas and cantatas to the great oratorios creditably performed in the large auditoriums and parks by the children from the public schools. There are even orchestras and bands in some of the schools. These are able to assist in the music association with choruses of children; and churches, theatres, clubs and private individuals are seeking, and even competing against each other, to unite with the schools. Elgin, Ann Arbor and Dayton have already given remarkable offerings at low prices. Another step in advance has been made by the recognition by the schools of private instruction in music and by granting credit to pupils for work done outside. The public high schools, with the colleges and universities, are also allowing the courses taken with accredited music schools and private instructors to count for admission. A large number of high schools practise chorus singing and maintain musical appreciation classes; and certain of the more progressive offer instruction in the technique of music, in solo-singing and in instrumental work. In Richmond, Ind., for instance, the teacher of public school music was engaged on condition that he devote half time to municipal music. In Wisconsin there is a popular movement to create by law a city social centre where the musical and other recreations of the people may be more compactly and more intelligently controlled than under the present system of system. It has been proposed that community directors be appointed from among principals of high schools and officials of like standing, with a definite salary for each office. Churches.—For a very large proportion of the adult population church music includes practically all the serious music which they are in the way of hearing, and carries the one complete opportunity for chorus singing. A number of churches, recognizing the fact, are dealing with the situation from its many points of view; and some are very wisely opening their doors to good secular work, in the lighter as well as the heavier vein,—operettas, pageants, etc. The American Guild of Organists has nobly responded to the adoption of the Savills system of organ teaching. The church choir is in some districts doing much of the work formerly sustained only by the choral society; these choirs being found to have more influence upon the community than the work of the soloist. A number of churches, both in this country and abroad, have established America's Musical Shrine at Bethlehem, Pa., and at Worcester Cathedral, England, where fes-
COMMUNITY MUSIC

tivals of music have been annual events for nearly 200 years, have generously cultivated the love of song and instrumental music.

Specific Organizations.— Early in the last quarter of the 18th century the Stoughton (Mass.) Musical Society, which still flourishes, was founded by William Billings, a tenant by trade, but an eccentric amateur of some genius. This energetic man gave a healthy impulse to popular music that is yet felt. About the same time the excellent Handel Society of New Hampshire was organized; and the year 1807 saw the foundation of the Massachusetts Musical Society. On 8 Jan. 1792, at Medfield, Mass., the "father of music in America," Lowell Mason, was born. To him we owe our best ideas in the promotion of music among the masses. He pointed the way to a higher order in church music, introduced music into the public schools, popularized class chorus singing, spread the art of teaching music on the rational inductive plan and established teachers' conventions. He died in 1872. In various corners of New England musical festivals with large choruses and orchestras, formed from small choral societies of neighboring towns, are held regularly. Two typical instances of these are the concerts at Conobe Lake Park by a chorus of over 300 singers from four nearby towns,—Lowell and Lawrence, Mass., and Manchester and Nashua, N. H.—under the direction of Eusebius G. Hood; and the Litchfield Country Choral Union at Norfolk, Conn. (originally, in 1897, the Norfolk Glee Club; and united with the Litchfield, Torrington and other local organizations in 1899, with a total membership, in 1914, of 677), conducted by Richard P. Paine, and promoted and housed by the generosity of Mr. and Mrs. Carl Stoeldel.

Scattered widely over the country, a number of cities and towns of small size have lately come into prominence and have sometimes astonished critics of high standing with their general musical activity and, particularly, with performances of the 'Messiah,' the 'Creation' and other classic oratorios. Two signal examples are to be found in Bethlehem, Pa., and in Lindsborg, Kan. At Bethlehem, by the admission of perseverance of Mr. J. Wolle, extending over 30 years, a choir has been nurtured up to such a high standard that its renditions of Bach are conceded to be the best of any of this kind in America. The annual festivals of our Pennsylvania Oberammergau have for years attracted the music lovers of this and other countries. At Lindsborg, a little town with a population of only 2,000, the Bethany Oratorio Society performs Handel's 'Messiah' with a chorus of 500 voices and an orchestra of 40 pieces, during each Easter week. The chorus is more than 30 years old and has given Handel's masterpiece nearly a hundred times; and has, besides, undertaken all the standard oratorios. During the Easter festival the population is increased threefold,—visitors pouring into the centre from far and near.

Places of Amusement.— While the American citizen is a generous spender on concerts and other forms of musical activity, the status of musical taste and ability is generally admitted to need advancement. Audiences are characterized as being too good natured and too careless of standards. That the leaders of music in our numerous communities are creating a warmer and more spiritual understanding between themselves and their audiences is the most hopeful of all signs. Even in unexpected quarters the people have been shown invariably to follow a good lead. At the New York Rialto Theatre, a vaudeville and music picture house, music of a high standard was lately tried with such success that the orchestra soon became the chief feature of the performances.

Possibilities in the Ordinary Community.— The signs on the horizon point to the responsibility for the development of community music being in the hands of city governments; though, as yet its progress has been due mainly to private enthusiasm and enterprise. In a number of communities professional musicians during prolonged visits unite the amateur talent of a neighborhood, and with a few imported players produce worthy musical festivals. The results at Meriden, N. H., in the Pageant of 1913, under the musical direction of Mr. Arthur Farwell, and in similar performances in other places, show how well the folk of small country places may be inspired by an occasion to play music of a high grade most acceptably. (See Pageants and College Dramatics.) And the possession of an excellent band or orchestra has proved a possibility for the most unpromising of communities. Most of the great orchestras in large cities are maintained through a guarantee fund by subscribing citizens on a private basis. In one State a bill has recently been passed for the support of a State orchestra that will have a complete and regular circuit. In a number of places throughout the country music, concerts and lectures for adults are part of the educational system. One community extends musical instruction to all who are willing to embrace the offer. In New York, Boston, Rochester and in La Porte, Ind., a special official has been appointed to supervise the city music. In New York three municipal concerts began in the spring of 1910 on a new untried basis under the administration of Mayor Gaynor. There were bands in about 30 of the 150 parks in the city on one evening of the week during summer. Sometimes bands performed all recreation sites every evening for a season, and sometimes on five or more evenings, with afternoon folk-dancing for the children on the piers. In Central Park the crowds were enormous; and at Tottenville, S. I., the farmers and others gathered round in their wagons to listen to the worlds' masterpieces played by an excellent local band that for the first time in 20 years had joined the professional ranks. In many other centres throughout the country bands and orchestras are engaged by the authorities to give free concerts to the people in summer and even in winter. In the State of Wisconsin, any city, town or village is now authorized and empowered to conduct public concerts in parks (to be paid for out of the park funds) and in various kinds of auditoriums (to be paid for in any way that the board, town council or other stated official may determine).

Citizens as Performers.— The highest spiritual point in community music would appear to have been reached in the extension of a welcome to everybody, trained and untrained,
COMMUNITY MUSIC

to sing in chorus. The wisest heads in the movement rule that in every healthy community there should be opportunity for all people to sing as much as they wish, and that at least one combined function might be held, of an informal sort, and almost without direction. The success that has already attended the carrying out of this principle has been extraordinary. The supervisor of city schools reports that in Anoka, with a population of 3,000, everybody was invited, everything was donated, and over 2,000 more than the whole population of the town arrived to sing 'Home, Sweet Home,' 'Come Thou Almighty King,' 'Suwanee River,' etc. Recently in Minneapolis Park, at a free concert with a chorus of children, no less than 15,000 people attended. But perhaps the most remarkable expression of this kind is found in the Community Chorus movement, an outgrowth of the Music School Settlement of New York, that in a very short space of time has taken whole communities by storm. It is essentially democratic and includes all who would meet together for the joy of singing, regardless of sex, rank, or without dues. Hundreds of community choruses have been formed, and reports of organization and inquiries are entering from every state in the Union. New York, Buffalo and the Oranges (N. J.) have community choruses of over 1,500. Kansas has over 20 community choruses, with the University of Kansas in support of the movement; Wisconsin is carrying out the community music idea in the broadest fashion and has a leader in the University of Wisconsin. Newspapers in New York and everywhere are devoting full columns to accounts of the movement and its affairs. In New York the Community Chorus has sung every week since its organization, 9 Jan. 1918. During the summer seasons its "sings" were held every Sunday afternoon in Central Park with thousands present. It gave the memorable "Song and Light" festival in Central Park, 13-14 Sept. 1916, with over 50,000 citizens taking part; and the effect was so overwhelming that its repetition was temporosely demanded for the following evening. On 26 Dec. 1916 before an audience of 10,000 Handel's "Messiah" was given with 1,000 voices (80 per cent of the performers never having heard the work before beginning rehearsals); and in the Hippodrome, 29 April 1917, an audience of 4,500 joined eagerly in the community singing under Mr. Barnhart's direction and responded enthusiastically to the inspiring addresses of Mr. John C. Freud, editor of Musical America, and the Hon. Cabot Ward, park commissioner of the city of New York; this performance like all the rest of the chorus being free to the public in every sense. Another spirited organization on somewhat similar but graded and slightly exclusive lines is the People's Choral Union of New York, with from 600 to 1,200 members creditably performing the great oratorios and large choral works, organized by Dr. Frank Damrosch. The Frank Damrosch Choral Union has, in the Samuel W. Cole, who, as early as 1897, conducted free choral classes for the people of Boston. In Chicago the "musical evenings," instituted by Mr. Arnold Dresden of Chicago University, and promoted by the Women's Trade Union League, gained the hearty co-operation of the park commissioners and have proved eminently successful.

Beyond the large choral clubs there are the smaller organizations; such as the Frauenchor and Maennerchor of the German communities in the United States, and the various types of choirs in the communities of Wales and other countries. The enormous extent of musical activity possible in a country is evidenced by the numerous competitive musical festivals of Europe. Blackpool, England, for example, has such a festival with about 5,000 competitors from all over England entering 64 types of contests, including choruses of 60 voices and all variations of fewer numbers for men or women or both men and women, down to solo.

In the United States the closest resemblance to such festivals is found in the Saengerfest and the Eisteddfod. At a recent Welsh celebration in Pittsburgh by Cambro-American, the chief interest was music, although there were competitions in other arts. The choirs came from the mines, mills and factories for the most part. For Christmas and other festivals by various sorts of communities, see above.

Instrumental Music.—There are many nurseries of instrumental music scattered over the great cities of the world, but perhaps the most significant of them all is the Music School Settlement on the East Side of New York. In 1917 there were 1,100 enrolled pupils, as well as an "outside" department and a very long waiting list, with a staff of 100 teachers. There are four orchestras, aggregating 200 players, a wind instrument department, a musical bureau which secured over 300 paid engagements for pupils in 1916, a library of 2,500 readers, an instrument department with 100 instruments for the use of pupils, lectures, concerts, festivals and plays. There is a social centre in charge of a head resident and her assistants who manage the various clubs, etc., and help the music teachers in the effort to develop the children physically, mentally and morally. There are 15 nationalities represented; and the terms to pupils run from 50 cents for an individual lesson to 10 cents for a class lesson. A limited number of scholarships are provided for talented pupils who cannot pay these fees. The Maidstone movement in England is of the same type.

The National Union of School Orchestras, London, was founded in 1905, giving its first performance at the Crystal Palace with 700 girl and boy violinists, with such success that in 1914 the performance at the Crystal Palace was given by 6,800 children. But even these figures represent but a small fraction of violin-playing children over the kingdom; for with 5,000 schools having orchestras already formed there are at least 200,000 children who are members or adherents of the Union. There are scholarships which entitle the winners to advanced instruction at the Guildhall School of Music. The official mouthpiece of the organization is The Young Musician, published monthly in London for one penny. The various objects and interests of the National Union of School Orchestras, as well as many other important matters, are discussed by Mr. Paul Stoever, "A New Mission for the Violin" (in the Proceedings for 1915 of the Music Teachers National Association, Hartford, Conn., 1915).
COMMUTATOR — COMO

A curious and remarkably successful attempt to increase violin playing in Great Britain was made recently by a firm of musical instrument makers who distributed complete violin outfits for the moderate sum of $5. In a short time no fewer than 400,000 people had received instruments.

The Music Teachers' National Association with headquarters in Hartford, Conn., has a special committee for community music.

DUNCAN MACDOUGALL.

COMMUTATOR, a piece of apparatus used in connection with many electrical instruments for reversing the current from the battery. There are various forms, which will generally be found described with their proper instruments. See ELECTRICAL TERMS.

COMNENUS, or COMENENI, kōm-nēnē, an extinct family of Byzantine sovereigns, originally from Paphlogonia, which numbered, on the throne of Constantinople (1057 to 1204) and on that of Trebizond (from 1204 to 1461), 18 emperors, besides 19 kings and numerous independent princes. When the Crusaders had overthrown the throne of the Comneni in Constantinople, and established the Latin empire there in 1204, a prince of the ancient house of the Comneni founded an independent state at Trebizond in Asia Minor, where he was governor. The last sovereign of this house was David Comnenus. From him, it is said, was descended Demetrius Comnenus, a French captain of dragoons, who died without children at Paris in 1821, with the title of Maréchal de Camp. But his descent cannot be historically traced. Ducange asserts without hesitation that Mohammed II, the conqueror of Constantinople, after he had obtained the empire of Trebizond, so called (which was scarcely as large as a French department), from the Emperor David, by a treaty, sent for this prince and his seven children to Constantinople. In order to get possession of the income which had been secured to the Greek prince he ordered him to be put to death, with all his children, at Adrianople in 1462, under pretense of a conspiracy. This is confirmed, according to Ducange, by all contemporary writers—Chalcondylas, Ducas, Phranzes. A remarkable member of the family was the Princess Anna Comnena, daughter of the Emperor Alexius I, who flourished in the first half of the 12th century.

COMO, kō'mō (anciently COMUM), Italy, capital of the province of Como, in Lombardy, 24 miles northwest of Milan in a delightful valley at the foot of Lake Como. It is a bishop's see. The city contains some antiquities, a splendid marble cathedral dating from the 14th century and 12 beautiful churches; also a cabinet of natural history and natural philosophy. During the 11th and 12th centuries Como was at the head of the Ghibelline party, and the revival of Milan. In 1127 it was destroyed by the Milanese and rebuilt by Frederick II in 1159. Later it was ruled by the Rusca family and in 1335 came into the possession of the Visconti. In 1589 it was a centre of the agitation headed by Garibaldi. Here was born Pliny the Younger and Volta and Giongo, writers, also the popes Clement XIII and Innocent XI. A number of the inhabitants travel about with small-wares, such as mirrors, spectacles, little pictures. Even in the time of the Roman emperors this taste for emigration manifested itself. The inhabitants of Como were then to be found in all parts of Italy in the capacity of masons. Silk, velvet, optical glasses, shoes, stockings, metal work and knit wear are manufactured. The province of Como has an area of 1,349 square miles and a population of 515,134. It has fine pastures, and yields grain, olives, wine and silk. Population of the commune 43,439.

COMO, Lake (LAGO DI COMO, lâ'gō dē kō'mō, anciently Lacus Larius), a lake in the north of Italy, at the foot of the Alps. Toward the middle it is divided into two branches by the point on which is situated Bellagio. The branch extending toward the southwest to the city of Como goes under the same name; that which turns to the southeast to Lecco takes the name of Lake Lecco. The length of the lake to Bellagio is 16 miles; that of the southwest branch 19 miles and that of the southeast branch 12½ miles. The greatest width is two and a half miles. More than 60 rivers and rivulets flow into it, and the Adda passes through it. It is about 700 feet above the level of the Lake. The water of Lake Como, the most delightful of all the lakes in Upper Italy, is surrounded by mountains 3,000 or 4,000, or even 7,000, feet high, which descend toward the lake, and in many parts are
CLOTHED with woods. It is bordered by delightful gardens and country seats. Fish, particularly trout, are caught in the lake. The neighboring country is rich in minerals—iron, copper and lead.

**COMO STAGE,** a thin mass of shales and sandstones representing clays and sands deposited in a fresh-water lake that covered southern Wyoming, and extended into Colorado. The exact age of the beds is still in dispute; they have been assigned to the top of the Jurassic, though there are good reasons for placing them at the base of the Cretaceous. The beds are remarkably rich in fossils of land reptiles and mammals, including such giant saurians as *Aeolosaurus*, and are typically developed near Como, Wyo. See *Cretaceous System*; *Jurassic Series.*

**COMONFORT,** Ignacio, ig-ná-sé-o ko- món-fort, Mexican general; b. Pueblo, 12 March 1812; d. 13 Nov. 1863. He became captain of cavalry in 1832, in 1834 was made prefect and military governor of the district of Tlapa, and in 1842 he was elected member of the National Congress. This Congress was soon dissolved, and Comonfort resumed his functions in Tlapa, displaying great energy in repelling the aggressions of hostile Indians. Appointed 3d alcalde of the capital, and afterward prefect of western Mexico, he relinquished these positions to engage in the war with the United States; and on Santa Anna’s dissolving the army and leaving the capital open for the Americans, Comonfort commenced organizing guerillas, when he was summoned to the Congress of Queretaro, where a treaty of peace was concluded with the United States. He was now chosen senator by his native state, and served in this capacity until 1851. In 1852-53 he was the representative in Congress of the newly created state of Guerrero, and acted as custodiam house director of Acapulco and other places until Santa Anna’s return to power, when he was dismissed from office. He now joined Gen. Juan Alvarez, raised the standard of rebellion, proclaimed the plan of Ayutla, 11 March 1854, and compelled Santa Anna, who endeavored to secure it, to retire. At the end of the campaign in 1855, Santa Anna was finally compelled to abdicate. Alvarez assumed the supreme government, but shortly afterward delegated his authority to Comonfort, who became provisional president of Mexico, 11 Dec. 1855. He soon met, however, with the most strenuous opposition on the part of the clergy, the army and the large body of the Conservative party. The junta of Zacapoaxtal announced itself on 19 December against the President, and a little later the seat of revolution was transferred to the city of Puebla. Over 5,000 men assembled there in February 1856. Comonfort marched against them, forced the rebels to surrender on 20 March, promulgated on 31 March a decree ordering the confiscation of the property of the Church, followed on 28 June by another decree forbidding the clergy to hold landed estate. At the same time he sent a Mexican envoy to Rome to settle with the Holy See the questions raised by the revolution. But the Mexican clergy made all possible effort to prevent his reception, while at home they labored to undermine the government. Congress, which was opened by the President, 5 Feb. 1857, assembled under very inauspicious circumstances. It proceeded, however, to draw up a new constitution which vested the legislative power and the control over religious and military affairs exclusively in Congress. The President, finding it impossible to meet the difficulties which agitated the country under such restrictions, was eventually constrained, on 29 October 1857, to apply for extraordinary powers. These were granted by Congress on 4 November and he was proclaimed constitutional President on 1 December. His position, however, became more and more critical. Opposed by the clergy and the army, he found himself isolated, and could only depend upon the brigade of General Zuloaga, which was attached to him personally. By a pronunciamiento at Tacubaya, 17 December, this brigade, too, declared itself against the new constitution, but appointed Comonfort chief of a new government. By a new pronunciamiento, however, of 11 Jan. 1858, they discarded him altogether, and the insurrection which broke out on that day in the capital led to a fierce struggle of several days. Appointing Juarez attorney of the Supreme Court, provisional President, Comonfort attempted to regain his authority by force of arms, but in vain. On the morning of 21 January the capital was in the hands of the rebels. The House of Representatives convoked on the same day by Zuloaga, appointed that general provisional President, while Juarez convened a Congress at Guanajuato, to guard the rights of Comonfort. The latter in the meantime, deserted by his soldiers, and unable any longer to maintain his power, repaired to the United States. He returned in 1861 and was Minister of War in the Juarez cabinet. He was also appointed general of one of the armies of the Republican party, and for a time he held command of Zaragoza. He was sent to the relief of Puebla in 1863, but he was defeated by an Imperialistic force to which the city was afterward forced to surrender. Subsequently Comonfort was killed by a party of guerillas who shot him from ambush.

**COMORIN.** See Cape Comorin.

**COMORO ISLANDS,** a volcanic group in the Indian Ocean, between the northern extremity of Madagascar and the continent of Africa. They are four in number—Angareja (called also Comoro), Mohilla, Johanna and Mayotta. In 1843 France took possession of the last mentioned island, and the others were taken under the protection of the same country, by treaty, in 1886. They are extremely fertile, well stocked with cattle, sheep, hogs and birds of various kinds. They produce, likewise, sweet and sour oranges, citrons, bananas, honey, sugar-cane, rice, ginger, coconuts, etc. The people are chiefly engaged in rearing cattle, and in the manufacture of coarse cloths, jewelry and small arms. They are proselyted Mohammedans, but fetish worship is customary. Pop. Arabs and negroes, 70,000.

**COMPANY** (Old Fr. *compagnie,* from Lat. *companiones,* "mess,* from com-,* "with,* and *panis,* "bread*), an association of individuals formed for some purpose of mutual advantage, especially for business purposes. The commercial use of the word *company* now has two separate uses: in general of a firm or corporation; and particularly of the silent members of a business house whose
names do not appear in its style but are comprehended by the affix "and Company." Historically the earliest occurrence of the term in connection with business enterprise dates back to the 14th century when the merchant adventurers of England about 1359 began trade. English commerce and empire are equally indebted to the efforts of the company system developed in the 17th century. The East India Company, the Muscovy Company and the Turkish Company carried English trade into eastern Europe. The East India Company won the major part of the Asiatic trade for England, and gained possessions of India and administered that country until the middle of the 19th century. The Virginia Company and the Massachusetts Bay Company prepared the way for English colonization in America, but never flourished. The history of the Hudson Bay Company is another interesting episode because of the combination of territorial and trading grants which it long held and because it still enjoys trading privileges. England still employs the same method of opening up trade, and the North Borneo Company, the British East Africa Company and the famous South Africa Company were formed between 1880 and 1890. Germany with her new imperial policy fosters the formation of such associations, and in 1884 the German East Africa Company was started, with the object of extending trade and colonization. The London City companies also are historically important as outgrowths of the medieval guilds and because for many years membership in them was a necessary preliminary to political privilege of any sort; their authority was curtailed in 1725 and by the reform bills of the 19th century, but members of the companies are still the only electors for civic offices.

In modern commerce companies may be most conveniently divided into the simple firm or partnership, which is a mere mutual agreement, and the stock company, which, by reason of its complex character and quasi-public nature, comes under State control and has displaced to a great degree the simpler method. In the stock company, instead of a private agreement, the members, under State authorization, make a company with a fixed capitalization divided into a certain number of shares, possession of which carries the right to vote, proportionally to holdings, on matters of business policy. State regulations require in all cases that one of the contracting parties be a resident of the State in which the company is incorporated, and that an office of the concern be located in the State. Other requirements vary in different States, especially in the matter of fees, which some of the western States have reduced to a minimum for the sake of attracting business to the State, and replenishing its treasury; and in the breadth and range of powers granted by the charter. The corporation laws of the State of New Jersey, together with its convenient situation near New York, have drawn a tremendous volume of business to it. See CORPORATION; TRUST.

A particularly American class of stock company is the industrial, which is essentially adapted to mine-exploiting or the development of agricultural industries. The mode of government it differs from the usual shareholder controlled company, as it is largely managed by a professional. See STOCK BANKS; PARTNERSHIP.

COMPANY, in military nomenclature regularly designates an integral part of a regiment or battalion and consists of 100 men. A looser and typically American use of the word applies it to any small body of soldiers or uniformed men, especially as independent of a State or national soldiery. These independent companies form a valuable supplement to army and State militia, as was evidenced by their service in the Spanish War. See ARMY ORGANIZATION; TACTICS.

COMPARATIVE LITERATURE. See LITERATURE, COMPARATIVE.

COMPARATIVE PHILOLOGY. See LANGUAGE, SCIENCE OF.

COMPARATIVE PSYCHOLOGY. Animal psychology, comparative psychology and genetic psychology should be defined together and by contrast, first, because they are intimately related, and second, because there is serious disagreement between popular or current usage and strictly technical usage. Briefly, animal psychology designates certain materials of observation; comparative psychology, a particular scientific method of procedure; and genetic psychology a particular aim, goal or purpose, namely, genetic or historical description of mind. These statements may be somewhat expanded as follows.

Animal psychology actually means, in common usage, the study of mind in animals exclusive of man. Logically, it should mean the study of mind in animals (including man) as contrasted with plants, for there appears adequate ground for assuming that mind exists in plants.

Comparative psychology has long been used as practically synonymous with animal psychology, that is, as the study of infrahuman animals. Logically, and by analogy with other sciences, it should mean the application of the method of comparison to the phenomena of mind wherever and however presented for observation. Its meaning in terms of purpose and method should be the same as that of comparative anatomy, comparative physiology, comparative philology or comparative literature, namely, the more nearly complete and more profitable knowledge and understanding of a group of facts by comparison thereof with more or less closely related facts. The problems of origins and of developmental relations must ever be prominent in a comparative science. Secondly, the comparative method contributes directly and importantly to genetic description.

In genetic psychology is the study of the evolution of mind (phylogeny of mind) in plants and animals and of the development or growth
of mind (ontogenesis of mind) in individuals. This branch of psychology is defined solely in terms of its primary purpose or aim, which is genetic description. Indeed, genetic psychology is simply the historical aspect of the study of mental life. Animal psychology, as also plant psychology, child psychology, abnormal psychology and social psychology, should contribute facts to genetic psychology, and comparative psychology should supply specialized methodological assistance. But genetic psychology as a special aspect of the general science should be restricted to no particular group of mental facts, to no single method. Instead, it should command all materials and all methods in the interests of a description of the processes of mental development and mental evolution. See Animal Psychology; Genetic Psychology; Psychology.

Robert M. Yerkes,
Professor of Psychology, University of Minnesota.

Comparhyth, kom-pär-rê’tê. Domenico Pietro Antonio, Italian philologist: b. Rome 1835. At first he gave his attention to mathematics and natural science. Afterward he studied Greek by himself and in 1859 was appointed professor of Greek at the University of Pisa. He soon after removed to Florence and thence to Rome where he lectured on Greek antiquities at the university and studied the excavations in the Forum. He is also eminent in Romance philology and in the social history of the Middle Ages. After 1884 he edited the Musco italico di antichità classica. His more important works are 'Saggi dei dialetti greci dell' Italia meridionale' (1866); 'Virgilio nel medio evo' (1872; Eng. trans., 1899); 'Papiro ercolanese' (1875); 'La commissione omerica di Pisciattaro e il ciclo epico' (1881); 'Iscrizione arcaica del foro Romano' (1900). With D'Ancona he edited 'Comedi e racconti del popolo italiano' (9 vols., 1870-91); and was also one of the editors of Rivista di filologia e d'istruzione classica.

Comparison, in grammar, the variation of an adjective or adverb used to express a higher and the highest degree, or a lower and the lowest degree of what is denoted by the word, thus modified in its grammatical form. The positive can scarcely be considered as a degree, as it denotes the quality generally without comparison. The comparative compares two things only, the superlative compares one thing with any number of others. In English the comparative is generally formed by the addition of er, the superlative by the addition of est, to the positive or monosyllabic adjectives and dissyllabic adjectives ending in y, or by the use of the words more and most, less and least, when the adjective is of more than one syllable and does not end in y. Adverbs are nearly always compared by the latter method. There are some adjectives, such as good, better, best; little, less, least, that do not form their degrees of comparison in the regular manner.

Compass, Mariner's, an instrument to ascertain the direction of the attraction of the earth for a movable magnet or a set of magnets. Similar instruments consisting of a magnetized needle resting on a pivot are used by the soldier or woodsman to determine directions on land. In the mariner's compass a thin circular sheet of mica is supported so as to turn with great freedom in a horizontal plane about its centre. This is called the compass-card. The bearing usually consists of a small plate of agate let into the card, and has a conical hole at the centre, and this rests on a fine needle-point of hard steel. This arrangement gives very little friction. To the under surface of the compass-card several parallel magnets are attached. Many experiments have been made to find the best arrangement for the magnets, but there is probably still something to be learned on this question, though the scheme patented by Lord Kelvin, in which the needles are suspended from the card in such a way that the moment of inertia of the card about every diameter shall be the same, is the most generally used. The compass-card is marked with a star of 32 rays, which are called the rhumbs, or the points of the compass. A line joining two of these points diametrically opposite is or ought to be exactly parallel with the magnetic axis of the arrangement below; and at the extremities of these points are marked N. (north) and S. (south), E. (east) and W. (west) are marked at the extremities of another diametral line at right angles to the first. The other points have also names; and to repeat these from memory in order, beginning at north and going round the whole circle, is what sailors call "boxing the compass." Most compasses are also graduated in degrees, either separately in each quadrant from north and south, or from 0° to 360° from north in a clockwise direction.

The card is supported, as we have said, on a steel point, which is attached either to a hemispherical bowl of thick copper, or to a thick copper ring when the compass is to be used for night-sailing in which case a lamp placed below the ring shines up through the mica card and makes the markings on it visible. This thick copper bowl or ring is called the compass-box. Its use is to damp the vibrations of the needle; for it is found that the presence of a large mass of copper properly placed damps the vibrations of a freely suspended magnet rapidly, while it does not at all prevent it from coming to rest in the proper position. In certain forms
of compass, part of the weight of the card is borne by a non-freezing liquid, which also serves to damp its oscillations. The compass-box is suspended on gimbals, which are two concentric copper rings. The larger turns on a horizontal axis, whose extremities rest on the inside of the case that contains the compass. The smaller ring turns on a horizontal axis at right angles to the former, and resting on the outer ring. The compass-box is attached to the inner ring, and its weight tends to keep both horizontal. Thus supported, the compass-box and card always remains horizontal however the ship rolls or pitches. The chief difficulty in making use of the compass arises from the magnetism of the ship itself. In iron ships particularly, the magnetism of the ship greatly interferes with its indications. The effect of

12th century the compass became known in Europe. Whether it was learned from the Orient is not certain. The Italians ascribe the invention of the compass to Flavio Gioja, a native of Amalfi, giving the dates 1300-20, but it has been shown that he can be credited only with some important improvements of the instrument. The discovery of the variation of the needle has been generally attributed to Columbus, but is now supposed to have been known much earlier. See Gyroscopic Compass; Magnetism.

F. J. Evans and Archibald Smith, 'The Admiralty Manual for the Deviations of the Compass' (new editions from time to time); Lyons, 'Treatise on Electro-magnetic Phenomena and the Compass and its Deviations Aboard Ship' (New York 1901-19); Smith, 'Practical Compass Adjustment' (Seattle 1903).

COMPASS PLANT (Silphium laciniatum), a tall composite yellow-flowered plant growing on the prairies of the Mississippi Valley, and remarkable from the fact that its erect radical leaves stand so that their edges point almost exactly north and south, especially in midsummer. This is said to be due to the action of light, and to depend on the leaves having an equal number of stomata on either face. The plant is known in some localities as 'resinweed' because it contains such a large amount of resinous matter. A European species of lettuce (Lactuca scariola) has received the same name.

COMPASSES, mathematical instruments used for describing circles, measuring lines, etc. They consist simply of two pointed legs movable on a point or pivot. For describing circles the lower end of one of the legs is removed and its place supplied by a holder for a pencil or pen. Hair compasses have a spring tendency to keep the legs apart, and a finely threaded screw by which the spring can be compressed or relaxed with the utmost nicety, and the distance of the legs regulated to a hair's-breadth. Bow compasses have the legs united by a bow passing through one of them, the distance between them being adjusted by means of a screw and nut. Proportional compasses, used for reducing or enlarging drawings, have the legs crossing so as to present a pair on each side of a common pivot. By means of a slit in the legs, and the movable pivot the relative distances between the points at the respective ends may be adjusted at pleasure in the required proportion. Beam compasses are used where greater lengths are needed than can be secured by the ordinary pivot compasses. Points are arranged on a sliding bar so they can be clamped at different distances from each other. Triangular compasses, having three legs, are used when it is desired to transfer the vertices of a triangle. Club compasses, or bullet compasses, are constructed with a ball instead of one of the points of the ordinary compasses; the ball being arranged so as to turn in a hole or socket.

COMPENSATION, that which is given or received as an equivalent for services rendered, losses sustained, sufferings endured or in pay-
COMPENSATION — COMPETITION

ment of a debt; amends, remuneration, payment, recompense. When one is sued for a debt, it is competent for him, partially or wholly, to bar the claim by alleging that he is the plaintiff's creditor for services rendered or money lent. If the sum claimed from the plaintiff is found to be the exact equivalent of that for which he sues, the two are held to compensate or balance each other. Contrary, be it less, it diminishes by so much the prosecutor's claim. If, however, the defendant feels that he owes the plaintiff more than that individual is indebted to him, he is required at the outset to pay into court the smaller sum for which he admits himself to be responsible.

Compensatio injuriarum is a defense against actions for damages claimed for slander, false accusations and like causes.

COMPENSATION, Workmen's. See ACCIDENTS, CAUSES AND PREVENTIONS OF; WORKMEN'S COMPENSATION.

COMPENSATION BALANCE, or PENDULUM, a balance-wheel or pendulum for a watch or chronometer, so constructed as to make isochronal (equal time) beats, notwithstanding changes of temperature. This effect is usually attained by having the balance-wheel cut into two segments, the arcs being fixed at one end each. This allows space for the expansion and contraction to counteract the varying strength of the spring. A compensation pendulum is generally what is known as a mercurial pendulum or a fidiron pendulum. It is constructed of two different metals, such as brass and iron, which so work against each other, that the expansion of the one downward is counteracted by that of the other upward. By this arrangement the pendulum does not vary in length, and consequently, in frequency of vibration, whatever the temperature may be. Arnold's compensation balance-wheel for chronometers and watches is constructed on a similar principle. See CHRONOMETER.

COMPENSATION INSURANCE. See WORKMEN'S COMPENSATION.

COMPENSATION PENDULUM. See COMPENSATION BALANCE.

COMPETITION, a term nearly equivalent to the phrase "struggle for existence." Lamarck was the first to point out definitely the fact of competition in the cases of man and the sloth, but it was not until a half-century later that Darwin and Wallace emphasized its far-reaching importance as a biological agent in evolution. Competition may be most strikingly illustrated by a case in which it is entirely absent. The Great Salt Lake of Utah is inhabited by the brine shrimp (Artemia salina), which abounds in enormous numbers in the dense briny waters; hundreds may be dipped up in a dish of water and thousands captured by a few sweeps of the tow-net. As the water is so salt that no other animal can live in it except a maggot near shore, it has absolutely not an enemy, and there is no other form to compete with it. Its food is a floating green alga (Polyctis packardi). It is absolutely harmless and without means of defense, and lays but few eggs; yet its success in point of numbers is beyond all precedent. Another case is that of a fly (Ephydra gracilis) whose larva abounds at the margin of the same lake. These two cases illustrate how a species may abound in profusion, though not crowding out other forms, since there are no competitions.

A familiar example of crowding out of native species by those introduced from foreign countries in the struggle for existence among plants is the ox-eye daisy, which was introduced from Europe, first appearing in Leicester, Mass., in 1740. Many of the species introduced throughout New England green fields of grass became white with its flowers; it drove out even the grasses introduced. On the other hand, in central Europe, throughout France, the Pyrenees and the Alps, as recently observed, it grows sparsely, never in extensive patches. Other examples are the introduced European injurious insects, the gipsy moth, the scale insects and many others, whose numbers in the Old World are kept within due limits by ichneumon parasites, but which in the United States and Canada, owing to the absence of their natural enemies, breed in unlimited numbers. Another case is that of the Colorado potato-beetle, which spread eastward from comparatively limited tracts in the Rocky Mountain region, and invaded the Eastern States to the shores of the Atlantic. The English sparrow, introduced during a period from 1850 to 1870, has become, owing to the lack of competition, a grievous pest, driving out the native birds.

The periwinkle (Littorina littorea) of the European coast; introduced on our shores, about 1855, has multiplied to such an extent that it lives between tide-marks in millions, to one of our native species of the same genus. Such cases as these throw light upon the subject and prove that there is a silent but unceasing struggle for existence going on over nearly all the earth's surface. Yet in the case of desert plants which grow sparsely, separated by barren spaces, there is, as Henslow has observed, no struggle for existence.

Nowhere is the agency of competition more marked than in human society. In the lower savage races, as in the black race of Africa or the natives of Australia, the scattered tribes have confined their contests to simple raids, and no single people or sub-race has gained marked pre-eminence over another, with the exception of the Hottentots and Bushmen, who were largely exterminated by negro tribes from the North. But as we ascend to the higher or white race, to the Semitic, the western Asiatic and European peoples, we have examples of the sudden rise to power and pre-eminence of vast hordes of barbarian peoples under Tamerlane, the Grand Mogul, Attila and other conquerors, which have swept over vast territories and crushed the weaker, more peaceful or even civilized but less resistant nations. The rapidity with which the Arabs overran and still dominate northern Africa in language, social customs and religions; the Mongolian movements eastward into China, and westward to the borders of Europe; the successive rise and irresistible waves of the great races, from the eastward to northern Europe, throughout prehistoric and historic times; the colonizing and expansion of the powers of Greece, of Rome, of the Norsemen, Anglo-Saxon, the Spanish, French and German peoples; the success of the white race in the struggle for existence, the apparent disappearance of the lower, weaker races, less favored intellectually and morally, some of which
had become fossilized, or semi-fossilized, and practically inept and unfit,—all these phenomena, which are historic facts, are of a piece with what we witness, though in a less distinct and marked way, in the plant and brute realms. The old, though injustice, moral degeneration, suffering and evils which attend human progress are pitiful and deplorable.

In the economic as in other fields, competition is the natural law, and is taken to represent, through the free play of individual self-interest, the "survival of the fittest." Here the surest means of success is the underselling of competitors. In its natural or unrestricted form, each nation or corporation or individual produces the goods most adapted to its economic conditions or its talents, securing trade in competition with like products. Under the old mercantilist theory, colonies existed solely for the benefit of the mother country, and their trade was kept strictly as a preserve for the dominant nation, it being manifested that what one nation gains in trade the other necessarily loses. This narrow theory was exploded by political economists beginning with Adam Smith, the view since taken being that every country is benefited by the prosperity of its neighbors. Economic competition naturally finds its most expansive field of operations in an open market, from which barriers, tariff or otherwise, have been removed. Due to its adoption of a free-trade policy, the British Islands may be considered as almost the only country in which there is unrestricted world-wide competition. The "survival of the fittest" implies the driving of the weakest to the wall; and in its operation in the last century it was seen that this involved the ruin not only of weak and inefficient competitors, but was a fruitful means of underselling by concerns with large capital at command for the purpose of driving competition from the field and ultimately establishing monopolies. It has also led to cut-throat competition when goods are sold or dumped down for sale at less than cost of production; or among laborers when competition for jobs has led to the lowest price for labor becoming the standard, or to displacement by the application of machinery throwing workmen out of employment and occasioning distress. The rise of the trade union movement, having for its object the stimulation of wages, and the protection of the laborer, and of employers' associations to combat these, and the passing of factory and workshop legislation, all tend to modify competition. Thus competition has tended to bring into operation its opposite, combination, and this again has led to monopoly and price control. The era of business consolidation which began in the United States more than 20 years ago, with its resultant control of raw material and finished product alike, and the operation of the big trusts, have in many industries made competition a dead letter. In the great natural monopolies of lighting, water and transportation, the results are in line with the law, benefiting at the expense of the consumer, and the opinion has steadily grown that these utilities must be operated on behalf of the public. The difficulty that faces schemes for the elimination of competition is that in its replacement the constant spur to human energy and resourcefulness which the system affords may be lost.

Bibliography,—Consult in the field of natural history, Darwin's "Origin of Species," Huxley and Wang run beneficial, though the injustice, moral degeneration, suffering and evils which attend human progress are pitiful and deplorable.

The "survival of the fittest" implies the driving of the weakest to the wall; and in its operation in the last century it was seen that this involved the ruin not only of weak and inefficient competitors, but was a fruitful means of underselling by concerns with large capital at command for the purpose of driving competition from the field and ultimately establishing monopolies. It has also led to cut-throat competition when goods are sold or dumped down for sale at less than cost of production; or among laborers when competition for jobs has led to the lowest price for labor becoming the standard, or to displacement by the application of machinery throwing workmen out of employment and occasioning distress. The rise of the trade union movement, having for its object the stimulation of wages, and the protection of the laborer, and of employers' associations to combat these, and the passing of factory and workshop legislation, all tend to modify competition. Thus competition has tended to bring into operation its opposite, combination, and this again has led to monopoly and price control. The era of business consolidation which began in the United States more than 20 years ago, with its resultant control of raw material and finished product alike, and the operation of the big trusts, have in many industries made competition a dead letter. In the great natural monopolies of lighting, water and transportation, the results are in line with the law, benefiting at the expense of the consumer, and the opinion has steadily grown that these utilities must be operated on behalf of the public. The difficulty that faces schemes for the elimination of competition is that in its replacement the constant spur to human energy and resourcefulness which the system affords may be lost.
tive Man's Recreation. the natural gift to be quiet, and go a-angling. The born fisherman is necessarily a lover of quiet and a lover of nature in her peaceful natural aspects, and he is likely to be something of a philosopher and to have a bookish tinge to his thoughts, as he sits hour after hour by the stream-side. Otherwise he can scarcely be called a compleat angler. Such a man, with a pervading tincture of quaint old-world piety, was Walton himself, and it is because he chanced to be so typical an example of the angling fraternity and was able, in speaking for himself, to speak so authentically for all anglers of all time, that 'The Compleat Angler' has become the sacred book of those, who, as Walton was fond of reminding his readers, follow Saint Peter's calling; and that Walton is not only 'Honest Izaak,' but also 'Saint Izaak,' the patron saint of the brethren of rod and reel. Walton in his writing, as Lowell has pointed out, has an innocent air of not knowing how it is done. It is all art, or at least says so, without the art, but the art is there, all the same. Artlessness in literature, while it begins in a natural grace, des gratia, is never achieved without the expenditure of that art which conceals itself; and Walton possessed the possession of a literary gift which was not dependent on a limited subject matter for its exercise. That is, he was not merely a born angler, but also a born writer; in his degree, an artist in words. Otherwise, he would only have anglers for readers, whereas 'The Compleat Angler' is for all who love good literature. No doubt, it was Walton's artless art which led him to choose the form he has given to his book, that of a prose pastoral, with 'Fiscator' and 'Venator' (who have 'well overaken' each other on 'Tottenham Hill,' 'this fine fresh May morning'), for the chief interlocutors; with an occasional falconer,—'Aucups'—and milkmaid, thrown in. This form, recalling Theocritus and Virgil, gives a gentle dramatic setting and interplay of character, as also an open road, a gipsy quality, to the discourse. It has the charm of the walking-tour of two friends along a river-side, who, while they fish the stream, talk of the antiquity of anything, or 'Hood to dress the club,' or of the curiosities of natural history as found in Aldrovandus and Gessner, and other naturalists of the time; and,' whilst this shower falls so gently upon the teeming earth,' sit together under the honey-suckle hedge, and recite to one another old-fashioned poetry but choiceely good, I think much better than the strong lines that are now in fashion in this critical age — Dubartas, Sir Walter Raleigh and 'holy Mr. George Herbert.' Then, with the twilight, an old Dutch English inn for supper, with a hostess, and her daughter to sing them an old-world ballad at bedtime. For 'Merry England' still lives in this book—that is another of its claims for remembrance—Herrick's England of the Morris-dance and the maypole, and a peasantry that still cared for music and flowers. And the old English countryside, with its homes of ancient peace, its primroses and cowslips and hawthorn, as well as its various rustic characters, lives in this book as perhaps nowhere else in literature out of Shakespeare's plays. For this reason, it may with justice be described as the one English pastoral. This special quality of green 'quiet' is the more surprising as 'The Compleat Angler' was written in that time of storm and stress succeeding the execution of Charles I. It was first published in 1653, and from that date on—such a remarkable appeal has this quiet book had for mankind—a new edition has, on the average, been published every two and a half years. Walton was a meticulous reviser of his work, and in 1676 (being then 83; he died at 90) he gave forth his final definitive edition, the 5th. To this edition he invited his friend Charles Cotton to add a second part, which has thus become an integral, not unnecessary, portion of 'The Compleat Angler.' It has the value, moreover, of commemorating a charming friendship, a friendship the more surprising as Cotton was a brilliant young man-about-town, and Walton a patriarchal associate of bishops and deans. But both men had the gift of humanity, and it is by that sovereign gift, inclusive of all others, that 'The Compleat Angler' still remains a classic in a day when classic action is the final admonition—'Study to be quiet' (1 Thess., iv, 11). 'The Compleat Angler' has been a favorite book with many famous writers. Dr. Johnson considered 'the preservation and elucidation of Walton's pious work,' and such different men as Scott, Wordsworth and Lamb have been among his many disciples.

RICHARD LE GALLIENNE.

COMPLEMENT, that which fills up to a certain unit. Thus the complement of an angle is the angle which would, by addition, make the given angle a right angle; and the complement of a number is a number which, by addition, make the given number equal to the next higher unit, or the next higher power of 10.

In medicine the complement or the complementary body is supposed to be a substance in the blood serum that is necessary for its antibacterial or bacteriolytic action. In order to bring about a lysogenic action (Pfeifer phenomenon), two bodies seem to be necessary in the blood serum. One known as the immune serum is developed during the process of immunization. It alone cannot cause bacteriolytic. There must be present in the blood serum another body, the complement. It is also called alexine or cytase. See IMMUNITY.

Complement also has the signification of that which is added as ornamental but not as necessary, as an accessory or appendage or as an accomplishment. It has exactly the same origin as compliment, which is used to express a formal act or expression of civility, respect or regard.

COMPLEX NUMBERS. See ALGEBRA.

COMPLEX VARIABLE, Theory of Functions of a. 1. Function.—The Theory of Functions of a Complex Variable deals with ordinary complex numbers, \( z = x + yi \), where \( x \) and \( y \) are real, and \( i \) denotes the pure imaginary number \( \sqrt{-1} \). Just as real numbers are represented by points or rays in the plane, so complex numbers are represented by points in a plane, called the complex plane, \( z \) corresponding to
that point whose Cartesian co-ordinates are $(x, y)$. The distance $\sqrt{x^2 + y^2}$ of $z$ from the point $z = 0$ is called the absolute value of $z$ and is written $|z|$. Let $S$ denote a region of the plane bounded by one or more closed curves. To every point $z$ of $S$ let one or more numbers $\omega$, real or complex, be assigned according to some definite law. Then $\omega$ is said to be a single- or multiple-valued function of $z$: \( \omega = f(z) \). For the present we shall restrict ourselves to single-valued functions.

2. Continuity and Limits.— The function $\omega = f(z)$ is continuous in the region $S$ if, when $z$ describes any continuous curve in $S$, the image $\omega$ of $z$ describes a continuous curve in the $\omega$-plane. The variable $f(z)$ is said to approach $b$ as its limit, if, when $z$ approaches a along an arbitrary path, the corresponding point $\omega = f(z)$ approaches the point $\omega = b$; in symbols,

$$\lim f(z) = b.$$ 

A complex variable $z$ is said to become infinite: $\lim z = \infty$, if its absolute value becomes infinite; i.e., if the corresponding point of the complex plane recedes indefinitely, no matter in what direction.

3. Derivative.— The function $\omega = f(z)$ has a derivative, $f'(z)$, if the quotient $dw/ds$ approaches a limit, when $dz$ approaches 0:

$$\lim_{dz \to 0} \frac{dw}{dz} = f'(z) = Dz \omega.$$ 

When $z$ is the independent variable, 

$$\frac{dw}{dz} = Dz \omega,$$

and it is shown, as in the differential calculus, that 

$$dz = dz \omega \quad \text{and} \quad dw = Dz \omega dz,$$

the latter relation holding no matter what the independent variable may be. The general rules for differentiation apply here, e.g., 

$$d(U + V) = dU + dV,$$ 

Moreover, we have 

$$\frac{d\omega}{ds} = n\omega^{n-1}, \quad n = \text{pos. integer}.$$ 

Hence it follows that all rational integral functions, i.e., polynomials in $z$, and all other rational functions of $z$, can be differentiated according to the same rules as reals.

Theorem: The necessary and sufficient condition that the function 

$$\omega = u + vi = f(x + yi)$$

have a continuous derivative is that the real functions $u$ and $v$ of the real variables $x$ and $y$ have continuous first partial derivatives satisfying the Cauchy-Riemann Differential Equations:

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \quad \text{and} \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}. \quad (1)$$

The condition is necessary. For since we shall always get one and the same limit, no matter along what path $dz$ may approach 0, let $dz$ pass first only through real values: $dz = dx$; thus 

$$\lim_{dz \to 0} \frac{dw}{dx} = \frac{\partial \omega}{\partial x} = D_1 \omega.$$ 

Secondly, let $dx$ be pure imaginary: $dx = idy$; then 

$$\lim_{dy \to 0} \frac{dw}{idy} = \frac{\partial \omega}{\partial y} = D_2 \omega.$$ 

Hence 

$$\frac{\partial \omega}{\partial x} = \frac{1}{i} \frac{\partial \omega}{\partial y},$$

and it remains only to separate the real and the pure imaginary terms. We omit the proof of the sufficiency of the condition.

Two functions which satisfy relations (1) are called conjugate functions.

Example: Let 

$$\omega = e^{\varphi \cos \gamma + i \sin \gamma}.$$ 

Then 

$$\frac{\partial \omega}{\partial x} = e^{\varphi \cos \gamma} \frac{\partial \varphi \cos \gamma}{\partial x}.$$ 

Hence $\omega$ has a derivative, and furthermore 

$$\frac{\partial \omega}{\partial x} = \omega.$$ 

A function which is single-valued throughout a region $S$ and has a continuous derivative in $S$ is said to be analytic in $S$. The terms holomorphic, monogenic and syntonic are also sometimes used in this sense.

4. Conformal Mapping.— Given any two functions 

$$u = \psi(x, y), \quad v = \phi(x, y), \quad (2)$$

we may interpret them geometrically as transforming the points of one plane into the points $(u, v)$ of a second plane. Thus a region $S$ of the first plane will be mapped, if certain further conditions are fulfilled, in a one-to-one manner and continuously on a region $S'$ of the $(u, v)$-plane. For example, let 

$$x = x^2 - y^2, \quad y = 2xy.$$ 

Here the first quadrant of the $(x, y)$-plane is mapped on the upper half of the $(u, v)$-plane, the family of lines $y = \text{const.}$ going over into the family of equilateral hyperbolas whose axes lie in the co-ordinate axes, and the family of lines 

$$v = \text{const.}$$

going over into the orthogonal family, whose asymptotes are these axes.

If $u$ and $v$ have continuous first partial derivatives and if their Jacobian 

$$J = \begin{vmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{vmatrix}$$

does not vanish, then, at least for a restricted region $S_a$ about a point $(x_a, y_a)$, the equations (2) will always define a one-to-one map of $S_a$ on a region $S_b$ including the point $(u_a, v_a)$. This map will represent approximately (i.e., to infinitesimals of higher order than the first) a projection — in other words strain — of the immediate neighborhood of $(x_a, y_a)$ on that of $(u_a, v_a)$, a small circle about $(x_a, y_a)$ going approximately into an ellipse about $(u_a, v_a)$. If, however, $u$ and $v$ are conjugate functions, the ellipse be-
COMPLEX VARIABLE

(b) The Trigonometric Functions. When $x$ is real, we have from (3)

$$
\sin z = \frac{e^{iz} - e^{-iz}}{2i}, \quad \cos z = \frac{e^{iz} + e^{-iz}}{2}
$$

The right-hand sides of these equations have a meaning for complex values of the argument. By means of them we define the functions $\sin z$, $\cos z$:

$$
\sin z = \frac{e^{iz} - e^{-iz}}{2i}, \quad \cos z = \frac{e^{iz} + e^{-iz}}{2}
$$

These generalized functions are single-valued and analytic for all values of $z$ and satisfy the same functional relations as $\sin x$, $\cos x$, etc.

(c) The Inverse Functions. The function $\log z$ shall be defined as the inverse of the exponential function:

$$
e^{\text{clog } z} = e^{w} = e^{\log z}
$$

Setting $w = u + iv$, $z = r (\cos \phi + i \sin \phi)$, we have $e^{u + iv} = e^{u} (\cos \phi + i \sin \phi)$. Hence

$$
u = \log r, \quad v = \phi + 2k\pi,
$$

and

$$
\log z = \log |z| + (\phi + 2k\pi)i.
$$

Thus it appears that the logarithm is no longer single-valued when complex numbers are admitted to consideration. For example,

$$
\log 2 = 0.693 + 2k\pi i.
$$

In a similar way each of the other inverse functions is defined. We find

$$
\cos^{-1} z = i \log (z + \sqrt{z^2 - 1})
$$

and

$$
\tan^{-1} z = \frac{1}{2} \log \frac{z + i}{z - i}
$$

From the foregoing it appears that in the domain of complex quantities the trigonometric functions can be expressed in simple form in terms of the exponential function and conversely; while the inverse trigonometric functions express themselves in terms of the logarithm. Thus the formulas of integration:

$$
\int_a^{b} \frac{dx}{a + bx} \left\{ \begin{array}{cc} \tan^{-1} \left( \frac{x}{\sqrt{b/a}} \right), & ab > 0; \\
2 \sqrt{-ab} \log \frac{a + x + \sqrt{b}}{a - x + \sqrt{b}}, & ab < 0,
\end{array} \right.
$$

are applicable in no wise akin, are seen to be equivalent in the complex domain.

6. Laplace's Equation. (a) Flow of Heat or Electricity. Let the points of the boundary of a homogeneous (or more properly isotropic) conducting substance be maintained at given temperatures (for example, a steam-pipe, the interior being kept at 100° and the exterior at 0°). Then a flow of heat ensues within the conductor and the temperature at any given point approaches a limiting value, $u$, as time goes on. In fact, if each point were brought to this limiting temperature, it would continue there so long as the boundary conditions are maintained and we should have a steady flow. The corresponding temperature $u$ satisfies Laplace's Equation in three dimensions:

$$
\Delta u = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0.
$$

If in particular the solid be bounded by cylindrical surfaces whose elements are parallel to
the $a$-axis, and if the given temperature be constant along each element, then $u$ will evidently be constant along any line parallel to the $a$-axis, and we shall have in substance a two-dimensional flow, for which

$$du = \frac{\partial u}{\partial x} dx + \frac{\partial u}{\partial y} dy = 0.$$  

We may conceive the solid itself in which the flow takes place as two-dimensional if we think of a thin section as cut out of the above solid by two planes parallel to the $(x, y)$-plane and very near together. The flat faces of this slab are then to be thought of as coated with some adiabatic substance, so that no heat can enter or leave the slab across these faces.

The electrical problem is mathematically identical with the heat problem, $u$ being interpreted as potential instead of temperature. As conductor consider for example a piece of tinfoil whose edge is connected with a thick piece of copper. Let one pole of a battery be attached to the copper and the other to the tinfoil at an interior point. We thus have a point source.

The curves $u = \text{const.}$ are called isothermals or equipotential curves. The orthogonal trajectories of these curves $u = \text{const.}$ are the lines of flow.

(b) Flow of an Incompressible Fluid. Consider the flow of an incompressible fluid constrained to move between two parallel planes, the particles which lie in any line perpendicular to the planes at any moment always remaining in that line. If there be a function $u$ whose partial derivatives with respect to $x$ and $y$ give the components of the velocity of each particle of the fluid along the axes, then $u$ is called the velocity potential. If $u$ does not depend on $t$, we have a steady flow with velocity potential, and $u$ here satisfies Laplace's Equation.

Conversely, let $u$ be any harmonic function, i.e., a solution of Laplace's Equation, in two dimensions. Then this function defines a steady flow of heat, electricity, or an incompressible fluid with velocity potential.

Let us turn now to analytic functions of a complex variable:

$$w = u + vi = f(x + yi).$$

Differentiating the first of the equations (1) with regard to $x$, the second with regard to $y$, and adding, we see that $w$ satisfies Laplace's Equation. Hence

**Theorem**: Every analytic function of a complex variable defines a steady flow of heat, electricity, or an incompressible fluid with velocity potential.

The converse is also true. Let us first recall the condition that $P dx + Q dy$ be an exact differential, namely,

$$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}.$$  

If this condition is fulfilled throughout a finite region $S$, then

$$\int P dx + Q dy$$

taken over the complete boundary of $S$ will vanish. Furthermore, if $S$ has but a single boundary,

$$\int_{(x, y)} P dx + Q dy$$

will be a function of the upper limit $(x, y)$ alone, not of the path of integration; cf. Goursat, 'Cours d'analyse,' Vol. I, §152. It can now be shown that, given a steady flow of heat or electricity, a possible flow results if we interchange the equipotential lines and lines of flow.

Returning now to the main question, let $w$ be any solution of Laplace's Equation, and form the function

$$v = \int \frac{x}{(x, y)} \frac{\partial u}{\partial y} dx + \frac{\partial u}{\partial x} dy + C.$$  

Then the value of the integral will be independent of the path of integration. Then at least if we confine ourselves to a finite region $S$ with a single boundary. The derivatives of this function have the values

$$\frac{\partial v}{\partial x} = \frac{\partial u}{\partial x}, \frac{\partial v}{\partial y} = \frac{\partial u}{\partial y}$$

and thus satisfy (1). Hence $u$ and $v$ are conjugate functions, and $u + vi$ is an analytic function of $x + yi$.

The relation here pointed out between the theory of functions of a complex variable and certain problems of mathematical physics was employed by Riemann (1851-66) as a means of investigation in the former subject, and his method has been further developed by Klein (since 1881) and others.

7. Cauchy's Theorem. Let $f(z)$ be single-valued and continuous throughout a region $S$, and let $C$ be a curve lying in $S$. The integral of $f(z)$ taken along $C$ is defined much as a curvilinear integral is in the calculus. Let $C$ be divided by the points $z_0, z_1, \ldots, z_n = b$ into $n$ arcs; set $z_0 + 1 - z_2 = \Delta z$. Then if, as $n$ increases, the lengths of all the arcs approach 0,

$$\lim_{n \to \infty} \sum_{k=0}^{n-1} f(z_k) \Delta z_k = \int_C f(z) \, dz.$$  

The following theorem, due to Cauchy (1825), is fundamental.

Cauchy's Integral Theorem. Let $f(z)$ be single-valued and continuous throughout a finite region $S$, inclusive of the boundary, and let $f(z)$ be analytic within $S$. Then the integral of $f(z)$, extended over the entire boundary $C$ of $S$, has the value 0:

$$\int_C f(z) \, dz = 0.$$  

Writing $f(z) = u + vi$, $z = x + yi$, we have

$$\int_C f(z) \, dz = \int_C (udx - vdy) + i \int_C (vdx +udy).$$

But each of these latter integrals is an exact differential (§6), since $u$ and $v$ are conjugate functions. Hence, by the theorem of §6, each integral vanishes.

By means of this theorem many real definite integrals may be computed. In fact, it was through the attempt to obtain a rigorous deduc-
extended along the boundary of the region indicated. Its value is 0. Hence

\[ \left( \int_{OA} + \int_{AB} + \int_{BO} \right) f(z) dz = 0. \]

Now let \( OA = R \) increase without limit. The first integral thus becomes the well-known integral of the Theory of Probability:

\[ \int_{-\infty}^{\infty} e^{-r} dr = \frac{\sqrt{\pi}}{2}. \]

The second integral can readily be shown to approach the limit 0. In the third,

\[ z = r (\cos \theta + i \sin \theta) = \frac{1}{\sqrt{2}} (1 + i) r. \]

Hence

\[ \frac{\sqrt{\pi}}{2} + \frac{1}{\sqrt{2}} (1 + i) \int_{-\infty}^{\infty} e^{-r^2} dr = 0. \]

Setting \( e^{-r^2} = \cos r^2 + i \sin r^2 \) and separating reals and pure imaginaries, we obtain the evaluation of the Fresnel integrals:

\[ \int_{-\infty}^{\infty} \cos r^2 dr = \frac{\sqrt{\pi}}{2}. \]

The residue of a function \( f(z) \) in a point \( a \) in whose neighborhood, with the exception of the point \( a \) itself, the function is single-valued and analytic, is defined as

\[ \frac{1}{2\pi i} \int_{C} f(z) dz, \]

the path of integration \( C \) being a closed path surrounding the point \( a \) and containing no other singularity of the function. If \( f(z) \) is single-valued and analytic in a finite region \( S \) except at a finite number of points lying within the region, then the sum of the residues of \( f(z) \) at these points is given by

\[ \frac{1}{2\pi i} \int_{C} f(z) dz, \]

where \( C \) refers to the boundary of \( S \).

8. Development into a Taylor’s Series.—In 1831 Cauchy extended Taylor’s Theorem to functions of a complex variable and at the same time discovered a simple test for the range of values of the variable for which the series converges. Let \( f(z) \) be single-valued and analytic in a region \( S \), and let \( a \) be an interior point of \( S \). Let \( K \) be the largest circle that can be drawn in \( S \) with \( a \) as centre so as to include in its interior no point of the boundary of \( S \). Then, for all points \( z \) within this circle, \( f(z) \) can be represented by the series

\[ f(z) = c_n + c_n(z - a) + c_{n+1}(z - a)^2 + \ldots \]

where

\[ c_n = \frac{1}{2\pi i} \int_{C} \frac{f(t) dt}{(t-a)^{n+1}} = \frac{f^{(n)}(a)}{n!}. \]

and

\[ |c_n| < M r^{-n}, \]

where \( M \) denotes the maximum value of \( |f(z)| \) on the circumference of the circle \( |z - a| = r \).

Example. Let \( f(z) = (1 - 2\mu z + z^2)^{-1} \), where \( \mu \) is a real constant numerically less than 1. Here either value of the function is continuous and analytic except where the radicand vanishes the

\[ 1 - 2\mu z + z^2 = 0, \quad z = \mu \pm \sqrt{1 - \mu^2}, \]

i.e., at two points on the unit circle about \( z = 0 \). Hence we can develop either value of the radicand into a Taylor’s series:

\[ \frac{1}{\sqrt{1 - 2\mu z + z^2}} = P_0 + P_1 z + P_2 z^2 + \ldots \]

where the coefficients \( P_n \) depend on \( \mu \) alone, and the series will converge for all values of \( z \) within the unit circle.

The proof of the theorem is based on Cauchy’s Integral Formula, by means of which the value of the function \( f(z) \) at any interior point of \( S \) can be expressed solely in terms of the value of \( f(z) \) along the boundary, \( C \), of \( S \):

\[ f(z) = \frac{1}{2\pi i} \int_{C} \frac{f(t) dt}{t - z}. \]

This formula is deduced directly from Cauchy’s Integral Theorem, and is analogous to the theorem in the Theory of the Potential by which the value of a harmonic function \( u \) at any point within a region is expressed in terms of its value \( U(z) \) on the boundary, and of a function peculiar to the shape of the region, namely, the Green’s Function \( G \):

\[ u = \frac{1}{2\pi} \int_{C} \frac{U(z')}{z - z'} ds. \]

In fact, each formula can be deduced from the other one. The whole theory of functions of a complex variable can be based on Cauchy’s Integral Formula as well as on the Taylor’s development.

Conversely, let

\[ c_0 + c_1 z + c_2 z^2 + \ldots \]

be any power series converging for values of \( z \neq 0 \). Then it can be shown that this series converges within a certain circle of radius \( R \) and (excepting the special but important case that it converges for all values of \( z \) and thus represents a so-called integral transcendental function of \( z \)) diverges outside the circle. Within this circle, called the true circle of convergence, the series represents an analytic function and forms in fact the Taylor’s (or Maclaurin’s) development of this function about the point \( z = a \).

9. Other Series.—(a) Laurent’s Series. If \( f(z) \) is single-valued and analytic within a circular ring of radii \( r_1 \) and \( r_2 \) about the point \( a \), then \( f(z) \) can be developed into a Laurent’s Series:

\[ f(z) = \sum_{n=-\infty}^{\infty} c_n (z - a)^n, \]

convergent for all values of \( z \) within this ring:

\[ |z| < |z - a| < r_1. \]

Here

\[ c_n = \frac{1}{2\pi i} \int_{C} \frac{f(t) dt}{(t-a)^{n+1}} = \frac{f^{(n)}(a)}{n!}, \]

where \( C \) denotes a closed curve lying within the ring and encircling the point \( a \), and \( M, r \) have the same meaning as in § 8.
(b) Lagrange's Series. Kepler's problem of developing a root $w$ of the equation

$$w = a + z \sin w$$

(or more generally a function $\Phi (w)$ of this root) according to powers of $z$ led Lagrange to formulate the following problem: To develop a root $w$ of the equation

$$w = a + \varepsilon f(w),$$

or more generally a function $\Phi (w)$ of this root, according to powers of $z$. He thus obtained the series that bears his name:

$$\Phi (w) = \Phi (a) + \varepsilon \Phi' (a) f(a) + \sum_{n=1}^{\infty} \frac{\Phi^{(n)} (a)}{n!} (\varepsilon f(a))^n.$$

Example: Let $f(w) = \frac{1}{\sqrt{1 - 2aw + z^2}}$, then $\frac{\partial w}{\partial a} = (1 - 2as + z^2)^{-\frac{1}{2}}$ and

$$\frac{1}{\sqrt{1 - 2as + z^2}} = 1 + \sum_{n=1}^{\infty} \frac{z^n}{n!} \frac{d^n}{dn^2} \left[ (at - 1)^n \right] \frac{1}{n^2}.$$

Thus the form of the coefficients $p_n$ in the example of § 8 is determined:

$$p_n(a) = \frac{1}{n!} \frac{d^n}{dn^2} \left[ (at - 1)^n \right] \frac{1}{n^2}.$$

These functions are known as Zonal Harmonics.

10. Roots and Singular Points.—A function $f(z)$ is said to have a root or zero at an interior point $a$ of the region $S$ of § 8 if $f(a) = 0$. It follows that $f(z)$ can then be written in the form

$$f(z) = (z-a)^m \left[ \frac{c + a + (z-a) + \ldots}{} \right],$$

where $m$ is a positive integer and $c + a + \ldots = 0$ (unless $f(z) \equiv 0$). The point $a$ is called a root or zero of order $m$; $f(z)$ is sometimes said to have $m$ roots at $z = a$. A circle of definite radius can always be drawn about the point $a$ containing no further root of $f(z)$.

If $f(z)$ is single-valued and analytic throughout the neighborhood of a point $a$ with the exception of a point itself, and if $f(z)$ becomes infinite no matter how $z$ approaches $a$, then $a$ is called a pole of $f(z)$. Since $1/f(z)$ then has a zero in $a$, $f(z)$ can be written in the form

$$f(z) = \frac{\varphi(z)}{(z-a)^m},$$

where $m$ is a positive integer and $\varphi(z)$ remains finite and different from $0$ at $a$; $f(z)$ is said to have a pole of order $m$, or to have $m$ (simple) poles in $z = a$.

If, however, $f(z)$ does not approach a limit when $z$ approaches $a$, and does not have a pole there either, $a$ is called an essential singularity. In the neighborhood of such a point Weierstrass has shown that the function comes as near as one pleases to any arbitrary preassigned value.

11. Linear Transformations.—The linear transformation

$$Z = \frac{as + b}{cs + d}, \quad ad - bc \neq 0,$$

plays an important rôle in the theory of functions. If $c = 0$, we have an integral linear transformation. Interpreted geometrically as a transformation of the plane into itself, it comprises as special cases:

(a) $Z = s + b$, i.e., a translation;

(b) $Z = saz$, a rotation;

(c) $Z = Az, A > 0$, a stretching.

The general integral linear transformation can be generated by a succession of these transformations.

If, however, $c \neq 0$, we need to consider one further transformation:

$$Z = \frac{a}{1 + b},$$

This corresponds to an inversion in the unit circle: $R = 1/r$, followed by a reflection in the axis of reals: $Y = -y$.

The general linear transformation carries circles over into circles, straight lines being regarded, as in the geometry of inversion, as circles with infinite radii. The infinite region of the plane is considered as a point (not, as in projective geometry, as a line), and this is the convention which it is desirable, for reasons that cannot be named here, to make in the theory of functions. We speak of the point $z = \infty$.—Cf. an article by F. N. Cole, 'Linear Functions of a Complex Variable,' Annals of Math., Ser. 1, Vol. 5 (1894), p. 121.

12. Multiple-Valued Functions.—When in the definition of § 1 more than one value is assigned to each point of $S$, the first thing to be done is to group these values in such a way that they form several single-valued functions. Consider for example the function $\sqrt{z}$. Setting

$$w = Re^{i\phi}, \quad s = r e^{i\phi},$$

we have

$$R = \sqrt{r}, \quad \phi = -\frac{\phi}{2}, \quad \phi + \pi.$$

If now we sever the plane along a line running from $z = 0$ to $z = \infty$, say along the positive axis of reals, we can then spread out two single-valued functions each analytic in this region, namely,

$$w = \sqrt{r} e^{i\phi} \quad \text{and} \quad w = -\sqrt{r} e^{i\phi},$$

and these two functions together exhaust the values of the multiple-valued function $\sqrt{z}$. Let us, therefore, consider two planes instead of one, each severed along the cut in question and lying one above the other like the leaves of a book, and assign the values $w_0$ to the points of the one plane, $w_1$ to those of the other. We observe, furthermore, that the values of $w_1$ along the upper side of the cut in its leaf and those of $w_0$ along the lower side of the cut in the second leaf agree with each other. Let these two edges be united, so that $z$, moving continuously in the surface thus formed, will pass from leaf I to leaf II without interruption when it crosses the positive axis of reals from the upper side. Similarly the values of $w_1$ along the lower edge of the cut in leaf I and those of $w_0$ along the upper edge of the cut in leaf II correspond. Hence we shall unite these two edges. The final result is a closed surface of two sheets in which the function $\sqrt{z}$ is single-valued. The sheets cut through each other along a line; but the point $z$ in crossing this line is not at liberty to pass into either sheet. $z$ has not come to a fork in the road, but to a switch which has already been set, and its further course is definitely determined.

The point $z = 0$ is called a branch-point, the cut a branch-line.

More generally, let

$$G(a, z) = A_a z + A_{a+1} z + \ldots + A_m z = 0$$

be an algebraic equation. Then to each value
of $z$ correspond in general $m$ distinct values $w_1, \ldots, w_m$. Mark the points $a_1, \ldots, a_s$ (finite in number) for which this is not the case. Draw a curve $C$, not cutting itself, through these points and continue $C$ from the last point to $z = \infty$. Then spread out $m$ leaves over the $x$-plane and cut each leaf along $C$. The $m$ values $w_1, \ldots, w_m$ of the function can now be chosen at the points of these leaves so as to form $m$ single-valued functions analytic throughout these regions. Finally, corresponding edges of the leaves are to be connected along each of the segments into which $C$ is divided by the points $a_1, \ldots, a_s$. The result is a closed surface on which $w$ is a single-valued function of $z$. If $G(w, z)$ is irreducible, the surface will consist of a single piece, and conversely. A branch-point in which $\mu$ leaves are connected in cycle is said to be of order $\mu - 1$.

The surfaces here described are due to Riemann (Göttingen, thesis for the doctorate, 1851) and are known as Riemann's Surfaces. Corresponding to any given analytic function there can always be constructed a Riemann's surface on which the function becomes single-valued. In all ordinary cases the leaves are joined together in cycle in branch-points, and they always pass over into each other along function lines, never merely at isolated points. See ANALYSIS Situs.

13. Analytic Continuation.—If a function $f(z)$ be single-valued and analytic in a region $S$, it may happen that the function can be defined in an adjacent region $S_1$ in such a way that the extended function is analytic throughout the enlarged region $(S, S_1)$. In this case $f(z)$ is said to be continued analytically beyond the region $S$ into the region $S_1$.

Consider, for example, a function given by the power series (4). Let $a_s \neq 0$ be an interior point of the circle of convergence $K$. Develop the function by Taylor's Theorem about the point $a_s$. The new power series, which proceeds according to powers of $z - a_s$, will surely converge within a circle tangent internally to $K$, and it may converge throughout a larger circle $K_1$. In the latter case analytic continuation is possible, the region $S_1$ corresponding to the part of $K_1$ exterior to $K$. We are now in a position to complete the definition, according to Weierstrass, of an analytic function. Let $f(z)$ be analytic in a given region $S$. Continue $f(z)$, if possible, analytically beyond $S$. Repeat this step so long as it is possible to do so. The most extended function that can thus be generated out of the given function is known as the monogenic analytic function $f(z)$. It is uniquely determined by the values of $f(z)$ in $S$. Weierstrass employed the method of overlapping circles and series so as to form power series for obtaining the successive analytic continuations. The function is completely defined as soon as any one of these power series, called elements, is known.

The rational functions and the elementary functions $e^z$, $\log z$, etc., are examples of monogenic analytic functions. By an algebraic function is meant any monogenic analytic function which satisfies an algebraic equation, $G(w, z) = 0$, where $G$ denotes a polynomial. Every irreducible algebraic equation in $w$ and $z$ defines such a function.

Two analytic functions which agree in value with each other along an arc of a curve, however short, lying wholly within their domain of definition, are identical throughout their whole extent.

It may happen that the singular points of an analytic function are not isolated, but exist in every internal of a curve (for example an arc of the whole circumference of a circle, the latter being the case with the function defined by the series

$$\sum_{n=1}^{\infty} \frac{1}{n!}$$

throughout the interior of the unit circle $|z| < 1$, so that the function is analytic up to the curve, but cannot be extended beyond it. Such a curve is called a natural boundary. A region of the plane into which a given function cannot be continued analytically is called a lacunary space.

14. Reflection in Analytic Curves.—A curve which can be represented by the equations

$$x = f(t), \quad y = \varphi(t), \quad a \leq t \leq b,$$

where $f$ and $\varphi$ are both developable by Taylor's Theorem about every point $t_0$ of the above interval and where, furthermore, $f'(t)$ and $\varphi'(t)$ never vanish simultaneously in the interval, is called an analytic curve.

Let $S$ be a region bounded in part or wholly by an analytic curve $\Gamma$ having no multiple point. If $u + iv = f(z)$ is analytic in $S$ and takes on real boundary values along $\Gamma$, then $f(z)$ can always be continued analytically across $\Gamma$. In particular, let $\Gamma$ be an arc of a circle. Then the analytic continuation is effected by inverting $S$ in this circle and assigning to $f(z)$ in the transformed points values conjugate to those in the original points. The method is fundamental in the study of minimum surfaces, and of the elliptic modular and the automorphic functions.

15. Dirichlet's Principle.—In order to show that a simply connected region $S$ can be mapped in a one-to-one manner and conformally on a circle ($\S 4$), it is necessary to establish the existence of a function $w$ which is single-valued and continuous in $S$, (b) satisfies Laplace's Equation ($\S 6$) throughout the interior of $S$, and (c) takes on preassigned values along the boundary of $S$. In similar cases in mathematical physics Gauss, Thomson and Dirichlet had attempted to give a proof of the existence of such a function by making connections with a skilfully constructed corresponding problem of the Calculus of Variations. Riemann adopted this method in order to obtain his existence proofs, both for the present problem and for the case of algebraic functions corresponding to a $p$-fold Riemann's surface. The problem of the Calculus of Variations which matches the present problem is as
follows: To find a function $u$ which is continuous in $S$, together with its first derivatives, takes on the prescribed boundary values, and makes the integral

$$\int_S \left[ \left( \frac{\partial u}{\partial x} \right)^2 + \left( \frac{\partial u}{\partial y} \right)^2 \right] dS$$

a minimum. If such a function exists and if, furthermore, it has continuous second derivatives, then it will satisfy Laplace’s Equation within $S$ and thus yield the desired solution. It was assumed by the mathematicians named above that the problem of the Calculus of Variations necessarily has a solution. This method of proof is known as Dirichlet’s Principle. Weierstrass pointed out the insufficiency of the reasoning involved in the assumption to which we have just called attention. Other methods of proof were then devised by Schwarz and Neumann. Recently Hilbert has, with considerable labor, partially filled the gap in the original method.

16. Weierstrass’s and Mittag-Leffler’s Theorems. — It is always possible to form a polynomial which has $n$ roots situated arbitrarily in the complex plane. The question presents itself as to whether this theorem can be extended to transcendental integral functions. This question Weierstrass answered in 1876 as follows: Let $a_n, a_{n-1}, \ldots$ be any set of points in the complex plane such that $\lim a_n = \infty$ when $n = \infty$. Then there exists an integral transcendental function $G(z)$ which has in each of the points $a_n$ a zero of arbitrarily preassigned order, and does not vanish for any other value of $x$. The most general such function is given by the formula

$$G(z) = e^{\phi(z)} f(z),$$

where $f(z)$ denotes a particular function of the class in question and $\phi$ is a rational or transcendental integral function. This theorem has formed the point of departure for many recent researches, chiefly of French mathematicians.

Mittag-Leffler’s Theorem. — Let $a_n, a_{n-1}, \ldots$ be any set of points in the complex plane such that $\lim a_n = \infty$ when $n = \infty$. In each of these points let an arbitrary polynomial in $1/(z-a_n)$:

$$f_n(z) = A_n^{(n)} z^{k_n} + A_{n-1}^{(n)} (z-a_n)^{k_{n-1}} + \cdots + A_1^{(n)} (z-a_n)^{k_1}$$

be chosen. Then there exists a single-valued function $F(z)$ analytic throughout the whole plane except at the points $a_n$ and behaving in each of these points like $f_n(z)$; i.e., the difference

$$F(z) - f_n(z)$$

has no singularity in the point $a_n$. The most general such function is given by the formula

$$F(z) = \sum \frac{\phi(z)}{G(z)} + f(z),$$

where $\phi(z)$ denotes a particular function of the class in question and $G(z)$ is an integral function, rational or transcendental.

17. Elliptic and Abelian Integrals. — The motion of a simple pendulum and the length of the arc of an ellipse lead respectively to the elliptic integrals

$$\int_0^x \frac{dx}{\sqrt{1-y^2}}, \quad \int_0^x \frac{ydx}{\sqrt{1-x^2}}$$

where $y = (1-x^2)(1-\beta k^2), \quad 0 < k < 1$.

If we set the first of these integrals equal to $u$ and let $x$ take on complex values, then the inverse function $x$ defined by

$$x = \int_0^s \frac{ds}{\sqrt{1-(1-u^2)(1-k'^2)}}$$

turns out to be a single-valued function of its argument $w$ having two linearly independent periods ($\S$ 38) and being analytic throughout the whole $w$-plane except for poles. A generalization which now presents itself is the following: The integrand in each of the foregoing cases is a rational function of $x$ and $y$, and these variables are connected by an algebraic equation. Consider, therefore, generally an algebraic equation

$$G(w, x) = 0,$$

where $G$ denotes an irreducible polynomial in $w$ and $x$, and construct the Riemann’s surface corresponding to it. Let $R(w, x)$ be any rational function of $w$ and $x$. Then, setting $w$ equal to the algebraic function of $x$ defined by the foregoing equation, we have in $R(w, x)$ a function which is single-valued and in general continuous on the above surface. If now we extend the definite integral

$$\int R(w, x) ds$$

along an arbitrary path on the surface, we have before us an Abelian Integral. It is obvious that the logarithm and the inverse trigonometric functions, e.g.,

$$\sin^{-1} z = \int_0^z \frac{dz}{\sqrt{1-z^2}}$$

are special cases of Abelian integrals. When the equation $G = 0$ is of the form $w^p = f(x)$, where $f(x)$ denotes a polynomial in $x$ of degree $\geq 4$ having all distinct linear factors (or can be thrown into this form by means of birational transformations), the integral is called a hyper-elliptic integral.

The only Abelian integrals whose inverse function is single-valued are those which lead to the exponential (including trigonometric) and the elliptic functions. The Abelian Functions are single-valued periodic functions, not of a single argument, but of $p$ independent variables, where $p$ denotes what is known as the deficiency of the corresponding Riemann’s surface $G(w, x) = 0$. They have $2p$ periods. These functions arise as the inverse functions $\xi(u_1, \ldots, u_p)$, $\eta = 1, \ldots, p$, of a system of $p$ equations:

$$u_1 = \int_{a_1}^{x_1} \phi_1 dx_1 + \cdots + \int_{s_1}^{x_p} \phi_p dx_p,$$

where the integrals $\int \phi dx$ are $p$ linearly independent Abelian integrals on the Riemann’s surface for $G(w, x) = 0$.

18. Automorphic Functions. — A function $f(x)$ is said to admit a linear transformation into itself if

$$f \left( \frac{az + b}{cz + d} \right) = f(x),$$

where $a, \ldots, d$ are constants and $ad - \beta \gamma \neq 0$. A familiar class of such functions are the
periodic functions. Here the transformation reduces to a translation:

\[ f(x + \omega) = f(x). \]

The most general single-valued periodic functions of a single variable \( \omega \), which are in general analytic, are the simply and doubly periodic functions, i.e., those functions whose periods can all be expressed as integral multiples \( n \omega \) of a single primitive period \( \omega \) or else in the form \( n \omega + n' \omega' \), where \( \omega' \) is a primitive pair of periods. In the latter case \( \omega' \) cannot be a real quantity.

If the coefficients are integers and \( a \omega - b \gamma = \pm 1 \), we have the elliptic modular functions. More generally the coefficients may have non-integer values, being restricted only in such a way that the transformations form a "discrete group." These most general functions, including the special cases above mentioned, are known as the automorphic functions.

19. Definite Integrals.—The \( \Gamma \)-function may be defined by the definite integral

\[ \Gamma(t) = \int_0^\infty e^{-t x} \, dt, \]

the variable of integration \( t \) being real and positive. This integral converges only for values of \( x \) which lie to the right of the axis of pure imaginary \( x \) in the complex \( x \)-plane. A new definite integral can be formed as follows which converges for all values of \( x = -n \), where \( n \) denotes a positive integer, namely,

\[ \int_C e^{-t x} \, dt, \]

extended over the loop indicated in the figure.

![Fig. 5](image)

It is readily shown that the second integral is equal to the first multiplied by \( 1 - e^{\pi i x} \) for all values of \( x \) for which the first integral converges. Hence we have generally

\[ \Gamma(x) = \frac{1}{1 - e^{\pi i x}} \int_C e^{-t x} \, dt. \]

By means of this integral the \( \Gamma \)-function has been systematically treated.

The above is an example of a loop integral, i.e., a definite integral extended over a certain loop-circuit. Such integrals have been generalized, being extended over double circuits, and these latter integrals are an aid in the study of the solutions of certain linear differential equations.

20. Functions of Several Variables.—In each of \( n \) complex planes let a region \( S_1, \ldots, S_n \) be given, and let \( z_k \) be an arbitrary point of \( S_k \). Then the set of values \( (z_1, \ldots, z_n) \) is called from analogy with the case \( n = 1 \) a point. The totality of these points constitutes the region \( S \). In every point of \( S \) let a function \( f(z_1, \ldots, z_n) \) be uniquely defined. The idea of the limit and of continuity can be extended at once to such a function. \( f(z_1, \ldots, z_n) \) is said to be analytic in \( S \) if it is continuous in \( S \) and if, furthermore, when all the \( z_k \) but one, \( z_m \), let us say, are held fast, \( f \) is then analytic in \( S_m \); this condition to be satisfied for \( m = 1, \ldots, n \). For brevity let \( n = 2 \). Cauchy's Integral Formula becomes

\[ f(a_1, a_2) = \frac{1}{2 \pi i} \int_{C_1} \frac{f(t_1, a_2) \, dt_1}{t_1 - a_1} \int_{C_2} \frac{f(a_1, t_2) \, dt_2}{a_2 - t_2}. \]

The function can furthermore be developed by Taylor's Theorem as follows: Let \( (a_1, a_2) \) be an interior point of \( S \), and let \( K \) be the largest circle that can be drawn in \( S \) about \( a \) as centre, containing in its interior no boundary point of \( S \). Then

\[ f(a_1, a_2) = \sum \frac{1}{m!} \frac{d^m f}{dt^m} \bigg|_{t=a_1} (a_2 - a_1)^m, \]

where

\[ \frac{d^m f}{dt^m} \bigg|_{t=a_1} = \frac{1}{m!} \int_{C} \frac{f(t, a_2) \, dt}{(t - a_1)^{m+1}}. \]

and \( s \) is some arbitrary interior point of the circle \( K \). We have, as in the case \( n = 1 \),

\[ \int_C e^{-t x} \, dt = 2 \pi i \sum \Gamma(t) \frac{e^{-t x}}{t}, \]

where

\[ |z_k - a_k| = r_k, \quad |z_k - a_k| = r. \]

The idea and the method of analytic continuation can be extended without difficulty to functions of several variables, and thus the monogenic analytic function is completely defined. For implicit functions and analytic configurations lying in hyperspace the reader is referred to the author's report in the Encyclopädie, §§ 44 and 47 (see below).

The following theorem is due to Weierstrass: Let \( (b, a_1, \ldots, a_n) \) be an interior point of a region \( S \) in which \( f(w, z_1, \ldots, z_n) \) is analytic. Let \( f \) vanish at this point; but \( f(w, a_1, \ldots, a_n) \) shall not vanish identically. Then

\[ f(w, z_1, \ldots, z_n) = \sum (a_1 w + a_2 z_1 + \ldots + a_n z_n)^p, \]

where \( \phi(w, z_1, \ldots, z_n) \) is analytic throughout a certain neighborhood of the point \( (b, a_1, \ldots, a_n) \) and does not vanish there, while each of the coefficients \( A_1(z_1, \ldots, z_n), \ldots, A_n(z_1, \ldots, z_n) \) is single-valued and analytic throughout a region including the point \( (a_1, \ldots, a_n) \) in its interior. The excluded case \( f(w, a_1, \ldots, a_n) \equiv 0 \) is also treated by Weierstrass.

William F. Osgood,
Professor of Mathematics, Harvard University.

COMPLEXION, the term generally used to signify the special color or hue of a person's skin. The human skin, till the time of Malpighi, was supposed to consist only of two parts —the epidermis or outer skin, and the cutis or
true skin; but that anatomist, about the middle of the 17th century, discovered between these a cellular texture, soft and gelatinous, to which the names of rete mucosum, rete Malpighi, or Malpighian tissue, have been given. He demonstrated the existence of this membrane at first in the tongue and in the inner parts of the hands and feet; but by his subsequent labors, and also by those of Ruysh and other anatomists, it was proved to exist, between the epidermis and cutis, in all parts of the human body. Malpighi, on the discovery of this membrane, offered a conjecture respecting the cause of the color of negroes. He supposed that this membrane contained a juice or fluid of a black color, from which their blackness arose. The actual existence of a black pigment has been since ascertained. The rete mucosum is of very different colors in different nations; and the difference of its color so completely agrees with the difference of their complexions, that there can be no doubt that it is the sole, or, at least, the principal seat of the color of the human complexion. Its thickness varies in different parts of the body; and the depth of its color, for the most part, is in directness. It is now, however, not regarded as altogether a distinct tissue, being considered rather as the innermost and newest layer of the epidermis or cuticle. The black color of the negroes is destroyed by whatever destroys the rete mucosum, as wounds, burns, etc.; the scar remaining white ever afterward. The greatest contrast in complexion is between the fair white peoples of northern Europe and the aborigines of America.

The nature and color of the hair seem closely connected with the complexion. In proportion to the thinness of the skin and the fairness of the complexion the hair is soft, fine, and of a white color; this observation holds good not only in the great varieties of the human race, but also in albinos. Next to them in fairness of complexion is the Teutonic race, the rufla coma (fair locks) of whom were a distinguishing characteristic even in the time of the Romans. The Celtic people are not so fair as the Teutonic, and their hair is darker and less inclined to curl; but it is perhaps more difficult than in the case of the Teutons to be sure of unmixed blood. But though the color of the hair is evidently connected with the complexion, yet its tendency to curl does not appear to be so. Many brown-complexion Celts have curled hair; the Mongolian and American races, of a much darker complexion, have hair of a darker color, but long and straight. Among that portion of the Malay race which inhabits some of the South Sea Islands, soft and curled hair is said to be met with. The color of the eye is also connected with the complexion. In the African, Professor Sommer remarks that the white of the eye is not so resplendently white as in Europeans, but rather of a yellowish brown, something similar to what occurs in the jaundice. The iris in the negroes, in general, is of a very dark color; but the iris in the Congo negroes is said to be bluish gray. The Teutonic tribes are not more distinguished by their fair complexion than by their blue eyes, — carulei oculi, while the iris of the darker-colored Finn is brown, and that of the still darker Laplander black. The color of the eyes also follows, in a great degree, in its changes, the variations produced by age in the complexion. The most singular class of people in point of complexion are the albinos, but albinism is not confined to the human race. An intermediate complexion is produced where children are born from parents of different races. If the offspring of the darkest African and the fairest European intermarry successively with Europeans, in the fourth generation they become equal in appearance. If the instances are reversed, the result is reversed also. Along with the successive changes of complexion is also produced a change in the nature and color of the hair; though, in some instances, the woolly hair remains when the complexion has become nearly as fair as that of brown people in Europe. It does not, however, always happen that the offspring is of the intermediate color between that of the respective races to which the father and mother belong; it sometimes resembles one parent only, while perhaps, in the second or third generation, the color of the other parent makes its appearance. An instance has been given of a negro who had twins by an Englishman: one was perfectly black; its hair was fairer than to its thickness. It is now, however, not regarded as altogether a distinct tissue, being considered rather as the innermost and newest layer of the epidermis or cuticle. The black color of the negroes is destroyed by whatever destroys the rete mucosum, as wounds, burns, etc.; the scar remaining white ever afterward. The greatest contrast in complexion is between the fair white peoples of northern Europe and the aborigines of America.

The generally received opinion concerning the variations of complexion was that there is no difference in the different races of man throughout the globe is, that they are caused entirely by the influence of climate. Respecting the primary color of man the supporters of this opinion are not agreed. The opinion that climate alone will account for the various complexions of mankind is very plausible, and supported by the well-known facts that in Europe the complexion grows darker as the climate becomes warmer; that the complexion of the French is darker than that of the Germans, while the natives of the south of France and Germany are darker than those of the north; that the Italians and Spaniards are darker than the French, and the natives of the south of Italy and Spain darker than those in the north. The complexion also of the people of Africa and the East Indies is brought forward in support of this opinion; and from these and similar facts the broad and general conclusion is drawn, that the complexion varies in darkness as the heat of the climate increases; and that, therefore, climate alone has produced this variety. But it can be shown that the exceptions to this general rule are very numerous; that people of dark complexions are found in the coldest climates, people of fair complexions in very warm climates, and the same complexion throughout a great diversity of climate, and races differing materially in complexion dwelling near together.

1. In the coldest climates of Europe, Asia and America, of a bluish or grayish complexion. The Laplanders have short, black, coarse hair; their skins are swarthy, and the irides of their eyes are black. According to Crantz the Greenlanders have small, black eyes; their body is dark gray all over; their face brown or olive; and their hair coal-black.
The complexion of the Samoedese and other tribes who inhabit the north of Asia is very similar to that of the Laplanders and Greenlanders, who are Eskimos by race. Humboldt's observations on the Norwegian blacks and the Finns and the Laplanders live scarcely differs; and yet their complexion, and the color of their eyes and hair, are widely different. There is a great diversity of color and features among the Morlachs, who inhabit Dalmatia. The inhabitants of Kotar, and of the plains of Seigu and Knin, have fair blue eyes, broad face and flat nose. Those of Duare and Vergoraz, on the contrary, have dark-colored hair; their face is long, their complexion tawny and their stature tall. M. Saucier, who traveled among the Tartars in the southern provinces of Russia, describes a race or tribe as having countenances as white and fresh as any in Europe, with large black eyes. In the south of Africa we find the Kafois, who are of a brown or iron-gray color, and the Hottentots of a yellow color. In the island of Madagascar, according to Mr. Sibree, the observer finds almost every shade of color from a very light olive, not darker than is seen in the peoples of the mountains, through all gradations of brown to a tint which although not black is certainly very dark. In the quality of the hair, too, there is a good deal of difference; the lighter-colored people having usually long, black and straight hair, while the darker tribes have, as a rule, shorter and more frizzly hair.  

Besides a Malayan olive-colored race, people with the negro complexion and features are found in the Philippine Islands; and in Java, the Hindu and Malay character may be clearly traced in the complexion and features of the two classes of inhabitants which are found in that island. In several of the Moluccas is a race of men who are blacker than the rest, with woolly hair, inhabiting the interior, hilly parts of the country. The shores of these islands are peopled by another nation, whose inhabitants are swarthy, with curled, long hair. In the interior hilly parts of Formosa the inhabitants are brown, frizzly haired and broad-faced; while the Chinese occupy the shores. It is observed that there are two great varieties of people in the Pacific islands; the one more fair, the other blacker, with their hair just beginning to be woolly and crisp. The first race inhabits Tahiti and other of the Society Islands, the Marquesas, the Friendly Isles, Easter Island and New Zealand; the second race peoples New Caledonia, Tanna and the New Hebrides, especially Mallicolo. If we examine the relative situation and latitudes of these islands on a map, we shall be convinced not only that darker complexioned people are found where the climate is comparatively colder, but that the same complexion is found under very different climates. It is probably that a burning climate will render the complexion very dark, and that a climate of less extreme heat will bronze the complexion of the fairest European; but there are some material points in which the dark-gold, blonde hair, or naturally fair-skinned variety of mankind, caused by climate, differs from the dark complexion of all the other varieties of the human race.

1. The offspring of the Caucasian variety is born fair; the offspring of the other varieties is
born of the respective complexion of their parents. Ulloa informs us that the children born in Guayaquil of Spanish parents are very fair. The same was the case in the West Indies. Long in his history of Jamaica, expressly affirms "that the children born in England have not, in general, lovelier or more transparent skins than the offspring of white parents in Jamaica."

But it may be urged that his is not the case with respect to the other nations of the Caucasian variety, who have been settled in warm climates from time immemorial, and that the question ought to be decided by the Moors, Arabsians, etc. Their children, however, are also born fair complexioned, as fair as the children of Europeans who live under a cold climate. Russell informs us that the inhabitants of the country round Aleppo are naturally a fair complexion, and that with proper care, preserve their fair complexion to the last. The children of the Moors, according to Shaw, have the finest complexions of any nation whatsoever; and the testimony of Pollet is directly to the same effect. "The Moors are not naturally black, but are born fair, and when not exposed to the heat of the sun remain fair during their lives."

2. Individuals belonging to the Caucasian variety, that inhabit warm countries, preserve their native fairness of complexion if they are not exposed to the influence of the climate; while there is a uniform black color over all the parts of a negro's body. The hue which Europeans assume is the same, though the tinge may be lighter or darker, whether they settle in Africa, the East Indies or South America. They do not become, like the natives of those countries, black, olive-colored or copper-colored; their complexion merely resembles that of a tanned person in this country, only of a darker tinge. The negroes that are settled in the West Indies or America do not assume the copper color of the Indians, even though a milder climate may have some effect on the darkness of their complexions. The children of Europeans and negroes and of Indians are all born, in America, of the same reddish hue; but in a few days those of the negro begin to assume the black complexion of their parents, those of the Indian the copper complexion, while those of the European either continue fair, if kept from the influence of the sun, or become tanned; not black like the negro, or copper-colored like the Indian, if exposed to its influence. Europeans who settle in Canada, or in the northern parts of America, where the climate resembles that of their native country, do not assume the complexion of the Indians, but continue fair like their ancestors. The same observation may be made respecting the Russians who are settled among the Mongolian variety, in those parts of the Russian Empire in Asia, the climate of which resembles the middle or northern parts of European Russia. Indeed the wide extent of country over which the Mongolian variety is spread, including the extreme north of Asia, and also the far north of the continent, and the mild temperature of the middle parts of that continent, and the warmth of the southern parts of China, is in itself a proof that dark complexion does not arise either from the influence of the climate.

Lastly, radical varieties of complexion are always accompanied with radical varieties of features. We do not find the olive color of the Mongolian variety with the features of the Malay; nor the brown color of the Malay with the features of the Mongolian; nor the light skin of the Ethiopian variety, or the red color of the American, united with any set of features but those which characterize their respective varieties. It, however, by no means follows that the hypothesis that the sanguine races having once been originally formed must be adopted, because climate is not adequate to the production of the radical varieties of complexion which are found among mankind. Man, as well as animals, has a propensity to form natural varieties; and the variations may in process of time involve all the tissues so as to yield permanent differences in color and quality of hair, color of skin, size and form of bones, especially those of the skull and limbs. See Epidermis; Histozy; Malpighi; Races and Nations.

COMPLINE, the last or seventh of the daily canonical hours in the Roman Catholic breviary; the complement of the Vespers or evening office. Saint Benedict, in the 6th century, added Compline to the hours, thus making the number seven, answering to the prayers of which the psalmist speaks of "seven times a day." Matins and lauds were classed as one hour.

COMPLITENSIAN POLYGLOT, the earliest complete polyglot edition of the Bible compiled and printed in Alcalá. It was made by seven scholars under the auspices and at the expense of Cardinal Ximenes. It was begun in 1502, and finished in 1517, but was not actually published till 1522. It consists of six folio volumes. In the Old Testament, on the left hand page are the Hebrew original, the Latin Vulgate and the Greek Septuagint; and on the right hand page, the Vulgate, the Septuagint, with Latin translation above, and the Hebrew, with primitives belonging to that language on the outer margin. At the lower part of the page are two columns used for a Chaldean paraphrase and a Latin translation. The Greek Testament, constituting part of the Complutensian Polyglot, was the first complete edition of that part of Scripture printed.

COMPOSING-MACHINES, a general title for all classes of machines that compose or set either type or matrices, arranging them in lines and columns for printing. There are four prominent types of these: (1) Those that set matrices in line and cast therefrom a solid line or slug, as the Linotype, Intertype, Linograph and Monoline; (2) those that cast and set type, as the Monotype and Graphotype; (3) those that set and distribute ordinary founders' type, these being the only ones properly styled type-setting machines, as the Thorne (or Unitype), McMillan, Empire, Dow, Fraser, Kastenbien, etc.; and (4) those that impress male dies into soft material and cast lines from these impressions.

Historically, the type-setting machine comes first, William Church of Connecticut designing a machine, which was patented in England in 1822, that was the first practical effort in this direction. He employed a keyboard, and stored the type in channels. From 1842 to 1872 there were 57 United States patents granted on composing machines, and from 1822 to 1872 a like number were patented in Great Britain. The
most noteworthy of these were the Mitchell and the Alden machines in the United States, and the Kastenbein, Hattersley and Fraser machines in England. These machines all came into use during the period between 1853 and 1872, and a few were invented or constructed over 50 different machines designed to supersede the compositor, practically all of which failed of commercial success. During the period between 1880 and 1890 the Thorne type-setting machine, originating in Connecticut, came into considerable use, being employed by many newspapers throughout the United States, and beginning to find a market abroad. During this period the Burr and McMillan machines also found some sale in the United States, and the Fraser, Hattersley and Kastenbein in England and Germany. In 1898 the Thorne was remodeled and renamed the Simplex, and later the Unitype.

Of all the machines devised for setting founders' type, the Unitypes were the most successful, but its manufacture was practically discontinued about 1914. The types are contained in 90 channels, set radially in the periphery of an upright cylinder. As the operator pushes the keys, the type called for are pushed out of the lower ends of the channels and carried around on a circular raceway to the point where they are brought into line. A second operator draws to him from the composed type thus emerging enough to form a line of the desired length. This he puts in the galley and justifies, or spaces out to length, by hand. The leads, or spaces between lines, are also inserted by this operator. The type is distributed by an upper grooved cylinder, this being performed automatically in the later machines. In the last models of this machine one operator did (or could do) all the work.

The Empire machine, first known as the Burr, was a modification of the Kastenbein. It was not successful, and required three operators. It therefore fell into disuse as the one-man machines became common. Nickel type was employed, and a machine would handle only one body size of type.

The McMillan machine, developed in Ilion, N. Y., was provided with automatic justification, thus dispensing with the labor of one operator. The distributor was a separate machine, operating quite simply at a speed of about 10,000 ems an hour. These machines were used for some years by the New York Sun and the Devinne Press.

The Cox type-setting machine attracted considerable notice in the printing trade in Chicago and New York in 1898. The most unique feature of this machine was the employment of crimped or corrugated spaces made of lead. The line was overset in length, and then squeezed down to measure by compressing the corrugations. This justification was satisfactory in some respects, but the crimped spaces created difficulty in many others, and its use was abandoned.

The Calendoli type-setting machine, developed in France by a priest of that name, attracted much attention because of the wonderful claims made for its speed. Though exploited for several years, it was never perfected for the market. It employed short types grooved so as to slide on rails, and the keyboard had numerous combinations to enable the operator to strike whole words or syllables at a single motion of the hand.

There was exhibited at the Pan-American Exposition in Buffalo, in 1901, a one-man typesetting machine that appeared to work successfully. It was the invention of Alexander Dow, and handled founders' type, being adapted to use the several sizes in one machine. The justification or spacing out of the lines was entirely automatic, requiring no thought by the operator. Had this machine been brought out at an earlier date, doubtless it would have secured a larger sale.

Among other composing-machines that have been built in the United States, and attracted the attention of the printing trade at one time or another, are the Converse, projected about 1894, which did good work, but was obstructed by previous patents; the Paige, on whose development nearly $2,000,000 was spent, and which proved too costly to construct for the general market; the two machines built for Cornell and Columbia universities as mechanical curiosities; the St. John Typobar, consisting of cold-pressed metal clamped on a steel base, to form a line; the German Typoletter or Chadwick, a little machine for enabling a compositor to set type with both hands; the Johnson, which justified the lines by sawing a space of the required width; the composite type-bar machine, in which short, notched type were transformed into a line or type-bar by casting metal around their bases and between them; the Sears, in which dies were impressed in a block of wood, and a slug cast from the matrix thus formed; the Risley and Lake, in which the type were impressed in a soft sheet like blotting paper, and a stereotype taken after a quantity had been thus impressed, and the Heath Matrix Typograph, of the same class; and the Goodson Graphotype, which resembled the Monotype, but was much smaller, employing only 100 characters. The Graphotype was later rebuilt, but failed to find commercial sale.

The Scudder Monoline machine produces a slug like that of the Linotype, and was barred out of the United States as an infringing machine. It was much smaller than the Linotype and did a more restricted class of work. Early in the present century it passed into the hands of the Mergenthaler Linotype Company, and was never placed on the American market.

The Linotype is a machine designed to do the work of both type setting and type casting, by substituting for lines of individual type metal bars or slugs with raised letters on one end. These bars, when arranged in page form, have the same appearance as pages of separate type and may be used either to print from direct or to produce stereotype or electrotype plates in the usual manner. The machine will produce type faces of any kind desired, from 5 to 36 point, some up to 60 point; requires but one operator, and gives work equal to five or six hand compositors, furnished with ordinary type.

The Linotype was invented in 1885 by Ottmar Mergenthaler, a German by birth, then living...
COMPOSING-MACHINES

In 1866, Baltimore, and first put into practical use by the New York Tribune in 1886. Since then it has come into general use by newspapers and printing offices throughout the world.

The machine contains as fundamental elements several hundred brass matrices. Each matrix consists of a flat plate having in one edge a female character or matrix proper, and in the upper end a series of teeth which are used for distributing the matrices to their proper places in the magazine of the machine. Matrices are also made having two characters, Fig. 1, as for instance, a Roman and Italic letter, either of which may be used at will. There are in the machine a number of matrices for each letter, and also matrices representing special characters and spaces.

The general organization of the machine is shown in outline in Fig. 2. It represents an inclined fixed magazine, containing channels in which the assorted matrices are stored and through which they slide, entering at the upper and escaping at the lower end, one at a time. Each channel in the magazine has at the lower end an escapement B, connected by a rod C with a finger key D, representing the letter or character of the matrices in the corresponding channel. There is a key for each character, and also keys for quads and for the wedge spacers.

The operation of the various keys results in the selection of the matrices and spacers and their collection in assembler G, until it contains all the characters to be represented in one line of print. After the line is thus composed, it is transferred mechanically, through the path indicated by dotted lines in Fig. 2, to a position in line of type required, and it determines both the measure and the body of the line. While the line is in place in front of the mold, the wedge spacers are pushed up through the line, which is instantly and exactly justified thereby.

Behind the mold, there is a melting pot M, heated by flame from a gas, gasoline or electric heater. After the matrix line is in place against the front of the mold, as shown in Fig. 2, a pump forces the molten metal through the pot mouth into the mold, against and into the characters in the matrix line. The metal instantly solidifies, forming a slug having on its edge raised characters formed by the matrices. The slug is then automatically removed from the mold, being trimmed to the proper length and thickness by knives. The line is then lifted from the mold and shifted laterally, until the teeth in the upper end of the matrices engage the horizontal rib on a bar which rises, as shown by dotted line at R, lifting the matrices to the distributor at the top of the machine. The matrices pursue a circulatory course through the machine, starting singly from the bottom of the magazine, passing through line being composed, thence to the mold, and finally back to the top of the magazine. This circulation permits the operations of composing one line, casting from a second and distributing a third to be carried on concurrently, and enables the machine to run at a speed exceeding that at which any operator can finger the keys. There are a dozen or more models of Linotypes in present use with a wide latitude of accomplishment. The modern models handle all type bodies from 5 point to 36 point, and assemble matrices from all magazines in one line. All machines set from 4 to 30 ems pica measure. Wider measures are obtained by assembling two or more slugs end to end. The later models have many added conveniences, and the larger machines carry two or more simultaneously acting distributors. From one to four interchangeable magazines are supplied with individual machines. Each magazine contains two-letter matrices representing 180 characters. On models 16 and 17, each having two magazines, the mere touching of a key brings either magazine into operation, rendering available 360 characters from one keyboard of 90 keys. In other models an auxiliary magazine is added with keyboard of 28 keys representing 56 characters, making a total of 416 characters in the machine.

The quadruple magazine Linotype carries eight faces, and gives the operator 720 characters from one keyboard. In 1915 the quadruple magazine head-letter machine was brought out for setting newspaper display heads in 48-, 54-, or 60-point. It will be apparent that the modern machines can set the great majority of advertising and display composition, as well as the straight body reading matter, to which they were originally confined. Among recent improvements is an electrically heated metal-pot for heating the metal. This not only reduces the nuisance from lead fumes, but permits extremely close regulation of the temperature of the metal. In 1918 there were over 35,000 Linotypes in actual use all over the world.

The Monotype Composing Machine, type-and-rule caster, is so named because it casts each character on a separate body and auto-
matically assembles them into lines and columns ready for the press. The system consists of two separate mechanisms, a keyboard and a casting machine, frequently looked after by one operator. The equipment is arranged to make production continuous, for both keyboard and caster are busy on the same job, but should either be temporarily stopped it does not interfere with the other, which keeps right on producing. The composition is done on the keyboard, which perforates the paper controller ribbon for the casting machine, consisting of 225 keys, has the same arrangement of characters for every alphabet as any standard typewriter. The keys are coupled by means of keybars with valves, which admit air beneath small pistons, which in turn drive the punches through the paper controller ribbon when a key is depressed by the operator. When the key is released, the punches withdraw from the paper and the controller ribbon feeds forward ready to receive the perforations for the next character. The arrangement is such that certain combinations of perforations across the paper ribbon will position the matrix for the desired character over the mold at the casting machine.

In addition to the key and perforation mechanisms, the keyboard has a counting and justifying mechanism. The counting arrangement counts the width of each character as struck and adds it to the width of the characters previously struck in the line, so that the operator can tell at a glance just how much has been put into the line and how much space still remains. The justifying mechanism consists of a pointer which rises one notch each time the space bar is struck, to put a justifying space between words, and a cylinder (the justifying scale) which revolves automatically when the operator has put sufficient characters and spaces in the line to bring it within four eams of the end of each line. The surface of this scale is divided into small rectangles, each containing numbers which refer to the justification keys on the keybank. The keys corresponding to the two numbers indicated by the pointer are struck by the operator, when sufficient characters have been placed in the line, the matrices are produced by these keys set the wedges at the casting machine to produce spaces the correct width to exactly justify the line.

The casting machine is entirely automatic in its operation and is controlled by the controller ribbon perforated at the keyboard. Two hundred and twenty-five matrices are carried in the matrix case; and, for different combinations, characters may be substituted, or the matrix case removed and a new case inserted in the machine. The face of the type is cast in the matrix, but the body of the type is cast in the mold on which the matrix seats while the type is being cast. The type comes out on the casting machine in automatically justified lines, as previously described, and these lines are assembled on an ordinary galley ready for the makeup man. It composes type in any measure up to 60 picas and in sizes from 5- to 24-point; when required, measures up to 120 picas may be composed at the keyboard. The duplex keybank unit comes in two forms; the semimagnificent type in two different faces, point, sizes and measures; the same keystroke that produce the ribbon for magazine columns in 8-point, for example, also produce the ribbon for the same matter in 10-point for book pages, etc.

When operated as a type-and-rule caster, the Monotype casts type for the cases, borders and space material, both high and low, in sizes from 5- to 36-point. An ingenious new unit casts rules and both high and low lines from 2- to 12-point in continuous strips, and automatically cuts them to any required measure from 6 picas to 25 inches in length.

The versatility of the Monotype and the ability to supply practically everything needed in the composing room has made possible the non-distribution system now in use in many newspaper and book and job printing offices. The machine-set matter as well as the hand-set matter, when used, is simply pushed off the imposing stone into the melting pot and recast into new material for every job—type, borders, leads, slugs, etc.—this new method proving more economical than distribution by hand for re-use. The Monotype thus, while a composing machine, is also a practicably small type foundry which supplies the greater part of the material needed in the composing room.

The Intertype composing machine, introduced in 1913, is manufactured on the exclusive patents of Ottmar Mergenthaler, combined with many modern improvements. The operator manipulates a keyboard of 90 keys, and matrices are arranged in lines, automatically spread to column measure, and carried to the mold, where a line-slug is automatically cast, while the matrices are returned to their original position by an automatic distributor. Either the matrices supplied by the manufacturer or linotype matrices may be used. One standard machine is built, on the unit principle, to which every improvement can be added by the purchase of more units. Thus the purchaser of a low-priced machine does not have to discard it to secure the conveniences of the higher-priced machines. From one- to three-magazine machines are made, and the one-magazine machine is readily changed into a three-magazine outfit, which will supply 540 characters from the one keyboard. A simple lever movement brings a new magazine to operation. The Intertype is remarkable for its scientific design and the small number of parts used in its construction; the escapement has only two parts. All Intertypes produce from 5 to 36 point body, and 5 to 30 ems pica measure.

The Linograph machine is manufactured in Davenport, Iowa. It is very similar to the 1900 style of Linotype, plus a number of modern additions. It is designed to supply the needs of the small newspaper desiring a low-priced machine. The Linograph composing-machine supplies a product either in single type or in line-slags, at the choice of the operator. It was brought out in England in 1914, and is not yet in general use. Several inventors have tried to produce a one-man machine that would cast and set single type at one operation, at a speed commercially profitable. Such a machine is theoretically possible. The Goodson, Wicks, Pierson and other type-casting and setting machines have been developed more or less experimentally, at great expense, but have not found general sale. The Wicks machine casts type at a speed of 60,000 an hour, and was used for some years on a London newspaper.
COMPOSITE—COMPOST

CHARLES H. COCHRANE,
Of the Staff of Newspapers.

COMPOSITE, at 'compound,' a family of dicotyledonous plants, the greatest order in the vegetable kingdom, usually herbaceous in temperate and colder climates and shrubby in dry and hot regions, and seldom, apparently only in tropical zones, growing as trees. The leaves are never accompanied by stipules; they most commonly are alternate, arranged, and sometimes opposite or whorled. But the true mark of the order is the compound flower, from which it gets its name and which makes it one of the simplest orders to identify, the daisy or aster being the commonest type and the name aster family or sun-flow family being sometimes used. The true blossom is a head made up of many florets, flat as in the aster or approaching a conical shape as in the black-eyed susan. This head is set in a involucre of leafy bracts, which to the lay observer resemble petals and give the compound flower the appearance of a single bloom. The calyx, joined to the ovaries, crown them, save in a few cases, with the pappus, which is usually hairy, toothed or bristly, and coming to maturity at the time of fruitional frequently furnishes the seed with a sort of wing facilitating dispersion by the wind. The corolla, tubular, ligulate or labiate, divides into five lobes at the summit. The anthers are united in a tube into which the five stamens are also joined into one. The ovules at fruitional up and become achenes (q.v.). Among the florets, which naturally fall into two classes, the fertile ones of the disc and the sterile ones of the ray, grow bracts called paleae or chaff, except where the receptacle is naked. The classification of the order Composite is difficult, if for no other reason because it contains about 11,000 genera and more than 1,000 species, that is, about one tenth of the higher vegetable forms. The simplest division is into Liliiflora, with all the florets ligulate or strap-shaped, and Tubuliflora, with disc florets not ligulate. The latter class is by far the larger. The Liliiflora contains only the one tribe, Cichorieae, often classed as a distinct family, of which the food-plants, lettuce, salsify and chicory, are the best known members. In the other sub-order, the Tubuliflora, are 12 tribes: Veronicae, with 41 genera, ironweed being a common member; Eupatorieae, with 35 genera, including the medicinal plants, ayapana, bitterbush, boneset and hemp agrimony; Asteraceae, including the typical asters, dahlias, etc.; Heliantheae, with the artichokes and daisies; Inuleae, of which elecampane may be mentioned as an example; Helineae, sneezeweed being an American member; Anthemidioeae, including the different varieties of camomile, the chrysanthemum and the marguerite; Senecioneae, with lining, subtribe; and the older-fashioned foliage plant called dusty miller; Calenduleacae, including the marigolds; Articotideae, with only one genus, occurring in South Africa and Australia; Mutisaeae, another scantily diffused tribe; and Cynaraceae, including the artichokes.

The Compositae may be regarded, especially from a consideration of their flowers, as the highest order in a scale of vegetable evolution. Their peculiarly efficacious methods of pollination, this process being simplified by the close set florets which permit of insect-fertilization or wind pollination, and by a peculiar action of the style which in the individual flower is shaped to catch the way of wind or insect. Dissemination also is highly developed, there being three prominent types, the plumose pappus, as in dandelion and thistle, which is wind-sown; the hooked achenes, as in the burdock and tickseed, which fastens to passing animals, and the gummy seeds of other plants, which are dispersal adaptations. On the order in general consult Bentham. 'On the Classification, History, and Geographical Distribution of the Composite' (1873).

COMPOSITE ORDER, a term denoting the last of the five orders of architecture. As its name implies, it is composed of two orders, the Corinthian and the Ionic. Its capital is a vase with two tiers of acahntus leaves, like the Corinthian; but, instead of stalks, the shoots appear small and, and adhere to the vase, bending round to hard the middle of the face of the capital; the vase is terminated by a fillet, over which is an astragal crowned by an ovolo. The volutes roll themselves over the ovolo, to meet the tops or the upper row of leaves, whereon they seem to rest. The corners of the abacus are supported by an acahntus leaf bent upward; and the abacus itself resembles that of the Corinthian capital. In detail, the Composite is richer than the Corinthian, but it is less light and delicate in its proportions. Its architrave has only two social and the cornice varies from the Corinthian in having double modillons. The column is 10 diameters high. The principal ancient examples of this order are the temple of Bacchus at Rome, the arch of Septimius Severus. The Composite order differs from the Corinthian in the design of its capital and in no other way. The capital is made up of the foliage of the Corinthian and the volutes of the Ionic capital. Most of the Byzantine capitals were based on the Roman Composite in its varying forms. The Italians, in their attempts to follow the ancient Roman Composite, have vitiated the true Composite forms, and in this they have been followed by some famous foreign architects, notably by Imigo Jones.

COMPOSITION, in law, an agreement between debtor and creditor or creditors, by which the latter accepts part of the debt due in satisfaction of the whole. Composition also bears the secondary meaning of the sum or rate paid or agreed to be paid in compounding with creditors.

COMPOSITION OF FORCES AND MOTIONS. See Mechanics.

COMPOST, any mixture of decomposed organic matter with earth, used as a fertilizing compound. A compost is most frequently made by alternating layers of sods and stable manure in piles three or four feet thick and sprinkling them with lime, sub-tribe, and the older-fashioned foliage plant called dusty miller; Calendulaeae, including the marigolds; Arctotideae, with only one genus, occurring in South Africa and Australia; Mutisaeae, another scantily diffused tribe; and Cynaraceae, including the artichokes.

The Compositae may be regarded, especially from a consideration of their flowers, as the highest order in a scale of vegetable evolution. Their peculiarly efficacious methods of pollination, this process being simplified by the close set florets which permit of insect-fertilization or wind pollination, and by a peculiar action of the style which in the individual flower is shaped to catch the way of wind or insect. COMPOST, any mixture of decomposed organic matter with earth, used as a fertilizing compound. A compost is most frequently made by alternating layers of sods and stable manure in piles three or four feet thick and sprinkling them with lime, sub-tribe, and the older-fashioned foliage plant called dusty miller; Calendulaeae, including the marigolds; Arctotideae, with only one genus, occurring in South Africa and Australia; Mutisaeae, another scantily diffused tribe; and Cynaraceae, including the artichokes.
portions of manure and fertilizer to soil and organic matter composts may be obtained suitable for various purposes; rich ones for succulent crops and less rich for plants that must be kept stocky. In a general way the term compost is also used for any heap of decaying vegetable or organic matter which is to be used as a manure. Thus stable manure and litter become compost heaps; also the piles of leaves, etc., from which leaf mold is obtained for greenhouse use. Directions for making compost for particular kinds of plants may be found in all books on gardening, floriculture, etc., and many of the works dealing with manures and manuring also devote space to composting. A mixed dish is called a compost or compote; and the term is also applied to a composition for plastering the exterior of houses. In this latter use it is often popularly contracted to compo.

**COMPOSTELLA**, kōm-pōs-tā'la, Order of Saint James of, an order of Spanish knights formed in 1175 to protect from the Moors the Castile and Leon who had inched in vast numbers to Santiago de Compostella Galicia, Spain, where the relics of Saint James the Great were preserved. At first there were but 13 members of the order, but it grew rapidly in numbers and they became not only strong defenders of the relics of their patron but champions of Christianity against the invasion of the Moors. In time this order attained great wealth, thereby exciting the jealousy of the Crown, which succeeded in securing the grand-mastership in 1522 after which the order rapidly declined. On the overthrow and expulsion of the Moors from Spain in 1492 the excuse for the existence of the Society ceased, and the following year Ferdinand and Isabel, who then ruled Spain as joint sovereigns, took possession of the abbeys, villages, towns and landed property of the Compostella order and held them until 1522, when a papal bull vested the grand-mastership permanently in the Crown.

**COMPOUND ALCOHOL**, rectified spirits to which have been added one or more flavoring ingredients. They are called also compounds. The chief compounds are gin, British rum, British brandy, and some grades of American whiskey, cordials and liqueurs, such as curaçao, loewage, cherry brandy, noyeau, rum shubr, etc., are also denominated compounds. These are prepared by adding to clear rectified spirits various essences or oils and sweetening with sugar or syrup. Sweetened compounds usually contain from 20 to 35 per cent of proof spirit.

**COMPOUND AMMONIA, or AMINES,** a large and very important class of complex substances derived from ammonia by replacement of the hydrogen of an organic radical. They are termed primary, secondary or tertiary, according as one-third, two-thirds or the whole of the hydrogen is replaced by an organic radical. They are found in nature in the vegetable alkaloids and among decomposition products of animal and vegetable organisms. They are all basic in function, combining with acids to form crystalline salts. They have an alcoholic odor, the specific member of the group are gases and volatile liquids, generally inflammable, with a pungent fishy odor. As the molecular weight increases they become more stable, and the higher members are solid and odorless. They are of great importance in the investigation of the constitution of various organic bodies. See AMINE.

**COMPOUND ANIMAL.** See Colonial Animals.

**COMPOUND DUTIES.** See Duty.

**COMPOUND LOCOMOTIVES.** See Locomotive.

**COMPOUND STEAM-ENGINE.** See Steam-engine.

**COMPOUNDING A FELONY, the act of accepting from a felon, by the person aggrieved, a return of the goods, a consideration or a reward, on the express condition that he will not prosecute the felon. The mere failure to prosecute a person committing a crime is not, even if the goods are returned, compounding a felony; but the essence of the action is the agreement not to prosecute in consideration of any kind. It is usually illegal to accept the return of money or goods stolen or to hide or condone other illegal acts performed or procured by the offending party or another, in his interest, upon a promise of immunity from prosecution or the withdrawing of evidence. The person aiding the felon is an accessory to the crime and can be prosecuted, although the person committing the crime has never been tried. In English law, to advertise a reward for the return of stolen goods renders the advertiser liable to a fine.

**COMPRESSED AIR.** Compressed air has a wide application in the various branches of mechanical engineering and in the arts and manufactures. As compared with steam, compressed air transmission of power is valuable and convenient because (a) its loss in transmission through pipes is relatively small, (b) the question of the disposal of exhaust steam underground is avoided and (c) the exhausted air is a help in ventilation. Although electricity has become a rival of compressed air in many branches of work, their spheres of usefulness are not identical. The first cost of an electric plant is lower than that of an equivalent compressed air plant; but a point soon reached where compressed air transmission becomes the cheaper. In recent years the principles of air compression have become better understood and a substantial improvement has taken place not only in the design of the compressors themselves, but also in the installation of pipeline and in the operation of the machines. In the production, transmission and employment of compressed air a greater total efficiency is now realized than was formerly thought possible.

**Cooling During Compression.** If air at atmospheric pressure and 60°F. could be compressed to 100 pounds gauge pressure and all the heat due to the work of compression taken away as fast as generated, so that the temperature during compression would remain constant, the mean effective pressure during one stroke of the air piston would be 30.2 pounds. If, on the other hand, none of the heat due to the work of compression was taken away the mean effective pressure during the stroke would be 41.6 pounds and the terminal temperature would reach 485°F. As the power required for compression is directly proportional to the mean effective pressure, it will be seen that the additional power required in the latter case is
sors, the inlet valves are of the spring weighted poppet type, this difference as to its effect upon capacity and efficiency becomes a serious matter. Then again, the entering air comes in contact with the cylinder walls, cylinder head, piston and clearance surfaces which have become highly heated by doing its work the previous stroke, and is heated thereby to a temperature above that of the surrounding air. This not only reduces the volume of free air at the outside temperature which can be handled, but also raises the terminal temperature of compression. It is essential to economy in air compression:

(1) That the percentage of clearance be kept as small as possible. (2) That the inlet and outlet areas should be large in order to reduce friction losses and heating and to ensure the complete filling of the cylinder at all speeds. (3) That the entering air should pass through short ports, in a solid stream, and over as small an extent of heated surface as possible. (4) That the cylinders and cylinder heads should be water-jacketed or water-cooled as much of the heat of compression as possible. To accomplish this as well as to facilitate cleaning, all water spaces and pipes should be large and ample supply of cooling water used, as the water-jacketing of the cylinders being retained for the reason above stated. Where the work of compression is done in two or more cylinders, it is customary to fix the ratio of cylinder volumes as to divide the work equally between the cylinders. By using two-stage compression and cooling the air between the stages to its initial temperature (60°F.), without considering the cooling by water-jacketing, it is possible to reduce the mean effective pressure to 35.5 pounds as compared to 41.6 pounds, which is equivalent to a saving of 15 per cent. At the same time the terminal temperature will be only 245°F. instead of 485°F.

Hydraulic Compression of Air.—The method of compressing air by means of falling water forms a most interesting topic in the subject of air compression. One of the old forms of compressing air is by means of a trompe or water bellows. Many improvements have been made on this early apparatus and distinct types developed from it, prominent among which are the Frietzell, Balloche, Krahmuss, Taylor and Arthur devices. There are several phenomena in connection with hydraulic air compression that at first sight seem paradoxical. In compressing air by hydraulic means, the air becomes drier during the compression, but whatever water remains between the water spaces of humidity at the end of compression it will be saturated with moisture. Again isothermal compression is secured and, generally speaking, at uniform temperature a given volume of air implies a capacity for a certain weight of water whether the air is at a pressure of one or 100 atmospheres, but if the air is compressed through a range from one to 100 atmospheres, its volume will be reduced, if the compression is isothermal, to 1/100 part of the original volume, and in consequence 99/100 of the weight of moisture it originally held will be precipitated. In connection with this type of compressor it has been found that the compressor air contains less oxygen than the free air of the atmosphere and in consequence the air is not as beneficial as air from other types of compressors. The losses inherent in hydraulic compression are:

The heat expanded in impregnating the water with air; (2) a loss which may be called the slip due to the velocity with which the bubbles tend to escape, and (3) a loss due to the increasing solution of the air in the water with the increasing pressure as the water and air descend.
MULTI-STAGE COMPRESSION.—It frequently happens that high pressures are demanded for commercial purposes, and in order to satisfy this demand, avoid the danger of explosion due to adiabatic compression, engineers have adopted a multi-stage system of compression—compressing the air partly in one cylinder, passing it through an intercooler where its temperature and volume are reduced, and then compressing it still further in a second cylinder, and, if the pressures required are high, this compressed air is passed to a second intercooler, thence to a third cylinder and in some cases a third intercooler and a fourth cylinder, and required to secure the desired compression pressure economically. The advantages of this system of compression more than offset the extra expense in constructing the compressor. The larger the volume of the intercooler, the more time is required for the compressed air to cool for this reason receiver intercoolers, as they are termed, are more efficient than those of small volumetric capacity. See Air Compressors; Air Pump; Condenser; Power Transmission. Bibliography: Bibl. Peale, 'Compressed Air Plant' (ib. 1913); Unwin, 'Compressed Air' (ib. 1903); Simons, 'Compressed Air' (ib. 1914).

EDWARD S. FARROW, Consulting Civil and Military Engineer.

COMPROMISE OF 1820, in American political history, a national law enacted by Congress 6 March 1820. In 1819 the Territory of Missouri, with a population of 60,000, demanded admission into the Union as a slave State. Arkansas was preparing to make similar demands. Such action would have given the South the balance of power in Congress, and the North made this a national issue. The North controlled the House of Representatives, while the South controlled the Senate. A deadlock was inevitable, and a party of compromise sprang up, which succeeded in producing a temporary arrangement acceptable to both parties. This was the compromise of 1820. It divided the Louisiana Purchase between freedom and slavery, the line being drawn at 36° 30' N. lat. See UNITED STATES—ABOLITION AND THE FREE SOIL MOVEMENT.

COMPROMISE OF 1833. Henry Clay's tariff compromise, to prevent civil war on account of nullification by South Carolina. The tariff of 1828 was regarded by the South as injurious and inequitable, raising its expenses and reducing its income, and laying burdens upon it without compensating advantages. The tariff was borne in the hope that Jackson, a Southern man, would throw his influence against it, but when he signed the amended act of 1832, leaving the duties much as they were, South Carolina took the lead in revolt. On 19 Nov. 1832, a convention called by its legislature declared the act of 1828 and its amendments null and void, forbade its enforcement in the State or appeal to the Supreme Court regarding it, and decreed secession in case the United States should attempt to use force. On 4 Dec. 1832, Jackson's annual message mildly criticised the tariff as overgrown and needing gradual retreatments on revenue bases, and apologised for the popular resistance, which he thought the laws adequate to suppress. The nullifiers and their opponents alike thought he had surrendered to the former as in the Cherokee case (see Cherokees); but on the 10th, apparently from a sudden shift of his national feeling, he issued a powerful proclamation against them, characterising nullification as an absurdity incompatible with the existence of the Union, and declaring that it would be resisted by the express national force. There was great enthusiasm throughout the North, and general approval even in the South, but South Carolina returned a defiant counter-proclamation, and Calhoun resigned the Vice-Presidency, to be immediately returned to the Senate as the champion of nullification. To remove the grievance the House Committee of Ways and Means on the 27th reported the Verplanck Bill, reducing the tariff within two years to the standard of 1816, the primitive basis. But the President, angered by the new South Carolina threat, asked for a bill to enforce the law by military power, and extend Federal jurisdiction over revenue cases—called by the people the Force Bill, and by the South Carolinians the "Bloody Bill." Bibliography: Bibl. Peale, 'Compressed Air Plant' (ib. 1913); Unwin, 'Compressed Air' (ib. 1903); Simons, 'Compressed Air' (ib. 1914).
originated in the Senate. This was met by the shrewd device of moving the House to strike out all but the enacting clause of the Verplanck Bill, thus leaving the City to the Senate for concurrence,—which it did the next day, and the Senate adopted it. South Carolina, which had appointed 1 February for the nullification ordinance to go into effect, repealed it, and the country hailed it as a great deliverance. Clay himself later confessed, however, that he doubted whether he had done wisely. The nullifiers denied that they had abandoned a jot of their contention; hailed the result as a proof that it was the only means by which the South could obtain justice; and persisted to have postponed the date of its operation only out of friendship to Virginia, which sent a commissioner to deprecate it. It is certain that the South won both the material and the moral fruits of the victory. Consult Schurz, 'Life of Henry Clay' (Vol. II, Chap. 14); also other lives of Clay and biographies of Jackson and Calhoun.

COMPROMISE OF 1850. The Missouri Compromise of 1820 (q.v.) had divided the Louisiana Purchase between free and slave territory at 36° 30' (the general boundary between Arkansas and Missouri), except that Missouri was to be slave. The extreme pro-slavery members, about one-fifth of the House and one-fourth of the Senate, based their opposition on the ground that Congress had no power to legislate on slaveholding in the Territories, it being a fundamental right implied in the Constitution; but the majority admitted the jurisdiction by passing the bill. The joint resolution for admitting Texas in 1845 extended the same line to any new bodies formed out of that State; and was supported by the most ultra slavery men, as taking the merest sliver from them and securing solidly the enormous remainder. When the Mexican War seemed likely to add new territory, the Wilmot Proviso (q.v.) of 8 Aug. 1846, attempted to bar slaveholding from it, as did existing Mexican law; and the struggle to prevent this transformed political parties. After the annexation had taken place, 2 Feb. 1848, bills for organizing the Territories of New Mexico and California were introduced; at first in an omnibus bill with the Clayton Compromise, to force all of them to permit slaveholding; then to extend the Missouri compromise line to the Pacific (including all slave territory nearly all the present New Mexico and Arizona and the entire southern half of California); then the Democratic Senate receded from the Oregon 'hold-up,' and the House repeatedly attempted to organize the other bodies as territories with the proviso; while the Senate regularly killed the bills, and once attempted to attach its own as rider to an appropriation bill. This went on till the end of 1849, when the gold discoveries in California forced the hand of both the Southern slavery party and its Northern allies. The immense immigrant population, there formed a constituency favorable to the slave, and demanded admission of California as a State. Even the deniers of the right of Congress to legislate on slavery had always admitted that the people of a State had the right to live under any constitution they pleased; and the Democrats, to hold their vote in North and South, now took the position that the inhabitants of an inchoate State should be allowed to decide their own destinies. As this meant the immediate reinforcement and ultimate supremacy of the Whigs and Democrats began to draw together and formulated the doctrine that the people of a Territory had no right to exclude the industrial or social system of any part of the Union; that Congress should force them to rescind such exclusion if made; and that, if permitted, was a wrong which justified secession. But California was not a Territory: it was a body of unorganized settlers who would come in as a State from the first, and certainly could be admitted by Congress on their own terms. The Southern leaders, therefore, resolved that they should not be admitted except by passing through the territorial stage, so as to come under the congressional prohibition. Zachary Taylor, a slaveholder, but a moderate and just-minded man, had been inaugurated as President in March 1849, and his first Congress met in December. The Senate had a large Democratic majority; the House was so evenly divided that the few Free-State men could not uphold the balance, and it required 63 ballots and three weeks to elect a speaker, Howell Cobb, of Georgia. On their meeting Taylor had sent a message recommending California's wish to become a State, to their favorable consideration; on 21 Jan. 1850, he sent a special message, declaring that the people would not sustain them in denying the Californians the right of self-government. The South, nevertheless, was passionately determined not to yield; and Henry Clay undertook one of the great compromises which were the pride of his life, the shortest-lived and most destructive compromise in American history. The difficulty was to find anything that either side wanted badly enough to take as a price for yielding. For the South, this was found in the Fugitive Slave Law (q.v.), which Alexander H. Stephens declared to be the very essence and heart of the whole compromise and the breach of which by the Northern personal-liberty laws was accounted the crowning justification of secession; and in a money indemnity to Texas for abandoning her claim to the Rio Grande as a western boundary, which that State was ready to fight for, but the payment for which left the market value of her bonds, largely held in the South. For the North, it was found in the admission of California as a free State and the prohibition of the slave-trade in the District of Columbia—the latter a mere sop, as slavery was not abolished in the District. The sacrifices were, that the South gave up the right of insisting that no free State should be admitted into the Union except as paired with a slave State, and so in her own view gave the North the fruits of the Mexican War; the property gave up the right of stopping the interstate slave trade, though this was later stricken out. On 16 January a bill had been brought into the Senate to organize the Territories of California, New Mexico, and Utah. The Senate refused to take up the bill. Clay unfolded his compromise, in eight resolutions: (1) admitting California with her free-State Constitution; (2) organizing the remainder of the newly acquired lands as territories, without restriction as to slavery, as it was deemed not to be desirable to introduce it, and was likely to be introduced, merely staving off
the question till they formed State governments; (3, 4) annulling Texas' claim to New Mexico, but paying her a blank indemnity; (5, 6) non-abolition of slavery in the District of Columbia without the consent of Maryland, but prohibition of the slave trade in it; (7) a more adequate Fugitive Slave Bill; (8) non-interference with the interstate slave trade. Clay said that the question with the South was one of interests, with the North one of sentiment, and the latter was easier to sacrifice than the former. The Northern members and their constituents did not agree to this, nor did the South as to the equivalents; and after two months' debate the question was referred to a compromise committee of 13, of which Clay was chairman. On 8 May it reported a bill of four parts, known in history as the Omnibus Bill (for excellence, there for have been others), to be passed or rejected as a whole. The essential changes were, that New Mexico and Utah were forbidden to pass laws respecting slavery, that California should not be admitted unless the blank for the Texas indemnity should be filled with $10,000,000 and that no mention was made of the interstate slave trade. It will be observed that this revised compromise were pretty much all by the South. The bill of course embodied the specific legislation needed to make the resolutions effective. Part 1 consisted of the provisions for admitting California, New Mexico and Utah, and indemnifying Texas; parts 2 and 3 were the Fugitive Slave Law of history; part 4 the provisions about the District of Columbia. This bill was strenuously debated for nearly three months more, until 31 July, and amended until one item only was left, that admitting Utah, which passed the next day. Meantime Texas was arming and threatening war, and other States proposing to aid it; and Congress saw that the bills must be passed in some shape. The items were therefore voted on as separate bills, and all passed in Clay's form: Texas bill—Senate, 10 August, 30 to 20; House, 4 September, 108 to 97. California—Senate, 13 August, 34 to 18; House, 7 September, 150 to 56. New Mexico—Senate, 14 August, 27 to 10; House (together with the Texas bill), 4 September, 108 to 97. Fugitive Slave Bill—Senate, 23 August, 27 to 12; House, 12 September, 109 to 75; District of Columbia—Senate, 14 September, 33 to 19; House, 17 September, 124 to 47. The Fugitive Slave Law, the vital part of the compromise, was also its assured ruin, as it gradually turned the entire North into abolitionists; but the immediate cause of its collapse was the Kansas-Nebraska Bill (q.v.), which repealed not only the Missouri Compromise, but the present compromise which practically reaffirmed that. Consult von Holst, 'Constitutional History of the United States' (Vol. III); Benton, 'Debates of Congress'; Stephens, 'War between the States' (Vol. II); and lives of Clay.

COMPOSAGNATHUS, kómp-ság-ná'θhus, a genus of extinct reptiles of the Cretaceous dinosaurs (see Dinosauria) of the Jurassic Period, of very small size, hardly larger than a domestic cat, and slenderly proportioned. A very perfectly preserved skeleton has been found in the lithographic limestone of Solenhofen in Bavaria. It is remarkable as being the most bird-like reptile known. It had a light, bird-like head, very long neck and hind limbs, small forelimbs and many teeth. It is supposed to have walked or hopped in an erect or semi-erect position just as a bird does. In this position it must have resembled a bird very much.

COMPTOMETER, kom-pô'tô'me-ter (from Fr. compter, to count + Gr. meter, a measure), an adding and calculating machine, on which can be performed rapidly and accurately all arithmetical problems involving addition, multiplication, division and subtraction. The name was coined by Dorr E. Felt, inventor of the machine, in 1885. The comptometer is now widely used on all forms of figure work in all lines of business in the United States and throughout the world. It differs from all the earlier constructive efforts directed to the production of mechanical calculating devices in that it was the first successful multiple-order machine to be wholly operated by the rapid depression of keys, an advantageous feature as a time-saving factor. Illustrative of the fundamental principle of direct key operation and its simplicity in practice are the following brief descriptions of how the results are obtained.

 Addition is performed by merely depressing the keys according to the numbers to be added. The item 346, for example, is added by striking the 3-key in the third or hundreds column, the 4-key in the second or tens column and the 6-key in the first or unit column, and the answer appears in the register. Subsequent items are added in the same manner, the accumulated total being shown in the register. To multiply, the fingers are placed on the keys representing one factor, which are struck according to the digits of the other factor. For example, to multiply 578 by 463, place the fingers on 578 and strike three times; move one column to the left and strike six times; once more to the left and strike four times and the register shows 267,614. Each key also bears on its top a small figure which indicates the power of that key for subtracting and dividing. These operations are the converse of adding and multiplying and
are likewise performed by simply depressing the keys, but with reference to the small figures on the keys. The only function of the lever at the side of the machine is to zeroise or cancel the answer registered preparatory to the beginning of a new operation. In its commercial application, the use of the comptometer extends in principle to all arithmetical calculations of accounting, including additions; extending and footing of invoices, inventory, payrolls, estimates; making engineering, astronomical and scientific calculations; in all of which, fractions (decimal) expressed, are as easily handled as whole numbers. Provision for the addition of common fractions is made by inclusion in the keyboard of a set of fractional columns. By this means fractional values are automatically accumulated and carried forward in progressive order from the lower to the next higher denomination. To meet special requirements, such as the adding of fractional denominations of foreign currency of various kinds, the different unit divisions of weights and measures, and special uses in the various departments of commercial accounting, suitable combinations of fractional columns are employed. Thus the pounds, shillings, pence and farthings comptometer, widely used in England and other parts of the British Dominions for adding British currency, is provided with fractional columns of 20ths, 12ths and 4ths. In a similar manner a model with fractional columns to 12ths and 16ths serves for adding British-Indian currency, consisting of rupees, annas and pies. 12 pies = 1 anna, and 16 annas = 1 rupee. Another model supplied with fractional columns to 40ths is used for adding funts and pouvoirds, the Russian measure of weight, in which 40 funts = 1 poold. A combination designed for the use of contractors, engineers and architects has columns for 12ths and 16ths which facilitate the adding of feet, inches and fractions of inches. Fractions in 60ths are provided for adding hours and minutes; and double 60ths for adding hours, degrees, minutes and seconds in the compilation of astronomical and geographical data. The formation of many other combinations is possible on the comptometer.

Mechanical arithmetic, as practised on the comptometer, being universal in its scope, constitutes in itself a complete system of mathematics. It is, of course, based on fundamental laws of mathematics, many of which are employed in arithmetical operations by the mental method but utilizing others not ordinarily so used. It is one the less a distinctive system in that it involves as many and as varied rules as are involved in the performance of arithmetical operations by the instrumentality of paper and pencil. The full significance of the difference between the processes employed in mechanical and mental arithmetic could be clearly shown only by the aid of illustrative examples too lengthy for insertion in this article. The system of applied mechanical arithmetic, with the rules for its application to all forms of arithmetical calculations, was first originated and developed by Mr. Fleet. Consult McGill, D. E., 'Applied Mechanical Arithmetic' (Chicago 1895).

COMPTON, Edward, English actor: b. London 1854. He made his début at the new Theatre Royal, Bristol, in 1873 and in London at Drury Lane in 1877. In 1879-80 he accompanied Adelaide Neilson on her American tour. He organized the Compton Comedy Company in 1881 and with this built up a repertoire of over 50 plays in about 30 years. He was associate manager of the Kennington Theatre in 1911 and toured as Nobody in 'Everywoman' in 1912-13.

COMPTON, Henry, English bishop: b. Compton Wynates, Warwickshire, 1632; d. Fulham, 7 July 1713. He was the youngest son of Spencer, 2d Earl of Northampton, studied at Oxford, and after the Restoration became a cornet in a regiment of horse. After he left the army for the Church, became bishop of Oxford in 1674, and bishop of London in 1675. Charles II made him a member of his privy council, and entrusted to him the education of his nieces Mary and Anne. He was distinguished for his hostility to the Roman Catholic Church. After the accession of James II, Dr. Sharp, rector of Saint-Giles-in-the-Fields, having become highly obnoxious to the court, Compton was required by a royal order to suspend him. His refusal to obey was made the ground of a pension. He was restored to his see at the Revolution of 1688, and, together with the bishop of Bristol, made up the majority of two in the House of Lords for filing the vacant throne. He performed the ceremony of the coronation of William and Mary, and was afterward appointed one of the commissioners for revising the liturgy. During the reign of Anne he was put on the commission for the union of England and Scotland. The reconciliation of dissenters with the Church of England was one of his favorite projects.

COMPTROLLER, State. An officer—sometimes an auditor—directly responsible to the legislature, who sees that all legal requirements for the payment of State funds are complied with, that claims are valid, that the payment of same have been authorized and that the funds have been appropriated and are available, whereupon bills are paid on his warrant. He supervises the State finances to the extent also of compelling clearness, completeness in the accounts, the indication of all receipts and the legality of all disbursements. In some States the comptroller has been partly supplanted by the board of control. Consult Ashley, R. L. 'The American Commonwealth' (New York 1908); Bryce, James, 'The American Commonwealth' (rev. ed., New York 1914); Wilson, Woodrow, 'The State' (rev. ed., Boston 1909).

COMPTROLLER OF THE CURRENCY, the name of the head of the currency bureau of the United States Treasury Department. He has special jurisdiction over the national banks of the country, supervising and examining them and recommending legislation for their regulation, besides approving all applications for the establishment of new banks. He has charge of all the national bank examinations, which are held every six years. He has charge of all the national bank examinations, which are held every six years, and five times each year, upon call, the national banks must render to him, according to furnished forms, a report of their condition. He may place a bank in receivership if satisfied that it is insolvent, but must exercise a large amount of discretion and sound business judgment since, particularly in times of panic and commercial depression, it may be unwise to
compel a bank literally to comply with the terms of the law. Under the act of 23 Dec. 1913 the comptroller is a member of the Federal Reserve Board and has supervision over the reserve banking system created by that act. The comptroller also issues circular notes to the national banks and exchanges old currency for new. Consult Fairlie, J. A., ‘National Administration of the United States’ (New York 1905).

COMPROLLER OF THE TREASURY. The act of 1789 establishing the Treasury Department provided for an auditor, who should see that accounts against the government are in proper form, and a comptroller, who should see that such accounts conform to the law and that payments of same have been authorized by statute. By the Dockery law of 31 July 1894 the duties of the comptroller, which are largely judicial, are more clearly defined, all appeals from the auditor’s findings being referred to him, while he is the one also who advises the disbursing officers regarding the validity of payments, if any doubt should exist as to the interpretation of an appropriation bill or other statute under which such payments are to be made. Though nominally a subordinate officer in the department, the comptroller has authority over all financial expenditures, subject only to review by the judicial courts; he can revise all accounts; he supervises the assistant comptroller, who has authority to countersign all warrants; his decisions are binding on the Secretary of the Treasury; and in his province on questions of law he is independent of the Attorney-General. In 1895 one comptroller even claimed the right to determine the constitutionality of the sugar bounty of the McKinley tariff of 1890, refusing to endorse warrants to pay such bounties to domestic producers of sugar. Consult Hotchkiss, W. E. ‘The Judicial Work of the Comptroller of the Treasury’ (Ithaca, N. Y., 1911).

COMPULSORY ARBITRATION. See ARBITRATION, INDUSTRIAL.

COMPULSORY EDUCATION. See EDUCATION, Compulsory.

COMPULSORY HEALTH INSURANCE. See SOCIAL INSURANCE.

COMPULSORY VOTING. See VOTE; VOTERS; VOTING.

COMPURGATION, a mode of defense allowed by the Anglo-Saxon law in England, and common to most of the Teutonic tribes. The accused was permitted to call a certain number (usually 12) of men, called compurgators, to swear to his innocence in testimony to his innocence. They were persons taken from the neighborhood, or otherwise known to the accused, and acted rather in the character of jurymen than of witnesses, for they swore to their belief, not what they knew; that is, on the accused making oath of his innocence, they swore that they believed he was speaking the truth. Compurgation in the ecclesiastical courts was not abolished till the reign of Edward I., and was used in some civil cases as late as 1833. The Assize of Clarendon, 1166, is credited with helping strongly to the doing away with compurgation in the King’s Courts as a mode of trial for crime. Consult Blackstone, ‘Commentaries on the Laws of England’; Pollock and Maitland, ‘History of English Law’.

COMPUTING SCALES. As is well known, the weight of a commodity is ascertained in order to form a basis for ascertaining its value at a given price per pound if in the United States or Great Britain and her colonies, or at a given price per kilogram in nearly all other civilized countries.

The computing scale is an instrument by which the value is obtained, mechanically, at a given price per pound or kilo, thus avoiding any error of making the calculations mentally, and causing the operation of weighing and ascertaining the value to be more speedily accomplished.

The computing scale business, as a successful commercial enterprise for the world, was inaugurated in 1891. Several earlier attempts were made, but without success. The business has rapidly increased since the above date, and hundreds of thousands of these machines are now in use throughout the world. Until recent years the United States was by far the largest market, but they have been introduced into Europe, South Africa, Australia and both the east and west coasts of South America, besides Canada, Mexico and West Indies Islands, until export trade in computing scales amounts to several hundred thousand dollars per year.

Construction of Computing Scales.—Broadly speaking, there are two types of computing scales: first, the variable leverage type, and second, the computed-chart type. The first type consists of a mechanism wherein the leverage of the computing beam may be varied so as to conform to the several units per pound or price per pound.

The computed-chart scale is further divided into two distinct kinds: first, the beam scale with computed chart, and second, the automatic scale with the computed chart. The former, or beam scale with computed chart, is a manually operated scale, operated as in ordinary scales by the movement of a sliding counterpoise, this sliding poise passing over the computed chart, and when the load is balanced by the movement of the poise, pointers on the poise indicate the total value of the commodity being weighed at the several prices per pound provided for on the computed chart.

The second, or automatic computing chart scales, are so constructed that when a commodity is placed upon the scale pan the load is automatically counterbalanced by the use of either counterbalancing springs or a pendulum counterbalancing weight, moving either the computed chart past a stationary indicator or moving an indicator past or over the stationary computed chart, the indicator in either instance having placed thereon the several prices per pound, and each price per pound placed adjacent to a pointer or other means of indication showing the total value of the commodity being weighed at the several prices per pound provided for in the construction of the scale.

The automatic chart scale is further divided into two distinct types of scales with respect to the construction or arrangement of the chart: One type being constructed upon the principle of arbitrarily dividing the pound into as many parts as there are cents in the price per pound as a means of computing weight. For instance, at 11 cents per pound the pound is divided into 11 parts, each part representing one-eleventh of
a pound. The other type is constructed on the principle of dividing the pound into ounces and fractions of ounces on the binary system as a means of computing values. In other words the pound is divided into uniform fractions of the pound as in ordinary pound and ounce scales, and the true commercial value of each subdivision of the pound is indicated on the chart at the several prices per pound provided therefor. See BALANCE; WEIGHING MACHINES.

COMSTOCK, Anna (Botsford), American natural history scientist, artist and engraver: b. New Canaan, Conn., 7 March 1844; d. New York, 21 Sept. 1915. In 1863 he enlisted in the 17th Connecticut regiment, served under General Gilmore and was mustered out in July 1865. Later he became secretary and special agent of the New York Society for the Suppression of Vice and completely identified himself with its work. It is said that largely through his special efforts 2,500 criminals were brought to justice and over 80 tons of indecent literature and pictures seized and destroyed. He wrote 'Frauds Exposed; How the People are Deceived . . . and Youth Corrupted' (1880), an exposure of various schemes operated through the mails; 'Traps for the Young' (1881); 'Flogging Outrages'; or, 'Improving the Breed of Horses at the Expense of the Public Morals' (1887); 'Morals Versus Art' (1887); and minor tracts for the furtherance of his work.

COMSTOCK, George Cary, American astronomer: b. Madison, Wis., 12 Feb. 1855. He was graduated at the University of Michigan 1877 and from the law department of the University of Wisconsin 1883, devoted himself entirely to astronomy and since 1887 has been professor of that subject and director of the Washburn Observatory, and since 1906 dean of the Graduate School in the University of Wisconsin. He is a member of the National Academy of Sciences. He has written 'Text-Book of Astronomy' (1901); 'Field Astronomy for Engineers' (1902); 'Method of Least Squares' (1890); and numerous papers upon astronomical subjects.

COMSTOCK, Harriet Theresa (Smith), American author: b. Nichols, N. Y., 1860. She was educated in public schools and in the academy at Plainfield, N. J. She married Mr. Philip Comstock in 1888. Since 1895 she has become known as a prolific writer of juvenile stories and is author of 'Molly, the Drummer Boy' (1900); 'Cedric the Saxon' (1901); 'A Boy of a Thousand Years Ago' (1902); 'A Little Dusky Hero' (1902); 'Tower or Throne' (1902); 'When the British Came' (1907); 'The Queen's Hostage' (1907); 'Janet of the Dunes' (1912); 'Joyce of the North Woods' (1913); 'Camp Brave Pine' (1913); 'A Son of the Hills' (1913); 'The Place Beyond the Winds' (1915); and 'The Vindication' (1916).

COMSTOCK, John Henry, American entomologist: b. Janesville, Wis., 24 Feb. 1849. He was graduated at Cornell University 1874; was United States entomologist at Washington, D. C., 1879-81, professor of entomology and general invertebrate zoology at Cornell 1881-1914, and since that date professor emeritus. His investigations deal with the morphology, classification and economic relations of insects. In this work he has been assisted by his wife, Anna Botsford Comstock (q.v.). He has been a constant contributor to the literature of his subject, the pullicity of his contributions being evidenced by the fact that many of his works in book form: 'Report on Cotton Insects' (1879); 'Introduction to Entomology' (1888); 'Manual for the Study of Insects'; 'Insect Life' (new ed., 1901); 'Elements of Insect Anatomy' (3d ed., 1887); 'How to Know the Butterflies' (with his wife, 1904); 'The Spider Book' (1912); 'The Wings of Insects' (1897).

COMSTOCK, John Lee, American writer on physics: b. Lyme, Conn., 1789; d. Hartford, Conn., 21 Nov. 1838. He received a common school education, studied medicine, and during the War of 1812 was assistant surgeon at Fort Trumbull, Conn., and on the Northern frontier. He settled in Hartford, Conn., practised medicine until 1830, when he became an author by profession and attained remarkable success in the compilation of textbooks for educational purposes. His 'Introduction to Mineralogy' (1832) was used at West Point; of the 'Elements of Chemistry' over 250,000 copies were sold; while the 'System of Natural Philosophy' (1831) had a sale of over 900,000 copies (94th ed., New York 1847) and was translated into the chief European languages. Others were 'History of the Greek Revolution' (1828); 'History of the Precious Metals' (1844); 'History of Quadrupeds' (1829); 'Grammar of Chemistry' (1825); 'Introduction to Botany' (3d ed., 1835).

COMSTOCK, Theodore Bryant, American geologist: b. Cuyahoga Falls, Ohio, 27 July 1849; d. 26 July 1915. He was graduated at Pennsylvania State College 1868, and at Cornell 1870, where he was professor of economic geology 1875-79. In 1873 he was geologist to Capt. W. A. Jones' Wyoming and Yellowstone Park expedition and accompanied Hartt's expedition to Brazil 1870. He was professor of mining engineering and physics in the University of Illinois 1885-89, and assistant State geologist of Arkansas 1887-88, and of Texas 1889-91. He founded the Arizona School of Mines, was its director 1891-95, and president of the University of Arizona 1893-95. He was at various times engaged as manager, engineer and consulting expert to many mining companies and syndicates, both American and foreign. He published 'Outline of General Geology' (1878); 'Classification of Rocks' (1877);
COMSTOCK LODE — COMTE

"Notes on the Geology of the San Juan Country" (1882); "The Geology and Vein Structure of Southwestern Colorado" (1886); the last two in the "Transactions" of the American Institute of Mining Engineers; and short papers in the "American Journal of Science, American Naturalist and Engineering and Mining Journal."

COMSTOCK LODE, a remarkable vein near Virginia City, Nev., carrying silver sulphides with some native silver and considerable native gold. The wide vein is a faulted fissure following the contact of a basaltic dike with the andesite country rock, the latter of Tertiary Age. The gange is mainly quartz. The ores are of recent origin, and the waters ascending along the fissure are hot, making mining costly. Some wonderfully rich ore bodies, "bonanzas," were found in certain of the mines along the lode, and the history of its discovery, the great mining speculations based on it, and the final abandonment of nearly all the mines, reads like a romance. At present the deepest shaft on the lode is being reopened. The total yield of the lode from its discovery in 1859 up to 1890 was over $340,000,000; the greatest yield for a single year was $38,000,000 in 1877. The yield has declined since 1890. The Comstock Lode has been a great interest to scientists. In 1868 Von Richthofen studied here the geologic relations of the ore bodies and Van Hise, Becker and others evolved the modern classification of igneous rocks through their studies of the formations. Ruxton conducted experiments here to determine temperature variations at different depths. Consult Becker, "Geology of the Comstock Lode and Washoe District." (in "Monograph of the United States Geological Survey," Vol. III, Washington 1882); Lord, "Comstock Mining and Miners." (in "Monograph of the United States Geological Survey," Vol. IV, ib. 1883); Reid, "Structure and Genesis of the Comstock Lode." (Berkeley, Cal., 1905).

COMTE, könt, Isidore Auguste Marie François Xavier, generally known as Auguste Comte, a famous French philosopher; b. Montpellier, 19 Jan. 1798, of a strict Catholic family; d. Paris, 5 Sept. 1857. He was very precocious in his intellectual development; in his own words, at the age of 14 he went through all the necessary stages of the revolutionary tendency, and felt the necessity of a general political and religious rebirth. In 1814 he entered the École Polytechnique at Paris. Though the school was broken up by the government in 1816 for political reasons, Comte remained in Paris and developed a close acquaintance with Saint Simon (q.v.), from whom he learned the need of substituting a new spiritual power for the medieval hierarchy in Church and State. Later he moved to Tübingen, a place developed between these two men, dating from the publication of Comte's "Plan des travaux scientifiques nécessaires pour réorganiser la société," which found the greatest hindrance to the development of society in the continual recurrence of antipathy and reaction. In 1825 he married Caroline Massin, but the marriage was unfortunate from the start. The following year he began to lecture on philosophy at his own house, but after his first few lectures he was struck down by an attack of insanity, which resulted in an attempt at suicide. This proved to be temporary, however, and in 1828 he was again able to carry on his intellectual labors and his lectures. In 1832 he became tutor in mathematics at the École Polytechnique, and in 1837 examiner at the same institution. He also engaged in secondary-school teaching. He held the post of examiner for some 10 years, but incurred the displeasure of his colleagues by some reflections on mathematics and its position. His British disciples including Anogthers Grote and J. S. Mill (q.v.) then supported him, sending him $1,200 in 1843. For the rest of his life he lived on the proceeds of a public subscription initiated by Littre in 1848. He was separated from his wife since 1842, and in 1845 he met Clotilde de Vaux, whose husband was serving a life sentence. He became excessively fond of her, and after her death the following year had another, though a less serious, attack of mental aberration.

Besides the book already named Comte wrote "Cours de philosophie positive;" "Discours sur l'esprit positif;" "Calendrier positiviste;" "Système de politique positive;" "Bibliothèque positiviste;" "Catholicisme positiviste;" "Appel aux conservateurs, par le fondateur du positivisme;" "Synthèse subjective;" "Système de logique positive." Comte believed that knowledge passed through three stages of development, the "theological" stage, in which imagination plays the greatest part in giving accounts of things. The "metaphysical" stage, in which abstract principles replace the imaginary deities of the theology, and in which the tendency to unification takes the lead; and the positiv stage, where both imagination and argumentation are subordinated to observation, and agreement with the facts becomes the ultimate scientific criterion. The facts arrange themselves in certain irreducible groupings, which are at least as many as there are distinct sciences, so that the unity of knowledge is subjective, not objective. These sciences Comte classifies according to the order in which they have reached their positive stage, as follows: mathematics, astronomy, physics, chemistry, politics, sociology, and anthropology. This order is also the decreasing order of breadth of scope in the sciences concerned and the order of the importance therein of induction as compared with deduction. Comte devotes special attention to sociology and ethics; he finds the division of the forms of civilization into militaristic, juristic and industrial quite parallel to the threefold division of science. He desires to unite the treatment of the emotional and intellectual needs of man. For this purpose a new religion becomes necessary, the "Religion of Humanity," and a new political Utopia. See POSITIVISM.

COMTE, Pierre Charles, French painter: b. Lyons, 23 April 1823; d. 1895. He studied at Paris as a pupil and adopted son of Robert Fleury, and exhibited his picture 'Lady Jane Grey,' in 1847, which won him considerable attention. His other works include 'Crowning of Ines de Castro' (1849); 'Henry III Meeting the Duke of Guise' (1855); 'Joan of Arc at the Coronation of Charles VII' (1861); 'Ot Scene at Fontainebleau' (at Washington, D. C.); 'Gipsies Before Louis XVI'; 'The Last Visit of Charles V to the Castle of Ghent,' 'Winter' (1876); 'Don Quixote' (1877); 'Dante' (1878); 'Francis I at Fontainebleau' (1880).

COMTE DE PARIS, dé pâ-ré. See PARIS, LOUIS PHILIPPE ALBERT D'ORLEANS, COMTE DE.

COMUS, kó'más (Greek κομας), in ancient Greece the name given to a kind of festal procession in honor of some of the gods (as Bacchus) and sometimes in honor of victors in the public games. The term had also the wider sense of revel and merrymaking. This name was also given to a divinity supposed to preside over such festive occasions, but as his name does not occur in early ancient writers whose works have been preserved, he is evidently a creation of later times. He is first mentioned by Philostratus (about 200 A.D.).

COMUS. This is the title given to a masque by John Milton, produced in honor of the Earl of Bridgewater, upon his entrance on his duties as Lord President of Wales, at Ludlow Castle, on Michaelmas night, 29 Sept. 1634. The young Puritan poet was induced to furnish the words and music for the entertainment—such things were not in favor with most of his coreligionists—by a family friend, Henry Lawes the musician, who gave instruction to the Earl of Bridgewater's children. Three of these acted in the masque, and Lawes himself took the part of the Attendant Spirit besides furnishing the music. Apparently Milton about a year before had rendered Lawes a similar service by writing for him the less elaborate 'Arcades.' We know little of the composition of 'Comus' or about its composition, save that it was written during what is called Milton's 'Hortond period,' but it was evidently talked of admiringly, since in 1637 Lawes, to furnish friends with copies, printed an edition without the author's name, to which was prefixed a very complimentary letter by Sir Henry Wotton. In this edition, as well as in Milton's editions of his shorter poems in 1645 and 1673, the designation is not 'Comus,' but 'A Mask.' A manuscript copy in Milton's handwriting and another supposed to be in that of Lawes are extant. 'Comus,' has naturally been subjected to much scholarly investigation, and numerous 'sources' have been suggested—chiefly, the Circe myth as treated in the Odyssey and by poets drawing on that, notably Spenser; George Peele's play 'The Old Wives Tale,' which gave Milton the kernel of his simple plot; Fletcher's 'The Faithful Shepherdess'; a play in Latin entitled 'Comus' by the Louvain professor Erycitus Puteanus (Hendrik van der Putten); and Ben Jonson's masque 'Pleasure Reconciled to Virtue.' That Milton drew to some extent upon these and other works seems indisputable, but the fact does not impair his essential originality, which is seen, not merely in the unsurpassed charm, purity and philosophical elevation of his poem taken as a whole, but in his developing the shadowy Comus of mythology into a well-defined and not unimpressive character. Criticism of 'Comus' has been in the main highly laudatory, not a few persons preferring it and the other poems of the 'Hortond period,' 'L'Allegro' and 'Il Penseroso' and 'Lycidas,' to the works of Milton's later years, including even 'Paradise Regained,' the severe strength of 'Samson Agonistes,' will not find these qualities present in large measure in 'Comus.' On the other hand, one who delights in the fascinating style of 'Comus,' in the noble idealism of its portrayal of the power of virtue, in the pure lyrical and pictorial qualities of the closing portion beginning with the invocation to 'Sabrina fair,' is not likely precisely to renew his delights in the later poems. It is more cathartic and sensible to enjoy this poet both in this product of the graceful strength of his early genius and in the more powerful achievements of his riper years. We shall do this the more certainly if we avoid a tendency observable in some critics to deal with 'Comus' as though it were a regular drama. In its use of blank verse, its comparatively long speeches, its diminished insistence upon the more spectacular elements of the typical masque, 'Comus' does approximate a play, and thus Milton may be said to give some handle to those critics who demand from him a more realistic and convincing handling of his characters. One can, therefore, understand how some people regard the great speeches as fine poetry put into the mouths of uninteresting puppets, and how one biographer actually has the heart to call the elder brother a prig. But after all 'Comus' is not a play but a masque developed into a philosophical poem, and in this more or less unique capacity it should be judged. One may doubt whether the ideals of personal purity have ever been more inspiringly set forth than in this poem, in which quiescience and nobility seem to be perfectly blended. From such a point of view one does not need to realize the plight of the lost lady exposed in the wiles of the enchanter, or to enter into the feelings and watch the actions of the two brothers who seek to rescue her, with the intensity of conviction and sympathy that would be required if 'Comus' made the same demands as a regular drama. What one has to do is rather to give one's self up to the beauty of the style and the nobility of the thought, more or less leaving the action and the characterization to take care of themselves. WILLIAM P. TREN'T.

Professor of English Literature, Columbia University.

COMYN, klm'n, John, THE ELDER, Scottish noble: d. about 1300. He was one of the commissioners sent to confer about the marriage of the Maid of Norway to Prince Edward of England. On the competition for the Scottish throne in 1291 Comyn put in a claim as a descendant of Donald Ban.
COMYN, John, Scottish noble: d. Dumfries 1306. He was called the "Red Comyn," was chosen one of the three guardians of Scotland and defeated the English at Roslin in 1302. He submitted to Edward I in 1304 and was killed by Bruce in the Convent of the Minorites at Dumfries in 1306, a well-known episode in the life of the great Scottish king. A sort of vendetta followed and many of the Comyns of succeeding generations perished in attempts to avenge the death of the Red Comyn.

CONN, kòn, an Italian preposition signifying with, and of frequent occurrence in musical phraseology; con amore, with feeling; con brio, brilliantly; con gusto, with taste, etc.

CONANICUT, an island of Rhode Island, situated in the lower part of Narragansett Bay. It is about nine miles long and one mile wide. The town of Jamestown is near the east shore and there is a lighthouse at the north end. Pop. of township about 1,200.

CONANT, Alban Jasper, American artist: b. Chelsea, Vt., 24 Sept. 1821; d. New York, 3 Feb. 1915. He settled in St. Louis in 1857, and during the Civil War visited Washington and painted portraits of President Lincoln, Secretary Stanton and Attorney-General Bates. He was a curator in the University of Missouri for eight years and made valuable studies of the archaeology and antiquities of the Mississippi Valley. In 1870 he was appointed Délégué Correspondant de l'Institution Ethnographique de Paris. He published 'Footprints of Vanished Races in the Mississippi Valley' (1879, 4to i); 'The Archaeology of the Missouri Valley'; 'My Acquaintance with Abraham Lincoln,' etc.

CONANT, Charles Arthur, American economic writer: b. Winchester, Mass., 2 July 1861; d. New York, 5 July 1915. He was for some years after 1880 a journalist in Boston, from 1889-1901 was Washington correspondent of the New York Journal of Commerce and in 1903 became treasurer of the Morton Trust Company. He did important work for the gold standard and the gold-exchange standard and aided in the development of a monetary system in the Philippines. He was a member of the New York Chamber of Commerce committee on currency reform (1900), which recommended a central bank; and in 1910 he was American delegate to the Hague Conference on Bills of Exchange. He wrote many articles for periodicals and encyclopedias on American banking and on Latin-American finance and trade, and published 'A History of Modern Banks of Issue' (1896); 'The United States in the Orient: the Nature of the Economic Problem' (1900); 'Alexander Hamilton'; 'Securities as Payment'; 'Wall Street and the Country' (1904); 'The Principles of Money and Banking' (1905).

CONANT, Hannah O'Brien Chaplin, American author: b. Danvers, Mass., 1809; d. Brooklyn, N. Y., 18 Feb. 1865. In 1830 she married Thomas Jefferson Conant (q.v.). She was a translator of considerable knowledge of Oriental tongues, which enabled her to share in the biblical studies of her husband. She frequently contributed to the literary and religious periodicals of the day, and in 1838 became editor of the Mothers' Monthly Journal at Utica, N. Y. She published 'Lea: or the Baptism in the Jordan,' by G. F. A. Strauss (1844); 'First Epistle of John Practically Explained,' by A. Neander (1852); 'The New England Theocracy,' by H. F. Uden (1859), all translations from the German; 'The Earnest Man: Sketch of the Character and Labors of Dr. A. Judson' (1855); 'The English Bible: Popular History of the Translation of the Holy Scriptures into the English Tongue' (1856; English ed., 1859; new ed., 1881).

CONANT, Thomas, Canadian descriptive writer: b. Oshawa, Ont., 1842; d. there, 14 March 1905. He was educated in the public schools and at Eddystone Seminary in Geneva, N. Y., and achieved distinction with brilliant sketches of scenery and articles on Canadian and other subjects.

CONANT, Thomas Jefferson, American biblical scholar: b. Brandon, Vt., 13 Dec. 1802; d. Brooklyn, N. Y., 30 April 1891. He was graduated from Middlebury College in 1823, and between 1825 and 1857 taught the classics and biblical literature in Columbia College, Waterville (now Colby) College, Steele Pass, and Colison, now Colgate, University, Hamilton, N. Y., and Rochester Theological Seminary. Taking up the studies that soon gave him a wide reputation, he was appointed by the American Bible Union one of a committee to prepare a revision of the English version of the New Testament. He was also a member of the American committee on the English revision of the Old Testament, and his revisions were highly esteemed and constantly used by the English revisers. His numerous publications include translations of the 11th and 17th editions of Gesenius' 'Hebrew Grammar'; 'Job; Revised Version, and Notes' (1856); 'Matthew, Revised Version' (1860); 'Baptizein, Its Meaning and Use' (1860); 'Genesis, Revised Version' (1868; 1873); 'The New Testament; Common Version Revised' (1871); 'Psalms, Revised' (1871); 'Proverbs, Revised' (1872); 'Greek Text of the Apocalypse, as edited by Erasmus' (1873); 'Prophecies of Isaiah, Chapters 1-12' (1874); and 'Historical Books of the Old Testament, Joshua to 2 Kings' (1884).

CONATION (from Lat. conari, to attempt), a term in its original sense used simply to express the idea or to designate the act of attempting or undertaking something. In present usage it is appropriated by psychologists to the expression of desire and volition as manifested in or constituting voluntary agency, although as a factor in consciousness and effort its precise implications appear not to have been finally determined. In the exertion of the muscles, and in direct conscious attention, the agency of conation in an individual finds its two representative aspects. Attention, desire and endeavor, with their accompanying states of thought and feeling, are held by psychologists to be the completing aspects of conation; while others maintain that its function is limited to the sensations of straining, with consequent states of consciousness, pleasurable or otherwise, arising from the action of the muscles. Whether conation is to be regarded as simple or complex in its psychological aspects remains therefore a question for further research and experiment. Consult James, 'Principles of Psychology' (New York 1890); Titchener, 'Experimental Psychology'
CONSEPCIÓN, Bolivia, a lake in the central portion of the department of Santa Cruz.

CONCEPCIÓN, Chile, province lying between the provinces of Nuble and Bio-bio. Area 3,532 square miles. It is divided into the departments of Coelemu, Puchacay, Rere, Concepción, Talcahuano and Lautaro. The importance of its capital, its commercial activity and its numerous ports make this the most interesting province in the south of Chile. Two of the largest bays in the republic are on its coast, those of Talcahuano, which is defended by fortifications, and Arauco, which includes the ports of Lota and Coronel, notable for their coal mines. The city of Concepción (55,000 inhabitants) is the capital. Talcahuano (15,500 inhabitants) is a military port, with a dry-dock for repairing warships and mercantile vessels, and at the same time an active commercial port. Products of the whole southern region are brought to it for exportation, and it supplies cities of the interior with general merchandise. The port of Tomé (5,000 inhabitants), situated near rich agricultural districts, exports a large quantity of wine and has a woolen mill, etc. Penco, a small port 10 miles by rail from the city, is now flourishing at Plattsburg, N. Y., being its president from 1893 to 1897. In 1889 Georgetown University conferred upon him the title of D.D., and in 1896 Laval University, Quebec, bestowed the same honor. He was chosen rector of the Catholic University in 1896, made a domestic prelate in 1897, consecrated titular bishop of Samos, 24 Nov. 1901, and appointed bishop of Monterey and Los Angeles, 27 March 1903. He was a frequent contributor to various periodicals, and is the author of 'New Testament Studies' now used in many Catholic schools.

CONCENTRATION CAMP, sometimes applied to rendezvous near an intended point of departure of troops; but generally to a camp into which non-combatants are gathered in time of war. In China in 1899-1901, 98 many peaceable and defenseless people were forced to abandon their homes in the agricultural regions and were imprisoned upon the barren waste outside the residence portions of the cities, and within the lines of the forts. In 1861-1865, 15,000 British also carried on a scheme of concentration of non-combatants—men, women and children—during the Great Boer War, and in which provision was made for the education of Boer children. Provision was made at Mindanao, in the Philippines, in 1892, for the accommodation of non-combatants during the military measures undertaken by the American government. In 1914 about 5,000 Mexican revolutionists, driven across the border into American territory by government forces, were detained and interned temporarily in concentration camps.

CONCENTRIC, similar figures having a common centre are called concentric.

CONCENTRIC WEATHERING. See EXFOLIATION.
CONCEPCIÓN, Paraguay, also called Villa Concepción, the second city of the republic in commercial importance, though not in the number of its inhabitants. It is situated on the left bank of the Paraguay River, 125 miles from the city of Montevideo, where the steamers navigating the upper Paraguay regularly touch. The principal buildings are the city hall, custom-house, parish church, market and some fine private residences. It has a line of street-cars, telegraph, telephone service, two banks, and several commercial houses that trade directly with Argentina and European cities. Yerba-maté or Paraguayan tea and cattle are the principal items of the city's commerce. Pop. 15,000.

CONCEPCIÓN, Philippines, former district of the island of Panay, now part of the province of Iloilo, situated on the northeast part of the island; area 683 square miles. The former capital, Concepción is a pueblo situated on the east coast of the island, 47 miles northeast of Iloilo; pop. 4,552. Pop. of the district about 20,000.

CONCEPCIÓN, Philippines, town (pueblo) in Tarlac province in the island of Luzon, 12 miles south of the town of Tarlac. It has an important sugar industry; rice, tobacco and corn are also raised in the surrounding country. Pop. 12,593.

CONCEPCIÓN DEL URUGUAY, Argentina, city in the province of Entre Ríos, on the Uruguay River about 160 miles north of Buenos Aires. It is connected by railway with Paraguay, and the river is navigable for large vessels, thus rendering the city an important shipping point. It is in an extensive and fertile agricultural region and the trade consists chiefly of these products and cattle and packed meat. There are also some salting establishments in the city. A national college and a normal school are located in the city. Concepción del Uruguay was founded in 1778 and was originally called Concepción-del-de-la-china; was formerly the capital of the province and is now the episcopal city. Pop. 6,111.

CONCEPT. A concept is an idea which has been formed by thinking, and which is permanently embodied in language by a word or other definite symbolic expression. There are two main differences between a concept and a perception. In the first place, the latter seems to be directly presented through the senses and does not imply any conscious reflection. And again, a perception as presented has always a particular individual form, while a concept is an ideal construction, and, as such, has universal significance. For example, I may perceive through my senses the particular object which I call my watch; but to form a concept of watch is to think in general terms the relation of the object to the purpose of the whole. The concept must also be distinguished from the mental image which appears in memory or imagination when the object is not directly present in sensation. The latter is always a particular psychological process, and the former adequately represent the general relations of the concept. We must not confuse the presence of images in the mind with thinking. It is true that a concept cannot be represented in terms of psychological content except by a particular image, and it probably always is represented by some such image. But the concept is a universal mode of thinking, and the psychological imagery which accompanies it is largely individual and indifferent. The universal relations of the concept of triangle, for example, are not limited by the form of this particular figure which I represent to myself mentally, or draw upon paper, though the latter may aid me in comprehending those relations. The concept is ideal in character; it is a universal significance, and must never be confused with a particular psychological image.

Socrates was the first to bring this universal element of knowledge into clear light. When the Sophists pointed to the differences and variations of perceptions and feelings in individuals, and drew the conclusion that objective knowledge was impossible, Socrates showed that concepts which are true for all men can be discovered and defined, and that this is the true quest of thought. Amid the flux of individual opinion, science is still possible, since it is constituted by this system of universal concepts. Plato and Aristotle developed further the Socratic doctrine of concepts and gave it an ontological application. By means of the concept, the true form or permanent essence of things is said to be apprehended, as opposed to its accidental and changing appearances. The question as to the nature of the concept played an important part during the Middle Ages. (See Nominalism, Realism, Conceptualism.) The view that is perhaps most commonly held to-day regards the concept as derived by abstraction (q.v.) from perceptual experience, by selecting out what is common in a number of instances and combining these common elements into a general idea. It must not be forgotten, however, that concepts are not formed by the piecing together of psychologically common elements in a mechanical way, but are the products of thinking; and that thinking is itself judgment or interpretation of significance in universal terms. It is true, as Kant said, that concepts without perceivers are empty, and that thinking does not go on in a vacuum apart from concrete experience. But the concept is not universal because it has been compounded out of elements that are common to a number of objects, but because it is the mind's expression in terms of ideal significance. Concepts, however, can attain to any degree of elaboration only through the aid of language. The relation between thought and the words which express it is of the closest and most intimate kind. The word comes up in itself the results of the conceptualizing process, thus giving to it a reality and permanence which make progress possible. It is through learning the words of a language that we are able to share in the concepts of other men and other generations. Language is thus a permanent record of thought's achievements, and its development is not something external to the evolution of thinking, but in one aspect may be said to be a different side of the same process. The concept then cannot be defined apart from its expression in language; for this expression is no mere external and accidental feature of the idea, but is organically and necessarily connected with it.

JAMES E. CREIGHTON,
Professor of Logic and Metaphysics, Cornell University.
CONCEPTION. This is a term signifying the beginning of the life of the child following fertilization, which latter is brought about by the union of the spermatozoan with the ovum. After orgasm (see Coitus), the male elements, or spermatzoa, many thousands of which are discharged in coitus, commence to move toward the mouth of the uterus, largely attracted by alkaline chemical substances which characterize the mucus membranes of the cervix and uterus. On entering the uterus they swim against a current there at a rate of about one-eighth of an inch a minute. The entire length of the uterus can thus be traveled in about an hour or less. The ovum may be met in the uterus or in the Fallopian tube when fertilization takes place. The spermatozoan may live from five to eight days in the uterus or tube — the ovum a similar length of time — and impregnation may take place at any period between menstruations, although it is more likely when coitus precedes or follows within seven to eight days of the menstrual period. See EMBRYOLOGY.

CONCEPTION, Immaculate, of the Blessed Virgin Mary. A dogma of the Roman Catholic Church, declared infallible by Pope Pius IX in 1854. See IMMACULATE CONCEPTION.

CONCEPTION OF OUR LADY, Sisters of the, an order of nuns, founded in Portugal in 1484 by Beatrix de Sylva, in honor of the Immaculate Conception. It was confirmed in 1489 by Pope Innocent VIII, and the Cistercian rule was adopted. In 1489 Cardinal Ximenes put the nuns under the direction of the Franciscans, and imposed on them the rule of Saint Clara. The order subsequently spread into Italy, Belgium and France. The Sisters of the Immaculate Conception of the order of Franciscans were established at Little Falls, Minn., in 1891 by sisters from Italy. They now have several hospitals, an orphanage, an extensive school and nearly 100 teachers.

CONCEPTUALISM, kôns-șép-tu-al-izm, in metaphysics, a doctrine in a sense intermediate between realism and nominalism. Conceptualism assigns to universals an existence which may be called logical or psychological, that is, independent of single objects, but dependent upon the mind of the thinking subject, in which they exist as notions or conceptions. Thus, for instance, according to conceptualism, the meaning of a general class-name as horse, red, can be fully represented in thought or be actually present to the consciousness. Locke was the best known advocate of this psychological doctrine, which is little known outside of English-speaking countries. See NOMINALISM; REALISM.

CONCEPTUALIST, one of a metaphysical sect — if indeed it has coherence enough to be called a sect — which arose in the Middle Ages during disputes between the Nominalists and the Realists; or one who holds the views of conceptualism. The conceptualist school sought to occupy an intermediate position, but is approximated much more nearly to the Nominalists than to the Realists.

CONCERT, a public performance of musical compositions without the aid of scenic representation. They were unknown before 1672 when the first concerts were established in London by John Banister. Briton continued the practice after Banister's death in 1679 and in 1725 the concerti spirituali were established in Paris in the form of harpsichord recitals. They were soon copied by organizations in France, Germany and England. The foundation of the Berliner Singakademie in 1790 inaugurated public performances of large choral works with orchestra. Consult Hanlick, E., Geschichte des Konzertwesens; Pohl, K. F., 'Mozart and Haydn in London' (Vienna 1867); Schering, A., Geschichte des instrumentalkonzerts bis auf die Gegenwart! (Leipzig 1905).

CONCERT PITCH, the pitch of a certain note in the musical scale adhered to by the general body of musicians. The middle C (seated on the ledger-line which unites the G and F clefs) is produced by a string making, according to theorists, 512 vibrations per second. In England, however, the pitch has risen to 538, while in Germany it is 528, and in France 522. The gradual rise of the pitch from the theoretical 512 vibrations is attributed to the necessities of piano-tuning on the one hand, and the desire to attain a more intense and brilliant sound on the other. See PITCH; also MUSICAL ELEMENTS AND TERMS.

CONCERTINA, kon-ser-té-ná, a musical instrument invented by Sir Charles Wheatstone in 1829. It is generally polygonal in shape, is held between the hands so that the fingers drop naturally down on studs which raise the valves and allow the air (supplied by the bellows between the finger-boards) to act upon a series of metal tongues of the same construction as those of the accordion or harmonium. The usual range of the instrument is from the lowest G on the violin to the C three and a half octaves higher, including the chromatic tones. The German concertina is a much less perfect instrument, as only tones on a limited number of keys can be performed on it.

CONCERTO, kôn-chár'ë-ò, a kind of composition first introduced by the Italian musicians of the 17th century, really a symphony with a solo instrument. The principal composers and artists in this department are Corelli, Vivaldi, Rodes, Baillot, Kreutzer, Alard, Beriot and Vieuxtemps. Subsequently concertos were written for other instruments, such as the flute, the piano, etc. Among the most successful composers for the piano are Bach, Mozart, Hummel, Chopin, Schumann, Reis, Czerny and Thalberg. Concertos are written in the so-called sonata or symphony form in three movements, an allegro, an andante, or adagio and a lively rondo. Except in the tutti the orchestra should be as subservient to the instrument for which the piece is written as it should to a vocalist. It is found for any instrument capable of technical or heroic treatment. Between the solo there are orchestral interludes — ritornelli, which most often treat the thematic material more fully. The Concerto da Camera, or Chamber concerto was popular before the days of full symphony orchestras, a string quartet and cembalo being sufficient to accompany the solo instrument. Concerto da chiesa or church concerto was more loosely applied, meaning often a work for voices and organ. Concerto grosso is an express concerto applied to the great or grand chorus of the concerto, or to
CONCH—CONCHOS

those places of the concert in which the ripienos and every auxiliary instrument are brought into action, for the sake of contrast and to increase the effect. All the 18th century concerti for two or more solo instruments are concerti grossi.

Concerto spirituale was a concert at Paris, performed in the religious seasons, when the theatres were closed. The pieces performed, however, were not always of a spiritual kind. It was introduced in 1725 by Anne Danican, called Philidor.

CONCH, kōn'ké, a name of certain large marine gastropods, especially of the king conch ( Strombus gigas), abundant in the southern United States and parts of the West Indies. In Florida the shells are made into horns, used for calling the farm hands, as is still done in the East Indies with shells of the genus Triton. Conch shells were in use over a large extent of territory in Mexico, Central and the northern part of South America for the manufacture of beads many centuries before the discovery by Europeans of the New World. This is one of the shells used for making cameos, and great quantities are collected in the Bahamas and shipped to Liverpool for this purpose to some extent, but more for conversion into the manufacture of bricks and articles, in allusion to which industry the native whites of the Bahamas are called "Conches." Conch shells are also used very extensively in the manufacture of lime and porcelain. The name is also applied to two large sea-snails, the Fulgor carica and Scytoctopus canaliculata, common on most parts of the Atlantic coast.

CONCHA, kōn'chā, José Gutierrez de la (Marqués de la Habana), Spanish general: b. Cordova, Argentina, 4 June 1809; d. Madrid, Spain, 5 Nov. 1895. He went to Spain in childhood, entered the army, took part in the struggles in South America, and against Don Carlos, was appointed lieutenant-general in 1839, and officiated as captain-general of the Basque provinces 1843-46. He was captain-general of Cuba 1849-52, when he was replaced by Cañedo. Joining his brother Manuel (q.v.) in opposing the government, he was banished from Spain in 1854, and fled to France, where he was detained at Bordeaux. After the July revolution of 1854, he was reappointed captain-general of Cuba, and, with the exception of a short suspension of his functions by Narváez's administration in 1856, when Lersundi was appointed his successor, he continued to hold office until December 1858, when he tendered his resignation. Returning to Spain he was at various times Minister to France, president of the Senate and Minister of War, and captain-general of Cuba again 1874-75.

CONCHA, Manuel de la (Marques de Duero), Spanish general and statesman: b. Cordova, Argentina, 25 April 1808; d. Muro, 28 June 1874. He was a brother of José Gutierrez de la Concha (q.v.), fought in early life against Napoleon and the revolted Spanish colonists in South America, and afterward against Don Carlos. In 1847, during the complications with Portugal, he was put in command of 6,000 men, and took possession of Oporto. Having issued at the end of 1853, in concert with O'Donnell and Bravo-Murillo, the famous protest against the policy pursued by the government, he was banished from Spain after the revolution of July 1854, and repaired to Paris; but was soon recalled to Madrid by the outbreak which terminated in the exile of Maria Christina, the downfall of Narvaez and the restoration of Espartero. Concha was now made inspector-general of cavalry and marshal; but on 12 Oct. 1856, when Narvaez came again into power, he was compelled to relinquish these posts. He was killed in the battle of Muro while serving in the republican army against the Carlists.

CONCHOID, kon'koid, a curve, shell-like in flexure (whence the name), invented by Nicomedes in the 2d century B.C., and used by him for finding two mean proportionals. If a straight line always passes through a fixed point o, and a point q, fixed into the revolving line, always moves along the line a b, then any point p in the revolving line always at the same distance from v will trace out a conchoid. And, since the length q p can in any position of the revolving line be measured either toward or from o, it is evident that, corresponding to any given length assigned to q p, two conchoids can be described, one above and the other below the line a b. These are known as superior and inferior conchoids. Moreover, with a given point o, and a given straight line a b, any number of pairs of different conchoids can be described by varying the length q p. Moreover, the shapes of all such curves will vary according to the length of q p. Thus, if q p is less than the perpendicular from o on a b, the shape is as given in the adjoining figure, and this isolated point o is also a point on the curve.

The equation of the conchoid is

\[ x^2 = (b + y)^{a^2 - y^2} \]

when a denotes the length of the modulus and b the perpendicular distance from o to the line a b.

CONCHOLOGY, kön-köl'ó-jé, the science of shells. See MOLLUSCA.

CONCHOS, kon'chos, or CONCHAS, Mexico, river in the state of Chihuahua; rises high up in the Sierra Madre, flows southeast, northeast and then north through a beautiful country, comprising rich table-land, and empties into the Rio Grande near Presidio del Norte, after a course of about 350 miles. It is the largest tributary of the Rio Grande, and very little inferior in size to that river itself. Its principal branches are the Florido, Buenavista, San Pedro, Chihuahua and Balleza,
which, with their lesser tributaries, water more than one-third of the state.

CONCHYOLIN, kon'-krô-lin, an organic base allied to chitin (q.v.), which enters into the composition of the shells of mollusks. The conchylolin forms a thick cuticular layer of organic matter containing carbonate and a slight proportion of phosphate of lime. In dead shells the conchylolin soon disappears, leaving the shell much more brittle than when it was alive.

CONCIEGRIERIE, la, lâ kö-zô-rô-kô-rô. A noted prison in Paris, which was a part of the Palais de Justice. Many royal prisoners were there confined, and during the Reign of Terror it was the scene of fearful butcheries. 369 prisoners being put to death in one week. Marie Antoinette went from her cell in this prison to her execution.

CONCILJUM IN TRULLO, or CONCILIJUM QUINISEXTUM (Council in Trullus, Fifth-Sixth Council). A council or synod of the Church convened in a hall (called the Trullo) of the Imperial palace at Constantinople in 689. It was an assembly of Eastern and Western bishops called for the purpose of enacting canons of Church discipline; this the council did, adding to the existing canons 102 new ones and confirming ancient canons that had fallen into desuetude. Its work was to supplement the decrees of the 5th and 6th councils of the Church: hence it is known as the Quinisext Council.

CONCLAVE, both the apartment in which is conducted the election of a Pope and the college of cardinals assembled there. The procedure in electing popes is substantially the same to-day as it was in 1274 when it was prescribed by the Council of Lyons. When a Pope dies, a secretary of the college of cardinals summons all the cardinals to an election to be held on the 10th day after the demise. In whatever city the Pope dies, there the conclave must be held. The conclave apartment must be immediately prepared in such a place and manner as will ensure safety of person and non-interference from outsiders. If the conclave is held at Rome, the cardinals, of the papal palaces are divided by wooden partitions into small rooms or cells, two or at most three cells for each cardinal and his personal attendants. The apartments all open on one corridor, and to that there is but one means of access from without, and that is strictly guarded. After the 10 days have elapsed, i.e. cardinals all assemble in the Vatican church and assist at the Mass of the Holy Ghost, after which they form a procession and proceed to the conclave, each one taking the apartments assigned to him. The first day of the conclave is open to the public, and numerous persons, high and low, avail themselves of the permission to enter. In the evening all outsiders leave, and the cardinals must remain until a Pope is chosen. A two-thirds majority vote is requisite. Since 1848 food is prepared in the conclave; if no election is had after five days the food supply is restricted to bread, wine and water, or rather used to be, for the right to eat is now much relaxed. A cardinal coming from a distance is admitted after closure. The election is made by scrutiny, that is, by ballot, or by compromise, that is, by a committee chosen by a majority of the conclave, or by acclamation. Formerly each cardinal in the name of his country had the right of excluding a candidate not acceptable to his government. This privilege he could exercise but once during the conclave. The last time this right of veto was allowed was at the conclave of 1903 when Cardinal Rampolla was excluded as obnoxious to Emperor Francis Joseph of Austria. On 20 Jan. 1904, Pius X prohibited any cardinal, under pain of excommunication, to exercise the right of veto. The cardinals take an oath to this effect. Cardinals only may vote, but non-cardinals are eligible to the Papacy. All are sworn to secrecy. No voting by proxy is allowed. A two-thirds vote is necessary to elect. Sometimes a conclave has sat many weeks, or even months, before reaching an election, the conclave which elected Pius VII (1799) sat for six months. The conclave in which Leo XIII was elected Pope consisted of 62 cardinals, and it began its session the evening of 18 Feb., 1878. The scrutiny of the morning of the 20th showed that Cardinal Pio d'Aragona was elected, and the election was then ended and he was made Pope by acclamation. The conclave at which Pius X (q.v.) was elected began its session 31 July 1903, and the first ballot was cast the morning of 1 Aug. The scrutiny of the morning of 4 Aug., the seventh ballot, showed that Cardinal Sarto, patriarch of Venice, was elected. He chose the name of Pius X. This conclave was remarkable as being the first of which a cardinal from the United States was a member.

CONCONE, Giuseppe, joo-sép'pe kôn-kô'ô-nâ, Italian teacher of vocal music; b. Turin 1810; d. there, June 1861. From 1838-48 he was a teacher at Paris, and then became organist of the royal chapel at Turin. He wrote a large number of vocal exercises which are still used in the teaching of singing.

CONCORD, Mass., town in Middlesex County, on the Concord River and on the Boston & M. Railroad, 20 miles northwest of Boston; settled in 1635. It is situated in a beautiful valley, and has several manufacturing establishments. It is a prison of the Massachusetts Reformatory. The town has an excellent public library and a national bank. The government is by town council, and the municipality owns the waterworks and electrification plants. At the beginning of the Revolution the Americans had a large stock of arms and military stores at Concord. General Gage, the British commander in Boston, hearing of this, sent a body of soldiers to destroy these stores, and on their way (19 April 1775) they fought the battle of Lexington, the first of the war. When they reached Concord, the same day, they destroyed what stores they could find, but were soon driven off by the Americans. Concord is celebrated as the home of many authors—of Ralph Waldo Emerson, Nathaniel Hawthorne, Henry David Thoreau, Amos Bronson Alcott, Louisa May Alcott, the poet William Ellery Channing and others. Pop., about 6,500. Consult Hurst, 'History of Middlesex County' (Philadelphia, 1890).

CONCORD, N. C., county-seat of Cabarrus County, on the Southern Railroad. Here are
large industrial interests, including cotton goods, foundry and machine-shop products, etc. There are also roller mills, a cannon manufactory and brick works. Concord is an old place to which in recent years new industries have brought rapid growth. The Jackson Training School and Scotia Seminary are located here. Pop. 8,715.

CONCORD, N. H., city, capital of the State and county-seat of Merrimack County, on the Merrimack River, and on the Boston & M. Railroad, 75 miles northwest of Boston. The city has an abundance of water-power, and manufactories of carriages, shoes, twine, electrical apparatus, silverware, leather goods, machine-shop products, etc. The United States census of manufactures for 1914 recorded 85 industrial establishments of factory grade, employing 3,178 persons; of these, 2,856 were wage earners, receiving annually $1,956,000 in wages. The capital invested aggregated $5,701,000, and the year's output was valued at $67,310,000, or $3,032,000 was the value added by manufacture. Near Concord are extensive quarries of a fine-grained white granite. There are three national banks with a combined capital of $550,000 and a surplus of $77,000, and one local private banking house. The assessed property valuation exceeds $20,000,000. The city is well laid out, has finely shaded streets, is well lighted, and its waterworks are excellently constructed. The noteworthy buildings include the State-house, a fine building of Concord granite, the city hall and courthouse, the State prison, State insane asylum and the United States government buildings. The public schools are 26 in number and are admirably organized and conducted, and represent a property valued at more than $325,000. This city is the seat of the well-known Saint Paul's School (Episcopal) for boys. Concord was settled by whites in 1725, on the site of the Indian village of Pennacook. It was called by this name until 1733, then incorporated as the town of Rumford, and became a city in 1853. It is noted as the place near where Hannah Dustin (q.v.) made her escape from Indian captors. Pop. 22,000.

CONCORD, an expression used in music denoting a combination of two or more sounds pleasing to the ear, and requiring no further combination before or after it to make it so. Concors are the eighth (or octave), the fifth, third and sixth. Their ratios are 2:1, 3:2, 5:4, 5:3. The two first are called perfect, because they are not liable to any alteration by sharps or flats. The two last are called imperfect, as being alterable. The fourth is considered as a discord by some authorities; as a component part of an inversion of the perfect chord it may be classed among the concords. See COUNTERPOINT.

CONCORD, Book of (Liber Concordia), the name given to a collection of confessions of faith which are generally accepted by the Lutheran Church. The Formula of Concord (1580) was the result of conferences and discussions upon the following subjects: The Rule of Faith and the Creed; Original Sin; Free Will; Justification; Good Works; The Law and the Gospel; The Third Use of the Law; The Lord's Supper; The Person of Christ; The Descent of Christ into Hell; The Customs of the Church; Predestination and Election; Heresies and Sectaries. The whole received the sanction of a large number of the Germans. Other subjects treated in the Book of Concord are The Three Ecumenical Creeds; Apostles' Creed; Nicene-Constantinopolitan; Athanasian; The Six Particular Confessions of the Lutheran Church—Augsburg, Apology of the Augsburg, Smalcald Articles, Catechisms of Luther (larger and smaller). Consult Schaff, 'Creeds of Christendom' (Vols. I and III, New York 1878).

CONCORDANCE, a book in which the more important words of a volume or collection of writings are arranged alphabetically, part of a passage being extracted with each and the place of its use specifically given. The first known concordance of the Bible in any language was that of Saint Anthony of Padua, who was born in 1195, and died in 1231. His work was called 'Concordantiae Morales,' and was of the Latin Vulgate. It formed the basis of a more elaborate concordance, also of the Vulgate, that of Hugo de Clermont, better known as Cardinal Hugo. This was published in 1244 a.d. The first Hebrew concordance was that of Rabbi Mordecai Nathan, begun in 1438 and finished in 1448. The first Greek concordance to the New Testament was that of Xystus Betuleius, whose real name was Birk; it came forth in 1546 a.d. The first English concordance to the New Testament was that of Thomas Gysbon, before 1540 a.d.; the first to the whole English version of the Bible that of Marbeck, 1550 a.d. The last of course, preceded the appearance in 1611 a.d. of the authorized version of the Bible. The elaborate and well-known work of Cruden appeared first in 1737. All these works, with the exception of the last named, have been superseded by vastly improved works by modern scholars. Of the Septuagint the standard is that by Hatch and Redpath (London 1897); of the Vulgate, that by Coornaert (Bruges 1892); and that by Peutler, Etienne and Gantois (Paris 1902); of the Hebrew Bible the best is that by Furst and Delitzsch, in Latin (Leipzig 1841) and also that by Davidson, Tregelles and others, in English (London 1873); of the Greek New Testament are those of Bruder (Leipzig 1842; 5th ed., Gottingen 1900); in English Moultrie and Gedden (New York 1897); of Luther's Bible the best is that of Bächner (Jena 1740; 23d ed., Berlin 1899); of the English Bible in addition to Cruden are those by Young (Edinburgh 1879), Walker (Boston 1874) and Strong (New York 1894).

Scholars have also compiled concordances of the works of several great authors. The first known concordance to Shakespeare was that of Ayscough, in 1790. Mrs. Mary Cowden Clarke's elaborate and most useful work was first published in London in 1845, and in 1894 appeared a still more excellent one, that of John Bartlett, published in New York. A concordance to Milton was published in Madras in 1856 and 1857, and one to Tennyson in London in 1870 and another in 1912. Others of this kind are 'Dante's Works,' by E. A. Fay (Boston 1889); 'Omar Khayyam,' by J. R. Fultin (London 1899); 'Chaucer,' by the Chaucer Society (London 1872); ' Pope,' by E. Abbott (ib. 1875); 'Cowper's Poetical Works,'
CONCORDAT—CONCRETE

by J. Neve (ib. 1887); 'Gray,' by A. S. Cook (ib. 1909); 'Dickens,' by G. A. Pierce (ib. 1887); 'Brownling,' by Molineux (New York 1896).

CONCORDAT, kōn-kōrd'ät (concordatum, or, plur., concordata), a compact or convention entered into by the Holy See and a secular government to determine their respective powers and rights in the regulation of ecclesiastical affairs within the jurisdiction of the state which is a party to the compact. The earliest example of such compacts is the convention between Calixtus II and the Emperor Henry V, concluded at Worms in 1122: it marked the end of the great dispute about investitures. In 1448 was concluded the so-called concordat with the German nation, or with the Emperor Frederic III, under which the patronage of ecclesiastical dignities in the empire was divided between the Imperial Crown and the Holy See.

A more comprehensive compact is that of which the foundation was laid at Constance in 1848, and subsequently modified by the Frankfort Concordat, and by that of Vienna, which last continued in use till the end of the Holy Roman Empire. A concordat was concluded at Worms in 1122. It was then modified by the Lateran Concordat of 1516, by the Concordat of 1801, and by the concordats of 1803, 1817, 1818, 1827, 1832, and 1848. A new concordat was concluded at Vienna in 1855. Its chief provisions were that the Pope should have direct communication with the bishops, clergy and people; and archbishops and bishops with their priests and people, and the right to govern their seels according to the canon law. Education was put under the control of the Church. The bishops were to settle what books should be used. All questions of marriage, except so far as they involved civil consequences, were reserved exclusively to the ecclesiastical courts. The emperor had the power of choosing bishops, but with the advice of the existing bishops. The Church might acquire new property; but once acquired, it should not be sold or mortgaged without the consent of both Pope and Emperor. A concordat was set aside in all the dominions of the Emperor of Austria. In Italy, an agreement regulating the election of bishops was concluded with Nice and Savoy in 1451, and a formal concordat was made with Sardinia by Benedict XIV in 1746, and with Naples in 1741, and a new concordat was entered into with Naples by Pius VII in 1818. Charles V of Spain concluded a concordat with Adrian VI and Clement VII, and a further concordat was made by Clement XII and Philip V in 1737. A concordat with Portugal was made by Benedict XIV in 1741. Memorable is the concordat of 1515 between Leo X and Francis 1; the King agreed to annul the pragmatic sanction of Charles VII, which restricted the right of appeal to Rome; and in return the Pope conceded to the king the right of nomination to all Church benefices within the realm, with a reservation of the annates to the Holy See, and with the proviso that the nominees should be acceptable to the Pope. A further concordat was concluded 15 July 1801 between Pius VII and Napoleon as First Consul; it recognized the legal exist-
CONCRETE BRIDGES

and cement is termed the matrix, and the broken stone or other addition is styled aggregate. The aggregate may be stone, but may be slag, coke, broken bricks, gravel or pebbles. The ideal aggregate is broken, sharply angular and irregular stone, as this material mixes better with the matrix than recrystallized pebbles, round pebbles, or the more spongy brick shell or coke, although broken stone or gravel may be used advantageously in connection with pebbles, even in such small proportion as three to five. Broken limestone is especially efficacious as an aggregate, possibly because of an affinity between the molecules of carbonate of lime in it and the matrix. The proportions of the various parts approximate 1 part of cement, 3 parts of sand and 4 to 6 parts of aggregate, but no fixed norm is to be followed, the true rule being that the cement paste is to be thoroughly incorporated with sand coating each particle and that the matrix thus formed shall fill all interstices in the aggregate. In the process of mixture there are two methods of working, one where the cement is very wet and the other scarcely more than moist. The spraying is followed by a mixture by shovel or by mixing machines. These machines are of two types: continuous, a trough or cylinder with a screw shaft which works until the mixture is complete; and intermittent, a box being rotated slowly. The concrete may either be made into blocks, one layer of comparatively small depth being made at a time. But the newer method is applied to its place on the building or foundation in the soft state and allowed to harden there. The world is indebted to Germany for the revivification of the concrete industry. They diffused a wider knowledge of the artificial manufacture of cement from lime and clay (see PORTLAND CEMENT), and demonstrated that the degree of expansion and contraction of structural steel and concrete under changes of temperature were the same. The United States was very prompt to make use of this development, which has so greatly altered building construction throughout the civilized world. While the large use of concrete is a comparatively modern development, it was employed in ancient times and in some of the most renowned works of history. The famous stones employed by the Babylonians and the early Egyptians, as well as among the Greeks and Romans and at the present day in Barby and among the nations of Malabar, were all a species of beton. Fliny mentions that the columns which adorn the peristyle of the Egyptian labyrinth were of this material, and the great length of time it has existed (over 3,600 years) shows the durability of this mode of construction. Puzzone, a volcanic soil, formed the basis for an excellent natural hydraulic cement used by the Romans. The aggregate consists of broken stone and was poured in wooden molds. In Rome the pyramid of Ninnus is formed of a single block, as was also the square stone that formed the tomb of Porsena, which was 30 feet wide by 5 feet high. The Romans made free use of this material in constructing their walls, aqueducts, piers and roads, many portions of which exist at the present day. The mere and innumerable utility of local crushed stone is so much exposed to the effect of winds that breaches were continually being made in it by the force of the sea, and to such an extent that in former times the Moors were compelled to employ a large number of workmen to repair it, at an annual expenditure of over $60,000. Between 1833 and 1840 the French rebuilt this with concrete, or beton, as it was then called, this being among the earliest of modern successful use of artificial cement-made stone. The action of the sea is so tempestuous here that the engineers calculated that stone blocks would have to be of about 350 cubic feet to remain in place. The impracticability of quarrying and transporting such enormous blocks of stone led to the employment of artificial stone or beton. Two kinds of blocks were manufactured: the first in the water, in the place they were intended to occupy, and the second on shore, to be afterward thrown into the sea. In the process of reconstruction, these blocks were used as follows: Those of the first kind, made in lined caissons, formed an outer sea line; on these blocks molds were placed filled with beton, and after these second blocks had set, they were long across the entire sea, forming a line in front of the first; the intervening space was then filled up with blocks of natural stone. Behind this embankment thus formed, the ground was dredged to a depth of over six feet, and the whole of this space filled up with a continuous mass of beton. The entire work was performed in five years, at a cost of less than $420,000, notwithstanding that the mole, at the time of the occupation of Algiers by the French army in 1830, was in a state of complete dilapidation, in spite of the extensive repairs which had been annually executed upon it by the Moors during a period of two centuries. Marine works of the above character present numerous advantages over constructions in which natural stone is employed, of which the following are some of the most prominent: (1) immediate stability, while ordinary pierre perdue is never secure; (2) incomparably greater facility in transportation, which is always expensive and troublesome when blocks of stone are to be quarried exceeding 100 cubic feet; (3) a considerable reduction in the height of the pier, and consequent economy of cost; and (4) that the system can be applied in every locality, now that our advanced knowledge of the subject of hydraulic mortars enables us to manufacture beton in any quantity which may be needed. See CONCRETE BRIDGES; CONCRETE CONSTRUCTION; PORTLAND CEMENT.

CONCRETE BRIDGES. These include arch, girder, slab, truss and trestle forms. The location of piers, length of span and thicknesses of main members will be determined by the character of foundations and loading to be carried; the width by the traffic, and the height by high water mark, and adjoining property, and the length of flood discharge, and channel width. The character of finish, ornamentation and other aesthetic features will be determined by the situation. Since concrete bridges are permanent, they should provide for increased loading of future. On important highways, motor trucks of 30 tons must be carried; and on interurban bridges, from electric cars of from 75 tons to electric locomotives of 100 tons.

Reinforced Concrete Archs are either of closed-spandrel or open-spandrel type. The first type is similar in form to a stone masonry
arch, with thinner sections. The reinforcement should be about 1 per cent of the crown section in both extrados and intrados, and should continue throughout the arch ring, bonding into the piers. The two lines of reinforcement should be connected at the spring with substantial wiring, sufficient to transmit stresses. Reinforcement should run transversely to the arch ring and be tied in the spandrel walls. Reinforcement may be preferably rods, or a lightly built-in framework (Mellen System). W. J. Douglas ('American Civil Engineer's Pocket Book') gives a formula for the cost of a reinforced concrete bridge with ordinary foundations as follows: Cost in dollars = 0.8 b^2 / d where b = width in feet, l = length in feet and d = average depth in feet of bed of stream below roadway level (1916).

Arch bridges are developing into the open spandrel type, becoming more articulated and skeletonized; similar to the development from the Gothic to the Romanesque. In the open spandrel type, the loads are carried by a slab deck to transverse walls or columns, and in turn by these to the arch ring. A further development is to divide the arch ring into two or more separate ribs upon which columns rest to carry the load of the deck. The extreme articulation of the Arroyo Seco Bridge is notable.

By such skeletonization, the designer can more certainly arrange the shape of the arch ring to the load, span and rise, and more economically carry the loads and reduce the weight upon the foundation. The subsequent life of the structure due to expansion can be better provided for. Waterproofing is also more simple.

For high rise bridges of usual width the open-spandrel type is more economical. Closed-spandrel, earth-filled arches, when of low rise and under 100 foot in span, are usually more economical than open-spandrel arches.

In both open- and closed-spandrel types sidewalks may project beyond the faces of the structure and so reduce the length of the pier.

Form of Arch Rings.—When circumstances of waterway and head room permit, the shape of the arch ring may be chosen from the standpoint of economy, and will then vary with the character of loading. For instance when the load is uniform per horizontal unit of length, as in open-spandrel structures, the parabolic curve is chosen (see Arroyo-Seco Bridge). For closed-spandrel, earth-filled arches with a ratio of rise to span greater than one-fourth, an ellipse is suitable, and when this ratio is less the curve should be between a segment of a circle and an ellipse. In this case the curve is approximated to by a three or five-centered curve. An arch springing down low upon the piers imposes less transverse action on the pier.

Expansion and contractions due to change of temperature must be provided for in concrete bridges. Heavy concrete sections demand provision for a range of 35°C. or 40°C. only. Sliding joints provide for movement of floor system and must often be waterproofed.

Arch Ring Thickness.—Empirical formulas for determining the thickness of arch rings at crown are generally used. The thickness of an arch ring should increase toward the spring, except for hinged arches. The radical thickness at any point may be taken as the crown thickness, multiplied by the secant of the angle which the radial section makes with the vertical. For segmental and three-centred arches, the thickness at the spring is from two to three times the crown thickness. However these dimensions, useful for preliminary plans, should always be checked by an analysis, using the method of the elastic theory.

The approach work of these arches must often receive attention and at times they are faced with cut stone. However, by the use of selected aggregates, or by tooling and setting of stoning, ornamental appearances are secured and are preserved, when the arch is properly waterproofed. It is of importance, however, that arch lines and surfaces be kept simple and accentuated, and not lost in inappropriate and meaningless applications of ornament. The use of pedestals, massive lighting standards is satisfactory. The design of overhangs, off-sets, pilasters gives relief from the flatness.

In the United States, arch rings are usually built continuous with the piers. Rarely in this country, but more often in Europe, the arch ring is built in two parts with hinges at the crown and at the abutments, with the object of fixing the action line of the loads, thus lessening the flexure on the ring, and the effects of change of temperature.

Cantilever Concrete Bridges have the appearance of arches but are composed of balanced cantilevers. These are suited to spans too long for girders; and, since they exert only a vertical pressure, they will fix foundation conditions too yielding to withstand the thrust of a real arch. The cantilever arms are ribs supporting a slab and beam deck. Examples of such highway structures are Hopple Street, Cincinnati, Ohio, 70-foot span; Wayne County, Mich., 100-foot 6-inch span; Runnymede Avenue, Cincinnati, Ohio, 72-foot span; Washington Street Bridge, Norfolk, Conn., 50-foot span.

Bowstring and Open-web Cased Girders are common in Europe and increasing in the United States in cases where arch construction through limitations of heading or foundation conditions do not permit an arch.

The Benson Street Bridge over Mill Creek, at Lockland, Ohio, is an example of an arch with a suspended floor consisting of slabs and girders to which suspension is attached.

Slab Bridges, used up to 25-foot span, consist of a simple slab span to which the parapets are attached, resting on abutments. A highway bridge of 22-foot span, for instance, has a slab thickness of 12½ inches, reinforced with rods, spaced 5½ inches c.c.; and parapets 4½ inches above the slab; ½-inch rods spaced 12 inches c.c. run transversely to the bridge. Expansion slidding joints of tarred paper or galvanized iron are placed on top of the abutments. Vertical drain pipes drain the roadway.

Girder Bridges are used up to 50 feet span and may be preferably of deck type, where there is headroom, or of the through type. The two or more girders receive the deck slab. A span of 30 feet, for instance, has three girders 17 inches wide and 2 feet 9 inches deep below the deck slab which is 10 inches thick. For additional information see Bridge.

Railroad Trestles are built by placing previously molded slabs on concrete bents, spaced

15 to 20 feet, composed of concrete of vertical piles and a concrete cap. They are also built in place.

W. K. Hatt,
Professor of Civil Engineering, Purdue University.

**CONCRETE CONSTRUCTION. A Historical Account.**—As in the history of other arts we find early disclosures of the principles of action of various after constructions. Before construction in reinforced concrete strengthening of brick masonry arches by iron ties to prevent opening of cracks in tension was well known. In 1836 Brinell experimented with brick beams so strengthened and found the two acted together. In 1871 Sir Shafto Adair built a concrete arch of 50-foot span with a rise of five feet three inches, containing an embedded iron skeleton frame. The treatise on concrete by François Coignet, of France, published in 1861, describes the embodiment of an iron meshwork in concrete to increase its resistance to tension, and describes the making of pipes. It is said that he built a roof slab 12 inches thick and 20-foot span, in 1852 at Saint Denis. (Concrete, London, June 1910).

Coignet's patent of 1869 consists in the introduction in the body of the structure of double headed nails, double T pieces, clamps, hoops — for the purpose of strengthening some and giving it greater cohesive strength. The iron was to be interlaced so that by the combination of the metallic skeleton and of agglomerated artificial stone paste the thickness of the walls or size of articles might be considerably reduced and yet great strength be attained. Troughs were to be strengthened at the corners by iron clamps.

The book by Thaddeus Hyatt published in 1877 discloses improvements in fireproof construction, describes experiments in reinforced concrete beams and analyzes the principles of action of these. He protects the I beams from fire by a covering of concrete, and between these he builds slabs reinforced for tension by plates of iron placed vertically in the bottom of the slab and connected by small round rods. He understands the mechanics of the reinforced concrete beam; and the part played by the metal in moment and horizontal shear. He also investigated experimentally the elements of strength of the two materials, strength, modulus of elasticity, expansion and contraction, fireproof qualities. Hyatt was a practical contractor, a successful inventor, and his book is the first definite treatment of reinforced concrete.

J. F. Monier, a gardener, was one of the fathers of reinforced concrete. His first work was in making flower pots. His first patent was dated 1867 and the drawings disclose many of the elements to-day employed. In 1884 the rights of the Monier patents for Germany were purchased by Wayss & Company, which, after experimental and theoretical study, published a brochure entitled 'Das System Monier,' describing the various engineering applications of reinforced concrete. Following this it was rapidly introduced in the construction of buildings, railroad structures and public works. In 1892 the important names of Hennebique and E. Coignet appear. Their designs of beams and bridges extended reinforced concrete to a new construction of a monolithic character. In eight years, between 1892 and 1899, Hennebique applied reinforced concrete to 3,000 constructions, including bridges, buildings, stairways, retaining walls, reservoirs, piles, etc. Other well-known practitioners of that time are Cottauin, Bordenave, Bonna, Matrai,
CONCRETE CONSTRUCTION

Melan. The French Exposition of 1890 showed many remarkable structures in reinforced concrete. Considerable after 1900 brought new ideas. Since then the range of size and importance has been extended, scientific data for accurate computation obtained experimentally, and principles of action more clearly known.

In the United States, Ransome in 1884-95 was building various structures with hoop iron and wire rope. A house of reinforced concrete with beams and slabs was built in the United States by Ward in 1875. Thatcher applied the Melan system to bridges. J. Kahn and A. L. Johnson designed and built up a wide range of structures. After 1902 the university laboratories were fruitful in research. For further reference consult P. Christie, "Le Béton Armé" ed. by Béranger, Paris.

Composition.—Concrete here considered is composed of hydraulic cement (generally Portland cement) and a fine and coarse aggregate and water. Mortar is composed of cement, fine aggregate, and water. Subsequently the mixture sets by chemical action. Fine aggregate is usually sand but may be crushed stone or gravel screenings graded from fine to coarse up to 1/4-inch size; the coarse aggregate is pebbles, broken stone or slag, up to a size depending upon use. For buildings and bridges where steel reinforcing is used the maximum size should be not greater than 1/2 inch. For concrete in large masses, such as piers, sizes up to 21/2 inches may be used. Under proper precautions large boulders may be embedded in the concrete. Occasionally banks of gravel are found of approximately the proper proportions of fine and coarse aggregate. For mass concrete cinders, composted of hard, clean, vitreous clinks free from sulphides, unburned coal or ashes may be used. The fine aggregate should be hard, free from organic matter; 5 per cent of clay, if finely divided and nonadherent, may be allowed. Not more than 6 per cent of fine aggregate should pass a standard sieve having 100 meshes to the inch. Dirty sand when rubbed in the palm will discolor the hand. Avoid very fine sand. Sand or gravel is cleaned by washing.

Proportions.—For reinforced concrete foundations for structural concrete, engine foundations, tanks, arches, a real rich proportion of 1 part cement to 6 parts of fine and coarse aggregates by volume; usually 1 cement, 2 sand, 4 broken stone or pebbles (1:2:4). For reinforced columns up to 1:1:2. For ordinary foundations, walls of buildings, floors, side-walls, use 1:2½:5. For heavy walls, piers and abutments, an ordinary mixture of 1:3:6. For unimportant work, in large mass, as ordinary foundations, backing, farm floors, a lean mixture of 1:4:8 may be used if well handled. These proportions assume that the voids be filled in the fine and coarse aggregate approximately 50 per cent. In important work the most favorable proportions to yield the densest mixture are determined by experiment. A grading of sizes of aggregate approximating an ellipse, vertex at zero size, is the ideal.

A mixing should be done for at least one minute in a batch concrete mixer machine. If mixed by hand ingredients should be turned at least six times on a watertight platform until homogeneous in color. The cement should be spread on the sand and the two well mixed by turning over three times. Then place this on the coarse aggregate, add the water and turn over. Generally the amount of water should be such as to yield a plastic concrete, whose surface will be horizontal in a container, but in which the concrete will not sink. However, a dry concrete may be tamped into place for foundations, walks, curbing, etc. Before mixing and placing concrete should not be allowed to set. Fresh concrete, as on a subsequent day, should not be placed on partially set concrete until the old surface has been cleaned of laitance or dirt, roughened and wetted, and slushed with a mortar of 1 part cement to 2 parts fine aggregate.

Concrete should not be deposited in freezing weather unless special precautions are taken to heat the aggregate, the water and to protect the concrete. Salt is used to lower the freezing point of the water in amount of 1 per cent of the weight of the water for a temperature of 32° F. and an increase of one per cent for each degree of lower temperature to a maximum of 10 per cent. The strength of the concrete is not greatly affected. Salt should not be used in reinforced concrete. Wet concrete may be continuously placed under still water by use of a tremie or pipe with lower end buried in the flowing mass.

Usually forms of wood or steel are required to hold concrete to the desired shape while hardening. Accidents are likely when forms are removed too soon. Two weeks to one month in important structures are needed. A simple test is that a tenpenny nail will bend and not drive in concrete. Frozen concrete may be detected with a torch. Expert inspection is necessary where collapse is possible.

Strength.—The following table gives the expected compressive strength of various concretes at 28 days, in pounds per square inch:

<table>
<thead>

<tr>
<td>Cinders</td>
<td>800</td>
<td>700</td>
<td>600</td>
<td>500</td>
<td>400</td>
<td>112</td>
</tr>
</tbody>
</table>

The expected strength of 1:2:4 concrete at 28 days is 2,000 pounds per square inch. The tensile strength is about one-tenth and the shearing strength about two-thirds the compressive strength. True shearing failures are difficult to procure; usually tensile failures result.

The modulus of elasticity ranges from 2,500-000 to 3,000,000 pounds per square inch. Usually in design it is assumed to be 2,000,000, or one-fifteenth that of steel. The bond or resistance to withdrawing steel or iron rods from 1:2:4 concrete at 28 days is: For plain and deformed rods at first slip, 260 pounds per square inch of contact surface; at ultimate strength, for plain rods, 400; for rods with deformed surface, 600 pounds per square inch. A plain rod should be embedded 40 diameters.
to develop its tensile strength. Concrete grows in strength with age. With compressive strength at 28 days is 70 per cent, 14 days, 0.50; 28 days, 1.0; 60 days, 1.20; 3 months, 1.25; 4 months, 1.30; 6 months, 1.35; 1 year, 1.45; 3 years, 1.50.

The quantity of concrete is less than the sum of the fine and coarse aggregate, since the coarse aggregate fills the voids in the coarse aggregate. Fuller's rule is: The number of barrels of Portland cement required for a cubic yard of concrete is the sum of the parts of the ingredients divided into 11. Let c equal number of parts of cement; s equal number of parts of sand; e equal number of parts of broken stone or gravel; P equal number of barrels of Portland cement to cubic yard of concrete.

Then \( P = \frac{\text{c} + \text{s} + \text{e}}{11} \).

Then \( P \times e \times \frac{27}{3.8} = \text{number of cubic yards of sand required for one cubic yard of concrete} \).

Then \( P \times e \times \frac{27}{3.8} = \text{number of cubic yards of stone required for one cubic yard of concrete} \).

A barrel of Portland cement weighs 93 pounds. Here 38 is the number of cubic feet of loose sand or gravel required for a cubic foot of cement. For a proportion of 1:2.4 a cubic yard of concrete requires 1.57 barrels of cement; 0.44 cubic yard of sand; 0.88 cubic yards of stone.

Safe working stresses are (in per cent of compressive strength): For bearing on concrete, 33 per cent; for axial compression, piers and plain columns, 22.5 per cent; for compression in extreme fibre of beams, 32.5 per cent; for bond, plain bars, 4 per cent; deformed bars, 5 per cent. A tensile stress of 40 to 50 pounds per square inch, when shrinkage cracks are not likely, and the conditions are not critical, may be allowed. Coefficient of expansion and contraction of concrete with temperature for one degree Fahrenheit is 0.0000055 to 0.0000060. Expansion joints must be provided about every 30 feet in plain concrete. By use of steel expansion is reduced, and distributed with a number of fine cracks that do not seem to affect the structure. Concrete shrinks when it hardens, and when it is handled as an wet, and is not hardened in water. Sudden change in dimension of sections should be avoided, or fillets should be used.

Destructive Agencies.—In all cases concrete should be impervious to water. Steel embedded in good watertight concrete is preserved from corrosion above or below water level. Stray electric currents may cause corrosion of steel but the concrete is practically immune. Sea water, entering porous concrete, is likely to cause disintegration. Frost acting on water in porous concrete will cause spalling. Strong acids and organic acids and rapid crystallization of alkali salts under wet and dry conditions attack concrete. Mineral oils have no action.

Concrete has low heat conductivity, and is a good fireproofing material. Dehydration begins at 500° F. and is completed at 900° F.; but is confined to outer surfaces of two to three inches, in conflagrations. The most severe fire test of the Edison factories at West Orange, N. J., 9 Dec. 1914, in which temperatures of from 1000-2500° F. were developed, showed reinforced concrete buildings (in this case of defective design) to withstand such extreme fires satisfactorily; columns and beams suffered spalling and some failure; the cost of restoration was from 10 to 15 per cent.

Imperviousness of concrete to water is best ensured by a dense concrete mixed wet. Dry or porous concretes are rendered less pervious by various integral compounds or surface coatings; many of these are of temporary effect. Hydrated lime, in amount of 10 per cent of the cement, has been recommended.

Structures, such as retaining walls, bridge floors, subways, basements, are waterproofed by a membrane made up of one or more layers of fabric impregnated with asphalt, or coal tar pitch, cemented together with asphalt or coal tar pitch preparation. The fabric may be a wool felt, an asphalt felt or burlap. From two to six layers are used often. The membrane is protected from abrasion or other injuries by a covering of asphalt mastic or paving brick.

For damp-proofing, coal tar pitch, either dissolved in benzine or applied hot, is painted on like a paint. Surface of concrete must be dry. A coal tar paint when made up of oil part kerosene, four parts Portland cement, 16 parts refined coal tar, is very effective and may be applied cold.

Cost of Waterproofing.—Cost of coal tar when applied in three coats is 3/4 cent for material and 3/4 cent for labor per square foot. Cost of membranes is from 20 to 45 cents per square foot, including protection. For surface work a mixture of concentrated lime and alum in proportions one pound lime to five pounds alum is used successfully by the United States army engineers. Paraffine applied hot is sometimes used. A wall may be impermeable, but not damp-proof, for the water may enter by capillary action into minute openings and eventually may render damp the air of a room where there is little circulation of air. The secret of success is dense concrete laid continuously.

Efflorescence.—The whitish or yellowish stains that occasionally appear on a concrete surface exposed to action of the weather are due to the leaching out of lime that has been left hard at the surface. The more waterproof the concrete the less probable these are. Unsightly appearances are also due to leakage through construction or shrinkage joints.

Surface Treatment.—Surface of concrete may be treated to improve its appearance by scrubbing off the film of mortar when green or tooling it when hard, to expose the aggregate, which may be selected for aesthetic effect. A wash of 10 per cent acid solution is also used. Plastering or stucco on concrete must be applied with care. (See Stucco.) For large and important structures, smooth forms and careful spading of dense concrete against these forms is preferable to any other effects. For ornamental work, best effects are produced by use of dry selected aggregate next to forms and by setting-in tiling. By the use of the cement gun fine aggregate and cement and water are blown by air pressure through a nozzle onto a surface to be covered.

Cost.—The cost of concrete depends upon cost of cement, sand and some upon conditions of work and size of work. Where forms are simple, cost ranges from $4 to $7 per yard.
Thin sections, with expensive forms and handling, will bring this up to from $10 to $20 per yard. A reliable estimate must take account of all of the circumstances.

Applications of Massive Concrete.—Massive concrete, or plain concrete not reinforced with steel, as used up to about 1850, is applied to solid retaining walls, piers, dams, retaining walls, short arches, etc. In these uses, the principal stresses are compressive. No tension is expected on the concrete. For instance in a massive retaining wall, the resultant force of the lateral pressure of the earth on the wall, and the weight of the wall is directed outwardly downward and acts within the middle-third of the horizontal width of the wall. Consequently no bending action exists and no tension exists in the concrete on the interior face of the wall. Structures of massive concrete are the old stone masonry forms built in concrete.

With metal reinforcement to carry principal tensile stresses, concrete structures can become more constructed in compression, more skeletonized, and the members can withstand bending action.

The advantages of massive concrete over stone are availability of local materials; use of unskilled labor and machinery in mixing and placing; adaptability for placing in small spaces; monolithic character of resulting structure. The following elements need careful consideration: Cost of forms, expansion and contraction; uncertainty of quality of materials, demanding skilled inspection; appearance of surfaces; necessity of good foundations to prevent cracks due to settlement in an unyielding material.

Application of Plain Concrete.—Sidewalks usually are 4 to 5 inches thick on a foundation of porous material 10 inches thick. For a 4-inch walk, the base is a dry tamped concrete 3 to 3½ inches thick, and laid in blocks about 6 feet long, or the width of the walk, separated by a joint, formed by tarred paper or sand. After a few of these blocks have been laid, and protected from dirt and dust, and before they have set, the wearing surface of mortar from ¾ to 1 inch is placed, is leveled with a straight edge and floated with a plasterer’s trowel. The final float is performed from two to five hours afterwards. Grooves are made in the wearing surface just above the joints in the base. Skill is necessary in properly floating the surface at the right time. The finished wall must be protected from the hot sun. Basement floors are constructed in the same manner except that a wetter concrete may be used for the base, and in cellars the joints omitted. Driveways are similar to sidewalks, and are from one inch thick for ordinary traffic up to five inches for heavy trucking.

Concrete roads are now established construction. Knowledge of the necessity of skilled contractors, very best materials, for difficult service conditions have been gained at expense of early failures. National conferences on concrete road building in 1914 and 1916 crystallized practice. The travel on rural and suburban roads has increased rapidly in recent years and changed in character to motor driven. The tendency to destroy the surface of ordinary water bound roads; so that the maintenance of these throughout the entire year to meet the demands of modern conditions has become impracticable from an economic standpoint.

The selection of clean, hard, well-graded aggregates is of the utmost importance. Practice in supplying reinforcement to minimize cracks, or in inserting transverse joints, is not yet settled. The function of the small amount of reinforcement supplied is to keep together two portions of the concrete which have inevitably cracked due to settlement or shrinkage, and so prevent failure of the slab, rather than to prevent cracks. The latter remain small and soon fill up. Reinforcement is so formed of reticulated metal, as wire mesh, expanded metal, in amount about 28 pounds per 100 square feet of surface. Transverse joints ¾ inch thick spaced 36 feet apart are filled with fibre matrix or bitumen and are protected by metal plates which, however, may be omitted if the filler is of a character that runs out under traffic.

A single track road should be 10 feet wide, and a double track road 18 feet wide. On each side is a macadam or gravel strip for turning out, the total width of roadway is 20 and 26 feet, respectively. The thickness of the roadway slab is 6 inches at the edges and increases to 7 or 8 inches at the middle, depending upon loads and other circumstances. The slab is built either with a wearing surface on a concrete base as in sidewalks, or preferably as a one course slab floated on the surface. In 1914 there were 14,200,000 square yards built, equivalent to 1,500 miles of 15-foot roadway, and in 1915, some 15,000,000 square yards.

The cost of constructing concrete roads in 1915 in the United States, excluding grading, drainage or roadbed, varied from 88 cents to $1.28 per square yard, depending upon locality and other conditions. In 13 States out of 17 the cost was less than $1.12 a square yard, or $6,570 a mile for one mile of single track road 10 feet wide.

Maintenance of concrete roads is taken to mean, not the repair of obviously defective construction, resulting from careless workmanship and poor materials, but such work has been usually done in filling cracks or joints or small holes, with tar and sand. The care for such work in Ohio in 1914-15 was $29 per mile for 122 miles. Extensive data of cost of maintenance are lacking. It may be estimated that the maintenance cost just cited is not likely to be exceeded in pavements one to five years old.

Concrete walls for foundations and cellars may be made 1:3:6. A 10-inch thick wall will stand when hardened a pressure of 6 feet of earth, and if supported laterally by joists may be 6 inches thick. Building walls are single, or double with an open space. A single wall 6 inches thick is equivalent to a 12-inch brick wall. Each face of a hollow wall is 3 or 4 inches thick, and the air space may vary in middle, 9 inches being an extreme. The concrete should be wet to flow readily in the forms. Concrete building blocks with air spaces of various designs are machine made of rather dry or porous concrete. These are apt to be of inferior quality, concrete and unsightly in place. With special machinery and aggregates a satisfactory wall can be secured. Plain concrete is used for retaining walls, piers, dams, in about the same sections as the stone

masonry it displaces. The sections of brick or stone arches may be reduced from 10 to 20 per cent. Some reinforcement of arches is always advisable. Reservoirs and tanks, chimneys, silos, etc., should be reinforced. Special extension of uses of concrete on the farm is to be noted.

Reinforced Concrete.—Reinforced concrete is concrete with metal, usually steel embedded to assist in carrying tensile stress. Good concrete carries tensile stress in the earlier stages of loading up an extension corresponding to about 5,000 pounds per square inch in the steel, after which the steel does increasing duty. Computations for design omit this tension in the concrete. Steel is also used to assist in carrying compression in concrete in columns, arches and the compression flange of beams. Steel is also inserted in concrete to provide for shrinkage when setting and expansion and contraction under change of temperature and to minimize effects of settlement.

A simple beam of plain concrete breaks on the tension face. When tension is added, the maximum tensile stress of the concrete in compression on the upper face has reached only about 1/10th its capacity. When steel rods whose cross section equals about 1/100th of the cross section of the beam are introduced in the tension side, the beam becomes more nearly of equal strength in both faces of 1:2:4 concrete. Its capacity is very largely increased. The composite action of the steel and concrete depends upon the bond between the steel and concrete. The possibility of carrying tensile stress through the concrete by steel leads to great flexibility in design, and allows new forms and constructed sections. The advantage of such construction in difficult situations is marked. Reinforced concrete has thus replaced stone or brick masonry in many fields of construction, such as retaining walls, arches, foundations, and has opened up new fields in reservoirs, tanks, buildings, conduits, chimneys. The combination possesses in a large degree the advantages of both steel and concrete. Steel is protected from corrosion and fire, and is used in its most economic form. Expensive connections, use of skilled labor and scarcity of product in rush times are obviated. The artistic possibilities are apparent. As in plain concrete construction, the necessity of care in inspection of materials and building operations, the effect of freezing weather or of rapid drying, the dead weight on foundations and the problems of waterproofing need consideration.

Systems in reinforced concrete, such as the Monier, Hennibique, Kahn, Johnson, etc., are named after the inventor of a special arrangement of reinforcing to provide for the stresses, or for a specially formed bar, or unit assemblage of bars. These are described in special treatises. Patents in reinforced concrete are many, and the designer must have knowledge of some of them to anticipate payment of royalties. Recently there has been a tendency in the courts to invalidate patents that claim rights to the use of reinforced concrete on the ground that only mechanical skill, and not inventive faculty, is required to place steel where tensile stress is to be met, or else to interpret the patent to narrow claims covering only the particular thing described in the patent.

Use of Steel.—Steel for reinforcing is in form of bars, usually round or square with ordinary surfaces (plain bars) or deformed surfaces, such as corrugations, lugs, bent fins. The endeavor is to design the bar so that the cross section may be equal throughout. Reticulated metal, such as expanded metal or woven mesh, is also used for short spans, and to resist volumetric change. Steel in low carbon steel, especially when bars of greater diameter than one inch are to be used, but high carbon steel, both from billets and rerolled from steel rails, is extensively used. Usual thicknesses of steel rods are: for slabs 1/4-inch to 3/4-inch; for beams 3/4-inch to 1 1/4-inch; for girders up to 2 1/4 inches.

The amount of steel in a beam depends upon the unit working stress for which the structure is designed. For stresses of 16,000 pounds per square inch in the steel, and 750 in the concrete in compression, a beam or slab is balanced mechanically, i.e., will have the assumed stresses, when 0.87 of 1 per cent of steel is present. This statement is based upon the use of the conventional method, in which the columns longitudinal steel is used up to 4 per cent and spiral steel from 1 to 2 per cent. In arches, 1 per cent of the cross-section at the crown both in the extrados and the intrados. Reinforcement for temperature is generally from 0.25 to 0.4 per cent of the cross-section which is subjected to temperature change.

Structural Forms in Reinforced Concrete.—Reinforced concrete construction is generally continuous and monolithic, all parts of the structure being tied together except for expansion joints. In this it is contrasted to wooden or steel construction where the parts act more as separate units. Concrete beams or girders are reinforced with about 0.9 per cent of steel at the lower side at the centre and an equal amount over the support when continuous. The latter amount is obtained by bending one-half of the bars up from the bottom around the quarter-point of the span, the remaining one-half coming from the other side of the support. The bars that are not bent continue horizontally to the support. Width of beams and girders is generally one-half to one-third the depth. The ends of beams and girders are strengthened against shear when necessary, by use of web reinforcement consisting of stirrups either vertically or inclined upward toward the support, rigidly attached to the horizontal bars and running to the top of the beam. The bent bars also provide this strengthening, which is necessary when the unit shearing stress (that is the load carried to the support divided by the cross-section of the beam above the horizontal steel), exceeds 40 pounds per square inch. In no case should this shear stress exceed 120 pounds per square inch in strengthened beam. The size of beam depends upon loading. A moment of 1/12WL must be provided for in continuous beams. W = total load on beam and L = span from clear to clear plus 1/2 of depth of beams. A non-continuous span must be a moment of 1/4WL. This resisting moment is calculated by multiplying the area of the steel by the unit stress and by a leverage (about the compression centre) of approximately 1/3 of the depth of the beam above the steel.

Slabs run between beams, and are designed upon the same principles as beams. Slabs have
spans from 4 to 20 feet. For usual loads a span of 8 feet between beams is economical.

Columns may be reinforced by from 1 to 4 per cent, longitudinal rods well tied together by $\frac{3}{4}$ and $\frac{3}{8}$ wire at distances not to exceed 10 times the diameter of the rod. There should be a bar in each wooden construction. A modern type, the so-called flat-slab floor, dispenses with all beams and girders, and uses a continuous flat slab of equal thickness throughout, supported on columns with flared heads. At times the slab thickness is increased around the columns, a so-called "dipped panel." The reinforcing consists of bands of small rods $\frac{3}{4}$-inch to $\frac{3}{8}$-inch diameter; in the 4-way system running diagonally between columns and also directly; in the 2-way system the rods run rectangularly at right angles to the sides of the panel and are spaced more closely near the column. The rods are bent up from the bottom of the slab to the top about the $\frac{3}{4}$ distance of the span to pass over the column in the 4-way, or over the column and the edge of the panel in the 2-way. Rods that are spliced should pass over to the third point of the adjoining panel. The flared head of the column should be 0.225 of the span between column centre, and the flare should be not more than 1/4 vertical. The slab thickness should be not less than 1/3 the span length. The greatest bending moment exists around the column heads. These flat slab buildings offer more favorable installation of sprinkling systems, spread light farther in the interior, provide a given head room with less height of building and offer economy in forms and in construction. The General Electric Company's factory building at Fort Wayne, Ind., has a "Corridor" flat slab floor with panels 25 feet by 25 feet. The slab is 13 inches thick at the centre and 23 inches thick at the columns. The expanded head of the column is 60 inches in diameter. For a live load of 400 pounds per square foot, the two-way reinforcement of the panel consists of $\frac{3}{4}$ corrugated bars spaced $\frac{3}{8}$ inches in the centre of the panel, then $\frac{3}{8}$-inch bars spaced $\frac{3}{2}$ inches, decreasing to $\frac{3}{4}$ inches spacing near the columns. The Soo Terminal at Chicago is an elevated railroad yard, 400 feet by 20 feet wide, and $\frac{3}{4}$ feet by 20 feet, carrying the heaviest engines. Columns 12 feet 10 inches high, spaced 24 feet square, are 32 inches in diameter, and flared out to a 5-foot 6-inch capital. The slab is 18 inches thick at centre and 30 inches thick for an area of 9 feet square, surrounding the columns. The reinforcement is 4-way, consisting of $\frac{3}{4}$-inch rods spaced $\frac{3}{2}$ inches. The structure is without expansion joints.

An excellent type of floor slab is composed of hollow tile spacers between reinforced concrete joists, giving a stiff, light flat ceiling that holds plaster well. Some buildings are constructed by erecting previously and separately molded elements as columns and slabs. Occasionally a light structural steel framework is erected and supports the forms. After the concrete is poured, the framework becomes the reinforcement.

Finish of concrete floors is similar to wearing surface in sidewalks. If a wood floor is desired, nailing strips of wood about 2 inches by 4 inches spaced 16 inches are laid on the rough slab and embedded in a lean cinder concrete. Linoleum may also be laid directly on a smooth, lightly regulated floor. Various special floor finishes have been devised.

Footings in uniform soils should be designed for equal soil pressure so that the settlement of the entire building shall be uniform to avoid cracks. Typical modern type, the so-called flat-slab floor, dispenses with all beams and girders, and uses a continuous flat slab of equal thickness throughout, supported on columns with flared heads. At times the slab thickness is increased around the columns, a so-called "dipped panel." The reinforcing consists of bands of small rods $\frac{3}{4}$-inch to $\frac{3}{8}$-inch diameter; in the 4-way system running diagonally between columns and also directly; in the 2-way system the rods run rectangularly at right angles to the sides of the panel and are spaced more closely near the column. The rods are bent up from the bottom of the slab to the top about the $\frac{3}{4}$ distance of the span to pass over the column in the 4-way, or over the column and the edge of the panel in the 2-way. Rods that are spliced should pass over to the third point of the adjoining panel. CONCRETE CONSTRUCTION 478

Concrete, two inches or more in thickness, is laid on wire cloth, attached to a mandrel; after rolling the wire cloth becomes a spiral in the pile, which is also wrapped around with wire. Separately molded piles are made under favorable conditions as to concrete. (See Piles.) In the McArthur construction a hole is driven to a firm stratum, and enlarged at the bottom by tamping.

Walls of concrete buildings are preferably of skeleton construction, with wall girders and columns, and curtain walls of concrete 6 inches thick, or of brick or tile. The surface is often veneered with brick, tile, marble, etc., which is tied on with metal ties, previously fixed in the concrete.

Stairs of concrete are reinforced as beams between floor and landings. For common spacings of about 6 feet from floor to landing, the steps are 5 inches thick from the re-entrant angle of tread to bottom, with 1/4-inch round rods 6-inch centres; at each floor is a girder about 10 inches by 15 inches deep and the landing is made of steel-reinforced concrete 6 inches thick, when the stairs are parallel; if at right angles, the landing is hung by rods to a girder above the stairway.

Windows of wire glass in metal frames, sliding or pivoted either horizontally or vertically, are a part of the complete equipment of a modern reinforced concrete building.

Partitions are of concrete 3 or 4 inches thick, slightly reinforced against shrinkage cracks; but metal lath and plaster terra cotta tile, or plaster lath partitions are more common. Metal lath and plaster partitions 4 inches to 6 inches thick have a framework of steel studding running between floors, upon which is fastened the metal lath, which is then plastered with a mixture of lime and cement mortar in three coats: the first and scratch coat with hair or fibre. The hollow space may be filled with cinder concrete. Metal lath of various commercial forms with integral projecting ribs need no separate studding. Plaster blocks made chiefly of gypsum, or plaster of Paris, with an admixed fibre are easy to handle and cut, but are not as fireproof as other forms.

Considerable ingenuity is shown in devising forms of light concrete beams, factory made, for floor systems of buildings.

Floor Loadings.—Concrete will spread heavy loads, on small areas, to adjoining portions not so heavily loaded and thus permits of partial overloads. Such loads are often loaded to as much as twice the design load, and therefore there should be conservative designs to begin with. As a test of workmanship it is common practice to load a simple panel or two adjoining panels with a test load equal to twice the design load plus once the dead load. Floor live loads per square foot to be provided for are: Boston practice: dwellings and apartment-houses and public hotels, 50 pounds; office floors, and for public rooms of apartment and public hotels, 100 pounds; floors of retail stores and public buildings, 125 pounds; schoolhouses, other than floors of assembly rooms, 80 pounds and for floors of assembly rooms, 125 pounds; drill rooms, dance halls and riding schools, 200 pounds; warehouses and storerooms, 225 pounds. Concrete floors are designed up to 1,000 pounds per square foot. Ordinarily the increase in loads to allow for impact is small in concrete structures, from 20 to 50 per cent of the live load in bridge floors, and none in arch rings or heavy members.

Reinforced concrete retaining walls appeared early in the art before 1894. In the L type the vertical stem which holds the transversely-acting earth pressure is a cantilever. There is also a cantilever transversely acting horizontal base, projecting back, acting upon which the weight of earth distributes the lateral pressure. This type is used up to heights of about 18 feet. Reinforcement runs vertically down the face of the vertical stem next to the earth, and is anchored in the base. Horizontal rods run on the upper side of the base (the heel) and are anchored in the vertical stem. The horizontal base may project in front of the wall to form a cantilever toe with rods in the bottom. Reinforcement in the exterior outward face of the vertical stem provides for shrinkage and expansion. Expansion joints may be provided. In excess of heights of about 18 feet, the counterfort type is used, in which the vertical stem and horizontal base are connected on the inside by counterfort walls. The vertical and horizontal elements now become slabs carrying earth pressure and weight to the counterforts which are designed as vertical cantilevers, and to which the slabs are well tied. Types of plain and reinforced concrete retaining walls merge into one other.

Abutments for bridges are similarly designed. Cellular construction in about the same manner and similar construction in reinforced concrete is a logical development, by which thin sections, properly reinforced, replace heavy masses.

Reinforced concrete dams have a sloping water tight reinforced concrete deck or slab supported on vertical concrete walls. The water pressure increases, instead of opposes, stability. The sloping deck may continue to rise over a crest and fall to an overfall slab sloping down stream. The two slabs are connected by vertical walls or buttresses. The deck slab is designed to carry the water pressure to the vertical walls. The Schuylerville, N. Y., dam is 250 feet long and 25 feet high. Vertical walls, 10 foot centres, 12 inches thick, support a deck tapering from 8 inches to 12 inches thick, while the overfall apron is 8 inches thick. A foot bridge passes under the dam, supported on the vertical walls. Such dams are commonly known as Amberson dams.

Open concrete reservoir walls are designed upon similar principles to those applied to retaining walls. Expansion joints and watertightness are important. There are lined with a concrete bottom 4 inches to 8 inches thick, preferably reinforced with a mesh of metal. Covered reservoirs have concrete bottoms carrying the upward pressure to columns that also support the concrete roof. Roof and bottom may be groined arches or slabs. Reservoirs of groined arches in the United States have spans from 10½ to 16 feet, a depth of from 1 foot 6 inches to 4 feet, and a crown thickness of 6 inches. Since the exterior walls are supported by the roof, thinner sections are needed than for open reservoirs. A circular reservoir wall supported on a spigot needs a ring of reinforcing at the top.

Reinforced concrete water tanks must be
constructed of impervious concrete, and are generally built in one operation of wet concrete. They should be reinforced, not only for mechanical stress, but for shrinkage. The thickness of the concrete is 8 inches high, and 4½ feet in diameter. The walls are 10 inches thick at the top. Rings of deformed round bars ¾-inch in diameter, are spaced 6 inches vertically in centre of wall, intersected by ¾-inch vertical rods, spaced 5 feet centres.

Examples of reinforced concrete stadia and grandstands are found at Harvard, Tacoma, Syracuse, Yale. These offer a suitable appearance, require no repairs and prevent accidents that arise from lack of maintenance of wooden structures. The following statistics show seating capacity of well-known stadia:

Stadia, Circus Maximus, Rome, estimated 380,000; Colosseum, Rome, estimated 45,000 to 100,000; Yale Bowl, 125,000; Athens Stadium, 50,000; College of City of New York, 10,000; Syracuse, 20,000; Tacoma, 20,000; Harvard, 43, which are at 30 feet, 10,000; and Princeton, 11,500. Construction cost per seat ranges from $36 for the stadium of the City of New York, $8.50 for the Princeton Stadium to $7.35 for the Yale Bowl.

Grain and ore bins, coal pockets are other considerations that are common.

W. K. HATT,
Professor of Civil Engineering, Purdue University.

CONCRETE MACHINE MIXERS. Machine mixers used in the United States may be grouped into three classes: (1) continuous; (2) batch and (3) gravity mixers. The continuous mixer usually consists of a central shaft, to which are attached arms or paddles, rotating in a long trough. The paddles are set at such an angle that they have an endless screw action, cutting and pushing the materials down toward the lower end of the trough, out of which a continuous stream of concrete flows. Two types of machines are used—one in which the materials are thrown into the trough by men standing at the sides of the machine, part shoveling sand and part stone, another in which the materials are placed in hoppers at the head of the trough and measured automatically. Batch mixers are divided into cube mixers, the double cone or Smith mixer and the Ransome or drum mixer. In operation the batch mixer is turned 10 or 15 times or more after charging and then the materials are discharged. The gravity type the falling materials strike baffle plates, which throw them together in their descent through the machine. The materials are measured in layers on a platform above the machine, and then shovelled into it.

CONCRETE SHIPS. For vessels of moderate size, reinforced concrete has taken its place as a real shipbuilding material. It possesses obvious advantages for the building of many useful types of craft. Among its recommendations are simplicity and rapidity of construction, the readiness with which repairs can be executed, high resistance to strain and shock, incombustibility and fire-resistance, relatively low cost and the virtual elimination of maintenance charges. Experience appears to show that the skin-resistance of a reinforced concrete vessel to passage through water is slight, owing to the smoothness of the surface and the absence of joints, and the ease with which scraping can be effected.

Reinforced concrete lends itself to the most modern developments in shipbuilding design, and although the skin of the hull must necessarily be thicker than when steel plates are used, it need scarcely be thicker than would be the case if timber were employed. Assuming three inches to be the thickness adopted, the weight per square foot would be less than that of steel one inch thick. Therefore the question of dead-weight does not appear to constitute a very serious objection, especially in view of the fact that the weight of the hull of a vessel is small in comparison with the weight of equipment, fittings and cargo.

After America’s entry into the war in April 1917, the pressing need for ships and the existing congestion in American shipyards led to the consideration of utilizing other materials than wood and steel for shipbuilding. The most promising alternative was found to be reinforced concrete. Its application to the construction of ships was at once studied intensely by prominent engineers of Britain and America. Fortunately valuable pioneer work in this field had been proceeding successfully for a decade or more and showed the way along which successful development was possible.

History.—The first example of what we know as reinforced concrete was a rowboat built in 1849 by M. Lambot, of Carces, France. The process of construction was patented and M. Lambot exhibited his work at the Paris Exposition of 1855. The French government investigated the work of M. Lambot in 1850, but, as usual, further development was left to private initiative. In 1899, Carlo Gabellini, of Rome, Italy, began the construction of concrete scows and barges. His process was developed by 1905 that a 150-ton barge was constructed for the city of Civita Vecchia. The following year another barge was built for the military harbor at Spezia, for the use of the Italian navy. This latter barge before acceptance was put to the severe test of being driven against some piling and afterward being rammed by a steel towboat. Results of these tests were so satisfactory that construction of similar boats and barges followed.

Methods of Construction.—In the Gabellini method the first step in laying down the vessels consists of placing reinforcement for the keel and ribs. This reinforcement, which usually consists of round steel rods, is then covered on the outside with water-resistant mesh, to which a 1-inch coat of cement mortar is applied by hand. Next a somewhat thinner coat of mortar is placed on the inside, following which forms for the ribs and keel are put in place and the concrete is poured. The ribs run both longitudinally and transversely so that a checkerboard arrangement results, the pockets being 10 inches deep and the ribs about 2 inches wide. Over
CONCRETE CARGO STEAMSHIP "FAITH" ARRIVING IN SEATTLE AFTER HER MAIDEN VOYAGE FROM SAN FRANCISCO

The "Faith" is the first and the largest concrete ship built in America.
CONCRETION—CONCUBINAGE

these ribs ½-inch wire mesh is placed with a thin mortar covering plastered on. Finally a third ½-inch wire mesh is pressed into the soft mortar and the entire surface towed over. This completes the hull. Bulkheads are next concreted and the boat finished with a wooden sheer strake and gunwale.

The first concrete boat in Holland was built in 1887 by the Fabriec van Centemijzer Werken. This firm first built barges up to 11 tons capacity, which proved so successful that plans were elaborated resulting in the building of barges 64 feet long and 14 feet beam, of 55 tons capacity. Briefly, the system of construction consisted of building longitudinal and transverse bulkheads spaced approximately on 6-foot centres, thus providing a cellular construction, which made the ship practically unsinkable. German shipbuilders, in 1909, at Frankfort-on-the-Main, constructed a concrete freighter of 220 tons. Simple forms were set up and concrete placed between them. A concrete sailboat was built in 1912 by Johannes Lescher of Dessau. He embodied the latest principles of sailing vessel construction as to shape of hull, etc. In 1914 the Sydney Harbor Trust had constructed a pontoon of reinforced concrete for use in Sydney Harbor, N. S. W. It is 110 feet long, 33 feet 3 inches wide at the bow, 67 feet 7 inches at the stern, has a draft of 7 feet 9 inches and deck area of 6,000 square feet. The total displacement is 783 tons. Concrete barges have been in use for some years on the Manchester Ship Canal, and one on the Welshland Canal has successfully withstood very severe tests since its installation in 1910. Concrete barges built on the Panama Canal in 1911 proved good examples of what service such barges could render under adverse conditions. In this case concrete was selected as the construction material because no skilled labor for steel or wood ship construction was available, nor could steel plates nor suitable seasoned timber be obtained within the time required. Concreting materials were at hand in large quantity and the expediency of using concrete suggested itself as a happy solution of the problem. Concrete barges have been constructed also and placed in successful operation at Baltimore Md. and Mobile, Ala.

In 1917 a concrete lighter was built at Porsgrund, Norway, and its success led to the construction of larger ships at the same plant. In the same year a 500-ton concrete motorship was built in England for coastwise and channel traffic. At the end of the first half of 1917, 20 or more barges and ships of similar type were in use on the Paris ship canal. Canada came forward in the same year with a concrete ship proposed for lake traffic. A concrete ship approximating 3,000 tons was built for trans-Pacific service at Redwood City, Calif., in 1917, and a New York company in the same year built a 700-ton concrete barge, and in 1918 had contracts in hand and work progressing on a number of vessels. Norway came to the forefront in this field in 1917 in the numbers of concrete barges, lighters and ships varying from 200 tons up to 3,000 tons, launched. Some of these are in ocean traffic between Norway and Russia. The year 1918 saw rapid advances in the construction of concrete ships, due to the great necessity of overcoming the losses in merchant tonnage through Germany's submarine warfare. This development has been chronicled in the daily press and in the periodicals of the trade. Concrete and Concrete Ships' (issued by the Portland Cement Association, Chicago 1918), from which the foregoing account has been compiled; Concrete and Constructional Engineering (Vols. XI, XI, XII, London 1916-18); Modern Marine (Cleveland, August 1917); Scientific American (28 July 1917; 17 Nov. 1917); Shipping Illustrated (New York, 23 June 1914; 18 Aug. 1917; 29 Sept. 1917; 20 Oct. 1917); The London Times (Engineering Supplement, 25 May 1917).

CONCRETION (the act of growing together), the act of becoming united into one mass. (1) In a restricted sense the term is used to signify a solid mass, a clot or a lump formed by a process of growing together, as in animal economy, the hard substances that occasionally make their appearance in different parts of the body, as well as in the solids as in those cavities destined to contain fluids; in the former case they are denominated concretions or ossifications; in the latter, calculi. The concretions are named from the parts of the body in which they occur. Fecal concretions or stones, their being found in that part of the brain called the pineal gland, consist of carbonate and phosphate of calcium with organic matter; salivary concretions, as being discovered occasionally in the salivary glands, also consist mainly of earthy phosphates; pancreatic concretions are hard substances found in the pancreas; pulmonary concretions, which have been sometimes coughed up by consumptive persons, contain mucus and albumen in addition to the salts; hepatic concretions, of which the liver is sometimes full, are composed chiefly of cholesterol, mucus and coloring matter; urinary concretions are found in the bladder, and their constituents are very variable, uric acid, urates, fibrin, oxalates, phosphates and several other bodies being found. Gouty concretions consist of urate of sodium and small quantities of other salts with organic matter. Concretions have been discovered in the intestines and stomach of plants, but more frequently in the bocies of other animals. Those found in the intestines of a horse were examined by Fourcroy, and found to consist of magnesia, phosphoric acid, ammonia, water and animal matter. (See CALCULUS). (2) In geology concretion signifies an aggregation of mineral matter, in concentric layers and cast in a spherical form which is frequently flattened. (3) In logic concretion is the act of rendering a concept more determinate or definite.

CONCRETIONS, masses of mineral matter, sometimes arranged in concentric layers, sometimes with a radiating structure, sometimes almost structureless, which have been built up particle by particle by circulating waters within the mass of another rock. Most concretions are circular or nearly so, but some are long and others occur in irregular shapes. Concretions of flint are common in limestone, and concretionary masses of iron pyrites frequently occur in coal. They vary greatly in size ranging from a fraction of an inch to several feet.

CONCUBINAGE, the act or practice of cohabiting without a legal marriage; the state of being a concubine; a natural marriage as distinguished from a legal marriage. Among
the Greeks concubinage was allowed even to married men; the number of their concubines, also, was unlimited. Among the Romans concubinage was neither unlawful nor disgraceful. It was, moreover, formally permitted to unmarried men by the Lex Julia, and by the Lex Papia Poppea, but with the provision that it should be limited to a single concubine, and that only women of mean descent, as freed women, actresses and the like, should be chosen for the purpose. The children begotten in concubinage were not considered as legitimate, but were called natural, and the right of inheritance of the concubine and her children was very much limited. With the introduction of Christianity concubinage ceased; and, indeed, Constantine the Great made laws intended to put a stop to it. Concubinage also signifies a marriage with a woman of inferior condition, to whom the husband does not convey his rank. By French law the presence of a concubine in the house entitles the wife to a divorce. See MARRIAGE.

CONCURRENT JURISDICTION, the jurisdiction of different courts authorized to take cognizance of the same case. In certain cases the court which first takes up a case has what is called the right of prevention, that is, the right of deciding upon that case exclusive of the other courts, which but for that right would have been equally entitled to take cognizance of it. In civil cases it lies with the suitor to bring his cause before any court he pleases, which is competent to take it up. Concurrent, also called cumulative, jurisdiction is opposed to priori jurisdiction. Where concurrent jurisdiction exists in the United States courts a decision of a State court may be taken up to the Supreme Court for review.

CONCUSSION OF THE BRAIN, a term applied to certain injuries of the brain resulting from blows and falls, though unattended with fracture of the skull. Stupor or insensibility, sickness, impeded respiration and irregular pulse are the first symptoms, and though these may subside there is always for a time more or less risk of serious inflammation of the brain setting in. Although all the conditions attending concussion of the brain have been carefully studied experimentally yet authorities disagree as to the causes which induce it. These causes have been variously stated as laceration of minute blood vessels, molecular changes in the brain cells or changes in the cerebrospinal fluid. The patient should be put to bed at once with the head low, and kept warm; but stimulants should, except in special cases, be withheld. All excitement should be avoided, and for some time after apparent recovery great care is necessary.

CONDÉ, kōndā, the name of a French family, the younger branch of the Bourbons, who took their name from the town of Condé, department of Nord. One Godfrey de Condé, about 1200, was in possession of a part of the barony of Condé. His great-granddaughter, Jeanne de Condé, married, in 1335, Jacques de Bourbon, Comte de la Marche, and the barony of Condé went to their second son, Louis de Bourbon, Comte de Vendôme, whose great-grandson, Louis de Bourbon, Prince of Condé, in virtue of his blood-relationship to the royal family, assumed the title of Prince, and is regarded as the founder of the new house of this name.

CONDÉ, Henri (ōn-rē) II de Bourbon, Prince de: b. 1558; d. 1646. At the request of Henry IV he became a Catholic. In 1616 he was sent to the Bastille, where he remained for three years. After the death of Louis XIII the prince was liberated, and was made Minister of State to the regent.

CONDÉ, Louis (lōo-ē) I de Bourbon, boor bôn, Prince de, French general: b. Vendôme, 7 May 1530; d. 15 May 1599. He married the granddaughter of the Constable de Montmorenci. He served his early campaigns in Piedmont, but first distinguished himself at the defense of Metz, besieged by Charles V in 1552. Affronted at court, and hated by the Guises, he joined his brother, the king of Navarre, at Nérac, and joined the Huguenots in 1559. In 1560 he took part in the Amboise conspiracy to overthrow the Guises. He was arrested and sentenced to death, but was discharged after the death of Francis I and was made governor of Picardy through the influence of Catherine de Medici (q.v.) who was then in France. He soon after appeared as head of the Protestants, and was defeated and captured at the battle of Dreux, 1562. After being over a year in prison he was liberated, and for four years he kept the peace but fresh persecution of the Huguenots called him to arms again. In 1567 he fought the battle of Saint Denis without decisive result. Two years later the Protestants were defeated, and Condé was taken prisoner, badly wounded, at the battle of Jarnac, 13 March 1569. He was almost immediately assassinated by Captain Montesquiou, a Swiss soldier who was probably acting under orders from the Duke of Anjou. See COLIGNY, GASPARD DE.

CONDÉ, Louis II de Bourbon, Paris; or, French general: b. Paris, 8 Sept. 1621; d. near Fontainebleau, 11 Dec. 1666. He was the son of Henri II, Prince de Condé (q.v.) and during the life of his father bore the title of Duc d'Enghien. He immortalized this name in the battle of Rocroi, in which the aged 62, he defeated the Spaniards (1643). The same year he was sent to Alsace to help Turenne. Wherever he appeared he was victorious. He besieged Dunkirk in sight of the Spanish army, and gained this plagues for France in 1646. The death of his father in this year made him head of the Condé family with all its vast wealth and extensive estates; so that there were in the kingdom only the king himself and the Condés who were more important personages than he. He was given command of the army in the Netherlands and appointed captain-general of the French forces. A great victory at Leas in 1648 won him a wonderful reputation. During the troubles of the Fronde he at first took the side of the court against the Parliament and the nobles, and after a siege of a few months brought back the young Louis XIV to Paris (1649); but believing himself ill requited by Mazarin, and having himself the head of the faction of the Petits Maîtres. Being captured, however, he was imprisoned by Mazarin (1650), and was not released till after the lapse of a year. He at once put himself at the head of a new Fronde, and entered upon
negotiations with Spain. In spite of several checks he then marched upon Paris, where he was met and defeated in the suburb Saint Antoine (1652). The battle which ensued was indecisive; and Condé, finding himself abandoned by many of his friends, retired to the Netherlands, and joined the Spaniards, who appointed him generalissimo of the Spanish army. He was defeated in the battle of Dukenburg (1653), but was restored to royal favor by the Peace of the Pyrenees in 1659. In 1668 he was charged with the reduction of Franche Comté (then belonging to Spain), which he accomplished in three weeks; and in 1674, at the head of an army sent by Louis XIV against the United Provinces, defeated the Prince of Orange (afterward William III of England) at Senec. He was unequal, however, to take advantage of this victory, as he was obliged to withdraw into Alsace to defend it against Montecuccoli, to whom it was thrown open by the death of Turenne in 1675. He succeeded in driving Montecuccoli across the Rhine. This was his last triumph. For years after this he engaged in business in the low countries and in Paris, where he devoted himself to the sciences.

**Conde, Louis Joseph de Bourbon, Prince of: b. Chantilly, 9 Aug. 1736; d. Paris, 13 May 1818.** In the Seven Years' War he distinguished himself by his courage and skill, and at the outbreak of the Revolution he sided with the monarchy and afterward formed in 1792, at Worms, a little corps of emigrant nobility, which joined the Austrian army under Wurmeser. In 1795 he entered with his corps into the English service. In 1797 he entered the Russian service, but in 1800, after the separation of Russia from the coalition, re-entered the English service. The campaign of 1800 ended the military career of the prince. He returned to Paris in 1814; where, being appointed president of a bureau of the Chamber of Peers, he remained some time, but at last retired to Chantilly. He published "Essai sur la Vie du Grand Condé, par L. J. de Bourbon, son 4me Descendant" (1800).

**CondeLL, künd dēl, Henry, English actor:** d. was last seen in Dubarry's agitation. With John Heming he edited the famous first edition of Shakespeare's plays, 1623. He belonged, as did Shakespeare, to the lord chamberlain's company of players and is named in Shakespeare's will.

**Condensation,** the reduction of anything to another and denser form, as of a vapor or gas to a liquid, or a liquid to a solid; the passage of gases or vapors from the ærial form to the liquid state. It is sometimes called also the liquefaction of vapors. It may be due to one of three causes: cooling, compression or chemical affinity. Before the first or second of these causes can operate, the vapor must be saturated. Various salts also condense vapors by means of chemical affinity. When vapors are condensed their latent heat becomes latent. The latent heat of condensation of liquids is the reduction of a liquid to smaller bulk, with a proportionate increase in the specific gravity.

**Condensed Milk** as generally manufactured and sold fresh daily for delivery to consumers is milk reduced in volume by the evaporation of water in vacuum. No other constituent part of the milk is removed. This article is not put up in hermetically sealed cans nor intended for long-distance shipments.

**Sweetened condensed milk** is the product resulting from the evaporation of a considerable portion of water from milk to which sugar (sucrose) has been added for the purpose of preservation. It contains not less than 28 per cent of milk solids and not less than 8 per cent of milk fat.

**Sweetened condensed skimmed milk** is the product resulting from the evaporation of a considerable portion of the water from milk from which the greater part of the milk fat has been removed to which sugar (sucrose) has been added for the purpose of preservation. It contains not less than 28 per cent of milk solids.

**Evaporated milk** is the product resulting from the evaporation of a considerable portion of the water from milk and contains not less than 25.5 per cent of milk solids and not less than 7.8 per cent of milk fat.

**Evaporated skimmed milk** is the product resulting from the evaporation of a considerable portion of the water from milk from which the greater part of the milk fat has been removed. It contains not less than 22.5 per cent of milk solids.

**Early Experiments.**—The first application of a practical process for condensing milk was made by Gail Borden, who was born in Norwich, N. Y., in 1801, and at the time of his experiments a resident of New York, through his adaptation of the vacuum evaporating process on original lines. Most of the earlier experiments of previous investigators were what might be called "open process." The earliest known patents for reducing the volume of milk or attempting to preserve it are the following:

- Newton, 1835.—For evaporating in "any known mode" alludes to the vacuum pan as affording a good method of introducing warm air through the milk.
- De Lignac, 1847.—Evaporating in large, flat, shallow pans, heated by steam bath to 190° F., product put in tins, sealed and again heated to 210° F.
- Grimwade, 1847.—Preserving milk by "the mixing of saltpetre with the milk, and then exposing it to heat in a vacuo, so as to evaporate and extract the aqueous particles thereof" and then enclosing "in bottles from which the air has been previously exhausted." Never put in practice.
- Louis, 1848.—Evaporating in shallow pans, with steam jacket, etc.
- Grimwade, 1855.—Carbonate of soda or potash is first added and the milk then evaporated in pans with agitation until a doughlike substance is obtained, sugar is then added, and the mass pressed by rollers into ribbons, further dried and then pulverized. Practised for some years.
- Cook, 1853.—Evaporating in steam evaporating pans.
- Borden, 1856.—In vacuo, put into successful practice and has superseded all others.
- House, 1857.—Substantially like De Lignac's, except evaporating at lower temperature.

Gail Borden's experiments began shortly after 1851 and his first application for a United States patent was made in 1853 which was at first rejected on the ground that it lacked novelty and usefulness. The patent, however (No. 15,553), was granted 19 Aug. 1856, on the following claim:

**Producing concentrated sweet milk by evaporation in vacuo, substantially as set forth, the same having no sugar or other foreign matter mixed with it.**

This was followed by other patents: No. 1,306 dated 13 Mar. 1862; No. 1,389 dated 10 Feb. 1863; No. 2,105 dated 14 Nov. 1865; No. 2,226 dated 17 April 1866.
Every feature of Borden’s various claims as well as the state of the art was carefully and thoroughly investigated by the patent office examiners.

**Necessary Sanitary Regulations.**—Experience covering a period of over half a century establishes the fact that the sanitary precautions surrounding the manufacture of condensed milk, evaporated milk, etc., are the most stringent, and necessarily so, because the safety of the business depends upon thoroughness. Not only are the cattle inspected by competent veterinaries, but rules and regulations of the strictest kind provide for the cleanliness of these cattle, proper feeding of wholesome, non-fermenting foods, cleanliness of stables, the isolation of the milk room, cooling facilities, in fact every well-tested plan that facilitates the production of pure rich milk handled in the most cleanly manner. While seemingly these rigid requirements involve some extra expense on the part of the dairyman, he is more than compensated by having a steady, firm market for his product at better prices than he can get anywhere else. The consumer is benefited by obtaining a pure and uncontaminated product at a most reasonable price. There are of course, concerns in the business whose facilities and experience do not enable them to perform all this and who give the public cause for concern, which have been established for many years.

The receiving platform is an interesting sight, for as the farmers deliver their cans of milk, each is examined by a trained inspector and tested. If it is not found to be up to the standard of the company, it is rejected. From the receiving room, the milk is drawn into what is called the “well room” where preliminary heating is effected in specially designed heating wells. If sweetened condensed milk is to be made, the necessary amount of sugar is dissolved in the milk at this point. The mixture is then drawn to the vacuum pan where the condensing process takes place in accordance with formula as to temperature, vacuum, etc., as found to be most satisfactory. The mixture is thus best qualified for making the highest grades. The concentration is continued until the density indicates the milk to be of the desired composition. It is then drawn from the vacuum pan and cooled to the proper temperature for canning, before being conveyed to the sealing room. In the case of sweetened condensed milk, the product is supplied to the filling machines which automatically deliver the exact quantity desired into the cans. These are in turn capped, sealed and labeled by machines, and are then packed in cases for transfer to the warehouse where they await shipment. If the product made, however, is evaporated milk, it is conveyed to the processing room, where the necessary sterilizing of the sealed package is performed in large steam retorts. After the cans have been cooled, they are packed in cases and sent to the storage room.

A condensed milk plant properly operated buys its supplies in large quantities; milk-sugar, tin cans or tin plate for making its cans (a factory sometimes containing a complete can-making tin-shop); lumber in shooks for making boxes; so that nearly all the work incidental to completing the product is done in the fac-

tory. Such a plant represents a large investment.

**Chemical Analysis.**—As condensed milk forms such a very large and important item of food, especially for the infant, it is proper in this article to incorporate information on the question of analysis that the public may be correctly informed on the subject. For some years past, the methods for the analysis of condensed and evaporated milk products have been very unsatisfactory. Unless operated by analysts of considerable experience, the results were inclined to be decidedly misleading. It is a matter of record that many chemists have erroneously reported samples of superior brands of milk as skimmed or partly skimmed, when in reality, the error was solely in the work of the analyst.

In order to clarify this situation, the Milk Section of the National Canners Association appointed a committee to develop a method of analysis which would prove satisfactory to both the milk trade and the Federal authorities. After an exhaustive survey, the Rose-Gottlieb method was finally selected as being the most accurate and reliable one available. At the same time, collaborative studies were being conducted by the Association of Official Agricultural Chemists for the purpose of finding a method which would give consistent results in the hands of any competent analyst. As a result of this work, this organization adopted the Rose-Gottlieb method at its last meeting. In order, therefore, to secure official recognition, all analyses of condensed and evaporated milk products should be guided by the above recommendation. The fact that such a satisfactory method is now in use should do much to prevent such unfortunate misrepresentations as have occurred in the past.

**Food Value.**—An analysis of condensed milk (preserved) of high average quality would be about as follows:

<table>
<thead>
<tr>
<th>Component</th>
<th>Per cent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fat</td>
<td>8.10</td>
</tr>
<tr>
<td>Protein</td>
<td>8.18</td>
</tr>
<tr>
<td>Cane sugar</td>
<td>8.18</td>
</tr>
<tr>
<td>Milk sugar</td>
<td>10.39</td>
</tr>
<tr>
<td>Ash</td>
<td>0.80</td>
</tr>
<tr>
<td>Water</td>
<td>27.72</td>
</tr>
</tbody>
</table>

The following analysis is representative of the evaporated milk now sold on the market:

<table>
<thead>
<tr>
<th>Component</th>
<th>Per cent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fat</td>
<td>9.30</td>
</tr>
<tr>
<td>Protein</td>
<td>10.39</td>
</tr>
<tr>
<td>Cane sugar</td>
<td>10.39</td>
</tr>
<tr>
<td>Milk sugar</td>
<td>7.12</td>
</tr>
<tr>
<td>Ash</td>
<td>1.31</td>
</tr>
<tr>
<td>Water</td>
<td>72.98</td>
</tr>
</tbody>
</table>

Of all the foods available to the public, it is doubtful if any rank as high in purity, keeping quality and uniformity. For infant feeding, household uses, for supplying the army and navy, shipping trade, exploring parties or pioneer life, no food article prepared has greater value.

A. W. Milburn,
President Borden’s Condensed Milk Company.

**CONDENSER.** One who or the thing which condenses. Some of the methods in general use are:

**Steam-engine.**—An apparatus for reducing to a liquid form the steam in front of the piston, so as to obtain a partial vacuum at that point, and thus utilize the natural pressure of the atmosphere. Watt invented the injection condenser and the separate condenser. The surface condenser has a series of flat chambers or tubes, usually the latter, in which the steam
is cooled by a body of water surrounding the tubes.

In the jet condenser the steam and water meet in an air-tight chamber. A modified form of the jet condenser, known as the siphon condenser, is used in distilling. Distilled water for ships' use is obtained by the condensation of steam in a surface condenser. Condensers are always employed on ocean-going steamships, never on locomotives. Elsewhere the practice varies.

Distilling.—The still-condenser is an apparatus generally made of the worm-tube form; the coil containing the alcoholic vapor traversing a tube which receives a constant accession of cold water, condensing the vapor in the coil. The liquid escapes at a cock valve below.

Metal.—An apartment in which metallic or deleterious gaseous fumes are condensed to prevent their escape into, and contamination of, the atmosphere. The device consists of a prolonged duct for the fumes, with showers of water to condense the arsenical, sulphurous and other volatile matters. It also serves an economical purpose in saving gaseous fumes of lead, zinc, mercury, sulphur, antimony and similar metals.

Electricity.—An instrument for concentrating electricity by the effect of induction. It usually consists of confolded sheets of tinfoil, whose layers are separated by a thin sheet having the conducting surface.

Other forms are the Leyden Jar, and the variable condensers made of metal sheets which can be moved in and out through an air gap, that are used in wireless telegraphy and for other similar purposes. With induction apparatus, a condenser may be used as a device for absorption or suppression of the extra current induced by the rapid breaks in the main current. See ELECTRICITY; INDUCTION.

CONDENSING AND NON-CONDENSING ENGINES. See STEAM-ENGINES.

CONDER, Claude Reignier, English army officer, b. 1754; d. 1810. He was educated at University College, London, and entered the Royal Engineers. He was chief of the Palestine survey in 1872-78 and in 1881-82. Later he served in Egypt and Bechuanaland and in 1884-91 as surveyor and director of the Ordnance Survey headquarters on the Transvaal border. In 1895 he was engaged in relief work in Ireland and served on the Irish Ordnance Survey from 1900 to 1905. He wrote much on the topography and archaeology of Palestine. His published works include 'Tent Work in Palestine' (1878); 'Judas Maccabeus' (1883); 'Heth and Moab' (1883); 'Memoirs of the Palestine Survey' (1883; 1890); 'Primer of Bible Geography' (1889); 'Palestine' (1891); translation of the Peshitta (1894); 'The Latin Kingdom of Jerusalem' (1897); 'The Hittites and their Language' (1898); 'The Rise of Man' (1908); 'The City of Jerusalem' (1909). He was also a contributor to Smith's 'Bible Dictionary' and made a series of illustrations for Bunyan's 'Pilgrim's Progress' in 1869 and made illustrations and maps for his own books.

CONDER, Josiah, Anglo-Japanese architect: b. London, 28 Sept. 1852. He was educated at the Bedford Commercial School (now the Modern School). He studied at the South Kensington Art Schools and Slade Life Classes at University College. He became architectural assistant to the late William Burges and became a student of the Royal Institute of British Architects. In 1876 he was engaged by the Diet of Japan as architect to the Imperial Japanese Engineering College, Tokio, and as architect of the Public Works Department. He designed and erected many government buildings and private buildings in Tokio. He was a professor of architecture at the Imperial Tokio University. In 1884 he received the fourth class decoration of the 'Rising Sun' and in 1894 the third class of the Sacred Treasure. He is now retired and receives a life pension from the Japanese government, still retaining the position of honorary adviser in architecture to the Home Office and engages also in private practice. His publications include 'The Floral Art of Japan'; 'Landscape Gardening in Japan'; 'Notes on Japanese Architecture'; 'Paintings and Studies by Kawanabe Kyosai.'

CONDILLAC, kôn-dé-yâk, Étienne Bonnot de Mably de, French philosopher: b. Grenoble, 30 Sept. 1715; d. Beaugency, 3 Aug. 1780. He founded an international reputation on 'The Essay on the Origin of Human Knowledge (or Sense Perceptions)' (1746); duly succeeded by the celebrated 'Treatise on the Sensations' (1754), the central standpoint of these and other works being what is, philosophically speaking, sensationalism; a belief, that is, that what we know we know only through the senses, and hence our ideas of deity, love, the soul, etc., are largely modified forms of the objects that impress us in our daily material experience. These standpoints were practically those of French philosophy till the advent of Cousin. Among his other works are 'Traite des Sensations' (1755); 'Cours d'Etudes' (1755); 'Le Commerce et le Gouvernement Considerés Relativement l'un à l'autre' (1776); 'La Logique' (1781); 'Langue des Calcus' (1798).

CONDIMENTS, substances employed at table for the purpose of imparting a flavor to or seasoning ordinary foods. The principal condiments are common salt, butter, oil, vinegar, sugar, honey, mustards, spices, pickles, etc. These not only are pleasing to the appetite but also supply various wants of the system, many of them being necessary to the proper functioning of the alimentary system.

CONDITION, in law a statement of terms, a provision or stipulation, as in a contract, by which the parties thereto consent to be bound; or an undertaking to do something, pay money or other consideration, etc., as a proviso in an agreement by which the other parties thereto bind themselves to perform some act in return. Conditions must be made at the time of the original conveyance or contract, but may be by a separate instrument, which is then considered as constituting one transaction with the original. Unlawful conditions are void. Conditions in restraint of marriage generally are held void; but this is not the case of restraining from marriage to a particular person, or restraining a widow from a second marriage. A condition in general restraint of alienation is void, but a condition restraining alienation for a limited time is good. Where
CONDITIONAL IMMORTALITY — CONDITIONED

land is devised, there need be no limitation over to make the condition good, but where the subject of the devise is personality without a limitation over, the condition, if subsequent, is held to be in terrorem merely, and void. But if there be a limitation over, a non-compliance with the condition devalues the bequest. A limitation over must be to persons who could not take advantage of a breach. Performance should be complete and effectual. An insconsiderable casual failure to perform is not non- performance. Any rule that has an innate test in the estate may perform the condition, but a stranger gets no benefit by performing it. Conditions precedent, if annexed to land, are to be strictly performed, even when affecting marriage. Conditions precedent can generally be entirely performed, and usually at any rate equity will not interfere to avoid the consequences of non-performance.

The word "condition" also means the situation of every person in some one of the different classes of persons within the general order of society and allot to each person therein a distinct separate rank. For instance, at common law, a person under 21 is an infant, with certain disabilities and privileges. Every rule is presumed to know the condition of the person with whom he deals.

CONDITIONAL IMMORTALITY, a tenet held by a theological school which denies the inherent immortality of the soul, and the consequent doctrines both of eternal misery and of Universalism as contrary to the teachings of nature and of revelation. Its advocates maintain that the Bible sets immortality before men as something to be sought after (Rom. ii. 7), as a divine gift offered on certain conditions (Rom. vi. 23; John iii. 15, 16), and as a matter of hope and promise in the present life (Titus i. 2); that this immortality is not a present possession (Mark x. 30), and is to be realized by the assumption of a spiritual body at the resurrection of regenerate men from the dead (Luke xx. 35, 36), an event synchronous with the second coming of Christ (1 Cor. xv. 51, 52). Divine testimony, no less than experience, they say, declares unequivocably that man has the same natural life as all other animals (Eccles. iii. 19), and only those who by faith and obedience are united to Christ have the promise of immortality. The Calvinistic doctrine of eternal misery is untenable, the punishment of sin being death or everlasting destruction, to be inflicted subsequent to a judgment after the Lord returns (2 Thess. i. 9, 10). The dogma of Universalism, the only alternative to endless torment if the soul must live forever, is also, they maintain, unfounded, since the punishment of sin (death) is said to be everlasting, like the life which is the reward of the righteous (Matt. xxv. 46). The Conditional Immortality Mission began in Great Britain in 1878. It has an organ The Bible Standard, published monthly by the secretary. Churches have been established in the United States.

CONDITIONAL LIMITATION. (1) A condition providing for the determination of an interest in land upon the happening of a particular contingency. It is a present interest only, lasting until terminated by the happening of the contingency, and is synonymous with a limited or qualified fee, such as a grant of an estate in land so long as the grantee shall remain unmarried or while any of his children are minors. At common law a contingent interest formerly remained in the grantor of such an estate, and upon the happening of the contingency the property reverted to the grantor or his heirs. This rule was abolished in England by statute late in the 13th century, thus making such an estate an absolute fee, but in many States of this country it has been held that the old rule that the estate determined only upon breach of a condition, as where land is devised to A while he remains in a given city or State, and if he fails to do so, the property to vest in B conditionally. Upon the happening of the prescribed contingency, the estate first limited comes to an end, and the subsequent estate arises. . . . A conditional limitation is therefore of a mixed nature, partaking both of a condition and of a limitation: of a condition because it defeats the estate previously limited; and of a limitation because, upon the happening of the contingency, the estate passes to the person having the next expectant interest, without entry or claim. 63 Am. Dec. 725 (at 727). This form of estate is common both in Great Britain and the United States.

CONDITIONED, Philosophy of the, or Philosophy of the Unconditioned. The name given by Sir William Hamilton to certain philosophical views first promulgated by him in an article contributed to the Edinburgh Review, in October 1829, forming a critique on Victor Cousin's philosophy, especially of his doctrine of an absolute cause. The Unconditioned is regarded by Sir William Hamilton as a genus including two species: the Infinite, or the unconditionally unlimited, and the Absolute, or the unconditionally limited; and the thesis which he maintains and expounds in the essay referred to, and which forms one of the leading doctrines of his philosophical system, is that the Unconditioned, as thus explained, is entirely unthinkable. In his mind can conceive, and consequently can know only the limited, and the conditionally limited.

. . . . Conditional limitation is the fundamental law of the possibility of thought.8 This he illustrates by stating that we can neither conceive an absolute whole, the whole infinite, so great that we cannot conceive it also as a part of a still greater whole; nor an absolute part, that is, a part so small that we cannot conceive it as a relative whole, divisible into still smaller parts. And this he declares to hold good as to
space, time and degree. "The Conditioned,"
he goes on to say, "is the mean between two
extremes — two unconditionates, exclusive of
each other, neither of which can be conceived
as possible, but of which, on the principles of
common sense, either simple or positive. It
represents no object to the thought, and can afford
no real knowledge. From this, however, we
are only to learn that our faculties are weak,
and that hence we have no right to constitute
our capacity of thought into the measure of
existence. Although then we are unable to
conceive anything above the relative and finite,
it is quite competent to us to believe in the
existence of something unconditioned beyond
the sphere of all that is conceivable by us. This
doctrine was adopted by Mansel, dean of Saint
Paul's, and applied by him to determine the
limits of religious thought. It was combated by
John Stuart Mill. Consult Hamilton, 'Discus-
sions on Philosophy' (1852); Mill, 'Examination of Sir William Hamilton's
Philosophy' (1865); Mansel, 'Limits of Reli-
rigious Thought' (3d ed., 1870).

CONDOM, kŏn-dŏn, town in southeast
France, in the department of Gers, on the Baise
River, which is here crossed by two stone
bridges, 23 miles northwest of Auch. It con-
tains an ancient church, a Gothic edifice of the
16th century, and in the outskirts are a number of
handsome villas. The manufactures are iron founding, saw milling, porcelain, woollen
yarn, leather and brandy. It was formerly the
capital of Pays-de-Condomois. Bossuet was
appointed Bishop of Condom in 1669, but re-
mained here only one year. Pop. 6,380.

CONDONATON, in law, a forgiveness of
injury, such as to restore the person who has
committed an offense to the same position
which he or she held before it was committed.
In an action on the ground of adultery it is a
legal plea in defense. If the act is committed
aneon, the conndonation is annulled and the
old charges are reconsidered.

CONDOR, the popular name of the great
vulture of the Andes, formed by a misprinci-
pation of the Indian name kunter, which, ac-
cording to Humboldt, is derived from another
word in the language of the Incas, signifying
"to smell well." This species (Vultur gryphas,
Linn., or Sarcoramphus gryphas) belongs to the
family (Cathartidae) of diurnal scavenging
birds, and which is distinguished by the fol-
lowing characters: The bill is elongated and
straight at base; the upper mandible is covered
to the middle by the cere; the nostrils are
medial, ovoidal, protuberant, naked and naked;
the tongue is canaliculate, with serrated edges;
the head is elongated, depressed and rugous;
the tarsus rather slender; the lateral toes equal;
the middle toe is much the longest, the inner
free and the hind one shortest; the first pri-
mary is rather short, the third and fourth are
longest.

The natural history of the condor was in a
fair way to rival the ancient fables of griffins,
basilisks and dragons or even of exceeding
the roc of Sinbad the Sailor, in extravagant
exaggeration, until Humboldt placed it upon the
basis of truth. His careful measurements es-
ablished the fact that the wonderfully gigantic
condor is not generally larger than the lâm-
mergeyer, or bearded vulture of the Alps,
which it closely resembles in various points of
character. These birds prefer to dwell above
all animal life, and at the extreme limit of even
Alpine vegetation, inhaling an air too highly
rarefied to be endured, unless by creatures ex-
pressly adapted thereto. From such immense
elevations they soar upward until their great
bulk diminishes to a scarcely perceptible speck,
or is lost to sight. The condor is a carrion
bird, and is quickly lured to the plains by the
sight or scent of a carcass. To such a feast
considerable numbers repair, and commence
their banquet by first plucking out the eyes, and
then tearing away the tongue of the animal;
next to these the bowels are eagerly sought for,
and devoured with that gluttony which dis-
tinguishes the whole vulture tribe. Tschudi
mentions one in captivity which ate 18 pounds
of meat in a single day and had its usual
appetite the day following. The appetite of
these birds seems to be limited, generally to
a quantity of food that can be gorged into their
stomachs; and when thus overloaded they ap-
pear sluggish, oppressed and unable to raise
themselves into the air. The Indians profit by
this condition to revenge themselves for the
robberies which they commit upon their flocks,
and, watching while they eat until flight has
become exceedingly difficult, attack and secure
them by nooses, or knock them down with poles
before they can get out of the way. If the
condor, thus loaded, succeeds in rising a short
distance from the ground, he makes a violent
effort, kicking his feet toward his throat, and
relieves himself by vomiting, when he soon
ascends out of reach. Many, however, are sur-
prised, and are captured or killed before they
are able to ascend. But the condor does not
exclusively feed upon dead or putrefying flesh;
it attacks and destroys deer, vicuñas and other
medium-sized or small quadrupeds; and when
pinned by hunger a pair of them will at-
tack a bullock, and by repeated wounds with
their beaks and claws harass him until, from
fatigue, he thrusts out his tongue, which they
immediately seize and tear from his head; they
also pluck out the eyes of the poor beast,
which, if not speedily rescued, soon falls a
prey to their voracity. It is said to be very
common to see the cattle of the Indians on the
Andes suffering from the severe wounds inf-
clicted by these rapacious birds. It does not
appear that they have ever attacked man. When
Humboldt, accompanied by Bonpland, was col-
clecting plants near the limits of perpetual snow,
they were daily in company with several con-
dors, which would suffer themselves to be quite
closely approached; and in these cases every
alarm and never showed any disposition to act
offensively. The nesting-time of the condor
varies with the latitude and the place selected
for the nest is usually some inaccessible ledge
of rock. It lays two white eggs from three
and a half to four inches long, which are hatched
in about seven weeks. The development
of the young birds is very slow, since
they are not able to fly until they are a year
old, and they have to remain with the parent

— Vol. 7 — 31
birds for a year or two longer. They are occasionally seen even on the shores of the southern ocean, in the cold and temperate regions of the southern hemisphere, and so closely approach the shores of the Pacific. Their sojourn, however, in such situations is but for a short time, as they seem to require a much cooler and more highly rarified air and prefer lofty solitudes from 10,000 to 15,000 feet above the level of the sea. When they descend to the plains they alight on the ground rather than upon trees or other projections, as the straightness of their toes renders the first-mentioned situation most eligible. Humboldt saw the condor only in New Granada, Ecuador and Peru, but was informed that it follows the chain of the Andes from the equator to the seventh degree of north latitude into the province of Antioquia. There is now no doubt that it ranges from 9 or 10 degrees north of the equator to the Straits of Magellan. The king vulture (S. papa) is another bird of the same genus.

The head of the male condor is furnished with a sort of cartilaginous crest, of an oblong figure, wrinkled and quite slender, resting upon the fore part of the beak and having about a fourth of its length; at the base of the bill it is free. The female is destitute of this crest. The skin of the head in the male forms folds behind the eye, which descend toward the neck and terminate in a flabby, dilatable or erectible membrane. The structure of the crest is altogether peculiar, bearing very little resemblance to the cock's comb or the wattles of a turkey. The auricular orifice is of considerable size, but concealed by folds of the temporal membrane. The eye, which is peculiarly elongated and farther distant from the beak than the eagle's, is of a purple hue and very brilliant. The neck is uniformly marked by parallel longitudinal wrinkles, though the membrane is not so flabby as that covering the throat, which appear to be caused by the frequent habit of drawing the neck downward to conceal or warm it within the collar or hood. The collar in both sexes is a fine silken down, forming a white band between the naked part of the neck and beginning of the true feathers and is rather more than two inches broad, not entirely surrounding the neck, but leaving a very narrow naked space in front. The rest of the neck, back, wings and tail are of slightly grayish-black, though sometimes they are brilliantly black; the feathers are triangular and placed over each other tile-wise. Humboldt never saw male condors with white backs, though descriptions of such have been given by Molina and others. The primaries are black; the secondaries in both sexes are exteriorly edged with white. The wing-coverts, however, offer the best distinction of the sexes, being grayish-black in the female, while in the male their tips, and even half of the shafts, are white, so that his wings are ornamented with beautiful white spots. The tail is blackish, wedge-shaped, rather short and contains 12 feathers. The feet are very robust and of an ash color. The middle toes are longer than the others. The claws are blackish, very long and but slightly hooked. The four toes are united by an obvious but delicate membrane; the fourth is the smallest and has the most crooked claw. The largest male condor described by Humboldt was three feet three inches long from the tip of the beak to the tip of the tail; height, when perched, with the neck moderately extended, two feet eight inches; from the tip of the bill to the extreme extent of the wing, eight feet nine inches. Humboldt states that he never saw a condor which measured more than nine feet across the wings; but a specimen described by Dr. Shaw measured 14 feet. Notwithstanding, therefore, what is said by Humboldt of the general coloration of the wing plumage of the anate, and why the condor of the Andes, we cannot avoid believing that a full-grown individual of the latter species would be much more than a match in every respect for any European species. The condor is peculiarly taciturn of life and has been observed, after having been hung for a considerable time by the neck in a noose, to rise and walk away quickly when taken down for dead, and to receive several pistol bullets in its body without appearing greatly injured. Its plumage defends its body to a considerable degree from the effects of shot. It is easily killed when shot, or struck sufficiently hard, about the head.

A very similar species is the Californian condor, or part of the beak and hind part of the bill it is free. The female is destitute of this crest. The skin of the head in the male forms folds behind the eye, which descend toward the neck and terminate in a flabby, dilatable or erectible membrane. The structure of the crest is altogether peculiar, bearing very little resemblance to the cock's comb or the wattles of a turkey. The auricular orifice is of considerable size, but concealed by folds of the temporal membrane. The eye, which is peculiarly elongated and farther distant from the beak than the eagle's, is of a purple hue and very brilliant. The neck is uniformly marked by parallel longitudinal wrinkles, though the membrane is not so flabby as that covering the throat, which appear to be caused by the frequent habit of drawing the neck downward to conceal or warm it within the collar or hood. The collar in both sexes is a fine silken down, forming a white band between the naked part of the neck and beginning of the true feathers and is rather more than two inches broad, not entirely surrounding the neck, but leaving a very narrow naked space in front. The rest of the neck, back, wings and tail are of slightly grayish-black, though sometimes they are brilliantly black; the feathers are triangular and placed over each other tile-wise. Humboldt never saw male condors with white backs, though descriptions of such have been given by Molina and others. The primaries are black; the secondaries in both sexes are exteriorly edged with white. The wing-coverts, however, offer the best distinction of the sexes, being grayish-black in the female, while in the male their tips, and even half of the shafts, are white, so that his wings are ornamented with beautiful white spots. The tail is blackish, wedge-shaped, rather short and contains 12 feathers. The feet are very robust and of an ash color. The middle toes are longer than the others. The claws are blackish, very long and but slightly hooked. The four toes are united by an obvious but delicate membrane; the fourth is the smallest and has the most crooked claw. The largest male condor described by Humboldt was three feet three inches long from the tip of the beak to the tip of the tail; height, when perched, with the neck moderately extended, two feet eight inches; from the tip of the bill to the extreme extent of the wing, eight feet nine inches. Humboldt states that he never saw a condor which measured more than nine feet across the wings; but a specimen described by Dr. Shaw measured 14 feet. Notwithstanding, therefore, what is said by Humboldt of the general coloration of the wing plumage of the anate, and why the condor of the Andes, we cannot avoid believing that a full-grown individual of the latter species would be much more than a match in every respect for any European species. The condor is peculiarly taciturn of life and has been observed, after having been hung for a considerable time by the neck in a noose, to rise and walk away quickly when taken down for dead, and to receive several pistol bullets in its body without appearing greatly injured. Its plumage defends its body to a considerable degree from the effects of shot. It is easily killed when shot, or struck sufficiently hard, about the head.

A very similar species is the Californian condor, or possibly the California condor, which may be easily distinguished from the true condor, which it nearly equals in size, by the lack of the white neck-ruff and of the caruncle of the male. The California vulture formerly ranged on the Pacific coast into British Columbia, but its habitat is said to be shrinking and now reaches only to Monterey on the north. The species may be approaching extinction. Like the condor, in addition to feeding on carrion, it attacks and kills young or sick animals, particularly lambs and calves. The rough nest of sticks, in which two dirty-white eggs are laid, is built on the ground, rock ledges or stumps. Consult Adams, 'The Condor' (Vol. IX, California 1907); Beebe, 'Zoological Society Bulletin, No. 31' (New York 1908); Darwin, 'A Naturalist's Voyage' (London 1860); Lucas, 'Annual Report of the United States National Museum' (Washington 1891); Stejneger, 'Riverside Natural History' (Vol. IV, Boston 1885). For the California condor consult the following: 'Condors and Condor Eggs' (American Museum of Natural History, No. 32' (New York 1909) and Finley, 'The Condor' (Vols. VIII, IX, X, California 1906, 1907, 1908).

CONDORCANQUI, kön-dör-kän-ke’, José Gabriel ("TUPAC AMARU"), Peruvian revolutionist: b. Tinta 1742; d. Cuzco, 18 May 1781. He is called "The Last of the Incas," and in 1771 took the name of Tupac Amaru. In 1780 he incited the Peruvian Indians to rebellion against Spain, professing a design of restoring the dynasty of Manco Capac. This rebellion was the most important in South American colonial history. For some time the contest raged with doubtful success; at length, however, the natives fell away from him and he was taken and executed. The cruelty of the Spaniards in this insurrection ultimately led to the independence of Peru and to other causes.

CONDORCET, kön-dör-sa’, Marie Jean Antoine de [1743-1794], French philosopher and mathematician: b. Ribemont, Picardy, 17 Sept. 1743; d. Clamart, 28 March 1794. He was educated by the Jesuits and showed a taste for mathematics at a very early age. Later he studied at the College of Navarre at Paris. At the age of 21 he pre-
sented to the Academy of Sciences an 'Essai sur le calcul intégral.' His 'Mémoire sur le problème des trois points' appeared in 1767. Both works were afterward united under the title of 'Essais d'analyse.' The merit of this work gained for him in 1769 the distinction of a seat in the Academy of Science. With astonishing facility and versatility Condorcet treated the most difficult problems in mathematics; but his genius inclined him rather to lay down beautiful formulas than to pursue them to useful application. He became the friend of D'Alembert, Turgot and Voltaire, whose opinions influenced him greatly. His mind seized upon social problems, which he solved in a manner equally as brilliant as that of his famous contemporaries. In defense of free internal trade in corn, he wrote 'Lettre d'un laboureur de Picardie à M. N.' and 'Réflexions sur le commerce des blés' (1776). Against religious domination he wrote 'Lettre d'un théologien.' He also supported the American Revolution with great enthusiasm. His principal writings on this subject are 'Lettres d'un citoyen des États-Unis sur les affaires présentes' (1788); 'Lettres d'un bourgeois de Newhaven à un citoyen de Virginie' (1787); 'Réflexion sur l'esclavage' (1786). He became the friend of Talleyrand, who persuaded him to contribute to the 'Encyclopédie,' to which he responded by his facile and brilliant 'Éloges des académiciens de l'Académie Royale des Sciences morts depuis 1666 jusqu'en 1769' (1773). The ability which he manifested in this work gained for him life secretaryship of the Academy of Sciences. In 1777 his 'Theory of Comets' gained the prize offered by the Academy of Berlin. The aversion of the minister Maurepas to Condorcet delayed his entrance into the French Academy till 1782. In 1785 appeared a distinguished mathematical treatise on the doctrine of probability. In the following year he married Sophie de Grouchy, a sister of Marshal Grouchy, a talented and beautiful woman. At about this time Condorcet became inspector-general of the mint, and at his residence at the Hôtel des Monnaies, there gathered the 'Intellecti' of Paris. His 'Vie de Turgot' and 'Vie de Voltaire' appearing in 1789-92 became popular immediately. In point of style they are the best of his works.

When the Revolution finally came, Condorcet's eager and indefatigable pen rushed to the support of the democracy. He was chosen a member of the municipality of Paris (1790) and later a representative for Paris in the Legislative Assembly, of which he became a secretary. In this capacity he composed the addresses of that body to foreign powers and developed a strikingly comprehensive public instruction, which, after the turmoil of political strife had abated, was put into effective operation and still remains the basic structure of the French system of education. His program of organization had five steps: (1) primary schools; (2) secondary schools; (3) institutes; (4) lycées; (5) the Society of Arts and Sciences. After the flight of Louis XVI, Condorcet denounced royal authority as an anti-social institution and supported the National Assembly. He was in this body for Aisne and directed his first efforts toward the framing of a constitution, which was rejected. The trial of Louis XVI by the Convention was offensive to him, since he did not believe that body right in exercising judicial functions. He voted in favor of the removal of Louis and the infliction of any punishment except death. His critical and independent attitude toward the new constitution and toward the oppression of the Girondists and the terrorist principles of the party of the Mountain brought down on him the suspicion of the revolutionists. He was declared an outlaw. Refuge was found for him at the home of Madame Vernet, who did all in her power to prevent his escape and surrender to his enemies, even at the peril of her own life. Her words were remarkable for their lofty sympathy: "The Convention, Monsieur, may declare you outside of the law, it cannot place you outside of humanity." While at her house he wrote 'Esquisse d'un tableau historique des progrès de l'esprit humain,' by which he is best known. This work is a philosophical treatise on the history of man, tracing his evolution from a barbaric stage to the age of reason. He conceives that the chief errors in civilization have been brought about by the mismanagement by the clergy and monarchs. He outlines the future of man's progress on three lines: (1) The destruction of influence between nations; (2) the destruction of inequality between classes; and (3) the unlimited improvement of individuals, mentally, morally and physically. Condorcet derives his theories from no spiritual postulates. His appeal is always to reason and to emotion aroused through reason. He finally quitted the house of Madame Vernet, and was captured in a half-famished condition at Clamat by a member of the revolutionary tribunal of that town. His captors threw him into prison, pending trial, and on the following morning he was found dead, either from apoplexy, exhaustion or poisoning.

CONDOTTIERI, kön-döt-tvä'rē, class of mercenary adventurers in the 14th and 15th centuries, who commanded military bands, amounting to armies, on their own account and sold their services for temporary engagements to princes and states. The bands under command of the Condottieri were well armed and equipped. Their leaders and the men in their armies considered military skill; but, as they took no interest in national contests, except to receive pecuniary advantages, the wars between them became a sort of bloodless contest, in which the only object of each was to extricate as many prisoners as possible for the sake of the ransom. This singular system of warfare was put to an end by the more serious military operations of the French, who invaded Italy under Charles VIII. Though many Condottieri acquired much honor as well as wealth, one only attained to high rank and independent power; this was Francesco Sforza,
CONDUCTING TISSUE.—CONDYLE

ally a peasant, who in 1451 made himself Duke of Milan and transmitted that sovereignty to his descendants. Consult Semerau, 'Die Conduttiere' (Jena 1899); Block, 'Die Condot-tieri: Studien über die sogenannten unblütigen Schlachten' (Berlin 1913).

CONDUCTING TISSUE, in botany, the system of vessels by which water and aliment is brought from one part of a plant to another.

CONDUCTION (from Latin conductio, bringing together). In botany, this is the technical name for the process whereby water and food-stuffs are transmitted from the roots of a plant to its trunk or stem and leaves. The paths by which these substances traverse the plant are well known. They enter the thin-walled root-hairs by osmosis, the food-salts being in a state of aqueous solution. From this point up, there is good evidence that the path of the water and the salts dissolved in it lies through the tracheids and the long tubular vessels of the xerophytic bundles, which are situated in the wood of the roots and stems of the Dicotyledons and Conifers, and form part of the conducting system of the young wood, however, takes part in this upward flow of sap. The motive force in the process has only recently been understood: the osmotic pressure of the juices of the root unquestionably plays a large part in the matter, but it is alone unable to make the sap rise to the tops of our larger trees. Furthermore, a cut branch with its end dipped in water will still show a flow of sap. Furthermore, if a living twig be divided under mercury, the wood-vessels will be found to contain some of the mercury on microscopic examination. As mercury will not enter a capillary tube of cellulose except under the action of a force, this result indicates that the pressure in the wood-vessels is less than that of the atmosphere. There could not be the case if root pressure were the only agent tending to produce the upward flow of sap; there must be accordingly some force producing a suction from above. This force is furnished by the osmotic attraction for water of the leaf-cells, whose contents are concentrated by evaporation and the consumption of their water in the photosynthesis of carbohydrates. This action is propagated from cell to cell until it reaches the vessels of the stem, each cell being, to put it loosely, sucked dry by its thirsty predecessor. This suction, producing a pressure in the vessels less than that of the atmosphere, causes the sap to give up part of its dissolved gases. This is probably one of the reasons why the vessels of a plant contain gases, which are, of course, in a state of rarefaction.

It has been shown that the path of the carbohydrates and other substances generated in the leaves is quite different from that of the water which comes up from the roots with its dissolved salts. For example, a girdled twig will keep green if its end is immersed in water, which shows that wood transmits water, but it will send down roots only from points above the injured region, because the portion of stem between the girdle and point of exit of the stems is able to retain food-material from the leaves and of growing thereby. The bark, therefore, and more specifically the bast layer of the bark, as it has been shown, is the path of the sap, descending from the leaves. This layer contains the remarkable sieve-cells—elongated cells placed end to end in long chains, with the plates between adjacent cells in these chains perforate, forming numerous small holes. The mechanism of the transmission of food-stuffs appears to be diffusion.

In addition to the tracheids, vessels and sieve-tubes, we find another system of tubes in the vascular tissue of plants. This system bears the milky juice or latex of such plants as the rubber-tree, the dandelion and the milkweed. Though there is evidence that the latex exercises a nutritive function, the nature of this is not thoroughly known. Consult Timrians, C. A., 'The Life of the Plant' (trans. by A. Cheremetieff, London 1912). CONDUCTION OF HEAT. See HEAT.

CONDUIT, kond'dit, in a general sense a medium or means of conveying; anything serving as a channel for passage or transmission; in architecture, a long narrow passage between two walls or underground, for secret communication between various apartments, of which many are to be found in old buildings; also a canal of pipes for the conveyance of water, a sort of subterraneous or concealed aqueduct. The construction requires science and care. The ancient Romans excelled in them and formed the lower parts, whereon the water ran, with cement of such an excellent quality that it has become as hard as the stone itself which it was employed to join. There are conduits of Roman aqueducts still remaining, of from five to six feet in height and three feet in width. ·Conduits in modern times are generally pipes of wood, lead, iron, cement, reinforced concrete, or sometimes pottery, for conveying water from the main spring or reservoirs to the different houses and places where it is required.

CONDURANGO, kond-dú-ráng'go, or CUNDURANGO, (from the native Peruvian cundur, condor, and ango, vine), the bark of the Marsedenia Condurango or perhaps Macro-scepsis, a medium-sized twining plant of Ecuador and adjacent states. It is somewhat bitter; at one time it was much vaunted as a specific in the treatment of cancer.

CONDYLARTHA, kond-di-lär'ths-ra, a primitive order of fossil ungulates of the early part of the Tertiary Period, collateral ancestors of the later hoofed animals and connecting them with the primitive clawed animals, especially with the Credonta. They were mostly of small size, five-toed, omnivorous, with bunodont teeth like those of the pigs, long tail, small brain and other primitive features. Phenoacus, of the Lower Eocene, of the size of a wolf, is the largest and best known. Remains of Condylarthra are found chiefly in North America, but also in Europe and in South America. They became extinct in the Middle Eocene.

CONDYLE (Fr. condyle, Lat. condylus, Gr. kondulos, knuckle), kond'îl, in anatomy, a protuberance on the end of a bone serving to form an articulation with another bone, and more especially given to the prominence of the occipital bone for articulation with the spine; to the distal extremity of both the humerus and femur and to the proximal articular extremity of the lower jawbone of mammals.
CONDYLE, in ancient Greece, a linear measure one-eighth of a foot.

CONE. Helen Gray, American poet; b. New York city, 8 March 1859. Since 1899 she has been professor of English in the New York Normal College (now Hunter College). She is the author of 'Oberon and Puck; Vestiges; Gravies; A Gor Swed'; 'Baby Sweety's Hearts' (1890); 'The Ride to the Lady and Other Poems' (1891); 'Soldiers of the Light' (1910). She assisted Jeannette L. Gilder in editing 'Pen Portraits of Literary Women' (1887).

CONE, Orello, American educator and author; b. Lincole, N. Y., 16 Nov. 1835; d. 23 June 1905. He was professor of biblical languages and literature in Saint Lawrence University, N. Y., 1865–80; president of Bucilet College, Ohio, 1880–96; and Richardson professor of biblical theology in Saint Lawrence University, 1900–05. He published 'Gospel-Criticism and Historical Christianity' (1891); 'The Gospel and, Its Earliest Interpretations' (1893); 'Paul, the Man, the Missionary, and the Church' (1898), edited 'Epistles to the Hebrews, Colossians, Ephesians, Philemon, etc.' (1901); 'Rich and Poor in the New Testament' (1902).

CONE, Spencer Houghton, American clergyman; b. Princeton, N. J., 30 April 1855; d. 26 Aug. 1855. After a varied career as school teacher, actor, journalist and government clerk, he joined the Baptist Church in 1813 and began to preach. He was chaplain of the House of Representatives, 1815–16; pastor at Alexandria, Va., for seven years; of the Oliver Street Church, New York, for 18 years, and of the Broome Street Baptist Church in the same place from 1841 until his death. He was president of the American and Foreign Bible Society, 1837–50, and of the American Bible Union from its formation until he died. For many years he was one of the most popular and influential clergymen of his denomination in the United States. There is a 'Mémoire' of him by his son, Spencer Wallace Cone (1819–88).

CONE. (1) In geometry, the solid figure traced out by a right-angled triangle is made to revolve round one of the sides that contain the right angle; this is more strictly a right circular cone. A more comprehensive definition may be given as follows: Let a straight line be held fixed at one point and let any other point of the line be made to describe any closed curve which does not cut itself; the solid figure traced out is a cone. The moving line is known as a generating line or generator of the cone. When the axis of the cone, that is, the line joining the fixed point to the centre of symmetry of the closed curve, is perpendicular to the plane of the base, the cone is right; and when in addition the curve which the second point describes is a circle, the cone is a right circular cone. Cones whose axis are inclined to their bases at any angle other than a right angle are known as oblique cones. If a cone be cut in two by a plane parallel to the base, the lower portion is called a frustum or a truncated cone. The geometry of a cone is important on account of the curves called conic sections, which are obtained by cutting a right circular cone by planes in various directions. The cubic content of a cone is one-third of that of a cylinder on the same base and of the same altitude. The cubical content of the cone is therefore found by multiplying the area of the base by the altitude and taking one-third of the product. The area of the slant or curved surface of a right circular cone is obviously equal to that of a sector of a circle of radius equal to the slant height, an arc equal to the circumference of the base. It is therefore obtained by multiplying the slant height by the circumference of the base and taking one-half of the product.

(2) In botany, a dry compound fruit, consisting of many open scales, each with two seeds at the base, as in the conifers; a strobilus.

(3) In geology, the heap or mountain of ash, cinders and lava piled up around a volcanic vent. Small cones on the flanks of larger ones are called parasitic. The term cone is also applied to the mound of silicious sinter (q.v.) built up around a geyser. See GEYSERS; MOUNTAINS; VOLCANO; and the section on Volcanism in the article on Geology.

CONE-NOSE. A true bug (Conocephalus sanguinipes) of the family Reduviidae, related to the bedbugs and having similar habits in the South; it is nearly an inch long and black, blotched with red. In 1898 much excitement was occasioned in the North by newspaper accounts of attacks by "kissing-bugs," which were two related species, Opismus personatus and Melanolestes picipes, the former frequently found in dirty houses feeding upon cockroaches, bedbugs, etc., and breeding in dusty corners. The bite is pleasant, but not poisonous.

CONE-SHELLS, or CONIDAE, a family of ctenobranchiate Gastropoda, so called on account of their form. All the cones have a similar external outline; the aperture is long and narrow, the head of the larval shell is more or less lengthened, the proboscis elongated, the foot is splay and abruptly cut off in front, the tentacles are rather widely separate and the eyes are placed on these organs. All of the species are carnivorous. Several hundred species have been described; about one-fifth of them from tropical American waters. Owing to their beauty and variety the cones are much sought by collectors, who pay extravagant prices for the rarer forms. The textile cone-shells (Conus textile), brought from Mauritius, a handsome species four or five inches in length, are marked with narrow, angular lines of dark brown, variegated with dashes of yellow and irregular white spots. They haunt the fissures and holes in rocks and warmer pools in coral reefs. They all take a moderate range of depth, varying from 1 to 40 fathoms.

CONEPATL, or CONEPATE, kö-né-pát, the name given in Mexico to Conepatus, the large white-backed skunk of that region. See SKUNK.

CONES, Pyrometric, or SEGER CONES, instruments for measuring heat, consisting of three-sided pyramids about two and a half inches high and one-half inch base. They are composed of fusible substances and are graded so that they melt each at its own temperature. The cones were invented by Dr. Hermann Seger, of Berlin, for use in pottery kilns and have since been largely adopted. An earlier method of heat measurement was the
fusible alloys invented by Prusse. Alloys of silver, gold and platinum were so calibrated that they would, as to melting-point, cover the whole compass of the two extremes of fusion of the metals. Many objections to these were found in practice, notably the expense and liability to loss. The Seger cones perform the same service and are very inexpensive. The cones range in numbers from 1 to 36. The cone numbered 22 is the highest. In practice two or three cones, approximating the required temperature, are set upright in the kiln upon a morsel of soft clay. The softer of them will, as the temperature reaches the proper point, bend over and melt, to be followed in regular order by the successive higher numbers. They can be easily seen through the hole left in the kiln wall for the inspection of trials.

**Conessi-Bark**, the bark of *Holarhena anti-dysenterica*, of the family Apocynaceae, a plant of India, used as a tonic, a febrifuge and an astringent in diarrhoea. The plant is a shrub with opposite leaves and terminal cymes of flowers.

**Conestoga**, kon-es-to'ga, or **Conestogas**, a tribe of Indians belonging to the Iroquois linguistic stock, and formerly living on the lower course of the Susquehanna and at the head of Chesapeake Bay. At the time of the settlement of Virginia (1607) the Conestoga were at war with the Mohawks, whom they had almost exterminated. Later they became a source of serious trouble to the white settlers. With the Dutch and Swedes they were more friendly than with the English. By 1675 the tribe was holding land on the eastern bank of the Susquehanna River in Maryland. Giving way before the Iroquois they retreated southward, committing depredations upon the white settlements. Some of the refugees of the tribe escaped to North Carolina; others after submission to the Iroquois returned to the Susquehanna. In 1701 the Conestoga made a treaty with William Penn.

**Coney, Cony** (Lat. cuniculus; M. E. cony, cunig, rabbit). The word is believed to be of Hispanic origin and to have been borrowed into Latin. The name was formerly given in England to the rabbit. In the western United States, the name is applied to a distant relative, the pika (q.v.), although this creature has little resemblance to the rabbit. The term as found in Scripture is a translation of the Hebrew shaphen, the local name for the Syrian species of hyrax, or daman. The word Coney enters into a number of family and local names, as for example, Cunningham (Conyngham), Coney, Coningsby, Conington and Conynthrop. The fur of conies or rabbits once much used in England, was called cony. The word also has the signification of a simpering, dute, gull. In the 17th century in England the den of thieves, cheats and swindlers was known as their warren, and their victims as conies, which, in this case, was a play on the sense of young, inexperienced rabbits. This is the origin of the term simpleton as attached to the rabbit. See HYRAX.

**Coney Island**, New York city, small island in the borough of Brooklyn, about 10 miles southeast of the borough of Manhattan. It is about five miles in length and from half to three-quarters of a mile in width; separated from the mainland by Coney Island Creek, a narrow tidal inlet, Gravesend Bay and Sheepshead Bay. It is connected with the boroughs of Manhattan and Brooklyn by steam and electric railroads and steamboat lines. It is a noted day summer resort and has numerous bathing houses, hotels, concert and other amusement halls, carousels, pavilions, electric lights and a fine cycle path connecting it with Prospect Park, Brooklyn. Coney Island is divided into four sections: Sea Gate, the home station of the Atlantic Yacht Club; West Brighton; Brighton Beach and Manhattan Beach. There is a lighthouse at Sea Gate and many summer colonades, besides the Atlantic Yacht Club House. Sea Beach is the site of several charitable sanatoria and is a popular pleasure resort. Brighton and Manhattan have extensive hotels and are the preferred resorts for the wealthier class. There is a splendid theatre at Brighton Beach and also the Brighton Beach race-track. Coney Island was one of the first landing-places of the Dutch, and for over 200 years was considered a worthless waste. In 1840 steamboats began making excursions there and for 25 years it was a popular resort. In 1875 steam railroads were built and since then the island has been the most popular resort in the immediate neighborhood of New York. In 1903 the city opened a small public park on the island; again in 1911.

**Confrarretio**, kon-far'ē-ā'tyo, the most solemn of the three ceremonies of marriage used among the ancient Romans. The other forms of marriage were *coniunctio* and *usus*. These last are the only ones mentioned by Cicero, which shows that confarretiation had fallen into disuse before his time. The ceremony was performed by the *pons maximus*, or *flamen dialis*. A formula was pronounced in the presence of 10 witnesses, and the man and woman partook of cake of salted wheaten bread; part of which only they ate, the rest being thrown upon the altar. One of the rite was a sheep. The cake was called *far*, or *panis farreus*, hence the term "confarretio." By this form the woman was said to come into the possession of her husband by the sacred laws, and became a partner of all the sacred rites, those of the penates as well as the lares. If the husband died intestate and without children, the wife inherited the whole property like a daughter; if there were children, she received with them an equal share. The offspring of this form of marriage were called *patrimi* or *matrimi*; and from them were chosen priests and priestesses, especially the *flamen dialis* and vestal virgins. In the reign of Tiberius, he wished for a priest of this pure lineage, but the ceremony had fallen into disuse, so that three patricians thus qualified could not be found. Confarretatio could only be dissolved by a form of divorce equally solemn, called *disfarreto*. The custom of bride cake is a relic of confarretio; until within 200 years it was made of wheat or barley, without fruit.

**Confectionery** (Lat. conficiere, "to put together," "compound," "prepare"), a general term for any preparation with sugar as a base, used as a sweetmeat and containing nuts, fruits or other flavoring. In the United States confectionery is commonly called "candy,"
CONFECTIONERY TRADE

name which suggests etymologically conserved fruits or seeds; in England "boiled sweets" is the usual term, derived from the commonest method of preparation. Historically the earliest use of confectionery was to disguise the taste of unpleasant medicines, a method dating back to the primitive smearing with honey the rim of a cup holding a bitter draught, a practice common with Greek and Roman doctors. The medicinal use was long the commonest, fruit confectionery later took precedence. In Italy, even in the Middle Ages, confetti were used in the mock battles of the carnival maskers. The true development of the manufacture of confectionery began in the 19th century, and in England, where the trade spread after the great exhibition of English dealers at the Exposition of 1851, to Germany and France. The latter country took the lead in the manufacture of elaborate bonbons and confitures and was especially superior in its chocolate candies. But the greatest growth of the business and especially the greatest increase in the variety of confections has been in the United States. The custom of making confectionery without the use of sugar was common in Mexico and in the Conquest. Different kinds of fruits were dried, mixed and compounded so as to make sweetmeats. The Indians soon learned the value of sugar in sweetening and preservation of these compounds; and "confectionery" in the modern sense was used in Mexico and Central America before it appeared in Europe where it was probably brought through the medium of Spain.

CONFECTIONERY TRADE. It is doubtful if there is any modern industry that has experienced more radical changes during the past hundred years than the trade of confectionery-making. Prior to the year 1831, the manufacture of "boiled sweets," as candy was then called, was largely an English specialty that the manufacturers of Great Britain might be said to have had almost entire control of the industry. In fact, it was not until the time of the great international exposition at London that the confectionery trade of Great Britain first became interested in what was going on in the United States and how much their British brethren had achieved, but their unique display of candies and sweetmeats gave such an impetus to the trade that the effect was felt in every part of the civilized world. Germany imitated all its choicest products; France excelled, especially in the making of chocolate bonbons, and the candy-makers of the United States returned from the "big show" with ideas that soon made the imitation of English sweets unnecessary.

In spite of the fact that England had long been the great candy-making country of the world, however, there had been confectioners in the United States long before the opening of the London exposition, and there are ample records in proof of the fact that they, too, had produced original creations that other nations were glad to copy. As early as 1816 there were no less than 20 confectioners in the city of Philadelphia, all of whom were engaged in the manufacture of various kinds of goods that the constantly widening demands of the business have required. While the actual manufacture of candy has extended until it has become one of the nation's greatest industries, it has created a number of skilled industries, each of which now represents a special business of no slight importance. Thus, for example, the making of confectioner's machinery is now a separate industry in which a
great amount of capital is invested, and the business of confectioner's supplies represents an annual product that is by no means to be despised.

There are other factors that have played an important part in this extension of the confectionery industry. The low prices of sugar and the other materials used in the making of confectionery have exerted an influence, the effect of which cannot be disregarded, while the introduction of new and improved machinery in all our candy factories has a tendency to reduce the cost of manufacture to such a degree that the American producers have been able to make the best goods at a cost so low as to bring them within the reach of all.

Much of the credit for this satisfactory condition of affairs is due to the labors of the members of the National Confectioners' Association of the United States. This organization, founded in 1860, is a leading candy manufacturer in the country, has for its declared purpose to advance the standard of confectionery in all practical ways, and absolutely to prevent hurtful adulterations; to promote the common business interests of its members; and maintain more intimate relations between them; to take united action upon all matters affecting the welfare of the trade at large.

Since this association has been in existence, the results of its work have been clearly manifested in the securing of necessary legislation in the several States by means of which the manufacture or sale of all candies containing harmful ingredients or poisonous coloring matters has now been prohibited by law; by effectually stamping out all attempts at adulteration which were once so common among the makers of the cheaper grades of goods, and by the establishment in the mind of the consumer of a degree of confidence in the purity of the American product that is a strong argument for the purchase of such goods. As the result of this happy combination of circumstances we have the great American confectionery industry to-day.

Candy may be divided roughly into hard and soft grades. The hard candy is made of sugar, glucose, flavoring and coloring, with sometimes additions of nuts, etc. Starch is a leading constituent of soft candies. The hard candies were the first to be made by machine, but gradually mechanism has been developed for making soft and fancy candies largely by machinery, and makers of high-priced, hand-made candies are kept busy devising new concoctions to keep ahead of the machine products. Starch is used for slabs, steel proving more satisfactory. The product is melted and poured on a slab and cold water run on. It is rolled up, then canned and cooked, more heat being required in summer than in winter to ensure a hard candy. When cooked it is poured on a slab and rolled cold water run on. It is now seldom touched up, steel proving more satisfactory. The product is then sold in copper kettles and cooked, more heat being required in summer than in winter to ensure a hard candy. When cooked it is poured on a slab.

In a large candy factory the sugar, glucose, starch and other materials are brought to the top of the factory, where all operations are begun. Here are the steam-jacketed cooking kettles. If starch goods are being made, the cooking kettle used is directly over the "depositor" machine on the floor below, but often the mixture may go down by gravity. If hard candy is being made, the first kettle is right over the continuous cooker. If it is cream candy, the kettle is positioned to discharge to a cooler; when cooled the cream goes to a beater and is distributed in trucks. The centers or soft interiors go to a coating machine, styled an "enrober," which supplies the familiar chocolate coating, and then to the coolers and packers. Traveling platforms are employed where gravity is not available. In the modern candy factory the forms used are exact, everything is measured and weighed and no guesswork permitted, hence spoiled batches are rare.

Very numerous machines have been developed for performing the different processes and producing the forms of confectionery. The number of machines required for a varied product was so great that an equipment became burdensome to the manufacturer. Therefore in recent years the machine manufacturers have bent their energies to reduce the number of machines required in a candy factory, and to simplify the processes, as well as to eliminate hand labor. One of the most interesting of these machines is the Mogul, which is really a combination of machines grouped in one. It takes a pile of starch trays filled with candy and starch, hardened to the desired degree, picks the bottom tray from under a pile, carries it to a screen and turns it upside down, delivering the contents to the screen, restores the tray to position, passes it under a cascade of starch, levels off the starch and brushes it up neatly, prints all the starch molds in a tray at one operation and adds the exact amount of candy desired, then delivers the tray to a truck to go to the drying-room. The starch coated with starch is automatically cleaned by the machine for reuse.

The work of this Mogul machine is done in some factories by three machines, the Simplex starch buck, which cleans molded candy, refills and levels the trays; the Springfield printer, which prints the molds in the leveled trays of starch; the Springfield depitor, which deposits candy into molds. The enrobing machine, which chocolate-coats centers, is often provided with an attachment for making extra heavy bottoms, as for chocolate drops. The enrober has an ingenious decorating attachment. The centre candy is rotated under a fine stream of colored chocolate or other tinted liquid and may thus be decorated with an endless variety of patterns. An enrober will dip 6,000 cream bars a day.

The old-fashioned vacuum pan is disappearing from candy factories and the continuous cooker taking its place. Its principle is to heat the sugar, glucose and less water and give a glossy product. The disc reducer and disc refiner for chocolates displaces a whole line of old machinery. The reducer grinds the chocolate, mixes in the granulated sugar, butter, etc., and the mixture
is pumped as a fluid to a revolving disk operating between two stationary corrugated discs, where the mixture is refined in a few seconds. The candy-maker also uses gooseberry or ball machines for making candied fruits, and the machinery for the packing tables, wrapping machines for doing up the candies in dainty individual wrappers, syrup coolers, cream beaters and a variety of minor conveniences.

Statistics.—Few industries have grown as rapidly and extensively as the confectionery industry of the United States. In the 30 years from 1880 to 1910, the number of employees and the gross production increased nearly six times. The capital invested has risen from $8,886,000 in 1880 to $97,467,000 in 1914. In 1900 there were more candy factories (2,921) than in 1914 (2,317), but the total 1900 production of confections was valued at only $35,997,000, as against $170,645,000 in 1914, a gain of over 200 per cent. The number of persons employed in the industry, receiving annually $33,813,000, of which the 53,658 factory operatives got $21,472,000, and the clerks and salaried men $12,341,000. This was over three times the amount paid in 1890. The materials used rose from $35,354,000 in 1900 to $101,015,000 in 1914; and the factory production from $60,643,000 to $170,845,000. But to this latter figure must be added upward of $5,000,000 production of confectionery made in bakeries and other establishments, leaving the total of 1914 as a round $175,000,000. In 1916 the figure was estimated to be $200,000,000. These totals are somewhat misleading, however, for the true measure of an industry is not its gross production, but the value created above the cost of the materials used. This latter according to the special census of 1914 was $69,930,000 in the factories and about $3,200,000 in the other manufacture, leaving $73,000,000 as the actual measure of the industry in America, above the cost of materials used. These figures include the establishments making chewing gum which is classified by the United States Census Bureau as a branch of the confectionery industry. (See CHEWING GUM). New York is the leading State in confectionery, having 18 per cent of the production; Pennsylvania and Massachusetts each have nearly 12 per cent, Illinois 8, Ohio 5 and Michigan 2 per cent of the national output.

The chocolate and cocoa industry lives mainly on supplying the confectionery trade with materials, producing $22,390,000 of goods in 1910. Probably $13,000,000 of this went into candies. The most costly ingredient is of course the sugar, bought from the refineries, and the next the glucose, purchased of corn products manufacturers. For further detail of the confectionery industry consult Grilten, *Modern Practical Gum Work Manual* (1911); Friedman, *Common Sense Candy Teacher* (1912); and the files of the *Candy News*.

CONFEDERACY. Daughters of the. See United Daughters of the Confederacy.

CONFEDERATE STATES OF AMERICA. The name adopted by the Southern States which seceded from the Union and formed a government at Montgomery, Ala., 9 Feb. 1861, comprising South Carolina, Georgia, Florida, Alabama, Mississippi and Louisiana, with Jefferson Davis of Mississippi President, and Alexander H. Stephens of Georgia Vice-President. Texas, Arkansas, Tennessee, North Carolina and Virginia afterward joined, and Missouri and Kentucky became disputed territory, the Federal Congress designating, for each receiving and welcoming delegations claiming to represent those States.

The act of secession was passed by each State in full confidence that the legal right peaceably to secede was assured by the Constitution. And if the interpretation of any ambiguous provisions or expressions in any contract is to be governed by the joint intent of the parties at the time of making it, this right to secede must be conceded by all impartial historians.

Goldwin Smith, the English historian, has written: "Few who have looked into the history can doubt that the Union originally was, and was generally taken by the parties to it to be, a compact, disjointed political association of States; and both the North and South would have said, at pleasure; certainly on breach of the articles of union."

Henry Cabot Lodge of Massachusetts has written: "It is safe to say that there was not a man in the Union, from Washington and Hamilton on the one side, to George Clinton and George Mason on the other, who regarded the new system as anything but an experiment entered upon by the States, and from which each and every State had the right peaceably to withdraw, a right which was very likely to be exercised."

In 1863, at the purchase from France of the Louisiana territory, and again in 1812, at the declaration of war with Great Britain, influential and leading public men in New England not only asserted the right of secession, but urged its exercise, in the celebrated Hartford Convention (q.v.) in 1814–15.

Nowhere, however, until 1860, was the issue actually made. Had it been made in the earlier days, it would doubtless have been accomplished peacefully. But in all human affairs, political, social, moral or commercial, there are silently but forever at work forces which make for the survival of the fittest, and the passing away of the unfit; and these forces, when at last a crisis has been reached, declare themselves, and operate with a volcanic power, against which the barriers of no constitution can prevail.

Within the lifetime of a generation, the moral sense of a majority of the civilized world had grown to condemn the institution of slavery; and the invention of steam-power, railroads and telegraphs had begun to knit communities into nations, to their great commercial advantage. The prejudices against slavery gave rise to issues between the sections of the country, which became inflamed by events—such as the raid of John Brown—until certain States were wrought up to the point of seceding.

But now—born, not legitimatley of the Constitution, nor of consent between the States (which could never have generated anything more cohesive than a rope of sand), but of inexorable laws of nature—there stood a giant in the path. Perhaps, indeed, it was of origin unsanctioned by legal form. But it was born of proximity and geographical dependency, and it was nourished by the prosperous tide of commerce already beginning to transform the entire world. It already felt itself the natural
heir to the vast and rich territory within its grasp. There it stood in the way of peaceable secession—a young nation, which denied the right of secession and stigmatized it as rebellion.

In vain did President Davis plead his constitutional rights, in a message to his Congress: "We protest solemnly, in the face of mankind, that we desire peace at any sacrifice, save that of honor. In independence, we seek no conquest, no aggressiment, no concessions of any kind, from the States with which we have lately been confederated. All we ask is to be let alone; that those who never held power over us shall not now attempt our subjugation by arms."

It needed now but a first blow to precipitate a war to the death. Concerning first blows, Richard Cobden once said: "From the moment the first shot is fired, or the first blow is struck, in a dispute, then farewell to all reason and argument: you might as well attempt to reason with mad dogs as with men when they have begun to spill each other's blood in mortal combat."

The first blow came speedily, but by deliberate intent of neither party. In Charleston a status quo had been agreed upon by both sides, to permit negotiations. On 25 Dec. 1860, Maj. Robert Anderson seized Fort Sumter. He did so by night, without orders, and contrary to his instructions, abandoning Fort Moultrie and disabling its guns. President Buchanan was about to order him to return to Fort Moultrie; but before he could act, the order had been approved so enthusiastically by Northern politicians that he did not dare to reverse it. Holding Fort Sumter, he was then constrained to dispatch an armed force to provision and supply it. Thus the Civil War was begun, the Confederates not waiting for the arrival of the armed force, but making their attack.

This breaking out of hostilities brought into the Confederacy the Border States, not so vitally interested in the subject of slavery, but who hated to see the South's right to its institutions and to the state, to life, liberty, and the pursuit of happiness. The Confederates recognized the right of the Union to declare war, but not the right to advocate war. The Union, and the Rebel, universally applied to the two armies by the North, but by the passionate claim of the Confederates that their struggle was for that liberty of self-government so dear for ages to the Anglo-Saxon race. And at the Fort Monroe conference in February 1865 between President Lincoln and Vice-President Stephens, the South's surrender of her claim to integrity of the Union was the one point upon which Lincoln insisted, and the one which Stephens could not meet, in the attempt to destroy him, and to this he stuck with a desperation that caused the Union to accept the Union for the sake of the Union.

The combatants were very evenly matched, and as each side was in deadly earnest, the final outcome of the contest was inevitable from its beginning. On the Union side was a population of 30,000,000 whites, comparatively destitute of all those elements of military strength. Even their agriculture was so little devoted to food products that actual starvation of men and horses in their armies finally hastened the inevitable end.

Besides the whites, there was a population of 3,000,000 slaves. It was believed by many at the North that if their freedom was proclaimed by President Lincoln, as a war measure, while their masters were absent in the field, they would rise in insurrection, or at least desert their labor in mass. The experiment, however, being tried, proved a failure. The slaves generally remained faithful everywhere, except in the sections overrun by the enemy. During the four years of the war there were actually mustered into the Union army 2,986,304 men. The Confederate numbers cannot be accurately known, but the total white male population between the ages of 18 and 45 was, by the census of 1860, 984,475. In 1864 the number of men in service was extended to include all between 17 and 50, an act which was described by General Grant as "robbing the cradle and the grave." Nearly 2,000 battles and skirmishes were fought, and in them the number of killed and wounded on the Union side is officially given as 389,345. The numbers on the Confederate side are not accurately known, no complete records existing, but they are estimated at about 30,000.

Of lives lost in the war from battle, wounds and disease, the official records of the Union army report 316,516. The lives lost in the Confederate army could not have been less than 250,000.

The Confederates appreciated the odds against them, but with firm conviction of the righteousness of their cause they trusted to be able by fortitude and endurance to wear out and discourage their adversaries. The fighting itself was often very desperate, as shown by the casualties upon both sides, which frequently exceeded the casualties of the severest battles of Europe. Upon three occasions, some historians have imagined, the Confederates were within reach of very important results.

At Bull Run, the first battle of the war, the Federals were completely routed and Washington might have been captured, it is supposed, had the victory been followed up. Gettysburg is considered by many to have been the crisis of the war, a desperate attack by the Confederates being repulsed. But there is strong evidence that the greatest period of discouragement on the Union side followed the battle of Cold Harbor, 3 June 1864. It was, however, of brief duration; the engagements at Petersburg and Gettysburg and elsewhere soon followed and made it apparent that the Confederate resources were approaching exhaustion.

There are notable parallels between the war for the Union as against the war between Great Britain and the Boers, in the issues involved and in the course of their events. Like the Confederates, the whole of the Boer population considered themselves fighting for personal liberty as against the assertion of foreign power. Like the Confederates, the Boers fought practically without pay; and although they were
inferior in numbers their important engagements were generally victories; or, if not victories, were drawn battles. And as the end came to the Confederates, so it came to the Boers only with their utter extermination, their being worn out, rather than defeated in battle.

But a great contrast is to be found in the treatment of the two peoples after their defeat. That of the Boer was liberal and generous, fully in accord with the civilization of the day. The policy of the treatment of the South and the effort must have been made to put the political control of the country into the hands of the Kaffirs. Of course the efforts to give the negro political control over the Anglo-Saxon at the South were foredoomed to failure. They prolonged ill-feeling for 10 years; but subsequent events, notably the Spanish War, at last inaugurated a new era in which few traces of it yet linger. And it is due to history to record that it is unlikely that any such evil ever have been made, but for the assassination of Lincoln. Although for this unspeakable crime and folly the South was in no way responsible, it brought upon her a whirlwind of resentment and at the same time demonstrated that President Lincoln's forebodings of the evil to come had already risen to the height of his great opportunity as a statesman, and was now planning terms of liberality upon which to reconstruct the Southern States.

Within the few days that intervened between the surrender at Appomattox and the assassination of Lincoln, one in his close confidence prophesied that his plans of reconstruction would “win over the South’s good will and affection, and astonish the world.” And in giving his plans effect, no one can doubt that he would have had the cordial as well as powerful aid of General Grant, who had already set the example of magnanimity, and won the gratitude of Lee’s army by the generosity of his terms of surrender.

History records no crime greater than that of the assassin, who cheated the civilization and humanity of the world of the great example which Lincoln would have set to all nations, and who would have made amends through the sections, bringing poverty and distress to the South, to the North the mortifying failure of its political experiment and to the negro only an injury. But in connection with the negro question, as it confronts us to-day, it may be remarked that the problem of the races can be safely committed to time and to the racial instincts implanted by the Creator.

The Constitution which was adopted by the six States in Montgomery, February 1861, and in turn accepted by the others, was modeled closely after that of the United States. It forbade the slave-trade, or the importation of slaves from any foreign country other than the slaveholding States and Territories of the United States. It forbade “bounties” or “trusts” and provided a “tariff for revenue.” It allowed the President to veto any part of a bill and approve the remainder, giving his reasons for such action; and fixed his term of office at 6 years and made him ineligible for a second term.

The internal history of the Confederate States during the Civil War furnished a most instructive lesson as to the weakness of the bond by which they had associated themselves. Already, before the close of the war, it had proved itself but little better than the federation of the colonies for the Revolutionary War. The last message of President Davis to the Confederate Congress, in the spring of 1865, had been the answer to the report upon the message by a committee of the Senate, contained much crimination and re-crimination, and revealed an utter loss of confidence between the executive and the legislative branches, fatally paralyzing all action, and impossible to be healed. In a letter to the Secretary of War, on 5 March 1865, Judge John A. Campbell, assistant secretary, wrote: “The political condition is not more favorable. Georgia is in a state that may properly be called insurrectionary against the Confederate authorities. Her public men of greatest influence have cast reproach upon the laws of the Confederacy and the Confederate authorities, and have made the execution of the laws nearly impossible.” In several of the other States there were also serious issues between State and Confederate authorities.

View of these facts, and of the history of all confederations of many small countries, it may now be clearly seen that the prisons for which the South contended so strenuously would have proved but a calamity had she won it. There would have been in the country a condition of unstable equilibrium, with many centres of disturbance, which would surely have involved further division and probably future wars. To-day her people are citizens of a nation second to none in military renown or commercial strength, or in its power and influence for peace and civilization among the peoples of the earth. Were the right peaceably to secede, for which the South cheerfully endured all the bitterness of war, now tendered her as a free gift, every State would unanimously reject it as a curse.

Few generations of modern times have confronted sterner problems than did the men of the South in 1861. In the natural world, whenever the climate has changed, the fauna and flora have had to change to conform to new conditions. This is the law of evolution, the one great truth of which man must agree. Eternal Justice will alone prevail through “Conformation to Environment.” And the natural resistance to change by all interests in possession makes evolution mean war to the death of the least fit and the survival of the fittest.

Had the South been quick to apprehend these truths, then being first published to the world by Darwin, she might have accepted compensation for her property in slaves and surrendered her constitutional rights to secede. Had she done so, over 500,000 lives and $10,000,000,000 of property would have been saved.

But the Anglo-Saxon is not a ready barterer of what he deems his rights.” Nor would any nation thus founded upon “consent” have commanded confidence, or even inspired the national pride and loyalty which form the greatest treasures of a people. The conflict, with all its death and destruction, its sorrows and its sufferings, was but the necessary baptism of this nation, legitimating its disputed birth by a verdict in the great high court of war, rendered in accordance with the laws of evolution, beyond which there is no appeal.
CONFEDERATE STATES OF AMERICA

But while the generation which so lavishly poured forth blood and treasure may rightfully cherish to the last an ardent affection for its "Lost Cause," with its leaders and its heroes, not only its own children but all succeeding generations, will enjoy great and enduring benefits and blessings, the very fruit of the despiration of its struggle and of the utterness of its defeat.

Influential in its influence upon national character, and upon the standing of this nation among other nations, it is no small matter to have made the record for valor and devotion to principle which the South has set; or to have produced such leaders and types as Lee and Jackson and their colleagues.

Briefly it may be said that the rise and fall of the Confederate States of America constitute the most important feature of modern history, marking the sudden birth of a great nation. Such a nation could not have been founded in peaceful debate. The world may eventually reach a stage of development where such an event may be possible, but it had not done so in 1860. Previous to that date there was no assurance of stability to the nation. Since 1865 no convulsion could shake it. Succeeding years only demonstrate to the inhabitants of every section the increasing advantages of living in an undivided and an indivisible country. See United States — The Confederacy.

EDWARD PORTER ALEXANDER.

CONFEDERATE STATES OF AMERICA, Recognition of the. The failure of the Confederate government to secure recognition was not due to lack of confident or persevering effort or deficiency in the resources or agents sent abroad. Unsuccessful in its effort to negotiate a peaceful separation by a commission sent to Washington, and failing in a plan to form an alliance with Mexico, it continued to press for recognition at the chief courts of western Europe. At the beginning its hope of success was largely based upon the dependence of Europe on the supply of Southern cotton and no serious consideration was given to the possibility of a blockade such as that which became the determining factor in preventing independence.

It continued to expect that the need of cotton would force recognition or intervention by England and France or by France and Spain, whose West Indian possessions she offered to guarantee in return for the recognition of the Confederacy. This hope was temporarily raised by the Trent affair, by the earlier policy of the British government in failing to prevent the escape of Confederate cruisers built in English ports, by Lee's invasion of the North preceding the battle of Gettysburg, and by the later complications of France in Mexico which encouraged Napoleon to favor a counterpoise to the growing strength of the United States. They declined with the progress of events, but were revived by the prospects of an Anglo-American or a Franco-American war and by attempts to impress England and France with the belief that the United States was planning aggression against neighboring possessions or that the restoration of the Union would result in an aggressive war against England and France and finally feeling that European public opinion was opposed to slavery the Confederacy in its last death struggle offered emancipation for recognition and intervention.

Attempts to secure recognition of independence failed because of conditions over which the Confederate government had no control and could not fully appreciate. Recognition was prevented largely by the determination of England, the proclamation of emancipation, the increasing success of Federal military operations, and the obstinate persistency of the Federal government in avoiding any official communication which might be interpreted as a recognition of the existence of even a de facto Confederate government. To this may be added the friendly attitude of the Russian government and the hesitation of the English government to join France in a policy which would have been resonated by the American government as excessively unfriendly. Although during the war, the United States government, usually through military officers, from necessity communicated informally and unofficially with the agents of the Confederate authorities in regard to such questions as exchange of prisoners and terms of surrender, it persistently avoided any formal act which could have been interpreted as a recognition of the Confederate government. This is illustrated by the charter of the Hampton Roads Conference. The Federal courts have always held that the Confederate States were "an unlawful assemblage without corporate power" and that the government of each separate indestructible State when it chose to act as a part of the Confederate States did not exist either de jure or de facto. The British proclamation of neutrality of 13 May 1861 (followed by similar declarations by France, Spain and other powers), which recognized the belligerency of the Confederacy on the ground that it was justified by the declaration of an effective blockade of the insurgent ports by the de jure government at Washington at the beginning of the war, was strenuously but unsuccessfully opposed by Seward who affirmed that the neutrality proclamation of the European powers would be liable to be construed as a recognition of independence and really created the belligerency of the Confederacy which had not exhibited a single privateer upon the ocean nor shown capacity
to maintain any kind of warfare except in its own harbor. This concession of belligerency was not withdrawn by England and France until June 1865 although Seward took steps early in 1862 to secure its revocation or reversion. Charles Francis Adams took some control from the Confederates by his act had released the United States from liability for the misdeeds of the Confederates toward her. The United States courts have repeatedly decided that a state of civil war, which entitled the Confederacy to recognition as a belligerent, did not exist until President Lincoln issued his proclamation of 16 Aug. 1861 (based on the act of Congress of 13 July).

In the face of reported danger of European recognition of Confederate independence Seward urged that the likelihood of success was the only ground for recognition frequently issued instructions or circulars defining the American position against such action or against any form of European mediation or intervention. Seward early notified England and other powers that the recognition of the *so-called Confederate States* would be regarded in the United States as intervention and war to create a hostile state within the national boundaries—and that it would result in the immediate suspension of diplomatic relations and would be resented on the principle of self-preservation. He objected to the reception of Confederate commissioners by other nations or the consideration of any proposals which might seem to recognize the Confederate States in any way except as a part of the United States. Although he continued to insist that the informal reception of Confederate emissaries by officials of foreign governments was improper and unfriendly to the United States and consistently governed his own conduct accordingly in cases of unofficial missions from other countries, he left untried the policy of retaliatory non-intercourse which he early proposed in his instructions to Adams. In the summer of 1861 he revoked the exequatur of a British consul at Charleston who with the authority of his government had conducted negotiations with the Richmond authorities in regard to the rights of neutrals; and he could not grant the right claimed to communicate with a *de facto* government such as the central authority at Richmond or the governors of separate States to provide for temporary security of persons or property of British subjects or to claim redress and reparation although Earl Russell declared that such communications did not imply any acknowledgment of the Confederacy as an independent state. With the knowledge that France and England, acting in concert on questions relating to the American Civil War, might try by combined pressure to prevent the United States from regulating its own internal affairs, he announced that he could not recognize any combination or understanding of the powers, and insisted upon dealing with each government separately. He also declared Napoleon's offer of mediation, the officiousness of which was rebuffed by Congress. Seward's efforts to prevent recognition were greatly aided by the Russian government which refused the invitation of the French emperor in the autumn of 1862 to co-operate on some plan of intervention to stop the Civil War, and later sent its fleet to American waters to show friendship for the American Union just after the crisis of the middle of 1863 during which Napoleon, before the arrival of the news of Gettysburg and Vicksburg, had hoped to push the careful government of England into a policy of joint recognition and intervention.

CONFEDERATE VETERANS' ASSOCIATION, a federation of all organizations of survivors of the Civil War on the Southern side. This association was organized in New Orleans 10 June 1889. Its avowed purpose is strictly social, literary, historical and benevolent. Its constitution says that it "will endeavor to unite in a general federation all associations of Confederate veterans, soldiers and sailors now in existence or hereafter to be formed; to gather authentic data for an impartial history of the War between the States; to preserve relics and monuments of the same; to cherish the ties of friendship that should exist among men who have shared common dangers, common sufferings and privations; to care for the disabled and extend a helping hand to the needy; to protect the widows and the orphans, and to make and preserve a record of the resources of every member, and, as far as possible, of those of our comrades who have preceded us in eternity." State organizations are authorized, and are called divisions. Local organizations are termed camps. Of these there are about 1,200 organized into three departments: Army of Northern Virginia; Army of Tennessee and the Trans-Mississippi Department. The badge worn on the lapel of the coat is a miniature Confederate flag, square in form. The official organ, the *Confederate Veteran*, is published at Nashville, Tenn. The organization numbers about 50,000.

CONFEDERATION, Articles of, See UNITED STATES — ARTICLES OF CONFEDERATION.

CONFEDERATION OF THE RHINE. A league of German princes which was formed, under the protection of Napoleon, in 1806. In the war of 1805, which turned out so unfortunately for Austria, several of the princes of the south of Germany allied themselves to France. The Peace of Pressburg (26 Dec. 1805) gave the first impulse to the entire dissolution of the German empire, by conferring crowns on the electors of Bavaria and Württemberg, and on both, as well as on Baden, complete sovereignty, such as had been already exercised by the other great German states. Ultimately 16 German princes made a formal declaration of their separation from the Emperor and the Empire, in the act of confederation signed at Paris 12 July 1806, by the kings of Bavaria and Württemberg, the elector arch-chancellor of the Empire, the Elector of Baden, the new Duke
of Clèves, and Berg (Joachim Murat), the Landgrave of Hesse-Darmstadt and other less important rulers. Other princes soon joined, and ultimately the confederacy extended over a space of 125,160 square miles, with 14,608,886 inhabitants; and the body of forces were increased from the originally stipulated number of 63,000 to 119,180. After Napoleon's Russian campaign of 1812 the whole structure fell to pieces in 1813. Consult Rambaud, 'La dévolution française,' 1804-1815 (Paris 1876), and any good history of Germany.

CONFERENCE (Lat. conferre, "to bring together") (1) In general a meeting for consultation, discussion, instruction or the like; or any interview for interchange of views. The term is specifically applied to consultations between committees of the two Houses of Congress in the United States, and to similar consultations between delegates of the two Houses of Parliament in Great Britain. Such conferences are usually called to discuss the provisions of a treaty regarding to which the two houses are disagreed, with the object of effecting an agreement between them. (2) A term much used in ecclesiastical government, etc. The annual meetings of Wesleyan preachers in England for deliberation on the affairs of the body are called conferences. In the United States the Methodist Episcopal Church has an assembly called the general conference, which meets once in four years; numerous assemblies called annual conferences; district conferences; and quarterly conferences; these assemblies variously dealing with local or general interests of the Church. In the Roman Catholic Church there are instituted pastoral conferences, chapter conferences, etc.; and in various Protestant denominations there are stated local or general assemblies of chosen delegates from individual churches, who meet to consider or adjust denominational affairs. (3) The word conference also covers international meetings, and there have been many noted international conferences, some of which have been of a religious nature. Of these latter a very notable gathering was the ecclesiastical conference called together by King James I of England and which met at Hampton Court Palace in 1604, for the establishment of a common creed. It led to King James' famous translation of the Bible which is still known to all Protestant English-speaking readers as the Authorized Version. Another famous ecclesiastical gathering was that known as the Savoy House conference, which at a meeting held in 1661 made some important changes in the Prayer Book of the Established Church of England. Political conferences have been many and some of them important. The conferences of London and Geneva both held in 1804; two other conferences of London held respectively in 1867 and 1871 and the Balkan conference also held in London (1912-13) form links in the chain of modern history; while the conference of The Hague of 1899 and recent meetings of a similar nature have attracted general attention.

CONFERVA (Lat. con, "together," and fervere, "to be hot"), kon-fèr'va, a genus of green algae. Most species are marine, though a few are freshwater. The name is also applied to a genus of the chlorophyceae.

CONFESSION, in criminal law, the voluntary admission or declaration made by a person who has committed a crime or misdemeanor, to another, or of the agency or participation which he had in the commission of the crime, and confessions are those made before a magistrate or in court in the due course of legal proceedings. Extra-judicial confessions are those made by the party elsewhere than before a magistrate or in open court. Confession is admissible only when voluntary; but the usual inducements of fear, threats, promise or hope of favor held out to the party in respect of his escape from the charge against him, by a person in authority, it is not allowed. Likewise, if the confession is made in answer to questions not containing or in any way implying threats or bribes, it is then admissible. A confession differs from a statement or declaration in that the former applies to an acknowledgment of guilt after the deed has been committed and does not apply to a mere statement or declaration of an independent fact from which such guilt may be inferred. The court primarily determines whether the confession is voluntary or not. If the various evidence conflicts as to whether the confession is voluntary, the court may leave it to the decision of the jury with the direction that they shall reject the confession, if on hearing the whole evidence, they are convinced that it was not the voluntary act of the defendant. See CRIMINAL LAW.

CONFESSION, Sacramental, the act of a penitent accusing himself of his sins to a priest who has power to grant absolution, it is called auricular confession because addressed to the ear (auricula) of the minister of the sacrament of penance, and not made in open congregation; though of course were such public confession to be made the priest would, unless the laws of the Church should forbid, possess the same power of absolution as in auricular confession. The law of the Catholic Church, as defined by the Council of Trent, requires that the faithful shall confess to a duly commissioned priest all their mortal sins, and are advised to confess venial sins, committed after baptism and since a previous confession and absolution, so far as they can recall them by a diligent examination of their conscience. The penitent is strictly required to confess all his mortal sins, their kind and number as well as he can recall them; wilful concealment of a mortal sin or even of what the penitent may erroneously deem a mortal sin, renders the confession of the penitent and the absolution of the minister null, and both of these acts must be done over again and made good. If a penitent, after examination of his conscience, fails to recall any mortal sin he is under obligation to confess that sin afterward and to receive absolution for it. See ABSOLUTION.

CONFESSION AND AVOIDANCE, a plea showing new facts by which it is designed to negative the allegations in the pleading of the adverse party. It may apply to the whole or to a part of the pleading, but if only to a part it must be so stated. This plea expressly or impliedly admits at least the apparent truth of the allegations of the plaintiff. All statements in confession and avoidance must be both specific and clear. Pleas in confession and avoidance must conclude with a verification.
CONFESSION OF FAITH — CONFESSIONS OF SAINT AUGUSTINE

They must plead matter either in excuse and justification or in discharge, as a release.

CONFESSION OF FAITH, Westminster, a document prepared by the Assembly of Divines which met at Westminster in obedience to an ordinance of Parliament issued 12 June 1643. The whole number of the assembly amounted to 174 members, 32 of whom were members of Parliament appointed as lay assessors. The greater part of the assembly were Puritans. One of the chief results of the deliberation of the Assembly was the framing of the Confession of Faith, intended to be that of the national Church of Great Britain. In England it nominally held this position for a short time. On the return of the Scottish commissioners it was laid before the General Assembly of the Church of Scotland, by whom it was adopted as the creed of the Church by the act of assembly of 27 Aug. 1647. It has been adopted by the other Presbyterian churches generally, in some cases, however, with certain reservations; theology and discipline are thoroughly Calvinistic. See CREEDS; WESTMINSTER ASSEMBLY.

CONFESSIONAL, in Roman Catholic churches and chapels, a kind of enclosed seat, stall or box in which the priest sits to hear persons confess their sins. The confessional is often not unlike a sentry-box, the priest sitting within and the penitent kneeling without and speaking through an aperture. Many confessinals are in three divisions or compartments, a canopy, for the reception of the priest; the side compartments, which communicate with the centre by grated apertures, are for the penitents. The word confessional is often used in the sense of the tomb of a martyr or confess. Sometimes an altar was erected over the grave and the name was extended to the altar. If a church was erected over the tomb another altar was placed, in the building, exactly over the tomb with its altar below. The upper altar was called a confession or confessional.

CONFESSIONS, Les, an autobiographical work of Jean Jacques Rousseau (q.v.). It was written during the six most agitated years of his life, from 1765 to 1770; and his state of health at this time, both mental and bodily, may account for some of its peculiarities. The first six books were not published until 1781, and the second six not until 1788. According to more than one critic, the 'Confessions,' however charming as literature, are to be taken as documents of evidence with great reserve. They form practically a complete life of Rousseau from his earliest years, in which he discloses not only all his own weaknesses, but the faults of those who had been his friends and intimates.

CONFESSIONS OF AN ENGLISH OPIUM EATER. The 'Confessions' exist in two distinct forms. The earliest form, containing the two papers printed in the London Magazine for September and October 1821, appeared the next year (1822) and passed through no less than six editions in the next 30 years with extraordinary success. In 1843 Hesse began a series of articles in Blackwood's Magazine, under the title 'Suspicia de Profundis, being a sequel to the Confessions of an English Opium Eater,' but the series ran through only four numbers. In 1856, however, when he collected and arranged his writing for a uniform edition, he rewrote the volume of 1822 throughout, enlarging it to nearly three times its original dimensions. The introductory chapter, in particular, which in 1822 had been a brief account of his early years, was now enormously expanded by the insertion of some matter from the Suspicia and by crowding into it a multitude of incidents and experiences, many of which have no connection with opium eating and some of which seem to have been drawn rather from his imagination than from his memory.

This enlarged edition is really a vivid picture of De Quincey himself, not only as the opium eater, but as the scholar, the critic, the gossip. His mind was abnormally active; but he could never follow a straight line of thought or course of narrative. Everything reminds him of something else. But if the story takes a long time to get anywhere the path is yet thick with curious incident and subtle observation. Even the dreams and phantasies of the opium eater were not due principally to opium. De Quincey was a dreamer always. His early childhood, years before he ever tasted the drug, was largely passed in a floating dream; in his autobiographical papers we find record of hours when visions in sight or sound, vague and solemn, came upon him with the compelling sense of reality. The effect of opium in later years seems to have been to re-call these earlier experiences with strange vividness, to combine other incidents with them, and to repeat them habitually in his dreams. Indeed, the very best specimens of what he calls his dream phantasy seem not to have been suggested by any particular experience, or to have owed anything to the influence of opium. That wonderful fragment, the Three Ladies of Sorrow, from the Suspicia, is an embodiment of three of the darkest forms of human grief, mysterious but strangely vivid, but without a hint of anything morbid in its genesis — a work of the pure creative imagination.

It is in such passages as this we may see at its best that particular form of prose-poetry in which De Quincey claims to have been of his own invention. He always admired the large, sonorous style of the early 17th century men, and sometimes caught their manner very success- fully. In the 'Confessions' is an apostrophe to opium imitated from Walter Raleigh's famous apostrophe to death, which is quite as lofty as its original. This elaborated style is indeed ill adapted to the rambling gossip that makes up so large a part of De Quincey's writing, but his passages of reverie and dream owe their strange effect upon our sensibilities very largely to their stately movement and music. Consult Saintsbury, 'Essays in English Literature' (1780-1880); Stephen, Leslie, 'Hers and His Library' (1st series); Winchester, C. T., 'A Group of English Essayists.'

CALES T. WINCHESTER.

CONFESSIONS OF SAINT AUGUSTINE. The. Autobiographies are as a rule utterly conventional and commonplace, interesting only to those immediately connected with the author. We have any number of them that are waste paper, but a few of them like Cellini's life of himself, Montaigne's 'Essays,' and Rousseau's 'Confessions,' show that when a
man pours himself out he can make a supremely human document that is enduring literature. Among these immortal autobiographies, probably the work that has had most influence, in the intellectual world at least, is "The Confessions of Saint Augustine" (354-430 A.D.). He wrote them shortly after he became bishop of Hippo, just before 400 A.D., when he was in his early forties. The fact that the book has maintained its popularity for over 1,500 years shows from how close to the human heart it is written. For the Confessions are the history of Augustine's heart. We have two other sets of autobiographic documents from his hands, the "Retractations," which are the story of his mind, and his letters, which give an account of his activities. These two are little known beyond the narrow circle of students of theology and Church history. Most writers of autobiography seem to think that it is the story of their minds and their actions that will fill all the cellars of Augustine's immortal record of his affections which still continues to attract the attention of each generation of thinkers shows that it is by the heart men live. Saint Augustine's Confessions will not have how it is to many, people imagine, an account of past deeds and above all not an avowal of youthful transgressions as such. The word confession is used in the biblical sense of the Latin word confiteri as an acknowledgement. Augustine's Confessions are quite literally the acknowledgment of a soul forced to admire the action of God within itself, though it has to admit the many obstacles that it placed in the way of Divine influence. It is full of the psychology of human conduct, though so many people seem to think that only in comparatively recent years have men begun to reflect thus carefully on their inner activities. It has been said of the book, "neither in respect of penetrating analysis of the most complex impressions of the soul nor communicative feeling, nor elevation of sentiment, nor depth of philosophic views, is there any book like it in all literature." As Augustine was one of the profoundest intellectual geniuses of human history, full of science for his marvelous insight into human motives and his capacity to describe the various states of the soul and the facts of the spiritual world, it can be readily understood why this little book in which he set no barriers in his desire to reveal for God's honor and glory all that had gone on within him in the motivation of his life should be of supreme human interest. He was a psychologist of the psychologists, and while he was the greatest of the Fathers of the Church in the sense of being the authoritative expositor of the esoteric meaning of more of her doctrines than any other, he is also the patron and master in their own estimation of more of the hereticks of the ages than any other, because the matter that he dealt with was so profound that it is rather easy to twist his meaning to anyone that the disciple may wish to have in order to support his own opinion. The psychology of the Confessions has probably more interest for our generation than other features of the work. The modern psychologist into child psychology in the first book exemplifying that a child has definite tendencies away from law and order toward neglect of study and precept, learns not by rules but by example, and observes closely the inconsistencies of elders, has drawn many a one to reading the rest of the book. The boy Augustine was very human, hated Greek and liked "the empty tales of the poets," and blames like everyone else the methods of his education and yet confesses how much more of good than of ill came to him from it. He went through his salad years when he liked to pity himself and has a chapter "On Weeping and Why It Is So Fretted." Above all he shows very clearly how much personal affection meant to him. The death of a friend overwhelms him, but companions serve to distract him; his mother rescues him, not his principles; he comes under the personal influence of Ambrose; always it is personality that draws him. He soon came to realize that the claims of his intellect for satisfaction were incapable of fulfilment. "For I withheld my heart from all assent dreading a downfall; and came nearer being killed by the blow of education. For I wished to be as assured of the things I saw not, as I was that seven and three are ten. But as it happens that one who has tried a bad physician fears to trust himself to a good one, so was I afraid I could not be healed, but by believing, and for fear of believing falsehoods, refused to be cured." (Book VI, chap. 4). Augustine's Confessions will probably always continue to be a favorite book for those who have learned the lesson that the heart life of man is ever so much more important than his intellectual life. Consult "The Confessions of Saint Augustine" (The Ancient and Modern Library of Theological Literature, New York 1886); Schaff, "Saint Augustine" (ib. 1854); Farrar, "Lives of the Fathers" (London 1889); Harnack, "Augustin's Confessionen" (Giessen 1895). Many modern writers on philosophic subjects have monographs on some phase of Augustine's thought: Renan, Eucken, Spalding, McCabe, Reuter, etc. JAMES J. WALSH, Author of 'Catholic Churchmen in Science.'

CONFESSOR, in the Roman Catholic Church has two principal significations. (1) Denoting a canonized male saint outside of the classes of the apostles, evangelists and martyrs. The only saints, who in the Church publicly venerated in the Church after death were, in addition to the Blessed Virgin and the apostles, the martyrs; and such are all the saints named in the Roman canon of the Mass, though the Milan canon (Ambrosian) has the name of other saints. (2) The other meaning of the word confessor, the priest who hears confessions, answers to the more correct Latin word confessarius. The confessor, minister of the sacrament of penance, does not exercise that ministry simply in virtue of his having received priestly order: he must receive jurisdiction from the bishop of the diocese. The general law of the Church requires each of the faithful to resort to the confessional at least once in every 12 months, and to make confession each to his own parochus or parish priest; but under the law they may now lawfully confess to any priest who has due authorization from the bishop.

CONFIDENTIAL OR PRIVILEGED COMMUNICATION. In law, a communication made by one person to another which the
CONFIRMATION — CONFUCIUS

latter cannot be compelled to give in evidence as a witness. The laws of the United States and of some other countries are, that all communications made between a client and his agent, between the agent and the client, or between the several parties to a suit, shall be treated as confidential; but in some minor points the practice varies in the different States. Legal agents are of course required to produce any papers entrusted to them by their clients, which the clients themselves would otherwise have been required to produce. The privilege of confidentiality regarding disclosures made to a medical adviser, even although it may have been necessary for the patient to make them in order to enable the physician to understand and treat his case, have not been defined by statute, but the custom has been that such communications are privileged. The same holds true regarding confessions made to a priest. No instances are cited. Confession as such has never been revealed by a priest. Communications made between husband and wife during marriage are in some States not admissible as evidence, although in most civil cases a husband and wife may legally be called as witnesses against each other. The laws in the United States differ in different States regarding the admission of testimony of husband or wife for or against each other.

CONFIRMATION (Lat. confirmare, "to make strong"), one of the seven sacraments of the Roman Catholic Church; in the Lutheran, the Anglican, and the Protestant Episcopal Church confirmation is not a sacrament, but only a solemn rite wherein the one who is confirmed renews in the face of the Church the promises made on his behalf by his sponsors in baptism. Confirmation addresses the person upon whom it is conferred to the status of a communicant and to full membership in the Church. In the early times of the Catholic Church the sacrament or rite of confirmation was immediately after baptism even of infants; hence the two rites have often been, even by orthodox writers, viewed as one; and in the Greek and Oriental churches this custom still persists. But in the present discipline of the Latin Church confirmation is usually administered about the 12th year, though a child might be held competent to receive it at the age of seven. It is customary for the confirmand to take an additional name as a memorial of the rite. In administering it the bishop — and the bishop is the ordinary minister of this sacrament — with chrism (q.v.) marks the sign of the cross on the forehead of the recipient, and gives him a gentle slap on the cheek, in signification that he must be ready to suffer for Christ's name's sake. The formula of words used by the bishop in signing the confirmant is, "I sign thee with the sign of the cross and I confirm thee with the chrism of salvation, in the name of the Father, and of the Son, and of the Holy Ghost."

CONFISCATION. In international law, the act of one state in appropriating property belonging to another state or to its subjects, either as a belligerent right or as a punishment for carrying contraband of war, blockade running or the like. The term is used also to indicate the seizure of property by the state as an act of punishment for non-compliance with the law, as for violation of internal revenue regulations. In English law some early authorities, including Blackstone, seem to use the term as a synonym for "forfeiture." If it has been held to embrace only seizure by the Crown of goods found on a felon, but not claimed by him, and to articles dropped by a thief fleeing from justice. (See Forfeiture.) By statute in England, passed in 1914, enemy property which had been subjected to confiscation by the Crown was placed under the care of a legal custodian.

In Roman law goods which had been subjected to confiscation by the state were called by the civilians bona confiscata, and belonged to the fiscus, or imperial treasury. One form of confiscation long known to international law is called angaria or angry, which is defined as the seizure or destruction of neutral property by a belligerent when urgently necessary, with due compensation later. This right was exercised in the Franco-Prussian War by Germany.

In the United States, enemy property has frequently been confiscated under international law and by Federal statute. In 1912 during the Civil War, Federal statutes were passed providing for the confiscation of property used for insurrectionary purposes, and these statutes were later held to be constitutional by the Supreme Court. Congress, dating from the adoption of the Constitution, has had the exclusive power of confiscation of alien property. Shortly after the outbreak of hostilities with European powers in the spring of 1917, the United States seized a large number of ships belonging to Germany and Austria found afloat in various ports, under a well-known rule of international law justifying the act. By a Federal statute enacted 6 Oct. 1917, a legal custodian was appointed for all alien enemy property confiscated in the United States during the war then pending.

By proclamation of the President of the United States, 20 March 1918, under the authority conferred upon him by the Naval Bill of 1917, "in exercise of our indisputable rights and in accordance with the law and practice of nations," 68 ships, representing about 470,000 tons, belonging to Holland, lying in United States ports, were confiscated. The seizure was condemned by Germany and also in other quarters, as in Holland, as a violation of the rules of international law. It has been vigorously defended, however, as lawful by eminent jurists and justified by the law of angaria or angry, long recognized in legal usages as stated above, and also as incorporated in The Hague conventions of 1899 and 1907. At about the same time Great Britain, claiming under the same right, took control of a number of Dutch ships representing about 400,000 tonnage.

CONFISCATION ACT OF 1861, a United States statute "to confiscate property used for insurrectionary purposes." See Confiscation.

CONFUCIUS, künk-fú'shi-âhs (Latinized form of Chinese K'ung-futze, the Master Kung), Chinese philosopher: b. province of Shan-tung, about 551 b.c.; d. in Lu, 479 b.c. His father, Kung Shuh-liang-heh, who was of royal descent, died three years later, and the
boy was reared in comparative poverty by his mother, Ching-tsai. At the age of 17 he was made inspector of corn-markets, keeper of granaries and overseer of public fields; he made such a good record that he gained the favor of the governor. At 19 he married, and some four years later he began his career as a teacher. By 520 he had worked out the general doctrine of his philosophy and departed very little thereafter. The disregard for the moral law then prevalent in the province of Lu induced him to make a study of the ancient writings of China. At the age of 22 he had already become a well-known teacher and expounder of the ancient writings, and many noted persons gathered at his house to gain instruction from him. He had no intention of teaching a new religion or philosophy. He aimed to bring men to a realization of the utility, beauty and truth of the old. He bent all his energies to reviving old customs; and in this he set a fashion still strong in China to-day. In 517 B.C. he was induced, by two members of one of the principal houses in Lu, who had joined his band and brought the capital with them, where he had interviews with Lao-tze, the founder of Taoism. Though temporarily driven from Lu to Ts'i by a revolution, he soon returned thither with an increasing following; and there he remained for 13 years, during which he kept constantly in view his mission as a philosophical teacher. At the age of 52 he was made chief magistrate of the city of Chung-too. So striking a reformation was made by him that he was chosen for higher posts, became minister of crime, and with the aid of two powerful disciples, elevated the state of Lu to a leading position in the kingdom. Through the political intrigues of the governors of neighboring states Confucius was removed from office (496 B.C.), and became a wanderer in many parts of China for 13 years.

In 485 he returned to Lu, but would not take office. The death of his favorite disciples, Yen Hwin and Tze-liu, in 481 and 478, did much to turn his own, which took place in the latter year. Confucius left no work detailing his moral and social system. His five canonical books ('Yih-king'; the 'Shu-king'; the 'Shi-king'; the 'Le-king'; and the 'Chun-tsun') are grouped with the 'Four Books'; by his disciples, the 'Ta-ho or Great Study'; the 'Chung-yung or Invariable Mean'; the 'Tun-yu or Philosophical Dialogues'; and the 'Hi-tse,' written by Meng-tse or Mencius. (Consult 'Sacred Books of the East'). The teaching of Confucius has had, and still has, an immense influence in China, though he hardly can be said to have founded a religion or a philosophy. All his teaching was devoted to practical morality and to the duties of man in this world in relation with his fellows. In it was summed up the wisdom acquired by his own insight and experience, and that derived from the teaching of the sages of antiquity. He sought to attain a happy tranquillity throughout the Chinese kingdom. It was the achievement of the observance of the five obligations of human society: Those between sovereign and minister; father and son; husband and wife; elder and younger brother; and between friends. It was, according to his teaching, incumbent on all to perform the reciprocal duties arising from each relationship. In his teachings there is a strong feudal leaning which advocates almost unlimited authority for the sovereign over the minister; for the father over the son; the husband over the wife; the elder brother over the younger. Subordination to superiors he looked upon as one of the greatest of all essentials for the existence and proper conduct of the state. To these must be added virtuous conduct among men and among friends. The education of the young he declared to be the foundation of the welfare of the state. Democracy had not yet made its appearance in China and Confucius' ideal of government was a paternal despotism wisely and honestly directed and administered. This position he modified by the assertion that a ruler's maintenance of power should depend upon his just and upright conduct and his honest endeavor to make his government good.

His philosophy is not deep, but its general tendency is good, affecting strongly the usual intercourses of life. It is thoroughly practical and terrestrial, and it avoids theology and metaphysics and all those subjects that Confucius could not of disciple, to view rigidly as rules of life. He never attempted to solve questions that he considered beyond his reach. Fast and hard rules of morality and action he made to govern the intercourse of the human race; and in this sense he tied China's civilization to a system for hundreds of years. He occupied himself altogether with the problems of this world and let the next take care of itself. From the Christian point of view, therefore, there is nothing spiritual about the work of Confucius. His attitude toward spiritual questions he has put clearly upon record: "To give one's self up earnestly to the duties incumbent upon men and, while respecting spiritual beings, to keep aloof from them, may be considered wisdom." His teachings have left China more materialistic and less spiritual than is any of the other great nations. While he instilled morality and national and individual honesty, yet more than 24 centuries of his teachings have not driven superstition and ignorance out of the land, nor improved the government, nor raised the condition of the masses of the people, nor driven illiteracy out of the nation. They have retarded the progress of democracy in a people, in spirit, essentially democratic, and they have encased the national spirit in a hard shell of rules and conventionality from which it has just begun to make spasmodic efforts to free itself. The thinking people have, however, begun to realize dimly that his philosophy is, in many ways, unsuited to an age in which the spirit of all progressive government is expressed by the will of the people. Since the overthrow of the monarchy, candidates for public offices are no longer required as formerly to pass a rigid examination in the "nine classics." As the teachings of Confucius gave their strong sanction and support to the despotic form of government which ruled China, almost uninterruptedly for more than 30 centuries, the royal family and the nobility naturally gave it to it an importance that it did not intrinsically possess. They saw to it that there were magnificent shrines erected to Confucius in every city, town and community throughout the land, and the high priests were specially honored, so that they became one of the mightiest forces in the
direction of the life of China. However honest they may have been in the fulfilment of their great duties and obligations, they have hung upon the chariot wheels of progress.

JOHN HUBERT CORNW, Editorial Staff of the American

CONFUSION (Lat. confusio, *a mixing together*), the act of confusing or mingling together two or more things or notions that are properly separate. (1) In mental diseases acute confusion occurs in the early stages of general paralysis, in acute mania, in melancholia, in dementia praecox, and in most of the insanities. It might be called an initial symptom of insanity. The characteristic symptoms are lack of correct appreciation of external expressions, loss of continuity of thought, with a certain enfeeblement of judgment. There are certain insanities characterized purely by acute confusion. See INSANITY.

(2) Confusion is used, in a legal sense, in civil law, to signify the merger of two titles in the same person. In both civil law and Scots law it implies the extinction of an obligation or servitude through the fact that the two parties whose divided position is necessary for the continuance of the debt or obligation become one person. This might happen when one of them became the heir of the other for instance.

CONGÉ D'ÉLIRE, kohn-zhah-deh-layr (Fr. *leave to elect*), in England, the sovereign's warrant authorizing the dean and chapter of a vacant see to proceed with a new election. The nomination to bishoprics, originally understood to have been vested in the Christian people, who made it by election, was afterward transferred to the sovereigns of most states, and remained with them till the 11th century, when, with the assistance of the Pope, it was wrested from them and conferred upon the clergy. In England, the Constitutions of Clarendon, in 1164, conferred the election on the chapters, and this right was formally confirmed by Magna Charta, subject, however, to a right in the sovereign to grant a congé d'éliére, and also to confirm the chapter's choice. Thus matters remained till the Reformation, when the Crown made a very important encroachment, and provided by 25 Henry VIII c. 20, that though the dean and chapter were still required to go through the form of an election, the person to be chosen should previously be absolutely fixed by the sovereign. This act is still the regulating statute, and not only provides that on every vacancy in a see the sovereign may grant a license to proceed to the election of a successor, and with it a letter containing the name of the person to be elected, but that, if the dean and chapter delay the election beyond 12 days or elect any other person than the one named in the letter, or do anything else in contravention of the act, they incur the penalties of a præmunitio, that is, forfeiture of goods, deprivation of certain civil rights and imprisonment. Any bishop or archbishop neglecting to assist at the consecration and investment of the bishop-elect, within 20 days after the legal announcement of his election, is liable also to the penalties of præmunitio.

CONGENITAL DISEASE, a disease which the new-born child inherits from its father or mother, or it may be its grandparents. Syphilis, gout, congenital anomalies such as hare-lip, web fingers and toes, etc., are among the few truly congenital diseases. During child-birth children may acquire infections, but these are not truly congenital diseases. It is often very difficult to tell whether a child becomes diseased in the parturient canal of the mother, at the time of birth, or through accident, or through contact with the mother following birth. See CHILDREN, DISEASES OF.

CONGER, kön'ger, Edwin Hurd, American diplomatist: b. Knox County, Ill., 7 March 1843; d. Pasadena, Cal., 18 May 1907. He was graduated at Lombard College in 1862, served in the Union army 1862–65, was graduated at the Albany Law School in 1866, and was elected to Congress in 1884 and twice re-elected as a Republican. He was Minister to Brazil (1890–95), and then to China. He was at his post throughout the Chinese crisis of 1900, in Peking, being imprisoned with his family and the entire diplomatic corps in the British legation from 20 June to 15 August. His rescue on 20 August was effected by the allied powers barely in time to save him and his colleagues from a general massacre. He was appointed Ambassador to Mexico early in 1905 but resigned in August of that year.

CONGER EEL, a species of marine eel (*Leptocephalus conger*) with a long dorsal fin reaching forward nearly to the head and continuous posteriorly with the caudal; the pectoral fins present; strong, close-set teeth in the jaws; mouth and eyes large, and scales absent. The conger is a large eel, the ordinary specimens commonly captured along the New England shores being four feet long while those living in the open sea are six to eight feet, and weigh 50 to 60 pounds, and, in rare cases, upward of 100 pounds. Very little is known of their habits in the natural state, but they are easily kept in aquaria and are known to be ravenous creatures, which devour fishes, crustaceans and mollusks, and even the smaller members of their own species. From observations made on specimens in captivity in England Dr. Cunningham has concluded that, as in many other fishes, spawning takes place but once; the females, upon the approach of that period, ceasing to feed and undergoing degenerative changes in respect to the skeleton and other parts. Spawning occurs in the deep sea and during development a transparent band-like larva is formed which was long ago described as a distinct genus under the name of *Leptocephalus*. The conger is a prolific fish, producing about 3,000,000 eggs. After nightfall the conger eel may be induced to take the hook and affords good sport.

CONGESTION (Lat. congestio, *accumulation*), an abnormal amount of blood in the
vessels which is caused by pressure on the arteries or by obstruction to the emptying of the veins. It is usually due to some acute inflammatory reaction, causing rapidity of the heart beat or dilatation of the blood vessels with consequent congestion in some area. If venous congestion, as a rule, the cause is due to some constriction of the venous return to the heart. Congestion is present during many diseases, and may be caused temporarily by over exertion of the heart, or a severe blow, fall or cold. See Cold.

CONGLENTO, England, a market town and borough of Cheshire, in a deep valley, on the Dane, 26 miles south of Manchester. Among the chief buildings are the town hall and grammar-school. Congleton is a seat of the silk manufacture, ribbons, handkerchiefs, and other articles being made; it also carries on fustian-cutting, the manufacture of agricultural implements, rope-making, brewing, etc. Near it are collieries and quarries, and salt in abundance. In the neighborhood. Pop. 11,300.

CONGLOMERATE (Lat. conglomeratus, "rolled together"), or PUDDING-STONE, a firm sedimentary rock made up of rounded detrital pebbles and even boulders, the interstices usually filled with sand or other fine-grained rock material. Silica is the common cementing material, calcite and limonite coming next. The pebbles and boulders may be of any kind of rock, though quartz and quartzite are the most frequent, since the most resistant material in gravels. According to the character of the pebbles, different names are given, as quartz conglomerate, limestone conglomerate, etc. Conglomerates grade through pebbly sands and sandstones into true sands and sandstones. Under dynamic stress, in the folding of rock strata, the pebbles of a conglomerate may be much distorted, and by further metamorphism a conglomerate may pass into a gneiss. Some notable conglomerates are the copper-bearing Calumet and Hecla conglomerate on the Keweenaw Peninsula, Michigan, of Algonkian Age; the great conglomerate at the base of the coal measures of Carboniferous Age, in Pennsylvania and adjacent States; the Roxbury conglomerate of uncertain age, near Boston, Mass.; and the famous "Bark)<" possibly of Permian Age, on which are located the great gold mines of the Transvaal. See BRECCIA; GNEISS; ROCK; SANDSTONE.

CONGO. See Kongo.

CONGO FREE STATE. See Kongo.

CONGO SNAKE. See Kongo Snake.

CONGREGATION (Fr. congrégation, Lat. congregatio, from congregate, to come together in a body), a gathering or collection of persons; usually a religious assembly; in its most ordinary use, an assembly of Christians met in one place for worship. (1) In the Roman Catholic Church, it often designates a sort of board of cardinals, prelates and divines, to which is entrusted the management of some important branch of the affairs of the Church. Thus the Congregation of the Index examines books and decides on their fitness for general perusal. The Congregatio de Propaganda Fide is instituted for the propagation of the faith, in the interests of the government of the Church in non-Catholic countries. The Congregation of Relics inquires into the genuineness of supposed relics. The Congregation of the Holy Office takes cognizance of heresies, etc. The Congregation of Rites regulates the festivals and offices of new saints. There are numerus of congregations. The word is also used in the Roman Catholic Church to describe communities of ecclesiastics who live together under rule, but without being bound by vow, or at least by solemn vow. Such are the Congregation of the Oratory, the Congregation of the Most Holy Redeemer, usually called Redemptorists, etc. See Congregation of Our Lady of Calvary; Congregation of the Mother of God; Free Congregations.

(2) In the Old Testament, congregation has the religious sense of the whole body of the Hebrew people gathered together and set apart for the service of God; while in the Christian Church it bears both the older meaning of the Church in general and also that of an assembly of worshippers, in a restricted sense.

(3) Congregation was also the name given to the Protestant Reformers in England during the reign of Mary.

CONGREGATION OF BISHOPS; CONGREGATION OF THE CONSISTORY, etc. See Congregations of the Sacred.

CONGREGATION OF OUR LADY OF CALVARY. A French order of Benedictine nuns, which had a somewhat stormy career. Organized at Poitiers in the early part of the 17th century, the Society, after having played an important part in the religious life of France, was broken up during the Revolution, its members dispersed over the face of Europe. The order was reorganized and again secured a firm footing in the land of its birth. See Congregation.

CONGREGATION OF THE MOTHER OF GOD. A monastic order instituted at Lucca, Tuscany, about 1574 by GiovanniLeonardi. It was originally known as Clerks Secular of the Blessed Virgin, and later, while Leonardi was still alive, as Clerks Regular of the Blessed Virgin, a name it kept until the Society was suppressed in 1867. The former residence of the clerks, who also kept a large, flourishing and famous boys' school, is now the Public Library of Lucca. On its reorganization the Society was known popularly as the Congregation of the Mother of God.

CONGREGATIONAL EDUCATION SOCIETY, a body incorporated at Boston 1816, for the purpose of educating youths for the gospel ministry. After changing its name several times, in order to cover the scope of its work in secondary and missionary schools, it finally adopted the name it now holds and included in its purpose, not only the support of students, but of all schools of Christian teaching.

CONGREGATIONAL METHODIST CHURCH, an ecclesiastical body in the United States, organized in Monroe County, Ga., by seceders, lay and clerical, from the Methodist Episcopal Church, in 1852. The movement was in the direction of a more democratic or congregational polity, designed to give the members of the local churches larger and more direct control of their own affairs; but the body still preserves the more essential forms
of organization and procedure, such as the conference system, etc., characteristic of the Methodist Episcopal Church. It has a membership of over 20,000 distributed among about 350 churches.

CONGREGATIONALISM had its origin in an attempt in England to carry the principles of Reformation regarding the authority of Scripture to their radical consequences. Accepting the Bible as the sole rule of faith and practice, the founders of Congregationalism sought to find in it not merely an authoritative source of Christian doctrine; but, also, a complete, adequate and binding pattern of church government and organization. They grew out of the Puritan party of the reign of Queen Elizabeth, of which party they were the most advanced wing. They shared fully the intense Calvinism of that party and differed from it only in matters affecting church organization and government. The great majority of the Puritans held to the conception of a national Church, of which all baptized and named communicant members of the kingdom were members. The reformation of this Church, though earnestly to be sought by private Christians, they viewed as ultimately the work of the national government, and hence they held it to be a duty to remain in the Church of England, while laboring for what seemed to them its betterment. This reformation involved, in the conception of the Puritans generally, the establishment everywhere of a learned, earnest, preaching ministry; of efficient discipline; of what they deemed a more scriptural organization of the Church; and the use of such vestments and forms of worship as seemed to them to be without biblical authority or to savor too strongly of Roman usages.

The founders of Congregationalism sympathized with these aims and criticisms of the Puritans, but, unlike the majority of that party, they believed that the reforms which they desired in the Church of England should come about through the initiative of the Church of England, without separation from that Church of those who criticized it. Hence the early Congregationalists of England were called "Separatists." They rejected the thought of a national Church. They believed that the only proper form of the visible Church is the local congregation, composed of a company of professed disciples of Christ who can claim personal religious experience, and are united to Christ and to one another by a voluntary covenant which transforms a company of Christians into a Church. Of these congregations Christ is the immediate head. Each, they conceived, is completely self-governing, choosing its own officers and administering its own discipline. While no earthly authority outside of such a Church has jurisdiction over it, each such congregation owes advice and aid to its sister congregations as necessity may require. This mutual responsibility and helpfulness has always led American Congregationalists to reject the name "Independent" which is popularly attached to the churches of this order in Great Britain. The officers of such a local Church were conceived by the founders of Congregationalism, following carefully the New Testament model, to be a "pastor," and a "teacher" who should preach and administer the sacraments; a "ruling elder" who should aid the "pastor" and "teacher" in the administration of discipline; "deacons" to administer the financial affairs and charities of the congregation, and "widows" to care for those in illness and the poor. In their revolt from the prescribed liturgy of the Church of England they held that public prayer should be in the vernacular, and like the Calvinists generally, they gave the chief place in public worship to the sermon.

Though Richard Fitz and his associates, whose congregation at London was broken up by the English government in 1567, may be deemed the earliest organized Congregationalists, the first clear presentation of Congregational principles was made in the works of Robert Browne, a graduate of the University of Cambridge in 1572, who passed from Puritanism to Separatism, probably in 1579, organized a church at Norwich in 1580 or 1581, and issued a series of tracts in defense of his views, from his exile at Middleburg in Holland, in 1582. Though Browne not long after confounded the Church of England, his work was taken up by others, notably by Henry Barrowe, a lawyer of London, and Rev. John Greenwood and Rev. Francis Johnson in the same city, where a Congregational church was organized in 1592. In 1593 Barrowe and Rev. John Penny were hanged at London for opposing the ecclesiastical authority of Queen Elizabeth, and the Church in London was driven into exile. It found a refuge in Amsterdam under the care of Francis Johnson and Henry Ainsworth.

Contemporaneously with the later of these events, an apparently independent movement in the vicinity of Gainsborough and Scrooby, led at first by William Brewster, the postmaster at Scrooby, Rev. Richard Clyfton, rector at Babworth, and later also by Rev. John Robinson and Rev. Johan Smyth, resulted in the organization, about 1606, of congregations at Scrooby and Gainsborough, which were compelled to seek refuge speedily in Holland. That of Scrooby settled, in 1609, at Leyden under the pastoral care of Robinson, and a portion of this congregation, led by William Brewster, William Bradford and Edward Winslow, crossed the Atlantic in the Mayflower ship in 1620 and laid the foundations of Plymouth Colony in 1620, thus establishing the first of the Congregational colonies in America.

The settlers of Plymouth were Separatists, but during the years immediately succeeding their establishment in the New World, the course of politics in England under James I and Charles I was such as to lead many of the Puritans to despair of the attainment of the reforms they desired in Church and State in the home land. The consequence was a large Puritan emigration across the Atlantic; and the establishment, in the course of a decade (1628-38), of the three Congregational colonies of Massachusetts Bay, Connecticut and New Haven. These Puritan settlers were all led by the radical development of their own principles in a new environment, and the influence of Plymouth example, to establish churches on the Congregational model, at their settlement in New England.

These colonies differed slightly from one another in the degree in which they applied theocratic principles to the organization of the State. In Massachusetts from 1631 to 1664, and
in New Haven from 1639 to 1665, when New Haven was absorbed in the Connecticut Colony, the franchise was confined to church members. In Connecticut and Plymouth colonies no such restriction existed. Deacons were elected by the church; they were not, as in the New England churches as a whole, a body standing as a separate and independent corporation. The pastor was the ruling elder; the deacon, the first member of the class next below the ministry; the teacher, a class above the deacon. This was the system of church officers already described, and believed by the founders of Congregationalism to be scriptural, outlasted the first generation of the settlers of New England in only a few instances. While they existed they were pastor, teacher, and ruling elder, all received salaries from the churches they served, but the latter had to be elected by the teachers and ruling elders soon disappeared, leaving only a pastor and a variable number of deacons. The modern growth of organization and methods of Christian work has led to the establishment of other officers, such as a clerk, a treasurer, a Sunday-school superintendent, and often one or more standing committees, and no feeling now exists that officers should be limited to those mentioned in the New Testament or as possessed by the early Church. The pastor remains, with rare exceptions, the only salaried officer. The support of public worship which was originally by voluntary gifts, and has always been so in New England, was not raised by levying taxes in 1629, a matter of public taxation in all the Congregational colonies. In Connecticut this relation to the State which made Congregationalism practically a State-supported Church lasted till 1818, and in Massachusetts till 1834; but since the latter date Congregationalism has nowhere enjoyed State aid.

The high-wrought spiritual impulse manifested by the first settlers of New England was followed by a period of decreasing religious interest, affecting the second, third and fourth generations on New England soil. This condition was terminated by a series of revivals, of which the first manifestation was in that at Northampton, Mass., under the pastorate of Rev. Jonathan Edwards. It was marked, however, by much excitement, and was followed by a period of spiritual decline lasting through the troubled years of public conflict and dispute which ended with the adoption of the Constitution of the United States. It resulted in serious controversy in the churches of New England as to its merits, those who opposed it as on the whole harmful being called Old Lights while those who favored it were nicknamed New Lights. In the teachings of Jonathan Edwards (1703-58) a theological movement of importance in American religious history began; and the modified Calvinism of the Edwardsean school was further developed by Joseph Bellamy (1719-90), Samuel Hopkins (1721-1803), the young Congregationalist Jonathan Edwards (1745-1801), Timothy Dwight (1752-1817), and Nathanael Emmons (1745-1840) into a distinctive New England theology. In eastern Massachusetts, on the other hand, a liberal school arose before the American Revolution, which grew slowly and was made clearly evident in the Unitarian separation of the early years of the 19th century—a separation that had its most conspicuous manifestation in the adhesion of Harvard College to the liberal side in 1805, though the full significance of the division was not apparent until 10 years later.

With the decade beginning in 1791, the Congregational churches of New England experienced a series of revivals which were repeated at intervals until 1858. Under these impulses not only was the membership of the churches much enlarged, but a rapid development of agencies for missionary evangelization and religious education. The churches of Connecticut, which had already done home missionary work in Vermont and New York for more than 20 years, organized their General Association in 1798 as the Missionary Society of Connecticut. A missionary society
was formed in Massachusetts in 1799. In 1801 the New Hampshire Missionary Society was inaugurated, and in 1807 a similar organization was effected in Vermont. These societies were chiefly engaged in home missions in the then Western States and Territories, though some work was done by them among the Indians. In 1811 the American Board of Commissioners for Foreign Missions came into being and enlisted the activities of the Congregational churches in evangelization abroad. This society was followed, in 1815, by the formation of what is now known as the Congregational Home Missionary Society, now known as the Congregational Home Missionary Society was organized to undertake home missionary work. These were followed later by the formation of the American Missionary Association, in 1846, for labor, especially, among the negroes and Indians. The United States Agency is the organization which has done a large missionary and educational work in the South since the Civil War. In 1853, the Congregational Church Building Society came into being, under the title of the American Congregational Union—an organization the work of which is sufficiently described by its more recent name. All these societies still exist and serve as agencies for the missionary activities of the Congregational churches of the United States. By the action of the National Council of 1913, ratified by these societies, the voting membership of the council are voting members of each of these national societies, which are then brought into direct relations to the churches. A considerable consolidation of these societies has been planned but the details have not been fully worked out.

Contemporary with this awakening of missionary activity and immediately consequent upon the passage of Harvard University to the liberal side occurred an extensive development of theological education, beginning with the opening of Andover Theological Seminary in 1808. Bangor Theological Seminary was founded in 1816; and, in 1822, the theological department of the Yale University was organized. Local disputes in Connecticut growing out of the modified type of Edwardian theology presented by Prof. Nathaniel W. Taylor of Yale led to the organization in 1834 of what is now known as Hartford Theological Seminary. The theological department of Oberlin College came into existence in 1835, and the westward growth of the denomination brought about the opening of Chicago Theological Seminary in 1838, and of the Pacific Theological Seminary, now at Berkeley, Cal., in 1869. The latest school for ministerial training that is opened at Atlanta, Ga., in 1901. These eight theological seminaries are the principal agencies for the training of the Congregational churches of the United States. The Congregationalists of Canada have a seat of ministerial education in the Congregational College of Canada, established in 1830, and now affiliated with McGill University at Montreal. New England has 11 Congregational colleges do a work similar to that of the theological seminaries on this side of the Atlantic.

To the close of the 18th century the Congregational churches of the United States were practically confined to New England; and, in the subsequent westward extension of New England emigration, Congregationalism and Presbyterianism long worked together in the formation of churches in the newer States under the so-called "Plan of Union" of 1815. This "Plan" was repudiated by the Old School wing of the Presbyterian body in 1837, and by the Congregational churches, through the "Albany Convention," in 1852. Congregationalism has now extended its force to those parts of the United States, especially, which have been settled through New England emigration. Throughout the latter half of the 19th century, the Congregational churches of the United States have felt an increasing denominational consciousness, which has found its expression, among other ways, in the gathering of bodies representative of these churches as a whole. A "Convention" met at Albany in 1852, a "National Council" at Boston in 1865, and since 1871 a "National Council" has met every three years. In 1913, by a new constitution then adopted, its sessions became biennial. Besides this "National Council" in which delegates of the churches of the United States are regularly assembled, the churches of each State are represented in an annual "Conference"; and the churches of smaller districts, usually counties, meet in more local "Associations." None of these bodies are in any sense courts of discipline, but they gather for deliberation, consultation and joint action by committees, or otherwise, in matters of common concern.

Each Congregational church is a self-governing body, capable of choosing its own officers, expressing its creed in such forms as seem best to it, determining the conditions for the admission of its members, and ordering its public worship as it seems most fitting. But while a Congregational church is a self-governing democracy, Congregationalism, always in the United States, and increasingly in Great Britain, has insisted that its churches are knit together in sisterly fellowship, and owe, therefore, to one another, advice in all matters of importance, discipline, and mutual helpfulness. Hence in questions of serious ecclesiastical concern such as the settlement or dismissal of a pastor, the management of a case of discipline which the local church finds it impossible to handle, the organization of a new church, and the like, Congregational usage in the United States, though not in Great Britain, requires the summons of an "advisory council" composed of a variable number of churches, chiefly from the vicinity, which are represented in the council by their pastors and a delegate each. These councils oftentimes also include a few individuals summoned by name as experts in the matter under consideration. By such a council are met for the particular occasion, advice is given; and, though this advice is not obligatory, it is seldom that the opinion of such a council is disregarded.

Membership in a Congregational church is conditioned on the vote of the local church itself, in view of the candidate's profession of faith in Christ, evident determination to live a Christian life and acceptance of the covenant
obligations of Christian service in connection with the local company of Christian disciples of which he desires to become a member. While all matters of concern in a local congregation are determined, ultimately, by the votes of the membership, Congregational churches transact their business chiefly through the use of committees, and a standing prudential committee to assist the pastor and deacons is appointed in most churches of numerous membership.

By while each church is thus free to establish such a test of the faith of candidates for its membership as it deems proper, Congregationalists in representative assemblies or in a more informal way have always been ready to testify to their faith of public creed declarations. Examples of such witness-bearing have been the approval of the doctrinal portion of the Westminster Confession by the New England churches by the Cambridge Synod in 1648; the modification of that confession by delegates of the English churches gathered at the Savoy, London, in 1658, and its publication as the Savoy Declaration; and the substantial confirmation of this Declaration by the churches of Massachusetts in 1680, and of Connecticut in 1700. Later examples of the same readiness of Congregationalists to witness to their beliefs is seen in the Principles of Religion adopted by the Congregational Union of England and Wales in 1833; the Burial and Deaconry Decrees by the National Council of the United States in 1865; the Commission Creed issued by a committee of the same American body in 1883 and the brief statement of faith and polity prefixed to the constitution adopted by the National Council which met at Kansas City in 1913. All of these statements have been regarded, however, as testimonies rather than as tests of ministerial fitness or church-fellowship.

Aside from its representation in the United States, Congregationalism is strongly entrenched in Great Britain, where its adherents are often known by the name Independents. The churches of this order in Great Britain are grouped together in county and district Unions and Associations and are represented in the Congregational Union of England and Wales and the Congregational Union of Scotland. In general, however, the Congregational churches of Great Britain have emphasized mutual accountability and organization into representative bodies much less than those of the United States. Congregationalism is credibly represented in the Dominion of Canada and in Austria, as well as in missionary soil, where the two extensive Congregational missionary agencies, the American Board, and the London Missionary Society, have labored. An International Council, representative of all lands in which Congregationalism has found a home, held its first session in London in 1889 and its second at Boston in 1909 and its third at Edinburgh in 1908.

Congregationalists in foreign countries numbered 666,669 on 1 Jan. 1914, of whom by far the larger number are in the British Isles. There are:

- In England and Wales: 453,457
- Scotland: 35,666
- South Africa: 22,427
- Japan: 16,102

and the rest in other countries.

The Congregationalists of the United States reckoned their communicants at 763,182 in 1915, with 6,993 churches and 5,923 ministers. The enrolment in Congregational Sunday-schools of the United States in 1915 was 757,873. The home expenses of the churches of the United States for the year 1914 were $107,731,311; their benevolent contributions in 1914 were $2,272,040.

The American Board of Commissioners for Foreign Missions by which the missionary work of Congregational churches of the United States is carried on reported the following statistics for the year 1915: Mission stations, 103; out stations, 1,458; American missionaries, 656; native laborers, 4,777; churches, 676; communicants (members), 80,844, of whom 5,834 had been added during the previous 12 months. The London Missionary Society, through which the foreign work of the churches of Great Britain is chiefly carried on, reported, during the same period, 1,730 stations and out stations, 480 missionaries, 6,907 native laborers, and a church membership of 82,319, of whom 4,000 had been added the previous year.

While the title Congregational designates a particular fellowship of churches, or religious denomination, in the United States and Great Britain, the Congregational form of church organization, especially in its aspect of the self-government of the local congregation, is that of many other religious bodies, notably of the Baptists, the Quakers, and the Quakers of certain branches of the Adventists, and Lutherans, so that the Congregational polity is much more widely extended than the adherents of the churches which officially or popularly bear the Congregational name.

WILLIETON WALKER.

Professor of Church History, Yale University.

CONGREGATIONS, Religious, communities or orders, bound together by a common rule either without vows or with solemn vows. In France the name is so used as to include associations or confraternities of the laity. A group of monasteries is sometimes called a Congregation, when they unite themselves closely by ties of government and discipline and by similarity of rule. The Cassinese congregations of Benedictines and the Congregation of Cluny are examples. The Holy See of the Catholic Church uses the term to designate a committee of cardinals entrusted with a department of Church affairs, such as the Congregation of Rites, which regulates the festivals and offices of new saints.

CONGREGATIONS, The Sacred. A Congregation is a college or corporation of the Catholic Church consisting of a certain number of Cardinals, for taking charge of, discussing and deciding matters which belong to certain particular branches of business. The primacy of the Roman Pontiff of his very nature demands that his counsellors and assistants should be selected throughout the world from among those who have personal knowledge and experience of places and persons in cases submitted for examination or judgment.

To this fact councils owe their origin. They did not, however, suffice. The need of a permanent body at the side of the Pope was felt to be opportune. Thus the College of Cardinals arose. When all the Cardinals were convoked in presence of the Pope to deliberate on a par-
ticular point or to transact an affair of importance, this Convocation was called a Consistory. From this Consistory of Cardinals the Roman Congregations took their origin.

The chief author of the Sacred Congregations was Sixtus V. He arranged all the ecclesiastical affairs of the system and distributed them among 15 different congregations.

Afterward Clement VIII, Gregory XV, Urban VIII, Clement IX and Pius VII added other congregations. They are divided into Ordinary and Extraordinary, and according as they are permanent or constituted only for a time.

The congregations consist of Cardinals, only one of whom holds the office of Prefect unless the Holy Father reserves that preface for himself. As Secretary, usually a titular Archbishop is appointed. In order that the decisions of the Congregations be valid it is necessary that not fewer than three Cardinals make up each Congregation, unless the Pope by a special indult exempts him from this number.

The power of each Congregation is limited to the matters assigned to it by the Pope, and the sphere of its jurisdiction extends over the whole Church.

The method of procedure varies according to the nature of the Congregations, the scope of power that is exercised and the diversity of the cases presented for deliberation or settlement. Routine matters of no great moment and which are not of special importance may be settled by the Secretary or the Prefect; while serious questions and judicial causes are laid before the whole Congregation and moreover must be brought to the personal attention of the Pope.

The decisions of the Congregations on the questions proposed are usually given in the simplest forms—for example, "Affirmative" or "Negative."

There can be no true appeal from the sentences of the Sacred Congregations as they are the decisions of the highest tribunals. However, a new hearing may be asked and obtained.

The Roman Congregations are the following:

1. Congregation of the Consistory

This Congregation is the solemn gathering of the whole college of Cardinals present in the Curia and assembling before the Pope for consultation and definition of certain most important ecclesiastical affairs. The Consistory is of two kinds, Public and Secret.

According to the present discipline only certain solemn acts are now performed in the Public Consistory, such as the giving of the red hat to the new Cardinals after they have been appointed in the Secret Consistory. In the Secret Consistory are made the promotions to the Cardinalate; appointments of bishops and their transfer from one diocese to another; the granting of Pallia; creation, division and union of diocese; selection oflegates; a later in the College of Bishops, the allocation of the most important Church matters, and in general consultations about affairs that are of most serious moment.

The Congregation of the Consistory has ordinary power and consists of from 8 to 12 Cardinals. Its secretary is the same as that of the Sacred College of Cardinals.

Annexed to this Congregation is the Con-

The Council of Trent in its twenty-fifth session solemnly declared its confidence in the efforts of the Roman Pontiff to remove by opportune declarations and remedies any difficulties or doubts arising from its Tridentine Decrees. Hence Pius IV instituted a congregation of eight Cardinals to look after the execution and observance of the Council's decrees. Pius V and Sixtus V enlarged the faculties of the Congregation. Its duties now lie in the interpretation of disciplinary decrees of the Council of Trent and in the taking of measures regarding the observance of these decrees, and finally it has the power of judging in cases which are implicitly or explicitly contained in these decrees. It has a Prefect, a Secretary, an assistant secretary, and an auditor and several consultants.

Joined to the Congregations of the Council are:

a. The Special Congregation upon the State of Churches.

b. The Special Congregation upon the Revision of Provincial Synods.

c. The Special Congregation upon the Residence of Bishops.

d. The Congregation of Ecclesiastical Jurisdiction and Immunity.

5. Congregation of the Affairs of Religious, or of Bishops and Regulars.

This Congregation owes its origin chiefly to Sixtus V. Its special duty is to settle affairs which concern bishops and regulars. Hence it has competency in all cases which regard the proper administration of dioceses by their bishops, excepting only those cases which require an interpretation of the Council of Trent. It receives appeals made to the Apostolic See against bishops, etc.; replies to difficulties which may arise in the administration of a diocese; examines, approves or disapproves the alienation of Church property, etc. It settles contentions which arise between different religious orders; examines complaints caused by the election of a superior-general or other superiors or by their administration. In a word this Congregation has competency in all that regards the proper rule and direction of religious orders in the Church. It is constituted upon similar lines to the other Congregations, having a Prefect, Secretary, etc. Annexed to it also are two Special Congregations, namely:

a. The Congregation for Discipline of Regulars, established by Innocent XII.

b. The Congregation of the State of Regular Orders.
in the divine offices and generally in the worship of God and the veneration of his Saints, form a grand object lesson for the people of God. They exhibit an external expression of the faith and love.

To see that these rites are diligently observed, to reform and amend, if need be books on sacred rites and ceremonies, to make, execute and interpret liturgical laws and solve the doubts arising in the execution of them, to prepare the causes of beatification and canonization, the Congregation of Rites was instituted. It owes its origin to Sixtus V, being instituted by him by the Constitution of 22 Jan. 1587.

The Congregation is two-fold, the Extraordinary, which occupies itself only with the beatification or canonization of saints; and the ordinary which decides the other questions pertaining to the jurisdiction of the Congregation of Rites.

The number of cardinals assigned to it depends upon the reigning Pontiff. There is the usual Prefect, the Secretary, an ecclesiastic who is called the Promoter of the Faith, and who has also an assistant, a chancellor, and a household, whose duty is to arrange and correct the offices of the Saints and other such matters. Besides these there are a number of Consultors taken from the ranks of the secular and regular clergy.

United with this Congregation is the Holy Ceremonial Congregation, which has supervision of the liturgical and non-liturgical ceremonies used in the Papal Court.

7. Congregation of Indulgences and Relics. By his Constitution "In Ipsi" a of 6 July 1669, Clement IX instituted the Sacred Congregation of Indulgences and Relics. He invested the Congregation with the authority to resolve all doubts and difficulties about indulgences and relics and to correct abuses, to prohibit the publication of false or apocryphal indulgences, to authenticate relics recently discovered and to oversee the granting of indulgences and the distribution of relics.

The Congregation of Indulgences is formed on similar lines to those of other congregations. It has the form of a Prefect, a Secretary and Consultors, etc. It does not grant any indulgences; the Pope does that. All Rescripts or general concessions of indulgences must be shown under pain of nullity to the Secretary of the Congregation. Leo XIII ordered an authentic publication of all its decrees from the year 1668 to the year 1882. The work was brought out by Fr. Pustet and Co. and has been declared authentic.

The first vestige of the Propaganda is found in a Commission instituted by Gregory XIII for the purpose of keeping the Catholics of the Greek rites in the faith, back schismatics to the unity of the Church. After being perfected by Clement VIII it was finally erected as it is now constituted by Gregory XIV on 22 June 1622. Of all the Congregations, the Propaganda for English-speaking countries is the most interesting because of the dioceses of these countries at the present time are subject to it. All the business which the faithful of missionary countries, clergy and laity, may have with the Holy See is done through the Propaganda.

In these countries it has exclusive jurisdic- tion and holds the place of all the other congregations. Missionary countries, in the language of the Church, are such as have no episcopal sees and whose ecclesiastical affairs are administered by delegates and vicars of the Pope. These vicars apostolic are usually bishops and are called titular bishops from the fact that they derive their title from some ancient see which no longer exists. But even after episcopal sees and dioceses are canonically erected in these missionary lands with bishops having ordinary jurisdiction, the Propaganda frequently retains the government of them. This is the case in the United States, England, Ireland, Scotland, Australia, Canada, Holland and some other countries.

The power of the Propaganda is legislative, judicial and gubernative. Hence it can make laws, decide controversies and rule over the countries in which it has jurisdiction. The resolutions and general decrees impose upon its subjects the obligation of obedience and are not merely the expression of a probable opinion, as was once asserted.

The Congregation is presided over by a Cardinal who is called Prefect-General. There is also one who is called Prefect of Economy. One of the other officials is a Protonotary Apostolic whose duty it is to collect the acts of martyrs who have sacrificed their lives in missionary countries. Almost every week the ordinary meeting is held, while the general assembly takes place usually once a month.

The principal work of the Propaganda is the spreading of the Catholic faith throughout the world. Consequently it has sent and still sends out many missionaries to preach the Gospel. To prepare young men for their missionary labors Urban VIII instituted the "College of the Propaganda" which is attached to the Palace of the Congregation. Connected with the Congregation of the Propaganda are:

a. The Congregation for the Affairs of the Oriental Rites.

b. The Congregation for the Correction of Books of the Oriental Rite.

c. The Examination of the New Constitutions of Religious Orders depending on the Propaganda.

d. The Commission for the Examination of the Reports of the Bishops and Vicars Apostolic under the Jurisdiction of the Propaganda.

e. The Commission for the Reunion of Dissenting Churches.

9. Congregation of Studies.

It was begun by Sixtus V and instituted by Leo XIII. In the bull of Sixtus V the four famous universities of Paris, Oxford, Bologna and Salamanca are mentioned. Leo XIII enlarged the powers of the Congregation and extended its authority over all the Catholic universities in the world.

Its power lies in the erection, constitution and administration of the Catholic universities, for which, having consulted the Pope, it lays down standards concerning the professors, methods, academical decrees, etc.; solves doubts about right and wrong in each country; adjudicates disputes arising between the different universities regarding the degrees or privileges. By a Catholic University is meant one which confers degrees by apostolic authority. Those erected in recent years are the universities of Lille, Paris, Lyons,
Angers, Fribourg, Ottawa, Laval and Washington.

Annexed to the Congregation of Studies is the Commission for Historical Studies.

10. Congregation for the Fabric of Saint Peter's.

The building of Saint Peter's Basilica in Rome was undertaken by Julius II in 1506. It took years to complete it and a large outlay of money was required in its building and afterward in its preservation. In 1506 a special Congregation was established to administer the affairs of Saint Peter's. In 1593 Clement VIII erected a special Congregation for the Fabric of Saint Peter's.

The Cardinal Archpriest of the Basilica is its Prefect. The scope and office of the Congregation, inasmuch as it is of practical moment to the Universal Church, has regard to donations for pious causes and to certain questions about obligations of saying masses; for example, the transferring of them from one church to another or from one altar to another; the extension of time for the saying of them; their reduction in number, etc.

11. Congregation for Extraordinary Ecclesiastical Affairs, concerning itself only with those matters which are submitted by the Supreme Pontiff through the Cardinal Secretary of State and especially matters having connection with civil laws and relating to concordats.

12. Congregation of Seminaries and Universities, instituted in 1915.

Besides the foregoing Congregations, the Sovereign Pontiff may at any time establish others or diminish the number of those already existing. Thus in 1895 Leo XIII established a commission for the work of fostering the reconciliation of non-Catholics with the Church.

Saint Francis Seminary, Milwaukee.

CONGRESS (Lat. 'coming together' or 'meeting'), a meeting of rulers or representatives of nations, to treat of treaties between different governments. It is necessary to distinguish the meeting in which preliminaries are settled, from the principal congress, which is to bring the affair in question to a decision. The plenipotentiaries when they meet, after mutual greetings, appoint, in a preliminary conference, the day on which the congress is to be opened, and determine the manner in which business is to be transacted, the forms of negotiation, the order of precedence among the different powers and the time of session. The congress opens by the exchange and perusal of credentials among the plenipotentiaries, which, in case the negotiating parties have referred to the arbitration of a mediator, are given to him. The envoys of the contending powers then carry on their negotiations directly with each other, or by the intervention of a mediator, either in a common hall or in their own residences by turns, or, if there is a mediator, in his own house. Acceptance of superiors is continued either by writing or by verbal communication, until the commissioners agree upon a treaty, or until one of the powers dissolves the congress by recalling its minister. Such meet-
ings of the representatives of different countries are sometimes called conferences. The nominal difference between a conference and a congress is this, that the representatives of the different countries at the former are the ordinary ambassadors of the respective countries at the court at which the conference is held, while the representatives at the latter are specially deputed for the purpose. Among congresses of the 19th century the chief are the Congress of Vienna, 1815; of Paris 1856; of Berlin 1878; The Pan-American Congress at Washington, D. C. (1888-90).

CONGRESS, Continental. The first recognition of a solidarity of interests among the English colonies in America, and attempts at joint action against a common foe, were made in 1690, by Jacob Leisler, revolutionary dictator of New York; and his efforts were stimulated by the fact that New York bore the first brunt of Canadian invasion, and needed help. He invited the other colonies to send delegates to New York and contribute men and money for a counter-invasion; but none farther south than Maryland responded. A much more comprehensive plan was devised by Franklin in 1754 (see ALBANY CONGRESS), but fell through. In 1765, on occasion of the Stamp Act (q.v.), a colonial congress from all the North except New Hampshire, and only South Carolina of the South below Maryland, met at New York 7-25 October, but took no action except to petition Parliament. In 1773, when the Revolution was impending, Franklin renewed his former suggestion in a letter to the assembly of Massachusetts, whose agent in London he was, but still nothing was done.

The next year, however, on receiving news of the Boston Port Bill, Virginia proposed to the other colonies a Continental Congress in the fullest sense; that is, including Canada, for it was not doubted that this recently subjugated province would gladly join in a revolt against its conqueror. Massachusetts, New Hampshire, New York, New Jersey, Pennsylvania, Delaware, Maryland, and Virginia, others followed, and the first real American Congress met in Philadelphia, 5 Sept. 1774, sitting till 26 October. Canada, however, was not represented; nor was Georgia, though it was shared in all succeeding Conventions. Instructions to the delegates did not contemplate separation or forcible resistance, but only the proposal of measures to 'restore harmony' with Great Britain; and the Congress merely drafted addresses to the king and the people of that country, to the Canadians, and to their own constituents, and recommended non-importation and non-exportation agreements, and the forcible resistance to any forcible attempt to carry out the Parliament's taxation measures. It also advised the immediate election of delegates to a fresh Congress in Philadelphia 10 May 1775; which was carried out by various bodies — legislative assemblies in some cases, popular conventions or committees of safety (q.v.) in others. None of these had any legal power to act for this purpose, and the title of all alike was the will of the force majeure of the people; for the loyalist section had equal right to oppose the elections, and it was tacitly recognized, if not written in the title. The fact that this Congress was considered necessary at all, and was to have power to organize combined resistance to Great Britain, would be conclusive evidence that the
leaders of independence had determined on independence unless highly improbable concensions were made, were it not for the extreme necessity, namely, the incurable disease of the country, occasioned by the present rule of the British Parliament; and by the necessity of calling the Continental Congress into being, it only doing so under irresistible urgency from public opinion. A parallel case is the memory of the hopes of accommodation and conciliation by Union leaders not only in 1860-61, but throughout the Civil War. The frequent charge of hypocrisy against the Revolutionary leaders involves one against all the patriotic statesmen of the decade before 1860.

As soon as war was actually proclaimed by Great Britain the second Congress assumed the fullest powers of sovereignty; much greater than those of the British Parliament, for it combined the powers of that body with those of the king, being itself both executive and legislative head of the nation. It raised military and naval forces and directed belligerent operations with them, authorized privateering, contracted treaty alliances, issued national currency, etc., in both capacities. This was by no usurped power, but by the urgency of the people, who were far more anxious to have the powers than it was to exercise them. The provincial congresses appealed to it for authorization, and the people urged it to more energetic action. Its crowning act was the Declaration of Independence: its business from 12 July to 20 August the debating of the scheme of government it had drafted (see United States—Articles of Confederation), but which was not put in force for five years, and for which it was perhaps slight misfortune to have waited. It sat till 12 Dec. 1776.

The session of 20 Dec. 1776 has been hastily called the third Continental Congress; for the delegates were selected entirely by the State legislatures, and the body as a whole had a title more definite and regular, though not in reality more legal. But in fact, the second Congress, from the opening on 10 May 1775, was a continuing body in perpetual session; with no definite term of sitting or terms of membership; the State legislatures which had selected the members did not specifically send new ones for the new session, but each chose them for such terms as it pleased—Congress exercising no right of control in this matter—and recalled them at will. Each State had but one vote, all being thus equal, as in the Senate, where each has two; but in the Senate the members have individual votes. This provision in the Continental Congress was avowedly made only because a census could not then be taken to ascertain the relative populations. As under the Confederation, the Congress dealt with States, not individuals; and much of the impotence with which it is reproached in the Revolution was involved in this, though not all of its follies and mischiefs in the last four years are due to the Congress. But the Congresses which claimed their share of the military patronage then as they do of the civil patronage now.

A history of the Congress is a history of the country during its lifetime; but some of its migrations are significant of military reverses and recoveries. From 20 Dec. 1776 to 4 March 1777 it sat at Baltimore; 4 March to 18 Sept. 1777, at Philadelphia; 27 Sept. 1777, at Lancaster, Pa.; 30 Sept. 1777 to 27 June 1778, at York, Pa.; 2 July to 28 July 1778, at Annapolis, Md.; to 4 March 1778, at Philadelphia. But before this it had ceased to be the Continental Congress, and had become the Congress of the Confederation, on 2 March 1781, after the ratification of the Articles by Maryland. Congress of the Confederation included Bancroft, Hildreth, Schouler, Von Holst, etc.; Fiske, ‘Critical Period of American History’ (1888).

CONGRESS, Library of. The National Library of the United States, an institution in Washington, D. C., since its removal from the Capitol in 1809, occupying the building erected for its accommodation under the acts of Congress of 15 April 1866, 2 Oct. 1888 and 2 March 1889, at a cost of $6,347,000 (limit by law, $6,500,000) exclusive of the land, which cost $585,000. The building occupies three and three-quarter acres upon a site 10 acres in extent at a distance 1,270 feet east of the Capitol, and is the largest and most magnificent library building in the world. In the decorations, 40 American painters and 40 sculptors were represented. The floor space is 326,195 square feet or nearly eight acres. The book stacks contain about 100 miles of shelving, affording space for 3,540,000 octavo books and 84,000 volumes of newspapers. Annual appropriations are made by Congress for various purposes. In 1916 these amounted to $660,105, covering service and contingent expenses $451,400; purchase of books, $98,000; building and grounds, $116,645. The number of employees is 541; for the library proper, 255; distribution of cards, 44; disbursement and care of buildings and grounds, 134; legislative reference, 17; and for the copyright office, a distinct division of the library, 91. The main reading room, the periodical reading room and a reading room for the blind, are open to the public from 9 a.m. to 10 p.m. week-days, and from 2 p.m. to 10 p.m. Sundays and holidays, except Christmas Day and the 4th of July. The Library of Congress was established in 1800, destroyed in 1814 by the burning of the Capitol, afterward replenished by the purchase of the library of ex-President Jefferson, 6,760 volumes (cost, $23,950); in 1851, 35,000 volumes destroyed by fire; in 1862, partially replenished by an appropriation of $75,000; increased (1) by regular appropriations by Congress; (2) by deposits under the copyright laws; (3) by gifts and exchanges; (4) by the exchanges of the Smithsonian Institution, the library of which (40,000 volumes) was, in 1866, deposited in the Library of Congress, with the stipulation that future accessions should follow it. Fifty sets of government publications are placed at the service of the Library of Congress. Its last performance of exchanges through the Smithsonian. Other special accessions have been: the Peter Force collection (22,329 volumes, 37,000 pamphlets), purchased 1857, cost $100,000; the (Count de) Rochamboult papers (munusolum), purchased 1883, cost $20,000; the Toner collection (24,484 volumes, numerous pamphlets), gifts in 1882 of Dr. Joseph M. Toner; the Hubbard collection (engravings), gift in 1898 of Mrs. Gardiner G. Hubbard; in 1905, 72 manuscript maps once owned by Richard, first Earl Howe, and 860 letters received by President Van
Buren. Notable recent accessions are the Wecker library of Sanskrit literature, 3,018 volumes, 1,002 pamphlets; the Hattala (Slavonic, about 1,500 volumes); Yudin (Russian, 80,000 volumes); the Hufieldt-Kass (Scandinavian, 5,000 volumes); the John Boyd Thacher collection of Incurabula (deposited); the Deinard collection of Minnesota, consisting of upward of 14,000 titles given to the library by Mr. Jacob H. Schiff in 1912 and 1914; the Henry Harrisse bequest, 1914, of 220 volumes and pamphlets, mostly dealing with early phases of American history; and the gift, 1915, from Mr. Nieh Chi-Cheh, vice-chairman of the Honorary Commercial Commission from the Republic of China, consisting of a diary kept by his grandfather, in 40 volumes. The entire collection, now the largest in the American hemisphere and the third in the world, is rich in history, political science, in Federal documents and Americana in general, including important files of American newspapers and original manuscripts of colonial, revolutionary and formative periods. At the end of the fiscal year 1915 the collection comprised 2,563,873 printed books and pamphlets (including the law library which, while a division of the Library of Congress, still remains at the Capitol), manuscripts, maps and charts, pieces of music and photographs, prints, engravings and lithographs, numbering about 1,000,000. While it is primarily and essentially a reference library, it maintains an inter-library loan system by which special service is rendered to the representatives of the loan of rare and unusual books to other libraries for the use of investigators engaged in serious research. Through its distribution of printed catalogue cards it also places at the disposal of all libraries, large or small, the best expert cataloguing and book information at a price much below the cost of even the crudest manuscript cataloguing. The service which perhaps reaches more citizens than any other is the response made to letters of inquiry from all over the world on any conceivable topic. The relations of the Library of Congress to the other government libraries (which number about 63 out of a total of 137) are also of necessity very close, since they are all concerned in the same service to the government. Its relations to the libraries of Washington city, not governmental, while less direct, are hardly less intimate. They all draw from its immense reservoir, and their acquisitions and even their management are largely influenced by their proximity to the Library of Congress. Several of the larger government libraries have attained a real distinction, notably the Library of the Surgeon-General's Office, 4th and B streets S. W., which is now perhaps the leading medical library of the world containing about 525,000 volumes and pamphlets; the library of the Department of Agriculture at 12th and B streets, consisting of about 150,000 volumes; the library of the Bureau of Labor Statistics, of the Reclamation Service, of the Bureau of Standards, and of the Bureau of Railway Economics; while the libraries under the jurisdiction of the Smithsonian Institution offer, an interesting group to those concerned with the natural sciences. The largest is the library of the National Museum, containing 45,000 volumes, and about 75,000 unbound pamphlets, the largest assemblage of the transactions of learned societies which exists in the country. Together the Library of Congress with its affiliations is considered by many who are familiar with the national libraries of foreign countries to be more truly a national library than any other in the world in the extent and variety of the functions it performs and the service it renders to libraries and to citizens throughout the country. The chief librarians since its inception have been: 1800-14, the contemporary clerk of the House of Representatives; 1815-29, George Watterston; 1829-61, John S. Meehan; 1861-64, John G. Stephenson; 1864-97, Ainsworth R. Spofford; 1897-99, John Russell Young; Herbert Putnam since 1899.

CONGRESS AND EXECUTIVE. See Executive.

CONGRESS OF RELIGIONS or WORLD'S PARLIAMENT OF RELIGIONS. A congress held at the Columbian Exposition, Chicago, in 1893, in an attempt to bring together in one great world convention representatives of all the religious creeds of the world. The congress was very successful, and all its meetings passed off in perfect harmony, notwithstanding the doubt previously expressed in many quarters as to the expediency of calling such a congress at the World's Fair which was to be essentially a bid for the amity and co-operation of the nations. The Congress of Religions, which was what its name implies, was made up of representatives of the creeds of all the great countries of the world; and it treated under every aspect of religion. It was the outcome of many attempts to bring together the great religions of the world. The idea of a union of this kind had often appeared in Chinese fiction and poetry; and at both China and Japan had led the way in religious toleration by allowing various creeds to flourish side by side in their respective territories hundreds of years before religious toleration was thought of in Europe. More than three centuries ago John Comenius, the great religious thinker and reformer, had suggested such an idea. Almost half a century ago the Free Religious Association of Boston advocated the idea of a congress of the various religions of the world with a view to making a scientific study of religious thought, origin and growth. In 1873, the great Buddhist Emperor of India, Asoka, called a congress of all the religions of the East, and more especially those of India, at Palatiputra, now Patna; and he acted the same minds of the East in religious circles in the congress, which was a pronounced success. So the religious centres of India, owing to their comparative liberalism, were ready to respond to the call issued in 1891 for a Congress of Religions to be held in Chicago in connection with the World's Fair in 1892. The exposition was unavoidably postponed until the fol-
lowing year and with it the meeting of the Congress of Religions. This was fortunate for the latter as it gave the organizers much more time to reach the leaders of religion thought throughout the world. The World's Parliament of Religions, as the congress was ultimately named, set for its aim a wide and varied program which included the bringing together into a congress of leading representatives of the great historic religions of the world; the showing of the important truths held by various religions; the promoting of the spirit of human brotherhood among religious men of diverse faiths; the setting forth of the important distinctive truths held and taught by each religion and by the various branches of Christianity. It aimed to indicate the impregnable foundations of theism and the reasons for man's faith in immortality; the spiritual and other effects of the various religions upon literature, art, commerce, government and domestic and social life. The Congress was asked to consider what light each religion has afforded or may afford to other religions; the present condition and outlook of religions among the leading nations of the world and the light religion has thrown upon the great problems of the present age, such as temperance, labor, education, poverty, wealth. The promoters expressed their hope of eventually bringing about permanent international peace by bringing the nations of the earth into a more friendly fellowship. Consult "World's Parliament of Religions," a collection of the addresses made at the congress and an account of the proceedings of the same.

CONGRESS OF THE UNITED STATES. The legislative branch of the Federal government of the United States. The discussion of this body falls naturally into three parts: (1) The constitutional mandates concerning it; (2) its own rules and usages; (3) its practical functions as developed by historical evolution.

1. By the first article of the Constitution, the legislative power of the country, so far as granted at all, is vested in the Congress of the United States, which shall consist of a Senate and House of Representatives.

The Senate must consist of two senators from each State (thus equalizing the power of the States to safeguard their own interests), elected by the State legislatures for six years; the terms so arranged that one-third are vacated every two years, making it a continuing body. Each legislature fills any vacancy in its State delegation caused by death or resignation, but if one occurs while it is not in session, the governor of the State may fill it pro tem. till the legislature meets. A senator must be 30 years old, nine years a citizen and an inhabitant of the State which elects him; but the legal definition of residence is impliedly left to the State. The president of the Senate is the Vice-President of the United States, who has only a casting vote; but in his absence, or on his accession to the presidency, it shall choose a president pro tempore. In impeachment trials the Senate is impartial, to be decided by a two-thirds vote; if the President is impeached, the chief justice presides; it can inflict no punishment but removal from and disqualification for office. No treaties are valid without the consent of two-thirds of the Senate; nor any appointment to office by the President without the consent of a majority of it, unless Congress takes away this power from the senatorial half of itself, which it is not likely to do.

The House must consist of members chosen for two years by popular election, so that each House is a new body; the voters to be the same who choose the most popular branch of each legislature; each member must be 25 years old, seven years a citizen, and an inhabitant of the State. The number from each State must be graded by population, determined by a decennial national census (in the body of the Constitution, three-fifths of the slaves are to be counted in, a provision made obsolete by the Thirteenth Amendment). These representatives must not exceed one to 30,000 inhabitants—which would allow a maximum of about 2,550 at present, in place of the actual 440. The members receive an annual salary, determined by Congress, the amount of which at present is $7,500. In case of vacancy, the State executive is to issue a writ of election to fill it. The House chooses its own speaker who receives a salary of $12,000. And lastly, it has the sole power of presenting the impeachments which the Senate has the sole power of trying.

The State legislatures were to fix the times, places and manner of electing members of either House, subject to the right of Congress to change anything but the place of electing senators, which was the legislative chamber until 1913, when the 17th Amendment to the Constitution, providing for the direct vote for senators by the people, was ratified and declared in force. But the numerous deadlock and failures to elect, due to the two branches of the legislature being under different political control, and the minority House refusing to meet the other for an election, led to the law of 2 July 1866, prescribing a uniform rule for all States. Congress is to meet at least once a year; on the first Monday in December unless it orders otherwise. The President can convene a special session on "extraordinary occasions"; but he cannot adjourn or prorogue it except in case of disagreement between the House and the Senate—"in such case as may be prescribed in the Constitution." The number of members for a House is to be decided by the Constitution of the State, but a majority of each house will not under any circumstances be less than one-third of the whole membership, and the House shall be by the nation. They shall be exempt from arrest during the session and in journeys to and from, and from liability for any utterances in debate—a reminiscence of the burning need of such provision in our earlier history; not often invoked now, and still less
often for creditable reasons. No member shall be appointed to any office created or its pay increased during his term—again a souvenir of temporary political squabbles; and no officeholder shall be at the same time a member. Bills for raising revenue by any tax shall originate in the House (originally a safeguard for the large States, against the small ones using their power in the Senate to throw the financial burdens on their richer neighbors); but the Senate can propose new taxes or increase old ones. The President must be reconsidered by, and the objections entered in full on the journal of, the House where they originated; and a two-thirds vote may pass it to the other House, a two-thirds concurrent vote of which makes it a law. (The first Congress, on the question arising, decided this to mean two-thirds of those present and voting, not of the whole membership.) Such votes must be yeas and nays and entered on the journals. A bill not returned by the President within 10 days (Sundays excepted) becomes a law ipso facto, unless Congress adjourns meanwhile, when it lapses. No order, resolution or vote of the concurrent Houses is valid without the assent of the President, except by concurrent vote of two Houses. The powers of Congress are generally those inherent in every sovereign assembly of the people; but there are two important restrictions. The President's veto (above) is a very real restriction tyrannical by a majority, perhaps not honestly obtained and always inviting dishonesty with such supreme power; and it retains full vitality, while the English royal veto has perished. Still more important is its confinement by the Constitution to the powers expressly granted: its laws are invalid if pronounced by the Supreme Court contrary to the Constitution, while a majority vote of the English Parliament could theoretically abolish the monarchy or hang the entire population. Too much is sometimes made of this. However, the implied powers of caring for the national welfare have been found in practice elastic enough for every claim of sovereignty. As to the Supreme Court, it is the creature of an act of Congress granting it authority, and as a whole system of national courts actually was; more simply, it can be and has been swamp and packed to reverse an unpopular decision, and if its decisions are defied (as under Jackson), it is powerless to enforce them. Hence it is very cautious about deciding political issues of burning intensity (see CHEROKEE NATION v. GEORGIA), except in the sense of the majority or opposing strong popular feeling. In a word, Congress is the ultimate sovereign. Its inhibitions by the Constitution reflect past history and the politics of the time curiously enough. It was not to prohibit the slave-trade before 1808, and not to grant titles of nobility—conversely, no one is to receive office, title or gift from any foreign potentate without its consent; it is not to suspend the habeas corpus except on account of rebellion or invasion, not to pass bills of attainder, not to lay export and import duties, not to regulate commerce, not to give preference to one State over another, nor to increase direct taxes on the people, not to give preferential duties between the States, or enforce clearances at ports outside a vessel's destined State. Not all of these things were needless fetters; and certainly the prohibition from drawing money except on regular appropriations, and the injunction to publish the disposition of the money drawn, was not one. There being at present 48 States, the number of senators is 96. The number of representatives has never been determined by the constitutional provision, whose minimum was fixed when the country had but 2,500,000 or so of inhabitants. The maximum has been slowly enlarged at each census, each State retaining all it had, while the States with increased population have been given more. The basis of apportionment under the census of 1910 is one representative to every 212,407 inhabitants. This furnishes the following representation for the several States: Alabama, 10; Arizona, 1; Arkansas, 7; California, 4; Colorado, 4; Connecticut, 5; Delaware, 1; Florida, 4; Georgia, 12; Idaho, 2; Illinois, 27; Indiana, 13; Iowa, 11; Kansas, 8; Kentucky, 11; Louisiana, 8; Maine, 4; Maryland, 6; Massachusetts, 15; Michigan, 13; Minnesota, 10; Mississippi, 8; Missouri, 16; Montana, 2; Nebraska, 6; Nevada, 1; New Hampshire, 2; New Jersey, 12; New Mexico, 1; New York, 43; North Carolina, 10; North Dakota, 3; Ohio, 22; Oklahoma, 8; Oregon, 3; Pennsylvania, 36; Rhode Island, 3; South Carolina, 7; South Dakota, 3; Tennessee, 10; Texas, 18; Utah, 2; Vermont, 2; Virginia, 10; Washington, 5; West Virginia, 6; Wisconsin, 11; Wyoming, 1; and 5 delegates from Territories as follows: Alaska, Hawaii and Porto Rico, 1 each; Philippines, 2; Puerto Rico, 2. Each House has its own system of rules for business (78 in the Senate, 45 in the House), with vital differences. The most far-reaching is the previous question in the House and the absence of it in the Senate. The reasons for the difference are obvious: the great number of representatives, and the fact that most bills are first introduced there, would make business not merely difficult but impossible if everyone could talk at will to any length; the smaller numbers and lesser business of the Senate enable free debate to be retained. The House restricts speeches to an hour; the Senate has no restriction except that a member cannot speak over twice a day on the same question. Each system of course has its own evil; the suppression of needful public light on bills in the one case, "filibustering" and holding up of public business by a factious or interested minority in the other. The business of both houses is done by committees; neither will consider bills or memorials at once on presentation, except on suspension of the rules—which to be sure, during the latest days of a session, lets through vast numbers of undebated, unexamined and unknown bills. But by rule they must be referred to some standing committee, of which there are now 48 in the House and 32 in the Senate, besides 10 select committees in the House and 12 in the Senate; and three joint standing committees. The functions of these committees are assigned by the rules; but as these lay over, two or three committees often contend vigorously for the possession of some one bill. In the Senate, these bills are presented in open session on the floor; in the House they are handed to committees, often with such reference or disposition as the presenting member wishes made. These committees are appointed in the House by the Speaker; in the Senate they are chosen by caucus of the majority party and elected by a single ye and
nay vote though the rules say by ballot "unless otherwise ordered." In case of differences between the Houses which continually occur, they are harmonized by committees of conference, three senators and three representatives. The most steadily powerful of these committees, which can obtain the floor at any time, are those on Appropriations in each house, disbursing the money in the treasury, and on Privileges and Elections, deciding the right of every member to his seat; next to these, on revenue (Ways and Means in the House, Finance in the Senate), with enormous power to help or harm the great businesses of the country—many think too much—and on Printing, which of course is an immediate matter. Next in actual favor come, perhaps, those on Rivers and Harbors and on Pensions, branches of that on Appropriations which they involve; and when new States are to be admitted, on Territories. In formal dignity the Senate at the last, and Foreign Affairs, on the Judiciary and on Military and Naval Affairs, take high rank; so in the House do those on Rules, Foreign Affairs, Judiciary, Military Affairs and Naval Affairs; and of course special circumstances at any time may temporarily make any one of these, or almost any other committee, the centre of interest to which everything else must give way. In some respects most important of all except the Appropriations Committee are the so-called conference committees, which do an immense share of the actual legislation of the country: they compromise conflicting business and political interests, include or exclude bills, decide on substitution, and being usually appointed in the crowded closing days of a session, generally have their recommendations heeded.

3. The changes in congressional functions and relations, from the intent of the framers of the Constitution, come under three heads: (1) The position of Congress as a whole regarding the executive; (2) the position of the two houses regarding each other; (3) the position of the whole body regarding legislation.

(1) The Constitution attempted a total separation and absolute equality between the executive and legislative branches, the latter deciding on measures of public welfare and the former carrying them out. How far this would be desirable if perfectly accomplished—altogether forbidding one branch of the government to think and the other to act—might be questioned, but will not be argued here. At any rate, it was never remotely realized except when both were in deadly need of the same thing, or one was content to forego thinking. The ideal example of its best is probably the Lincoln administration, a strong executive and a strong Congress with the same essential purposes; of its worst, the Johnson administration, where the thoughts of the one and the acts of the other were most irreconcilable, and what the one most wished done was what the other was most set on doing. More usually, one side or the other has been master. The extreme instance of executive mastery was the Jackson administration, the party leader, with a not too reflective popular majority behind him, got such legislation as he wished; of congressional mastery, each reader may prefer to choose his own instance. But there can be no question that the balance inclines more and more decisively to the congressional side. Of late years the results of attempted executive independence have been more picturesque than successful. The Senate, which has the confirmation of treaties and appointments and the duty of declaring war, has in some form what treaties and appointments it will confirm; and the body which can grant or refuse money for public purposes can decide what those purposes shall be.

(2) The changes in power between the Houses is not so dramatically obvious, but it is quite as notorious and is easily explicable. The Senate has some superiorities: its long terms both attract superior men on an average and enable them to acquire parliamentary knowledge and public weight; its committees are still its servants rather than its masters—preparing legislation for it to discuss, rather than merely killing most of it, and leaving the rest to run in an undiscussed huddle through the open sluice at the last moment. It has time and rules that permit some genuine argument, for its own and the public's enlightenment. But these very terms render seats so valuable and desirable that members are more loath to peril them than the House. Moreover, it is expected to have more independence than the House from the length of terms, has actually of late years had less backbone and less willingness to run counter to popular currents within its own limits. The committees are the Senate is expected to have more independence than the House from the length of terms, has actually of late years had less backbone and less willingness to run counter to popular currents within its own limits. The committees are the Senate. Moreover, the license of debate has too often been a mere license of wanton obstruction, bringing forward no new facts or illuminating discussion, but only exhibiting the spectacle of the will of 100,000,000 people nullified by one or two of its servants. This does not contradict, but only supplements, the other evil. On the other hand, the unity and dispatch of public business made possible in the House by the nominal autocracy and real leadership of the Speaker, aided by the committees and the previous question, have made it seem more and more the body where something is accomplished and the will of the people carried into execution.

(3) The drift of our form of government, and the shifting position of Congress and its organs within it, are to some extent matters of prophecy rather than fact; and political philosophers have been busy with them. But some things are certain, and though commonplace, must be recited. The Chief of the Speaker and the committees over legislation. That the Speaker is a totally different officer from the English Speaker is obvious. He puts motions, decides question of rule and order, and represses disorder, it is true; but instead of being a sworn judge he is a recognized party chief, with functions which approximate the English premier much more closely than the other. By his appointment of the committees he determines the line which legislation shall take, and in a way the bill which shall or shall not be considered; and by his daily power of recognizing members who wish the floor, in which he is held to none but party responsibility, he still further molds the total impression which can be presented from a majority in the public. But he is no autocrat; his very influence can only be exercised by appointing the chief party leaders to the committees, and once there, it is they and not he who hold the decisive power; he and they together, in fact, form something like the shaping committee which
is what the English Cabinet, headed by the premier, has fully become. The Cabinet office, however, has become more than the executive arm of the committees rather than of the President. These approximations to the English position have caused many to think that the transformation will be fully carried out, and the parliametary system established in fact if not in form in the future; the specious notion of having the full power of the premier, and the President becoming a dignified nullity like the sovereign of England. But there are still some vital differences, and it is not easy to foresee the process by which they will be overcome. It is true that the admission of Cabinet officers to the floor of either House, to expound their views and needs and explain doubtful questions, is within a simple permissive vote of that House at any time, and can perfectly well be made a standing rule; and that the consequent necessity of their being skilful speakers and capable expositors would profoundly modify the character of men chosen for that position. But the committee do not want information on the floor of the House of Representatives at all times. The House must attend to it there, and the rules would mostly shut it off before anything material had been communicated. They want it in their committee rooms, and that needs no change in the men and would involve none before the public. The officers cannot become primarily public speakers and secondarily executive officers unless the House gives up its time to debate; and the whole tendency is the other way, nor is it evident where the new time would be found or taken. The place where the charge would have to take place is in the Senate, if at all; but the power of legislation more and more drifts away from the Senate except as concurrent; and the new debaters, if they arrive, will seemly be more in the position of those in the House of Lords than of Commons, which would be immaterial. Still greater is the obstacle of fixed terms. The English members of the Commons remain no longer when the people vote that they do not want them, and it is consequently the great party object to obtain such a vote and to put the other party in a position where they must be disgraced if they do not ask the people to give one pro or con. But in the American member must serve out his term, and he can so do if his party has lost all public favor: the tremendous sweep of 1874 did not shorten any Republican member’s term for a day, nor imperil any piece of Republican legislation, for which they had an entire session after they were voted down, and as many special ones as the President had chosen to call; and similarly with reverses of the other side. This alone prevents debate from taking up time in the House; it is mainly a sham battle, a real one having been fought in committee. Still further, the English committee called the Cabinet is all of one party, represents it, goes down with it; and the bills it puts forward are the party’s bills.

L. M. COCKEELL
Late United States Senator from Missouri.

CONGRESS OF THE UNITED STATES, Sessions of and Political Parties in.
In accordance with the usage of the ‘Annals of Congress,’ the ‘Register of Debates in Congress,’ the ‘Congressional Globe’ and the Congresional Record, we have used the legislative day for the termination of the first 56 Congresses and the calendar day for the beginning of the 57th Congress in 1901. The legislative day of Congress in this connection is based on the fact that it does not recognize the calendar day but only the legislative day, nor are Sundays and the forenoon of 4 March recognized as legislative days. The legislative day of 4 March does not expire until 12 o’clock noon of 4 March.

In the Monthly Catalogue United States Public Documents (No. 195, p. 492, March 1911) is issued by the superintendent of public documents, as the following statement explains.

‘If on any day either Senate or House refuses to adjourn, but instead takes a recess, no matter of what duration, the legislative day continues without regard to the calendar day. This prolongation of the legislative day has, under the rules, various effects upon the status and the progress of pending bills and motions. Whether the day, legislative, or calendar, must, of course, be determined at the time of the event. The legislative day remains simply a legislative fiction. The calendar day, the real day, of course can not be affected by any action of Congress. In the Proceedings of Congress as reported in the Congressional Record both the fictitious legislative date and the true calendar date have been published in recent years when the two dates conflict. Of course as a general rule the two dates harmoniously agree. It is only when a parliament or session has expired that the fictitious legislative date sets the Gregorian calendar day at defiance. Almost the only cases in which any advantage of the legislative day affects the accuracy of the public records is when it makes the sessions of Congress seem to have closed at a time when they really did not close.

The Constitution fixes the duration of Congressional terms, but the constitutional provision for that has been construed at different periods. In the early years of the Republic it was generally held that the term of a Congress was lawfully ended at midnight of March 3 in the odd numbered years. As a matter of fact it never did end then. The word of legislation was usually continued far into the small hours of March 4, despite earnest protests often made. Finally, March 3, 1851, both the Senate and the House took official action determining that the legal date for the closing of Congress is 12 o’clock noon of March 4 (Consult A. C. Hinde, ‘Presidents of the House of Representatives,’ Vol. V., pp. 862-863). This ruling has been ever since invariably followed. Whenever the legislature varies from this date as the closing date of a Congress it is wrong. Minor departures, provided for by turning back the official clocks, and winked at by all departments of the government, have of course been disregarded in compiling the check list.’

In spite of this ruling and another in 1881, however, the Congressional Record continued to use the old legislative day as the running headline date until the end of the 56th Congress in 1901, though the text indicates the calendar days covered by the legislative day, which is very apt to confuse one not accustomed to this method. Moreover, in several instances (as in the last sessions of the 39th, 50th, 53d and 50th Congresses) 3 March was Sunday, wherefore the Record is antedated to 2 March (Saturday), though the pages of the volumes themselves indicate not only that Congress sat on Sunday but also on Monday, 4 March. Hence, while the Record shows that in these cases a member of either House made a speech on Monday, 4 March, calendar day, he is said to have spoken on Saturday, 2 March, legislative day.

Another source of probable confusion to those unfamiliar with Congressional proceedings is the method pursued by Gales and Seaton in printing the ‘Annals of Congress.’ The proceedings of some special sessions will be found in the volumes containing the proceedings of the Congress which had just expired. For instance, the proceedings of the special session of the Senate 8-26 June 1790 (which was the second part of the 4th Congress) will be found at the end of the proceedings of the second session of the 3d Congress. As they are incorporated there
without explanation or comment of any kind, the reader may be misled into supposing that this session of the Senate belonged to the 3d Congress.

When the government came into being in 1789 there were two parties—the Federalist and Republican, which, like European and English parties, were defined largely on class distinctions. For all practical purposes the first session of Congress was non-partisan, since the few Senators and Representatives who openly avowed anti-Federalist sentiments never acted together as a party. But when the measures of Alexander Hamilton (q.v.) were introduced and pushed, the opposition gradually began to assume permanent form, though members did not consider themselves strictly party men. The following figures indicate as nearly as possible the number of those who upheld and those who feared and disliked the government and its measures.

**FIRST CONGRESS**

First session—4 March to 29 Sept. 1789.
Third session—6 Dec. 1790 to 3 March 1791.
Senate—17 Administration; 9 Opposition.
House—38 Administration; 26 Opposition.

**Speaker of House**—Frederick A. Muhlenberg (Pa.).

After the first Congress opinions became more widely divergent and to the followers of Jefferson and Hamilton the names of Republicans and Federalists began to be attached. Still many members of Congress were pleased to called themselves independents, and not before the end of Washington's second term did party loyalty in its strict sense make its appearance. At the opening of the second Congress, the Federalists, being in the majority, took away the speakership from Muhlenberg and gave it to a recognized supporter of the administration.

**SECOND CONGRESS**

Special session of Senate—4 March 1791.
First session—24 Oct. 1791 to 8 May 1792.
Second session—5 Nov. 1792 to 2 March 1793.
Senate—16 Federalists; 13 Republicans.
House—37 Federalists; 33 Republicans.

**Speaker of House**—Jonathan Trumbull (Conn.), Federalist.

In the third Congress the party majorities were reversed, and accordingly the Republicans again placed Muhlenberg in the Speaker's chair. From this time the election of a Speaker was indicative of the party strength in the lower house, whereas the office of President pro tempore of the Senate, though regarded as a party office, did not carry with it in later years the power accorded to the Speaker and hence never involved a test of party strength. For that reason no mention is made here of Presidents pro tempore of the Senate.

**THIRD CONGRESS**

Special session of Senate—4 March 1793.
First session—2 Dec. 1793 to 9 June 1794.
Second session—3 Nov. 1794 to 3 March 1795.
Senate—14 Republicans; 17 Federalists.
House—57 Republicans; 48 Federalists.

**Speaker**—Frederick A. Muhlenberg (Pa.), Republican.

In the fourth Congress the parties were nearly evenly divided, but while at the outset the Republicans were supposed to have a majority, a moderate Federalist was elected Speaker, and on all important administrative measures the Federalists were able to control a majority. After the fourth Congress, how-

ever, party lines became fixed and easily distinguishable, wherefore the division in each house can be clearly indicated.

**FOURTH CONGRESS**

Special session of Senate—8–26 June 1795.
First session—7 Dec. 1795 to 1 June 1796.
Second session—5 Dec. 1796 to 3 March 1797.
Senate—14 Republicans; 17 Federalists.
House—52 Republicans; 54 Federalists.
**Speaker**—Jonathan Dayton (N. J.), Federalist.

**FIFTH CONGRESS**

Special session of Senate—4 March 1797.
First session—15 May to 10 July 1797.
Second session—13 Nov. 1797 to 16 July 1798.
Special session of Senate—17–19 July 1798.
Third session—3 Dec. 1798 to 3 March 1799.
Senate—20 Federalists; 12 Republicans.
House—58 Federalists; 48 Republicans.
**Speaker**—Jonathan Dayton (N. J.), Federalist; George Dent (Md.), pro tempore.

**SIXTH CONGRESS**

First session—2 Dec. 1799 to 14 May 1800.
Second session—17 Nov. 1800 to 3 March 1801.
Senate—19 Federalists; 13 Republicans.
House—64 Federalists; 42 Republicans.
**Speaker**—Theodore Sedgwick (Mass.), Federalist.

**SEVENTH CONGRESS**

Special session of Senate—4–5 March 1801.
First session—7 Dec. 1801 to 3 May 1802.
Second session—6 Dec. 1802 to 3 March 1803.
Senate—18 Republicans; 14 Federalists.
House—69 Republicans; 36 Federalists.
**Speaker**—Nathaniel Macon (N. C.), Republican.

**EIGHTH CONGRESS**

First session—17 Oct. 1803 to 27 March 1804.
Second session—5 Nov. 1804 to 3 March 1805.
Senate—25 Republicans; 9 Federalists.
House—102 Republicans; 89 Federalists.
**Speaker**—Nathaniel Macon (N. C.), Republican.

**NINTH CONGRESS**

Special session of Senate—4–6 March 1805.
First session—2 Dec. 1805 to 21 April 1806.
Second session—1 Dec. 1806 to 3 March 1807.
Senate—27 Republicans; 7 Federalists.
House—116 Republicans; 25 Federalists.
**Speaker**—Nathaniel Macon (N. C.), Republican.

**TENTH CONGRESS**

First session—26 Oct. 1807 to 25 April 1808.
Second session—7 Nov. 1808 to 3 March 1809.
Senate—28 Republicans; 6 Federalists.
House—118 Republicans; 24 Federalists.
**Speaker**—Joseph B. Varnum (Mass.), Republican.

**ELEVENTH CONGRESS**

Special session of Senate—4–7 March 1809.
First session—23 May to 26 June 1809.
Second session—27 Nov. 1809 to 1 May 1810.
Third session—3 Dec. 1810 to 3 March 1811.
Senate—28 Republicans; 6 Federalists.
House—94 Republicans; 48 Federalists.
**Speaker**—Joseph B. Varnum (Mass.), Republican.

**TWELFTH CONGRESS**

First session—4 Nov. 1811 to 6 July 1812.
Second session—22 Nov. 1812 to 3 March 1813.
Senate—30 Republicans; 6 Federalists.
House—108 Republicans; 36 Federalists.
**Speaker**—Henry Clay (Ky.), Republican.

**THIRTEENTH CONGRESS**

First session—24 May to 2 Aug. 1813.
Second session—6 Dec. 1813 to 18 April 1814.
Third session—19 Sept. 1814 to 3 March 1815.
Senate—27 Republicans; 9 Federalists.
House—112 Republicans; 68 Federalists.

After the War of 1812 came the era of good feeling, during which there was practically no opposition in Congress to Madison and Monroe, and while the old names persisted they ceased to have any political significance, beyond the
fact that few Federalists were appointed to offices under the national government. After 1815 the members of the House ceased to vote for a separate candidate for Speaker, so that it is almost impossible to state precisely the number of Federalists in Congress. Even in 1824, when the Republican presidential nomination was to be made, a rough guess placed the number of Federalists in Congress at 40 or 45, but this was only conjecture. However, as closely as it is possible to come, the division was as follows:

FOURTEENTH CONGRESS

FIFTEENTH CONGRESS
Special session of Senate — 4—6 March 1817. First session — 1 Dec. 1817 to 20 April 1818. Senate — 34 Republicans; 10 Federalists. House — 141 Republicans; 42 Federalists. Speaker — Henry Clay (Ky.), Republican.

SIXTEENTH CONGRESS

SEVENTEENTH CONGRESS

EIGHTEENTH CONGRESS

In 1825 Jackson became the presidential nominee of those opposed to the administration of President John Quincy Adams, which opposition ultimately developed into the Democratic party. But Jackson’s adherents had no definite policy in Congress, their main object being to elect Jackson, and hence the existence of Jacksonian majorities in the Houses of Congress had no legislative significance. With the Jacksonians it was purely a question of loyalty to their chief, and so long as he had no Congressional policy, his followers might differ widely on all other national issues save that of placing Jackson in the presidential chair. For some years the actual leadership in legislation was exercised by the minority members. In 1828 those who supported Adams took the name National Republicans, and the Jacksonians became known as Democrats.

NINETEENTH CONGRESS

TWENTIETH CONGRESS

TWENTY-FIRST CONGRESS

In the 22d Congress appeared some members of the Anti-Masonic party and there were some Democrats, followers of Henry Clay, who termed themselves Clay Democrats. After 1833 Jackson began to lose his following owing to his nullification policy (when the Nullifiers formed a separate faction) and his determination to have Van Buren succeed him in the Presidency, which drove into opposition a number of State Rights Democrats. In the 24th Congress the National Republicans, Anti-Masons and State Rights or anti-Van Buren Democrats banded together as Whigs. After Van Buren became President, the Democrats who opposed the sub-treasury plan became known as Conservatives, while a group of former State Rights Whigs supported Van Buren’s policy and the Nullifiers rejoined the Democratic party.

TWENTY-SECOND CONGRESS

TWENTY-THIRD CONGRESS

TWENTY-FOURTH CONGRESS

TWENTY-FIFTH CONGRESS

Beginning with the 26th Congress, the various factions opposed to Van Buren united under the name Whig and for the next 16 years, despite all disturbing influences, the two-party system held sway. In the 27th and 28th Congresses a few members were known as Tylerites but were soon absorbed in the Democratic party, while in the next Congress appeared the Native Americans who represented a movement against foreigners in the larger cities (see American Party). From 1849 to 1855 Congress contained a number of Free-Soilers, or Free Democrats as they afterward called themselves, composed of about an equal number of former Whigs and Democrats.

TWENTY-SIXTH CONGRESS
CONGRESS OF THE UNITED STATES

TWENTY-SEVENTH CONGRESS
Special session of Senate — 4—15 March 1841.
First session — 31 May to 13 Sept. 1841.
Third session — 5 Dec. 1842 to 9 March 1843.
Senate — 18 Whigs; 24 Democrats; 2 Tylerites.
House — 133 Whigs; 102 Democrats; 6 Tylerites.
Speaker — John White (Ky.), Whig.

TWENTY-EIGHTH CONGRESS
First session — 4 Dec. 1843 to 17 June 1844.
Second session — 2 Dec. 1844 to 3 March 1845.
Senate — 24 Democrats; 28 Whigs; 1 Tylerite.
House — 142 Democrats; 79 Whigs; 1 Tylerite.
Speaker — John J. Crittenden (Ky.), Democrat; George W. Hopkins (Va.), pro tempore.

TWENTY- NINTH CONGRESS
Special session of Senate — 4—20 March 1845.
First session — 1 Dec. 1845 to 10 Aug. 1846.
Second session — 7 Dec. 1846 to 3 March 1847.
Senate — 31 Democrats; 25 Whigs.
House — 143 Democrats; 77 Whigs; 6 Native Americans.
Speaker — John W. Davis (Ind.), Democrat.

THIRTIETH CONGRESS
First session — 6 Dec. 1847 to 14 Aug. 1848.
Second session — 4 Dec. 1848 to 3 March 1849.
Senate — 36 Democrats; 21 Whigs; 1 Independent.
House — 108 Democrats; 115 Whigs; 4 Independents.
Speaker — Robert C. Winthrop (Mass.), Whig.

THIRTY-FIRST CONGRESS
Special session of Senate — 5—23 March 1849.
First session — 3 Dec. 1849 to 30 Sept. 1850.
Second session — 2 Dec. 1850 to 3 March 1851.
Senate — 35 Democrats; 25 Whigs; 2 Free-Soilers.
House — 112 Democrats; 109 Whigs; 9 Free-Soilers.
Speaker — James W. T. Dowell Cobb (Ga.), Democrat; Robert C. Winthrop (Mass.), Whig, pro tempore.

THIRTY-SECOND CONGRESS
Special session of Senate — 4—13 March 1851.
First session — 1 Dec. 1851 to 31 Aug. 1852.
Second session — 6 Dec. 1852 to 3 March 1853.
Senate — 35 Democrats; 24 Whigs; 3 Free-Soilers.
House — 140 Democrats; 68 Whigs; 5 Free-Soilers.
Speaker — Linn Boyd (Ky.), Democrat.

THIRTY-THIRD CONGRESS
Special session of Senate — 4 March to 11 April 1853.
First session — 5 Dec. 1853 to 7 Aug. 1854.
Second session — 4 Dec. 1854 to 3 March 1855.
Senate — 38 Democrats; 22 Democrats; 2 Free-Soilers.
House — 159 Democrats; 71 Whigs; 4 Free-Soilers.
Speaker — Linn Boyd (Ky.), Democrat.

In 1854 the dispute over the Missouri Compromise (q.v.) caused a split in the Whig party, most of the Southern members and many of the Northern joining a new party called the American Party, or Know-Nothing party. The other Northern Whigs, the Free-Soilers and a few Democrats united to form the new Republican party (q.v.). When the 34th Congress convened there was much confusion as to exact party adhesion but by the second session there were three fairly well-defined groups.

THIRTY-FOURTH CONGRESS
First session — 3 Dec. 1855 to 18 Aug. 1856.
Third session — 1 Dec. 1856 to 3 March 1857.
Senate — 40 Democrats; 15 Republicans; 5 Americans.
House — 83 Democrats; 108 Republicans; 43 Americans.
Speaker — Nathaniel P. Banks (Mass.), Republican.

In the 35th and 36th Congresses the Democratic party was rent by the dispute over admitting Kansas under the Lecompton Constitution (q.v.), Douglas's followers opposing the administration. When the Civil War broke out in 1861 a Union party made its appearance in the northern slave States, later spread to the free States and ultimately for a short time was united with the Republicans.

THIRTY-FIFTH CONGRESS
Special session of Senate — 4—14 March 1857.
First session — 1 Dec. 1857 to 14 June 1858.
Second session — 6 Dec. 1858 to 3 March 1859.
Senate — 3 Anti-Lecompton Democrats.
House — 118 Democrats; 92 Republicans; 15 Americans; 11 Anti-Lecompton Democrats.
Speaker — James L. Orr (S. C.), Democrat.

THIRTY-SIXTH CONGRESS
Special session of Senate — 4—10 March 1859.
First session — 5 Dec. 1859 to 25 June 1860.
Second session of Senate — 26—28 June 1860.
Second session — 3 Dec. 1860 to 2 March 1861.
Senate — 36 Democrats; 26 Republicans; 2 Americans.
Second Anti-Lecompton Democrats.
House — 92 Democrats; 114 Republicans; 24 Americans; 7 Anti-Lecompton Democrats.
Speaker — William Pennington (N. J.), Republican.

THIRTY-SEVENTH CONGRESS
Special session of Senate — 4—28 March 1861.
First session — 4 July to 6 Aug. 1861.
Second session — 2 Dec. 1861 to 17 July 1862.
Third session — 1 Dec. 1862 to 3 March 1863.
Senate — 31 Republicans; 10 Democrats; 8 Unionists.
House — 105 Republicans; 43 Democrats; 30 Unionists.
Speaker — George A. Dix (Pa.), Republican.

THIRTY-EIGHTH CONGRESS
Special session of Senate — 4—14 March 1863.
First session — 7 Dec. 1863 to 4 July 1864.
Second session — 3 Dec. 1864 to 3 March 1865.
Senate — 36 Republicans; 9 Democrats; 5 Unionists.
House — 102 Republicans; 75 Democrats; 9 Unionists.
Speaker — Schuyler Colfax (Ind.), Unionist.

THIRTY-NINTH CONGRESS
Special session of Senate — 4—11 March 1865.
First session — 4 Dec. 1865 to 28 July 1866.
Second session — 3 Dec. 1866 to 2 March 1867.
Senate — 42 Republicans; 10 Democrats.
House — 149 Republicans; 62 Democrats.
Speaker — Schuyler Colfax (Ind.), Unionist.

The reconstruction question caused an upheaval in political as well as in social life and in the election of the 40th Congress caused a new party alignment, many who had been Unionists during the war period returning to the Democratic party, while the Republican party reappeared as an organization. Since that time the Republican and Democratic organizations have steadily opposed each other in the Congressional government of the country and every effort to destroy or supplant them has failed. After 1870 some Republicans who opposed Grant's administration joined the Liberal Republican party, and in 1872 joined the Democrats in an endeavor to prevent Grant's re-election. In 1876, however, most of the Liberals returned to the Republican ranks. In the 46th to the 49th Congresses were a group of Greenbackers of the so-called National party, and also a faction of Virginians called Readjusters, who ultimately were absorbed by the Republicans.

FORTIETH CONGRESS
Special session of Senate — 1—20 April 1867.
First session — 4—30 March, 3—20 July, 21 Nov. to 2 Dec. 1867.
Third session — 7 Dec. 1868 to 3 March 1869.
Senate — 42 Republicans; 11 Democrats.
House — 143 Republicans; 49 Democrats.
Speakers — Schuyler Colfax (Ind.), Republican; 3 March 1869, Theodore M. Pomeroy (N. Y.) Republican.

FORTY-FIRST CONGRESS
First session — 4 March to 10 April 1869.
Special session of Senate — 12—22 April 1869.
Second session — 6 Dec. 1869 to 15 July 1870.
Third session — 5 Dec. 1870 to 3 March 1871.
Senate — 56 Republicans; 11 Democrats.
House — 149 Republicans; 63 Democrats.
Speaker — James G. Blaine (Me.), Republican.
FORTY-SECOND CONGRESS
First session — 3 March to 20 April 1871.
Special session of Senate — 10–27 May 1871.
Second session — 4 Dec. 1871 to 19 June 1872.
Third session — 3 Dec. 1872 to 3 March 1873.
Senate — 52 Republicans; 17 Democrats; 5 Liberals.
House — 134 Republicans; 104 Democrats; 6 Liberals.
Speaker — James B. Brilliant (Me.), Republican.

FORTY-THIRD CONGRESS
Special session of Senate — 4–26 March 1873.
First session — 1 Dec. 1873 to 23 June 1874.
Second session — 7 Dec. 1874 to 3 March 1875.
Senate — 49 Republicans; 19 Democrats; 5 Liberals.
House — 194 Republicans; 91 Democrats; 14 Liberals.
Speaker — James G. Blaine (Me.), Republican.

FORTY-FOURTH CONGRESS
Special session of Senate — 5–24 March 1875.
First session — 6 Dec. 1875 to 15 Aug. 1876.
Second session — 4 Dec. 1876 to 4 March 1877.
Senate — 29 Democrats; 45 Republicans; 2 Liberals.
House — 169 Democrats; 109 Republicans; 14 Liberals.

FORTY-FIFTH CONGRESS
Special session of Senate — 5–17 March 1877.
First session — 15 Oct. to 3 Dec. 1877.
Second session — 3 Dec. 1877 to 20 June 1878.
Third session — 6 Dec. 1878 to 3 March 1879.
Senate — 36 Democrats; 39 Republicans; 1 Independent.
House — 153 Democrats; 140 Republicans.
Speaker — Samuel J. Randall (Pa.), Democrat.

FORTY-SIXTH CONGRESS
First session — 18 March to 1 July 1879.
Second session — 1 Dec. 1879 to 16 June 1880.
Third session — 6 Dec. 1880 to 3 March 1881.
Senate — 42 Democrats; 33 Republicans; 1 Independent.
House — 149 Democrats; 136 Republicans; 14 Nationalists.
Speaker — Samuel J. Randall (Pa.), Democrat.

FORTY-SEVENTH CONGRESS
Special session of Senate — 4 March to 20 May 1881.
First session — 5 Dec. 1881 to 8 Aug. 1882.
Second session — 6 Dec. 1882 to 3 March 1883.
Senate — 37 Republicans; 37 Democrats; 1 Independent.
House — 147 Republicans; 135 Democrats; 9 Nationalists; 2 Readjusters.
Speaker — J. Warren Kelvin (Ohio), Republican.

FORTY-EIGHTH CONGRESS
First session — 3 Dec. 1883 to 7 July 1884.
Second session — 1 Dec. 1884 to 3 March 1885.
Senate — 36 Democrats; 46 Republicans; 2 Readjusters.
House — 197 Democrats; 118 Republicans; 5 Readjusters; 4 Independents; 1 Nationalist.
Speaker — John G. Carlisle (Ky.), Democrat.

FORTY-NINTH CONGRESS
Special session of Senate — 4 March to 2 April 1885.
First session — 7 Dec. 1885 to 8 Aug. 1886.
Second session — 6 Dec. 1886 to 3 March 1887.
Senate — 34 Democrats; 43 Republicans.
House — 183 Democrats; 140 Republicans; 2 Nationalists.
Speaker — John G. Carlisle (Ky.), Democrat.

FIFTIETH CONGRESS
First session — 5 Dec. 1887 to 20 Oct. 1888.
Second session — 3 Dec. 1888 to 2 March 1889.
Senate — 37 Democrats; 29 Republicans.
House — 169 Democrats; 152 Republicans; 2 Labor; 2 Independents.
Speaker — John G. Carlisle (Ky.), Democrat.

FIFTY-FIRST CONGRESS
Special session of Senate — 4 March to 2 April 1889.
First session — 2 Dec. 1889 to 1 Oct. 1890.
Second session — 1 Dec. 1890 to 3 March 1891.
Senate — 39 Republicans; 37 Democrats.
House — 166 Republicans; 139 Democrats.
Speaker — Moses W. Cleaveland (N.Y.), Republican.

Beginning with 1890 the Farmers' Alliance movement, culminating in the People's party, or Populists, disturbed the balance of Republicans and Democrats, and, to add to the confusion, the question of the free coinage of silver was injected into political discussions, so that the two large parties were much cut up, there being Gold Democrats and Silver Republicans. Hence the task of determining the party affiliations of those elected by fusion or by these Congresses is very difficult since the claims of partisans vary widely, as do also all contemporaneous statements. But when the free silver issue had been abandoned, the scattered elements again entered the parties into which they had previously been members, and nothing arose to disturb this party alignment until the so-called Bull Moose movement of 1912, when the Republican party was split by the formation of the Progressive party. While the Progressive candidate Roosevelt received 88 electoral votes against eight for the Republican candidate, Taft, the Progressive party had not sufficient strength in Congress materially to influence legislation. In the election of 1916 large numbers of the Progressive voters returned to the Republican party.

FIFTY-FIRST CONGRESS
First session — 7 Dec. 1891 to 5 Aug. 1892.
Second session — 5 Dec. 1892 to 3 March 1893.
Senate — 39 Democrats; 47 Republicans; 2 Populists.
House — 235 Democrats; 88 Republicans; 9 Populists.
Speaker — Charles F. Crisp (Ga.), Democrat.

FIFTY-SECOND CONGRESS
Special session of Senate — 4 March to 15 April 1893.
First session — 7 Aug. to 3 Nov. 1893.
Third session — 3 Dec. 1894 to 2 March 1895.
Senate — 44 Democrats; 38 Republicans; 3 Populists.
House — 216 Democrats; 127 Republicans; 11 Populists.
Speaker — Charles F. Crisp (Ga.), Democrat.

FIFTY-THIRD CONGRESS
First session — 2 Dec. 1895 to 11 June 1896.
Second session — 7 Dec. 1896 to 3 March 1897.
Senate — 43 Republicans; 39 Democrats; 6 Populists.
House — 244 Republicans; 105 Democrats; 6 Populists; 1 Silver.
Speaker — Thomas B. Reed (Me.), Republican.

FIFTY-FOURTH CONGRESS
Special session of Senate — 4–10 March 1897.
First session — 13 March to 24 July 1897.
Second session — 6 Dec. 1897 to 8 July 1898.
Third session — 5 Dec. 1898 to 3 March 1899.
Senate — 47 Republicans; 34 Democrats; 5 Populists; 2 Silver.
House — 204 Republicans; 113 Democrats; 11 Populists; 3 Silver; 26 Fusionists (Democrats and Populists).
Speaker — Thomas B. Reed (Me.), Republican.

FIFTY-FIFTH CONGRESS
First session — 4 Dec. 1899 to 7 June 1900.
Second session — 3 Dec. 1900 to 2 March 1901.
Senate — 53 Republicans; 26 Democrats; 5 Populists; 2 Silver; 1 Independent.
House — 185 Republicans; 163 Democrats; 7 Populists; 2 Silver.
Speaker — David B. Henderson (Iowa), Republican.

FIFTY-SIXTH CONGRESS
Special session of Senate — 4–9 March 1901.
First session — 2 Dec. 1901 to 1 July 1902.
Second session — 1 Dec. 1902 to 4 March 1903.
Senate — 53 Republicans; 31 Democrats; 4 Populists or Silverites.
House — 197 Republicans; 151 Democrats; 9 Fusionists.
Speaker — David B. Henderson (Iowa), Republican.

FIFTY-SEVENTH CONGRESS
Special session of Senate — 5–19 March 1903.
First session — 9 Nov. to 7 Dec. 1903.
Second session — 7 Dec. 1903 to 28 April 1904.
Third session — 3 Dec. 1904 to 4 March 1905.
Senate — 57 Republicans; 43 Democrats.
House — 208 Republicans; 178 Democrats.
Speaker — Joseph G. Cannon (Ill.), Republican.

FIFTY-EIGHTH CONGRESS
Special session of Senate — 4–18 March 1905.
First session — 4 Dec. 1905 to 30 June 1906.
Second session — 3 Dec. 1906 to 4 March 1907.
Senate — 57 Republicans; 33 Democrats.
House — 250 Republicans; 136 Democrats.
Speaker — Joseph G. Cannon (Ill.), Republican.
CONGRESSIONAL DISTRICT—CONEEVE

SIXTIETH CONGRESS
First session — 2 Dec. 1907 to 30 May 1908.
Second session — 7 Dec. 1908 to 4 March 1909.
Senate — 61 Republicans; 31 Democrats.
House — 212 Republicans; 164 Democrats.
Speaker — Joseph G. Cannon (Ill.), Republican.

SIXTY-FIRST CONGRESS
Special session of Senate — 4–6 March 1909.
First session — 15 March to 5 Aug. 1909.
Third session — 5 Dec. 1910 to 4 March 1911.
Senate — 61 Republicans; 32 Democrats.
House — 219 Republicans; 172 Democrats.
Speaker — Joseph G. Cannon (Ill.), Republican.

SIXTY SECOND CONGRESS
First session — 4 April to 22 Aug. 1911.
Second session — 4 Dec. 1911 to 16 Aug. 1912.
Third session — 2 Dec. 1912 to 4 March 1913.
Senate — 41 Democrats; 51 Republicans.
House — 228 Democrats; 161 Republicans; 1 Socialist.
Speaker — Champ Clark (Mo.), Democrat.

SIXTY-THIRD CONGRESS
Special Session of Senate — 4–17 March 1913.
First session — 7 April to 1 Dec. 1913.
Third session — 1 Dec. 1914 to 4 March 1915.
Senate — 51 Democrats; 44 Republicans; 1 Progresive.
House — 291 Democrats; 172 Republicans; 9 Progressives;
7 Progresive Republicans at large.
Speaker — Champ Clark (Mo.), Democrat.

SIXTY FOURTH CONGRESS
First session — 6 Dec. 1915 to 8 Sept. 1916.
Second session — 4 Dec. 1916 to 4 March 1917.
Senate — 56 Democrats; 46 Republicans.
House — 230 Democrats; 196 Republicans; 7 Progressives;
1 Socialist; 1 Independent.
Speaker — Champ Clark (Mo.), Democrat.

SIXTY-FIFTH CONGRESS
Special Session — 5 March 1917 to 16 March 1917.
First Session — 2 April 1917 to 6 Oct. 1917.
Second Session — 3 Dec. 1917.
Senate — 53 Democrats; 42 Republicans.
House — 216 Democrats; 210 Republicans; 2 Progressives;
1 Prohibitionist; 1 Socialist; 2 Independents.
Speaker — Champ Clark (Mo.), Democrat.

Irving E. Rines,
Author of ‘History of the United States’.

CONGRESSIONAL DISTRICT. See District.

CONGRESSIONAL RECORD, a journal of the proceedings of the Congress of the United States, dating from 1799. Prior to that date the Senate held secret sessions only, but thereafter publication was required, save in the case of "executive sessions." Record has been the title since 1875; before that date the journal was entitled "Annals of Congress" (1789–99) for the House and "Journal of the House and Senate" (1790–1807) for both branches. Register of Debates until 1837, and until the end of 1874 Congressional Globe, and since then, its present name has been in use. Undelivered speeches on the grant of "permission to print" appear in the Record as if they had actually been given, and stenographic reports of debates are revised by the participants before being printed.

CONGRESSMAN AT LARGE, a national representative elected by the entire State and not as a member for some district. There is no permanent system of the sort, though many able political thinkers have wished for it and believed it would greatly raise the average of ability in the House; preventing the restriction of choice to the mediocre notabilities who chance to reside in a given district. In fact, however, there is no legal obstacle now to the voters of a district electing an outsider if they wish; but they rarely wish it, and if the general system were introduced, the experience of other political affairs makes it probable that the memberships would be "claimed" by given districts in rotation. At present, the only use of the plan is in giving a State the right to attach memberships assigned to it by the apportionment under a new census, until it can be redistricted, which is sometimes a long process with fierce political opposition. Many States have had one congressman at large, and some States still have them.

CONEEVE, kön'grēv, Richard, English essayist: b. Leamington, England, 4 Sept. 1818; d. Hampstead, England, 5 July 1899. He was educated at Rugby and Oxford and was subsequently a tutor in Wadham College, Oxford, resigning his post on becoming a Unitarian. Beside editing Aristotle's 'Politics' with notes (1855), he published 'Roman Empire of the West' (1855); 'The Catechism of the Positive Religion' (1858); 'Elizabeth of England' (1862); 'Essays: Political, Social, and Religious' (1874).

CONEEVE, William, English dramatist: b. Barیدے, near Leeds, 1670; d. London, 19 Jan. 1729. He entered the Middle Temple, London, to prepare himself for the legal profession, but soon deserted the law for literature. At a very early age he wrote a novel entitled 'Incoignita,' followed by his comedy of the 'Old Bachelor,' produced in 1693, and pronounced by Dryden the greatest play that he had ever beheld. His next play, the 'Double Dealer' (1693), was not so successful in representation as the comedy of 'Love for Love' (1695), proved extremely popular. Its success acquired for the author the patronage of Lord Halifax, who conferred on him several very lucrative posts, so that he was far more prosperous than most men of letters. Not content with his fame in comedy, he essayed tragedy; and in 1697 produced his 'Mourning Bride,' the reception of which was extremely favorable. The composition of four such plays before he reached the age of 28 is a remarkable proof of early genius in a line of composition demanding great observation and experience. The licentiousness of his writings caused him to be attacked by Jeremy Collier in his 'Short View of the Immorality and Profaneness of the English Stage,' to which Congreve published a lame and ineffective reply. He soon after closed his dramatic career with the 'Way of the World' (1700) and '1798–1724 for many critics as the most perfect of his comedies, but which was received so coldly that he resentfully determined to relinquish a species of writing in which, upon the whole, he had been eminently successful. A masque, entitled the 'Judgment of Paris,' and
CONGREVE—CONIBO 519.

'Semele,' an opera, neither of which was presented, close the list of his labors for the stage. He, however, continued to write occasional verses on public subjects; and in 1710 published a collection of his plays and poems. Dryden declared him to be the equal of Shakespeare. Steele dedicated to him his 'Miscellanies,' and Pope his translation of the Iliad. He was buried in Westminster Abbey, where a monument was erected to him by the Duchess of Marlborough. Congreve’s comedies are chiefly distinguished for the sustained flow of wit in the dialogue. But his characters are repulsive. It is now rare for any of his plays to be produced on the stage, which without rigorous pruning, to adapt them to modern manners, it would be impossible to do. His poetry is of little value. (See Way of the World, The).

CONGREVE, Sir William, English inventor: b. 20 May 1772; d. Toulouse, France, 16 May 1828. After passing through the Royal Academy at Woolwich he entered the artillery in 1791, served under his father, a lieutenant-general, and in 1804 took his post of comptroller, and also as second holder of the baronetcy, conferred in 1812. He invented the rocket which bears his name about 1804. It was first used in active service in the attack on Boulogne in 1804. He took an active part in army improvements; became a Fellow of the Royal Society in 1811; obtained a patent for manufacturing gunpowder in 1815; and one for the manufacture of bank-note paper in 1817.

CONGRUIST, CONGUIST, terms derived from the expression merisium et congruo, which signifies the view of some writers on the doctrine of divine grace and human merit, that though a man may not in the strict sense merit a given grace or favor of God he may be said to merit in a looser sense, on the ground that there is a certain congruity, a certain fitness with what we believe concerning the relation between man and his Creator, in assuming that the Creator will, out of his infinite mercy, grant to his faithful servants favors that they do not in any tolerable sense of the word merit. An example of merisium et congruo is had when a saintly man by his prayers obtains the conversion of a sinner: that conversion is not merited at all in any strict sense; but it is congruous, it is what we like to think about the Creator’s love for his chosen ones, that he should be moved to grant the petition of one who is admitted to his friendship.

CONHYDRIN, kōn-ẖdrīn, an alkaloid contained, along with conia, in the flowers and seeds of the hemlock. The physiological action of conhydrin resembles that of conia (q.v.), but it is not nearly so rapid or powerful.

CONI, kōn̩-'ē, or CUNEO, koo-n̩'-ē, Italy, capital of the province and district of Coni, on a high hill, at the confluence of the Stura and the Gesso, about 55 miles south of Turin, in a pleasant, well-cultivated district. The old fortifications, the arcades along the principal streets, a Franciscan church of the 12th century, a handsome town-house, with a tall tower, and a cathedral, are the picturesque items of the town. There are silk spinning-mills, and manufactures of silk, paper and woolen goods. Grain, hemp and silk forms articles of commerce. It was taken by Napoleon in 1796, given to the Austrians in 1799, and again given up to the French in 1801. Pop. 29,122.

CONIA, or CONINE (C₄H₄N₂), an alkaloid in the hemlock, discovered in an impure state by Gieszecke in 1827, and subsequently prepared in the pure state by Geiger, who recognized it as a vegetable base. It exists in union with malic acid, in all parts of the plant, but especially in the not quite ripe seed. When pure it is a colorless oily liquid, specific gravity 0.69, which changes by exposure to air to a brown fluid, and ultimately to a resinous, bitter mass, slightly soluble in water, soluble in alcohol, and when purified yielding a jelly with a butyric odor. It can be distilled without much alteration, provided the air be excluded, its boiling point being 168° C. At a higher temperature it burns with a bright smoky flame. It is slightly volatile even at ordinary temperatures. It has a very disagreeable odor, sharp and choking when strong; its taste is nauseous. It is somewhat soluble in water, readily in alcohol, ether and oils, and itself acts as a solvent of sublimate. It has a strong alkaline reaction when moist, and combines with the acids to form salts, most of which are crystalline but deliquescent. The salts are unstable in aqueous solution; they evolve the odor of the base and gradually change color. It precipitates the oxides of iron, zinc, manganese, aluminum, copper and the other heavy metals, from solutions of their salts. It is attacked by chlorine, bromine and iodine, and oxidized by nitric acid, yielding butyric acid. The poisonous action of conia has been minutely investigated, but although it has been proved to be rapidly fatal to all classes of animals when administered in doses of from 3 or 4 to 10 or 12 grams, the nature of its action is not fully ascertained; but the breathing and pulse are affected, and the extremities paralyzed. Some experimenters have tried its effect upon themselves, and according to their account the minutest doses produce burning in the mouth, vomiting, nausea and vomiting, pressure in the head, tottering, indistinct vision, cramps and other symptoms. Similar observations have been made on persons to whom the alkaloid has been given therapeutically. It has been shown that conia can be detected in a poisoned animal, even after a considerable time. The tonic power of conia seems to be little if at all affected by the introduction into it of the alcoholic radicals, methyl, and ethyl. The action is perhaps not so rapid, but it is the same in character, and takes place with quite as small quantities. In this respect conia differs from some other alkaloids, for instance, codeia.

CONIBO, kō-nēbō, a tribe of Indians belonging to the Panoan family in eastern Peru, allied to the Ucayali tribe. They were an agricultural people and built villages. The Spanish missionaries tried to convert them in 1663, but were driven out after 1695, when Father Ritchie was killed by the savages. They are now partially civilized and are often employed as canoe men and rubber gatherers. Their country is along the middle Ucayali River in north
CONIC SECTIONS — CONIFERÆ

CONIC SECTIONS, three curves, the hyperbola, the parabola and the ellipse, are called the conic sections, because these curves are formed by the intersection of the surface of a cone with planes that cut the cone in various directions. If the cutting-plane be parallel to the axis of the cone (fig. 1), the curve formed is the hyperbola, which has two branches, as shown in the figure. If the cutting-plane be parallel to a straight line on the surface of the cone (fig. 2), the curve formed is a parabola. Any other section is an ellipse (fig. 3). It must be noticed, however, that this general description includes three peculiar cases. In the case of a plane parallel to the axis of the cone, when that plane contains the axis, the section, instead of being a hyperbola,

is in this limiting case a pair of straight lines meeting each other at an angle equal to that of the angle of the cone so as to form a triangle (fig. 4). When a plane, which would otherwise form a parabolic section, is a tangent plane to the cone, the parabola degenerates into a straight line passing through the vertex of the cone. Lastly, when a plane that would otherwise form an ellipse is perpendicular to the axis of the cone, the ellipse becomes a circle (fig. 5). Lastly, when a plane cuts the cone only in the vertex, the conic section degenerates into a single point (fig. 6). A pair of points cannot be produced by any plane section of a cone, but on account of its analytical properties, this figure is also considered as a degenerate conic section. The properties of these curves are discussed under their several names. It will there be seen that other definitions may be given of the curves; and that from these their properties are more conveniently derived than from the consideration that they are formed by the sections of a conical surface.

The most important of these properties are that of being represented in a system of Cartesian co-ordinates by an equation of the second degree, and of being the locus of the corresponding lines of two projective pencils in the plane. The properties of these curves are of the greatest physical interest; and the geometry of the conic sections has, ever since the time of the Greek mathematicians, been considered as the best of the more advanced geometrical studies.

CONIFERÆ, a group of trees and shrubs consisting of about 40 genera and 300 species, which are most numerous in the temperate regions of the world, especially in the northern hemisphere. Among the few species found in the tropics, the most important are those belonging to the genera Araucaria (q.v.), Dacrydium, Pitypodium, and Dacrydium. In the Arctic regions and the correspondingly cold mountain climates various conifers approach very nearly the line of perpetual snow, and like other plants of such climates are reduced to gnarly dwarfed specimens with slight resemblance to those of the same species in less rigorous climates. In the United States and Canada about 15 genera and 100 species and sub-species are indigenous and of these the majority are native to the Pacific coast. In addition to the number of species mentioned fully 400 horticultural varieties must be added. These are listed in Bulletin No. 17 of the Division of Forestry, United States Department of Agriculture.

No forest trees are of more economic importance than the conifers. Their notable blending of maximum strength, stiffness, and durability with minimum weight, and their abundance have won them prominence in house, ship and bridge building, wharf making and sidewalk constructing, etc. They are also of great importance in planting, both for use and ornament, their evergreen habit (except in Larix) and the retention of their lower limbs until comparative age, making them especially good for wind breaks, these characters coupled with their conical form and the striking colors of their foliage rendering them particularly useful for grouping with deciduous trees and shrubs or for individual specimens in parks and upon lawns.

The species are characterized by straight shafts which elongate terminally, and, like the shape of the trees, form a more or less attenuated cone. They have either needle-shaped or awl-shaped leaves (except in Podocarpus) which are specially adapted by these forms and by the thickened epidermis to resist excessive transpiration, a necessary adaptation since the leaves are usually retained throughout the year. They have naked ovules which are fertilized directly by the exceedingly light pollen which is produced in enormous quantities and carried by the wind even miles away from the forests, to fall as so-called "showers of sulphur." These ovules are borne in a strobile which enlarges after fertilization into what is popularly known as the cone, the group being named from this character. The cone is an aggregation of scales, above the bases of which are borne the seeds. These are utilized as food, and have been introduced in the markets of the United States by the Syrians. The internal structure of the conifer is also peculiar to the group. Like the dicotyledons, the woody cylinder increases in girth by the external development, beneath the bark, of homogeneous woody fibres marked on two sides with circular discs and among which are few true vessels. Since these woody fibres are fitted together without overlapping, the grain of the wood is fine and uniform, which accounts for its easy working qualities, especially in the direction of the grain. Botanists divide the species into two great families, the Taxaceae and Podocarpaceae. The former includes the two tribes: Podocarpaceae, the leading genus of which is Podocarpus, with about 40 species, and Taxaceae, chief of which is the genus Taxus, the yew. The species of this family have more or less fleshy fruits. The Podocarpaceae embraces four tribes: Abietinae, the pure firs; Podocarpinae, in which bear but slight resemblance; Pinus, pines; Picea, spruces; Tsuga,
CONIINE—CONIUM 581

hemlock; *Abies* fir; and *Larix* larch; *Tasod- 
dear which includes *Tasodunum*, the bald 
cypress; and *Sequoia*, the redwood. The fureen-
necia, which includes *Thuja*, arborvitae; and 
*Juniperus*, juniper; *Chamaecyparis*, cedar;
*Araucaria*, including *Araucaria*, Norfolk Is-
land pine and its allies. The most widely di-
struted of these genera is *Tasodunum*. As doubtless the 
genera *Pinus* and *Juniperus*, and the most re-
stricted are *Tasodunum*, two species of which 
are indigenous to the United States and one to 
China; and *Sequoia*, of which only two species 
are known, both found in occasional groves on 
the Pacific Coast. During geological ages these 
two genera were far more widely distributed.

So far as is known from fossils conifers 
appeared on the earth in Silurian time, though 
they may have appeared earlier. They in-
creased and developed during the Devonian and 
Carboniferous ages. Unlike the acrogerons 
(ferns, ground-pines and horse-tail rushes); the 
conifers have increased rather than de-
clined since the Carboniferous. Species of your 
wood were abundant in North America in early 
Devonian time. In the Carboniferous the 
gymnosperms that grew in the great swamps 
were related to the cycads and yews. True 
conifers may have grown upon the drier hill-
sides. The genus *Walchia* began near the 
close of the Carboniferous, and in the Permian 
the conifers included species of *Dadoxylon*, 
*Pinites*, *Ulimania*, etc.; common Triassic coni-
fers are the genera *Polliza*, *Baiera* and *Ara-
ucaria*.

Conifers are propagated by means of seeds 
which may usually be obtained in autumn, 
though some species open their cones at irregu-
lar intervals through the winter and others only 
when artificial heat such as that of a forest fire 
is applied. The seed should be planted in a 
sandy loam, given a light mulch, of pine needles 
or sphagnum, and the seedlings kept free from 
weeds. They must be kept moist but not wet 
until they have formed their crown buds, 
which appear when they are about three months 
old. If proper methods are practised, trans-
planting may be done at any time of year, but 
spring is generally much the best season, since 
the roots are then most active and the check to 
growth less likely. As a rule conifers do not live 
upon light soils. They are attacked by a large 
number of insects and diseases both in foliage 
and trunk; but since these trees and shrubs are 
planted mainly for ornament or are growing in 
the forest where systematic war cannot often 
be successfully carried on, little attention has 
been given to the control of pests.

Standard fungicides and insecticides may be 
used effectively in some cases, care being taken 
to determine the mode of attack of the par-
ticular pest and then to treat. Consult Veitch, "Manual of Coni-
fers"; Beissner, "Handbuch der Nadelholz-
kunde"; Carrière, "Traité des conifères"; 
Bailey, "Standard Cyclopedia of Horticulture."

CONINE, CONEINE or CONNIE. See 
CONIA.

CONINGSBY, a novel by Benjamin Dis-
raeli, Lord Beaconsfield, published 1844. 
It was his sixth and most successful novel. 
In two years it went through ten impressions, 
and 50,000 copies had been sold in Eng-
land and the United States. It was a novel 
with a purpose; the author himself explained 
that his aim was to elevate the tone of public 
life, to ascertain the true character of political 
parties and especially to vindicate the claims of 
the Tories. Incidentally he wished to empha-
size the importance of the Church in the de-
development of England, and he tried to do some 
justice to the Jews. There are more than 
threescore characterized in the book; but its 
popularity came from people's interest in 
identifying them with men and women prominent 
in English social and political life.

CONINGTON, John, English classical 
scholar: b. Boston, Lincolnshire, 10 Aug. 1825; 
d. there, 23 Aug. 1868. He was educated at 
Beverley, Rugby, and Oxford, and in 1854 was 
appointed to the newly founded chair of Latin 
language and literature at Oxford, which he 
filled until his death. His greatest work is his 
edition of "Virgil" (4 vols., 1861-68), with its 
singularly subtle and suggestive essays. His 
edition of the "Agamemnon" (1848), and 
"Choéphori" (1857), of Æschylus are of less 
moment, though indeed the latter is admirable. 
In his later years he gave himself much to 
translation, the results of which are his trans-
lations of the "Odes" of Horace (1863), the 
"Æneid" (1866), in Scott's ballad-metre, the 
"Iliad" (1868), in the Spenserian stanza, and 
the "Satires and Epistles" of Horace (1869), in 
the couplet of Pope. His writings (with a 
memoir by H. J. Smith) were edited by J. A. 
Symonds (London 1872).

CONISTON LAKE, England, a lake in 
North Lancashire at the eastern foot of the 
Coniston Fells, nine miles west of Bowness on 
Windermere. It is five miles long, one-half 
mile broad, 147 feet above the sea, and its 
greatest depth is 260 feet. Its waters abound 
with trout and perch. On the eastern shore 
stand Ruskin's house, Brantwood and Tent 
House, once Tennyson's residence. The Old 
Man of Coniston, to the northwest, is 2,633 feet 
high.

CONIUM ("spotted hemlock"), the full-
grown fruit of *Conium maculatum* gathered 
while green. *Conium maculatum* is a stout, 
erect biennial, three to six feet high, with a 
much branching, smooth, furrowed, dark green 
hollow stem, covered with purplish spots, very 
widely present throughout Europe and natural-
ized in the eastern United States. It grows 
commonly in wet places, wayside brooks, 
swamps and dark, moist gardens. All parts of 
the spotted hemlock are active, but the poison-
ous principle conine is found most abundantly 
in the full-grown but unripe seed, the principle 
being a volatile alkaloid. Only fresh hemlock 
is of any service, and much of the lack of uni-
formity of results in the use of this drug as a 
remedy has come from the neglect of this pre-
caution on the part of the manufacturers of the 
drug. The composition of conium is complex. 
It contains a slight amount of volatile oil and 
two or three alkaloids, the most important of 
which is conine. Conine is present in small 
amounts only. It is a strongly basic, colorless, 
oily liquid, with a penetrating odor and a sharp 
taste resembling tobacco. It boils at 166° C.; 
its chemical formula is CH₃NH₂H₂C₆H₇CH₂CH₂.

It has been made synthetically, being one of the 
first of the alkaloids thus synthesized. The 
physiological action of conium is practically 
identical with the action of quinine. The gen-
CONJEVERAM — CONJUNCTIVITIS

eral effect is paralysis of the motor end organs of voluntary muscles; it is thus a motor de-
pensation. It is an irritant to the stomach, in-
creasing the salivary secretions. Its effect on
the heart is slight; its effect on the nervous sys-
tem is very little save in extreme poisoning,
when blood changes cause changes in the ner-
vous system. The early symptoms of poisoning
are heaviness of the muscles of the legs, and of
the eyelids, ptosis, staggering gait, muscular re-
laxation and muscular paralysis; paralysis of the
vocal chords causing derangement of speech;
dilatation of the pupil; and finally paralysis of the muscles of respiration with
asphyxia, convulsions and death. Treatment of
the poisoning is by means of the stomach-pump,
strychnine, coffee. Alcohol and rapid elimina-
tion by hot baths are desirable.

The therapeutics of conium is restricted. It is
very questionable whether it is of use in any
affectation other than habitual motor spasms of
voluntary origin such as spasmodic tics, torti-
collis and other like affections. It is certainly
of no value in spasmodic affections not
associated with voluntary action such as chorea,
epilepsy, myoclonus, etc.

CONJEVERAM, kōn-jē-ver-am’, CAND-
CHIPURA (*the Golden City*), a town of
Hindustan, in the presidency of Madras, dis-
trict of Chingleput. It stands in a valley, is
irregularly built, and from five to six miles
long, resembling a series of villages, inter-
mingled with gardens and cocoanut plantations.
Conjeveram is one of the Hindu sacred cities,
and is sometimes called the "Benares of the
south." There are here two splendid pagodas;
one dedicated to Vishnu, richly sculptured, and
highly venerated; the other, a larger and more
imposing structure, dedicated to Siva, from the
summit of which a magnificent view is obtained.
There are many smaller pagodas; and houses
of accommodation for travelers abound. Cott-
tons are manufactured. There is a flourishing
school here connected with the Free Church of
Scotland. Pop. 43,000.

CONJUGAL RIGHTS (Lat. conjugalis,
conjuta, conjoge, conjutor, conjux, "the
wife," or "wifely"), in law, the right which
husband and wife have to marital society,
comfort and affection. The suit for restitution
of conjugal rights is a matrimonial suit, cog-
nizable in the Divorce Court, which may be
brought whenever either the husband or wife
lives separate from the other without any suffi-
cient reason. Conjugal rights are matrimonial,
nuptial and connubial.

CONJUGATE FOCUS. See LENS.

CONJUGATION (Fr. conjugation, Lat.
conjugatio, "joining together"). In some uni-
cellular plants and in one-celled animals (Protoc-
a), after multiplying by self-division
perhaps for many generations, reproduction by
germs is brought about by a process called
conjugation. It may be illustrated by a flagellate
monad (Heteromita). In this form two indi-
viduals come together and completely fuse, the
result is a thin-walled zygote (the zygospore),
the protoplasm of which divides by multiple fission
into very minute spores or germs. Each of these
spores finally grows to become an adult
Heteromita. In a much more specialized pro-
zoan (Paramecium), after self-division has
been repeated for a certain number of genera-
tions, it is interrupted by conjugation. In this
case two individuals become applied by their
ventral faces, but do not fuse, but the nuclei
merely melt together, after which the two
original infusorians separate. This process is
akin to and anticipates sexual reproduction in
animals higher than protozoa. The process
seems to lend new life to the species; it is a
process of rejuvenescence, and is necessary for
the maintenance of the life and vigor of the
species.

CONJUNCTION, in astronomy, one of the
aspects of the planets. Two heavenly bodies
are in conjunction when they have the same
longitude—that is, when the same perpendicular
to the ecliptic passes through both. If they
have, at the same time, the same latitude—
that is, if they are both equally far north or
south of the ecliptic—they appear from the
earth to be in the same spot of the heavens,
and to cover one another. The sun and moon
are in conjunction at the period of new moon.
In the case of the inferior planets Mercury and
Venus, the conjunction is inferior when the
planet is between the earth and the sun, and
superior when the sun is between the earth and
the planet. In general, a heavenly body is in
conjunction with the sun when it is on the same
side of the earth, and in a line with the sun,
and it is in opposition to the sun when it is on
the opposite side of the earth, the earth being
in a line between it and the sun. Planets are
invisible when in conjunction with the sun,
except in rare cases when an inferior planet
passes over the sun's disc, and may be seen as
a speck on his surface. Conjunctions are either
geocentric or heliocentric, according as they are
actually witnessed from the earth, or as they
would be witnessed if observed from the sun.
In observing a conjunction from the earth's
surface it is usual to reduce the observation to
what it would be if made from the earth's
centre; by this means the exact times of con-
junction are more accurately fixed, and the
observations of one astronomer made available
to every other, wherever he may be on the
earth's surface. Grand conjunctions occur when
several stars or planets are found to
gether. Chinese history records one about
2500 B.C., which astronomers calculate actually
took place.

CONJUNCTION, that grammatical part
of speech which couples words, clauses and
propositions. Conjunctions differ from preposi-
tions in their mode of affecting the cases of the
nouns which they connect with the previous
word or phrase. The preposition is said to
govern the noun, that is, to determine its case;
the conjunction also may determine the case of
a noun, but in a different manner; it always
requires the case of the noun or pronoun which
follows it to be the same as that of the noun
with which it connects the second noun. The
conjunction also affects actively the modes of
verbs, though less frequently than English,
in other languages. Conjunctions are divided
into those that co-ordinate the clauses they
relate, such as "and," "or," "but," and those
that render one clause subordinate to the other,
as "if," "for," "when," "notwithstanding that.

CONJUNCTIVA DISEASES. See EYE.

CONJUNCTIVITIS. See EYE.
CONJURATION (Lat. conjuratio, 'a swearing together,' hence conspiracy), a conjuring, or causing, by magical means; the act of calling or invoking by a sacred name; solemn entracty; in law, an unlawful compact formed by oath. The term was formerly used especially in the sense of having personal confects with the devil or some evil spirit to discover secrets or effect some malicious purpose. Closely connected with this use of the word is the secondary meaning of a magical form of words used to invoke supernatural aid through incantation, enchantment or magic spell.

CONJURING, the production of effects apparently miraculous by natural means. The earlier professors of the art claimed bona fide supernatural powers; and in ages when the most elementary principles of physical science were unknown beyond a very limited circle, it was not difficult to gain credence for such a pretension. The modern conjurer makes no such claim, but tells the public frankly that his marvels are illusory. Of the conjurers of remote antiquity we have few reliable records; therefore, it is a reasonably safe conjecture that the prestige of the ancient mysteries rested in no small degree upon effects of natural magic. Perhaps the earliest really trustworthy authority is Reginald Scot, who in his 'Discoverie of Witchcraft' (1584) has enumerated the stock feats of the conjurers of his day.

The conjurers of Scot's time, and those of even much later date, were accustomed, in order to facilitate the substitutions on which a great part of their tricks depended, to wear an apron with pockets, known (from its resemblance to a game-bag) as the gibecière. A later school suppressed this tell-tale article of costume, and used instead a table, with cover reaching nearly or quite to the ground. This table concealed an assistant, who worked most of the required transformations, etc., either handing the needful articles to the conjurer as he passed behind the table, or pushing them up through traps in the table-top. Conus the elder, a French conjurer who flourished at the close of the 18th century, made a further improvement by discarding the concealed assistant, and using an undraped table with a secret shelf (now known as the servante) behind it, on which his substitutions were made. His immediate competitors did not follow his example, a whole generation of later conjurers, including Comte, Bosco and Philippe, retaining the suggestive draped table. Its death-blow, however, was struck by Robert Houdin (1805-71), with whom about 1844 a new era began. The most modern school of conjurers, following the lead of Wiljalba Frikell, etc., represented by Hartz, Herrmann, Buatier de Kolta, Verbeck, Lynn, Bertram, etc., generally aim at producing their magical results with the minimum of visible apparatus.

The word 'conjuring' also still bears all the meanings of conjuration; the sense in which the ancient conjurer always used it; and in which medicine men of savage tribes invariably use it to-day.

CONKLIN, Jennie Maria (DRINKWATER), American author: b. Portland, Me., 14 April 1841; d. New Vernon, N. J., 28 April 1900. She was educated in the public schools, and while still in her teens won fame with her stories for children. In 1880 she married Rev. Nathaniel Conklin. Her works include 'Miss Prudence'; 'Tessa Wadsworth's Discipline'; and 'Fifteen.' She originated the "Shut-In Society," an organization of invalids for correspondence.

CONKLING, Roscoe, American legislator: b. Albany, N. Y., 30 Oct. 1829; d. New York, 18 April 1888. He removed to Utica in 1846, studied law and was admitted to the bar in 1850. He was mayor of Utica in 1858, and sat in Congress as a Republican (1858-62 and 1865-67). During the Civil War in 1861 he became active supporter of the administration, appearing constantly in debates and on committees. He was elected to the United States Senate in 1867, 1873 and 1879, and as senator he supported the reconstruction policy, actively opposed President Johnson and was a staunch supporter of President Grant. He was active in almost every move of importance made by his party. He was one of the foremost advocates of the Second Civil Rights Act, in 1875; of the bill creating the Electoral Commission to settle the disputed election of 1876; and of the act calling for the resumption of specie payment (1875). He became an extremely influential member of his party; in 1876 receiving 93 votes for his presidential nomination, and in 1880, by his support of Grant and his personal opposition to Blaine, dividing the Republicans into two sections. In May 1881, he and his colleague, Thomas C. Platt, suddenly resigned from the Senate, owing to a dispute with President Garfield on a question of patronage, and sought re-election; but after a warm canvass, both were rejected, though vigorously supported by Vice-President Arthur. Conkling afterward
practised law in New York. He was appointed associate chief justice of the United States Supreme Court in 1882, but declined the position. Conkling was a thorough believer in the system of political patronage and he and Platt attempted to say where this patronage should go and to whom in the State of New York.

CONN, Herbert William, American biologist: b. Fitchburg, Mass., 10 Jan. 1859; d. Middletown, Conn., 18 April 1917. He was educated at Boston University and was professor of biology at Wesleyan University, Middletown, Conn. He published 'Evolution of To-day' (1886); 'The Living World' (1881); 'The Story of Germ Life' (1897); 'The Story of the Living Machine' (1890); 'The Method of Evolution' (1900); 'Agricultural Bacteriology' (1902); 'An Elementary Physiology and Hygiene for Use in Schools' (1903); and also over 150 scientific memoirs.

CONN, Lough, lō� kōn, a lake in the north of Mayo County, Ireland, united with Lough Cullin by a narrow channel. The two extend for about 13 miles and are studded with islands.

CONNATE WATER. See GROUND WATER.

CONNAGHT, kōn'nät, AND STRATHHEARN, DUKE OF, Arthur William Patrick Albert, English prince, sixth child and third son of Queen Victoria: b. Buckingham palace, 1 May 1850. He entered the Military Academy at Woolwich as a cadet in 1866; lieutenant, Royal Engineers, 1868; Royal Artillery 1869; captain, Rifle Brigade, 1871. On attaining his majority in 1871, Parliament voted him a grant of $75,000 a year, and an addition of $50,000 was voted on his marriage in 1879 to Princess Louise Margaret of Prussia. She died in London 14 March 1917 at the age of 57. Three children were born of the union, Princess Margaret (Crown Princess of Sweden), Prince Arthur and the popular Princess Patricia, in whose honor a Canadian regiment mobilized for the war was named 'Princess Pat's Own.' The Duke of Connaught led an active life of 50 years' public service. In 1870 he served in Canada, was assistant adjutant-general at Gibralter 1876-1879, when he was placed aide-de-camp to Queen Victoria. He commanded the Guards' Brigade in the Egyptian campaign of 1882, and in 1886 was sent to India to assume command of the Bombay army. He returned home in 1890, commanded at Portsmouth for three years, and then succeeded Sir Evelyn Wood as commander-in-chief at Aldershot. From 1900 to 1904 he commanded the forces in Ireland and was created fieldmarshal in 1902. In 1901 the Duke was elected Grand Master of Freemasons in England in succession to his brother, the late King Edward. On the reorganization of the War Office in 1904, he became the first inspector-general of the forces and president of the selection board. In 1908 he was appointed to the newly-created post of commander-in-chief and high commissioner in the Mediterranean. In 1910 the Duke opened the first Parliament under the Union of South Africa, in Cape Town, and in 1911 became governor-general of Canada for five years. Since his return to England in October 1916 he has taken an active part in national organization. With the sole exception of King George, no member of any English royal family has seen more of the world and especially of the British Empire, than the Duke of Connaught.

CONNAUGHT, Ireland, one of the four provinces, bounded east and northeast by Leinster and Ulster, south by Munster, and north and west by the Atlantic; length, north to south, 112 miles; breadth, 99 miles; area, 6,873 square miles. It is the smallest, most westerly and least populous of the provinces. Its west coast is much broken up by numerous bays and inlets, and is thickly studded with islands. The surface is rugged and mountainous, except in the central part, which is comparatively level. It is, on the whole, the least fertile of all the provinces. Agriculture and fishing are the chief industries. Sheep raising is largely engaged in. Connaught was formerly one of the Irish kingdoms. Its kings were of the race of O'Connor, but they were almost exterminated at Athenry in 1305. In 1590 the English divided it into six counties—Galway, Leitrim, Mayo, Roscommon, Sligo and Clare—one of which, county Clare, was afterward transferred to Munster. Pop. 610,984, 96 per cent being Roman Catholics.

CONNEAUT, Ohio, town of Ashtabula County, situated at the mouth of Conneaut Creek, on the Lake Shore and Michigan Southern, the New York, Chicago and St. Louis and the Bessemer and Lake Erie. It is quite a thriving town. It has a good harbor at the mouth of the creek, where there is a lighthouse. It is an important ore and coal port, being noted for its exceptional facilities for handling large cargoes. There are extensive railroad shops and manufactories of canned goods, self-sealing packages, bricks, shovels, leather, lumber, etc. Conneaut also exports molding sand and farm produce. The city contains three hospitals, a Carnegie library and a public park. The electric-light plant is owned and operated by the city, which was first incorporated in 1832. It is governed by a mayor, elected biennially, assisted by council.

CONNECTICUT, kōn-net'ik, "the Nutmeg State," "the Land of Steady Habits," or "the Constitutional State" (having framed the first written constitution of the United States) and is the southwesternmost of the six New England States. It is bounded by Massachusetts on the north, Long Island Sound on the south, Rhode Island on the east and New York on the west. Capital, Hartford. Area, 4,815 square miles; land, 145 square miles water. Pop. 1,244,479.

History.—There is no doubt that the claim of the Dutch to Connecticut by right of discovery was well founded, for the accounts of the voyages of Henry Hudson in 1609 and of Adrian Bloch in 1614 give the first descriptions which history records of this region. The attempts of the Dutch to maintain their foothold by this right were few and ineffectual, failing to prevent William Holmes of Plymouth colony from establishing a trading post at or near Hartford in 1633.

Settlement.—The first permanent settlement by the English was made in 1636, though a disastrous attempt had been made in the previous year by a company from Massachusetts to occupy the three original towns. In June 1636 Rev. Thomas Hooker and Rev. Samuel Stone, with about 100 men, women and children, made their way from Massachusetts to the Connecticut Val-

</table>
ley, and there re-established the almost aban-
doned settlements at the three towns which bore
the transplanted Massachusetts names of New-
town, Watertown and Dorchester, but were, in
the following year, respectively named Hartford,
Wethersfield and Windsor. Within a year from
the time of this settlement about 30 of the settler
had been wantonly killed by the Pequot Indians,
who appeared to be plotting the extermination of
the English. In May 1637 Maj. John Mason, with a
band of 90 men, was dispatched to attack the Peo-
quot stronghold in the present town of Groton.
Reaching, by strategic movements, the stock-
ade, where a large number of them were en-
camped, he took them completely by surprise,
slaughtering about 700 by setting fire to their in-
flammable wigwams and putting to death in
hand-to-hand conflict those who escaped the
flames. This resulted in the extermination of
the Pequot tribe, and secured to the settlers
exemption from Indian depredations for all
time to come.

The colonists now began to prosper under
the leadership of the pastors, Hooker and
Stone. Finding themselves outside of the juris-
diction of Massachusetts, to which they at first
submitted to appeal, they proceeded to form a civil
government of their own, adopting in 1639 the Constitution which
stands unique in history as the first written con-
stitution of a self-governing people. Its prin-
ciples had been preached from the pulpit by
Thomas Hooker, and its spirit, if not its form,
prevailed in the Federal Constitution which was
adopted through the influence of Oliver Ells-
worth, Roger Sherman and William Samuel
Johnson of Connecticut just 130 years later.

By this Constitution of 1639 much less rigid ecclesiastical control prevailed than in Massa-
echussetts Bay and Plymouth colonies, the people
were recognized as sovereign, and the authority
and even the existence of the ruler of Great
Britain was ignored. Meanwhile there had
sprung up in Quinnipiac a budding colony,
afterward known as New Haven colony, under
the leadership of Theophilus Eaton and the
Rev. John Davenport. This colony in 1639 ad-
opted the Reformed Church Discipline
ment in seven pillars of the Church, and dis-
franchised all who were not church members.
In 1662 John Winthrop, the younger, then gov-
ernor of Connecticut, obtained in England from
Charles II a charter which established Con-
necticut as an independent colony under the
constitution already adopted, and defined the
boundaries to include New Haven colony, which
was thus absorbed, though sorely against its
will.

Charter Rights.—From this time onward,
for 50 years, Connecticut was engaged in a
constant struggle to maintain the rights which
the charter had granted. Conflicting grants by
Charles II to his brother, then Duke of York;
boundary disputes; conflicts of authority with
other colonial governors; and the fear that the
charter might be annulled by royal decree, kept
the statesmen of the day in an attitude of con-
tinual vigilance, and schooled them in diplo-
macy. Having once been part of the English
history, and then only for a year and a half, did Connecticut lose that autonomy which
she cherished as her birthright. This was dur-
ing the usurpation of Andros, in 1687. But the
charter was preserved, though Andros de-
manded it. Its preservation was the result of
one of the Yankee tricks for which Connecticut
has always been famous, and which may have
had something to do with giving her the equivocal title of the Nutmeg State. The
charter was brought into the general court
toward nightfall at Andros' request. Candles
were lighted and, by some mysterious agency,
suddenly extinguished. During the darkness
which prevailed the charter disappeared. An-
dros assumed the government, and Secretary
John Allyn wrote "FINIS" at the close of the
record of the proceedings. In May 1689 came
the downfall of Andros, and the government
and charter reappeared, with the astute Gov-
ernor Treat once more in the chair, and an un-
dying reverence established for the old charter
oak, where, as tradition tells us, Capt. Joseph
Wadsworth hid the precious document when it
so suddenly disappeared.

War Services.—From the resumption of the
government under the charter to the close of
the French war in 1763, Connecticut saw much
military service, for which she furnished her
full quota, on other soils than her own. The
short intervals of peace during this long period
did not suffice to regain prosperity, and the
year 1763 found the colony impoverished by
contributions of men and money in the French
and Spanish wars, and confronted with the
odious news of the Stamp Act. The enforce-
ment of this measure was prevented by comp-
pelling the stamp-master to sign a paper stating
that he resigned "of his own free will."

In the War of the Revolution which fol-
lowed, the share of Connecticut forms a most
important feature, still hardly appreciated by his-
torians. The colony was amply, though quietly,
prepared in every way for the coming struggle
in 1775. Perfect unanimity prevailed. It was
unnecessary either to reconstruct the govern-
ment, as was done in Massachusetts, or to de-
pose the governor, as was done in all the other
colonies. Connecticut alone of all the 13 col-
ies had from the beginning a governor, Jon-
athan Trumbull, who was an ardent believer in
the cause of his country. He became a trusted
adviser and helper; governor-general, in fact.
Connecticut tradition asserts that the national
nickname, "Brother Jonathan," is derived from
the fact that Washington had used this sobri-
quen in speaking of Governor Trumbull. From
recent compilations of muster-rolls it is safe to
assert that Connecticut furnished 40,000 men
in her various enlistments in this war. In the
adoption of the Declaration of Independence
she was the first colony to instruct her dele-
"ates to vote for this measure. During the war,
she gained the title of the "Provision State,"
owing to the unstinted supplies which she sent
to the front in all times of need, relieving, for
example, the sufferings of the starving soldiers
at Valley Forge by sending forward dozens of
live cattle when Washington wrote Trumbull
that the army must disband unless supplies were
forthcoming.

As in the French, Spanish and Indian wars,
so in the Revolution, Connecticut's position was,
in a certain sense, Hamilton-like. Not a hint of
fighting was done on her soil, and it was done at
times when her own fighting men were serving
their country beyond their own immediate bor-
ders. The ravages of two of the most savage
massacres and two of the most barbarous raids of the war brought their horror and devastation to this little commonwealth. The Wyoming massacre was an attack on Connecticut settlers on disputed Connecticut soil, justly claimed under grants of the charter, which extended the western boundaries to the "South Sea" or Pacific Ocean, whose location was majestically ignored by Charles II and his advisors. Wyoming, or Wethersfield, in Pennsylvania, was at the time of the horrible massacre of July 1778 a county of Connecticut, having been previously a part of Litchfield County, and having been for 25 years settled by a Connecticut company after repeated repulses which only served to strengthen resistance and establish an apparently permanent foothold on the part of the settlers. The refugees, of whom women and children composed a large majority, fled to their homes in Connecticut after the massacre, the terrible results of which did not prevent many of the former inhabitants from returning to Wyoming, and once more establishing themselves in that beautiful region from which they had been so recently driven. The Groton attack, occurring toward the close of the war, 6 Sept. 1781. The raid was commanded by Benedict Arnold, to whom it is unfair to attribute the most disgraceful part of it. He was in New London at the time of the occurrence, his troops having burned a large portion of the town. The little garrison of Fort Griswold at Groton made a brave resistance against forces outnumbering them six to one. When, at last, the British entered the fort, Ledyard, the American commander, presented his sword to the officer in command of the British in token of surrender. This brute, whose name, fortunately for his memory, has never been discovered, received the sword and plunged it at once through Ledyard's heart. This was a signal for indiscriminate slaughter, in which hardly a man of this surrendered force was left unhurt, and few left alive.

The raids of Gov. William Tryon on Danbury, April 1777, and on New Haven, Fairfield and Norwalk, in July 1779, resulted in great destruction of property by fire and plunder, and in the loss of many lives on both sides. It may be truly said that never but twice did these invaders remain on Connecticut soil over night, and in each case took to their ships the next morning with Connecticut troops in hot pursuit.

Notwithstanding the terrible drain which the Revolution made upon her resources, Connecticut, through her wise financial policy, was better prepared, at the close of the war, to avail of the advantages of peace than were any of the other States with the exception of Delaware. It is hardly surprising that the War of 1812 should have been unpopular in Connecticut as well as in all New England; but too much opprobrium has been heaped on Connecticut by giving the protesting convention for all New England the name of the Hartford Convention for the sole reason that it was held, for convenience, in Hartford. It will be found that Connecticut furnished for this war, too, a goodly number of men, though there were some disputes as to the manner and form of doing it. For the half century following the war, peace and prosperity prevailed, broken only by the comparatively insignificant, but sufficient, contribution which was made to the Mexican War.

The outbreak of the Civil War in 1861, like the outbreak of the Revolution in 1775, found Connecticut with a governor in office who was equal to the emergency. Gov. William A. Buckingham, upon his own responsibility, called for a regiment of volunteers, 16 April 1861, when the condition of organized militia in the State to meet Lincoln's first call. The private citizens and the towns voted money to forward troops; and soon, instead of one, three regiments of volunteers reported for service, making it necessary for the governor to go to Washington to have three times the quota accepted under the call. At the close of the war, the official record shows that Connecticut had furnished 54,882 volunteers, which number was largely in excess of her quota.

Industries.—This war stimulated the industries of Connecticut, which had, at the time, reached a high stage of development. The demand which the large and suddenly equipped army and navy of the country made upon these industries was colossal. During the years which have followed the War, the development of manufactures has continued to keep up a healthy growth. This little commonwealth, originally composed of intelligent farming communities, has, by a perfectly natural process of evolution, developed into a manufacturing State which, small though it is in area, holds the rank of eleventh in the gross value of its manufactured products, and the rank of second in the per capita value of these products among the 52 States and Territories enumerated in the latest census. Still more significant is the fact that a larger number of patents in proportion to the population have been issued to Connecticut inventors than to those of any other State in the Union during the past 10 years.

It appears to be a fact that in early colonial times the same inventive genius which has developed in this little commonwealth was born of necessity, and that it was transmitted heredity down to the present day. The first settlers brought with them intelligence, broadened views of ecclesiastical control and little or nothing more. There were no industrial specialists among them; and a century after the towns of the colony had taken root in various parts of the soil the leading townsman, besides being still farmers with a growing tendency to trade, were each of them equal to any industrial or political emergency which might arise. Diaries covering the first half of the 18th century show, for example, that the diarist was a ship-carpenter, house-carpenter, millwright, surveyor, judge of probate, soldier and deputy to the general assembly, while pursuing the regular occupation of a trading farmer; and that his neighbors were equally versatile in their industrial and political pursuits. This diversity of individual talents naturally grew, in time, to specializing, as the resources and needs of the country increased. For the reason that it was held, for convenience, in Hartford. It will be found that Connecticut furnished for this war, too, a goodly number of men, though there were some disputes as to the manner and form of doing it. For the half century following the war, peace and prosperity prevailed, broken.
CONNECTICUT

attempts at mining for precious metals were equally unsuccessful, but the working of the Salisbury iron mines, which have been in operation since 1730, proved to be a lasting success. For generations, colliers, camp-kettles and other useful articles were furnished during the Revolution, including the chains which were used to bar the progress of the British fleet on the Hudson. The anchor of the British flagship on fire was made of iron from Salisbury iron in later days. The ore is a rich hematite, which, prepared by the use of charcoal, yields pig-iron which rivals the famous product of the Swedish and Norwegian mines.

Manufactures.—As early as 1749 we find that John Allyn had experimented in brass-making; and in 1768 the first paper-mill of Connecticut, if not the first in the country, was successfully established by Christopher Leffingwell of Norwich. Tinware was first made in Berlin in 1770, and furnished for a century or more an important industry in which the Yankee peddler exercised his wit and shrewdness. In 1773 Thomas Harland from London established at Norwich a shop for making and repairing watches and clocks. In this shop Eli Terry learned the mechanism of the timepieces of the day, and afterward applied his inventive genius to the manufacture of pillar- and cage-clocks, which he perfected in 1793. Other Connecticut inventors, especially Seth Thomas and Chauncey Jerome, have brought clock-making to, or very near, its present advanced stage. Eli Whitney, the inventor of the cotton-gin, though not a Connecticut man by birth, owed his fortune to the successful manufacture of firearms at New Haven in 1798, after having been robbed of his great invention in the South in 1792.

The first manufacture of sewing-machines on an extended scale was established by Elias Howe, at Bridgeport, followed in the same city by the improvements of Wheeler and Wilson. In 1844 Charles Goodyear of New Haven obtained his first patent for the process of vulcanizing India-rubber, a process entirely of his own invention, which revolutionized this important industry in his day, or rather made a new and still enormously increasing industry in the use of material which, without this invention, would have continued to occupy an unimportant place in the industries of the world. The invention of electro-silver plating is traced to the Rogers Brothers of Hartford. In 1846 these three brothers, Asa H., William and Simeon S., succeeded, after much experimenting, in finding a successful way of applying this process to articles made of various metals. From small beginnings, the business grew to large proportions, resulting in great establishments in Hartford, Meriden, Waterbury, Norwich and elsewhere.

The manufacture of textile fabrics had its beginnings in a small woolen factory in Hartford in 1788, and a small cotton mill in Vernon in 1804, but the growth of this industry to its present proportions did not begin in any marked degree till after the enactment of the Joint Stock Act, in 1837, allowing small sums to be capitalized and small proprietors to join their forces in manufacturing. This act, forming a long step in the evolution of the modern trust, had a direct influence in any marked degree upon the textile industries of the Union, and by Great Britain, thus changing the business of the world, was the work of a Connecticut man, Theodore Hinsdale.

Many cotton mills are on the Shetucket, Yantic and Quinnebaug rivers. The Ponemah Company, at Taftville, has a mill, which, when it was built, was the largest cotton mill in the world. The Willimantic Linen Company is one of the greatest thread producers in New England. More than seven hundred cotton spindles of the State are operated at Norwich, Thompson, Plainfield, Killingly and Willimantic. The woollen mills are more widely distributed throughout the State, at Vernon, Stafford, Broad Brook, New Britain, Norwich and elsewhere. Among the textile manufactures that of silk is important, having had its small beginnings so early as 1732 and now placing the State third in the Union in that industry. In 1914 the silk products were valued at $30,592,000. The works of the Cheney Brothers, at South Manchester, established in 1838, are among the largest in the country.

The manufacture of textiles, including silk, wool, worsted, cotton, felt, hosiery and knit goods, forms one of the leading manufacturing industries of the State. Recently manufactures gave employment to 226,264 wage-earners, receiving wages amounting to $15,210,000, with capital invested amounting to $620,194,000, and manufactured products valued at $545,240,000. Waterbury is prominent in making brass; Meriden in silver and plated ware; New Britain (which has the largest proportion of wage-earners, 34.2 per cent, and the greatest number of nationalities represented in its population) in hardware, cutlery and knife goods; New Haven and Bridgeport in firearms, corsets and rubber goods; Hartford in hardware and firearms. The variety of manufactured articles is noticeable, from blotting-paper to aircraft. Connecticut was the leading State in the value of firearms and munitions manufactured in 1910, two-fifths of the total for the United States having been reported; and that amount has been vastly increased since 1914. The output of Winchester's, Marlin's and Maxim's in New Haven, of the Union Metallic Company and American-British Company in Bridgeport, of Colt's in Hartford, besides other firms in Meriden, Norwich and elsewhere. The prodigious activity of these establishments has added many thousands to the population of those cities. Connecticut ranks first in brass and bronze products, in clocks and watches, corsets and plated ware, producing two-thirds of the total amount of the last in the United States; second in cutlery and rubber boots and shoes, the Canoe Rubber Company in New Haven turning out 25,000 pairs of rubber shoes every day. The automobile manufacturers show great increase since 1900.

Agriculture.—Although the history of agriculture in Connecticut presents a contrast to that of manufacturing by showing a decline in proportion to the population, agriculture is still second in importance among the industries. It must be remembered that the little commonwealth is the smallest but two of the States and Territories. Its area may be rather indefinitely divided into the central lowland, the coast, the eastern and western uplands, and the central lowland, lying in the valley of the Con-
necticut River, is from Middletown to the northern boundary best adapted to cultivation; and here it was that, after sprouting and growing, the first colonists, whose sole industry was agriculture settled.

From Middletown to the coast, the river leaves the lowland and cuts a narrow valley through the eastern upland. The portion of the eastern lowland between Middletown and New Haven is less fertile. The eastern upland varies in fertility, but contains some rich farming land. It has also the advantage of a lower average elevation than the western upland, where the only mountains of the State are found. One of these, Bear Mountain, reaches an elevation of 2,000 feet or more.

Hay and fodder rank first in value, as crops; tobacco, second; market gardening, poultry raising and dairy farms stand high as profitable employments. The large proportion of consumers, and, especially, the facility of marketing, generally, without middlemen, and often without even railroading, cause the profit from crops to be larger in Connecticut than in States more strictly agricultural. The whole output can be sold easily within the limits of the State; and the cities of New York and Boston offer good markets. Connecticut brings in $14.34 per acre for small fruits, more than any State except Florida; her apples bring in a return in bushels per tree surpassed by New York and Colorado only, and in value, by Massachusetts, New York, Colorado and Arizona only; and she raises more corn per acre than any other State, with an average yield annually of 53.2 and 48.5 bushels per acre. An acre of vegetables in Connecticut brings more money than in any other State except Massachusetts and New Hampshire. Peach raising is important, with large crops and corresponding profits. Wallingford and Glastonbury leading the State in that industry. The cultivation of tobacco began in the Connecticut Valley, near Hartford, as early as 1680. Improved methods of curing the harvested plants have added much to its value in late years, the tobacco being of the best quality for wrappers. Three types are raised, the Havana seed-leaf, principally on the west bank of the Connecticut River, the broad leaf, and the shade grown, mostly on the west side, the last having steadily increased in acreage, the advantage derived being still disputed. In all, 29,970,000 pounds were raised in 1915, valued at $5,095,000. Tobacco is worth more per acre as a crop than in any other State. In the other New England States, the number of dairy cattle has decreased since 1905, but Connecticut has maintained her dairy industry unimpaired. The raising of cattle for food has decreased. In 1915 the average value per acre of farm land for the whole State was $33.03; in the southwestern part, it was from $75 to $100 per acre. This average value of farm land increased 21.14 per cent between 1900 and 1910, and 1910 over 1910. In the Middle states, as much as during the preceding half century. From 1912 to 1915, there was a gain in value per acre of farm land of $7 for improved and $5 for unimproved.

The Shell-Fish grounds belonging to the State are an important source of revenue; and are protected by strict regulations under the careful watch of the Shell-Fish Commissioners, who keep the grounds guarded by patrol boats in all but very indelent weather.

Railroads.—The railroads are the New York, New Haven and Hartford, with 851 miles operated in the State and a total mileage of 2,004.58; New London and Northern, with 56.10 miles in the State, and 90.32 miles operated (in Connecticut and Vermont); Central New England, with 83.80 miles in the State, total mileage, 522.80; Central Vermont, with 58.60 miles in the State, total mileage, 572.60; Hartford and Connecticut Western, leased by Central New England, with 77.26 miles in the State, total mileage, 123.96; Norwich and Worcester, with 53.16 miles in the State, total mileage, 71.07 (operated by New York, New Haven and Hartford); South Manchester, total mileage, 3.15; Branford (freight only), total mileage, 4.20. The total mileage In the State is 999.58, and the total miles operated by companies in the State, 5,638.01 (all tracks). Since the government has taken over the railroads, it is difficult to give figures for revenue or profits, which in fact may vary from month to month.

The Public Utilities Commission reported, in 1915, 25 electric companies, 2 express companies, 12 gas companies, 15 gas and electric companies, 8 railroad companies, 22 street railway companies, 3 telegraph companies, 10 telephone companies and 87 water companies, most of these companies showing an increase of business.

Banking and Finance.—In the banking business of the State, the most important item is the deposits in the 82 savings banks, January, 1915, making a total of $335,080,694.93, and an increase during 1914 of $25,448,326.74. The State ranks third in the number of its savings bank depositors, if mutual or trustees savings banks only are considered, those being the prevailing kind in New England and the East. Considering stock savings banks, which are found in the other parts of the United States, California is third and Connecticut fourth. In 1915, the number of depositors was 629,655. There were 73 national banks of deposit, with aggregate capital of $19,784,300, and surplus of $11,121,000; 58 State banks and trust companies in the east side, and 46 in the west, with aggregate capital stock of $664,150; and 4 Morris Plan companies with gross resources of $421,125.30; and 20 building and loan associations.

The oldest bank of deposit in the State and the fifth in age in the United States is the Union Bank and Trust Company of New London, chartered in 1792, and still doing business under its old charter. Still earlier, in 1732, Thomas Seymour and others, of New London, secured a charter for banking purposes, but it was revoked within four years. The four oldest banks in the State, in Hartford, Middletown, New London and New Haven, are well on in their second century, and are still very prosperous. The New London and Trust Company of Middletown, chartered in 1872, is the oldest mortgage company in the country.

Insurance.—The insurance business of the State centres in Hartford, where are 7 stock companies, the 8 stock fire insurance companies, which represented, in 1916, in all, capital of $15,750,000, and surplus of $25,618,671.83; 12 mutual fire insurance companies report, in all,
a surplus of $2,447,520.61; and there are many other mutual companies. The 6 life insurance companies are all in Hartford, and reported, in 1914, assets amounting to $107,649,937.50. There were also 6 indemnity companies and 6 miscellaneous insurance companies. Of the many fraternal benefit societies, 8 reported in 1910 assets amounting to $107,649,937.50.

Religion.—The ecclesiastical history of Connecticut is full of interest and romance, and is an interesting study of the development of religion in this country. It is enough to say that, at the beginning, the colony stood unique as a compromise between the rigid ecclesiasticism of Massachusetts Bay and Plymouth colonies, and the religious liberty which Roger Williams was, at the time, establishing in Rhode Island. Unique though it was, it can be called a theocracy only at the beginning, for the State was then the Congregational Church, pure and simple, and though others than church members could vote, they were obliged by the early code to vote taxes for the support of the church. The process of emancipation from these theocratic conditions was slow, and did not come until the Journal of John Winthrop is to be taken as an authority; and in the theological tenets which were adopted from time to time under direction of the general court and otherwise, we pass through a maze of solemn discussions on the divinity of Christ, the Papacy, the Trinity, the communion of saints, a covenant, the Cambridge Platform, the Saybrook Platform, with the later New Lights and Old Lights arrayed against one another as Separatists and Conservatists. Legislation exempting the Church of England from taxation for support of the Congregational Church was had in 1727, and in 1729 was extended to cover cases of the Baptists and Quakers. In 1791, the right of incorporation was allowed, under certain restrictions, to all religious bodies. The first Baptist elder was ordained at New London in 1726, but the sect did not gain largely until the beginning of the 19th century. The Protestant Episcopal Church was not established under a regularly ordained bishop until after 1789; although it had been making beginnings before that time, but was practically exterminated during the Revolution, owing to the Toryism of its clergy. In 1789, the first Methodist Episcopal church in the State was established at Stratford. The first Roman Catholic church in Connecticut was established in 1830, and in 1843 the diocese of Hartford, embracing the entire State, was established.

The statistics of religious denominations are but partially available, only a few of the denominations publishing complete reports. The Protestant denominations are divided into many sects. The number of ordained ministers is given as follows: Advent, 23; African M. E. Zion, 15; Baptist, 209; Catholic Apostolic, 5; Greek Orthodox, 1; German Lutheran, 19; Swedish Lutheran, 17; Hebrew, 8; Methodist Episcopal, 177; Presbyterian, 14; Episcopal, 194; Roman Catholic, 432; Unitarian, 5; Universalist, 10.

Charitable Institutions.—The educational institutions which are partly or wholly sectarian in character will be mentioned in speaking of the general subject of education. The Board of Charities reported, in 1914, as in successful operation: 134 hospitals, public and private; 6 sanatoria for tubercular patients; 2 State hospitals for the insane; 12 private asylums for the insane; 1 colony for epileptics; 1 school for imbeciles; 2 schools for the deaf; 1 school for the blind; 2 homes for old soldiers; 8 county temporary homes for children; 67 almshouses; 20 private homes for old people; 19 private homes and asylums for children; and recent additions to the list have been made. Of these, the Roman Catholic Church supports 3 orphan asylums, 5 hospitals, 2 homes for aged poor, and the Swedish Congregational Association largely supports one orphanage. Of the almshouses, 61 are owned by the towns or cities in which they are situated, and 6 are owned and managed by private individuals, 101 towns caring for their poor in their own houses or in families. The Hartford Retreat for the Insane, the third in age in the United States, having been opened in 1821, holds a unique position, because, although a private institution, it was long under the direction in which State patients could be received; and some such are still committed to it each year.

Penal and Reformatory Institutions.—There are 1 State prison; 10 county jails; 1 State reformatory for male delinquents between 16 and 25; 1 school for boys; 1 industrial school for girls; 3 homes for young women offenders, of which last the Roman Catholic Church supports one. The State Reformatory, opened in 1913, is doing a very satisfactory work, and is an important addition to the correctional work of the State. The total expense to the State for the care of delinquents, defectives and dependents in 1914 was $1,946,571.92.

Education.—The educational system of Connecticut was planted almost literally with the first corn that was planted by the early settlers. From the small beginnings in the few towns, the present system of public schools has been evolved, aided materially in 1795 by the proceeds of the Western Reserve Lands, now in the State of Ohio, which were sold in order to establish a school fund. The lands, to the extent of about 3,500,000 acres, were granted to Connecticut by the United States in 1786 as a tacit compensation for her loss of the Wyoming territory by a decree of 1782. About 500,000 acres were granted by Connecticut to those within her jurisdiction who had suffered from the incursions of the British during the Revolution, and the remaining 3,000,000 acres were sold for the establishment of a school fund. That fund remains intact to the present day, and amounted, in October 1916, to $2,008,590.79, yielding an income of $116,650.55 for that year, and providing 43 cents of the $2.25 per child, distributed to the schools on the basis of enumeration. Another fund, known as the town deposit fund, was Connecticut's share of the apportionment from the surplus of the United States Treasury in 1837, and was given to the States to be held. Under the law of 1859, the entire income of this fund was to be used for education; but it has become so merged in the general treasuries of the towns that it scarcely has a separate existence. Beyond this State support, the common school system depends on taxation in vari-
ous towns and school districts to meet expense. By a recent decision of the courts, a school district may, in lieu of the payment made by the State of $2.25 per year for each enumerated school child, receive from the town the actual expense of conducting the schools for 188 days in the year.

Education is compulsory, within the limits of 7 and 16 years. The control of the common school system is varied, being by committees, either of towns or of school districts, or by a board of education (the tendency being toward the consolidation of districts in each town. Supervisors have been introduced with good effect, and in increasing numbers. Trade schools, where vocational preparation is given by practical experts in the different trades, are assuming a prominent place in the scheme of public education, and are well equipped. In addition to the common schools, to whose support it contributes, the State now supports four normal training schools for teachers. It also supports and aids agricultural colleges and an agricultural experiment station. In 1915, the public school buildings numbered 1,510, employing continuously 6,392 teachers, with many others employed at times. The average daily attendance during 1914 was 881. The value of school property was $283,193,194.84; the total expenditure for public schools as reported by towns was $9,590,562.67; the receipts on account of public schools, as reported by towns, was $7,636,423.37; received from loans, $1,949,796.13; indebtedness of towns on account of schools, $8,703,329.31. The expenditure per child registered in 1915 was $23.67; per child in average attendance, $30.87; the increase in cost per child in average attendance in the 10 years preceding 1916 averaged $1 a year.

In addition to the public schools, there are in the State 261 private schools, of which 82 are parochial schools of the Roman Catholic Church, 6 parochial schools of the Lutheran Church, and the rest are non-sectarian, being business colleges, boarding schools and secondary schools. These 261 private schools employ 1,726 teachers and are attended by 52,293 pupils. The larger institutions of learning are all supported by tuition and endowment, or church funds. The principal ones are Yale University, Wesleyan University, Trinity College, the Hartford Seminary Foundation, including Hartford Theological Seminary, School of Religious Pedagogy and Kennedy School of Missions, with other schools to be added; the Berkeley Divinity School, Saint Thomas Catholic Seminary, Saint Joseph Catholic Seminary, and the Connecticut College for Women at New London. Each of these, except the last, has a large library of its own, that of Yale University being the largest in the State with over a million volumes. The Yale Elizabethan Club owns the best collection of Tudor and Stuart drama to which the public has access in this country. The collections, mineralogical, geological and paleontological, of the Peabody Museum of Yale University are of great value, as are the collections of Greek and Etruscan vases, and of Bijouyvian antiquities, of the John Hay Museum, while the early Italian paintings, the photographs collected by the Yale Peruvian Expeditions and the Steinert collection of musical instruments. The State Library at Hartford contains a large and valuable collection of the laws and official documents of other States and the general government; besides which it has accumulated a general collection in which history is prominent; it also contains many rare and original documents, including the charter of 1662. In 1916, there were in the State 218 public libraries.

The principal historical societies are the Connecticut, the New Haven Colony, the New London County, the Middlesex County, the Mattatuck (of Waterbury), Historical societies, and the Bridgeport Scientific and Historical Society.

The growing desire for increasing the artistic sense of the community is shown by the organized efforts in New Haven, Bridgeport, Hartford and other places, for the purpose of developing beauty in their own domains.

Government.—The government of Connecticut has been conducted under two different constitutions, the first of which was adopted in January 1784 and the second, which was adopted as the result of a constitutional convention in 1818. This constitution, with its subsequent amendments, forms the basis of the government of the State in accordance with which the laws are passed and the executive and legislative powers exercised.

The General Assembly is composed of a senate consisting of 35 members, and a house of representatives, consisting of 258 members. One senator is elected from each of the senatorial districts; one representative from each of the 78 towns, and two each are elected from 90 towns. In 1911 the State was divided into 5 senatorial districts, instead of 4, for electing members of Congress. In 1914, 87 towns voted for no license and 90 for license, one being equally divided. The courts are the Supreme Court of Errors and the Superior Court, the judges serving for terms of eight years; the Court of Common Pleas for terms of four years, all of these judges being appointed by the general assembly on nomination by the governor. Judges of city, borough and town courts are appointed for terms of two years, by the general assembly. There are in the State 113 probate districts, the judges of which are elected by the people.

(Originally no one was to be chosen governor two years in succession; which accounts for the alternating terms of office. In 1660, this restriction was abolished by the free-
CONNECTICUT

mem. Until 1752, the legal year in England began 25 March, not 1 January. This with the difference of 11 days between Old Style and New Style, accounts for many apparent discrepancies in dates.

Marcus H. Holcomb... 1917-19

Population and Finance.—The population of the State, as estimated by the United States census in 1816, was 1,244,497, showing a great increase in recent years, and making it fourth in rank, as to density. Of this population, about two-thirds are native born and one-third foreign born. In 1910, 38 per cent of the population was classed as illiterate, being the smallest percentage of any State except Massachusetts with the exception of Kansas. The total grand list as computed in October 1916, by the State Board of Assessors, was $1,278,696,735. New Haven, Hartford and Bridgeport supply one-half of the grand list of the 19 cities. The receipts for the fiscal year ending 30 Sept. 1916 were $11,532,806.94; the expenses, $8,439,944.59.

Legislation.—In 1816, the State legislature was composed of 11 Democratic and 24 Republican senators; and 60 Democratic and 98 Republican representatives. Recent bills of importance include a Public Utilities Commission, Workmen's Compensation Act; one eliminating a congressman at large; the election of county commissioners by the people; the appointment of judges of the minor courts by the governor instead of the general assembly; the adoption of uniform laws as to the sales of goods and as to warehouse receipts, recommended by the Conference of Commissioners on United States Laws; bills to prevent infection with tuberculosis and to provide State hospitals for consumptives; to establish a State reformatory; appointing a public service corporation regulation commission; as to uniform bills of lading; creating a State civil service law; strengthening the corrupt practices law; for a "blue sky" law, regulating the use of airships; taxing woodlands; a general bank incorporation law; creating a State civil service commission; repealing the exemption of charitable bequests from a succession tax; taxing corporations on income rather than on capital. In the presidential election of 1916, the State gave a Republican majority, and elected a Republican governor.

In 1917 under the auspices and direction of Governor Holcomb the State took a foremost place in war preparation and production. A census of the resources of the State in men and materials was begun early in the year and complete returns were available by December. A home guard was established, numbering 20,000 members, of whom about half were fully equipped. By act of the legislature the governor received far-reaching powers, being authorized to take any steps he might deem necessary due to the emergency of the war. Commerce and manufactures thrived after the opening of the war due to the fact that the State contained hundreds of factories which were engaged in the manufacture of war munitions. The legislature of 1919 will consider a constitutional amendment granting suffrage to women.

CONNECTICUT AGRICULTURAL COLLEGE, a coeducational institution situated at Mansfield, Conn., eight miles north of Willimantic. It was founded in 1881 by the Connecticut general assembly as the Storrs Agricultural School. It became a land-grant college and likewise, through the extensive work of its experiment stations, an important factor in the State. Its name was therefore changed to the one it now bears. It offers courses leading to degrees in agriculture, domestic science and the mechanic arts. It covers 874 acres and has 11 buildings. Important work in agricultural experiments and university extension is conducted. The students number 214; instructors, 35.

CONNECTICUT COLLEGE FOR WOMEN, an institution for higher education at New London, Conn. It was chartered April 4, 1911. The curriculum includes instruction in the humanities, arts and sciences. It confers the degrees of A.B. and B.S. The campus comprises 340 acres. Elaborate plans have been perfected for the buildings, of which the architectural style is in general the domestic Tudor with some edifices in Collegiate Gothic. The college has received several generous gifts of money, including an endowment of $1,000,000 from the Hon. Morton F. Plant. In 1913 the trustees authorized the erection of an initial group of five buildings adequate for the use of the college at the outset. Construction has been proceeding on three and other buildings since early in 1914. The college opened in September 1915. Its foundation is due to the desire of the people of Connecticut to provide within the State adequate facilities for the higher education of women.

CONNECTICUT LAKES, four small lakes in the northern part of Coos County, N.H., which are connected with Connecticut River in the beginning of its course. They are named in numerical order, from southwest to northeast, the largest one, Connecticut Lake proper, being known as First Lake. The smallest two, Third Lake and Fourth Lake, which are very near the Canadian boundary, are the ultimate sources of the river.

CONNECTICUT RESERVE. See Western Reserve.

CONNECTICUT RIVER, a river of New England; it rises in Connecticut Lake on the northern border of New Hampshire, 2,000 feet above sea-level, forms the boundary between Vermont and New Hampshire and flows southward, passing through the western part of Massachusetts, the central part of Connecticut and falls into Long Island Sound. Its total length is about 450 miles, and its drainage basin is more than 11,000 square miles in extent. Its principal affluent is the Farmington which joins it above Hartford. Throughout its course between New Hampshire and Vermont the banks are wooded, the river bed very narrow and all affluents are small, but at certain seasons become so many torrents. The average fall in this upper course is from 18 to 32 feet per mile. After entering Massachusetts the river flows through Triassic shales and sandstones and the river valley becomes very broad. Near the Connecticut border and after its entry into the latter State the river opens widening its way through heavy deposits of sand, gravel and clay of the late Glacial Period. This portion is also marked by several rapids and waterfalls; of these the principal are the Enfield Falls, 10 miles above Hartford. The river valley from Middletown to the sea is narrow, the stream here working through the crystalline rocks of the lowlands. The valley is a great manufacturing region, ample water-power being supplied by the river at many points, such as Bellows Falls, Vt., Turners Falls and Holyoke, Mass., and Windsor Locks, Conn. Below Brattleboro, Vt., a great power dam has been constructed recently by the Federal government. The latter has had elaborate surveys made with a view of rendering the valley navigable as far as Holyoke. Subsidiary canals at present make it navigable for about 25 miles above Hartford, while from this city to the sea (50 miles) it is navigable for vessels drawing from 8 to 10 feet. There are constantly forming at the mouth of the river are removed by dredging. In Colonial times the river played a prominent part in the settlement of the region. It was the highway for the English and Dutch fur traders, and the fertility of the lands along its banks soon attracted settlers. Until the advent of the railway it remained the principal thoroughfare between the northland and the sea. Consult Bacon, E. M., "The Connecticut River and the Valley of the Connecticut" (New York 1906); Genthe, M. K., "Valley Towns of Connecticut" (American Geographical Society, Vol. XXXIX, No. 9, ib., 1907).

CONNECTICUT YANKEE IN KING ARTHUR'S COURT, a humorous tale by Mark Twain published in 1889. It is the story of a superintendent of an arms factory in Hartford, Conn., who one day lost consciousness from a blow received in a quarrel with his men, and when he awoke found himself in England at the court of King Arthur. The contact of the Connecticut Yankee with the Courtly, fairy tale gives rise to strange results; yet amidst all the fun and pathos, the courtliness, the sincerity, and the stern virtues—as well as what seems to us the ridiculousness—of the age are well shown.

CONNECTIVE TISSUE, the most important supporting tissue of the body, derived like bone and cartilage from the mesenchyme of the embryo. It is made up of cells, which are relatively scanty, fibres and an intercellular ground substance secreted by the cells. The cells may be ameboid (in embryonic tissue), or may be the vacculated so-called plasma-cells, or may assume a spindle-like or plate-like shape; and may contain pigment, granules of substance showing a peculiar affinity for certain dyes or fats, besides which leucocytes often invade connective tissue. The white fibres of connective tissue are formed in bundles, are easily stained by acid fuchsin, yield gelatin on boiling, and are digested by artificial gastric juice through the action of pepsin. The yellow fibres or elastic fibres, unlike the white branch and anastomose, are highly refractive, and during life, owing to the
tension under which they are, are straight. They are only slowly digested by the gastric juice, but rapidly by the pancreatic juice. Orcein acts as a specific stain for elastic tissue. The so-called reticulum is made up of fibres much like the white fibres, but not so easily attacked by artificial gastric juice.

Embryonic connective tissue is made up of spindle-shaped and ameboid, stellate cells, with few fibres and, in the less mature tissues, all of these white. The ground substance is fluid. Embryonic connective tissue is found not only in the foeti and infants, but also in tumors and during the regeneration of injured connective tissue.

Gelatinous connective tissue occurs only in the umbilical cord and in the vitreous humor of the eye. It contains plate-like cells and reticulum, sparse in the vitreous humor and relatively dense in the umbilical cord. The ground substance is gelatinous.

Acicular connective tissue occupies all otherwise unfilled regions. The white fibres form interstices. The elastic fibres are isolated and comparatively few in number. The cells are of all varieties. The ground substance is a fluid which can be coagulated by silver nitrate.

Dense white fibrous tissue consists mainly of parallel bundles of white fibres with plate-like cells in their interstices. Yellow fibres are scarce and there is little ground substance. This tissue forms most tendons, ligaments, fascial and muscular sheaths, and envelops many of the viscera. The valves of the heart, the chordae tendineae and the tendinous rings about the mouths of the great vessels are all formed from white fibrous tissue.

Elastic tissue is made up of bundles of elastic fibres with sheaths of white fibres. It contains but little ground substance. It is found in the ligamenta subflava dorsal to the spinal column and in the ligamentum nuchae supporting the head in the lower mammals.

Adipose tissue is composed of cells destined until they have become mere sacs of fat and of fibrous bands supporting these cells. It is found beneath the skin of many parts of the body, about the lymphatic nodes, adrenals and kidneys, in the mediastinum and the grooves of the heart wall, and in the mesentery and omentum.

Reticular tissue is found as the stroma of many glands and in bone marrow. Its tissue juice is lymph. It consists of a reticulum of fibres closely joined in anastomosing bundles, with cells of a plate-like nature at the points of bifurcation.

Lymphoid tissue is reticular tissue permeated by the close-packed spheroidal lymphatic corpuscles. Lymphoid tissue is found in the tonsils, spleen, thymus, lymphatic glands, and in Peyers patches and the solitary follicles of the intestine. More diffuse lymphoid tissue is found elsewhere in the respiratory and digestive tract.

Connective tissues are richly supplied with blood vessels and nerves. They are nourished by the lymph exuding from the blood capillaries. The waste products of metabolism are taken up by the lymph capillaries.

CONNELLEY, William Elsey, American author: b. Johnson County, Ky., 15 March 1855. Though almost entirely self-educated, he was for a number of years a school teacher in Kentucky and Kansas 1872-82. He went to Kansas in 1881 and was county clerk of Wyandotte County, 1883-88. For four years (1888-92) he was in the wholesale lumber business, and then engaged in banking. His leisure has been chiefly devoted to the study of the history and antiquities of the North American Indians, and the States of the Middle West. He compiled the first vocabulary of the Wyandot language, and has made valuable studies of the languages of the Delawares, Shawnees and other tribes. He is secretary of the Kansas State Historical Society. His papers have mostly appeared in the publications of the Ontario, Kansas, Nebraska and Ohio Historical societies, the Bureau of Ethnology and Smithsonian Institution. Some of their titles are 'The Provisional Government of Nebraska Territory' (1859); 'Notes of the Clan System of the Wyandots' (1899); 'Notes on the Folk-Lore of the Wyandots' (Journal of American Folk-Lore, 1900); 'James Henry Lane, the Grim Chieftain of Kansas' (1899); 'Kansas Territorial Governors' (1900); 'John Brown: the Last of the Puritans' (1900); 'The Overland Slag to California' (with Robert Gourley), 'The Mem- phis's Expedition' (1907); 'Quantrill and the Border Wars' (1909); 'The Ingalls of Kansas' (1909); 'Eastern Kentucky Papers' (1910); 'Life of Preston B. Plumb' (1913).

CONNELLSVILLE, Pa., borough in Fayette County, on the Youghiogheny River, and the Baltimore and Ohio and the Pennsylvania railroads, 57 miles east of Pittsburgh. It is the centre of the most extensive coke-burning region in the United States. Until 1903 the coke output of this region was from 40 to 50 per cent of the total output of the United States. The estimated annual output is about 21,000,000 short tons. It also contains one of the largest coal factories in the country. Other important industries are machine shops, pump works, brick works and coal mining. In 1900 there were 425 establishments, with a capital of $3,246,000, and giving employment to 1,264 persons. Salaries and wages paid during the year aggregated $818,000, and the value of the products $1,994,000, of which $1,205,000 were added by manufacture. It is the seat of Cottage State Hospital. Settled in 1770, Connellsville was erected into a township and named in honor of Zachariah Connell, the founder, in 1793, and was incorporated as a borough in 1800. It is governed by a mayor, elected for three years, and a common council. Connellsville contains the grave of Edward Braddock, the Irish general with whom Washington fought in the French and Indian wars. Pop. 12,645.

CONNEMARA, kon-ne-ma'ra, Ireland ("the Bays of the Ocean"), a hilly and mountainous district occupying the western portion of county Galway, about 30 miles long and 15 to 20 miles wide. The scenery of its broken coastline is very grand; in the sea inlets there is an abundance of fish; and there are numerous small lakes. It is subdivided into Connemara Proper in the west, Jar-Connacht in the south and Joyce County in the north.

CONNERSVILLE, Ind., the county-seat of Fayette County, situated on the Whitewater River and on the Cincinnati, Cleveland, Chicago
and Saint Louis and the Cincinnati, Fort Wayne and Louisville railroads. Among its features are a Carnegie library, a high-school building, Roberts Park and Fayette Sanitarium. Connersville manufactures automobiles, pianos, paper, gloves, brick, blowers, carriages, mirrors, furniture, and a large number of iron and steel products. The waterworks are owned by the city. It was incorporated in 1813 and is governed by a mayor, elected biennially, and a council. Pop. 7,738.

CONNERY, Thomas Bernard Joseph, American journalist: b. Ireland, 13 Oct. 1838. The greater part of his career was spent in the service of the New York Herald, on which he held nearly every position except that of financial editor, 1856-84. He was editor of New York Truth, 1885; Once a Week, 1893-95; Collier's Weekly, 1895. He was United States secretary of legation and chargé d'affaires in Mexico, 1866-68. He was a member of the New York Board of Education in 1902. He has published 'Don Tiburcio'; 'Black Friday'; 'History of American Comic Journalism'; 'Children's Manuals'; 'Essays on Literature'; 'Women of England'; 'All the Dead's Fault'; 'That Noble Mexican'; 'My Trip to Mars'; 'Violet Bland'; 'Forgotten Incidents: Lincoln's Visit to West Point'; also magazine articles.

CONNOR, Ralph. See Gordon, Charles William.

CONNOR, Selden, American soldier: b. Fairfield, Me., 25 Jan. 1839. He graduated at Tufts College, 1859; enlisted as a private in the 1st Vermont regiment 1861; became lieutenant-colonel of the 7th Maine regiment 1861, colonel of the 19th Maine 1864, and brigadier-general of volunteers June 1864. He was present at the battles of Fredericksburg, Gettysburg and the Wilderness, where he was severely wounded. After the war he held several minor Federal offices, was governor of Maine 1876-78, United States pension agent 1882-86 and 1897. On 3 Oct. 1889 he delivered the oration at the dedication of the Maine monuments at Gettysburg. In 1890 he became president of the Society of the Army of the Potomac, in 1896-99 was senior vice-commander-in-chief of the Order of the Loyal Legion, and in 1897 was again appointed pension agent, continuing in this office until the abolition by law of all pension agencies in 1913. His address on 'Hannibal Hamlin' was published in 1899.

CONODONTS (Gr. *cone-teeth*), minute fossils found in Palaeozoic strata. They look very much like the teeth of different kinds of fishes, some being simple slender pointed sharp-edged cones, while others are more complex, resembling in form the teeth of certain sharks. The old opinion was that they are minute teeth of fishes allied to the living hag-fishes and lampreys, but it is more likely that they are the jaws of annelids and naked mollusks. Consult Zittel and Rohon, 'Über Conodonten' (in Sitzungsberichte der königlich-bayerischen Akademie der Wissenschaften, Munich 1886).

CONOID, in geometry, a surface generated by a straight line moving parallel to a given plane in such a manner that it constantly touches a curve and a straight line; more generally, a surface generated by a line through two given straight lines and a given curve.

CONNOR, Athenian commander: d. after 392 B.C. Having been defeated in a naval engagement at Ágospotamos by Lysander, he for a time went into exile; but being aided by Artaxerxes, king of Persia, he returned and defeated the Spartans near Cnidus 394 B.C. Connor then began to rebuild the fortifications of Athens, and restored it to liberty and security.

CONNOR, of Samos, Greek astronomer and mathematician who lived in the 3d century B.C. He was a friend of Archimedes and invented the curve known as the Spiral of Archimedes. His works do not survive, but the main testimony to his genius is found in the laudatory comments in the surviving works of Archimedes.

CONQUEST, Ida (Mrs. Riccardo Bertelli), American actress: b. New York, June 1882. Her first stage engagement was in the age of eight, when she appeared as Little Berrick in the Boston Museum juvenile production of 'Pinafore,' a part she played over 300 times. Her professional debut was made in 1894 as Constance in 'The slippery Dog', at the Olga Nethersole, in Palmer's Theatre, New York. She had an ingenue part with the Empire Stock Company in 1896; and was leading lady with John Drew in 'Tyranny of Tears,' 'Second in Command,' and 'Richard Carvel,' in 1902; leading lady with William Gillette in 'Sherlock Holmes'; with Nat Goodwin as Helena in 'Midsummer Night's Dream,' 1903; starred with Charles Frohman in 'Girl with the Green Eyes,' 1904; and was leading lady with Richard Mansfield in 'Old Heidelberg,' 'Ivan the Terrible,' etc. She was leading lady with William Collier in 'On the Quiet,' 1905; appeared as Ann Whitfield in 'Man and Superman,' 1906, and later played in 'The Wolf' and 'A Little Brother of the Rich,' appeared with Nazimova as Asta in 'Little Eyolf,' 1910, and starred in 'The Talker,' 1911; after which she retired from the stage. She married Cavailler Riccardo Bertelli, of Genoa, Italy, 23 Oct. 1911. Others of her parts are Phyllis Lee, in 'The Charity Ball'; Carey, in 'Alabama'; Sybil, in 'The Dancing Girl'; Renée de Cochefort, in 'Under the Red Robe'; Babirole, in 'The Conquerors.' Consult Strange, 'Famous Actresses of the Day.'

CONQUEST, Right of. The appropriation of an enemy's territory by military occupation. In ancient times such occupation immediately passed title to the conqueror, but in modern times military occupation alone does not give such title to the invader. Title passes only when the invader manifests his intention of appropriating the territory by formal annexation, and when the acquiescence of the state from which it is taken shows the conqueror's ability to retain it. The Hague Conferences of 1899 and 1907 expressly detailed the rights and duties of the occupying power, with in 'Conventions Concerning the Laws and Customs of War on Land,' according to which the conqueror assumes ownership of all public property in occupied territory, and assumes the rights and obligations of the ousted state. The citizen of the conqueror is not compelled to transfer his allegiance to the conqueror, although in modern times they are given the choice of leaving the territory if they refuse to swear al-
legiance to the new government. See DIPLOMATIC RELATIONS of the United States with the principal foreign nations; BELLIGERENT; WARS of the United States.

CONQUEST OF MEXICO, The, a noted history by William Hickling Prescott, published 1843.

CONQUEST OF PERU, The, a history published by William Hickling Prescott (1847). Of the five books into which this work is divided, the first treats of the wonderful civilization of the Incas; the second of the discovery of Peru; the third of its conquest; the fourth of the civil wars of the conquerors; and the fifth of the settlement of the country. The first book hardly yields in interest to any of the others, describing as it does, on the whole, an unparalleled state of society. From the necessities of its material, the work is more scattered in construction than is the 'History of the Conquest of Mexico,' usually regarded as the author's most brilliant production.

CONRAD I, Emperor of Germany: d. 23 Dec. 918. He was elected king of Germany in 911; but Arnulf, Duke of Bavaria, and Henry, Duke of Saxony, disputed this title, and engaged the Huns to overrun Germany. Conrad, who was favored and supported by the Church, is said to have received a mortal wound in combat with these revolted chiefs, who were almost independent of the Crown, and the obedience of whom, therefore, Conrad was unable to command or win by other means. He is chiefly noteworthy for the revival in his case of the elective title to the crown.

CONRAD II, Emperor of Germany: b. about 990; d. Utrecht, 4 June 1039. He was the son of Henry, Duke of Franconia, and was elected king of Germany in 1024. Attempts were made to displace him, but without success, and in 1027 he was crowned emperor at Rome, in the presence of Canute, king of England, and Rudolph, king of Burgundy. He is regarded as the true founder of the Franconian or Salic line. He was often engaged in contests with the greater barons and princes of the empire, and endeavored to form a counterpoise to their influence by encouraging the formation of minor independent fiefs. With this end in view he bestowed on several of the larger duchies to members of his own family, and thus convert the elective empire into a hereditary monarchy similar to that of France. These designs, though conducted with considerable ability, failed, mainly in consequence of the incessant contests in which he was engaged with the popes. He crossed the Alps in 1026, defeated the Italians and had himself crowned king of Italy at Milan. After a war which occupied most of the years 1032-34 he conquered Burgundy and made it a part of his empire.

CONRAD III, Emperor of Germany: b. 1093; d. Bamberg, Germany, 15 Feb. 1152. He was the founder of the house of Hohenstaufen; and was elected emperor in 1138. His title was disputed by Henry the Proud, Duke of Saxony, and the rivalry of these two princes was the germ of the factions afterward so famous under the names of Guelfs and Ghibelines. In 1146, at the Diet held at Spires, Conrad was persuaded by the influence of Saint Bernard to undertake a crusade, on which he set out the following year at the head of a large army. It was fruitless and disastrous, and Conrad returned with the wreck of his army in 1149.

CONRAD IV, Emperor of Germany: b. Andria, Italy, 25 or 27 April 1226; d. Lavello, Italy, 21 May 1254. He was chosen king of the Romans in 1237, but was never crowned; was a son of the great Emperor Frederick II, and like him excommunicated by the Pope, Innocent IV, who set up a rival emperor in William, Count of Holland. On the death of his father in 1250, Conrad marched into Italy to recover the towns which had declared against him. He took Naples, but could not get the investiture of the kingdom of Sicily from the Pope. In the midst of his troubles and con- tentions, he died of fever.

CONRAD V, or CONRADIN OF SWABIA, German prince: b. 1252; d. Naples, 29 Oct. 1268. He was the son of Conrad IV, and the last of the Hohenstaufen. He accepted the invitation of the Italian Ghibellines to place himself at their head and the sale of a large portion of his possessions enabled him to raise troops. In the autumn of 1267 he crossed the Alps with 10,000 men, and at Verona was warmly received by the Scala family, the chief of the Ghibellines. He was received here, persuading him to part with his remaining possessions at a low price, deserted him with their followers, leaving but 3,000 men. The Ghibellines, however, remained true to him. Verona raised a large army, Pisa a fleet, and Rome, whose pontiff was forced to flee to Viterbo, opened its gates to him. Conradin entered lower Italy, and at Tagliacozzo met the French army under Charles d'Anjou, on whom the crown of Naples had been bestowed by Pope Urban IV. He beat Charles back, and his men, supposing the victory won, dispersed in search of plunder, when they were attacked by the French and utterly routed, 23 Aug. 1268. Conradin escaped, but was betrayed into the hands of Charles at Astura, who caused him to be beheaded in the market place of Naples. His extreme youth, his unfortunate fate and the stories that clustered about him made him a good and favorite subject of poetry and more especially of the drama.

CONRAD, Charles M., American soldier and statesman: b. Winchester, Va., about 1804; d. New Orleans, La., 11 Feb. 1878. He went with his father to Mississippi, and thence to Louisiana while an infant, received a liberal education, studied law, was admitted to the bar in 1828 and practised in New Orleans. He served several years in the State legislature, was elected to the United States Senate as a Whig in the place of Alexander Mouton, who had resigned, and served from 14 April 1842 to 3 March 1843. In 1844 he was a member of the State Constitutional Convention. He was elected to Congress in 1848, and served until August 1850, when he was appointed Secretary of War by President Fillmore, serving from 13 Aug. 1850 to 7 March 1853. He was one of the leaders of the Southern movement in Louisiana in December 1860, a deputy from Louisiana in the Montgomery provisional congress of 1861, a member of the first and second Confederate congresses of 1862-64, and also served as brigadier-general in the Confederate army.
CONRAD, Frederik Willem, Dutch engineer: b. Delft 1769; d. 1808. He was the pupil and friend of Brunings, who did so much for the construction of the sea dykes of Holland, and on his death succeeded him in his situation of inspector-general of sea dykes in the province of Rynland. He afterward held the office of administrator-general of the sea dykes in the Low Countries. He rendered a lasting service to his country by reclaiming large tracts of land from the sea, and more especially by the formation of a proper outlet for the waters of the Rhine.

CONRAD, Konrāt, Johannes, German political economist: b. West Prussia 1839; d. Halle, 21 May 1915. He was educated at the universities of Berlin and Jena. He was made professor of political economy at the latter institution in 1870 and at Halle in 1872. He was a member of the second commission appointed to revise the German Civil Code and took a prominent part in its deliberations. In 1878 he was appointed editor of the Jahrbücher für Nationalökonomie und Statistik and associate editor of the Handwörterbuch der Staatswissenschaften (1889–95; 2d ed., 1896 et seq.). He has published 'Das Universitäts-studium in Deutschland während der letzten fünf Jahr' (1884; Eng. trans. by Hutchison, with preface by James Bryce, 1888); 'Grundriss zum Studium der politischen Oekonomie' (1896–1909); 'Leitfaden zum Studium der Nationalökonomie' (1901).

CONRAD, Joseph, English novelist: b. Polonca in 1856, the son of a Polish revolutionary. He was educated in Cracow, and at 13 went to sea, becoming subsequently a captain in the merchant service. After a long experience as a sea rover, he settled in England and began putting his various experiences into literature. His writings include 'Almayer's Folly' (1895); 'An Outcast of the Islands' (1896); 'The Nigger of the Narcissus,' issued in America as 'The Children of the Sea' (1897); 'Lord Jim' (1900); 'The Inheritors' (with F. M. Hueffer, 1901); 'Youth and Other Tales' (1902); 'Typhoon' (1902); 'Mirror of the Sea' (1906); 'A Set of Six' (1908); 'Under Western Eyes' (1911); 'Twixt Land and Sea' (1912); 'Chance' (1914); 'Within the Tides' (1915).

CONRAD, Robert Taylor, American lawyer and dramatist: b. Philadelphia, 10 June 1810; d. there, 27 June 1858. He wrote for the press of Philadelphia; was a member of the Court of Criminal Sessions; and on its dissolution became editor of Graham's Magazine and associate editor of the Philadelphia North American. He was mayor of Philadelphia and judge of the Court of Quarter Sessions (1856–57). He wrote 'Aylmere' (1852), a tragedy in which Edwin Forrest played the role of Jack Cade; 'Conrad of Naples,' a tragedy; 'Poems' (1852).

CONRAD, Timothy Abbott, American paleontologist: b. Philadelphia 1803; d. there, 1877. In his youth he followed the occupation of publisher and printer in his father's shop. He became interested in natural history, and published papers on marine conchology in 1811, and in 1832 began to publish in parts his work on the fossil mollusks of the Tertiary formations of North America, which was the beginning of systematic research in that department. He became State geologist of New York in 1837, and worked as State paleontologist from 1838–41, issuing during that time his serial monograph on the Unionidae of the United States. It is upon this work and subsequent papers that his excellent fame rests. He finally returned to Philadelphia. Consult McRill, in Report of the United States National Museum for 1904 (Washington 1906).

CONRADIN OF SWABIA. See ConRAD V.

CONRIED, Heinrich, American impresario: b. Biebitz, Austrian Silesia, 13 Sept. 1855; d. Meran, Tyrol, Austria, 27 April 1909. Graduating from the Oberrealschule, and in 1874 he came to the United States, and was for several years a manager of German theatrical and operatic organizations. As director of the Irving Place Theatre, New York, he became known for excellent presentations of German classic drama, frequently repeated at Cambridge and other university centres. In 1903 he became director of the Metropolitan Opera-house, where he presented Wagner's 'Parsifal' for the first time outside Bayreuth. He resigned in 1908. Consult Moses, M. J., 'Life of Heinrich Conried' (New York 1916).

CONRING, Konrāring, Hermann, Dutch scholar: b. Norden, East Friesland, 9 Nov. 1606; d. Helmstedt, Brunswick, 12 Dec. 1681. He studied at Helmstedt and Leyden, devoting himself chiefly to theology and medicine, was appointed in 1632 professor of philosophy at Helmstedt, in 1636 professor of medicine, and remained in this city until his death. He was distinguished in almost every department of knowledge, and the title of a councillor was conferred on him by the kings of Denmark and Sweden and the elector of the Palatinate. He was then made professor of law. The German emperor likewise distinguished him. From far and near his advice was sought in political and legal cases. He did a great deal in compiling the history of the German Empire and for the improvement of German public law, in which he opened a new path. He wrote 'De origine juris Germanici' (1643); 'Exercitaciones de re publica Germanica' (1675); and very many other treatises to the number of over 100. His works, with his biography, were published in 1730. Consult Stobbe, 'Hermann Conring, der Begründer der deutschen Rechtsgeschichte' (Berlin 1870); Goldschlag, 'Beiträge zur politischen und publizistischen Tätigkeit H. Conrings' (Berlin 1884).

CONSELVI, Kon-säl-Vè, Ercole, Italian statesman and cardinal: b. Toscanella, 8 June 1757; d. Rome, 24 Jan. 1824. Having in 1797 entered the public service of the court of Rome in an humble capacity, he was four years later
CONSAQUINITY — CONSCIOUSNESS

one of the 12 auditors of the Rota, a commission in effect a supreme court of appeal in all matters secular as well as ecclesiastical. When the French took possession of Rome, Consalvi, falsely accused of having had part in an assassination, was for a while held in prison and then exiled. When Pius VI died, Consalvi was largely instrumental in procuring, in the conclave held at Venice, the election of Cardinal Chiaromonti to the papal throne as Pius VII, and thereafter was that pontiff's chief counselor; he was now second only to the Pope in all dealings with the European powers and specially with Napoleon. In the course of the controversies between Rome and the French emperor, he showed a firmness that won him the unwilling respect indeed of Napoleon, but also his irreconcilable enmity. It was while the Emperor was flushed with the victory of Austerlitz that he sent to Consalvi through Cardinal Fesch the message, "Tell Consalvi in case he loves his country he must either resign or do what I demand"; and the cardinal prudently withdrew from public life for a season. In 1809 he had an interview with Napoleon at Paris, in which the Emperor in effect made an apology for that act, but Consalvi persisted in his opposition to Napoleon's designs; and was one of the 13 cardinals who refused to concede the lawfulness of the second marriage of Napoleon. In punishment of his obstinacy in that matter he was held in confinement three years at Rheims. After the fall and banishment of Napoleon, he resumed his station in the papal court and devoted himself to the institution of many reforms in the government, being in effect chief governor of Rome and the papal states. He was always a liberal patron of art, literature and science. He left the bulk of his property to the poor. Consult Créтанe-Joly, 'Mémoires du Cardinal Consalvi' (Paris 1893).

CONSAQUINITY, relationship of persons descended from the same ancestry or common stock. Consanguinity may be either direct (known also as lineal) or collateral. Consanguinity is direct when the relationship is that which exists between ascendants and descendants, i.e., grandson and grandfather, father, son. It is collateral when the relationship is that which exists between persons who have the same ancestor but who are the issue of different children, as first cousins. Various degrees of consanguinity are recognized by law, but the manner of computing collateral consanguinity varies with the locality, depending on whether the civil or the canon law is followed. In the civil law the degrees from the common ancestor are numbered on both sides, brothers thus being related in the first degree and first cousins in the second degree. In the canon law, which is the same as the common law in this particular, the steps between the remotest person and the common ancestor are counted, brothers thus being related in the first degree and first cousins in the second degree. The rule for computing the degree of lineal consanguinity is the same for the canon, civil and common law. English law and the law of most of the States in this country follow the canon law in reckoning downward from a common ancestor. Consanguinity is an important question in the law of marriage, inheritance and descent, certain crimes as incest, and in determining the dis- qualifications of judges, jurors, etc. The term consanguinity must be carefully distinguished from affinity, which latter term means relationship by marriage, either through the husband or wife, and not through a common ancestor. See DESCENT IN LAW; INHERITANCE.

CONSCIENCE, kón-sý-ánk. Hendrik, Belgian novelist: b. Antwerp, 3 Dec. 1812; d. Brussels, 10 Sept. 1883. He was mostly self-educated. He entered the army in 1830 but resigned in 1836 and in the following year published his first novel in Flemish, 'In the Wonderful Year 1506.' It was a great success but the author was left under a burden of debt to his printer. 'Phantasy' and 'The Lion of Flanders' followed soon after. Conscience was one of the first to use Flemish as a medium of literary expression and his example heartened others, who had less patriotic courage, to do likewise. It also secured for him a measure of government patronage, being granted a post in a government office. He abandoned this for gardening and soon afterward was appointed to a seat in the Royal Academy of Painting. In 1845 he was made associate professor at Ghent and instructor in Flemish to the royal children, and in 1868 became custodian of the Wiertz Museum. He published in all over 100 works and the occasion of the publication of his 100th volume in 1881 was made a national celebration. His historical novels are inferior to his works dealing with Flemish home life, which he knew. In addition to those noted above, his most noteworthy works are 'How One Becomes a Painter' (1843); 'Poor Nobleman' (1851); 'The Good Luck to be Rich' (1855); 'Duke Carl's Justice' (1876); and 'Benjamin of Flanders' (1880). (See LION OF FLANDERS, TIRE; RIKKY-TIKKY-TAB). Consult the biographies by Eeckhoud (Brussels 1881) and Pol de Mont (Haarlem 1883).

CONSCIENCE, the mental basis of our judgments of moral obligation. The conscientious examination of a course of action consists in: (a) the fullest possible inquiry into the motives, results and other bearings of the action; (b) the approval or disapproval of the entire course of action in the light of this inquiry. The act of approval or disapproval does not appear to be essentially different in character from that involved in judgments of taste or of pleasure or the dicta of prejudice. It is the vastly wider scope of the preliminary examination, together with the fact that its judgments are most usually concerned with conduct and its principles, which make conscientious judgments off from all others of a normative nature. See ETHICS; NORM.

CONSCIENCE MONEY, stolen or wrongfully acquired money returned to its rightful owner when conscience is awakened to a sense of right dealing. In the United States such money paid into the treasury at Washington by self-avowed debtors anonymously is known as the conscience fund. In England the phrase is applied to money forwarded, as a rule anonymously, to the Chancellor of the Exchequer for unpaid income tax. It amounts to some thousand pounds a year.

CONSCIOUSNESS (Ger. Bescusstein; Fr. conscience; It. consciensa) is the term by which psychology distinguishes one of the two
CONSCIOUSNESS

great categories into which experience falls, viz., mental experience, from the other, physical experience. The one division, mental experience, includes all facts that may be construed as subjective, the other division all facts that are considered by the uncritical mind to be objective. From the first point of view the order of experiences has been customarily held to constitute a series of immaterial sequences that in their totality construct a personal life history; the latter has just as stoutly been located as forming a causal chain of events in a material world external to but reflected by the mental series. This picture of mind in reciprocal relationship with an external world portrays the naïve dualism of common-sense thought.

Regarded analytically consciousness breaks up into a series of processes producing sense-percepts, images of memory and imagination, associations, judgments, reasonings, feelings, emotions and volitions. Regarded from the standpoint of the reality these processes of consciousness constitute an individual mental history or mind. The objective facts above alluded to form the content of consciousness, forming in their entirety the world of external reality, a world distinguished into the two great subdivisions of living and non-living nature.

There is probably no term in the nomenclature of psychology that is subject to such vagueness of reference and ambiguity of meaning. Professor Ward has declared it to be "the vaguest, most protean, and most treacherous of psychological terms." Alexander Bain in his day discovered that it had already acquired thirteen distinct meanings, and he would doubtless find additional ones were he conversant with the vastly increased psychological literature of the present time. Considering this lack of fixity in meaning it seems almost audacious to attempt an accurate definition. But, holding the term to its most important significance, one may define consciousness as the aggregate of the mental processes of any period of life.

The question of the relation of consciousness to other biological functions is of great importance but one upon which present scientific knowledge throws little light. There is every reason to believe that states and degrees of consciousness are directly correlated with the activities of the nervous system, and especially with the functions of the great master-ganglion, the cerebrum. The evidence in question can be but briefly mentioned in this article. It is along two lines. First, comparative studies of the nervous systems of animals reveal the fact that their complexity increases pari passu with their level in the evolutionary series in other aspects of structure, and that with complexity of nervous system goes increasing intelligence in adjustable behavior. This is especially true of the cerebrum, the part of the nervous system that undergoes greatest elaboration as the animal scale is ascended, and also admits of the highest degree of organization under stress of the life experiences of each individual. Second, experimental studies on the nervous systems of the lower animals, supported by pathological evidence in the case of man, lead to the conclusion that the several conscious processes are conditioned upon neural activity of a definite kind. Furthermore, functions have been accurately located in special cerebral areas, impairment of which results in a decrease or cessation of the correlated form of consciousness. Collateral evidence is also to be found in the facts of sleep and hypnosis. The cerebral disturbance in the relaxed state of lowered blood circulation, probably has a lessened rate of metabolism, and is analogous to an important part of a mechanism temporarily out of gear with the rest of the system. Likewise during sleep consciousness is imperfectly suspended and disappears. The hypnotic state gives indications pointing in the same direction, though knowledge of the cerebral condition during hypnosis is so slight that one can speak only conjecturally. The hypnotic subject appears to the observer to have an artificially delimited consciousness. His attention is acute within a narrowed field of stimulation. He is oblivious to all suggestion outside of this restricted range. When restored to normal condition there is usually a more or less disoriented state of mind, with a start under face under the hypnotic spell, analogous to the usual treacherous memory for dreams when recall is attempted some time after awakening from sleep. It is probable that there is a corresponding condition of cerebral activities in minor disconnected systems, some of them heightened into intense activity at the expense of others which become partially or completely somnolent.

Psychological self-examination (introspection) coincides with the verdict of common-sense in distinguishing degrees of consciousness. That such degrees are to be found in the ascending animal scale is the inevitable inference from comparative studies of nervous mechanisms and of animal and human behavior. Evidence leading to the same conclusion comes from the scientific observation of a normal human being from earliest infancy to maturity. Further proof is found in the normal experiences of sleep and waking as well as in the unusual ones of swooning and anesthesia. The characteristic mark of consciousness at the lowest ebb is perceptual chaos and vagueness. The signs of full consciousness are great clarity and liveliness. A high degree of consciousness is hence practically identical with focalized attention, whereas a low measure of consciousness is similar to fleeting or scattered attention. It would seem from this that consciousness and attention are terms with essentially the same meaning.

Whereas older conceptions of consciousness regarded its contents as furnished entirely by sense-impressions, by intellectual intuitions, or by both together, more modern views have called attention to the contributions made by bodily movements. Recent views maintain that the stream of consciousness is a composite of external factors derived through sense and of other elements furnished by bodily movements and activities. These movements give rise to so-called kinesthetic (movement) sensations. All perceptual judgments, for example, are conditioned upon strains and tensions that blend with the other contributions of sense to construct the objects of our world. The contents of consciousness is just these objects or things plus the residue of memory images, images of imagination and ideas which form the sum-total of conscious experience.
The last statement leads to a reiteration of the fact that consciousness always has content. The content includes all the mental arts by which life adjustments are carried on, such as sense-percepts, images, thoughts, acts of will and feelings. Consciousness is thus seen to stand at the center of all mental life. Its function would seem to be the biological one of securing superior and far-reaching adjustments. It emerges at some unknown level in the animal scale in response to the necessities of living imposed by increasing complexity of structure. It is sharply contrasted with the purely nervous mechanisms of reflex, impulse and instinct. The acquired mechanisms of habit are usually preceded by a conscious stage of learning in which there is a temporary guidance of ideation, but lapse completely into the non-conscious when perfected. So likewise of other psychic functions when the psychic shock of initial performance is dulled through invertebrate use. From this fact it is manifest that consciousness is par excellence the organ of intelligent action. It is stocked with the percepts, images and concepts by means of which a more salutary contact with the world about us is secured.

A close word is required to speak of a very convenient antithesis to consciousness, the subconscious. Titchener defines it as 'an extension of the conscious beyond the limits of observation.' ('A Beginner's Psychology,' p. 336). The concept has proved its usefulness in abnormal psychology, especially in the departments of psychiatry and psychotherapy. The insane are often found to be dominated by complexes taking the form of dominant ideas and acting as urgent forces that overmaster self-control. Hysterical subjects exhibit similar compulsive psychoses of such power as to produce elaborate and persistent hallucinations. Oftentimes there is no memory of the original experiences out of which these complicated neuro-structures are pieced together by a diseased imagination. It is convenient to assume that the building up of these mental edifices of imagery takes place somewhere behind the veil, much as the apparent dream images are thrown into form behind the curtain of profound slumber before it is marshalled into the presence of the hazy consciousness of the partially aroused dreamer. The investigations of such eminent psychopathologists as Freud and Jung tend to confirm the significance of the subconscious as a convenient working hypothesis. It can scarcely be more; for direct evidence of its existence seems logically impossible.

WILLIAM J. TAYLOR,
The Brooklyn Training School for Teachers.

CONSCIOUSNESS, Biological Aspects of. Apart from subtle metaphysical or religious psychological distinctions we shall arbitrarily conceive of consciousness as those directing cerebral mechanisms which handle life's energy for the production of useful work, the word useful being used in an extremely broad sense. Just how consciousness grew out of tropisms, what its subtle distinctions may be from reflexes, what are its relations to the unconscious, these are matters which for the present lie outside of this discussion. It is here assumed that consciousness is a higher evolutionary product, assuming greater and greater control and precision as the opportunities and needs for adaptation to reality grow in the advancing animal scale. That consciousness may still be made a better and better instrument for adaptation to reality goes without saying.

Adaptation to reality is a complex function of the cerebral mechanism and we may follow Bergson in saying that it is through both instinct and intelligence that this takes place. In intelligent or logical activities consciousness is assumed. Is there a consciousness in instinct? This question brings one back to the matter of tropisms, of reflexes, and of the unconscious. To present this latter problem Bergson assumes two forms of consciousness, one in which consciousness is an absent factor and one in which consciousness is merely nullified. As he says both are equal to zero, but in one case zero expresses the fact there is nothing, in the other that there are two equal quantities of opposite sign which compensate and neutralize each other. Thus one may speak of the unconsciousness of a falling stone. In instinct however has a different type of unconsciousness. When one performs an habitual action, when a somnambulist automatically acts out a drama, as did Lady Macbeth, unconsciousness may be absolute and yet of what does it consist. Bergson holds with reason that the representation of the act itself resembles the idea so perfectly, and fits it so exactly, that consciousness is unable to find room between them. Freud, Jung and Bleuler would speak of this as a special kind of thinking in which consciousness is suppressed into unconsciousness by reason of emotional blocking. Fantasy thinking or autistic thinking results. The dramatization is the action and as Bergson shrewdly notices the representation is stopped by the action. As proof this latter author calls
to mind the fact that if the accomplishment of the act is arrested or thwarted by an obstacle, consciousness may reappear. It was there but neutralized by the action which fulfilled, thereby filled the representation. This inadequate act to represent calls consciousness. He is worth quoting further on this point since much of the knowledge of psychopathology gained by psychoanalysis tends to confirm a part of his attitude. If this point be examined more closely, it is found that consciousness is the light that plays around the zone of possible actions or potential activity which surrounds the action really performed by the living being. It signifies hesitation or choice. Where many equally possible actions are indicated without there being any real action (as in a deliberation that has not come to an end), consciousness is intense. Where the action performed is the only action possible (as in the action of the somnambulistic or more general automatic kind), consciousness is reduced to nothing. Representation and knowledge exist none the less in the case if a whole series of systematized movements are found, the last of which is already prefigured in the first, and it is in these, consciousness of the shock at the onset of an obstacle. From this point of view, the consciousness of a living being may be defined as an arithmetical difference between potential and real activity. It measures the interval between representation and action.

It may be inferred from this that intelligence is likely to point toward consciousness, and instinct toward unconsciousness. For, where the implement to be used is organized by nature, the material furnished by nature, and the result to be obtained willed by nature, there is little left to choice; the consciousness inherent in the representation is therefore counter-balanced, whenever it tends to disengage itself, by the performance of the act, identical with the representation which forms its counterpart. Where consciousness appears, it does not so much light up the instinct itself as the thwartings to which instinct is subject; it is the deficit of the instinct, the distance which the idea that becomes consciousness, so that consciousness, here, is only an accident. Essentially, consciousness emphasizes only the starting point of instinct, the point at which the whole series of automatic movements is released. Deficit, on the contrary, is the normal state of intelligence. Laboring under difficulties is its essence. Its original function being to construct unorganized instruments, it must, in spite of numberless difficulties, choose for this work the place and the time, the form and the matter. And it can never satisfy itself entirely, because every new satisfaction creates new needs. In short, while instinct and intelligence both involve knowledge, this knowledge is rather acted and unconscious in the case of instinct, thought and conscious in the case of intelligence. Before discussing this subject further a glance at the organs in which these mechanisms are concentrated may aid in fashioning a workable concept.

Consciousness: Localization. The general biological principle of the concentration of energy as a feature of advanced evolutionary development finds its expression for the psychical sphere in the more or less distinct localization of definite functions to certain portions of the brain.

For the purely vegetative activities such localization is as yet indefinite, but it is known that the areas governing the various members are accurately located. The important sense organs also show a like integration, and the localization of so-called centres for sight, hearing, smell and motor speech now admits of little question.

It is a more or less common based, on general grounds, as well as on the data afforded by physiological experiment and pathological observation, as well as by the study of the comparative psychology of the lower animals (by Romanes, Darwin, Morgan, Mills and Thorndike), that the higher mental processes (i.e., those that are more complex and those which have developed late in the evolution of the race) utilize the frontal lobes of the brain in their activities; but it is certain that, so far as the ego is concerned, taken in its totality, no such localization can exist. The whole body is a psychical organ, and the sense of the ego depends on such a multitude of sensory impressions that its location is coexistent with a mass of other psychical system in its totality. It is to be borne in mind that the complex nexus of associational fibres should be considered constant factors in the idea of a consciousness. The great modifications that occur in consciousness—due to the cutting out of action of certain of such associated fibres—is a constant feature in certain hemiplegic states, and probably some similar pathological entities lie at the foundation of some of the modifications or consciousness in some of the psychoses, notably general paresis.

Within recent years the labors of the histopathologists have brought into prominence the importance of minute structural changes of the connections of the various nerve processes; collaterals, axis cylinders and dendrites, forming plexuses of communication between various systems of nerve-cell groups. Such changes are closely correlated and are probably direct causative agents of many of the symptoms of mental disease, such as loss of attention, dimished initiative, amnesia, blunting of the higher ethical ideas, insomnia, and many of those psychical activities which modify conduct so largely, and hence are representative of the empirical ego.

From such a purely preliminary sketch it can be seen that it is futile to attempt to speak of a localization of consciousness as if such a faculty were a thing in se rather than a function of psychical nerve activities.

Connected, however, with this question there are to be considered certain localizations of some of the more clearly defined psychical activities.

Evidence derived from the lower animals points to the fact that following the cutting out of the prefrontal lobes there is more or less mental degradation. Close attention is lost, and observation which looks for the safety of the animal is often notably affected. Attention, judgment, memory and not only voluntary factors, are the ego which are partly modified by disease or injury to the frontal lobes, and with such are associated hesitation, fear, uncertainty and motor restlessness due to impaired inhibition.
CONSCIOUSNESS

Studies of monsters without a brain have shown that without a cortex, but yet possessing enough of the cerebrospinal mechanisms to bring spino-thalamohypothalamic fibres into play, many automatic activities may take place, notably sucking. Golt's celebrated decerebrate dogs and the later studies of Rothmann also have shown that highly complex reflex activities may be carried out by these pallium-minus dogs. Hence one may say that certain instinctive activities persist in these intelligent ones. In these lower activities there is that type of unconsciousness already spoken of as represented by the absence of consciousness. The thwartings to which the instinct is exposed in this case cannot give rise to consciousness. See CONSCIOUSNESS; CONSCIOUSNESS, DISORDERS OF.

SMITH ELY JELLiffe.

CONSCIOUSNESS, Disorders of. From the unconsciousness of death and that of accident, and the profound intoxications, to sleep; through the mild grades of unconsciousness in many of the psychic phenomena, somnambulism, the hypnotic state, and its allies; through normal walking consciousness; through the active states of dramatic abandon, ecstasy, the minor intoxications, to the distinctly diseased mental states of hysteria and epilepsy and the psychoses; finally to the living death of dementia, there is the gamut of the human psychological activities divided into a few cardinal categories which admit of general classification. Just what shall constitute a normal state and what an abnormal state must be left largely to study of majorities. Conduct is the great criterion of consciousness, and for most practical purposes it may be assumed that disordered consciousness is correlated with disordered conduct.

In discussing the subject of disordered consciousness it has been the custom to describe three types: exalted, diminished and perverted states. While this classification is extremely convenient for many purposes, it fails to give an idea of the clinical significance of any particular phase. It is only too frequently the case that the same clinical groups, hysteria or epilepsy, for example, will demonstrate all these separate phases, which at times are so close to each other or follow one another with bewildering rapidity.

The more important question seems to be: Given a definite mental state, which, judged from conduct, departs so far from what a broad experience teaches to be a fairly average state, to what factor or factors is such an abnormal state due, into what category does it fit, and how can it best be regulated or controlled to ensure the best results to the individual and to society?

The subject of categories of the clinical groupings of such disordered conscious states will be here only touched upon. Such a problem in classification is manifestly extremely difficult because of the richness of the emotional content of consciousness, and the few rather broad categories here proposed are to be regarded purely in the light of general convenience rather than as attempts to cover the entire ground.

The disorders of consciousness for the present purposes are broadly divided into a few general groups. There are: (1) Disorders of sleep and the allied phenomena; (2) disorders of the neuroses and psychoneuroses, including the phenomena of automatism, double personalities, amnesia, etc.; (3) the intoxications; and (4) the psychoses. Such a classification is manifestly incomplete and imperfect. Thus many of the phenomena of groups (1) and (2) are interchangeable. It is moreover popular at the present time to attribute most of the physical ills to various toxæmias, either autogenous or heterogenous, and it is certain that no hard-and-fast line can be logically drawn between certain maniacal states due to intoxication and those of a purely psychical etiology. In the present unsettled conditions of neutral pathology, to say nothing of psychological classification, the question of categories may be an academic one after all.

(1) Disorders of Sleep and Allied Phenomena.—(Dreams, Somnambulism, Trance, Lethargy, Cataplexy, Hypnotism, etc.). Under this category there are included a large number of closely allied phenomena, the most striking feature of which is a state originally termed by Janet dissociation of consciousness. In most of these phenomena the ordinary waking conscious state, with its refinements of judgment, inhibition, etc., is in turn suppressed, naturally or artificially induced, and the patient dramatizes his unconscious fantasies. The meaning of these dramatizations may be evident or they may suffer from a number of psychical modifications, such as conversions, distortions, dislocations, condensations, etc. (see article on DREAMS), which mechanisms make it difficult or impossible to understand the meaning of the whole fantasy. Consult Hirschmann, 'Freud's Theories of the Neuroses, Nervous and Mental Disease, Monograph Series,' No. 17.

Somnambulism.—The simplest type of such fantasies is found in some somnambulistic states. In these the individual may perform, while still asleep, many of the simpler acts of the waking state, and indeed even many extremely complex acts are carried to completion. The patient awakes without any conscious recollection of the acts performed, and often such acts have been harmful to self and society.

The clinical phenomena are not constant. The eyes are frequently closed, or open, or even wide open and staring. The pupils are apt to be sluggish in their reactions, but may be normal in diameter, dilated or contracted. The data collected by Gould and Fyle ('Anomalies and Curiosities of Medicine') may be referred to by those who would learn more of the complicated motor acts that many notable cases have been known to perform. Suicide and homicide have been committed by persons in the somnambulistic state. The somnambulistic state is recognized to be a special instance of autistic or fantasy thinking. The patient acts his unconscious fantasy, often with evident, but more often with complex and veiled, symbolisms. Association experiments and psychoanalysis seem to prove that the experiences lived during the somnambulistic state may be brought to consciousness. Some register is made in consciousness since a memory of them may be awakened. This does not mean that the individuals have a knowledge of what they were doing at the time it was done. This commonplace of medical science is one of the stumbling blocks of law, where the ignorance of lawyers has given rise to the stupid and
unjust definition of "responsibility." Somnambulistic performances carry out the general trend of the unconscious, i.e., toward fulfilment of instinctive desires.

Nightmare.—This is a painful dream state. In many instances, where such are extremely distressing, they have been known to precede grave cerebral disturbance, but it is not certain that they have any close relationship with the manifestations of certain types of hysteria. Here the fear of death appears in symbolic form. The more recent studies of Freud, Jones and others have pointed the way to a better hypothesis of these nightmares. They are discussed more fully in the article on Dreams.

Lethargy, Catalepsy, Trance.—These are terms used to describe atypical unconscious states which are as yet imperfectly classified, partly on account of the fugitive character of the alterations and partly because of the complications of the picture with other symptoms of the hysterical and epileptic conditions. The phenomenon of hypnotic sleep is best put in this category.

In catalepsy the prevailing phenomenon consists of the wax-like rigidity which the limbs can be made to assume, at times unconsciously; again, especially in the hypnotic condition, by the suggestion of the operator. In trance conditions there may be manifest a great variation of phases, most of which are accompanied by the hysterical state. All of these phenomena which occur in a variety of the psychoneuroses as well as in the psychoses, cataleptic states, lethargies, trances, etc., being extremely frequent in hysteria and more particularly in certain types of schizophrenia (dementia praecox), have been much better understood, thanks to Freud's ingenious hypotheses. They all represent, as stated, wish-fulfilling fantasy dramatizations, the precise significance of which can be laid bare by the principles of psychoanalysis.

(2) Disordered Conscious States in the Neuroses and Psychoneuroses.—No sharp dividing line separates the neuroses from the psychoneuroses so far as the prevailing disturbances of consciousness are concerned. Here under the neuroses are considered neurasthenia and anxiety neuroses, while hysteria and the compulsion neuroses (morbid phobias, fears, compulsion ceremonials, etc.) are here termed psychoneuroses. For neurasthenia, the chief phenomena are fatigue state, anxiety states in the anxiety neuroses, conversions of psychical unconscious states into physical phenomena (blindness for not willing to see, deafness for not desiring to hear, paralysis from fantasies of various kinds, etc.); indeed the whole gamut of somatic signs of hysteria may be mentally reviewed by the reader as falling under the formula conversion. Finally in the compulsion neuroses there is an erection of psychic defenses which show the phenomena of substitution. Here the sources of the emotion in unconsciousness are transferred or displaced to some irrelevant matter which comes to symbolize in a specific manner the nature of the unconscious, suppressed emotional situation.

In many neurasthenic states organic factors loom large in determining the feelings of fatigue in consciousness. Others again, however, are purely emotional in their development and here conscious and unconscious processes are in rivalry. The desire to be sick to escape obligation; the reversion to indifference unconsciously is a large motive. The libido, that is, the energy of these individuals, concerns itself with their own bodies and they live, in fantasy, as neurotics, the life of the cared-for and nursed child. Here unconscious fantasy helps to disguise the task—that is, to be independent captains of their own destinies.

In the anxiety neuroses, physical states are also present, such as flutterings, tremblings, gaspings for breath, air hunger, very frequently palpitation, fear of impending death, anxiety lest something may happen to self, to others or to material welfare, diaphoreses, mucous colitis, gastric irregularities of all types, etc. These make up the physical signs induced by the unconscious fantasy, largely of temptation. These patients are constantly repressed; they suffer from suppressed excitement and the symptoms mentioned constitute the outlet for the repression, the exact nature of which is veiled behind the symptom, not as a true conversion as in the hysterical mechanism, save in certain mixed anxiety hysterias. Freud and Stekel as well as many others assume that this type of disorder is found more particularly in those who find the demands of culture too arduous, and yet whose ethical attitude refuses to face a certain, often but not invariably a sexual situation. Unrequited affection, dissatisfaction with life's sternness, actual sexual stimulation without gratification—as in coitus interruptus, coitus reservatus, menopause, artificial and natural—unconscious temptations toward masturbatory habits that is, immediate discharge from consciousness—these are among the dynamic factors bringing about these peculiar modifications of conduct to meet these situations.

In hysterical conversions the mechanisms are more complex. Here the complexes play a more determining rôle and the cast-off and yet still retained complex is more precise and definite.

Thus the essential factor, so far as consciousness is concerned, is dissociation which, according to the original view as held by Janet, is due to an inborn weakness, namely, some factor in the constitution of the individual which predisposed him to this type of reaction. Hence, by the French school, and by those who followed Janet's teachings, the search for this inborn factor was made chiefly in the prenatal life of the individual, namely in heredity, and unfortunately as a correlate of such teachings a pessimistic attitude toward therapy was inevitable. The chief advance made in the hypothesis formulated by Freud was that the factor bringing about dissociation was not so much to be sought in heredity as to be looked for in the psychological dynamics of the nervous system, so that, for reasons which psychoanalysis has revealed, a certain group of ideas or complexes remained in the unconscious, but were still active. Hence arose the concept of repression as worked out by Freud.

Inasmuch, however, as the dynamics of the nervous system could not be interfered with, some form of expression of energy must take place. The repression acting upon this discharge of energy brings about the process of conversion, that is, there is a major discharge but the repression distorts it—puts a different
face upon it, so that the patient carries out the unconscious repressed wish in a form of dramatization known as the symptoms of the disease. This dramatization, concerning which a much more extended discussion will be found in the article on Hysteria, presents a number of distorted mechanisms which a study of the dream life has made clear. These distorting mechanisms permit the living out of the wish, at the same time that it remains practically unconscious. Mixtures of conscious and unconscious fantasy are present in practically all hysterical attacks, so that they present various combinations.

The symbolism of the attack itself may represent a number of things. Thus, among the commoner forms of dramatization one finds that:

1. The hysterical symptom is the memory symbol of certain actual traumatic impressions and experiences.
2. The hysterical symptom is a substitute created by conversion for the associative return of these traumatic experiences.
3. The hysterical symptom is like other psychic formations, the expression of a wish fulfillment.
4. The hysterical symptom is the realization of an unconscious fantasy, which serves a wish fulfillment.
5. The hysterical symptom serves to represent a sexual gratification, and represents a part of the sexual life of the patient.
6. The hysterical symptom corresponds to a return to a kind of sexual gratification which was real in infantile life, but which has since been repressed.
7. The hysterical symptom arises from a compromise between two opposed affective and instinctive impulses by which the one brings a partial instinct or component of the sexual repression to expression, the other seeks to suppress the same.
8. The hysterical symptom can become the representation of different unconscious non-sexual impulses, which cannot, however, be without a sexual meaning.
9. An hysterical symptom is the expression on the one hand of a masculine, on the other of a feminine, unconscious sexual fantasy.

These represent the more easily recognized interpretative formulæ of an hysterical attack, number 7 being the most frequent.

The chief interest, however, in interpreting this pantomime resides in the close similarity which it presents to the pantomimes of dreams and myths, and of fairy tales. We thus see that the misleading, incomprehensive and indistinct outlines of the attack consist:

1. In a combination of several simultaneous fantasies, for example, a recent wish and a revival of an infantile repression.
2. In a multiple identification when the patient undertakes to carry out the activities of both persons appearing in the fantasy.
3. In the antagonistic conversion of motor innervation so that a negativistic expression is to be interpreted in the light of its opposite.
4. In an inversion of the time sequences; this complicates the picture, just as an inversion in the motor character of the phenomenon and an hysterical attack may begin backward and work forward, just as a cinematograph film may be displayed running backward.

In hysterical dream states the unconscious activities may be readily understood by one who is capable of understanding the pantomime. The patient plays the part with unerring accuracy.

Compulsion Neuroses.—Here the unconscious factors are handled in a manner somewhat different from that seen in hysteria.
Under this head is usually placed a large number of obsessive, phobic and compulsive ideas which represent an unsuccessful repression of the psychosexual conflict. Unlike hysteria, the conflict is apt to come into consciousness; it cannot be entirely disguised by the distorting mechanisms. Conversion is not so frequent a phenomenon, but instead another type of reaction is met with, namely, substitution. By this is meant that the repressed conflict, breaking into consciousness, does not come into consciousness in its true light, but is immediately transferred or transposed, that is, substituted, upon something that is innocuous. A common illustration from everyday life illustrates in part this mechanism. Thus, an irritable husband with a burning desire to comment immediately on sitting down to breakfast, complains about the coffee; notwithstanding the fact that the coffee may be the same that he has been drinking for 15 years, on this particular morning it is atrocious. Here the psychical disturbance, the discomfort, the irritability is transposed or substituted upon the innocuous object, and one that has nothing whatever to do with the original source of irritation, but serves as a carrier or outlet for it. Thus the phobia, the compulsive act, the obsession becomes the innocent object for the expression of the emotional or complex disturbance of the patient. Thus, a patient will be unable to look upon a negro, will refuse to go out of the house without securing the door a number of times, or may have to put white papers under the beds, or in dark closets, have to look at people two or three times to be persuaded that they are not negroes, and a complicated ceremonial grows up about the question. The negro is only a symbol and behind the symbol lies the original difficulty.

To understand the activities of the unconscious in the compulsion neuroses is very difficult, but perhaps the most illuminating hypothesis that has been utilized for the explanation of these phenomena is that of Freud. He assumes that the fairly developed neurosis, say of a person of from 25 to 35, or even 40 years of age, represents the terminal stage of a complicated series of phenomena. The initial stage is usually laid down in childhood where, as a reaction to infantile attitudes, usually of a nature to satisfy sexual curiosity, then not known to be sexual, the patient comes to a sense of guilt concerning these activities. This sense of guilt is usually overcompensated for by little manifestations as it were of overgoodness. The children become very punctilious, very fond of their parents, intensely religious or intensely self-sacrificing, do everything they can to be good, which is hardly the normal stage.

They are compensating for something which needs to be compensated for apparently, and the compensation aids in pressing memories of the early experiences or fantasies into unconsciousness. It may be that this overcompensa-
CONSCIOUSNESS IN ANIMALS—CONSCRIPTION

tion is effective, as it frequently is in mystics, religious enthusiasts, zealots, reformers, extremists and cranks of various kinds, but not in the individualistically oriented, breaks down the original fantasies which have been put to sleep reawaken now with a much stronger imperativeness, and immediately a conflict arises, whereby the demands of the original instincts of gratification can be accomplished, and especially whereby the demands of a cultural attitude may be maintained. A ceremonial which represents these conflicting tendencies develops whereby the patient can keep his cake and eat it too. The mask that is worn is of various types, as any one who has had a large experience with compulsion neuroses can testify. Sometimes an overdetermined symbolism may in the course of time become extremely complicated. The patient is driven from one level to another, and in the search for rest lights upon a series of islands of safety as it were, to be away and have to search for a new one. Thus successive lines of defenses grow up, and in every old compulsion neurosis the ruling of the various lines of defense becomes an extremely difficult matter. It is highly probable that no compulsion neurosis can be analyzed within six or eight months, and some cases take one or two years. They constitute the hardest problems in the treatment of the psychoneuroses.

Intoxications.—An adequate discussion of the disturbances of consciousness in the intoxications would require a large volume. Those resulting from the action of alcohol alone would require a monograph. The mechanism of the influence of alcohol upon consciousness is one of intense interest, since in increasing dosage one can observe, along the retrograde path, the whole phylogenetic and ontogenetic development of consciousness. In comparatively small doses the conscious development of higher culture may be peeled off, then those of less advanced grades disappear; an individual man may in successive layers be shown through all of his psychical stages of development. At the vital level he represents the spinal animal, still feeling and living, but reflex orientation may be preserved. Consciousness is here reduced to unconsciousness and all of the reactions of the ancephalous monster may be preserved. Finally passing below vital levels alcohol reduces the human animal to a physico-chemical apparatus, in which the only functioning parts are the sympathetic metanerves. Here unconsciousness is at its lowest level, if unconsciousness one wishes to call it, for here mere tropisms show themselves. The lungs continue their oxygen exchange, the kidneys their chemical filtration and all other organs of the body carry out their physical chemical functions, but lacking all co-ordination, all interrelationship. Every cell is looking out for itself independently one of the other, anarchy and chaos rule, and only the vagus preserves its activity in respiration and in the heart beat. Here are bits of primordial protoplasm which started the evolutionary series. Everything that man is cannot be reached by the alcohol path, and as is well known it chiefly is the "has heens" that are acquired.

Psychoses.—Here disturbances of consciousness are most varied. It is practically impossible in the present state of our knowledge to apply the scheme of our stages of evolution to them. Certain psychoses reduce the individual to a physico-chemical level, such for instance as paroxysms, senile decay, even certain stages of dementia praecox drop to this level. The intoxication and infectious psychoses, those associated with disintegration and degeneration of brain tissues, also show the same results.

Other psychoses reduce him to a vital level, return him to the animistic stages of development, whereas others again only involve him in his higher psychical sphere. Here symbolism becomes affected, and although the patient may not come in conflict with his surroundings, nevertheless he is out of touch with certain types of reality. No consistent applications of the hypothesis can as yet be made to the psychoses without a much more extended discussion.

SMITH ELY JILLYFFE

CONSCIOUSNESS IN ANIMALS. See MIND IN ANIMALS.

CONSCRIPTION, the enlisting of men for military service by a compulsory levy, at the pleasure of the government. It is distinguished from recruiting, or voluntary enlistment. Conscription was enforced in the states of ancient Greece, most especially in Sparta. The name is derived from the Roman military constitution. Every Roman citizen was obliged to serve as a soldier from his 17th to his 45th year; the consuls announced every year by a herald or written order that a levy was to be made (miliis cogere collegere, scribere conscribere); and all citizens capable of bearing arms assembled in the Campus Martius or near the capitol, where the consuls assisted by the legionary tribunes made the levy, choosing as many men as were needed from each tribe. The renascence of conscription in the form of a scheme of universal service embracing the greater part of the population dates from the French Revolution. The combination of volunteers and conscripts which constituted the army prior to 1792 was replaced by a purely conscriptive scheme. However, as the administration of this scheme was left in the hands of the local authorities, the army soon became filled with vagabonds and criminals. After 1793 the revolution against war led to a considerable opposition to conscription. In 1798 the famous conscription law of Jourdan was enacted, which made all male citizens between the ages of 20 and 25 liable to a call to the colors. A most vicious clause in this law, which remained in force until 1870, and may fairly be charged with contribution to the loss of the Franco-Prussian War, was that which permitted the buying of exemption.

The German system of conscription dates from the degradation of Prussia after Jena. The treaty of peace, which forbade the maintenance of a large standing army, compelled Prussia to turn her army into a vast training-school, whereby at a small expense and without violating her treaty agreements, she was able to keep up her war machine to an extent of service that underwent a brief period of service with the colors. This system is now the basis of the military organization of the whole continent of Europe, and of Japan. It consists in compulsory service with the colors for a short period, a long
period in the various reserves and few exemptions. Switzerland (q.v.) is unique among the Continental nations in replacing the service with the colors by a few weeks' training each year.

Until the beginning of the European War, England and America were the only two countries which relied exclusively on the voluntary system. In England the voluntary system was attacked by Lord Roberts, but defended by Lord Haldane and Sir Ian Hamilton, on the grounds that the volunteer, especially the trained volunteer which the British long period of service furnished, was proportionally so much a better soldier for such remote and difficult wars as those into which Great Britain was likely to enter as to counterbalance his relative feebleness in numbers. Meanwhile, Australia had the distinction of being the first English speaking nation to initiate a limited compulsory military training and service. Until January 1916 England retained the scheme of voluntary service, but with a constitutional modification to prevent conscription from unoffical and official sources on those who did not enlist. In the autumn of 1915 Lord Derby devised a system whereby it was possible for a man to enroll himself for military service so that he might be called up when he was needed. Soon afterward certain restrictions were adopted prohibiting the emigration of unmarried men. These restrictions obviously had in view the ultimate adoption of compulsory service. This was enacted in a bill introduced by Mr. Asquith, the Prime Minister, on 4 Jan. 1916. The Derby scheme remained in effect until 2 March, when conscription came into force. The conscription scheme adopted is unique in exempting from armed service (not from all service whatever) those who have conscientious objections to warfare. The sincerity of their objection, however, is subjected to a rigorous examination. Ireland was excluded from the provisions of the act. See War, European.

Immediately upon entering into the European War America adopted conscription. (For the details of the scheme adopted, and for the practice of conscription in the War of the Rebellion, see Canada.) Canada also initiated conscription in 1918, but at the present time (March 1918), it appears that Australia, which had conscription for home service long before the War, is unlikely to adopt conscription for foreign service. It has been put to a vote, and has been rejected. The policy of England, the United States and Canada toward conscription in time of peace is as yet indeterminate. (For the organization of the conscript armies of the world, see Army; Army Organization.)

**CONSCRIPT DE 1813, Histoire d'un (History of a Conscript of 1813), a famous story, by Erckmann-Chatrian, published 1868-70.** The story turns mainly on the contrast between the perpetual mourning that is going on in families and the perpetual Te Deums for disastrous victories. This is the dominant note; and in the mouth of the humble conscirpt, this thesis, interpreted by scenes of daily carnage, is more eloquent and persuasive than if it borrowed arguments from history or philosophy. The style is simple, familiar; but never trivial or commonplace, and is always in harmony with the speaker. As the work was hostile to the Napoleonic legend, numerous obstacles were put in the way of its circulation at the time of publication. But notwithstanding, it was scattered in perfusion throughout France by means of cheap illustrated editions.

**Consecration**, an act by which material things and persons are dedicated to sacred uses and sacred ministries. Celebrations of rites of consecration are traced back to the earliest historic periods of Assyrian, Chaldaic, Egyptian and Hebraic civilizations. The word Consecration is also used in the Roman Catholic ritual and liturgy to signify the act of Transubstantiation (q.v.) by which the bread and wine are in the Mass changed into the body and blood of Christ. In the Roman Pontifical or ritual for episcopal consecrations there is a form for consecration of a bishop, consecration of a church, consecration of the sacred vessels used in the liturgy of the Church. In the consecration of a bishop—ordinarily performed by the metropolitan and two other bishops—the consecrating bishops impose hands on the bishop-elect and the metropolitan delivers to him the pastoral staff and the ring, emblems of his office, and anoints him with chrism, the sacramental mixture of olive oil and balsam, pronouncing the words by which is expressed the commission of authority to rule the Church committed to his charge. The consecration of a church is a very elaborate ceremony, requiring several hours to complete it: there is chanting of the office of Matins and Lauds by the clergy; there are processions of clergy, headed by the consecrating bishop and other bishops who may be present, around the walls outside and thrice around the interior, with continuous chanting of psalms; there is anointing of the doors, of the walls of the high altar; and a number of other rites. The consecration of the vessels destined for the service of the altar is also an episcopal function; it is a rite that has descended from high Christian antiquity: in this rite also chrism is employed.

**Consent** (OF. consent, Lat. consentire, "to agree"), in law, a free and deliberate act of a rational being. Any voluntary act by which the agent takes away his own power of giving a deliberate consent, such as partial intoxication, will not invalidate the consent; but it is invalidated by any undue means—intimidation, improper influence or imposition—used to obtain it. The law does not, in general, take cognizance of the wisdom or folly of men in entering into contracts before it enforces them; but where clear proof can be brought that a person has been wilfully misled or entrapped into a contract, it will refuse to enforce it. In pathology consent signifies an agreement or sympathy in virtue of which one affected part of the system affects another.

**Consequent Stream**, On a newly emerged portion of the sea bottom, forming a coastal plain sloping toward the ocean, the run off from rainfall gathers into little rivulets that flow down the slope to the sea. These channels
enlarge till finally the water courses constitute true rivers. Streams like this, whose course is determined as a consequence of the initial slope of the land, are called consequent streams. See also **Consequent Stream**.

**Consequential Damages or Losses**, in law, are losses incurred in consequence of an act, but not flowing directly from it. The liability for consequential damages resulting even from an unlawful act is more limited than that for direct damages, as it is presumed that the power of the law in tracing and enforcing such damages must be limited; but in some cases they can be enforced.

**Conservation of Energy.** See **Energetics.**

**Conservation of Matter.** See **Matter.**

**Conservation of Natural Resources.** The conservation movement, first clearly started in the United States in 1908, aims to protect and to develop the fullest permanent usefulness of the great national resources—forests, lands, minerals and waters—where such use has hitherto been accompanied by such great waste. Its chief principles are that the resources shall not be wasted, that the national resources shall be administered by the national government and that both public and private resources shall be administered with some reference to the interests of future generations. The movement is also part of a general effort to prevent the private monopoly of valuable resources. Its chief purpose is to secure by intelligent direction a wise and careful use of national resources, but not to withhold them from necessary use. In the case of some resources (as timber) its problem is to provide for renewal as used; in the case of others (as minerals) its problem is to secure more careful use or substitutes, and prevention of waste.

The American people, bred to carelessness and drifting policy, in the midst of plenty, became known for their wastefulness. In the long period of the settlement of new lands, the national resources, regarded as practically unlimited, were exploited with prodigal waste. The pioneers claimed the right to occupy and the right to exterminate whatever stood in the way of occupation. They destroyed valuable timber, wild game and fur-bearing animals. They would have exhausted the fishing grounds but for the work of the State and national fish commissions. Great lumber companies used commercial methods which proved even more destructive than the acts of the pioneer. Fires, both from heedless and intentional sources, were frequently more destructive than the wasteful methods of lumbering. Deforestation, resulting from American reckless policy, brought indirect losses even more serious than the direct loss of timber—the losses from erosion and serious depletion of soil, irregularity of stream-flow, flood and landslides. Unrestricted by national regulations, the cattle barons, by a system of wasteful exploitation, ruthlessly and unmercifully wasted the national pasture land of the great watershed between the Mississippi and the Rockies. The sheepherders followed and completed the work of depletion, precipitating disputes with the cattle men over the public range to which neither had a legal title. The pioneer farmers by reckless exploitation and unscientific methods exhausted the farm lands. The pioneer exploiters of coal mines exhausted the mineral resources by criminal waste. The pioneer oil men wantonly destroyed natural gas. The same spirit that characterized the early stages of exploitation in the mining of precious metals. The captains of industry were no less ruthless in the exploitation of the energy of human beings in factories, foundries and mines, and in railroading and enforcing such damages must be limited; but in some cases they can be enforced.

Americans, who until the close of the 19th century still exulted in the strength of their limitless resources, in the first decade of the 20th century began to regard the protection of the rights of the people in the public domain as more important than the immediate exploitation of its wealth, and began to favor public control and legislative limitations on private enterprise as essential to industrial liberty and the general welfare. Fearing the exhaustion of their natural resources, they expressed their fear in a well-developed movement for conservation. They urged man's duty to the soil with a view to restoration of fertility by scientific farming. They favored government projects for extension of irrigation begun by private enterprise. They sought to find plants and methods which would bring crops to semi-arid areas and irrigated deserts. They sought through national and State governments and great corporations to establish forest reserves to prevent exhaustion of timber and to prevent alternate floods and droughts, and encouraged scientific study of forest problems. They began an agitation to prevent waste of supplies of coal and iron, and to save coal supply, by urging the importance of the preservation and development of latent water power to produce electricity. They were awakening to the fact that power sites should be leased, not sold or given away, and that privileges of using this natural source of wealth should be granted on terms conserving the rights of the public to adequate service at a reasonable charge. They lessened the demands on forest and iron ore by use of cement as a substitute for wood and iron. Finding that a large amount of the resources upon which the future must depend were held by a comparatively few individuals or corporations, they began to demand that the unappropriated resources should be administered primarily for the benefit of the public, and that those already in private hands should be subject to government control. They began to urge selection of trained experts to study the economic utilization of resources, and co-operation to regulate the life of the community for the good of all.

With changes of conditions which brought a realization of changes from waste, the need of a national policy of conservation arose. A rise of prices of raw materials in connection with every resource is probably the strongest economic force leading to more scientific utilization, and this is the strongest guarantee of conservation, but it is not enough.

The Roosevelt administration first saw the importance of a more active national control of natural resources for the benefit of the public. In February 1907, calling attention to the waste of mineral resources, the President
CONSERVATION OF NATURAL RESOURCES

recommended legislation for separation of the title to the surface of the land from the title to the underlying mineral fuels, in order that the latter at least may be subject to competitive monopolizing or speculative private interests and kept for the public benefit. He considered that the conservation of our natural resources and their proper use constitute the fundamental problem which underlies almost every other problem of our national life. Early in 1907 he took the first practical step toward the solution of the problem by the appointment of the Inland Waterways Commission to investigate and recommend a full and comprehensive plan for the development and utility of the water resources of the country. In May 1908 he took the second step in calling at the White House a conference of governors to which facts regarding natural resources were presented by experts and at which plans for conservation were considered. This conference began a definite movement for conservation. Following its first meeting the President took an additional step by the appointment of a National Conservation Commission composed of men who were under the chairmanship of Gifford Pinchot who was head of the forestry division. This commission made the first national inventory of natural resources, published in 1909. It directed attention to the waste in extraction and treatment of mineral products, the decrease of soil fertility, the extinction of wild game and fur-bearing animals, the decrease of forests by timber industries and by fires, the waste of water in public and private irrigation projects and the great losses by failure to utilize the power of water flowing over government dams.

Disclosures of recent government investigations thus begun are appalling. Experts report that many natural resources are rapidly nearing exhaustion; that at the present rate of consumption and with present wasteful methods the timber can last only 30 or 40 years, that the supplies of available coal can be expected to last only 150 years, and the supply of petroleum only 50 years, that the supply of high grade iron can last only 100 years and the known copper deposits only 50 to 100 years.

Advocates of the new policy proposed not only to conserve by more economic methods of extraction, but also by substitutes to reduce the consumption. The storage and properly directed release of vast water power which has remained uncontrolled and unused can be made to save other resources from damage and at the same time to conserve enormous supplies of coal. By complete utilization of this neglected resource, floods may be reduced, better means for irrigation provided, waterways improved for navigation, and larger power securing industrial purposes.

President Roosevelt withdrew large areas of western public land from sale and settlement for the purpose of investigating their resources, and recommended legislation for protection of the interests of the general public in their forests. Later, after legislation had been passed, steps toward a national policy were taken by the creation of national forests (under acts of 1891 and 1907) and the Forest Service. The latter is a bureau of the Department of Agriculture which successfully protects and administers the public interest by wisely directing the growth of timber in the United States, protect the headwaters of every western river and aid in supporting half the sheep in the western ranges. It also co-operates from time to time with the State forest services. It protects the forests from fire and depredations, improves the conditions for timber growth, protects the water supply and utilizes the forage crop. Besides the practice of scientific forestry it conducts investigations and collects much useful information for dissemination. The new policy defeated the attempts to cede the national forests and the entire public domain to the Western States which cannot so well administer them in the interests of the whole people.

In the Far West a decided opposition arose against the new forest policy, but by 1911 the policy of Congress not to release any of the safeguards against the forestalling of land by corporations and large individual owners and to continue the forest policy and to reserve public mineral rights became clear.

In 1911-12 Congress began appropriations for the purchase of forest reserves in the Appalachian and White mountainous regions. In 1909, the first steps were taken to prevent plans of great capitalists to obtain control of valuable natural resources in Alaska. Ex-President Roosevelt led in the support of a plan of government ownership with leases to corporations.

The conservation policy was also manifested in the agitation to reserve water-power sites, to secure new laws for the disposal of coal lands and to modify the Homestead Act. By act of 1910, the President can reserve public lands for water-power sites or irrigation. The Secretary of the Interior recommended that the Federal government be authorized to lease such power sites at a moderate rate for a period of not to exceed 30 years. It has been urged that the development of power in navigable and source streams should be co-ordinated to reduce drain on other resources, to aid in the control of streams for navigation, to prevent soil wash and to purify water supply. The proper conservation of water power the most important thing is to prevent private monopolies from getting the sites and to preserve the use of them for the benefit of the whole people. The importance of this is indicated by the fact that 65 per cent of all the power of the United States was controlled by 10 groups of power interests, several of which were closely related by interlocking directorates. The new policy of national conservation defeated the latest selfish attempt of organized power interests to obtain in perpetuity and for nothing the unregulated control of water powers of navigable streams in the national forests and on the public domain.

Recently the Federal government has begun active participation in the reclamation of arid lands by irrigation projects which were first begun by private corporations as early as 1880. The national irrigation policy emerged from disputes of western farmers with the large private water companies which by 1900 had secured and developed the best irrigation sites, and also from the necessity of protecting rivers and lakes from which irrigating waters were drawn. The Federal government has encouraged irrigation by the desert land laws of 1877 and 1891, by the later Carey act of 1895 (modified in 1901 and 1908), and by the more
important Newlands reclamation act of 1902, by which the government began to reserve from settlement many areas of water supply and could hold the mountain streams necessary to fill reservoirs and use the water drained from the dams. Congress advanced $20,000,000 for the construction of irrigation dams to be satisfied from the proceeds of the sales of the improved land.

Congress has gone far toward committing the government to the policy of control by authorizing the President to withdraw public lands from private use whenever important for conservation of forest or grazing lands, water power, irrigation possibilities or scenic beauty, but has not yet determined the terms on which mining and development rights will be conceded. Little effort has been made to protect mineral resources from waste or improper exploitation. In 1900, Congress enacted a law authorizing the President to withdraw temporarily from settlement many areas of public property the coal and other minerals beneath the surface. The National Conservation Commission advocated the disposal of coal lands only under leases safeguarding the interests of both the mining investor and the public. Steps were taken to withdraw from private ownership the coal deposits in Alaska, and the government undertook the construction of a railway leading to the Mataluska coal field. This is the beginning of a new system in line with the example of many European countries.

Another illustration of the new policy of conservation is found in the guarding of the north Pacific seal fisheries by an international agreement of 1896 between the United States, Great Britain and Russia, and by a later treaty of 1911 in which Japan joined. To make resources safe from waste and unregulated monopoly, the advocates of conservation still urge legislation for the development of water power of the national forests and other public lands on terms fair both to the people and to the power interests, for improvement of public grazing lands by regulated use, for preventing by adequate penalties the needless pollution of streams, and for the utilization of the resources of Alaska for the benefit of the people.

JAMES M. CALLAHAN, Professor of History and Political Science, West Virginia University.

CONSERVATIVE, as applied to one of the two great parties in English politics, was first used by J. W. Croker in an article in the Quarterly Review for January 1830, and was by Macaulay, in the Edinburgh Review for 1832, referred to as a "new cast word." Conservative accordingly began to supersede Tory about the time of the Reform Bill controversies. The plural form of the word, or its equivalent in other languages, has been assumed as a distinctive name by certain political parties in many nations. These parties are sometimes actually, and always avowedly, opposed to changes from old and established forms and practices. In United States history these names have never been in general use, but in Van Buren's administration the name of Conservatives was applied to those Democrats that at the special session of Congress of September 1837 opposed the establishment of the sub-treasury system. In the Congress that met in December 1839 they had practically disappeared. The name was also assumed by Southern whites during the reconstruction period following the Civil War, to show their adherence to the old State governments, the abolition of which by Congress they opposed. In Virginia the name was in use until 1872. The name was also used in the North during this period. The Democrats applied it to themselves to draw moderate Republican voters. In the United States (1839-40) the name of Conservatives was adopted by seceding Democrats, 4 in the Senate and 14 in the House, who voted with the Whigs against the sub-treasury, though voting with their party on other questions. These themselves Conservatives, as wishing to conserve the prosperity of the State banks, which they held the sub-treasury to be a disguised attempt to ruin. They held the balance of power in the House 1837-38, and voted down in two successive sessions Silas Wright's sub-treasury bill, which had been passed by the Senate. The elections of 1838, however, returned only four of them to the House, and these ceased their active opposition—partly because the government had only escaped bankruptcy in 1837, on account of uncollectible claims against banks and individuals, by issuing fresh treasury notes in place of those canceled. The Whigs held the power and passed the Wright bill in 1840. In the Civil War the Northern Democrats, and especially the border State Democrats, often called themselves Conservatives, as wishing to preserve the old balance of State and national powers; and the name was much ridiculed by the other side. During the Reconstruction period, the Southern whites to a considerable extent took the name of Conservatives as wishing to preserve their old State governments, which they held to have the same existence and sovereignty as before the war, according to the declaration of the Northern leaders and Congress themselves, in stating the purposes of the war. The name, more particularly in Virginia, lasted down to 1872. See Tory; Whig.

CONSHOHOCKEN, Pa., town of Montgomery County, on the Schuylkill River and Canal, 13 miles northwest of Philadelphia, and on the Pennsylvania and the Reading railroads. It has a number of manufacturing interests, including blast furnaces, rolling-mills, woolen- and cotton-mills and pottery works, rubber works, surgical-implant works, the principal products of which form the basis of an extensive trade. The town was founded in 1830 and was incorporated as a borough in 1852. Pop. 7,480.

CONSIDERATION — CONSOLIDATION OF SCHOOLS

1808; d. 27 Dec. 1893. After being educated at the Polytechnic School of Paris, he entered the army, which, however, he soon left to promulgate the doctrines of the Socialist Fourier. On the death of his master (1837), Considérant became the head of his school, and undertook the management of the Phalanx, a review devoted to the spread of their opinions. Having gained the support of a young Englishman, Mr. Young, who advanced the money. Considérant estabished, on a large estate in the department Eure et Loire, a Socialist colony or phalanstère, but the experiment failed, and with it the Phalanx fell to the ground. Thereafter he continued to promote his views in the Democratie Pacifique. Among his numerous writings, the chief is the 'Destinée sociale,' dedicated to Louis Philippe, which contained little more than a review of the principles of Fourier. In 1849 Considérant as a member of the Constituent Assembly was arrested, imprisoned and compelled to flee from France. Near San Antonio, Tex., he founded a Socialist community, La Réunion, which flourished for a time, but afterward came to nothing and he retired to France, living in poverty, one which has the greatest claim to originality is his 'Socialisme devant le vieux monde' (1849). In religion Considérant was a conservative; and was also opposed to the Revolution.

CONSIDERATION, a legal term covering the principle governing contracts and signifying something in the way of price or compensation which may be of value to the contractor or of detriment to the contractor. In law no contract is valid if it does not expressly stipulate the amount or consideration for which any lease, sale or transfer is made. As there are various kinds of contracts recognized in law, so there are different sorts of considerations. The simplest case is that where one party surrenders some property right to another for a consideration. In many dual contracts the promises are mutual — each promising a consideration to the other. But whatever the nature of the contract — and they grow in complexity from day to day — no legal action can be taken upon them unless the consideration is clearly specified therein. But covenants are sometimes to perform direct benefits to the contracting parties. Promises made after services rendered cannot become the basis of legal action, because such services are not rendered in view of a consideration. Thus promising a reward after being saved from drowning, for instance, does not make one liable. Nor are promises binding when they involve the performance of what is one's legal duty, anyhow. No promise is legal which involves the performance of an illegal act. The adequacy or inadequacy of a consideration, however great or small, never matters in law. Thus, one may legally transfer property rights worth thousands of dollars in consideration of one cent.

If the law of contracts, could it be entered into here, would show the origin of the requirement of consideration. It clearly grew out of the original custom of requiring proof of damage or detriment suffered by the plaintiff seeking pecuniary consideration. Consideration as applied to a court in legal phrenology, means the judgment of the court, 'it is considered by the court' being equivalent to 'it is adjudged by the court.' See Contract.

CONSIGNMENT, in law, the act of sending goods, as to an agent, for sale; also, the goods so sent. The one who sends the goods is known as the consignor, and the one to whom they are sent is known as the consignee. Usually when a consignment is sent by common carrier a bill of lading is given which serves as a receipt and contract of shipment.

CONSIORY, in ecclesiastical usage, means a court or council of ministers and Church officials or dignitaries, for transaction of business relating to the Church. In the Roman Catholic Church the Consistory by eminence is the whole college of the cardinals, which is, so to speak, the Pope's senate, assembled at stated or occasional times to deliberate questions of Church administration. It is usually presided over by the Pope in person, but often by his delegate; the stated meetings are twice a month; the sessions are secret usually and the meeting is merely formal, but often they are public when the cause of the meeting is the conferring, creating or removing of the hat on newly created cardinals; or semi-public, Church dignitaries of rank inferior to the cardinalate being admitted, the purpose of the meeting being to discuss a canonization. In the Church of England every bishop of a diocese has a consistorial court for determination of ecclesiastical causes arising within his jurisdiction.

CONSIOLACIÓN DEL SUR, kon-sō-la-thē-ôn' dĕl soor, Cuba, the name of a district and a city in the eastern central part in Pinar del Río province. It has railroad communications with Havana. Pop. of the district about 17,000; of the city 3,062.

CONSIGLATO DEL MARE, kon-sō-lä-tô dĕl mà're, a compilation of sea laws. See Commercial Law.

CONSOLIDATION OF SCHOOLS, the term used when two or more rural school districts are made into one district, one school in one building replacing two or more small schools in several buildings. In most districts this includes the transportation of pupils to the school at the public expense, either in special vehicles provided by the school, or in private vehicles, the expense being paid by the school. The primary motive is to secure better educational advantages for the pupils of the rural districts. The district schools have been pitifully inadequate because their number made necessary small salaries, and therefore poor teachers and poor equipment. This plan of the consolidated school is, in brief, as follows: two, three, four or five existing school districts, each maintaining small, inefficient rural schools, vote to unite their schools, or are consolidated by some central authority. A three- or four-room schoolhouse, built on modern lines, well ventilated and heated is erected at some central location. Arrangements are made for the transportation of all of those students at a distance. The school is organized under a principal, and often several consolidated schools unite in employing a supervising principal and teachers in special branches. The stimulus has been great enough in many cases to instigate the formation of a high school, grade school
and a specialized teaching staff. This plan of union is not possible in mountainous or sparsely populated districts. The advantages are numerous, although at first a consolidator and pupil. Secondly the opportunity for the country boy or girl is made equal to that of the city pupil, on account of the increased curriculum, the better organization and instruction and the other activities opened up for the country child. A third advantage is the cheaper cost. The effect on the neighborhood has been to increase interest and pride in the school and the stimulating of effort to provide better trustees, teachers and equipment. The objections, that the consolidated school is impractical, burdensome to the children, and deprecates value of the property near which the school formerly stood, have been removed slowly by experience, and the consolidated school has become a well-recognized institution both in the United States and Canada.

The movement began in New York State in 1853, when an act was passed permitting consolidation, known as the Union School Law, incorporated as Title IX of the Consolidated Act of 1864. Massachusetts followed next, and the movement spread rapidly. The North Central States have made excellent progress in consolidation; and nearly every State has some provision for union schools.

CONSOLS, or CONSOLIDATED ANNUITIES, a public stock forming the greater portion of the national debt of Great Britain. It was formed in 1757 by an act consolidating several separate stocks bearing interest at 3 per cent into one general stock. At the period when the consolidation took place, the principal of the funds united amounted to £45,689,105; but as the addition of other loans it has increased so much that now, after considerable reductions, it still amounts to more than half of the national debt, which in 1914 reached the enormous sum of £3,443,799,000.

CONSONANCE. See CONCORD.

CONSONANT. See ALPHABET.

CONSORT, he, she or that which shares the same lot with another; a companion; a partner; an intimate associate; a wife or husband; applied in a modest way to persons of royal degree or position, in countries where women are able to reign, as a queen consort; a prince consort; that is, the wife of a reigning monarch, or spouse of a queen-regnant. It is also applied to a ship sailing in company with another.

The queen consort, the wife of the reigning king, is, in all legal proceedings, looked upon as a single, not as a married woman. She may purchase and convey lands, grant leases and do other acts of ownership without the intervention of the king. She may also sue and be sued in her separate person, and possesses courts and officers distinct from those of the king. She pays no toll, and is free from any fine which a court could impose upon women in general; but in other respects she is on a similar footing with the other subjects of the king. In her life and person, however, she enjoys the same protection as the king; it being high treason to design the death of either. The husband of a queen-regnant is not endowed by the constitution with any distinctive rights or privileges. All his privileges and honors, therefore, must emanate from the Crown, under the form of a warrant, grant or patent, or else be conferred by act of Parliament introduced after a royal message on the subject. Up to 1857, when the title of Prince Consort was bestowed upon him by letters patent, the late Prince Albert possessed no distinctive title and no place in court ceremonial but such as was accorded to him by courtesy. An opposite instance was that of Ferdinand of Aragon, who, on his marriage to Isabella of Castile, became joint ruler of that country.

CONSPIRACY, legally defined, a combination by two or more persons, by some concerted action, to accomplish a purpose or to accomplish a purpose not in itself unlawful, by unlawful means. Some of the more important common law conspiracies were those to commit treason or sedition, to murder, to cheat and defraud and to murder maliciously. The common law recognizes as an offense the agreement between the conspirators to do an unlawful act, and no overt act is necessary for the completion of the crime. Changes have been made in this holding of the common law by the laws of several of the States and by Federal legislation in the United States. Where the changes have been made it has been declared that an overt act was necessary to make the conspiracy a crime. Conspiracies are ranked as misdemeanors, except such as by acts of legislation have been declared statutory conspiracies, and punishable as such, and they are ranked as felonies. Consult Bishop, 'New Commentaries on the Criminal Law' (Boston 1900); id., 'Commentaries on the Non-Contract Law' (Chicago 1889); also 'Encyclopedia of the Laws of England' (2d ed., London 1907).

CONSTABLE, Archibald, Scottish publisher: b. Carne, Fifeshire, 24 Feb. 1774; d. Edinburgh, 21 July 1827. He was the original publisher of the Edinburgh Review, the poems of Sir Walter Scott, the 'Waverley Novels' and other well-known works. In 1826, however,
the firm was compelled to stop payment, with liabilities exceeding $1,250,000. Sir Walter Scott, who was heavily involved, practically sacrificed his life in the endeavor to meet his creditors. He died, with merciful relief his misfortunes. He became publisher of the Scots Magazine (1801) and of the Edinburgh Review (1802), and owner of the Encyclopedia Britannica (1812), which he enlarged. He edited also a Chronicle of Fife (1810) and wrote his History of Macclesfield (1822). Consult Constable, Archibald Constable and His Literary Correspondents (3 vols., Edinburgh 1873), and Lockhart, Life of Scott (7 vols., London 1838).

CONSTABLE, Archibald, and His Literary Correspondents, a work by Thomas Constable (1873). It is the story of the Edinburgh publishing house which established the Edinburgh Review; initiated the publication of cheap popular volumes of literature, art and science; and by a bold liberality in payment of authors, with remarkable sagacity in judging what would succeed with the public, virtually transformed the business of publishing. In October 1802 the first number of the Edinburgh Review appeared. The generous scale of payments Constable ventured — 2 guineas a sheet — startled the trade, and greatly contributed to make Constable the foremost among publishers of his day.

CONSTABLE, Henry, English poet: b. Newark, England, 1562; d. Liège, Belgium, 14 Oct. 1611. His chief work was his book of sonnets, Diana, published in 1592, when few sonnets in the Italian form had been written. He was probably the author also of the Forest of Fancy (1579), attributed to Chettle. Suspected of treason against Elizabeth, he was compelled to leave the country, and on his return in 1604 was confined in the Tower for a short time. His lyric Diaphenia and his pastoral Venus and Adonis take a high place in contemporary song.

CONSTABLE, John, English pastoral painter: b. East Bergholt, Suffolk, 11 June 1776; d. London, 1 April 1837. His father was a wealthy miller, and was at first desirous that his son should enter the Church, and then on finding him disinclined to that career, proposed that he should follow his own business. At the latter employment he continued for several years, but his favorite pursuit was painting, and in this he would occupy his leisure hours. After considerable objection on the part of his father, but encouraged by Sir George Beaumont, he entered as a student of the Royal Academy in 1799. For many years his progress as an artist was extremely slow. He did not sell a single picture to a stranger until 1814, but he had one of two private buyers who detected the promise of great things in his work. In 1816 he married secretly Maria Bicknell, who died in 1828. In 1819 his View of the River Stour attracted some attention, and procure him admission as an associate of the Academy. Duly one of power and recognition abroad: he was awarded the medal at Lille in 1824, and another at Paris in the following year. Then followed his admission as a member of the Royal Academy (1826)—a tardy recognition which he did not value much. Constable's pictures are remarkable for the truth and vividness with which country scenes and natural phenomena are represented. Fuseli said of them that they made him call for his umbrella; and a French critic declared that his leaves and grass were bespangled with morning dew. He chose "unpicturesque" localities for his exquisite pastorals, and was the first to abandon the brown grounding adopted by the Dutch School for fresh and natural tints. For the first 12 years of his career he was able to develop along his own line of art, to please buyers, and ever after that, it was by the inheritances to which he succeeded, not by what he earned, that he was enabled to live. Some authorities regard him as the founder of the impressionist school which culminated at Barbizon. Among the finest of his works are 'A View of Salisbury Cathedral'; 'The Cornfield'; 'The Lock'; and 'The Valley Farm.' Lately several good examples of Constable's art have been added to the Louvre, and the late Henry Marquand presented two fine pictures by him to the Metropolitan Museum of Art in New York. Consult Leslie, Memoirs of Constable (1845); Wedmore, Studies in English Art (1876-80); Brock-Arnold, Gainsborough and Constable (1881); Cheston, Les Monuments Anglais (1882); Muther, 'History of Modern Painting' (1896); Holmes, C. J., 'Constable and his Influence on Landscape Painting' (New York 1903); and memoirs by Henderson, M. S. (1903), Tompkins (1907) and Bankart (1910).

CONSTABLE (Lat. comes stabuli, count of the stable — master of the horses). 1. A great noble under the later Roman Empire, and so down through the Middle Ages; usually the commander-in-chief of the army; in France also of the navy, and the chief subject in the state, when Richelieu abolished the office in 1627, Napoleon revived the title but not the authority, and it lapsed with him. In England the lord high constable and the earl marshal held the courts-martial and courts of chivalry; but Henry VII left the office unfilled, and it is only revived temporarily for great pageants. There were constables who were wardens of castles, and whose office is still existent, hereditary or appointive. 2. In England, a petty constable was the chief parish officer for keeping the peace, but is now mostly supplanted by the police. 3. In the United States, outside of cities and incorporated villages, the constable is still the chief conservator of the peace. The office was borrowed from England, and in colonial times was of high importance, including functions now assigned to various other officers. In New England he was appointed by the selectmen, in Virginia by the hundred, in other provinces or States chosen by the town. He not only made arrests, imprisoned, had right of search and executing processes, etc., but he was often tax collector, overseer of poor, and even petty judge, and gave notice of town meetings. There was no legally defined scope of his duties, each community deciding them for itself, but the place was always considered one of power and recognition, and with about 1830, when his functions were given to the chief of police. The office of constable of the commonwealth has also been created in some States. Consult Bacon, 'New Abridgment of the Law'; Dalton, 'The Country
CONSTANCE

Justice: Containing the Practice, Duty and Power of the Justices of the Peace.

CONSTANCE (Ger. Konstanz, or Konstanz, ancient Constantia), Germany, city and lakeport in the grand-duchy of Baden, occupying the only territory belonging to Germany on the south side of the Lake of Constance, at the place where that lake communicates with the arm known as the Untersee, "Lower Lake," and where the Rhine issues from it, 35 miles northeast of Zürich. It is 1,800 feet above sea-level. The chief edifices are a cathedral, the Kaufhaus, in which the famous Council of Constance sat from 1414 to 1418, and which deposed three anti-popes, and condemned Huss and Jerome of Prague; an ancient palace; a grand ducal residence. The city has manufactures of linen and cotton goods, carpets, chemicals and sacking. Constance is said to have been founded in 378 A.D. by Constantius Chlorus as a bulwark against the Alemanni. In the Middle Ages, when it reached its height of prosperity, at the time of the Council it was able to receive 20,000 visitors, it was frequently called Kostnitz. It was annexed to the Austrian dominions in 1548, and to Baden in 1805. Pop. 27,919.

CONSTANCE, General Council of, the 16th ecumenical council of the Church, was held at Constance in Switzerland; it was presided over by Pope John XXIII, in its opening session 5 Nov. 1414, and was dissolved in its 45th session 1418. It was called at the suggestion of the Emperor Sigismund for the purpose of dealing with the Hussite heresy; of considering measures for the general reform of the Church, and of restoring peace to the Church, which was troubled with schisms owing to the rivalry of three claimants of the papal throne. There was Balbaspur Conza, styled John XXIII; his title seemed to be sound in point of law, but the man was eminently unfit for the office; then there was Peter de Luna, styled Benedict XII; he was a Spaniard, but was chosen by the French cardinals; his style, Benedict XII, was formally disallowed when the Pope, Vincento Marco Orsini, who at first assumed the style of Benedict XIV (1724), afterward changed that to Benedict XIII; and there was Angelico Corario, styled Gregory XII; both of these had been condemned as perjured men, heretics and schismatics, by the Council of Pisa, which Council deposed them; but they still claimed papal honors. Besides the healing of these schisms, the Council was called to take measures for reformation of Wiclifism in England and analogous heresies in Bohemia and elsewhere. Also the Council was to consider the ways and means of effecting a "reformation of the Church in head and members." In the Council were some of the eminent divines of the time, among them Pierre d'Ailly and Ger- son, chancellor of the University of Paris, both sturdy advocates of reform; and also bishops representing the churches of England and Ireland. It is said that more than 18,000 priests, together with their retinues and many merchants and artisans, formed the brilliant crowd that collected in the city. John Huss, chancellor of the University of Prague, summoned to plead in the Council to the charge of maintaining the Wiclifite heresies, attended, having come under a safe-conduct of the Emperor Sigismund. The Council condemned the doctrines of Huss and ordered him to be given up to the civil power, to be dealt with according to the laws: he perished at the stake. Jerome of Prague met with the same fate. Memorable among the acts of this Council is its decision of a question submitted to the fathers regarding the succession to the sovereignty of the margraviate of Brandenburg. The Council recognized the superior validity of the claims of Conrad of Hohenzollern; from him is sprung the royal line of Prussia. The Council in the 12th session 29 May 1415 published a decree deposing John XXIII, who after a while formally resigned. In the 14th session Gregory XII (Corario) gave in his resignation. Petrus de Luna (Benedict XIII) refused to resign: but being no longer sustained by the king of Spain, he was simply ignored, and Cardinal Otto Colonna was elected Pope 11 Nov. 1417 under the style of Martin V. The schisms caused by the rival popes were ended. After a few reformatory measures, quite inadequate for the needs of the situation, were enacted, the Council was dissolved 22 April 1418. Consult Richtenal, "Kronik des Konstilichen Konzil" (Augsburg 1553; Tübingen 1882); Creighton, "A History of the Papacy during the Reformation" (London 1882); Wylie, "The Council of Constance" (ib. 1900); Finkel, H., "Forschungen und Quellen zur Geschichte des Kon- stimtes Konzils" (Paderborn 1899); and "La France et le grand schisme d'Occident" (Vol. IV, Paris 1902).

CONSTANCE, Lake (anciently LACUS BRIGANTINUS; German Baden See), in central Europe, forming a common centre, in which Switzerland and the territories of Baden, Württemberg, Bavaria and Austria meet. Length, northwest to southeast, 40 miles; greatest breadth, about 10½ miles; area, 204 square miles; greatest depth, 827 feet; 1,309 feet above sea-level. At its northwest extremity the lake divides into two branches or arms, each about 14 miles in length; the north arm is called the Überlingen Lake after the town of Überlingen, on its north bank; the south branch the Zellersee or Untere. The Rhine enters the lake at Rheinweil, at its southeast extremity, and leaves it at Stein, at its northwest termination. The lake, the waters of which are of a dark green hue and very clear, are subject to sudden risings, the causes of which are unknown. In 1770 it rose in one hour from 20 to 24 feet above the ordinary level. It freezes in severe winters only. It is frequented by numerous aquatic birds, and contains a great variety and abundance of fish, including salmon, salmon-trout, pike and carp. The traffic on it is considerable, although its navigation by sailing vessels is rendered dangerous by sudden and violent squalls. There are numerous remains of lake dwellings on its shores. Steamers ply on the lake between Constance and various points on its shores. The principal towns are Constance, Bregenz, Friedrichshafen, Lindau and Rorschach. The land near is either flat or gently undulating, and interspersed with corn-fields, orchards and gardens, interspersed with ruined castles, and other remains of the Middle Ages, and with numerous towns and villages, producing altogether a very pleasing and striking effect.
CONSTANS, Flavius Julius, Roman emperor: b. about 320 A.D.; d. in Gaul 350 A.D. He was a son of Constantine the Great, and divorced his first wife with his brothers, Constantine II and Constantius II, receiving for his share Illyricum, Italy and Africa. Constantine, who invaded his provinces, having been slain in the battle of Aquileia, Constans became emperor of the whole West. He was weak, profligate and rapacious. His misrule caused an insurrection in Gaul under Magnentius; he fled to Spain, but was overtaken at the foot of the Pyrenees by the soldiers of the usurper, and slain. Constans protected the creed of Nice against the Arians and the Donatists, and closed the pagan temples.

CONSTANS, kon'sтанъ. Jean Antoine Ernest, French statesman: b. Béziers, 3 May 1833; d. Paris 1913. He was a professor of law in 1876, when he was elected a deputy and affiliated with the Left Centre. He was Under-secretary of State in the Freycinet Cabinet in 1879, and was Minister of the Interior in the Freycinet and Ferry cabinets of 1880-81. After serving for one year as governor-general of Indo-China, he was compelled in 1888 to resign this position as incompatible with his duties as a deputy. From 1889 to 1892 he was again Minister of the Interior, and his vigorous measures served to overthrow Boulangerism. In 1897 he was elected to the Senate, and in the following year became Ambassador to Constantinople.

CONSTANT, kon'stanъ. Jean Joseph Benjamin, French portrait painter: b. Paris 10 June 1845; d. there, 26 May 1902. He studied in the École des Beaux-Arts at Toulouse and Paris, and under Cabanel. A journey to Morocco in 1872 strongly influenced his artistic development. He has exhibited with growing distinction, at successive salons, from that of 1860, with his 'Hamlet,' his 'Samson' in 1872, his 'Scenes from Algiers' in 1873-74, his great historical painting of 'Mohammed II in 1453' in the Exposition of 1878, and in 1885 a large Oriental subject as melodramatic as possible, with splendid rendering of the human figure and strong effects of color. Other noted canvases by him are 'Le roi du désert'; 'Le tigre favori'; and portraits of Mme. Walters; Madame Gauté; Queen Victoria, exhibited in the Salon of 1901; Queen Alexandra; and De Blowitz. A good example of his portraiture is 'Mon Fils André' (Luxembourg), which took the medal of honor at the Salon in 1896. He was the fashionable artist of his time in Paris and London. His noble picture of 'Justinian' is in the Metropolitan Art Museum, New York. He was decorated with the Legion of Honor in 1878. He was a writer of repute, best known for his studies of contemporary French painters. Consult Strahan, 'Modern French Painters' (New York 1893).

CONSTANT DE REBEQUE, de-rebek', Henri Benjamin, French politician and author: b. Lausanne, Switzerland, 25 Oct. 1877; d. Paris, 8 Dec. 1880. His mother died at his birth and his father was an officer in the military service of Holland. He was brought up at Brussels at the home of Mme. de Nassau; studied at Erlangen in Franconia, and later at Oxford and Edinburgh where he met Mackintosh and became familiar with the government of the British Isles which he admired very much. He began his government studies in his paper 'Essai historique sur les mœurs des temps héroïques de la Grèce.' His ill health and general dissatisfaction with life caused him to leave England. He returned to Switzerland in 1786, where he showed a talent for journalism, leaving for Paris in the following year. Here at the salon de Suard he met Mme. de Charrière, a woman of great mental powers, 27 years older than himself, with whom he formed a liaison which lasted for almost 10 years. A wild affair took him to England for a brief visit. After his return he became chamberlain at the court of Charles William of Brunswick. Here he married Mlle. Wilhelmine, Baroness of Chram, a woman of little beauty but good intellect. His father became involved in political difficulties. The matter was finally settled satisfactorily with Benjamin's assistance and his father was not only exonerated but made a general. At this period Benjamin ventured on some new literary projects: 'Accounts of State and Memoirs of Paoli' (1768), 'De la religion'; he undertook a comparison of the customs of the Greeks with those of the Celts, Germans, Scotch and Scandinavians. After Brunswick's manifesto against France, he divorced his wife (1794) and returned to Lausanne. He now entered upon a period of political restlessness and personal entanglements which consumed his entire life. At Lausanne he met Mme. de Staël, for whom he conceived a violent passion, and followed her to Paris in 1795. In the republican circle of which she was the centre, he soon became an important figure. He was a staunch supporter of the Directory and of a moderate republicanism. The consistent factor in his political life was his desire to see France a well-governed state. In defense of this he published his first political pamphlet, 'De la force du gouvernement,' in which he sought to induce all the parties of the Directory to rally against the Counter-Revolution. This essay involved him in a duel with Bertin de Veauche—a one of a series of such encounters. In 1793 his title as a citizen had been contested on the ground of his Swiss birth, but his election as president of the canton of Luzarches and the reunion of Geneva and France in 1799 suppressed the question. About this time he formed the constitutional club of Salm, named after the hotel where it held its séances. It was formed to oppose the Royalist faction at the club of Clichy. In attempting to find a working middle ground, he joined forces with Barras and Tallleyrand against Carnot and Barthelemy—a move which he regretted later. In 1799 he was made member of the Tribunate where he was attacked violently for his republican sentiments, which alienated the trust of Napoleon, and in 1802 he was finally eliminated. Mme. de Staël was held accountable for his republicanism, and she was also banished. Constant followed her to Germany, where her salon again became renowned at Coppet. He spent some time in Weimar, where he became steeped in the religious and literary opinions of Schiller, Wieland, Schlegel, Müller and Goethe. He returned to Coppet in 1805; contracted a short liaison with Mme. Lindsay and eventually became married secretly to Charlotte de Harden-
CONSTANTIA—CONSTANTINE I

berg in 1808. At this time he produced a tragic poem, 'Wallenstein,' after the manner of Schiller's trilogy. At Hardenberg he lived for a while with his wife's parent, where he worked on his book on religion. Here he was influenced by the spiritual mysticism of Herder, Cremer, Schleiermacher and Heeren, and his sceptical philosophy was lost. His father died in 1812. Constant continued his studies and published several political pamphlets attacking imperialism. At Hanover, he received a visit from the crown prince of Sweden who conferred on him the Royal Star. After the abdication of Fontainebleau he returned to Paris and at the salon of Mme. de Staël once more became an ardent publicist in behalf of liberal principles and freedom of the press. A series of pamphlets set forth his views on these subjects. During the One Hundred Days his political position was decidedly weak. The return to Paris of Napoleon caused him to flee for a short time, but he soon returned, doubtless because of his unrestrained passion for the famous beauty, Mme. Récamier, and had an interview with her. In 1823 he was appointed a Councillor of State. After Waterloo and the return of Louis XVIII he went to England, where he published 'Adolphe,' the first psychological romance. It is largely autobiographical. Mme. de Charrière and Mme. de Staël are the prototypes of the heroine. In 1816 he returned to Paris, where he founded two liberal journals in which he renewed his advocacy of freedom of the press and liberal constitutionalism. In 1819 he was re-elected to the Chamber of Deputies; and again in 1824 and 1827. Enraged by his political activities, he was imprisoned but released. He then took part in the coronation of Louis Philippe, and on 27 August was made president of the Chamber of Deputies. His position was weakened by the acceptance of 200,000 francs from the king for the payment of his gambling debts which he had accrued when the death of Mme. de Staël in 1817 had caused him to withdraw almost entirely from society. In 1830 he was presented to the Royal Academy, but was rejected. Constant's egoism and his amours prevented his political ability from reaching its highest point. His greatest contribution to his party lay in his persistent fight for the freedom of the press. He was a poor debater, but the brilliant forcefulness of his philippics minimized that fault. His speeches are collected in 'Discours' (2 vols., 1828); his essays on government in 'Cours de politique constitutionnelle' (4 vols., 1817–20). His book on religion, 'De la religion considérée dans sa source, ses formes, et ses développements' (5 vols., 1825, 1833), is generally considered his best work. Consult Sainte-Beuve, 'Nouveaux lundis' (Vol. I, Paris 1863), and 'Portraits littéraires' (Vol. III, ib. 1864); Constant's own 'Cahier Rouge,' which contains his autobiography from 1767–87 (1907), and 'Journal intime' (1804–16, re-edited with 'Lettres à sa famille,' by D. Melegari, 1895); his letters to Mme. de Charrière and Mme. Récamier, edited by Mme. Lenormant (1882); Rudler, G., 'La jeunesse de Benjamin Constant' (1900); and 'Bibliographie critique' (1909).

ROSE BOOCHEVER, 
Editorial Staff of The Americana.

CONSTANTA, a district in the province of Cape of Good Hope, South Africa, on the eastern and northeastern slopes of Table Mountain range, and distant from Cape Town seven miles. Constantia consists of only three estates, High, Great and Little, which have long been famed for the quality of the wines produced upon them. The wines are sweet wines of delicious aroma, both red and white. Consult Mrs. Trotter, 'Old Cape Colony' (London 1909).

CONSTANTINE (kōn'stān-tīn) I. Pope. He was elected in 708 and died in 714. The principal events of his reign were the submission of Felix, archbishop of Ravenna, to Rome; and Constantine's confirmation of the Quinquennial Council at Constantinople. There was also an anti-pope of this name, who usurped the holy office in 767.

CONSTANTINE I. Flavius Valerius Aurelius Constantinus, called the Great, Roman emperor b. Naissus, in Moesia (Serbia), 27 Feb. 274; d. Nicomedia, 22 May 337. He was the son of the Emperor Constantinus Chlorus, and after the death of his father was chosen by the army to succeed him, and 306 Galerius was very unwilling to allow him the title of Augustus, and gave him that of Caesar only. Constantine, however, took possession of the countries which had been subject to his father, namely, Gaul, Spain and Britain. He overcame the Franks, who had formerly overrun the territory of Gaul, made prisoners of two of their leaders, followed them over the Rhine, surprised and defeated them. He then directed his arms against Maxentius, who had joined Mithridates and was his ally; 312. He conquered him, and in the campaign in Italy he saw, it is said, a flaming cross in the heavens, beneath the sun, bearing the inscription, 'In hoc signo vinces' (Under this sign thou shalt conquer). He accordingly caused a standard to be made in this form, which was called the labarum. Some days after this he vanquished the army of Maxentius, under the walls of Rome, and drove it into the Tiber. He then entered the city in triumph, set at liberty all whom Maxentius had unjustly imprisoned and pardoned all who had taken up arms against him. He was declared by the Senate chief, Augustus, and pontifex maximus. In the year 313, together with Licinius, he published the memorable edict of toleration in favor of the Christians. By this every one was allowed to embrace the religion most agreeable to his own mode of thinking, and all the property was restored to the Christians that had been taken from them during the persecutions. They were also made eligible to public offices. This edict marks the period of the triumph of the cross and the downfall of paganism.

Constantine had married his daughter to Licinius; but the latter, jealous of his fame, conceived a mortal hatred against him, which he displayed by persecuting the Christians. Both emperors took up arms and met in Pan- nonia 314 a.d. Licinius was beaten, but the conqueror granted him peace. He, however, renewed hostilities, was vanquished again, taken prisoner and put to death at Constantinople. Thus the latter became, in 325, the sole head of the Eastern and Western empires. His first and chief cares were the establishment of peace and order, and the propagation of his religion. Many beneficial decrees were proclaimed by him. Among these were those which
abolished all the establishments of debauchery, ordered the children of the poor to be supported at his expense, gave permission to complain of his officers, and promised that he would not only hear complaints, but compensate the complainants for injuries received, when they were proved to exist. He diminished the land-taxes and caused a new valuation of estates to be made. The country districts were always enriched by the property of criminals; but Constantine spared the property of their wives and ameliorated the condition of their children. Death in prison, he said, was a cruel punishment for the innocent, and an insufficient penalty for the guilty; he therefore ordered all trials of prisoners to take place at once. He forbade the use of unwholesome dungeons and oppressive chains. He gave leave to sick persons, widows and orphans to appeal from the local magistrates, and refused this privilege to their adversaries. It had been customary for the heirs of a person deceased to divide his slaves among them; Constantine forbade the separation in these cases of husbands from their wives and of their children from their fathers. To the Christians he gave permission not only to erect churches, but to be remunerated for the cost of them from his domains. Amidst all the cares of government and the occupations of war he found leisure to assemble the Council of Arles, to put an end to the schism of the Donatists. The ecumenical council held at Nice, in Bithynia 325 A.D., was attended by him in person.

On 26 Nov. 329 he laid the foundations of a new capital of the Empire, at Byzantium, upon the Bosporus, in Thrace. The city of Byzantium had been almost entirely destroyed by Severus; it was rebuilt by Constantine, enlarged and adorned with open squares, fountains, a circus and palaces, and called by his own name. Constantine divided the Empire into four parts, governed by four praetorian prefects. Toward the close of his life he favored the Arians, to which he was induced by Eusebius of Nicomedia; and he even banished many Roman Catholics. In the year 337 he fell ill in the neighborhood of Nicomedia, was baptized, and died after a reign of 31 years.

Constantine committed a great political error in dividing his empire among his three sons, Constantine, Constantius and Constans. His zeal for Christianity appears to have been excited not less by the knowledge that the religion which was embraced by a majority of the inhabitants of the Roman Empire must prevail, and that, of course, the strength of the government must be increased by protecting it, than by a wish to apply its consoling powers to the relief of a heavy conscience. He has been accused of inordinate ambition, excessive liberality and an Oriental fondness for parade. But he was brave in action, and unflagging in his intercourse with his subjects, the favor of his people, the terror of his foes. He was fond of the sciences as well as of arms, and gave them his protection. He read much, and wrote notes in his manuscript. In Eusebius we find many proofs of his theological learning. Some of the martyrlogists have counted him among the saints, and fix 20 May as his festival. The Greeks and Russians observe it upon the 21st of the same month. Among all the writers who have written on the life, influence and policy of Constantine, Gibbon, from the extent of his researches and the profoundness of his views, appears to deserve the first place, though his impartiality is more than doubtful. Consult Eusebius, Vita Constantinim; Gibbon, 'Decline and Fall of the Roman Empire'; Firth, 'Constantine the Great' (New York 1905); 'Cambridge Mediaeval History' (Vol. I. ib. 1911); Fletcher, 'Life of Constantine the Great' (1897).

CONSTANTINE II, Flavius Claudius Constantius, Roman emperor: b. Arles, Gaul, 7 Aug. 312; d. near Aquileia, Italy, 340. He was the eldest son of Constantine I, and received as his share of the empire, on the death of his father, Gaul, Spain and Britain. Being desirous, however, of possessing himself of the territory of his brother Constans, he invaded the latter's dominions, but was defeated and killed.

CONSTANTINE III, a son of the Emperor Heraclius: b. 3 May 612; d. 23 June 641. He reigned only a few months after his father's death.

CONSTANTINE IV, Flavius Constantius, Emperor of the East; surnamed Pogonatus, or the Bearded: d. 685. He was son of Constans II, whom he succeeded in 668. His two brothers, Tiberius and Heraclius, shared the title of Augustus, but had little or no share in the government, and indeed the chief power of the empire. The reign of Constantine IV, under the influence of suspicion, had them mutilated and put to death. Constantinople was unsuccessfully attacked by the Mussulmans in 672 and the six following years; and it was during these wars that the famous "Greek fire" was invented. He was unable to repel the attacks of the Bulgars who crossed the Danube and settled in the country which they still inhabit (679). Constantine convoked and took part in the sixth general council held at Constantinople, at which the doctrine of the Monothelites was condemned.

CONSTANTINE V, Emperor of the East: b. Constantinople 719; d. near Selymbria, Thrace, 14 Sept. 775. He was surnamed Comnenumus and succeeded his father, Leo the Isaurian, in 743. He sided with the Iconoclasts, and even, with the images of the saints, and persecuted the followers of the Roman Catholic Church. The important result was that the Pope turned to Pepin, king of the Franks, for protection, and thus shifted the dependence of the popes from Constantinople. In spite of his religious persecutions, he was a splendid civic ruler, and did much to restore trade and commerce. He died in an expedition against the Bulgarians.

CONSTANTINE VI, Flavius Constantinus, Emperor of the East: b. 771; d. Constantinople about 797. He was son of Leo IV, whom he succeeded in 780. Being only 10 years old when his father died, his mother, Irene (q.v.), was his guardian and regent of the Empire. On arriving at a mature age he wished to assume the government himself; but Irene, made cruel by ambition, had him imprisoned. He escaped in 790, exiled his mother, recalled her, and finally, ruined by his licentious living, and despised by his subjects, Irene led a conspiracy against him. He was imprisoned and his eyes were put out by her order. With him the Isaurian dynasty died out. Consult Schlosser, F. C., 'Geschichte der bildstrumen-
CONSTANTINE VII, Emperor of the East; b. 1055; d. 11 May 1095. He was the son of Romanus II, Emperor of the East, and succeeded Leo the Wise as sole ruler in 945. He was destitute of energy, and devoted himself chiefly to study and the patronage of arts and letters. He admitted colleagues to the throne so that the last five emperors were reigning together. He was poisoned by his son Romanus in 959. Constantine VII left a treatise on state affairs, a geography of the empire and the 'Life of the Emperor Basilius, the Macedonian.' Several important works, to which we are indebted for historical knowledge, undertaken at his instigation, were 'Historia,' 'Basilica,' 'Geoponica' (agricultural treatises), 'Iatrica' (medical handbook), 'Hippiatrica' (on veterinary surgery), 'Historia animalium,' a compilation of Aristotle's views on the subject by Aristophanes of Byzantium, with additions from other writers. Consult Migne, 'Patrologia Graeca' (cix, cxii, cxiii); Rambaud, A., 'L'Empire grec au xiiie siècle' (1870).

CONSTANTINE VIII, Emperor of the East; b. 1088; d. 1120. He was the son of Romanus II, succeeded John Zemisces, and was proclaimed emperor of the East, with his brother, Basil II, who held the principal authority till 1025, when he died. Constantine VIII was, after that, sole emperor.

CONSTANTINE IX, surnamed Monomachus, was emperor from 1042-55. He owed his position to his marriage with Zoe, the widow of Romanus III, who became empress in 1041. His reign was occupied with rebellions both at home and abroad. He had to wage war against the Turks, the Normans, the Patzinaks and the Russians.

CONSTANTINE X, Ducas, emperor from 1059-67: b. 1007; d. 1067. He was the husband of Eudoxia. He succeeded Isaac Comnenus, whose friend and minister he had been. He was unsuccessful in repelling the attacks of the Normans in Italy and of the Turks and Magyars, and thus lost large portions of the kingdom. He besieged the Russians in 1043. A plague was more effectual in resisting the encroaching enemies.

CONSTANTINE XI, Palæologus, Dragates or Dragoses, Emperor of the East: b. 1304; d. 29 May 1453. He was the son of Manuel II and the last of the Greek emperors, succeeding to the throne in 1448. His wife, Helena, was of the dynasty of Palæologus. He took possession of Morea and of much of the Peloponnesus and defeated the Turks in many battles. In 1446 Murad II forced him to surrender the Peloponnesus again. He was killed in bravely defending Constantinople against Mahomet II, who in 1453 besieged the city with 300,000 men. The heroic valor displayed by Constantine XI in this unequal contest demands our admiration; but valor was of no avail, the city was taken by storm, and thus ended the Greek Empire. Consult Mijatovich, 'Constantine, the Last Emperor of the Greeks' (London 1892).

CONSTANTINE, Nikolaevitch, Russian grand duke: b. Saint Petersburg, 21 Sept. 1827; d. there, 24 Jan. 1892. He was the second son of the Emperor Nicholas of Russia, and brother of the Emperor Alexander II, grand duke and great admiral of Russia. In the war of 1854-56 he had the defenses of the Baltic committed to his care, in conjunction with Admiral Lütke; but the policy of the emperor hardly allowed the prince any display of courage or ability. He supported his brother's liberal reform plans and worked earnestly for the enlightenment of Russia. He was made vicerey of Poland in 1862, but resigned next year. He was president of the council of state 1865-81, but being suspected of sympathizing with the revolutionary party was dismissed from office. When Alexander III became king, he removed his uncle from all of his important offices, and Constantine retired to the Crimea.

CONSTANTINE, Pavlovitch, Russian grand duke: b. Saint Petersburg, 8 May 1779; d. Vitebsk, 27 June 1831. He was the second son of the Emperor Paul of Russia, and with his brother Alexander was brought up under Catharine II. In the wars against France he distinguished himself by his personal bravery, though not by his capacity for command. He was the elder brother of Emperor Nicholas, to whom he ceded the crown on the death of Emperor Alexander I, their brother. Constantine was afterward made vicerey of Poland, and ruled that unfortunate country with great severity. Poland revolted in 1830 and he was obliged to flee. He died of the cholera.

CONSTANTINE, Africa, town in the French territory of Algeria, capital of the department of Constantine, on a rocky peninsula, 2,162 feet above the sea, 830 feet above the river Rummel, which washes it on two sides, and accessible only on one side. It is surrounded by walls, built by the Arabs chiefly with stones which the Romans had hewn and carved, and is entered by four handsome gates. The streets, though well paved, are narrow and dirty, and the houses are very indifferent. The only edifice deserving of particular notice is the palace of the bey, now the residence of the French governor. It is more remarkable for its internal decorations than for its external structure. Both within the town and in the vicinity Roman remains are common, and an episcopal see of a Catholic bishop. The modern or French portion has wide streets and open squares. Its principal buildings are the Palais de Justice, administration buildings, the Protestant church and a theatre. The French have here a college and the Mohammedans a seminary. The manufactures consist chiefly of woolen and linen goods and various articles in leather; the trade is in corn, linen and wax. It is connected by railroad with Philippeville, its port of entry, 47 miles distant, and with the largest towns in the territory. Constantine was built by the emperor whose name it bears, on the site of Cirta, the capital of the Numidian kings, which had fallen into decay. In 1837, after a long siege, the French took it by assault. Pop. 61,413.

CONSTANTINE, Arch of, one of the noted triumphal arches of the world, erected by order of the Roman Senate to commemorate the victory gained by Constantine over Maxen tus. It is situated between the Celian and Palantine Hills, and was built in 315. This monument of victory is well preserved, but
while it tells of the power of the Emperor Constantin, it also bears witness to the incompetency of the Roman sculptors of the period in which it was built. The whole design was copied, but not improved on, by the Greeks, whose reliefs were removed to the Arch of Constantine, and they illustrate the battles and victories of Trajan and not of Constantine. The parts copied or taken from Trajan are of superior design and workmanship, but the sculpture of the artists of the day, representing the deeds and victories of Constantine, are inferior in design and crude in workmanship. Four stately columns are on each face, one high and two lower entrances. The inscriptions proclaim the great deeds of the emperor. The arch was left standing in the Middle Ages probably because it was built by a Christian emperor. Consult Platner, 'Topography and Monuments of Ancient Rome' (New York 1911); Frothingham, 'The Mysteries of Constantinople Unveiled' (in the Century Magazine for January 1912); Frothingham, 'Who Built the Arch of Constantine?' (in American Journal of Archæology, 2d series, Vols. XVI, XVII, 1912, 1913).

CONSTANTINOPLE, Turkey ('the city of Constantine'), called Istanboul by the Turks (corrupted into Stamboul), from the Greek ισταντιον, to the city; in official Turkish always Constantinieh; capital of the Ottoman Empire, situated at the junction of the Bosporus and the Sea of Marmora, in lat. 40° 0' 16" N., long. 28° 59' 14" E. It is practically an agglomeration of three towns, Stamboul, Galata-Pera and Skutari, besides a number of suburbs scattered for a distance of 12 miles along both sides of the Bospors. The two first-named are on the European shore, divided by the Golden Horn, an inlet of the Bospors about 500 yards wide and nearly six miles long. Stamboul, or Constantinople proper, occupies the site of ancient Byzantium, built, like ancient Rome, on seven hills. The peninsula on which the city stands has the form almost of a triangle or, more correctly, of a trapezium, surrounded on all sides by water excepting the west. The Bospors is 12 miles long and 100 yards in extent. The eastern side projects into the Bospors; the western forms a lofty double wall of five miles in length, stretching across the promontory from the Sea of Marmora to the Golden Horn; on the opposite side of the latter, also occupying the extremity of a promontory, sometimes called the Peninsula of Pera, are the extensive suburbs of Galata, Pera, Top Hanch and Kassim Pasha. Galata (formerly Syke) and 'Sycé' (fig-trees) received its name from the fig-trees which were a settlement there. It is now the district where the banks, shipping agencies, stock exchange and offices of the representatives of European firms are established. Pera, adjoining Galata, is situated on the heights immediately above it, and is called the European or *Frankish* quarter. Here the Europeans, Levantines and most of the Greek and Armenian population live, and all the hotels, embassies and consulates are situated. Kassim Pasha is a dirty, insalubrious district around the dockyard of the Turkish fleet generally lies at anchor. Prominent on a plot of land stretching into the Golden Horn is the Admiralty, a fine marble building, and close by are the graving-docks, slips, building sheds and workshops. Directly above is the Naval Hospital. Opposite Kassim Pasha, on the Stamboul side, lies Phanar, a grimy suburb, inhabited mainly by Greeks. It is the seat of the patriarch and contains the relics of Saint George. Just beyond lies Balata, noted for its filthy condition, almost exclusively inhabited by Jews; the better class Jews live at Haskeuf, on a hill opposite Balata, with a large percentage of Armenians. Further up, on the opposite shore again, lies the village of Ayoub (Eyoub), exclusively inhabited by Moslems; no Christians are allowed to hold property here. The spot is deeply revered by the faithful on account of the mosque built by Mohammed II, the Conqueror, in which each succeeding sultan is girded with the sword of Othman at the coronation ceremony. The adjoining burial ground contains the mausoleums and graves of numerous high personages. Skutari, properly Uskudar, *over the Bospors*, stands on the site of ancient Chrysopolis; population, about 50,000. Its main objects of interest are the British and Turkish cemeteries and the convent of Howling Dervishes. The British Cemetery is the finest in Constantinople, and is situated at the Marmora end of Skutari near Haidar Pasha. In it are buried many British soldiers who died during the Crimean War; one part was reserved for the interment of British residents. Adjoining the cemetery is the Skutari Hospital, once the scene of the devoted labors of Miss Florence Nightingale (q.v.) and her staff of British nurses. The Turkish Cemetery is the largest in Constantinople—a vast city of the dead—a wilderness of tombs thickly planted with the funeral cypress. On a submerged rock off Skutari is the square lighthouse known as Leander's Tower, a name given to it by the Crusaders, though it has no connection with the legendary hero of that name. The Turks call it Kiz Kuleh, or the Maiden's Tower. It was first built as a mausoleum in 340 B.C., subsequently became a wooden lighthouse and was gradually replaced by a massive stone tower 90 feet hight. Skutari has several theological colleges, schools, baths and a large Turkish printing-press. Near by is Haidar Pasha and Kadikoufi, farther south, face the Sea of Marmora; the former is the terminal of the Constantinople and Angora Railway and a favorite Moslem picnic resort; the latter, standing on the site of ancient Chalcidon, is largely a European residential district, having all-day steamer communication with Galata. The other suburbs on the Asiatic side of the Bospors above Skutari are, next, Kuzunjik, a Jewish village where the Chief Rabbi resides; Beylerbey, exclusively Turkish, with a fine mosque and a white marble palace; the latter formerly contained the private menagerie of Abdul Aziz; Chengel Keui, a village; Kuleli, or Kuleh Bagtcheh (Garden Tower), where some 25 years ago Roman and Byzantine tombs, columns and marbles were unearthed; Vani Keui, founded 1665; Kandilli, on the site of ancient Perirrhous; Anadoli Hisar (q.v.); Kanlijia (bloody village), so named from the color of the rocks; Chihukli, where Saint Marcellus founded the Turkish Order of Vigilants in 420 A.D.; Pasha Bagtcheh, notable for its fine mosque built in 1763; lastly, Beikos, the largest village on the Bospors, with extensive vineyards and a palace built by Mehmet Ali.
Pasha of Egypt. Crossing over to the European shore again and starting from Galata up the Golden Horn, the following places of interest included with Constantinople are Top Haneh (cannon building, i.e., gun foundry); Kabat Tash; Besik Tash (reclade-stone), the tomb of Ghazi Khaireddin, the terror of the Christians; Orta Keui, a large village in the ancient Saint Phocas, containing great market-gardens, the Yeni Valideh Mosque, and residences of state ministers; near by is the imperial residence, Yildiz Kiosk, Kuru Chesme, a dirty village inhabited by Armenians and Jews, formerly the residence of Wallachian Hostodars; Armut Keui (q.v.), the Byzantine Michaelion; Bebek (q.v.), where the famous Robert College (q.v.) is situated; Rumelihissar, the "Citadel of Europe; Balta Liman, where the treaties of 1838, 1841 and 1849, relating to the Danubian tributary states, were signed; Boyaji Keui, a village; Emlagian, site of the ancient Kyparodis, famous for its cypress grove, mosque, marble feasting place, residences, and palaces; Stenia (q.v.); Yeni Keui, containing ambassadorial summer residences and magnificent villas of wealthy Levantines; Therapia (q.v.), the famous health resort; and Buyuk Dereh ("Great Valley"), also a summer resort for the wealthy, situated 11 miles from Galata.

Constantinople is far from being a beautiful city, yet its natural position and picturesque appearance combine to make it one of the most gorgeous sights in the world—at a distance, which in this case truly lends enchantment to the view. No other city can claim to be situated on two continents, Europe and Asia; and certainly none has a more thrilling and romantic history. Poets, artists and authors have endeavored in song, color and prose to depict the vision of Constantinople from the deck of a vessel on a fine summer's morning. It resembles rather some enchanted city of the Arabian Nights than a real town of stone, brick and mortar. The seven low-lying hills, covered with buildings of all descriptions down to the water's edge, painted in more colors than the rainbow can boast of, with white kiosks, marble palaces, cypress trees, minarets and cupolas piercing the heavens, with a background of the eternal sky and a foreground of the Sea of Marmora, in the limpid waters of which the town is reflected as in a mirror; the Golden Horn, crowded with shipping and bright with the flags of all nations; innumerable canoes (rowing and sailing boats) and steam launches bearing gaily-attired civilians and uniformed officials; the multitude of different languages and jargons that greet the ear, marking the dividing line between the poetic East and the prosaic West: all these make up a rare confusion of form, color and sound, land, sea, sky and water, that create a lasting and indescribable impression on the mind. Gibbon was fascinated by the scene, formed by Nature for the centre and capital of a great monarchy; Aubrey de Vere wrote that the view of Constantinople from the sea is the most splendid of all the pageants presented to the human eye by the metropolitan cities of the earth. More recently Dr. Edwin A. Grosvenor wrote, "In the word Constantinople there is the blended magic of mythologic romance, history, and poetry..."...the queen city of the earth, seated upon a throne..." He also calls attention to the remarkable fact that the same great parallel which encircles the globe between 40° 20' and 41° 50' in north latitude includes Constantinople, Rome, Madrid, New York and Chicago.

But the scene changes suddenly and painfully when the traveler steps ashore and proceeds to stumble along the narrow, dirty, wretchedly-paved alleys which do duty for streets, and climbs the rocky staircase leading from Galata to Pera. Until 1910 he had to pick his way cautiously among and over the countless manly, half-starved pariah dogs which infested the town and lived on street garbage. These have since been captured by gypsies, conveyed in caiques to the isle of Oxia in the Sea of Marmora and left to devour each other. Noisy, vociferating hamals or porters shuffle along the streets staggering under heavy loads and shouting "wárdá" (look out!). Donkey drivers and muleteers yelling at their animals; hawkers and peddlers shrieking out the excellence and cheapness of the residence, and palaces; Stenia (q.v.); Yeni Keui, containing ambassadorial summer residences and magnificent villas of wealthy Levantines; Therapia (q.v.), the famous health resort; and Buyuk Dereh ("Great Valley"), also a summer resort for the wealthy, situated 11 miles from Galata.

Population.—In the absence of any reliable official statistics the population of Constantinople is estimated at between 1,000,000 and 1,200,000, about half being Mohammedans and the rest Orthodox Greeks, Armenians, Jews, Europeans, Africans and Asians.

The climate is healthy on the whole but extremely variable, and unsuited for those suffering from pulmonary affections. The best time for visiting Constantinople is in April, May, September and October, before and after the hot season.

Walls.—Constantinople was formerly walled on all sides; very little now remains of the walls on the seaward sides, but those on the land side are still in a fair state of preservation and extend across the peninsula from Ayub to Yedi Kuleh (Seven Towers) on the Sea of Marmora, from which begin the Walls of Theodosius (3½ miles), a double line with a moat 64 feet wide and a breastwork 58 feet thick running between them. The moat is now divided into market gardens. The inner wall is 36 feet high and was flanked by 116 towers, of which about 90, in a dilapidated condition, still remain. The outer wall is 31 feet high and 13 feet thick, and was flanked with 78 towers, most of which are still there. Fourteen gates led through the wall, seven being formerly used for military purposes. Of the Seven Towers, the Byzantine citadel, three were destroyed by earthquake in 1758. The place also served as a state prison. The main gates are the Golden Gate, Yedi Kuleh Kapu, Yeni Kapu (New Gate), Silivri Kapu, Mevlevi Han Kapu, Top Kapu (Cannon Gate), Eghri Kapu (Crooked Gate) and Edirneh Kapu (Adrianople Gate). Near the Golden Gate is the grave of Ahmed Kiupruli Pasha, who was hanged on his return from the capture of Candia after a 24 years' siege of the gates in 1669. It contains historical associations, inscriptions and architectural embellishment. An excellent account of these is given in the Constantinople guide book of D. Coufopoulos (London 1895). Beyond Tekfur Sarai stand the Wall of Leo the

Constantinople

Armenian (813 A.D.) and the Wall of Heraclius (622 A.D.).

Monuments and Churches.—There are 379 mosques scattered over Constantinople and environs, all of them more or less distinguished by grandeur and beauty; but the most remarkable are the royal mosques, of which there are about 12. Among the finest are the Sancaktepe, the largest; the largest and most splendid is the Suleimanich, situated on the northeast side of the city, and standing in the midst of a large square, surrounded inside by an arcade upon pillars of granite and marble. Next to it in extent, but of much older date, is the famous mosque of Saint Sophia ("Ayiah Sophia"), near the east extremity of the city, the pattern of almost every mosque in the land; its walls and domes, of which last it has 20 of equal dimensions, springing from the same level, and sustained by 12 huge columns, are encrusted with mosaics, forming various figures and devices. The court or open square in which it stands is paved with marble and shaded by fine plane trees. It was restored by Italian and English architects in the 19th century by order of the sultan, and the layer of plaster removed by which the superb mosaics and frescoes that decorate its walls were covered. The mosque of Valens, also as that of the Sultana Valideh, was built by the mother of Mohammed IV, and is esteemed one of the most magnificent in the capital. It is constructed of white marble and has two peculiarly elegant minarets, encircled by three galleries of richly perforated workmanship. The principal dome rests upon four lesser ones, which appear to lift it to the clouds. The celebrated mosque of Sultan Ahmed is noted for its vastness and its enormous columns, 75 feet in circumference. The minarets are of great beauty and ascend to an immense height. The mosque of Sultan Bayazid contains the finest courtyard in the city. A vast number of pigeons haunt its precincts. Rustem Pasha mosque is remarkable for its tile work. The church of St. Irene, which is now used as a museum of ancient arms. Among its relics are the swords of Mohammed II and Skander Bey and an armet of Tamerlane. The Mehmet Pasha mosque is supposed to be the ancient church of Saint Anastasia Pharmacolytria, of the 5th century. All the other mosques are much less in size than those described, but very much resemble them in plan and other features. All of them are encircled by splendid columns of marble, Egyptian granite or serpentine, and have massive and highly ornamented gateways and porches, and handsome courts and cisterns for ablution. The church of the Fountain of Life and the Bichlerne Church are Byzantine edifices still belonging to the Greeks.

Monuments, etc.—Among other historic monuments of Constantinople are the magnificent tombs of the sultans Selim II, Mahmud II, Suleiman the Great and Mohammed II; the obelisk of Theodosius, the Serpent Column, the Colossus of the Hippodrome, the Porphyry or Burnt Column, Marcian's Column, the Column of Theodosius II in the Scraglio and the Column of Arcadius; the Philoxenos and the Basilica water cisterns; the China Pavilion; the Hippodrome ("At-Madian" or Circus), originally laid out by Septimius Severus on the model of the Circus Maximus in Rome, 1,300 feet long and 600 feet wide; the aqueduct of Valens; the fountain of Sultan Ahmed; and the fire towers of Galeta and Stamboul. The Imperial Museum of Antiquities contains a magnificent collection of treasures; of minor importance is the Museum of Ancient Costumes.

Palaces.—Besides the smaller palaces already mentioned, there are also the Dolma Bagctche and Yildiz Kiosk. The first of these, situated on the promontory named Seraglio Point, at the junction of the Bosphorus and the Sea of Marmora, was for centuries the residence of the Byzantine emperors and Turkish sultans. It now contains the Treasury, the Imperial College of Medicine, the Mint, an art school and the Museum of Antiquities. The beautiful Dolma Bagctche Palace (q.v.) lies on the Bosphorus, while Yildiz Kiosk, the residence of the sultan, is a collection of palaces and other buildings. (See YILDIZ KIOSK and HAREM). The Cheragan Palace, also on the Bosphorus, was destroyed by fire in 1910. It was built by Abdul Aziz, and here he committed suicide in 1876.

Bridges, Bazaars, etc.—Two iron pontoon bridges span the Golden Horn and connect Galata with Stamboul. They have each a draw to allow the passage of vessels. The bazaars are numerous; some are covered, others open. The covered bazaars have a somewhat mean appearance, resembling a row of booths at a fair, but the arrangement and manner of exposing the gay and glittering wares is sufficiently attractive. The principal or Great Bazaar consists of long avenues covered over with lofty arches of brick, lighted by apertures in the roof and branching off in different directions. The ceilings of the vaults, and various parts of the walls, are ornamented with painted flowers and devices. On each side of the passage are counters and stalls, with a wide passage between them, and on each counter sits the merchant, generally smoking his pipe or chibouk, with his crossed legs drawn under him. The bazaars, both the open and covered, are severely allotted to particular trades and merchandise; they are generally so crowded that it is difficult to pass through them. The numerous public baths in the city are mostly of marble, of plain exterior, but handsome and commodious within, with every accommodation and trinket requisite. They are divided into a number of circular rooms, lighted from above, and sufficiently spacious to admit a number of bathers at the same time. There are a vast number of coffee-houses and lodging-houses, called khans, dispersed throughout the city. The latter resemble immense stone barracks or closed squares. They are intended for the use of strangers during their temporary sojourn in the city, who may have an apartment here, with command of the key. Considerable modern improvements have been made in the commercial section of the city. Electric cars and telephones have been introduced. French and German waterworks companies provide water from reservoirs in the forest of Beograd.

Industry.—The few manufactures of Constantinople are chiefly confined to articles in morocco leather, saddlery, tobacco-pipes, fez caps, arms, perfumes, gold and silver emboideries, etc. but the foreign commerce is considerable. The Golden Horn is deep and commodious, well sheltered and capable of contain-
ing 1,200 large ships, which may load and unload alongside the quays. It is usually crowded with vessels and light boats, and presents a lively, bustling scene. Among the imports are corn, iron, timber, tallow and furs from the Black Sea and Russia; cotton stuffs and yarn, woolens, silks, wools, furniture, carriages, sugar, pepper and spices, spirits, etc. The exports consist of silks, carpets, hides, wool, goats' hair, madder, valonia, etc. In 1914 a tonnage of nearly 12,000,000 entered and cleared the port in 177,000 vessels.

History.—The city was founded, according to tradition, by a band of settlers from Megara under the leadership of Byzas, in 658 B.C., and received the name of Byzantium. It was in turn attacked by the Thracians, Bithynians, and even the Gauls; it was repeatedly invested by the Persians, who, during the campaign of Darius against the Scythians, compelled the town to surrender to Otanes, one of Darius's generals, and subsequently burnt it. After the battle of Plataea (479 B.C.) the Lacedaemonians, under Pausanias, took Byzantium from the Persians, and refounded the colony. Seven years later the town was captured by the Athenians; within 30 years it revolted and returned to its former allegiance. It was again besieged and taken by Alcibiades in 408 B.C. The Athenians remained in possession for three years when they lost the town again to the Spartans under Lysander. A few years later Xenophon, with his 10,000 passed through it on their march from Persia. In 390 B.C. it was once more brought under the sway of Athens. Philip of Macedon laid siege to the city in 340 B.C., but the Athenians, roused by the fiery eloquence of Demosthenes against the Macedonian conqueror, came to the rescue. After repelling Philip of Macedon, Byzantium had to submit, some years later, to Alexander, who passed it on to his successors. On the death of Lysimachus the city regained— and maintained—its independence for a century, until the mighty power of Rome invaded the region of Thrace and the Hellespont.

In return for the assistance it rendered to the Romans in their wars with Macedon and Antiochus, the Senate conferred on Byzantium the title of a "free city," lost these privileges under the Emperor Vespasian, and became an ordinary provincial town in A.D. 73. In the struggle between Septimius Severus and Pescennius Niger for the Roman Empire, Byzantium espoused the cause of the latter, but was captured by Severus after a three years' siege, and reduced to ashes. A few years later, however, he rebuilt the city, and embellished it with porticoes, magnificent public baths and a hippodrome. During the civil wars which followed the abdication of Diocletian, the city fortifications were restored, and afforded refuge to Licinius after his defeat by Constantine at Adrianople in A.D. 323. Constantine then advanced on Byzantium, and, by means of constructing rams and towers as high as those of the city, finally succeeded in taking it.

The name "Byzantium" now disappears, and "Constantinople" takes its place. The city is also called "New Rome," for it is raised to the dignity of capital of the Roman Empire, thanks to its geographical position, which alone is responsible for its vicissitudes and chequered fortunes. A new political centre was required for the reunited Empire; frequent wars with Persia, revolts of Asiatic nations, incursions of Scythians, troubles at Rome and a host of other considerations demanded that the capital should be transferred further eastward. So Constantine was established, the city was dedicated to the Virgin Mary, and the foundations of Saint Sophia were laid. The old capital was plundered of its art treasures to decorate the new, and a 40 days' festival inaugurated the second founding of the city. Immigration was encouraged, schools were built, liberal laws enacted and a bishop, afterward raised to the rank of patriarch, was appointed. Historic Church Councils were held on the Bosphorus—in 337 A.D., against the Arians heresy; in 359, when 150 orthodox bishops added their names to the Nicene Creed; in 553; in 681, when Pope Agatho presided; and again in 870, to condemn the iconoclasts, and when the Emperor Basil attended.

But Constantinople was not destined to tread the path of peace and Christianity. The decline had set in; the fall was at hand, and a new star had risen in the East—Islam. The city had been attacked by the Huns in 450; again by the Goths and Vandals in 473; by the Persians in 626. The Saracen conqueror, Moawiya, besieged the walls for seven years, and finally abandoned the enterprise. A second invasion by the Saracens under Moslemah was repulsed in 718, and toward the end of the 8th century the hero of the "Arabian Nights," the redoubtable Calif Harun al Rashid, planted his standard on the heights of Skutari, but was drawn off by concessions. During the 9th and 10th centuries Constantinople was assailed by six invasions—from Bulgaria, from Hungary, and four times from Russia.

In 1096 the Crusaders, under Godfrey de Bouillon, passed on their way to Jerusalem. The fourth crusade turned aside from their holy purpose, and decided to take Constantinople, with the aid of the Venetian Republic. The plan succeeded, and Baldwin, Count of Pflanders, the valiant leader of the Norman knights, was elected to the throne. This new dominion lasted 58 years, during which time the city became a large confederate city. During the rule of Alexius III, the city was again captured by the Crusaders, and in 1261 the new rule collapsed when the Crusaders evacuated Palestine, and the Greek Empire was restored, with the assistance of the Republic of Genoa. In return for their aid the Genoese were granted exclusive rights in Galata, which they promptly surrounded with walls, behind which they claimed independence, and defied the emperor. A state of civil war ensued within the city, which was kept up till the final conquest by the Turks. Sultan Bayazid determined to obtain possession of Constantinople in 1396. He commenced this task, but had to leave it suddenly to defend his own territories against Tamerlane. Bayazid was defeated in that encounter, and taken prisoner, in 1402. Twenty years later, his grandson, Murad II, after delivering his country from the Mogul yoke, led his victorious army to the gates of Constantinople. The reigning emperor, John Palaeologus, yielded to his demands, and purchased or "crowned" the city. Murad II was a true Moslem, and kept his engagements religiously. For the 30 years of his subsequent reign Constantinople was in-
sured against Turkish aggression. His son, Mohammed II, abrogated the treaty, and built a fort ("Cut-Throat Castle") on the European side of the Bosphorus, which remains to this day. In 1453 Mohammed arrived with 60,000 horse and 20,000 foot. The city could only muster 7,000 defenders. After a desperate struggle of 40 days, the city was captured, and Saint Sophia was converted from a Christian church into a Mohammedan mosque. The dust had claimed the Byzantine, the Roman and the Greek Empires, and the sword of Othman had held the city on the Bosporus against all comers for over four centuries and a half.

The more important historic events which have taken place in Constantinople since then may be briefly summarized. Peace was concluded there between Turkey on the one side and Venice, Spain and the Pope on the other, in 1540; another peace treaty between Turkey and Russia in 1770; and an abortive alliance between Prussia and Turkey against the ambitions of Russia and Austria. In 1821 a massacre of Greeks took place, in which the Greek Patriarch was hanged. The rising of the Janissaries and their complete annihilation occurred in 1826. In the same year 6,000 houses and many palaces were destroyed, whilst other serious conflagrations, as well as earthquakes, worked their havoc upon the city in 1714, 1755, 1856, 1863, 1890, 1893, 1894, and 1898 till 1910. The most disastrous fire for a century broke out 31 May 1918 and in two days covered 2½ miles of old Stamboul, destroying over 5,000 houses, 20 baths, a dozen bazaars and as many mosques. Over 200,000 were left homeless.

It was in Constantinople, too, that the alliance between Great Britain, France and Turkey against Russia was concluded—a few weeks before the Crimean War broke out. In the winter of 1876–77 the Great Powers held a futile conference here with a view to settling the Eastern Question, but could not prevent the Russo-Turkish war which followed. In February 1878 the Russian army reached almost to the gates of the city, and forced the Treaty of San Stefano upon the Porte, where by the new régime was announced. During the Balkan Wars of 1912–13 the Balkan Allies almost reached the walls of the city, and again in 1915 the French and British attempted to capture Constantinople by forcing the Dardenelles. See War, European.

CONSTANTINOPLE — CONSTELLATIONS

CONSTANTINOPLE, Strait of. See Bosporus.

CONSTANTIUS I, Flavius Valerius, Roman emperor, surnamed CHLORUS; b. about 250; d. York, England, 25 July 306. He was nephew of the Emperor Claudius II, became Caesar in 282, received Britain, Gaul and Spain as his government, and after re-establishing Roman power in Britain and defeating the Alamanni, became one of the Augusti in 305. He was distinguished for his intrepidity as a soldier and his breadth of humanity as a ruler. Constantine the Great, his son, was his successor.

CONSTANTIUS II, Flavius Julius: b. Illyricum 317; d. 361. He was the second son of Constantine the Great and Fausta, was emperor of Rome from 337 to 361, reigned first in the East, and waged a protracted war against the Persians, which prevented him from participating in the struggles of his brothers Constantine II and Constans in the West. After the fall of both he marched in 350 against Magnentius and Vetranio, who had usurped the purple. Vetranio submitted; Magnentius was finally crushed and committed suicide. Constantius marched over the whole empire. In 354, having returned to the East, he put to death his cousin Gallus, whom he had left there at the head of the army. He chose his cousin Julian as Caesar, and sent him to Gaul, where he succeeded in converting the Alamanni and the Franks. In 360 Julian was proclaimed emperor by the army at Paris. Constantius marched against him but died on the way in Cilicia. Julian was his successor. Consult 'The Cambridge Medieval History' (Vol. 1, New York 1911).

CONSTANTS OF NATURE, a term applied to various unchangeable quantities that are found to be characteristic of natural phenomena or relations. The propagation of light through space takes place invariably at the rate of 186,770 miles per second, and hence the velocity of light may be referred to as a constant of nature. In choosing the units of precise measurement, which form the basis of all calculations in pure and applied science, it is necessary in certain cases to employ the constant quantities of nature. The constants of nature characterize natural phenomena and enter into all the mathematical laws of science. Consult Lupton, Everett 'C. G. S. System of Units' (London 1902); Landolt and Bornstein, 'Physikalisch-chemische Tabellen' (4th ed. Berlin 1912); Clarke, 'The Constants of Nature' (5 parts, Smithsonian Miscellaneous Collections, Washington 1873-88).

CONSTELLATION, a famous United States vessel built in 1798, as one of the frigates ordered by the government for service against the Barbary pirates. It was commanded by Commodore Onslow and did service in capturing the French warship L'Insurgente, 1799, and won a brilliant victory over the French frigate La Vengeance (1800). During the entire War of 1812 the Constellation was blockaded at Norfolk. In 1815 she was part of Decatur's fleet in the Mediterranean, and was one of the squadron which captured the Moroc- con vessel Mashouda after a conflict. Consult MacIay, 'History of the American Navy' (Vol. I, 1900).

CONSTELLATIONS (Lat. con., together; + stella, *star*). From the earliest times men have formed certain groups of bright stars into constellations. Thus the names of the 12 zodiacal constellations are prehistoric. The same is true of many of those clustering about the north pole of the heavens. Quite a number bears the names of persons or of persons who were in some way connected with it, which determines the age of their formation approximately. The earliest description of the constellations of which we have any record is by Eudoxus, who lived about 360 B.C. This work is lost, but a poetic paraphrase of it by Aratus, who lived about 100 years later, is still extant. This work mentions 45 constellations. The earliest star catalogue which has survived to modern times is the 'Syntaxis', that is, 'Collection', which is usually known as the 'Almagest', which means 'The Greatest,' of Ptolemy. His observations were made between 121 and 151 A.D. The catalogue contains 1,028 stars divided among 48 constellations. The cataloguing was based on the ancient classification, and no permanent additions were made to it until 1602, when one constellation was added by Tycho Brahe. The next year appeared Bayer's 'Uranometria,' a series of star-maps containing 1,753 stars in 12 new southern constellations. These maps were decorated by a series of drawings made by Dürer, whose outlines have until recently served to ornament the constellations as represented on certain maps and stellar globes. These were the first star-maps published, although stellar globes were introduced in the middle of the previous century by Mercator.

Before Bayer's time it was customary to describe the position of a star by its location in the animal or figure represented by the constellation. Thus Aldebaran was the eye of the bull. From this it would appear that the ancients had manuscript maps with figures drawn upon them, but none of these maps have come down to our time. Bayer introduced the important innovation of naming the various stars with the letters of the Greek and Roman alphabets, a separate set of letters being used for each constellation, thereby greatly simplifying the designation of any particular star. Strangely enough he did not letter his 12 new southern constellations, so that these stars still had to be designated by the cumbersome methods of the ancients. In Flamsteed's catalogue, issued early in the 18th century, the stars are numbered in the order of their right ascension, and both letters and numbers are still in general use. From the earliest times some of the brightest stars have received special names, such as Sirius, Arcturus, etc. Although these are still in common use, there is a tendency among astronomers to substitute Bayer's nomenclature in their place.

Following Bayer a number of new constellations were introduced by various astronomers, notably Hevelius, Lacaille and Royer. Many constellations were proposed which have failed to meet with universal acceptance, and the number which is now generally adopted by astron-
omers is 67. There is no definite agreement as to their exact outlines. Indeed, such an agreement would be impossible unless the boundaries followed definite circles of the celestial sphere. All stars brighter than the 9.5 magnitude are now designated by their numbers in certain large modern catalogues. Fainter stars are located by their right ascension and declination at certain dates. These quantities correspond to terrestrial longitude and latitude.

The shapes of the constellations are entirely matters of accident, and in only a few instances are the brighter stars contained in them arranged in such a manner as to bear any resemblance to the object for which the constellation is named. The exceptions to this rule are the Scorpion, the Southern Cross, the Northern and Southern Crowns and the Southern Triangle. On the other hand, certain characteristic forms are obvious in the heavens which bear no relation to the name of the constellation in which they occur. The Great Bear, in Ursa Major, known in England as Charles Wain (or Wagon), the Y in Boötes, the Sickle in Leo and the Cross in Cygnus are well-known examples. Good modern star-atlasae have been published by Schurig and by Upton. For the most complete work in English on the early history of the constellations and the origin of the names of the stars, consult Allen, R. H., 'Star Names and Their Meanings' (1899).

WILLIAM H. PICKERING.

**Astronomical Observatory, Harvard.**

**CONSTITUTION,** a condition in which the normal number of evacuations from the intestinal canal does not take place, or one in which the feces are extremely hard and painful in passing. Constipation affects all ages, being prevalent in childhood, youth, adult life and old age. It can for the most part be regulated by proper hygienic living, but by reason of extreme carelessness in this regard is very prevalent.

The symptoms of constipation vary considerably. In infants there is always pain; the child cries, especially on attempts to defecate; there is usually much colic; there may be fever. In adult life the symptoms are fairly well marked. The patient complain with a drying of the mouth, there is pain on passage, due to hardness of the feces; and there may be feelings of bloating, coated tongue, headache or backache, all of which are characteristic of this condition. In fact the symptoms which are described very widely in patent-medicine circulars are the usual symptoms of ordinary constipation, and the patent-medicine business succeeds largely because it ascribes to this extremely common malady names of very much more dangerous illnesses. Practically most patent medicines are hardly more than cathartics.

The causes of constipation are in the main two,—lack of water in the intestines and lack of muscular tone of the unstripped muscle of the intestinal walls. Lack of water may result from insufficient drinking of water. It may also result from increased elimination of water, as in excessive sweating. It may also be the result of certain juices of the intestines,—the gastric juice, the bile from the liver and the pancreatic and intestinal juices.

These are all essential in adding fluid to the intestinal canal. Insufficient muscular power in the intestines may be due to a number of causes. Lack of tone of the body in general, resulting from insufficient exercise and insufficient food, is one of the most important. Bad dressing is a second cause for this loss of muscular tone. It may be a symptom of a nervous disorder such as is very frequently found in paraplegia, in locomotor ataxia and other grave spinal disorders, in which case the morbid paralysis is more or less permanent. Lack of muscular power may also be the result of taking fluid diet; thus the intestine has less of the proper type of stimulus and the muscular power is not invoked. A frequent cause of constipation is tea-drinking. The most frequent cause of constipation is unconscious hate. This causes too much tension in the muscles of the lower bowel with the retention of the feces.

The treatment of constipation is self-evident if one takes into consideration the two underlying causes and remedies them. The drinking of water, outdoor exercise, sunlight, the eating of food that has plenty of residue, such as bread, spinach, lettuce, cabbage, celery, etc.; these are very helpful. The first absolute necessity, however, in the treatment of constipation is to establish a habit of regular daily movement. In order to do this it is essential that a time should be taken which is ordinarily not interfered with, and the individual should consider a certain 15 minutes of the day to be sacredly devoted to this duty. So far as drugs are concerned in the treatment of constipation, they are best left alone; but if it becomes absolutely necessary that a drug should be used, it is a cardinal principle to remember that alternation of drugs is advisable. The same drug used day in, day out, and week after week, tends to diminish the power of the intestine and habituate it to a given drug. This results in some frightful cases of constipation.

In a few cases of constipation in which the cause is due to some obstruction, as some solid body situated near the intestinal canal and pressing upon it, surgical treatment is imperative. The use of external massage is largely useless. The normal stimulus to movement known as peristaltic within—it is largely of unconscious nerve origin. It does not come from without. Constant use of enemas for constipation is a form of intestinal masturbation and leads to serious forms of neuroses and psychoneuroses, even to psychoses—or insanities, in later life. Hence the best type of treatment for most chronic constipations is mental. See CATHARTIC.

**CONSTITUENT ASSEMBLY,** a name given to the first convention of the delegates of the French nation (1787–91) to distinguish it from the Legislative Assembly of 1791. It drew up and obtained the acceptance of the first of the famous revolutionary constitutions. The Constituent Assembly of 1848 had a similar aim. See ASSEMBLY, GENERAL; FRANCE, HISTORY.

**CONSTITUTION,** the fundamental law of a state, whether it be a written instrument of a certain date, as that of the United States of America, or an aggregate of laws which have been formed in the course of ages, like the English Constitution. Its primitive meaning is that of any law given force by
proclamation and put into effect by the power of the supreme head of the government or nation.

1. Constitutions, according to their origin or their fundamental principle, may be divided into three classes: (1) Those established by the sovereign power; (2) those formed by contracts between nations and certain individuals whom they accept as sovereigns on condition of their complying with the terms of the contract; (3) those formed by a compact between different sovereign powers.

1. The first class may be again divided into: (a) constitutions established by a free sovereign people for their own regulation, of which sort is the Constitution of the United States; and (b) such as have been, in some instances, granted by the plenary power of absolute monarchs to their subjects, and which in theory are the voluntary gift of the beneficence of the ruler. These are called by the French constitution: 1. constitutions d'arrangement, from the arrangement; 2. constitutions du droit, from the right.

2. The second great class of constitutions mentioned above includes such as have been formed by a contract between the future ruler and the people. These are mutually binding on each party as long as the other fulfills his duty. Such, in a great degree, is the British Constitution.

3. Some constitutions are compacts between several sovereign powers. Such was the Constitution of the German Empire and that of the United Provinces of Holland, and such is also the Swiss Confederation. The Constitution of the United States, though the different States call themselves sovereign, proceeded, in point of fact, from the people of the United States collectively, as is apparent from the very beginning of the instrument: "We, the people of the United States," and not "We, the States." Moreover, the Congress, established by this Constitution, has rights and powers far exceeding those which other confederate but entirely disunited governments are wont to allow each other. The Constitution, in short, unites all the States into one nation, the government being called by all parties the national government. Governments entirely and virtually distinct from each other never would, however closely confederated, allow a government, particularly a national government, to be established over themselves. The Constitution of the United States is more than a mere compact between independent sovereigns, yet less than the simple constitution of an unconfedered nation; it ought rather to be considered as forming one whole with the different constitutions of the States which have given up to the general government most of the rights of sovereignty, as that of making war and peace, etc.

II. In regard to political principles, constitutions are: (1) Democratic, when the fundamental law guarantees to every citizen equal rights, protection and participation, direct or indirect, in the government, such as the Constitution of the United States and those of some cantons of Switzerland; (2) aristocratic, when the constitution establishes privileged classes, as the nobility and clergy, and entrusts the government entirely to them, or allows them a very disproportionate share in it; such as a constitution as that of Venice, and such as, at one time, those of some Swiss cantons, for instance, Bern; (3) of a mixed character, to this latter division belonging some monarchical constitutions, which recognize the existence of a king whose power is modified by other branches of government of a more or less popular cast. The British Constitution is a great example of this division.

III. The forms of government, established by the various constitutions, afford a ground of division important in some respects; and, lastly

IV. The principle on which a constitution establishes the representation, or the way in which the people participate in the government, furnishes an important means of classification: (1) Some allow the people to partake in the government without representation, as was the case in many of the small states of ancient Greece, and also in the ancient Roman republic, and is still the case in several of the small Swiss cantons, in which the whole people assemble and legislate; it being obvious that such a constitution can operate only where the number of citizens is small, and even then, it is almost always objectionable; (2) some are of a representative character; that is, all the citizens do not take an immediate part in the government, but act by their representatives; constitutions fulfilling this sort of character is a general and equal representation, as those of the United States; or connecting the right of representation with particular estates and corporations. The term representative constitution is frequently applied exclusively to the former by way of eminence.

V. Representative constitutions may be divided into: (1) Such as are founded on the union of the feudal estates, the clergy, nobility, citizens and peasantry, the two latter of which derive their right of representation from the charters of the ancient corporations; (2) such as establish the right of a general representation, like the American Constitution, and such as partake of both characters, like the British Constitution. Those of the first class either originated in feudal times or have been since copied from such as did. The feudal states were conglomerates of many heterogeneous bodies; and it was reserved for later ages to unfold the true principles of government, to separate the essential from the unessential and injurious, to give stability, distinctness and extent to principles before unsettled, indefinite and limited in their operation. See articles on the different countries of the world for information respecting their various constitutions.

CONSTITUTION, Framing of the. When the resistance to British rule in America began, independence was not its aim, and provisional governments only were established in the several colonies, temporarily to take the place of the old government, to which had been suppressed. The several colonies jointly instituted the Continental Congress for the purpose of prosecuting the war. This Congress in June 1776 appointed a committee to frame an instrument of government. This was entitled the 'Articles of Confederation and Perpetual Union' (see CONFEDERATION, ARTICLES OF). It was not until 1 March 1781 that all of the States had finally signed it. Its defects were so numerous and serious that for a time it looked as if the Union would go to pieces. Several amendments were proposed and failed of adoption, chiefly because the approval of all States was necessary for an amendment.
By 1786 everything pointed to a speedy dissolution of the Union as it existed under the Articles of Confederation, when aid came from an unexpected quarter and quite by accident. This was the Annapolis Convention (q.v.), called to settle commercial disputes between Virginia and Maryland. The convention was held at Annapolis, Maryland, in 1786. The convention was attended by delegates from Maryland, Virginia, New Jersey, Pennsylvania, and New York. The convention was convened to discuss the problems of commerce and navigation between the states. The delegates agreed to a resolution calling for a more effective union of the states, and they appointed a committee to prepare a plan for a new constitution. This plan, known as the Annapolis Resolution, called for a convention to be held in Philadelphia in the fall of 1787 to consider the necessary amendments to the Articles of Confederation. The Annapolis Convention was the first step in the process that led to the creation of the United States Constitution. The Annapolis Convention was a significant event in the history of the United States, as it marked the beginning of a new era of cooperation and cooperation among the states. It laid the groundwork for the eventual adoption of the Constitution and the establishment of a more effective federal government.

power between the States. Under Randolph's plan, the Senate would have had 28 members, of which the three large States would have had 13; and the House 65, of which they would have had 26 — two-fifths of the latter and about half the former, who would have been able by a bargain with one or two of the smallest States, to choose the President and dictate the entire operations of the government. On the other hand, Paterson's plan was practically the Constitution plan in the wind and paper debates. The deadlock was absolute. John Dickinson of Philadelphia suggested consolidating the two plans, which was like consolidating a democracy and an autocracy. But on 21 June William Samuel Johnson of Connecticut proposed the "Connecticut plan," the one finally adopted, making the States equal in the Senate and proportional in the House. His colleague, Ellsworth, supported him; but the vote on it showed a tie, five large to five small States, and Georgia's delegation divided. The question was referred to a committee of one from each State, which reported a compromise to win over the large States by restricting the power of originating money bills to the House, which they would control, and sending the slave States by counting in three-fifths of the slaves as a basis of representation. With the addition of the power to the Senate to propose amendments to money bills, the compromise passed after a hot debate. The two New York delegates left the convention in wrath.

Another point which had to be compromised was the power of Congress over commerce. As matters stood, not only could each State lay any duties it pleased, so long as it did not violate treaties already made or take national property, and therefore fill the Union with prohibitive barriers, but a State like New York could ruin its neighbor, New Jersey, and deal a crushing blow at western Connecticut, whose port it was. Further, several States were not agriculturally diversified, but had one great crop of tobacco, or rice, or naval stores — a severe tax on which would bankrupt the entire State. The first of these difficulties was met at the outset by a provision limiting the power given to Congress to regulate commerce between the States; the second was acknowledged by the insertion of the prohibition to tax exports, as said. A "committee of detail" reported a draft Constitution 6 August. It had 23 articles (finally boiled down to seven); the President was to have one term of seven years, and be chosen by Congress; there was no Vice-President, and the Senate chose a president for itself. This was debated till 12 September, and amended to its present form. The slave-trading States were given their solatium in the shape of permission to continue the trade for 20 years, and the entire slave group were placated by the fugitive-slave provision; the Vice-President and the electoral system were added, and a restriction of Congressional control of commerce to a two-thirds vote stricken out. On 12 September a committee of five was appointed to revise its form, and the actual work was mainly done by Gouverneur Morris (p. 81). The draft was sent back, after a few changes — the chief requiring only a two-thirds instead of a three-fourths vote to pass a bill over a President's veto — and accepted. A new convention to consider amendments proposed by the States was voted down; they must take or leave it as it stood. Of the 55 delegates present, only 39 signed. On 17 September the convention adjourned. The Constitution and the resolutions of the convention were transmitted to Congress, which on 28 September ordered them sent to the several legislatures for action. (For the amendments, and the consequent difficulties about ratification, see Constitutional Amendments, History of.) Only three States — New Jersey, Delaware, and New Hampshire — refused unanimously; Connecticut, Pennsylvania, Maryland and South Carolina, by heavy majorities; Massachusetts, New Hampshire, New York (see Federalist, The) and Virginia by light ones, after a bitter and protracted struggle; North Carolina refused to ratify without many amendments and a bill of rights, and Rhode Island refused altogether till it was carried without her and she would have been shut out. There was great dissatisfaction, and only the commercial classes were heartily in its favor; John Adams said afterward that the Constitution was "extorted from the grinding necessity of a reluctant people." See United States — Articles of Confederation; United States — Federal Convention of 1787.

Constitution, Immutability of the. The Constitution of the United States is the product of a few great minds assembled in a brief convention. A great statesman (Gladstone) has termed it "the most wonderful work ever struck off at a given time by the brain and purpose of man." This characterization has been accepted by all thinking men. There have been, indeed, cavils at some provisions, and speculative suggestions of alterations and improvements by individual minds; but the universal wonder is that the framers of the Constitution did so well; and that wonder was never so great as now at the close of a stormy century, littered with the wrecks of governments and nations and dynasties and constitutions.

The "given time." The work was great, the difficulties many — most men then deemed them insuperable — and the work and its difficulties have had commentators and historians for 70 years or more; but will there be a single reader of this article who has noted how short a time it took to frame the Constitution? Has there been a single commentator or historian who has adequately shown how exceedingly brief the "given time" was? Less than a hundred working days measured it.

Moreover, the framers had had no means of previous personal communication by telegraph and almost none by mail; there were no stenographers or typewriters; there was, indeed, no clerical assistance; for the proceedings of the convention were secret and the clerical work was done by great men. When we see great conventions with modern facilities for rapid work spending months in putting a few patches on existing State constitutions, we can best appreciate the ability of the men who in 85 working days forged the great compact of the people of the United States with themselves — a compact which has lasted more than a century substantially unchanged, which survived the storm of the greatest civil war of the modern world, which has expanded with an unforeseen and unprecedented expansion of inhabited ter-
ritory from a narrow strip upon the Atlantic seaboard to the shores of the Pacific, and which, notwithstanding changed conditions of life and thought, has grown steadily in the power of moral obligation and become more and more truly the *supreme law* of nearly 100,000,000 people.

As the time was brief, so were the framers few. The convention was composed of 55 members; the Constitution was signed by 39, including Washington; 51 members took part in the debates (according to the most complete report we have of them, the Journal of Madison), again including Washington. It is generally assumed that he took no part in the debates; but Professor Fiske has said in words which cannot be too often brought before the American citizen:

> It was suggested that palliatives and half measures would be far more likely to find favor with the people than any thorough-going reform, when Washington suddenly interposed with a brief and immortal speech, which ought to be blazoned in letters of gold and posted on the wall of every house. Nearly all of the convention’s original members had died, and the convention’s work was practically done. Standing up, his tall figure drawn up to its full height, he exclaimed in tones unwontedly solemn with suppressed emotion: "To alter a Constitution is too probable that no plan we propose will be adopted. Perhaps another dreadful conflict is to be sustained. If, to please the people, we offer what we ourselves disapprove, how can we afterward defend our work? Let us raise a standard to which the wise and the honest can repair; the event is in the hands of God."

Some of the 55 took no real part in framing the Constitution, and some were obstructionists. Their objections may have exercised a wholesome influence on the convention, but added much to the cares and perplexities of the greater men who assumed the responsibility and did the work. But whether we take the 39 members who signed the Constitution, or the 51 who took part in the debates, or the 55 who composed the convention, the number seems perilously small to be entrusted with the titanic task of founding for all time a great and growing and intensely active republic. Edmund Randolph, speaking of the time when the Articles of Confederation were framed, apologetically called it "the then infancy of the science of constitutions and of confederacies." He might have said the same of the Constitution itself. He might have said the convention. Very little did the world then know of the science of constitutions or confederacies! He well summed up the new and added difficulties which confronted the convention, and which it must meet and overcome:

> The inefficiency of requisitions was unknown [to the framers of the Confederation] — no commercial discord had arisen among any States — no rebellion had appeared, as in Massachusetts — foreign debts had not become urgent — the havoc of the paper money had not been foreseen — treaties had not been violated; and perhaps nothing better could be obtained, from the jealousy of the States with regard to their sovereignty.

There were other difficulties which Randolph, like a tactful statesman, left unnoticed. At one end of the line of financial troubles Rhode Island stood intent on her great scheme of making fiat paper money the equivalent of gold and silver by imprisoning the citizen who charged more for a commodity in the one kind of money than in the other, and the line ended at the greatest custom-house of the country, her chief source of revenue, which she would be called upon to surrender to the new Federal government as a part of the price she must pay for coming within the sovereignty of the Constitution. Virginia owned a vast territory which she must cede that it might become the public lands of the United States. Even in the great and authority of the men who composed the convention there were dangers and impediments. Three of the greatest proposed things would have defeated the great work: Franklin, the wisest member of the convention, proposed that the legislative power be vested in a single house, which would have been substantially the House of Representatives; Hamilton, the brilliant genius of the convention, advocated a government of which the President and the senators should hold office during good behavior, that is, for life; Madison, the most sagacious statesman in the convention, would have cast the responsibility of legislation on the judiciary by lodging a veto power in the Supreme Court. Any one of these provisions would have wrecked the Constitution before it was adopted; and any one of them, if it had been adopted, would have given us a government essentially different from that which we possess.

There is still another extraordinary fact connected with the framing of the Constitution which has received little if any attention, and which is substantially no comment in the main body of philosophical research the first subject of investigation would be the means or process by which the framers worked. A true philosopher, contemplating the clearness and conciseness of the Constitution, the mannerly handling of the chief elements of the future government, the wonderful adaptation of insufficient means to a glorious end, would instantly exclaim, "Such a work is not born of the human mind completed!" What was the secret process by which these great inventors attained their grand results? And the philosopher would find, as he suspected, that even as the Constitution stands alone in the records of constructive statesmanship, so do the means and methods by which the convention did its work. It speaks truly for the century that none of the lesser conventions which have assembled frequently to experiment with State constitutions has done its work in the same way. In a word, there is nothing which equals the Constitution in the ingenuity and approach of the patient, painstaking workmanship of the great convention.

At the beginning, propositions for consideration and discussion were tentatively placed before the convention in an abstract form. These propositions were embodied in 15 resolutions, which were immediately referred to the Committee of the Whole. They were taken up one by one, and considered and discussed and amended or rejected or adopted or postponed for later consideration. The abstract of a part of a single day's proceedings will give a clear idea of the way in which the convention worked:

> Tuesday, June 5. Mr. Randolph's ninth proposition — The national judiciary to be chosen by the national legislature — Disagreed to — To hold office during good behavior and to receive a fixed compensation — Agreed to — To have jurisdiction over offenses at sea, captures, cases of foreigners and citizens of foreign States, of national revenue, impeachment of national officers, and questions of national peace and harmony — Postponed.

At the end of two weeks of such considera-
tion and discussion (13 June), the Committee of the Whole reported the conclusions which had so far been reached in the form of 19 resolutions. But everything was still abstract and tentative. No line of the Constitution had yet been written, and no provision had yet been agreed upon. The 19 resolutions in like manner were taken up, one by one, and in like manner considered and discussed and amended or rejected or adopted or postponed. Other propositions coming from one section were also considered; and so the work went on until 26 July, when the conclusions of the convention were referred to the Committee of Detail, and the work of reducing the abstract to the concrete began. The convention then adjourned to 6 August, to enable the committee to "prepare and report the Constitution."

On 6 August the Committee of Detail reported and furnished every member with a printed copy of the proposed Constitution. Again the work of consideration began, and went on as before, section by section, line by line. Vexed questions were referred to special committees,—composed of one member from each State,—amendments were offered, changes were made, the Committee on Detail incorporated additional matters in their draught, until, on 8 September, the work of construction stopped. But not even then did the labors of the convention cease. On that day a committee was appointed, "by ballot, to revise the style of, and arrange, the articles which had been agreed to." This committee was afterward known as the Committee of Style. It reported on 12 September, and the work of revision again went on until Saturday, the 15th. On Monday, the 17th, the end was reached, and the members of the convention signed the Constitution. Well might Franklin exclaim in his farewell words to the convention: "It astonishes me, sir, to find the system approaching so near to perfection as it does." He had been overruled more than once in the convention; provisions which he had proposed had been rejected; provisions which he had opposed had been retained; but he was a great man and sagacious statesman, and he had been accomplished. This article should treat of the Constitutional changes of the century. But the extraordinary fact is that from the framers' point of view there has been, with one trivial exception, absolutely no change in the Constitution of the United States. *Are there not 15 amendments,*) it will be asked, and *do not the presidential electors vote for a President and Vice-president in a different way, and is there not an unwritten change in the Constitution by virtue of which the selection of Presidents has passed completely to the people, acting through their political national conventions?* All these questions may be answered generally in the affirmative; and yet the fact remains that from the framers' point of view there has been, with one trivial exception, absolutely no change in the Constitution of the United States.

The work of the great convention was the making of a government; and the government which the framers made has remained absolutely unaltered. Madison, the one wary and sagacious statesman, carried the first 10 amendments through the first Congress at the first session to assuage public excitement and strengthen the new government and close the mouths of those who railed against it. He introduced into the 10th amendment a rule of construction which would not have been adopted by the convention, a clause which politically has made much mischief during these 100 years, but the necessity of judicial construction has amounted to nothing, namely, that powers not delegated or prohibited by the Constitution "are reserved to the States respectively or to the people." The other provisions of the amendment are little more than quotations from the Bill of Rights. The Constitution contained but few such declarations: That the writ of habeas corpus shall not be suspended; that no bill of attainder or ex post facto law shall be passed; that the trial of all crimes shall be by jury; that such trials shall be in the State where the crime was committed; that no attainder of treason shall work corruption of blood or forfeiture except during the life of the person attainted. The 10 amendments declare that Congress shall make no law respecting an establishment of religion or prohibiting the free exercise thereof, or abridge the freedom of speech, or the right of the people peaceably to assemble and petition the government. (Article I.) They provide that no person shall be compelled to be a witness against himself, nor be deprived of life, liberty or property without due process of law; nor shall private property be taken for public use without just compensation, etc. (Article II.) These are great principles and noble sentiments, but their efficacy depends upon the rectitude of the government and the vigor and integrity of the people. No Congress would ever have dared to *make a law respecting an establishment of religion,* though there had been no Constitutional prohibition; and many an unfortunate citizen has lived and died with his claim for property taken for public use still unpaid, notwithstanding the Constitutional guaranty of *just compensation.* In a word, the 10 amendments served their temporary purpose; they have doubtless warned off Congress occasionally when in the heedlessness of the short session it or in its excitement has been accomplished. They have in a few instances secured the individual citizen, judicially, in his natural right to life, liberty or property; they continue to be a standing moral restraint upon the legislative and executive branches of the government; and they form a noble declaome of great principles to be kept before the eyes of all American citizens; but, nevertheless, the judicial records of the century show that the government which the framers of the Constitution established would have moved on just as it has done, if these 10 amendments had never been proposed. The conscience and intelligence of the country have been the real safeguards of the citizen against them. The Eleventh Amendment was caused by the extreme ground taken by the early Supreme Court in Chisholm v. Georgia, 2 Dall. 419, and the incipient rebellion of that State. Its purpose was to overrule that decision and to exempt a State from suit by a citizen of another State, if Marshall had been upon the bench the decision would never have been made; and, singularly, it was overruled by the same court a hundred years afterward (Hans v. Louisiana, 134.
CONSTITUTION

U. S. 1). The Thirteenth, Fourteenth and Fifteenth Amendments grew out of the Civil War. They abolished slavery; they impose restraints upon State governments; they confer on some persons constitutional rights; they guarantee certain immunities to citizens and persons; and they contain some provisions relating to representation in Congress. Much litigation has been caused by them; some statutes have been held constitutional and some unconstitutional. The larger proportion of representation has fallen to the Southern States; the guaranty given to all citizens of the right to vote without regard to "race, color or previous condition of servitude" is not absolutely effective, and the government of the United States moves on precisely as it did before.

It has been said herein that from the point of view of the framers of the Constitution their work has been changed in only one trifling particular. That change relates to election of the President, and was effected by the Twelfth Amendment. Under the Constitution as it originally stood each elector voted for two persons for President. He who should have the greatest number of votes would become President; he who should have the least number of votes would become Vice-President. Under this provision, Mr. Lincoln, in 1861, would have become President, and Mr. Seward Vice-President. That is to say, the Republican electors, following the direction of their party, as expressed by the national convention, would have cast all their votes for Mr. Lincoln, and all but one for Mr. Seward. The purpose of the framers was a wise one: to secure for the country the two strongest statesmen of the party constituting for the time being the majority of the people, to fill the offices of President and Vice-President. No better plan could have been devised for obtaining a strong executive. We see a weak and modified application of the principle in national conventions when the defeated "wing of the party" is placated by being allowed to designate the candidate for Vice-President. But in 1861 there had been a tie, whereby the electors had failed to elect, and the election had gone into the House of Representatives. The Twelfth Amendment would not now exist; and if the original system had survived until the time of rapid communication by railroad and telegraph and better party organization, it is safe to say that it would now be in unquestioned operation. Political conventions would long ago have adopted its leading principle, and the struggle would have been as to which of the two strongest candidates should be first or second upon the ticket. The system would have given greater dignity to the office of Vice-President, and would have brought the possible importance of that office always before the eyes of the citizen. But whether we think well or ill of the original method, one thing is certain, that the only reason the Twelfth Amendment is a trivial one of administrative detail. After all the changes this country has passed through in the last hundred years — changes in civilization, of territory, of population, of ideas, education, and perhaps personal life — changes such as the world has never witnessed in one country or in one century, the only change made in the Constitution has been the paltry one of having the electoral vote cast in one form instead of in another.

The unwritten amendment of the Constitution, as it has been called, also relates to the selection of the President. It is said by some of the commentators, and indeed it is now generally believed, that the electoral colleges were intended to be "dead and purely ministerial" and that in this sense this is true — in the legal sense. The electors are not ministerial or administrative officers; they do not perform a specific work in a way determined by higher official authority; in legal contemplation their responsibility is the same as that of a judge. But the framers of the Constitution never supposed that the electors would disregard the political pledges upon which they were chosen, or that the American people, either directly or through their State legislatures, would blindly choose electors to evolve a President out of their inner consciousness. On the contrary, they contemplated the successful candidates receiving the votes of "a majority of the whole number of electors," and they required the electors to vote "in their respective States," and to vote on the same day. If they had framed a provision requiring all of the electors to convene at the seat of the government in one body, and then vote in their own way and time, instead of as President, there would be good reason for saying that actual deliberation was intended; but they did not give to the electors one single power or attribute by virtue of which they could deliberate.

That very thing was attempted and the attempt failed. The question before the convention was, in effect: "Where shall the deliberative power to choose the President be vested when the formal casting and counting of the electoral vote fails to elect?" The answering propositions were, "In the Senate," or "In the House of Representatives." Then Spaight, of North Carolina, said that he would prefer their [the electors] meeting altogether [all together] and deciding finally; and he moved "that the electors meet at the seat of the general government;" and all of the States except North Carolina voted against it. The evidence is therefore both negative and positive — the convention did not provide for the election of the President, did not provide for the necessary powers and means for deliberation, and positively refused to do so; and refusal is conclusive of non-intent.

The idea that it was ever intended that the electors should nominate the candidate for whom they themselves should vote is a myth which has been unthinkingly reiterated by most eminent writers, but which does not rest upon a single fact. Nothing perplexed the convention more than the subject of the executive. Plan after plan was weighed and found wanting. The electoral system was late in coming to the front, and was the solvent of many difficulties. Hamilton early foresaw the inevitable, and proposed that "the selection be made by electors chosen by the people." Madison, later, said that the option before the convention "lay between an appointment by electors chosen by the people and an immediate appointment by the people;" and he at the same time said that "the electors, should be chosen for the occasion, would meet at once, and proceed immediately to an appointment." It was as well understood then as it is now that they would but register the decree of the political power which appointed them. The internal evidence
of intent is even more conclusive. He who sup-poses that the framers intended that 13 different bodies should convene in 13 different places at one time for one object and for one day, and that object the selection of the executive of a nation, confesses a most superficial knowledge of the greatest constructive statesmen of their century and of the great work which they deliberately planned and built.

And what better could the framers of the Constitution have done, in principle, than to propose "an election by the people," was "almost unwill-ing to declare the mode which he wished to take place, being apprehensive that it might appear chimerical." "Who, who liked the prin-ciple, but thought the community not yet ripe," he was for waiting till the people should feel more the necessity of it." Governor Morris admitted "that difficulties attended this mode," but thought that they would be "found supera-ble." Madison liked an election by the people best, but acknowledged "the disadvantage this would throw on the smaller States." Ellsworth declared "the objection drawn from the different sizes of the States unanswerable."

It has been a fashion of late to speak of the electoral system as curious machinery which may give rise to serious complications; but viewed amid the difficulties and conditions and limitations of 1787, there is no stroke of practical statesmanship in the Constitution more wise and ingenious. The choosing of candidates into Congress; with the coming of the steamboat and the railroad it passed from the congressional caucus to national conventions; and yet, notwithstanding these radical changes of usage, the expansion of territory, the multiplication of States, and the unscrupulousness of political parties, there have been no more mishaps than are in-cident to any system of human device.

To foretell the future of the Constitution is to foretell the future of the American people. They will change before it is changed. As with Washington and Lincoln, the more we know of them the better they appear; so of the Constitution, the more we contemplate its trials the better it appears adapted to our national needs. With the growth of knowledge there has been a growth of reverence. The people will experiment with State constitutions and tear them up and experiment again, but when it comes to the Constitution — the great Constitution — there is a sturdy sentiment of "hands off," and that sentiment is incomparably stronger now than it was at the beginning of the century. Judicial construction has moved backward rather than forward, and where Marshall left it, it stands, substantially, to-day.

The amendatory provision of the Constitution is an unbarred door which may be opened at any time. It was wise and prudent of the framers to leave it thus unlocked. But he who tries to swing open that door will find two things of which he did not reckon: first, a vis inertia in the ignorance and indifference of common men; and, second, that there is always some one on the other side pressing back the door.

CHARLES C. NORTT, Late Chief Justice Court of Claims.

CONSTITUTION, The, or OLD IRON-SIDES (from the slightness of the injury her hull received in the fight with the Guerrière), one of the most famous vessels of the American navy, now fixed in Boston harbor. She was a 44-gun frigate of 1,576 tons; one of the six war vessels ordered by Congress early in 1794, on account of the Algerian piracies. (See BARBARY POWERS, U. S. WARS AND TREATIES WITH THEM.) During the war against Tripoli she was present at the engagement of 813 tons was in the face of the five bombardsmen's off Tripoli. When the War of 1812 broke out Hull started to join the New York squadron with her, 12 July; was cut off by a British squadron, including the Guerrière, but in a wonderful chase of three nights and two days out-maneuvred and escaped it. On 19 August, off Cape Race, she ran into and fought a battle with the Guerrière, a somewhat weaker English frigate which she left a total wreck after an engagement of 25 minutes, the English losing 79 of their crew, the Americans 14. The Guerrière was sinking and could not be towed into port; she was therefore blown up. Hull sailed into Boston with his prisoners, to such an ovation as few men have ever earned in short a time. In less than 25 minutes of actual fighting he had lifted the despised American navy and nation to an equality with the proudest of the world; and drew from Great Britain such an explosion of rage and humiliation as it has never known before or since. Later the Constitution was made Bainbridge's flagship for a cruise against English commerce in the East Indies. On 29 Dec. 1812 it encountered the Java, Captain Lambert, off the coast of Brazil, and at 2.10 P.M. joined action. The Constitution had 54 guns, with 787 pounds of metal; the Java 47, with 568 pounds. The crews were 480 and 426. One of the fiercest of naval battles ensued for nearly two hours, in which the Constitution's wheel was shot away at the outset, making its navigation difficult, and the English vessel was the better sailer anyway. But the American gundery was incomparably more intelligent and improved; and the opportunity for raking broadsides, while the British did not. As soon as the Constitution came to close quarters, she inflicted ruinous damage and frightful slaughter. The Constitution was taken into Boston for repairs, but when it was completed, Boston was closely blockaded, and she did not escape till New Year's Day 1814, under Capt. Charles Stewart. See UNITED STATES, WAR OF 1812.

In a cruise to the West Indies, Captain Stewart captured four prizes, with 24 guns and 76 men; one of them was the 14-gun schooner Picton. Again blockaded by a powerful British squadron she did not escape until 17 Dec. 1814. In 1815 she encountered two British vessels, the Cyane and the Levant.

The Cyane struck; the Levant temporarily escaped, but was overhauled by the Constitution, and surrendered also. The two ships had lost 35 killed and 42 wounded; the Constitution, 4 killed and 10 wounded. Cut off by a powerful British squadron at a neutral port whose neutrality the English treated with utter contempt, the Constitution and Cyane succeeded by fine seamanship in escaping, but the Levant was recaptured. In 1830 she was reported unseaworthy, and condemned to be broken up, but
CONSTITUTION OF MATTER — CONSTITUTION OF UNITED STATES 571

Oliver Wendell Holmes published in the Boston Advertiser his thrilling poem 'Old Ironsides' and the public clamor excited by it saved the noble vessel, which was rebuilt and again put in service in 1833. In 1855 she was laid up at the Portsmouth Navy Yard, but was used sometimes as a training-ship; in 1877 she was again partially rebuilt, and took her last trip across the Atlantic the next year. In 1897 she was roofed in at Boston Navy Yard, and is now berthed as a barracks ship, etc. Consult Hollis, 'The Frigate Constitution' (1900); Maclay, 'History of the United States Navy' (Vol I, 2d ed., 1898); Adams, Henry, 'History of the United States' (Vols. VI, VII, IX, 1900-01); Roosevelt, 'Naval War of 1812' (1882); Bonney, 'Naval Actions of the War of 1812' (1896).

CONSTITUTION OF MATTER. See GASES, KINETIC THEORY OF; MATTER; MOLECULAR THEORY.

CONSTITUTION OF THE UNITED STATES, the governing instrument of the United States of America, adopted in 1787, when it took the place of the Articles of Confederation. (By the Constitution of the United States.) Political discussion of the time played a much greater part in this instrument than its provisions in turn exerted on political history in the following period, which to a surprising degree may be attached to only two clauses of the instrument and to these two simply because of their vagueness, and their mutually contradictory nature. Section 8 (18) in defining the powers of Congress adds the blanket provision of power 'to make all laws which shall be necessary and proper for carrying into execution the foregoing powers, and all other powers vested by this Constitution in the government of the United States, or in any department or officer thereof.' The second historic clause occurs in the Amendments, where Article X reads: 'The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively or to the people.' So immediately upon the formation of the new government political parties arose, the Democratic-Republican party, strict constructionists of the elastic clause, who limited the powers of Congress to the minimum, and the Federalist party, in favor of a highly centralized government doing everything possible for and in the States. Around this fundamental difference may be grouped the great political questions up to and culminating in the Civil War, and to a less degree recent political discussions are based upon the same variance in interpretation of the Constitution, although neither party now holds to the strict construction theory as it was set forth in the writings of the Federalists. This change has been brought about very largely by practical experience of affairs, it being well known that the foremost strict constructionists who have come to the presidential chair were forced by the exigencies of administration to a broader exposition of the clause. This was notably the case in the administrations of Jefferson and of his immediate lieutenants and successors.

The text of the Constitution follows:

CONSTITUTION OF THE UNITED STATES

We the people of the United States, in order to form a more perfect union, establish justice, insure domestic tranquility, provide for the common defense, promote the general welfare, and secure the blessings of liberty to ourselves and our posterity, do ordain and establish this Constitution for the United States of America.

ARTICLE I

SECTION 1. All legislative powers herein granted shall be vested in a Congress of the United States, which shall consist of a Senate and House of Representatives.

SECTION 2. The House of Representatives shall be composed of members chosen every second year by the people of the several States, and the elections in each State shall have the qualifications requisite for electors of the most numerous branch of the State legislature.

2. No person shall be a representative who shall not have attained to the age of twenty-five years, and been seven years a citizen of the United States, and who shall not, when elected, be an inhabitant of that State in which he shall be elected.

3. Representatives and direct taxes shall be apportioned among the several States which may be included within this Union, according to their respective numbers, which shall be determined by adding to the whole number of free persons, including those bound to service for a term of years, and excluding Indians not taxed, three fifths of all other persons.

The actual enumeration shall be made within three years after the first meeting of the Congress of the United States, and within every subsequent term of ten years, in such manner as they shall by law direct. The number of representatives shall not exceed one for every thirty thousand, but each State shall have at least one representative; and until such enumeration shall be made, the State of New Hampshire shall be entitled to choose two senators and one representative, the State of Rhode Island and Providence Plantations one, Connecticut five, New York six, New Jersey four, Pennsylvania eight, Delaware one, Maryland six, Virginia ten, North Carolina five, South Carolina five, and Georgia three.

4. When vacancies happen in the representation from any State, the executive authority thereof shall issue writs of election to fill such vacancies.

5. The House of Representatives shall choose their speaker and other officers, and shall have the sole power of impeachment.

SECTION 3. 1. The Senate of the United States shall be composed of two senators from each State, chosen by the legislature thereof for six years; and each senator shall have one vote.

2. Immediately after they shall be assembled in consequence of the first election, and before they shall proceed to choose President, in such manner as they shall by law direct, they shall be informed of the names of all persons Eligible to that Office. And they shall elect a President pro tempore, who shall preside (in the absence of the Vice President, or when he shall exercise the office of President of the United States) until the Choice of the President or the Vice President shall have been made. In the mean time, the Congress may meet at such Place as they may have directed, and the business of the present Congress may in some degree be transacted.

3. The President shall have the sole power to try all impeachments. When sitting for that purpose, they shall be on oaths or affirmations. When the President of the United States is tried, the chief justice shall preside; and no other person shall assent to that trial. Neither shall any person held to answer for the treason, felony, or other crime, be tried by any civil court while the crime for which he was held to answer remains unpunished, unless he be discharged by the circuit court under the provisions of law.

4. The Vice President of the United States shall be President of the Senate, but shall have no vote, unless they shall be equally divided.

5. The President shall choose their officers, and also a principal officer for the conduct of the Government in their absence, and he may require the opinion, in writing, of the principal officer in each of the executive departments, upon any subject relating to the duties of their respective offices, and he shall have the power to Grant reprieves and pardons for offenses against the United States, except in cases of impeachment.

6. The President shall have the sole power to try all impeachments. When sitting for that purpose, they shall be on oath or affirmation. When the President of the United States is tried, the chief justice shall preside; and no other person shall assent to that trial. Neither shall any person held to answer for the treason, felony, or other crime, be tried by any civil court while the crime for which he was held to answer remains unpunished, unless he be discharged by the circuit court under the provisions of law.
CONSTITUTION OF THE UNITED STATES

in each State by the legislature thereof; but the Congress may at any time by law make or alter such regulations, except as to the places of holding, and times of choosing senators.

2 The Congress shall assemble at least once in every year, and such meeting shall be on the first Monday in December, unless they shall by law appoint a different day.

Section 5. 1 Each House shall be the judge of the elections, returns, and qualifications of its own members, and a majority of each shall constitute a quorum to do business; but a smaller number may adjourn from day to day, and may be authorized to compel the attendance of absent members, in such manner, and under such penalties as each House may provide.

2 Each House may determine the rules of its proceedings, punish its members for disorderly behavior, and, with the concurrence of two thirds, expel a member.

3 Each House shall keep a journal of its proceedings, and from time to time publish the same, excepting such private communications as may in their judgment require secrecy; and the yeas and nays of the members of either House on any question shall, at the desire of one fifth of those present, be entered on the Journal.

4 Neither House, during the session of Congress, shall, without the consent of the other, adjourn for more than three days, nor to any other place than that in which the two Houses shall be sitting.

Section 6. 1 The senators and representatives shall receive for their services, a compensation, to be ascertained by law, and paid out of the Treasury of the United States. They shall in all cases, except treason, felony and breach of the peace, be privileged from arrest during their attendance at the session of their respective Houses, and in going to and returning from the same; and for any speech or debate in either House, they shall not be questioned in any other place.

2 No senator or representative shall, during the time for which he was elected, be appointed to any civil office under the authority of the United States, which shall have been created, or the emoluments thereof shall have been increased during such time; and no person holding any office under the United States shall be a member of either House during his continuance in office.

Section 7. All bills for raising revenue shall originate in the House of Representatives; but the Senate may make or concur with amendments as on other bills.

2 Every bill which shall have passed the House of representatives, and the Senate, shall, before it become a law, be presented to the President of the United States; if he approve he shall sign it, but if he shall not return it, with his objections, to that House in which it shall have originated, who shall enter the objections at large on their journal, and proceed to reconsider it. If after such reconsideration two thirds of that House shall agree to pass the bill, it shall be sent, together with the objections, to the other House, by which it shall likewise be reconsidered, and if approved by two thirds of that House, it shall become a law. But if the votes of both Houses shall be equal, the President shall have a right to sign or veto it.

3 Every order, resolution, or vote to which the concurrence of the Senate and House of Representatives may be necessary before they shall adjourn, shall be presented to the President of the United States; if he approve he shall sign it, but if he shall not return it, with his objections, signed by him, to that House, within ten days (Sundays excepted) after it shall have been presented to him, it shall not be a law.

4 Every order, resolution, or vote which the concurrence of the Senate and House of Representatives may be necessary to adjourn shall be presented to the President of the United States; and before the Ten Days' Limit shall expire, he shall be approved by him, or disapproved by him, which shall be signified to that House, by the President, in such manner as he shall think proper; and if it shall be disapproved by him, it shall be repassed by two thirds of the Senate and House of Representatives, according to the rules and limitations prescribed in the case of a bill.

Section 8. 1 The Congress shall have power to lay and collect taxes, duties, imports and excises, to pay the debts and provide for the common defense and general welfare of the United States; but all duties, imports and excises shall be uniform throughout the United States.

2 To regulate commerce with foreign nations, and among the several States, and with the Indian tribes.

3 To establish a uniform rule of naturalization, and uniform laws on the subject of bankruptcies throughout the United States;

4 To coin money, regulate the value thereof, and of foreign coin, and fix the standard thereof, and theCoin of the United States;

5 To promote the progress of science and useful arts by securing to authors and inventors the exclusive right to their respective writings and discoveries;

6 To constitute tribunals inferior to the Supreme Court; and the Congress shall have authority to constitute inferior courts.

7 To declare war, grant letters of marque and reprisal, and make rules concerning captures on land and water;

8 To raise and support armies, but no appropriation of money to that use shall be for a longer term than two years;

9 To make rules for the government and regulation of the land and naval forces;

10 To provide for calling forth the militia to execute the laws of the Union, suppress insurrections and repel invasions;

11 To provide for organizing, arming, training, and disciplining the militia, and for conserving of good秩序 in the States respectively the appointment of the officers, and the authority of training the militia according to the discipline prescribed by Congress;

12 To exercise exclusive legislation in all cases whatsoever over such district (not exceeding ten miles square) as may, by cession of the States, become the seat of the government of the United States, and to exercise such other legislative powers as Congress may, from time to time, be granted.

13 To make all laws which shall be necessary and proper for carrying into execution the foregoing powers, and all other powers vested by this Constitution in the government of the United States, or in any department or officer thereof.

Section 9. 1 The migration or importation of such persons as any of the States now existing shall think proper to admit, shall not be prohibited by the Congress prior to the year one thousand eight hundred and eight; but a tax or duty may be imposed on such importation, not exceeding ten dollars for each person.

2 The privilege of the writ of habeas corpus shall not be suspended, unless in cases of rebellion or invasion the public safety may require it.

3 No bill of attainder, or ex post facto law shall be passed.

4 No capitation, or other direct tax, shall be laid, unless in proportion to the census or enumeration hereinbefore directed to be taken.

5 No tax or duty shall be laid on articles exported from any State.

6 No tax or duty shall be laid by any regulation of commerce or revenue to the ports of one State over those of another; nor shall vessels bound to, or from, one State be charged in transitu, in any other State, with any other tax than the duty on imports.

7 No money shall be drawn from the treasury, but in consequence of appropriations made by law; and a regular statement and account of the receipts and expenditures of all public money shall be published from time to time.

8 No title shall be授于 to public lands of the United States; and no person holding any office of profit or trust under them, shall, without the consent of the Congress, lay any impost or duties on imports or exports, except as may be necessary for the support of the direct taxes and internal revenue laws; and the net produce of all duties and imposts laid by any State on imports or exports, shall be the fund of the treasury of the United States; and the Congress may regulate the same subject, subject to the revision and control of the Congress.

9 No person shall be elected to the Congress, lay any duty of tonnage, keep any record, issue any storm signal, take any slave in the comma of peace, enter into any agreement or compact with another State, or with a foreign power, or engage in war, unless actually invaded, or in such imminent danger as will not admit of delay.

ARTICLE II

Section 1. 1 The executive power shall be vested in a President of the United States of America. He shall hold his office during the term of four years, and, together with the Vice President, chosen for the same term, be elected, as follows:

2 Each State shall appoint, in such manner as the legislature thereof may direct, a number of electors, equal to the number of Senators and Representatives in which it may be entitled to send to the Congress; but no senator or representative shall be elected who shall not have attained to the age of thirty years, been nine years a citizen of the United States, and who shall not, when elected, be an inhabitant of the same State with themselves. They shall make a list of all the persons voted for, and of the number of votes for each, which list they shall sign, and certify, and transmit sealed to the seat of the government of the United States within four days after the last day of November next. The President of the Senate shall, in the presence of the Senate and House of Representatives, open all the certificates, and the votes shall then be counted. The person having the
CONSTITUTION OF THE UNITED STATES

Section 2. 1. The Judicial power shall extend to all cases, in law and equity, arising under this Constitution, laws of the United States, treaties made or which shall be made, under their authority; — to all cases affecting ambassadors, other public ministers, and consuls; — to all cases of admiralty and maritime jurisdiction; — to controversies to which the United States shall be a party; — to controversies between State and citizens of another State; — between citizens of different States, — between citizens of the same State claiming lands under grants of different States, — between a State, or the citizens thereof, and foreign States, citizens or subjects.

2. In all cases affecting ambassadors, other public ministers and consuls, and those in which a State shall be party, the Supreme Court shall have original jurisdiction. In all the other cases before mentioned, the Supreme Court shall have appellate jurisdiction, both as to law and fact, except such as to which Congress may give to the人民法院 either exclusive or concurrent jurisdiction.

The [clause was changed by the Twelfth Amendment].

4. The Congress may determine the times of choosing the electors, and the day on which they shall give their votes; which day shall be the same throughout the United States.

5. No person except a natural born citizen, or a citizen of one of the United States, at the time of the adoption of this Constitution, shall be eligible to the office of President; neither shall any person be eligible to that office who shall not have attained to the age of thirty-five years, and been fourteen years a resident within the United States.

6. In case of the removal of the President from office, or of his death, resignation, or inability to discharge the powers and duties of the said office, the same shall devolve on the Vice President, and the Congress may by law provide for the case of such removal, death, resignation, or inability, both of the President and Vice President, declaring what officer shall then act as President, in case of the death of the President only, and what officer shall act as President and Vice President, in case of the death of both the President and Vice President. The President shall take the following oath or affirmation: — "I do solemnly swear (or affirm) that I will faithfully execute the office of President of the United States, and will to the best of my ability, preserve, protect and defend the Constitution of the United States."

Section 3. 1. The President shall be commander in chief of the army and navy of the United States, and of the militia of the several States, when called into the actual service of the United States; he may require the opinion, in writing, of the principal officer in each of the executive departments, upon any subject relating to the duties of their respective offices, and he shall have power to grant reprieves and pardons for offences against the United States, except in cases of impeachment.

2. He shall have power, by and with the advice and consent of the Senate, to make treaties, provided two thirds of the Senators present concur; and he shall nominate, and by and with the advice and consent of the Senate, shall appoint ambassadors, other public ministers and consuls, judges of the Supreme Court, and all other officers of the United States, whose appointments are not herein otherwise provided for, and which shall be established by law; but the Congress may by law vest the appointment of such inferior officers as they think proper, in the President alone, in the courts of law, or in the heads of departments.

3. The President shall have power to fill up all vacancies that may happen during the recess of the Senate, by granting commissions which shall expire at the end of their next session.

Section 3. 1. He shall from time to time give to the Congress information of the state of the Union, and recommend to their consideration such measures as he shall judge necessary and expedient; he may, on extraordinary occasions, convene both Houses, or either of them, and in case of disagreement between them with respect to the time of adjournment, he may adjourn them to such time as he shall think proper; he shall receive ambassadors and other public ministers; he shall take care that the laws be faithfully executed, and shall commission all the officers of the United States.

Section 4. The President, Vice President, and all civil officers of the United States, shall take oath before Congress, or before a committee thereof, to support this Constitution; and being duly sworn, shall take office on impeachment for, and conviction of, treason, bribery, or other high crimes and misdemeanors.

ARTICLE III

Section 1. 1. The judicial power of the United States shall be vested in one Supreme Court, and in such inferior Courts as Congress may from time to time ordain and establish. The judges, both of the Supreme and inferior courts, shall hold their offices during good behavior, and shall not be liable to removal, but during the term for which they shall have been appointed, and until their successors shall be appointed and shall take office, which term for the Supreme Court shall not end during the lives of the judges, and which shall not be diminished during their continuance in office.

ARTICLE V

The Congress, whenever two thirds of both Houses shall deem it necessary, shall propose amendments to this Constitution; or, on the application of the legislature of two thirds of the several States, shall call a convention for proposing amendments, which, in either case, shall be valid to all intents and purposes, as part of this Constitution, when ratified by the legislatures of three fourths of the several States, or by conventions in three fourths thereof, as the one or the other mode of ratification may be proposed by the Congress. Provided that no amendment which may be proposed prior to the year one thousand eight hundred and eight shall in any manner affect the first and fourth clauses in the ninth section of the first article; and that no State, without its consent, shall be deprived of its equal suffrage in the Senate.

ARTICLE VI

1. All debts contracted and engagements entered into before the adoption of this Constitution, shall be as valid against the United States under this Constitution, as under the Confederation.
CONSTITUTION OF THE UNITED STATES

ARTICLE VII

The ratification of the conventions of nine States shall be sufficient for the establishment of this Constitution between the States so ratifying the same.

Dated in Convention by the unanimous consent of the States present the seventeenth day of September in the year of our Lord one thousand seven hundred and eighty-seven, and of the independence of the United States of America the ten

Articles in addition to, and amendment of, the Constitution of the United States of America, proposed by Congress, and ratified by the legislatures of the several States pursuant to the fifth article of the original Constitution.

ARTICLE I

Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof; or abridging the freedom of speech, or of the press; or the right of the people peaceably to assemble, and to petition the government for a redress of grievances.

ARTICLE II

A well regulated militia, being necessary to the security of a free State, the right of the people to keep and bear arms, shall not be infringed.

ARTICLE III

No soldier shall, in time of peace be quartered in any house, without the consent of the owner, nor in time of war, but in a manner to be prescribed by law.

ARTICLE IV

The right of the people to be secure in their persons, houses, papers, and effects, against unreasonable searches and seizures, shall not be violated, and no warrants shall issue, but upon probable cause, supported by oath or affirmation, and particularly describing the place to be searched, and the persons or things to be seized.

ARTICLE V

No person shall be held to answer for a capital, or other infamous crime, unless on a presentment or indictment of a grand jury, except in cases arising in the land or naval forces, or in the militia, when in actual service in time of war or public danger; nor shall any person be subject for the same offense to be twice put in jeopardy of life or limb; nor shall be compelled in any criminal case to be a witness against himself, nor be deprived of life, liberty, or property, without due process of law; nor shall private property be taken for public use without just compensation.

ARTICLE VI

In all criminal prosecutions, the accused shall enjoy the right to a speedy and public trial, by an impartial jury of the State and district wherein the crime shall have been committed, which district shall have been previously ascertained by law, and to be informed of the nature and cause of the accusation; to be confronted with the witnesses against him; to have compulsory process for obtaining witnesses in his favor; and to have the assistance of counsel for his defense.

ARTICLE VII

In suits at common law, where the value in controversy shall exceed twenty dollars, the right of trial by jury shall be preserved, and no fact tried by a jury shall be otherwise reexamined in any court of the United States, than according to the rules of the common law.

ARTICLE VIII

Excessive bail shall not be required, nor excessive fines imposed, nor cruel and unusual punishments inflicted.

ARTICLE IX

The enumeration in the Constitution of certain rights shall not be construed to deny or disparage others retained by the people.

ARTICLE X

The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively, or to the people.

ARTICLE XI

The judicial power of the United States shall not be construed to extend to any suit in law or equity, commenced or prosecuted against one of the United States by citizens of another State, or by citizens or subjects of any foreign State.
CONSTITUTIONAL AMENDMENTS

ARTICLE XIII

Section 1. Neither slavery nor involuntary servitude, except as a punishment for crime whereof the party shall have been duly convicted, shall exist within the United States, or any place subject to their jurisdiction.

Section 2. Congress shall have power to enforce this article by appropriate legislation.

ARTICLE XIV

Section 1. All persons born or naturalized in the United States, and subject to the jurisdiction thereof, are citizens of the United States and of the State wherein they reside. No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any State deprive any person of life, liberty, or property, without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws.

Section 2. Representatives shall be apportioned among the several States according to their respective numbers, counting the whole number of persons in each State, excluding Indians not taxed. But when the right to vote at any election for the choice of electors for President and Vice President of the United States, representatives in Congress, and judicial officers of a State, was denied to any of the male inhabitants of such State, being twenty-one years of age, and citizens of the United States, or for any term of years or for any debt, way, expense in support of rebellion against the same, or given aid or comfort to the enemies thereof. But Congress may by a vote of two-thirds of each House, remove such disability.

Section 4. The validity of the public debt of the United States, authorised by law, including debts incurred in payment of pensions and bounties for services in suppressing rebellion, shall not be questioned. But neither the United States nor any State shall assume or pay any debt or obligation incurred in aid of insurrection or rebellion against the United States, or any claim for the loss or emancipation of any slave; but all such debts, obligations and claims shall be held illegal and void.

Section 5. The Congress shall have power to enforce, by appropriate legislation, the provisions of this article.

ARTICLE XV.

Section 1. The right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of race, color, or previous condition of servitude.

Section 2. The Congress shall have power to enforce this article by appropriate legislation.

ARTICLE XVI

The Congress shall have power to lay and collect taxes on incomes, from whatever source derived, without apportionment among the several States, and without regard to any census or enumerations.

ARTICLE XVII

Section 1. The Senate of the United States shall be composed of two Senators from each State, elected by the people thereof, for six years; and each Senator shall have one vote. The Electors in each State shall have the qualifications requisite for Electors of the most numerous branch of the State Legislatures.

Section 2. When vacancies happen in the representation of any State in the Senate, the Executive authority of such State shall issue writs of election to fill such vacancies; provided the legislature of any State may empower the Executive thereof to make temporary appointments until the people fill the vacancies by election as the Legislature may direct.

Section 3. This amendment shall not be so construed as to affect the election or term of any Senator chosen before it becomes valid as part of the Constitution.

CONSTITUTIONAL AMENDMENTS, History of. As shown in a preceding article (see CONSTITUTION, FRAMING OF THE), very few of the States liked the Constitution as a form of government at all, and fewer still were satisfied with it as an instrument. North Carolina had refused to ratify without amendments and a *bill of rights* limitation of the fundamental rights of human beings to which immense importance was attached by the mass at that time; Massachusetts and New Hampshire ratified with an appended urgent recommendation of certain amendments; New
CONSTITUTIONAL AMENDMENTS

York first ratified subject to the right to secede if her amendments were not accepted within six years, and finally changed "on condition" to "in the constitution." The mass of amendments proposed in the first Congress was enormous; 103 from the States themselves, and 42 from minorities in other States, besides long bills of rights from New York and Virginia. Some of them were duplicates; if any two were great; the House rejected them all and agreed on 17 articles in their place. The Senate cut them down to 12 and both Houses passed them; the first two failed of ratification by the States, the remaining 10 were accepted and went into force 15 Dec. 1791.

The text of the Amendments is to be found with the body of the Constitution.

The First Amendment (Article I) was violated by the government within a few years in the Sedition Act (see Alien and Sedition Acts), and had no effect in accomplishing its defeat, which was effected by a party revolution. Nor has it prevented "gag laws," or exclusion from the mails of whatever has been thought objectionable. Public opinion in these respects has been found more efficient than the Constitution.

General warrants were a principal grievance of the British customs laws, a fact which explains Article IV. "Life or limb" in Article V is a curious anachronism; modern laws do not prescribe the rack as a punishment. Probably the drafters of this provision used a current phrase without stopping to analyze its meaning.

The provision of Article VI against changing the venue was doubtless suggested by the attempts to take Americans to England for trial.

The intrepid jumble of possible and impossible dangers of Articles VII-X, inclusive, reminiscences of 17th-century persecutions and 18th-century customs laws, of the times of King John and those of George III, of grievances unthinkable except under foreign rule and of others likely enough under their own, of local provisions and world-wide provisions, is amusingly characteristic of the period and the people; perhaps rather any period and any people. The Amendments inspired the champions of a strong government with great weariness and disgust; but they are not all anachronisms or idle precautions. The Tenth especially (added by Massachusetts) has in practice restrained the action of the government greatly, especially in guiding the construction of the Supreme Court; and certain provisions of the Fifth, Sixth and Seventh have been great public safeguards, by no means out of date even yet.

See Chisholm v. Georgia, for the circumstances under which the Eleventh Amendment, put in force 8 Jan. 1798, was passed. Maryland had been sued by a private citizen, and submitted; Georgia was sued, refused to plead and threatened with death any one who served a writ in the suit; and she and Virginia pressed through an amendment forbidding such suits by individuals against States, but not vice versa.

The chief of Article XII is the naming of the candidates for President and Vice-President separately; the lack of which provision brought about a discreditable intrigue, and results political and personal by no means forgotten. (See Electoral System; Jefferson-Burr Imbroglio). Before this, the highest candidate was President and the next highest Vice-President; but now came an election which showed not merely the probability of the certainty of one, between the two candidates of the same party from mere party loyalty. Yet plain as this seems, the Amendment failed in the first Congress where it was introduced, passed in the House 12 Dec. 1803, only by the Speaker's casting vote. The Senate rejected the bare three-fourths of the States necessary, and declared in force 25 Sept. 1804. New Hampshire, Massachusetts, Connecticut and Delaware (Federalist States), rejected it. The Emancipation Proclamation had freed only the slaves within the States technically in revolt. In those where the Union forces alone had prevented it, as Maryland, or a powerful minority of Union men plus resolute Union commanders, as Missouri, and generally in the Border States, the slaves were still private property, nearly 1,000,000 in number. Movements to compensate the owners were abortive, partly because the owners would not listen to such proposals. The Thirteenth Amendment was introduced for entire emancipation and compensation payment. Its phraseology is essentially that of the Ordinance of 1787 (q.v.), repeated in the Missouri Compromise and the Wilmot Proviso (q.v.). It passed in the Senate April 1864, 38 to 6, and the House 13 June 55 to 66, but the latter was not the needed two-thirds. In the next session the House passed it, and it was ratified by 31 States, and proclaimed in force 18 Dec. 1865.

The Fifteenth Amendment, in fact a rephrasing of the Fifth, arose out of the first Civil Rights Bills (q.v.), which was pronounced non-enforceable as contrary to the decision of the Supreme Court in the Dred Scott Case (q.v.), that negroes were not citizens. As this decision was law until distinctly reversed, the Amendment was drawn in the first clause clearing away that decision. The other sections were: (1) A vote to the South to give the negro the vote; (2) to give the negroes a clear field by debarring the Congress leaders from it; (3) was obvious. It passed both houses in June 1866, by overwhelming votes, but a long struggle ensued over ratification. The old Confederate States rejected it, to which Congress retraced by the Reconstruction Act of 2 March 1867, constituting provisional governments in those States until they had ratified the Amendment, and they did so. Maryland, Delaware and Kentucky also rejected it; and New Jersey and Ohio were captured by the Democrats and rescinded their ratifications, though it was doubtful whether this could be done. But finally 33 States ratified without them, and the Amendment was declared in force 28 July 1868.

The Fifteenth Amendment was practically a substitute for the second section of the Fourteenth, which was found valueless. It once respect it was weaker than the other, which prescribed a penalty for the offense, while this prescribed none; "but its specification of the negroes as the class not to be excluded, and their race or color or former legal grounds for disfranchisement, gave it apparently a clearer legal footing. In fact, however, it has been found as little worth as the other. It passed both Houses in February 1869, by immense majorities, was ratified by 30
CONSTITUTIONAL CONVENTIONS — CONSTITUTIONALIZATION

out of 37 States, and declared in force 30 March 1870. New York fell into the hands of the Democrats and rescinded its vote; a new one was filed in the State Department, which reported that the State "claimed" to have rescinded its ratification, but paid no further attention to it. It is more than doubtful if such action of a State has the least validity.

The Sixteenth Amendment was passed by both Houses of Congress and on 31 July 1909 was deposited in the office of the Secretary of State. On 3 Feb. 1913 it received one more than the required three-fourths of the votes of the States when Delaware and Wyoming voted to ratify the amendment, and on 25 Feb. 1913 it was declared in force. The purpose of the amendment was to obviate the necessity of distributing direct taxes among the States in accordance with their respective populations. There was some objection to the words "from whatever source derived" since many believed that these words might be construed into the conferring of power on the national government to tax State and municipal bonds and other like properties, thus increasing the centralization of power and authority in the national government.

The Seventeenth Amendment, providing for the election of senators by the direct vote of the people, was introduced in Congress at the request of more than 30 State legislatures and in response to a popular demand that had resulted from 40 years of agitation. It was passed in the House 13 April 1912 and in the Senate 12 June, having already been ratified by 39 States of three States — Massachusetts (22 May), Arizona (3 June) and Minnesota (10 June). On 9 May 1913 Wisconsin ratified the amendment, being the 36th State to take such action, and the amendment was declared in force 31 May 1913. See CONVENTIONS, CONSTITUTIONAL; INITIATIVE; REFERENDUM.

Ratification of the Amendments. — I to X inclusive were declared in force 15 Dec. 1791. XI was declared in force 8 Jan. 1798. XII, regulating elections, was ratified by all the States except Connecticut, Delaware, Massachusetts, and New Hampshire, which rejected it. It was declared in force 28 Sept. 1804. XIII, the emancipation amendment, was ratified by 31 of the 36 States; rejected by Delaware and Kentucky, not acted on by Texas; conditionally ratified by Alabama and Mississippi. Proclaimed 18 Dec. 1865. XIV, reconstruction amendment, was ratified by 23 Northern States; rejected by Delaware, Kentucky, Maryland and 10 Southern States, and not acted on by California. The 10 Southern States subsequently ratified under pressure. Proclaimed 28 July 1868. XV, negro citizenship amendment was not acted on by Tennessee, rejected by California, Delaware, Kentucky, Maryland, New Jersey and Oregon; ratified by the remaining 30 States. New York rescinded its ratification, 5 Jan. 1870. Proclaimed 30 March 1870. XVI, the income tax amendment, was ratified by all the States except Connecticut, Florida, Pennsylvania, Rhode Island, and New Hampshire; was declared in force 25 Feb. 1913. XVII, the amendment providing for the direct vote of United States Senators by the people, was ratified by all the States except Alabama, Delaware, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, Rhode Island, South Carolina, Utah and Virginia. It was declared in force 31 May 1913. See CONVENTIONS, CONSTITUTIONAL; CONSTITUTION, FRAMING OF THE; UNITED STATES — THE FORMATION OF STATE CONSTITUTIONS; UNITED STATES — THE FEDERAL CONVENTION OF 1787; UNITED STATES — STATE CONSTITUTIONS OF THE.

CONSTITUTIONAL LAW. See LAW, CONSTITUTIONAL.

CONSTITUTIONAL MONARCHY. See Monarchy.

CONSTITUTIONAL UNION PARTY, in United States history, popularly known in its own time as the Bell-Everett party, from the names of its presidential candidates; the name assumed by the remnant of the Southern Whigs in 1860. The platform consisted of a preamble antagonizing all platforms in general as local, and a resolution recognizing as the only right and duty of every citizen the support of "no political principle other than the Constitution of the country, the Union of the States, and the enforcement of the laws." The leaders invited members of both parties to unite in forming a program ignoring the slavery issue altogether. In the election of 1860 it carried Kentucky, Tennessee and Virginia, and had a total popular vote of 589,581 and a total electoral vote of 39. After this campaign, the party was submerged in the Civil War and went out of existence.

CONSTITUTIONS, State. See UNITED STATES — THE FORMATION OF STATE CONSTITUTIONS; UNITED STATES — STATE CONSTITUTIONS OF THE; CONVENTIONS, CONSTITUTIONAL.

CONSTRUCTIVE CONTRACT. See QUASI-CONTRACT.

CONSUBSTANTIAL, having the same substance or essence; coessential. When the Arian controversy ran high in the Church, and with the view of settling it, Constantine was induced to summon the great Council of Nice in 325; the council pronounced in favor of the Athanasian view that the Second Person of the Trinity is homoousios with the Father. The difference between the persons of the Father and the Son, however, was maintained. To this the corresponding Latin term was consubstantialis. The Greek and Roman Catholic churches, as well as those of England and Scotland, with the leading Continental Protestant churches, still adopt this view; thus the second of the Thirty-nine Articles commences, "The Son, which is the Word of the Father, begotten from everlasting of the Father, the very and eternal God and of one substance with the Father." Similarly the Westminster Confession of Faith — the standard of the proper Presbyterian churches — teaches that "In the unity of the Godhead there be three persons of one substance." (Ch. ii, § 3).

CONSUBSTANTIATION, the doctrine that in the Holy Eucharist the real body and blood of Christ are present under the same substance with the bread and wine. The doctrine of Transubstantiation is that when the words of consecration are pronounced by the priest, the bread and wine are substantially changed into the body and blood of Christ, and
consequently cease to exist as bread and wine. The doctrine of Consustantiation, on the contrary, is that after consecration they continue to exist in their original form, but substantially conjoined with the body and blood of Christ. This doctrine, generally ascribed to John of Paris, as its earliest advocate, has had few, if any, confessors. The term "Consustantiation" is often incorrectly used to designate Luther's doctrine of the sacramental conjunction with the bread and wine, which is a very different thing from that of the substantial conjunction. Luther taught that the bread and wine are present in the natural, but the body and blood in a supernatural manner. The presence is not "consubstantial"; for while the elements are masticated, swallowed, digested, etc., the body of Christ, according to Luther's teaching, is present only when the element is received by the communicant, as the words of distribution are repeated, and no longer. The presence of the elements is comprehensible, visible, tangible; that of the body and blood incomprehensible, invisible, mysterious and inexplicable. The belief that the body and blood of Christ can be received in the same way as the bread and wine, the Lutheran Church designates as "Capernamitic error," as the people of Capernaum, in John vi, 52, seemed to have had such an impression. Consustantiation is sometimes called Impanation, which defines the relation between Christ and the elements in the Eucharist as a hypostatic union such as exists between the divine and human natures in Christ. Consul Hagenbach, "History of Doctrines" (Vol. II), and for the Roman Catholic view consult Streber, "Kirchenlexikon."

**CONSEULO,** which appeared from the hand of George Sand in 1842-43, a fantastic tale with a number of genuinely historical characters, reflects the innumerable theories of social reform and the mystical, quasi-philosophical ideas then in the air. George Sand was at that time under the influence of the religious radical Lamennais, of the humanitarian revolutionary Proudhon, of the Polish poet Chopin, of the Polish poet Mickiewicz and his Slavic mysticism. The action of "Conseulo" is placed in the middle of the 18th century. The heroine, a wonderful Venetian singer, is a fanciful portrait of the popular singer of that famous, Louise Abdinor Viardot. The character is made to embody the ideas of the Saint-Simonian socialists, of Liszt and of Lamennais, as to the sacerdotal role of great musical artists. She is the pupil of the noted composer and singing-master Forpora. Eluding a selfish and unworthy lover, she escapes and enters the castle of the noble family of Rudolstadt in Bohemia as music teacher. The heir of the family, Count Albert, loves her. He is a strange being, living a mysterious life, who speaks and acts as though he reincarnated previous human existence. Here is again seen the influence on the author of Leroux and his theories of the immortality of man in humanity. Conseulo, not sure of her own love, escapes again and wanders through the cold street, as a boy with his young musician Haydn. At the court of Maria Theresa in Vienna she rises to fame in spite of the jealousy of her former lover's mistress, Corilla. But she is recalled to Rudolstadt by the first citizens, and on his death bed, thus symbolizing the democracy of art and humanity and the union of classes. The later history of Conseulo is continued at equal length in the sequel, "Conseulo, la duchesse de Rudolstadt."

"Conseulo" seems to-day old-fashioned and long-winded, but it embodied the genius of its author and the aspirations of an age of reformers whose ideas were yet nebulous and impractical. On the other hand it did not strain the patience of readers who had not outgrown the long stories of wandering adventure like "Wilhelm Meister," nor entirely forgotten the mysterious castles of Mrs. Radcliffe. "Conseulo" remains, therefore, an important document for the understanding of past social theories as well as a once very popular work of fiction.

**CHARLES H. C. WRIGHT,**

**Professor of French Language and Literature, Harvard University.**

**CONSUL,** the title given to the two chief magistrates of the ancient Roman Republic and to the three supreme magistrates of the first French Republic during the last five years of its existence. In present usage the term indicates an official who resides in a foreign or other commercial centre as the representative of his home government and who is charged with the protection of his fellow-countrymen and the safeguarding of their interests.

The office of consul was created in Rome about 508 B.C., after the expulsion of the kings. The election to the consulship was annual, and only patricians were eligible until the Licinian laws opened the office to the plebeians.

In the history of France the title of consul appears after the fall of the Directory, when three consuls were appointed. The constitution of 13 Dec. 1799 gave to the first of these magistrates the real power, the others having only an advisory voice in the government. Napoleon Bonaparte became First Consul. In 1802 he was confirmed in the consulship for life, and in 1804 he abolished it by the establishment of the Empire. The office of consul in the present signification of the term had its origin in the extensive trade relations of the Italian cities of the 12th century.

In 1780 the first United States consul was commissioned. The consular system was established by acts of Congress in 1790 and 1792. The consuls are appointed by the Board of Foreign Trade, arranged by statute in three classes: (1) Those in which the incumbents receive a fixed salary and are not allowed to transact business; (2) those to which a fixed salary is attached and business transactions permitted; (3) those in which the incumbents are compensated by fees collected in their offices and are allowed to transact business. There were in existence, 25 Oct. 1902, 315 consular posts. Among the responsibilities devolving upon United States consuls are the regulation of shipping, the issuing of passports and of certificates of births, deaths and marriages, the caring for disabled seamen and the ensuring of justice to native-born or naturalized American citizens. Consuls also send reports to the home government concerning foreign trade conditions. In countries where the government is unstable or despotic American consuls are vested with exceptional powers. They may exercise judicial functions over lawbreakers of their own nationality, such as fining, confining to a prison, etc. Local powers and duties of consuls are determined by
treaty. Before entering upon his duties a consul must receive an exequatur from the government to which he is accredited. No radical change has been made in the consular service of the United States since its establishment. President Cleveland by executive order in 1895 applied civil service principles to consular posts of a certain class. Of late there has been considerable agitation in favor of reorganizing the system.

CONSULAR SERVICE OF THE UNITED STATES

The first consul of the United States was appointed 9 Dec. 1780, although the commissioners of the United States in Europe had exercised consular functions in addition to their diplomatic duties prior to that time. Five years afterward Congress declared by joint resolution that it was expedient that the United States should appoint consuls abroad, and expressly authorized American ministers in Europe to exercise the powers of consul-general in the countries to which they were accredited. The Constitution, adopted in 1787, conferred upon the President the power to nominate, and by and with the advice and consent of the Senate, to appoint consuls. While President Washington in pursuance of the authority given him by the Constitution appointed a number of consuls and vice-consuls, no detailed law regarding consuls was passed until 14 April 1792. That law, which was to carry into effect our consul treaty with France, did not create or even regulate a consular system, but merely recognized its existence by imposing upon it certain specified duties. The act of 1 May 1810 appropriated salaries for the consuls at Algiers, Tangier, Tunis and Tripoli, which for nearly 30 years were the only consular salaries provided by law. For the most part, the United States, like most other nations, started by appointing unpaid consuls from among American merchants residing abroad, or, if they were sent from America, by permitting them to enter into business as a means of ensuring support. Consuls were also allowed to retain as compensation the fees collected for official services performed.

This so-called system was found to work badly for the interests of the government as well as the individual citizen, and as early as 1816 the Secretary of State, to whose discretion the administration of the service was left, proposed to Congress to pay fixed salaries to the consuls at more important places, at least. Efforts in this direction were continued from time to time with the object of so providing for the compensation of consuls that they could devote their time to their official duties, but nothing was accomplished until 1855, when Congress passed the law in pursuance of which the reorganization of the consular service upon substantially its present basis was effected. The aim of this act was to reduce the service to a regular system somewhat in line with the British consular service by providing for fixed salaries to the principal consuls, prohibiting those consuls from engaging in business requiring them to remit to the Secretary of the Treasury all fees collected by them for performing official services. The appointment of consular officers is now in the hands of the President and by executive order of 1906 under the Lodge Act passed in that year, all consular officers except clerks, consular agents and vice-consuls, must pass a qualifying examination. The examining board consists normally of the Secretary of State, the Director of the Consular Service, the Chief of the Consular Bureau and the Chief Examiner of the Civil Service Commission.

Consular officers of the United States are divided into two classes, principal and subordinate. Principal officers are consuls-general and consuls. Subordinate officers are vice-consuls, consular agents, consular assistants, clerks, student interpreters and also interpreters. Consuls-general perform the same duties as consuls, and in addition have general supervision over consuls within the limits of their jurisdiction. There are five consuls-general at large, who inspect every consulate at least once in two years. Like consuls, consuls-general are appointed by the President and confirmed in the Senate. The senior vice-consular officers at a consulate fill the places and exercise the functions of consuls-general and consuls, when those officers are temporarily absent or relieved from duty. When the principal officers are present at their posts, they are subordinate to, and exercise their powers and perform their duties under, the direction of principal officers. They may be situated in a different city from their consulate. Consular agents are subordinate to principal consular officers excepting exercising the powers and performing their duties at ports or places different from those at which their principals are located. Their functions are not in all respects as extensive as those of principal officers, and they are not authorized to correspond with the Department of State. There are 40 consular assistants provided for by law. They are appointed by the President, after examination, and can only be removed for cause. They are assigned from time to time to consulates with such duties as the Secretary of State may direct. Besides these there are clerks at a salary from $300 to $1,500 a year and a corps of student interpreters, 10 in China, 6 in Japan and 10 in Turkey. The salary of student interpreter is $1,000, plus allowances for studying. When qualified, they may be appointed interpreters at varying salaries. Consular officers qualify by taking a prescribed oath, and all except consular agents and consular clerks are required to file a bond to the United States for the faithful performance of their duties. The salaries of consuls-general and consuls range from $2,000 to $6,000 a year. Vice-consular officers receive no fixed salaries, but when in business they receive half as much as the principal officer normally holding it. Consular agents receive as compensation one-half of the official fees collected by them up to $1,000. Consular assistants receive salaries of $1,000 for the first three years' service, after which their salaries are gradually increased to $1,800 a year. All fees for unofficial and notarial work are retained as personal compensation by the officers collecting them.

The duties of consuls of the United States are varied, and include the shipment, discharge
and relief of seamen of American vessels; adjustment of differences between masters and crews; reclamation of deserters; protection of citizens of the United States, settlement of estates of citizens who may die intestate in foreign countries; issuance of bills of health certifying to the sanitary condition of the cargo, passengers and crew of vessels clearing from foreign ports for ports in the United States; issuing and vising of passports; superintending the disinfection of merchandise exported to the United States from a district in which infectious diseases exist; execution of landing certificates; and certification of invoices of merchandise valued at more than $100 exported to the United States. The latter duty is highly important for the protection of the customs revenue, and makes it necessary for consular officers to examine carefully each invoice before certifying that the prices stated therein are correct. In case the merchandise is found to be undervalued, notice of the fact is sent to the collector of customs at the port in the United States to which the merchandise is destined.

Consular officers are not permitted to solemnize marriages, but they may, when requested, be official witnesses of the ceremony of marriage where one of the parties is a citizen of the United States. In such cases they give each of the parties a certificate of the marriage, and forward a certificate thereof to the Department of State. Under section 4082 of the Revised Statutes, marriages in the presence of a consular officer of the United States in a foreign country, between persons who would be authorized to marry if residing in the District of Columbia, are declared to be valid and to have the same effect as if solemnized in the United States, but the operation of this statute outside of the District of Columbia and the Territories is doubtful.

The exemptions and privileges of consular officers depend largely upon the treaties existing between the United States and the countries to which they are accredited. In the absence of treaties, consuls after receiving their exequatur are regarded both as officers of the state which appoints and the state which receives them under the special protection of international law. They may claim exemption from military service and service on juries, and the right to place the arms of their government over their doors.

In virtue of treaties and Title XLVI1 of the Revised Statutes, consular officers in China, Siam, Turkey, Morocco, Maskat, Persia, Zanzibar and Tripoli are invested with judicial powers. In China, Turkey and Siam, consuls are empowered to arraign and try all citizens of the United States, and to impose penalties against law, committed in that country, and to sentence offenders. They also have jurisdiction in civil cases between American citizens. In the trial of cases between citizens of the United States and subjects of China or Siam, the consul of the United States act in conjunction with the Chinese or Siamese officials. In case of disputes between Turkish subjects and citizens of the United States in Turkey, provision is made for the presence of the Dragoman of an American consulate at the hearing. The treaties with Persia, Maskat, Morocco, Zanzibar and Tripoli give consular officers jurisdiction over cases the parties to which are American citizens, and provide for the assistance of consuls in the trial by the foreign tribunal of cases in which one party is a citizen of the United States and the other a subject of the foreign power.

The duties of consular officers with respect to the development of our foreign trade are of comparatively recent origin, but, owing to increased competition among commercial nations, have become of special importance within the past few years. Every consular officer is now expected to have accurate knowledge of the conditions of trade and commerce of the place where he is located, and he is required to keep the Department of State fully informed regarding all matters of interest touching the industries, trade, commerce and manufactures of the country of his official residence. He must be alert and report promptly new markets for American products or manufactures, the construction of public works, changes in transportation rates and facilities, the opening up of new trade routes, changes in economic conditions within his district, improvements of old and development of new industries, including inventions or discoveries, development or decline of commercial and manufacturing centres, projects for great manufacturing or other industrial enterprises, river and harbor improvements, hygienic and quarantine measures, fluctuations in rates of wages, changes in tariff legislation, the enactment of patent, trade mark and copyright laws, and legislation preventing the adulteration of food, and all other information of value to the commercial and industrial interests of the United States. The information reported that may be of current interest is printed in a publication known as Daily Consular Reports, which has been issued daily since 1 Jan. 1898. Till 1903 they were known as Advance Sheets of Consular Reports. The reports are collected at the end of every month and printed in a periodical monthly, Monthly Consular Reports. Established in 1880, these comprehensive reports are prepared annually under special instructions of the Department of State with the object of presenting a statement of the trade, not only of the United States, but with the trade of the United States with other countries with each other, and these reports are published under the title of Commercial Relations. From time to time, at the suggestion of individuals or firms seeking information as to conditions in foreign countries, special reports are obtained from consuls and are printed in separate form.
The volume known as 'Consular Regulations,' the latest edition of which was published in 1890, contains all the laws, treaties and regulations which govern consular officers in the performance of their duties. This is supplemented by Circular Instructions to Consular Officers, the latest edition of which appeared in 1898. Consult also Senate Report, No. 1202 (50th Congress, 1st Session).

CONSULATE (Fr. consulat). The form of government in France from the overthrow of the Directory, 9 Nov. 1799 (Brumaire) to 18 May 1804, when the First Consul (Napoleon Bonaparte) was made emperor. After the fall of the Directory the Council of Ancients and the Five Hundred appointed three consuls—Bonaparte, Roger Ducos and Sieyès. Sieyès and Ducos soon retired on pensions and were replaced by Cambacères and Lebrun. On 24 Dec. 1799 Bonaparte became First Consul. The consuls were elected by the Senate for 10 years. The Senate itself was composed of 60 members appointed for life, and there were also a Tribunate of 100 members and a Legislative Assembly of 300 members. The powers of these chambers were greatly restricted while those of the First Consul were almost absolute; all members, councillors, naval and military officers, and nearly all judges being appointed by him. In May 1802 Bonaparte, who had already held a magnificent court at the Tuileries, was re-elected First Consul for 10 years, and in the following August he became First Consul for life. On 18 May 1804 Bonaparte was made emperor, having long enjoyed the prerogatives of the office in fact if not in name. (See FRANCE; NAPOLEON I). Consult Thiers, 'Histoire du consulat et de l'empire' (Paris 1845-62), and the numerous lives of Napoleon.

CONSULTA, the committee of three members of the Council of State of the Netherlands from 1559 to 1567, during the regency of Margaret of Parma. The three were Barlaymont, Viglius and the Bishop of Arras.

CONSUMERS' LEAGUE, an organization intended to promote better conditions among the workers by encouraging the purchase of goods made and sold under proper conditions. The work of the organization is based upon the principle that the purchase of an article tends to create a demand for that article, and that in the stress of modern competition manufacturers and merchants are unable to improve the condition of their employees while there is a constant demand for cheap goods, regardless of how cheapness is brought about. The movement had its origin in England in 1863. In 1883 the first consumers' league in the United States was organized in New York in 1891; its object was to investigate retail stores and to encourage the patronizing of those conforming to their standard of conditions. Similar leagues now exist in all the large towns of the United States and in many in Canada. The standard for a "fair house" demands: (1) Equal wages for women and men for equal work, wages to be paid by the week; (2) reasonable hours of employment according to local conditions, overtime to be paid for; (3) half-holiday in the summer; (4) retiring and lunch rooms to be separated and regulated according to the sanitary laws; (4) recognition of fidelity and length of service and general considerate treatment.

The National Consumers' League was organized in 1898 for the purpose of regulating conditions of manufacture rather than sale. The national organization is a federation of State leagues; the governing body is a committee consisting of representatives from the State leagues. The council annually elects a president, two vice-presidents, two secretaries and a treasurer; and these, with two representatives from each State league, constitute a committee of the council. Any person living where there is no local or State league may join the national society by paying a yearly fee. The main lines of its work are enlisting the aid and interest of authorities in the enforcing of labor laws and furthering of necessary legislation; investigating conditions of labor and awarding the use of the league's label to manufacturers conforming to their standard; educating public opinion by lectures, correspondence and literature. The standard for retail establishments entitled to the label demands: (1) That all State factory laws be complied with; (2) that the label be used only on goods made on the premises; (3) that no child under 16 be employed; (4) that no person employed receive less than 60 hours a week; (5) the league shall have the right of inspection. The national organization embraces leagues in all the States.

CONSUMPTION. There have been two meanings given by economists to the term consumption of wealth. By one group it has been made to include any utilization of wealth in which the wealth is used up or destroyed in the process. By another group it means only such utilization as gives direct satisfaction to a consumer. Under the first definition, coal is consumed when it is burned to make steam for the running of machinery as well as when it is burned to supply warmth for the comfort of the human body. Under the second definition only the latter use of coal would be called consumption. They who hold to the first definition are compelled to divide consumption into two kinds, namely, productive consumption and unproductive consumption. It is always explained, however, that the term unproductive consumption does not mean useless or unnecessary consumption. It means merely that wealth thus consumed, in contradistinction to that which is productively consumed, is not used up in the process of producing other wealth. It is used, rather, for the final purpose for which all wealth is produced, namely, the direct satisfaction of human desires or needs.

The tendency among recent writers is to use the term consumption in its narrower sense. By the consumption of wealth under this definition is meant the culmination of the whole economic process, namely, the satisfac-
tion of human desires. Wealth which is used up or worn out in the process of production is not itself yielding consumers' satisfactions directly. It is helping to produce other things which will directly satisfy consumers and may therefore be said to be indirectly satisfying desires. By the consumption of wealth, under this narrower definition, is meant its utilization in the direct satisfaction of human desires. The physician's automobile which is used in his profession is being worn out, but it is not being consumed in the technical economic sense. But when it is used for his own enjoyment or that of his family it is being consumed. Again, a thing may be in the process of consumption even though it is being used up very slowly. A diamond which is used as an article of pleasure or adornment is in the process of consumption even though it may never be really worn out. A substantial piece of furniture, when used for direct satisfaction, is being consumed. That is, if it is in a furniture store, the immediate purpose of the owner is to gain a profit from it rather than to enjoy it. Therefore it is not yet in the process of consumption. In short, the consumer of an article is the one whose satisfaction it satisfies directly. The article begins being consumed whenever it begins satisfying a consumer's desires directly, that is, when it has passed through all the channels of business and trade, where it was used for the purpose of getting an income, and passes into the possession of someone for whose satisfaction it was designed.

Most textbook writers on economics have regarded the consumption of wealth as a department of the subject, co-ordinate with such departments as production, exchange and distribution. None of them, however, has given as much space to it as to these other departments. The reason apparently has been the general opinion that consumption is essentially an individual matter with which the public has had little or no concern. Laws relating to consumption have been called sumptuary laws, and have generally been condemned, or only half-heartedly approved. There is a growing opinion, however, that consumption is quite as important from its effects on national prosperity, power and greatness, as any department of economics. Even the regulation of consumption, as in the case of laws regulating or prohibiting the use of alcoholic beverages, is becoming popular. Probably no movement of the present day in America is quite so popular or so democratic as the prohibition movement.

The importance of the consumption of wealth is further emphasized by the consideration that as many and as dire calamities have overtaken nations and peoples because of their irrational habits of consumption as because of inefficient systems of production, exchange or distribution. In fact, there is a very profound reaction of consumption upon all the other departments, particularly upon distribution. The standard of living of the laboring classes, which is a part of consumption, has much the same influence upon the price of their labor as that exercised by the cost of production upon the price of a material commodity. Again, the rate of the accumulation of capital upon which so many things depend, is largely determined by the habits of consumption. The effect of luxury upon industry and general national strength is one of the largest of all questions. These illustrations are enough to show that the subject of consumption deserves the most careful study and the most serious treatment which economists can give it. Systematic work on the laws of the process of consumption is scarce. Cuhel, 'Zur Lehre von den Bedürfnissen' (Innsbruck 1907), and Brentano, 'Versuch einer Theorie der Bedürfnisse' (Munich 1908). Examples of the application of the principles of consumption to the problems of progress are found in Patten, 'Theory of Prosperity' (New York 1902), and Sombart, 'Der moderne Kapitalismus' (Leipzig 1902). See Distribution; Income; Wealth.

THOMAS N. CARVER, Professor of Political Economy, Harvard University.

CONSUMPTION. See Tuberculosis.

CONTACT, in astronomy, a word used in describing eclipses of the sun and moon, and also the transits of the inferior planets. In a solar eclipse contact takes place at the instant when the limbs of the sun and moon just touch each other either exterioy or interiorly; in a lunar eclipse, when the shadow of the earth just touches the limb of the moon; and in the case of a transit of Venus or Mercury, when the limb of the planet just touches the earth's limb either exterioy or interiorly. The instant of interior contact and of exterior contact are distinguished by these names.

CONTACT ACTION. See Catalysts.

CONTACT METAMORPHISM. See Metamorphism.

CONAGTION. Before the time when the microscope and other laboratory aids showed the actual causes of many disease processes in the human — and other animals — body, the word contagion was surrounded by much mystery. At the present time the term "communicable" is preferable. Thus communicable diseases are those which result from actual or remote contact with the host. There are a great many such communicable diseases. The actual contagium or causative factor is known for many, while for others it has yet to be definitely ascertained. How the actual contagium is known, the method of the transmission is still in doubt. Thus in the group of exanthematous diseases such as measles, scarlet fever, smallpox, chickenpox, the actual contagion has not been demonstrated. For diphtheria, whooping cough, boils, carbuncles, tuberculosis, typhoid fever, cerebrospinal meningitis, gonorrhea, plague, cholera, pneumonia, erysipelas and influenza the actual causative agents are minute plants belonging to the group of bacteria. The contagium of syphilis, sleeping sickness, yaws, Aleppo boil and a group of related diseases are minute animalcules of the protozoa group. The contacts here are direct; while malaria, which is also a communicable disease, is caused by a minute animal form of the protozoa group, which is usually transmitted by an intermediary host, such as the mosquito. Thus in malaria the process is as follows: The minute animal form causing it is found in the blood and other tissues of the sick individual. This is taken into the body of a biting mosquito, usually of a special type, Anopheles; for the common chills and fever of the United States, the malarial parasite undergoes a series of
changes in its mosquito host and then is carried to a well individual through the bite of an infected mosquito. In former years much nonsense was talked and taught by physicians about miasmas, and dangerous night air, and the harm of dampness, etc. The dangers existed, not in a hypothetical miasm, but in real mosquitoes that usually flew and fed about dusk and which lived in wet, springy localities. If there were no patients with the parasite, there would be no malarial epidemics to be communicated. Hence malaria is stamped out either by getting rid of mosquitoes or isolating patients and preventing the mosquitoes from carrying away blood with the real cause.

Many communicable diseases are borne by the air and involve the respiratory tract. Influenza and pneumonia are among these. In epidemics breathing masks worn by the sick may prevent spread of contagions. Typhoid fever and cholera are usually communicated by means of the digestive canal. They are best eradicated by proper sanitation. They are not contagious.

A community which has had a typhoid fever is deficient in social intelligence. Such a community prefers corrupt politics to clean water supplies and good sanitation. With it goes the death of its young people. High percentages of typhoid in communities is in direct proportion to the social enlightenment of the same communities.

It may be said that so-called disinfectants, etc., which are used to prevent communicable diseases are a relic of the dark ages. *Cleanness is next to godliness* is a good maxim, but should apply to spiritual cleanliness as well. The fight against gonorrhea and syphilis is a losing one. The moral tone of the race is still too infantile to stamp these scourges out in the community as yet. Certain restrictive measures are of some service, but a higher degree of sexual intelligence is needed to combat these two prevalent communicable diseases. So long as knowledge of the most important function of the human race is considered improper, so long will gonorrhea and syphilis be widespread. When the community realizes the importance of the most important kind of knowledge to have, then that community will gain the ascendancy over the so-called venereal diseases, and those individuals who have grown away from their infantile sexuality will live.

There is a whole group of communicable diseases due to contagions from animals. Such are tape worm, hook worm, round worms, etc. Here the ova, or eggs, pass from the animal direct, through handling dirty animals, dogs particularly, or the fecal matter containing the ova is conveyed through water supplies, or through food contaminated by infected water. The old distinctions between contagion and infection are no longer tenable, hence the terms are used interchangeably, or better, supplanted by the term communicable.

SMITH ELY JELLIFFE.

CONTARINI, kön-tā′rē-nē, the name of a noble family of Venice, one of the 12 that elected the first doge. The most important members were DOMENICO, doge of Venice from 1043 to 1071 or 1073. He rebuilt Grado, and reduced the city of Zara, which had revolted. During his reign the rebuilding of Saint Mark's Church was undertaken. JACOPO, doge from 1075 to 1080. Under his reign the Venetians forced the city of Ancona to acknowledge their sovereignty over the Adriatic Sea. ANDREA, doge from 1367 to 1382. The Genoese, under Pietro Doria, had conquered Chioggia in 1379, and threatened even Venice. Andrea Contarini reconquered Chioggia, captured the Genoese fleet and delivered the republic from its enemies (1380). FRANCESCO, fran-chē′skō, doge from 1623 to 1625. Under him Venice, in alliance with Louis XIII of France, the Duke of Savoy and the Protestant cantons of Switzerland, reconquered the Pays de Vaud in 1624, of which the Austrians had taken possession. CARLO, doge from 1655 to 1656. Under his reign Lazzaro Mocenigo, admiral of the republic, in June 1655 gained a brilliant victory over the Turks in the Dardanelles. DOMENICO, doge from 1659 to 1674. During his government the Venetians resisted for five years the attacks of the Turks on the island of Candia; but on 26 Sept. 1667, after a siege and defense of unexampled obstinacy, Francesco Morosini surrendered the island. AMBROGIO, äm-brō′jō, from 1673 to 1677, was ambassador of the Republic of Venice to the King of Persia, Usun Kassan. The interesting description of his residence at this court first appeared at Venice in 1687, in Italian. GASPARO, diplomatist, who served as Venetian Ambassador to the Diet of Worms in 1521. From there he accompanied Charles V to the Netherlands, England and Spain and negotiated a permanent peace between the Republic and Charles V in 1529. Pope Paul III conferred on him the cardinal's hat in 1535. In 1541 he was papal legate at the Diet of Ratisbon, where he distinguished himself by his moderation. After his return he was sent as legate to Bologna, where he died in 1542. GIOVANNI: b. Venice 1549; d. 1603; was one of the most distinguished painters of his age. He worked in the style of Titian, and was particularly skilful in painting ceilings; for example, his 'Resurrection' in the church of San Francesco di Paolo, in Venice. VINCENZO, vën-chē′zō: b. Venice 1577; d. 1617; a scholar and poet, who in early life so great that the magistrates of Padua established a new chair of Latin and Greek eloquence only to retain the learned youth of 20 years of age in their city. He lectured there until 1614. At one time there were no less than 18 branches of the family; one of the most important was that of Contarini dallo Zaffo or di Giaffa who had been invested with the countship of Jaffa in Syria for their services to Caterina Cornaro, queen of Cyprus; another was that of Contarini degli Scrugni, so called on account of their great wealth.

CONTÉ, kön-tā′, Nicolas Jacques, French inventor: d. Annnon-sur-Orne, near Sées, 4 Aug. 1755; d. Paris, 6 Dec. 1805. He was at first a painter but afterward turned to the mechanical arts and when France was deprived through its war with England of its supply, he invented a substitute in the shape of a mixture of graphite and clay which was subsequently used for the manufacture of black lead pencils, known as *crayons Conté.* This process was the foundation of all subsequent manufactures of pencils. After several successful experiments in the use of the balloon
for military purposes he was made director of
the French Aérostatic Institute and chief of the
aérostatic corps of the army. He accompanied
the French army at the time of Napoleon's
expedition to Egypt and erected works in Cairo
from the manufacture of guns, ammunition, surgical instruments, bread and other necessaries.
He also invented a barometer (1798) similar to
Vidi's. In 1802 he instigated the foundation of
the Society for the Encouragement of National
Industry. When the results of the Egyptian
expedition were ready to be published, Conté
was commissioned to take complete charge of
its production. He endeavored to construct an
engraving machine for this purpose, but died
before the work was well under way. Consult
Jomard, 'Conté, sa vie et ses travaux' (Paris
1852).

CONTEMPORANEITY OF GEOLOGICAL STRATA. Formerly strata found
partly with identical, partly with allied fossils,
were held to be exactly contemporary, though
widely separated on the earth's surface; now
the same facts are used to establish the con-
trary conclusion. If each species came into
existence at a certain spot on the earth's sur-
face, from which it gradually spread in various
directions, it cannot have reached a remote re-

gion till some considerable time after its birth.
Two strata, then, widely separated in the world,
containing some species common to both, are
contemporaneous in this sense, that they were
formed while that species lived; but the stratum
near its birthplace is likely to be older than the
one to which it spread after it had already
multiplied greatly and rooted itself successively
in all of the intervening regions, wherever a
place appropriate for its habitation could be
found.

CONTEMPT, a wilful disregard or dis-
obedience of a public authority. The Consti-
tution of the United States provides that each
House of Congress may determine the rules of
its proceedings, punish its members for dis-
orderly behavior, and, with the concurrence of
two-thirds, expel a member. The same provi-
sion is substantially contained in the constitu-
tions of the several States. The power of
making rules carries with it that of enforcing
them, and the power to attach persons who
violate them, and to punish them for contempt.
Courts of justice have an inherent power to
punish all persons for contempt of their rules
and orders, for disobedience of their process
and for disturbing them in their proceedings.
The penalty is fine or imprisonment or both.
The guilty person may have these penalties re-
mitted by purging the contempt, i.e., by mak-
ing pecuniary reparation for any damage
resultant of his action, and by apologizing for
his fault. The breach of the rules of conduct
set down by the judiciary for certain persons,
thought committed out of court, is a contempt,
also. The use of this jurisdiction of punish-
ment for contempt in labor disputes has been
given the name of "government by injunction" as
an analogy to the courts of equity and of
punishing without trial by jury and the other safeguards
of criminal law. Consult Rapajje, 'Treatise on
Contempt' (New York 1884); and Oswald,
'Contempt of Court, Committal and Attach-
ment and Arrest on Civil Process' (London
1895).

CONTES BLEUS, könt' bé' (Blue Tales). The 'Contes bleus' of Edouard Laboulaye are
stories, mainly fairy tales, from various sources,
including the invention of the author, which
owe their charm not merely to the material of
folk-lore that they contain and to the stamp of
the popular imagination that it bears, but also
and in larger measure to the alert, graceful and
good-humored style in which they are told.
For Laboulaye was really very far from the
naive popular imagination in which fairy tales
were born, and even in retelling authentic ones
he slips in many a mischievous thrust at the
weaknesses of poor human nature, many a
sardonic reflection on social and political insti-
tutions, and often comes dangerously near
pointing a moral. Indeed he distinctly recom-
mands the reading of fairy tales for children
for their moral value. 'There is often more
moral stuff in a fairy tale,' he says, 'than in all
the history of Rome. They were born of the
wisdom of the race.' In proportion as he
draws more on his own invention, the majestic
becomes the transparent mask of whimsical
satire directed against the vices and foibles of
men and informed by the love of free and
liberal institutions of which Laboulaye was an
ardent defender. By the nimbleness of the
mind that plays about the most various themes
and touches grave questions with a laugh, by
the sparkling wit and the mordant irony, some
of these tales might almost almost be taken for
'sontes philosophiques' of Voltaire of a
lesser, good-humored Voltaire, without the
snee.

The 'Contes bleus' appeared in three vol-
umes: 'Contes bleus' (1853); 'Nouveaux
contes bleus' (1857); 'Derniers contes bleus'
(1883). They have been in part translated by
Mary L. Booth under the title Laboulaye's
Fairy Book' (New York 1896).

ARTHUR G. CANFIELD,
Professor of Roman Languages, University of
Michigan.

CONTES D'HOFFMANN, Les, opera
by Offenbach (q.v.), first produced in Paris,
10 Feb. 1881; in New York, 14 Nov. 1907.

CONTES DE FÉES, könt' dé fá' (Fairy Tales). The 'Contes de Fées,' or Fairy Tales,
published in 1697 under the name of "Perrault
Fils," was the only 10 years old, was
written by his father, the Academician Charles
Perrault, better known through his controversy
with Boileau about the relative merits of the
Ancients and Moderns. The stories were not
original, but belonged to the universal folk-
lore, as old as humanity itself; to Perrault
belong the credit of having given to them a

definite literary form, not entirely free from
certain mannerisms of the time, yet simple,
natural and well adapted to the understanding
of the minds of children. Such stories as 'Blue
Beard,' 'Puss in Boots,' and 'The Sleeping
Beauty' have become a part of the world litera-
ture of childhood, and have been widely
imitated everywhere.

Published under the title 'Contes de ma
mère l'Oye,' or Stories from Mother Goose,
both stories and title have caused many specula-
tions as to their origin. The most plausible
theory about the origin of such stories is that
the human mind in its infancy received the
same impressions from the various phenomena

584 CONTEMPORANEITY OF GEO.
M. STRATA—CONTES DE FÉES
of nature, and from its own feelings of hunger, fear, love, etc. The stories telling of such emotions were further modified by migrations to different countries and climes. "Mother Goose" has been said to represent many noted personalities, from the wife of Charlemagne to the Queen of Sheba, and even the Virgin Mary! She is more likely the personification of the "Grandmother" or the "Old Nurse" giving free rein to her imagination for the entertainment of young children. The "fables" do such wonderful things in these stories, as their name indicates (French: fée; Latin: fatum, fata, fate, destiny), the living representation of the many influences which affect our lives, mastered the mind instinctively attracted and affected by the unusual, the mysterious and the unknown.

Perrault's 'Fairy Tales' have been translated into all languages; they have brought about the collection of many stories of folk-lore in all countries, and have been widely imitated, particularly by the Brothers Grimm, Hans Andersen, etc., and in France by George Sand, 'Stories of a Grand Mother'; Ch. Norier, 'Evening Stories'; and Daudet, etc.

LOUIS A. LOISEAUX.

CONTESTED ELECTIONS. See Elections.

CONTI, könt′tě, the name of a distinguished French family, a younger branch of the Bourbon house of Condé, deriving its title from the small town of Conti near Amiens. It sprang from Armand de Bourbon, Prince of Conti, brother of the great Condé (b. 1629; d. 1666). He took an active part in the troubles of the Fronde both for and against the court, and married the niece of Mazarin. His son, François Louis (b. 1664; d. 1709) was brought up under the eyes of the great Condé, served with distinction under the Duke of Luxembourg, and was elected king of Poland by a number of the magnates, but declined the honor. The last of the house of Conti was Louis François Joseph, b. 1734; d. 1814.

CONTI, Augusto, Italian philosophical writer: b. San Miniato, Tuscany, 1822; d. 1905. He studied law at several Italian universities and practised in Florence until 1848, when he enlisted as a volunteer for service against Austria. Subsequently he practised law and taught philosophy at San Miniato. In 1855 he was made professor of philosophy in Lucca, in 1863 professor of the history of philosophy in Pisa, and in 1864 professor of mental and moral philosophy in Florence. His published works include 'Evidenza, amore e fede, o i criteri della filosofia' (1862, and subsequent editions); 'Storia della filosofia' (1864); 'L'Armonia delle cose' (2 vols., 1878); 'Filosofia elementare' (1869; 9th ed., 1879); 'Dio come ordinatore del mondo' (1871); 'Il vero nell' ordine' (1876, 1891). In these works Conti makes an earnest attempt to bring into agreement the teachings of different philosophical schools.

CONTINENT. A definition of continent based on the origin and development of land masses is not possible in the present state of our knowledge, and about all that can be done is to define a continent as a very large body of land. Africa, North America, South America, Europe, Asia and Australia are such land areas, but since Europe and Asia form a single land mass, many physical geographers speak of the two as one continent — Eurasia. There is also probably a land area of continental size in the Antarctic regions.

Origin of Continents. — The solid earth, the lithosphere, is largely covered by water, the hydrosphere; the proportion of land to water on the surface of the globe being about 1 to 2.63, making the land surface about 27.5 per cent of the total. The extreme height of the land above sea-level is about five miles (Mount Everest 29,000 feet), and the extreme depth of the ocean somewhat more; the extreme relief of the lithosphere is therefore over 10 miles. According to Lapparent the mean elevation of the continents is as follows: Europe 958 feet; Australia 1,118 feet; South America 1,702 feet; North America, 1,953 feet; Africa 2,007 feet; Asia 2,883 feet. The mean height of all land is estimated at a little over 2,000 feet, and the mean depth of the ocean at 12,000 to 15,000 feet. Therefore if the solid earth, the lithosphere, were free from inequalities, the hydrosphere would cover it, perhaps to a depth of about two miles. Inequalities of surface have, however, existed since the earliest geological time of which we have knowledge. The oldest rock formations show traces of sedimentary origin, and therefore represent in part the waste of land areas from the action of streams and the waves of the ocean. So far as North America is concerned the position of the continent had been determined in Archean time. What determined the position of this area other continents is, however, still an unsolved problem, though there are several theories, each with some show of reasonableness.

The generally accepted theory is that when the crust of the molten earth had solidified and cooled enough to allow the condensation of aqueous vapor, it cooled and contracted unequally, some parts cooling and contracting toward the centre more rapidly than others. Thus were formed areas of depression and elevation, the seas filling the former and the higher parts of the latter projecting above the water as land. The water would hasten cooling under the depressions, and thus the general tendency would be to increase the area and elevation of the land and increase the depth, but decrease the area of the sea. Those who hold that the earth was never molten believe that the oceanic segments are heavier than the continental (a fact substantiated by actual investigation), and that as a result, the continental blocks are forced aside and up by the settling of the heavier oceanic blocks.

Distribution and Form of Continents. — The distribution and form of continents show some curious features, and on these features theories of the origin of continents have been based. North and South America, for instance, are roughly triangular in shape, with the apex of the triangle at the south. Eurasia and Africa together form another roughly triangular land area tapering to the south, the Carpathian and Hope being the apex of the triangle. Owing to the lands tapering to the south, the northern hemisphere contains more land than the southern, and it is possible to divide the globe, by taking a north pole in the English channel, into
two hemispheres, one nearly all land, and the other nearly all water.

Continents consist typically of a great interior basin bordered by mountain ranges, this form being shown by the continents of somehow irreg. Cretaceous continent being an exception. In each continent the greatest mountain system faces the greatest ocean. In North and South America these mountains are on the west, facing the Pacific, with the smaller Appalachian Mountains, the Venezuelan Mountains and Brazilian highlands facing the Atlantic. In Africa the greatest range is on the east, facing the Indian Ocean, in Australia the greatest range faces the Pacific, and in Asia the Himalayas face the Indian Ocean. Omitting the mountains of Eurasia, the mountain chains of the world have a northwest-southeast or northeast-southwest direction, and on this account the continents taper toward the south.

From the base of the mountains to the sea there is a gentle slope or plain, and this plain extends frequently some distance beyond the shore, forming a continental platform or shelf. The outer edge of this platform is usually at a depth of about 100 fathoms (600 feet) when the bottom slopes rather sharply — forming the continental slope — to the depths of the ocean. Off the coast of New Jersey the 100-fathom line is 110 miles from shore, while on the coast of California it is only about 10 miles from shore. Great Britain stands on such a shelf and is really part of the continent of Europe. In the same way the East India islands to Celebes are part of Asia. New Zealand may be considered part of Australia.

**Permanency of Continents.** — It is one of the commonplacest of geology that the lands are continually changing; by weathering, by rivers and by the waves of the ocean the rocks are worn away and spread out as sediments on the sea floor. In some parts of the world the land is apparently rising, in others sinking. The northern coast of Norway is rising five feet in 100 years, the coast of New Jersey and parts of the New England coast are sinking. At Boston the shore is about a mile out 100 years, and on the New Jersey coast two feet. Yet geologists, while admitting the instability of the lands, differ as to the permanency of continents. Lyell believed that neither continents nor oceans — so far as any particular part of the earth is concerned — are permanent. His views have been opposed by later geologists, who have thought that while continents may change form, certain parts of the earth have always been covered by oceans, while others have not; the Atlantic and Pacific, for instance, while always oceans, while the continents, even if at times partly covered with water, have always been uplifts in the sea floor, or if not always, at least since Archean times.

It is, of course, that these uplifts have been under shallow, or epicontinental, seas many times. This is shown by the following facts. In the first place, chalk beds corresponding to the glossothine ooze that covers much of the ocean floor are found in epicontinents; in the second place, the study of fossils has shown that at times in past ages continents now separated by oceans had essentially the same fauna and flora. The evidence of deep-sea deposits shows that in Cretaceous time a fairly deep sea covered much of Mexico and parts of Texas, New Mexico, and Kansas, while another, or perhaps the same wide, deep sea covered southern Europe and northern Africa and extended across Asia to the Pacific. In Cretaceous time the relatively small continental land masses did not have their present form and arrangement, and theories as to the origin of continents based upon present land forms are at best of doubtful value. The evidence indicates that in Permian time the Antarctic land mass was of far greater extent than now, and joined South Africa, Patagonia and Australia. Again in Cretaceous time the evidence indicates that Brazil, south central Africa, Madagascar and India were connected by land masses, so that the Atlantic and Indian oceans had not at all their present shape. There is some reason for believing that no longer ago than the beginning of the Glacial Period the Arctic lands were of greater extent than now, Asia, North America and Europe being connected. Thus, while it is fair to assume that the position of the continents was determined ages ago, there is nothing permanent about their forms or the present distribution of land and water on the earth. **CONTINENTAL NAVY.** During the summer and fall of 1775, the British attempts to subdue resistance in the colonies on land was supplemented by harrying their shipping and coast. By the Articles of Union, were made prizes in violation of law. Gloucester was fired on, and Bristol bombarded to obtain provisions. Most of the colonies equipped armed vessels for themselves and commissioned privateers. On 5 October news came that two British transports were on the way to Quebec with military stores; and as our armies needed these worse than the British, Congress on the 13th appointed a board of three (Silas Deane, John Adams — afterward replaced by Christopher Gadsden — and John Langdon) to fit out two swift armed vessels and intercept these or any other store-ships. This board was the Navy Department of the Revolution for a time; it was turned into a marine committee, marine board, etc., with under boards called the Continental Naval Board, Board of Admiralty, etc. On 18 October Falmouth (now Portland) was bombarded and set on fire; and on the 30th two more and heavier vessels were authorized. In the interior of the ports, etc, made general managers of naval matters, subject to final decision by Congress, which appointed the officers down to third lieutenant — the "patronage" question being as burning here as in the Continental army. The beginnings of
the American navy were curiously auspicious for a nation of skilful and daring seamen, and for a body with so brilliant a subsequent record. The officers were largely incompetent, and the men mutinous. A brilliant exception was Captain Manly of the schooner Hudson, who captured several prizes, including a brig loaded with heavy guns, mortars and tools. Finally, on 25 Nov. 1775, Congress gave up the grisly pretense of being at loyal peace with Great Britain, and declared all ships of war employed against the colonies, and all supply tenders for them, lawful prize; authorized privateering and colonial courts to try prizes; adopted rules and regulations for a Continental navy; and on 13 December directed the marine committee to build and fit out five 32-gun frigates, five 28's and three 24's, by April next. These were estimated to cost $866,666.66, and were to be built at the leading colonial ports from Portsmouth to Baltimore, and elsewhere (Norfolk, Charleston, etc.), if thought advisable. Other vessels might be bought and equipped. On 22 December Esek Hopkins was made commander-in-chief. Among the first lieutenants was John Paul Jones. On 9 November two battalions of marines were sent out, and in the early eight cruisers had been collected at Philadelphia, and Commodore Hopkins started on a cruise, but was detained six weeks by the ice, and only got clear 17 February. He had been instructed to scan the enemy's ships upon the coasts of the Southern States; but finding nothing of Dunmore's squadron, sailed to New Providence in the Bahamas, where a quantity of British military supplies were stored, stormed the place, and carried off a quantity of stores and 80 cannon, besides the governor and some leading citizens as hostages. On his return he fell in with some armed vessels, which he captured, and the 20-gun frigate Glasgow, which, after a spirited fight, escaped. Congress held an inquiry into Hopkins' conduct in June, decided that he had exceeded his instructions, censured him and finally dismissed him. This did not encourage enterprise, and naval service became unpopular. No new naval commander was appointed until 10 April. Ten of that rank. The vessels, however, did some clever work, and captured many prizes; but the greater part of this service was accomplished by privateers. At the time of the Declaration of Independence our navy consisted of six regularly built war vessels and 19 merchantmen with naval armament, the whole with 422 guns. Against this the British had 78 men-of-war, with 2,078 guns.

Next in importance to the Bonhomme Richard's fight with the Serapis, the most creditable naval engagement of the war was Benedict Arnold's battle on Lake Champlain. The importance of the naval battles on this inland lake is hardly realizable now; but till the time of railroads the lake was the one route for a large invading expedition between Canada and New York or New England, enabling supplies to be transported where otherwise the mountains or the forests would have made it impracticable. The English had 29 vessels with 840 guns; four long ships and some 300 of the regular navy; and Indian allies. Arnold had 15 vastly inferior vessels, with 88 lighter guns, and about 750 men ignorant of naval service. Several of Arnold's vessels had to be abandoned and destroyed; two were captured; but several were saved in spots the English could not reach, by Arnold's heroic risk of himself. The British loss was about 40, the American about 80. But not the least of the British the campaign; the struggle had been so severe that Sir Guy Carleton, the commander, did not venture to assail Ticonderoga, and shortly after retired to winter quarters.

The most famous work done by the navy, however, resulted from commerce-destroying in British waters. Our fleets were nearly as much masters of the English Channel as the English were at the time of the Armada, though we never had more than three or four ships there at a time; for the English could not protect their own commerce. No other enemy ever disturbed the marine insurance rates, not even France across the channel; but in a short time now they rose to prohibitive rates, and the companies even refused to insure English bottoms at any premium, so that the Thames was crowded with French vessels. The alarm and fury of the English were shown not only in the excorciations of "pirate" which they lavished on the lawfully commissioned war vessels and their captains and crews, but in the misused of the latter with which they revenged themselves when they captured any, but in the abiding hereditary tradition of their writers: they then invented false accounts of John Paul Jones, and still term him a "notorious pirate," although he was no more a pirate than Nelson, and much less than Rodney, who even turned pirate on his own people. In 1776-77 the Lexington was engaged in this work, and in 1778 was joined by the Reprisal; but the former was finally captured and the latter founder'd. The Surprise was then secretly bought from England and fitted out at Dunkirk; but on her beginning to make captures the English government forced the French by threats to give her up. The Revenge was then bought, and became even more successful. But the most magnificent success was won by Jones (see BONHOMME RICHARD), in 1778-79. In the former year he closed a wonderfully successful 28 days' cruise in the Ranger—from 10 April to 8 May—capturing the Drake, a more powerful vessel than his own. In the latter the marvelous engagement of the Bonhomme Richard with the Serapis, the most creditable naval victory of the war, dwarfs all else. See Jones, John Paul.

Meantime Congress had ordered the construction of three 74-gun men-of-war, five large frigates and one or two smaller vessels; but as money ran short, they were never finished. At the end of 1778 the navy consisted of four 32-gun ships, two 28's, one 24, one 20, three 15, one 12 and one 10—14 in all, with 332 guns; while England had on the American coast 89 ships with 2,576 guns. In 1779 the most notable events were the capture on 7 May of seven transports with about 1,700 men and some 300 men, by a Boston squadron under Capt. J. B. Hopkins, son of the ex-commodore; that of eight prizes worth over $1,000,000, in July; that in August, by two Continental vessels on a short cruise, of six prizes with 54 guns; and on 7 May, the same day as the Dramatic and desperate action of an hour between two 12-gun brigs, the United States Providence and the British Diligent, in which the latter lost 8 killed and 19 wounded out of a crew of 53,
or over half. In 1779 and 1780 Capt. John F. Williams won two brilliant victories in 14-gun and 18-gun Massachusetts State vessels. But on 13 Aug. 1779 a heavy disaster befell the waning little Continental navy. Three vessels, a 32, a 14 and a 12, accompanied a fleet of Massachusetts privateers to dislodge the English from a fort near the mouth of the Penobscot; but, seven English war-ships coming up to reinforce the three already there, the privateers fled, and the Continental vessels had to be run up the river and destroyed. By the fall of Charleston four more—two 28's, a 24, and the celebrated 18-gun sloop Ranger—were captured or destroyed; another had been lost; and at the end of 1779 the navy had but six vessels left, so that it was very hard to run the English blockade. Officers and seamen were scarce also; for the English dreaded the American privateers and naval destroyers so much, few as they were, that they systematically refused to exchange prisoners, and connived at the desertion of Americans in pestilential hulks or prisons. In October 1780 the Saratoga, after taking three prizes, which were recaptured, foundered; and in 1781 the Trumbull was captured after a fight against superior force in which she was crippled. But the small remnant still won some victories. The Alliance on 28 May 1781 captured a 16-gun and a 14-gun brig; and early in 1782 the Deane captured four vessels with 48 guns. In April 1782 was fought a very brilliant action by a privateer, one of the most remarkable of the war: the Pennsylvania State cruiser Hyder Ally, Licut. Joshua Barney, having 16 6-pounder guns and 110 men, engaged the British sloop-of-war General Monk with 20 9-pounders and 136 men. Despite this enormous disparity of force—96 pounds of metal against 180 pounds—the American vessel forced the British to strike in half an hour, with a loss of 20 killed and 33 wounded, against 4 killed and 11 wounded. Another remarkable contest was won by a private Philadelphia cruiser, the Congress, off the Southern coast. She had 20 guns, but was manned almost entirely by landsmen, seamen being unobtainable. On 6 Sept. 1781 she fell in with a British 16-gun sloop-of-war, the Savage, with her regular complement of 150 officers and men. In about an hour and a half, lying so close that the guns scorched the opposing gunners, and shot were thrown by hand, the British vessel was fairly shot to pieces, and forced to surrender, with a loss of 8 killed and 24 wounded, against 30 of both on the privateer. The last naval fight of the war was between the Alliance, Capt. John Barry, and a heavy English ship, which the former drove off during a run to Havana. The Continental vessels lost during the Revolution numbered 24, with 470 guns. The British loss was 102, with 2,622 guns. The American navy and the privateers together captured about 800 prizes from the British. British privateers did not capture a single Continental vessel; American privateers captured 16 English cruisers, with 2,200 men, according to Mr. Maclay, 'History of the American Navy' (Vol. I, 1893); Cooper, 'History of the Navy of the United States' (1839), See Navy of the United States.

CONTINENTAL SHELF, that part of the ocean bottom covered with shallow water, and extending from the littoral belt out to the 100 fathom line. Beyond this line lies the continental slope, or edge of the continental block, merging into the abyssal seas. The sediments that accumulate on the shelf are often called shoal water deposits. Those that accumulate on the continental slope are termed aktian deposits, and this belt is sometimes called the aktian belt. The sediments of the deep sea are termed abyssal deposits.

CONTINENTAL SYSTEM, a plan devised by Napoleon to exclude Great Britain from all intercourse with the continent of Europe and thus compelling her to acknowledge the maritime law as established at the Peace of Utrecht. The history of the continental system began with the famous decree of Berlin of 21 Nov. 1806, by which the British Islands were declared to be in a state of blockade; all commerce, intercourse and communication with them were prohibited; every Briton found in France, or a country occupied by French troops, was declared a prisoner of war; all property belonging to Britons was accounted fair prize, and all trade in British goods was excluded. No vessel coming directly from Great Britain or British colonies, or which had been there since the publication of the edict, was to be admitted into any harbor, and all vessels attempting to avoid this edict by false declarations were to be confiscated, with all their goods, as British. The reasons assigned for this decree were, that Great Britain did not acknowledge the international law accepted by civilized nations, but treated every individual belonging to the country of the enemy as if found in arms; made even the crews of merchantmen prisoners of war; extended the right of conquest over merchantmen and private property, and the right of blockade over places and harbors not fortified; over the mouths of rivers; and, over whole coasts and countries. But many of these measures had always been taken, in maritime ways, even by France herself, as long as she had the means. One great reason for this and all the subsequent decrees of Napoleon was that he considered Great Britain his inveterate enemy and the enemy of the political doctrines which took their rise from the Revolution.

Great Britain immediately directed reprisals against the Berlin decree, first by an order in council of 7 Jan. 1807, by which all neutral vessels were prohibited to sail from one port to another belonging to France, or one of her allies, or to a nation so much under her control that British vessels could not have intercourse with it. Every neutral vessel which should violate this order was to be confiscated with her cargo. A second decree of 11 Nov. 1807 was much more oppressive to commerce. By this all harbors and places of France and her allies in Europe and the colonies, alike, were made the enemy of every country with which Great Britain was at war, and from which the British flag was excluded, were subjected to the same restrictions as if they were closely blockaded; all commerce in the manufactures and productions of such countries was prohibited, and vessels engaged in such commerce were to be confiscated, as also all those vessels whose certificates showed that they were built in the enemy's country. Another order in council declared the
CONTINENTALS

sale of vessels by the enemy to neutrals unlawful, and the intended transfer of property void.

Hardly were these orders promulgated when France made counter-reprisals. By a decree of Milan of 17 Dec. 1807, aggravated by a decree of the Tuileries 11 Jan. 1808, every vessel, of whatsoever flag, which had been searched by a British vessel, and consented to be sent to Great Britain, or had paid any duty whatever, if the vessel was then to be declared denationalized, and to have become British property; and in every case such denationalized vessel, as also those which had broken the blockade declared against the Ionian Islands, or had sailed from a British harbor or British colony, or those of a country occupied by the British, of which were destined for any such ports, were declared good prize. By the Treaty of Tilsit (1807) Russia consented to close her ports to English commerce. In order better to effectually annihilate the British commerce, the tariff of Trianon, respecting colonial goods, was proclaimed 3 Aug. 1810. This was extended by another decree of 12 September of the same year, and both were followed by the decree of Fontainebleau, 18 October, 1810, directing the burning of all British goods. These decrees were to be executed with more or fewer modifications in all countries connected with France. The consequence was that the price of colonial goods rose enormously; a regular smuggling trade was carried on at different ports; for instance, at Heligoland, which was sometimes so crowded with persons concerned in this business that a ducat was paid for a barrel to sleep in; thousands of substitutes for colonial goods, particularly for coffee and sugar, were invented, and a variety of manufactures grew up on the Continent which were the germs of very extensive and flourishing branches of industry. The system was abolished immediately after the fall of Napoleon. But its continuance on the English side was one of the causes of the War of 1812.

Consult Mahan, The Influence of Sea Power on the French Revolution and Empire1 (Boston 1894); Thierry, Histoire du consulat et de l'Empire2 (Paris 1853-62); Cime, Etude sur les traités de commerce et les traités de commerce (Paris 1875); Adams, Henry, 'History of the United States'3 (New York 1889-91).

CONTINENTALS, or CONTINENTAL ARMY, the army of the United States during the Revolution. In May 1775, after the battle of Lexington, the Provincial Congress of Massachusetts requested the Continental Congress to assume control of the forces which had gathered around Boston. Further outside pressure led the latter Congress in June to vote for raising a "Continental army" (the name "Continental" in all these cases expresses the hope, long entertained, that Canada would join the revolt), and for a loan of $2,000,000 to support it. On the 15th George Washington was appointed commander-in-chief; then four major-generals were appointed, Artemas Ward, Charles Lee, Philip Schuyler and Israel Putnam; and an adjutant-general, Horatio Gates. Lee was then in the army in Congress, and were only confirmed by Washington's influence, as men of approved military capacity. It is curious that Congress was right and Washington wrong, and that Lee's treachery and Gates' incompetence and intrigue nearly ruined the cause and Washington together. The brigadiers appointed were general officers in colonial service, with two others as adjutants. These colonial officers were confirmed in their rank and shortly given Continental commissions. For commissary-general was chosen Joseph Trumbull, son of the governor of Connecticut, Washington's right-hand man and adviser, who kept a great general. There was a further reason for this. The food surplus of the country came mainly from three great valleys—the Connecticut, the Hudson and the Delaware; the last two were held by, or liable to raids from the British during most of the war, and the Connecticut Valley was the one rich farming country which the British could not molest. Hence the first two commissary-generals were both Connecticut merchants. Washington appointed his aide, Thomas Mifflin of Pennsylvania, quartermaster-general; and Dr. Benjamin Church of Boston was made director of the army hospital. There was no paymaster-general till late in 1776, when William Palfrey of Boston was appointed. On 12 June 1776 Congress voted to create a "Board of War and Ordnance" of five members; in 1777 this was changed to a "Board of War," to consist of three persons not members of Congress. This board has not left an enviable historical reputation; but it lacked neither ability nor patriotism. In part its troubles were due to civilian misunderstanding of and contempt for military claims and feelings; in part to the insistence by the States on their share of army patronage, as now of civil patronage, which drove some of the best generals from the service and contributed to Arnold's treason.

The army was constituted by taking into colonial pay the militia regiments of the various colonies, and enlisting others for a year. The number on the war office rolls during 1775 was 27,443, besides an estimate of 10,180 militia for a few months' service during 1776, 46,891 regulars, 16,700 militia as before. Had these all been in the field and good troops, and well equipped, they would have been fairly sufficient, though not what could or should have been raised; but half or more were on paper, the material was poor, the equipment insufficient and the whole system incompatible with effectiveness. The term of enlistment was too short for the soldiers to learn their business; the militia absolutely refused to submit to discipline, and their insubordination affected the regulars. Washington during the campaigns of 1776 urged upon Congress a plan for a permanent army; but that body sent a committee to the camp at Harlem Heights, and generally in accord with his views, which Congress adopted. The "armies" of different sections were to be consolidated into one body, of 88 battalions with 750 men each, to be raised in the States according to population and resources; besides a Canadian regiment to be called "Congress' Own." The largest numbers, 15 battalions each, were to come from Massachusetts and Virginia. The men were to be enlisted for the war, with a bounty of 100 acres of land each at the end; officers, higher amounts; colonels, 500; and $20 bounty for each recruit. The States were to enlist their quotas, arm and equip them; and to appoint the officers from colonel down though Congress...
was to commission them. But the plan worked slowly and poorly. Enlistments for the war were so few that a three years' term was substituted for one. Even then some began and other States continued the policy of greatly increasing the bounties, and towns and counties bid still higher; but this rather made the process slower, men waiting to see how high the bids would go. Washington was shortly advised with dispatch powers to remove any officers under brigadier, and fill the vacancies at his discretion; and allowed to raise 16 extra battalions. This somewhat strengthened his scanty lines, and enabled him in a slight degree to rectify the mischief done by the State patronage, give commissions to good officers, and keep others from retiring. But even so, and despite incessant drafts from the militia, the total number of soldiers enrolled in 1777 was but 34,820 regulars and 10,100 militiamen; in 1778, 32,899 and 4,353; in 1779, 27,699 and 5,135; in 1780, when the Carolinians and Georgia were in British hands, and none of their troops were on the roll, 21,015 and 5,811; in 1781, when Cornwallis surrendered, 13,292 and 7,298. It would seem that if the British could have held out a little longer, or sent one more army to America, the Continental army would have melted into nothing without the country taking pains to keep it up.

The reason was not lack of men, nor any ruinous exhaustion of resources; it was simple administrative anarchy (see CONFEDERATION, ARTICLES OF), which could not collect and distribute the resources we possessed, and which left the soldiers half fed, less than half clothed, and for long periods unpaid. This was increased by a jealous dread of the army itself (see CINCINNATI, SOCIETY OF), bred by historical experience which they had as yet no other to counterbalance; they appreciated victories, but were not inclined to pinch themselves for daily supplies. In 1777 the soldiers' back pay was settled up in Continental money, at about 12 for one, though Massachusetts made good a part of the depreciation. Arrears steadily accumulated till the end of the war, though in 1778-79 a half-pay system for seven years was provided for the officers, and a gratuity of $80 for the men. In January 1781, the Pennsylvania regulars struck, and were pacified with difficulty and by certificates for their pay; the New Jersey troops followed suit; and Congress in alarm made requisition on the States for $879,342 to pay the arrears. About half the amount came in, and Massachusetts and New Hampshire sent gratuities to their men; but the rest lagged. About this time the Articles of Confederation were adopted, making the consent of nine States necessary for appropriations; Congress was even more helpless than before; and as the time of a general disbandment drew near, the officers began to fear that it was intended to turn them off without paying them, and if they did not receive it while in the field they never would. Meantime Congress was debating the subject. The later Federalist party wished to fund the army dues as well as the other public debts, and give the army interest-bearing certificates; the decentralizers wished to leave it to the States to settle each with their own troops. The officers, finding the half-pay project highly unpopular, wished to commute it for a lump sum, in cash or securities.

About this time, 10 March 1783, an anonymous letter called a meeting of the officers in camp at Newburg, and an anonymous address suggested to these, Massachusetts and New Hampshire, they should desert the country in a body, under Washington's lead. Washington denounced this call as seditious, but called a meeting himself, at which his influence kept patriotism uppermost; but he wrote urgently to Congress, and it finally agreed to minute the half-pay into five years' full pay in certificates at 6 per cent interest. The States were very indignant at this, New England especially denouncing the whole scheme of half-pay: the Massachusetts legislature passed a resolution that it tended to "raise and exalt some citizens in wealth and grandeur to the injury and oppression of others." The soldiers were furloughed on three months' pay till the British should evacuate New York, when they were discharged. The number of troops nominally furnished by each State is as follows:

CONTINGENT, a name often given to the quota of troops furnished by each member of a number of states composing a federation, or by each organization forming an army or navy.

CONTINUATION SCHOOLS, the term applied to those systems of training which are adapted to people already at work in business or industry, especially for girls and boys between the ages of 14 and 18. The original purpose of the schools was to provide that general education of which forced entrance into business or commerce at an early age deprived the workers. The development of the schools has been chiefly along the lines of substitution of further industrial training in place of the general education and of day in place of night classes. The movement began in Germany where such schools in some form existed for many decades, their general and national character having been developed since 1870. They are voluntary—it is his discretion for each local authority whether such a continuation school be established and the form, within reasonable limits, it may take. Two clauses in the Imperial Industrial Law of 1891 provide a limited measure of agreement. Clause 120 re-
quires employers of labor to grant to employees under 18 the necessary time to attend continuation classes in the daytime. Classes on Sunday are only permitted in exceptional cases. Class 146 R, however, does not compel a local authority to make attendance at a continuation school obligatory for all males under 18 not attending an approved secondary or trade school, and throws the responsibility for such attendance on the school's part or employer, usually on the latter. Since 1891 the system has spread in all sections of Germany and become practically obligatory. Girls are brought within the scheme, but almost always for domestic training only. Apparently two distinct lines of thought control the authorities. On the one hand, it is held that teaching should be definitely vocational—that is, specifically applied to the scholar's chosen calling. On the other, such a program of teaching is preferred as will produce a good citizen. The one demands technical skill, the other general efficiency. The former has moved in the direction of elaborately-equipped trade continuation school buildings. The latter is a very numerous class, especially in the smaller towns, and has hitherto been content with makeshift arrangements in elementary school buildings.

Two distinct types of buildings have been evolved. Examples of the first may be seen in the central continuation school at Bonn and in the central and northern continuation schools at Frankfort-on-Main. All erected within the last eight years, in none is there any trade teaching properly called. The first contains rooms for cookery and type-setting, the second a number of spare rooms in the basement eventually to be utilized for workshops, and the third rooms for cookery. In Bonn boys and girls are taught in the same building; in Frankfort they are separated. There is ample provision for the teaching of applied drawing and applied science; but most significant in these three examples is the generous provision for recreation. There are large rooms, artistically decorated and well furnished, where concerts and dances are held and lectures given on Sunday. The basement contains large rooms or alcoves for reading and games. In Munich, where trade-teaching is more conspicuously developed, is less external evidence of this social side of school life, and the buildings approximate very closely to the ordinary technical-school type. But Munich in providing scattered district schools obviates as far as possible the long journeys and waste of time involved by a huge central building.

In England continuation schools, chiefly in the form of evening classes, have spread more and more. They are not obligatory. Owing probably to the lack of expert teachers, the system has not proved as satisfactory as desired, but its weak points will be improved in time. In the United States, the plan has been adopted in many cities with considerable success and is a hopeful feature of American education. It adapts itself largely to local needs and admits of varied forms. Another happy feature is the prominence attached to the teaching and the practical side as an integral part of the course. The employers of large corporations, recognizing the value of further training, often provide such schools within their own establishments.

CONTINUITY OF STATE OF MATTER. See Critical Point.

CONTINUOUS VOYAGE. The doctrine of continuous voyage in international law was invented by Lord Stowell in the early part of the 19th century to justify the British morally to the neutral vessels which, in the war between Great Britain and France, endeavored to evade the rule prohibiting neutrals from engaging in the enemy's carrying trade. This evasion was sought by interposing a neutral port between the point of departure and the forbidden destination. It being unlawful for neutral vessels to trade between a French colonial port and a home port in France they attempted to legalize the voyage by breaking it at a neutral port, usually in the United States. Lord Stowell held, however, that the two voyages were in effect one and the same, and therefore illegal, although each separate voyage was in itself legal. During the Crimean War the French prize courts extended the doctrine of continuous voyage to the carriage of contraband and such cargoes, bound from one neutral port to another, were condemned whenever the evidence showed that the ultimate destination was in fact a port of the enemy. During the American Civil War the courts of the United States took the same view, on a large scale, likewise, to the carriage of contraband and blockade running. Thus British ships, with their cargoes, bound from England to the neutral ports of Nassau or Matamoras, were condemned whenever the evidence showed that the eventual destination was not a neutral port but in reality a port in the Confederacy. British writers on international law unanimously denied the legality of such an extension of the doctrine of continuous voyage and the British prize courts took the same view. Thus in the case of the Immina decided at the end of the 18th century, Lord Stowell refused to condemn a vessel bound from Danzig to Emden, both neutral ports, notwithstanding the fact that Emden was situated only five miles from the frontier of Holland, a country with which England was then at war and although it was notorious that the goods were to be reforwarded from Emden to the enemy country. During the Boer War, however, Great Britain for the first time abandoned her early attitude and undertook to apply the rule which her courts and text writers had formerly condemned, and seized a number of German vessels bound for the neutral port of Lorenzo Marquez.
in Delagoa Bay, on the ground that the real destination of the cargoes was enemy territory (The Bohemian Republics). During the European War the doctrine of continuous voyage was applied by Great Britain on an extensive scale to the carriage of goods between the United States and the ports of various neutral countries adjacent to Germany and Austria. The Declaration of London sanctions the extension of the doctrine of continuous voyage to the transportation of absolute contraband but forbids it in the case of conditional contraband, except where the belligerent has no sea board. Likewise it forbids the application of the rule to blockade running. Article 35 of the Declaration lays down the rule that conditional contraband is not liable to capture except when found on board a vessel bound for territory belonging to or occupied by the enemy, or for the armed forces of the enemy, and when it is not to be discharged at an intervening port. But the British order in council of 29 Oct. 1914 modified this provision so as to extend the carriage of conditional contraband and also reversed the established rule by placing on the owner rather than upon the captor the burden of proving an innocent destination. The effect of the order in council was to obliterate the distinction between absolute and conditional contraband—a distinction which had already been largely abolished by putting on the list of absolute contraband many articles which were not so by their nature. The American and other neutral governments protested against the extension of the doctrine of continuous voyage to the carriage of articles of conditional contraband between neutral ports and the establishment of presumptions of hostile destination which, it declared, were based on suspicion rather than upon evidence. Cargoes of conditional contraband shipped from American ports to the ports of Denmark, Holland, Norway and Sweden, it was argued, could not lawfully be presumed to be intended for the use of the enemy. There was a large local demand in all these countries for such goods—a demand which had been largely increased by the cutting off of their European sources of supply on account of the war—and it was impossible to admit the right of a belligerent to seize such cargoes and have them discharged locally and thereby sold at a profit in the event the enemy would be largely illusory unless the injured belligerent were allowed to apply the rule of continuous voyage to such traffic and seize cargoes whose ostensible destination was neutral territory but whose real destination was armed forces of the enemy. Manifestly the right of a belligerent to thus interfere with trade between neutral countries involves a serious encroachment on the rights of neutrals, but so long as the right of belligerents to blockade the ports of the enemy and intercept contraband trade between them and neutrals is admitted it would seem difficult to deny their right to apply a rule without which the weapons of blockade and contraband would in many cases be worthless. (See also BLOCKADE; CONTRABAND; Search; Right of.) Consult the authorities cited under BLOCKADE; CONTRABAND; and RIGHT OF SEARCH.

JAMES W. GARNER, Professor of Political Science, University of Illinois.

CONTORNIATI, kōn-tōr-nē'ā-tē, ancient medals which have occupied the attention of antiquarians for a long time, and, on account of their rarity, are highly esteemed in cabinets. They are formed of a thin plate of metal (not of two different sorts, as is often supposed) with a flat impression. They differ from other ancient coins by having a furrow upon both their sides, where the others have a wreath of pearls. These hollowed lines (It. contorni) may have occasioned their name. Another characteristic of genuine contorniata is a cipher composed of the letters EP or PE, of which no satisfactory explanation has as yet been discovered, together with numerous impressed characters, and a great number of palm branches, the cavities of which are often filled with silver. They are also adorned by a monogram on one side, and thereby are essentially distinguished from the *monograms,* so called in the language of the mint. They resemble the sigillo messa (contremarques) on the Roman medals and coins. All the proportion of such shipments were intended for local consumption and what proportion was intended to be forwarded for the use of the enemy. If after such goods were delivered and became a part of the common stock of the neutral, they were subsequently resold and referraded to a belligerent, it was in consequence of a new destination and the doctrine of continuous voyage did not apply.

To this argument the British government retorted that it was unable to admit the contention that if a belligerent was so circumstanced that his commerce could pass through adjacent neutral ports as easily as through ports in his own territory, his opponent had no right to intercept such commerce. The position of Great Britain was that the enemy was obliged, and the United States during the Civil War; the enemy was flanked by neutral countries through whose ports a steady stream of supplies was pouring in for the use of the enemy, and following the practice of the United States during the Civil War, Great Britain was endeavoring to cut off this supply by extending to its commerce the doctrine of continuous voyage. It is, if it was endeavoring to prohibit neutrals from doing indirectly what they could not do directly. Under the circumstances the right of blockade and the right to capture contraband goods going to an enemy would be largely illusory unless the injured belligerent were allowed to apply the rule of continuous voyage to such traffic and seize cargoes whose ostensible destination was neutral territory but whose real destination was armed forces of the enemy. Manifestly the right of a belligerent to thus interfere with trade between neutral countries involves a serious encroachment on the rights of neutrals, but so long as the right of belligerents to blockade the ports of the enemy and intercept contraband trade between them and neutrals is admitted it would seem difficult to deny their right to apply a rule without which the weapons of blockade and contraband would in many cases be worthless. CONTOUR—CONTRABAND

the games at the circuses in Rome and Constantinople. Consult Smith, 'Dictionary of Greek and Roman Antiquities.'

CONTOUR, kon'toor, the outline or defining line of any figure or body; also the horizontal outline of works of defense. When the conformation of the ground or works is described by contours or horizontal sections, these sections are taken at some fixed vertical intervals, and the distances of the surface at each interval above or below some assumed plane of comparison (usually sea-level) are given in figures at the most convenient places on the map. The contour lines, that is, represent the shore lines that a rise in the ocean would cause it to assume. Of course, embayments of this shore line correspond to valleys that would be drowned, and promontories to ridges. Contour lines, close together, mean that a considerable rise in the sea-level would have a comparatively slight effect in pushing back the shore line, which must therefore be situated on very steep ground. As water always flows down hill by the steepest path, and as a line so continued would meet more of them in a given interval than one that meets them slantingly, it is clear that the lines by which the rain is carried off the ground meet all the contour lines at right angles, and that consequently the streams must do likewise. This relation between streams and contour lines, coupled with the fact that streams flow along the bottoms of valleys, and consequently pass through the inmost points of embayments in the contour lines, is of the utmost value to the topographer, who always bases his contour map on its drainage.

Two contour lines cannot cross except where there is an overhanging cliff. A contour line cannot terminate; it must either be closed or run off the map. A closed contour line either encloses a hill-top or a depression, which in general has a stream leading from it. Such depressions are rare except in very dry climates, and even there usually contain a salt lake or marsh, so that confusion between hills and valleys is not likely to arise in reading the map.

It is possible to determine within fairly close limits whether of two points given on a contour map one is visible from the other. This is one reason for the immense superiority of contour maps over all others in military operations.

The contour interval varies according to the scale and purpose of the map and the nature of the terrain. In the United States army, maps with a scale of 12 inches to the mile are supposed to have a contour interval of five feet; those with a scale of six inches to the mile have a contour interval of 10 feet; those with a scale of three inches to the mile have a contour interval of 20 feet, and those with a scale of one inch to the mile have a contour interval of 60 feet. This makes the distance between the contour lines dependent only on the mean slope of the ground and not on the scale of the map. In mountainous country, however, the contour intervals may have to be doubled or trebled to obtain a legible map. See Map; Surveying; and the map of a part of the Housatonic quadrangle in Geological Survey.

CONTRABAND. Contraband (from contra bannum or banum, contrary to the ban or edict), is a term applied to certain articles which international law allows a belligerent to seize and confiscate even when furnished from neutral vessels, and which are being transported for the use of the enemy. By means of a blockade (q.v.) a belligerent may cut off all neutral trade and intercourse with his enemy; through his power to capture contraband goods he may prevent neutrals from furnishing the enemy with such goods as by the law of nations are regarded as contraband. These are the two principal weapons which international law places in the hands of belligerents for cutting off the over-sea commerce of their enemies, the effectiveness of each depending, of course, upon the sea power of the belligerent which employs them. Both may be resorted to at the same time, and in the hands of a nation which controls the seas they are a means of reducing the enemy to starvation and thus compelling him to surrender. International law, however, allows the citizens or subjects of neutral powers to carry on at their risk contraband trade, with either or all belligerents, subject to the rights of the injured belligerent to prevent and confiscate all such articles as fall within the category of the contraband. Their government is not bound to prohibit them from engaging in such traffic; on the other hand, it is not their duty to intervene to protect them from losses which they may sustain from having their goods captured by one of the belligerents.

Different governments have held different views as to what articles properly fall within the category of contraband and the policy of the same state has not infrequently varied from time to time, sometimes quite inconsistently. Grotius, the first great writer on the law of nations, classified articles into three groups: first, absolute contraband, or those used exclusively for war purposes; second, innocent goods, or those incapable of being used at all for military purposes; and third, conditional contraband, or those susceptible of being used both for purposes of peace and war. This classification has in practice been generally observed by belligerents, although there has been no agreement as to what articles fall in each class. The subject was discussed at the second Hague conference in 1907, but no decision was reached. It was again considered at the London Naval Conference of 1908-09 with more success, but the declaration adopted by the conference has not been ratified by any of the governments there represented. At the outbreak of the European War most of the maritime powers of Europe put the Declaration into effect with certain modifications, some of which related to the subject of contraband. The Declaration, although unratified, represents the nearest approach to an agreement among the maritime powers that has ever been reached. It enumerates a list of articles embracing such things as arms, munitions, armor plates, warships, military clothing and harness, pack and draft animals, etc., which are declared to be absolute contraband. It also contains a list of articles declared to be conditional contraband, and embracing such things as food-stuffs, cloth, coin, vehicles, air-craft, fuel, barbed wire, horseshoes, field glasses, etc.; and the third group embraces various articles.
which are declared not to be contraband at all, such as raw cotton, wool, silk, flax, hemp, rubber, rosin, rawhides, metallic ores, paper, soap, agricultural machinery, precious stones, clocks, feathers, etc. The price of such goods is considered as absolutely fixed, for article 23 of the Declaration allows belligerents to add other articles used exclusively for war purposes to the list of absolute contraband, and article 25 permits similar additions to be made to the list of conditional contraband. In the case of neutral contraband, it may not, however, permit the placing on the list of absolute contraband of articles which are susceptible of both innocent and warlike use nor does it allow belligerents to treat as contraband, either absolute or conditional, articles which are susceptible only of innocent use. The disregard of this rule by the entente allies during the European War in treating cotton, air-craft, copper, rubber, glycerine, zinc, lead, wool, tin, castor oil, and various other commodities as absolute contraband evoked a protest from the German government and was the subject of complaint in the United States and other neutral countries.

The rule governing the liability of contraband to capture varies according to whether the goods are conditional or absolute. The case of the London absolute contraband is in no small way due to the action of the British government in declaring the goods contraband. Under the Declaration of London absolute contraband is liable to capture if it is destined to any place within the enemy country or the territory occupied by him, or on the other hand, conditional contraband is liable to capture only when destined for the use of the armed forces or for the government of the enemy state, but it is presumed to be destined, when the goods are consigned to the enemy authorities, to a government contractor or to a fortified place or a naval base within the enemy country. These and other rules of the Declaration are admittedly unsatisfactory. The presumptions which it establishes in regard to hostile destination are vague; nothing is gained by condemning conditional contraband goods destined to a government contractor and allowing those consigned to a private merchant to go free, since the latter can sell to the government as readily as the former may; again even if a port is fortified, yet the existence of fortifications is no indication as to the ultimate use of the goods; almost every place in this age of railways may serve as a base of supplies; finally nothing is gained by preventing an enemy from obtaining supplies from a fortified place, a base or from a government contractor when he may obtain them with equal readiness from private dealers, through the power of requisition. The penalty for carrying contraband is the confiscation of the goods; likewise the vessel carrying the goods may according to the Declaration of London be condemned if the contraband constitutes more than half the cargo. Whether the captor may sink the ship with its cargo if he cannot take port was raised during the Russo-Japanese War in 1904 when the Russians sank the Knight Commander, a British vessel laden with contraband goods destined for Japan. The British government denied the legality of the act and demanded the payment of an indemnity by the Russian government. The sinking by a German cruiser during the European War of the American sailing vessel William P. Frye, laden with grain destined for England, evoked a protest from the government of the United States. In consequence of treaty stipulations between the United States and Germany, the German government agreed to compensate the owners of the vessel. But in the case of the Maria, a British vessel carrying contraband goods laden in England and sunk by a German cruiser, the German government declined to make compensation to the owners of the ship, there being no treaty between Germany and the Netherlands similar to that between Germany and the United States. It does not, however, permit the placing on the list of absolute contraband of articles which are susceptible of both innocent and warlike use nor does it allow belligerents to treat as contraband, either absolute or conditional, articles which are susceptible only of innocent use. Inasmuch as the majority of controversies between belligerents and neutrals are usually connected with trade in contraband and in view of the lack of agreement concerning what is and what is not contraband, it has been proposed to abolish the right of belligerents to interfere with such trade and to leave them merely the right of blockade. Such a proposal was made by the British delegation at the second Hague conference in 1907. The supporters of the British proposal pointed out that the right to interfere with trade between neutrals and belligerents is out of harmony with modern conditions of absolute or conditional contraband articles have greatly increased; that the increased size of ships has made search on the high seas more and more difficult, thus necessitating the taking of them in to distant ports and subjecting shippers to ruinous delays; and that improved railway facilities have made it impossible to prevent contraband from reaching belligerents. As evidence of the growing dissatisfaction with the existing rules in respect to the right of belligerents over contraband trade, it may be remarked that the British proposal received the support of 26 of the 35 states which voted on the proposition, only five voting against it. Another proposal which has been widely approved is the abolition of conditional contraband and the substitution of a single list of articles, by general agreement, these to be liable to capture if consigned to any person or place in the enemy country. See CONTINUOUS VOYAGE; SEARCH, RIGHT OF; BLOCKADE.

CONTRABASS. See Double Bass.

CONTRACT. Of the positive rules obeyed by men, in a society which has reached the stage in which we live, the greater part are made by contract; the lesser only are made by imperative law. Indeed, the speculative and philosophical writers of the 18th century on sociology and politics, under the influence of Montesquieu and Rousseau, were filled with a notion of a social contract as the origin of law. Obeying to the impulse thus given, they assumed that the form of contract is an instrument of separation of the parties was the original. The assumption was the outcome of their reasoning that social development began with a state of nature, in which innocence and simplicity prevailed, to a state of increasing complexity and sophistic-
Accordingly the simpler forms were believed to pertain to the older and more natural order of society. The history of contract shows the truth to be exactly opposite. The "ceremonial" contract, in which the failure to observe a strict technical formality was fatal to the obligation, is the real original. There is nothing in early times like the interposition of law to compel the fulfilment of a mere promise. The idea of the State intervening to enforce obligations resulting from one man's reliance on the word of another, and the slow growth, and in one realization was one of the latest fruits of civilization. Early law sanctioned only that promise which was solemnized by a prescribed ceremonial; and, when duly solemnized, a promise became a contract, which the law recognized and would enforce, even though obtained through duress or deception. Informal engagements the Roman lawyers called *pacts*, to distinguish them from *transactions with the copper and balance,* which alone were entitled to the name of *contracts.* The distinction is observed in our law to this day. The delivery of a cloud of earth is no longer an essential in the conveyance of land, but deeds and sealed instruments in general are still differentiated from ordinary contracts, and the writing or subscription is not merely verbal—it is radical, setting "specialties," as sealed contracts are called, in a class apart with respect to their legal validity as well as in their form. A "specialty" or sealed instrument, for instance, *obtains validity from its form alone, not from the fact of agreement or consideration moving*; it cannot be revoked after tender, even though the offer contained therein be not immediately accepted; and one who accepts the tender of a deed assumes the obligations therein imposed on him, even if he have given no expression to his intention to do so. Equity, of course, will give relief from a contract by specialty when obtained by fraud, under duress, etc. All contracts not under seal are called "parol contracts." "Parol contracts" may be made in writing or orally. Another distinction which is usually made—that between executed and executory contracts—might probably be eliminated. When a man goes to a jeweler or grocer, and agrees to pay a certain price for a certain article, the situation is exactly as if the contract, when made, had been in writing; and the carrier's risk would be in the sense of a warranty of title. The acceptance must be unconditional, for, if it is conditional, the acceptance is, in effect, a new offer; the minds of the parties have not met and there has been no agreement. Acceptance must be contemporaneous with the offer, or the latter may be withdrawn at any time before it has been accepted. A bid at an auction, for instance, has been held not to bind the bidder until the hammer has fallen. A party making an offer by mail, however, cannot withdraw the same after the party to whom it was addressed has made acceptance by post; though an offer by mail may be countermanded by telegram or phone before it has been assented to. An offer made in an instrument under seal cannot be revoked even though not immediately accepted by the party to whom the tender is made. The consensus of the parties must be real. Absence of consent not merely avoids an agreement but renders it a nullity. There is no real consent when one of the two parties does not mean the same thing as the other, or when an unavoidable mistake has been made of another such as when the object of an agreement does not exist, or where an agreement is made to buy a cargo *to arrive
ex Peerless, there being two ships of that name, one of which was intended by the buyer and the other by the seller. Fraudulent misrepresentation, of course, invalidates consent of the defrauded party and vitiates the agreement.Murder in the adven- ture of a ship, or the piracy of his wares are not necessarily fraudulent; representations are fraudulent in law only when made recklessly, with knowledge of their falsity or without belief in their truth. To invalidate consent it must have been materially induced by the misrepresentations. Only where the utmost good faith is required, as where one party stands in a fiduciary relation to another, may even the innocent misrepresentation or non-disclosure of facts invalidate an agreement ab initio. When the consent of a party is obtained by undue influence no contract has been made. Threats of injury to or the withholding of property, when made by a person in a position to dictate, constitute undue influence—as, where a banker refuses to honor the check of a customer unless the latter accedes to a false or fraudulent claim or warrant; a service unless a promise is made to which it has no right. Consent is nugatory, of course, when given under duress, meaning a threat of bodily harm to the promisor or the restraint of his liberty. The possibility of self-defense is not necessary: a practical impossibility is sufficient to avoid an agreement—for instance, to recover a ring known to be lying at the bottom of the sea. An agreement which imports to have a legal effect unknown to the law is void. An agreement may be expressed either in writing or orally, one may be inferred from a course of conduct. The latter is called an "implied contract." The intention of the parties must have been communicated from one to the other. In the case of the time of Edward IV it was said by the court in reference to an unexpressed acceptance, "your having it in your own mind is nothing, for it is trite law that the thought of a man is not necessary when the thought of a man is. In a developed system of laws it is not necessary that the offer and acceptance be made by the parties face to face. They may be communicated by post or by telegraph or telephone, by messenger or other go-between. A contract made by mail need not be contained in its entirety in one letter and the answer thereto; it may be the outcome of a long correspondence and may be made partly in writing and partly by word of mouth. A contract, unless it be a "principle," need not be exactly in writing and it may be made through agents. Contracts are sometimes said to be "implied in law." The term is not happily chosen, for an examination of the cases shows that obligations by legal implication do not spring from contracts at all. For instance, when one receives money which should have been sent to another he is under obligation to turn it over to the person legally entitled thereto. To say that he is under an implied contract to pay is illogical, however,—
of insurance. Accessory contracts are those—like (1) suretyship; (2) indemnity; (3) pledge; (4) warranty; (5) ratification—which create rights intended to be merely auxiliary to other rights. A contract of suretyship must be in writing according to the Statute of Frauds. Contracts are discharged: (1) by mutual agreement; (2) by performance; (3) by merger in, or substitution of, another agreement, also called novation; (4) by operation of law, i.e., prescription, statutes of limitation or laches caused by disability or legal incapacity (through infancy, lunacy, coverture, etc.) of one or more of the contracting parties. The right of action on a contract is assignable but the assignment must be in writing. Generally speaking, simple contracts as opposed to *specialties may be entirely informal, and need not be written down, either in whole or in part. The English *Statute of Frauds passed for the prevention of many fraudulent practices, which are commonly endeavor to be upheld by perjury or the sabotage of perjury. The renders void any contract for the sale of goods for the price of £10 and upwards, unless there be a part delivery of the goods, or part payment of the price, or some note or memorandum in writing of the bargain made and signed by the parties or their agents. The same statute, though it does not avoid the contract, allows no action to be brought on it until it has been written down and signed: When it makes an executor personally liable; or guarantees the debt of another; or creates a liability in consideration of marriage; or relates to an interest in land; or is not to be performed within a year. Another later English statute requires that the reacknowledgment of a debt that has been barred by the statutes of limitation must also be written and signed. The provisions of the *Statute of Frauds have been adopted with variations in most of the States of the Union. A written memorandum signed by the parties or their agents is generally required in the cases following:

1. Contracts by their terms not to be performed within a year from the making thereof.
2. A promise to answer for the debt, default or miscarriage of another person.
3. Contracts made in consideration of marriage, except mutual promises to marry.
4. Promise of an executor, or administrator, to pay debts of deceased out of his own property.
5. Contracts for the creation of any interest or estate in land, with the exception of leases for a short term generally one year.
6. Contracts for the sale of goods above a certain value, unless a portion of the price is paid or part of the goods delivered. The required value of the goods sold varies in different States from $30 to $200. In a number of the States no such provision exists.

7. In many of the States declarations or conveyances of trust estates.
8. In many States representations as to the character, credit or responsibility of another person.

Partial performance of the contract is generally held to dispense with the necessity for a writing.

Freedom of Contract.—The clauses of the State bills of rights, which prohibit the impairment or deprivation of life, liberty or property without due process of law, serve as a protection to the right to make contracts respecting personal services or property; with reference to the exercise of Federal power this right is protected by the Fifth Amendment to the Constitution; while, as regards action by the States, Amendment XIV provides that "no State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any State deprive any person of life, liberty or property, without due process of law. There are some limitations to the right to make contracts. The law ascribes to the competency of persons to make contracts determine the validity of contracts so made; thus, infants, lunatics and married women (to a limited degree) are regarded as incapable of entering into a legal contract, and the obligations assumed under contracts made by such persons, even though made voluntarily, are void or revocable. Contracts opposed to public policy or violating valid legislative restrictions or prohibitions cannot be enforced, nor do the constitutional provisions extend protection to the obligations of such contracts. The valid exercise of the police power of the State may necessitate the imposition of certain restrictions on private rights, but such restrictions on the freedom of contracts do not impair constitutional guaranties. Statutes may be passed in the public interest to regulate the sanitary conditions under which persons labor or to restrict the working hours of certain classes of laborers, such as women and children, and any contract made in violation of such prohibitions is invalid, since to this extent the State reserves the right to restrict the freedom of individuals to make contracts. By statutory provisions also the State may restrict the power of those in public employment to limit their obligations in this respect.

Impairment of Contracts.—Article I, section X, paragraph 1 of the Constitution provided that no State *shall pass any law impairing the obligation of contracts, and most of the State constitutions contain a similar limitation. But there is a distinction between contractual obligations and those that are not contractual which may be determined by the ordinary legal rules defining the validity of contracts. Any right to hold public office and the privilege of the elective franchise are not contractual obligations, and may be changed by subsequent legislation. Marriage and the inchoate rights of property existing in either party by virtue of marriage are subject to retrospective legislation. The constitutional prohibition applies not only to private contracts but to contracts made by a State or under its authority, wherefore no State by legislation may impair the obligations of its contracts. But the power to legislate on a subject may not be contracted away since once a legislature may not bind a succeeding legislature with regard to matters coming within the scope of general legislative power, though in some cases a grant of certain rights or privileges may be deemed irrepealable. Thus, holders of bank notes issued under State authority or holders of State bonds which by statute have been declared receivable in payment of public taxes are protected by constitutional prohibition against infringement of their rights through subsequent legislation which aims to modify or repeal the statute conferring such rights. The further issue of such notes or bonds might be prohibited, but those who have acquired them while
the statute was in force are possessed of so-called vested rights. Private individuals may not sue a State on its obligations. Charters granted to private corporations are contracts and, under the right to alter, amend or repeal, has been reserved to the State, the benefits accruing from such charters cannot be withdrawn or impaired by subsequent legislation (see DARTMOUTH COLLEGE CASE), though most States have constitutional or statutory provisions limiting the protection against such subsequent legislation usually afforded to such charters by their status as contractual obligations. The charters of public corporations may not be considered as contracts, and, being in the nature of legislation, are subject to modification or repeal at the legislative will, if no individual interests have been vested under them. McClain says that, in general, subsequent remedial legislation changing the general law relating to procedures does not impair the obligation of contracts already made; but if a contracting party be deprived by statute of any substantial relief for breach of contract by the other party, then such statute constitutes an impairment of the obligation of the contract and to that extent is prohibited. Hence, while the period of limitation within which actions on contracts may be brought is subject to the legislative change, such change cannot be applied to existing contracts if the parties thereto be deprived of a reasonable time within which to bring action for enforcing their rights under their contracts.

STEPHEN FEE.

CONTRACT LABOR. Previous to 1885, when on 26 February, the Contract Labor Law was passed by Congress, employers of large bodies of laborers were accustomed to arrange with their agents abroad for the shipment to this country of large numbers of an ignorant, servile class of foreign laborers—a practice that had a most disastrous effect upon home labor. These "assisted immigrants" reduced our labor market to a level with themselves, for not only was their passage-money paid, but they were bound by an agreement to work for a specified time at wages below those paid to resident laborers. A remedy for these evil effects was found in the passage of the Act above mentioned, which had a three-fold design, viz.: (1) to protect the interests of our own laboring classes; (2) to raise the standard of foreign immigrants; and (3) to check the immigration to this country of those who were unable to pay their own passage.

The main provisions of the Act are as follows:

First. 'The prepayment of transportation, or the assistance or encouragement of migration of aliens or foreigners under contract to labor in the United States, is unlawful.'

Second. 'Such contracts made previous to their making shall be void.

Third. 'Every person or corporation guilty of unlawfully assisting or encouraging the immigration of such laborers is subject to a penalty.'

Fourth. 'The master of any vessel knowingly bringing such laborers into the country is to be deemed guilty of a misdemeanor.'

Various amendments have been added to the original act, providing for the proper inspection of vessels to ascertain violations of the law, if any; to prevent the landing of aliens that come within the prohibitions of the Act, or their deportation, if landed; forbidding the soliciting of immigration abroad by promises of employment in this country; and extending the penalties for violation of the Act so as to include any who may assist in bringing in prohibited aliens. On 3 March 1903, the prohibitions contained in the above act were extended to all forms of implied contracts, and made to cover labor or service of any kind, whether skilled or unskilled.

The Contract Labor Law and its supplementary legislation have been declared constitutional under the clause giving to Congress the power 'to regulate commerce with foreign nations,' but the statute has been held by the United States Supreme Court to be directed only against the importation of unskilled cheap labor and to be applied solely to the "assisted immigrant brought into the country under contract to perform manual labor or service." It is held, therefore, by amendatory legislation since 1885, that domestic servants, actors, artists, lecturers, singers, ministers, professors and members of a family or relatives of residents not of certain other excluded classes, as persons insane, diseased, convicts, or paupers, shall be exempt from the prohibitory provisions of the Act, and are entitled to admission.

The above laws have failed, however, fully to protect immigrants from southern Europe against the labor contractors known as "agents," who, taking advantage of the immigrants' ignorance of our language and customs, have gained control of laborers of their own race and often make large fortunes by furnishing these laborers to American employers. Consult United
States Immigration Commission, 'Immigration Legislation' (1912).

**CONTRACT NOTES**, the same as bought and sold notes (q.v.).

**CONTRACT SURGEONS.** By virtue of the act of 2 Feb. 1901, the Surgeon-General of the United States Army, with the approval of the Secretary of War, may appoint as many civilian physicians as may be necessary as contract surgeons, at a compensation not greater than $150 per month. Contracts may be general or special. Special contracts do not require travel or the giving up of private practice, and are for medical services at arsenals and similar places, where the amount of work does not justify the appointment of a medical officer. A general contract obligates the surgeon to take station and change station as ordered. He receives pay as stipulated in the contract and the allowances of a first lieutenant. Contract surgeons on general duty for more than three months must pass an examination like that for admission to the Medical Reserve Corps. Contract surgeons on special duty have a similar degree of authority over Hospital Corps men to that of medical officers and are accorded the same respect. The policy of the Army at present is against the appointment of contract surgeons on general duty, and reserve medical officers are now taking their place in increasing the military medical establishment. Formerly the Army employed dentists known as contract dental surgeons; these are now known as acting dental surgeons. See **DENTAL CORPS**.

**CONTRACTILITY.** See **MUSCLES**.

**CONTRACTIONS**, abbreviations employed with the view of saving labor in writing, and also in former times with the view of saving parchment in extending MS. copies of works and deeds. See **ABBREVIATIONS**.

**CONTRAST.** A term employed in psychology to denote an enhancement of a sensory experience which is induced by another sensory experience of the same modality. Contrast is alleged by some psychologists to occur also in feeling, and the term is occasionally loosely employed as a principle of explanation of certain spatial perceptions.

The contrast-effect may be successive or simultaneous. In successive contrast the inducing precedes the induced sensation in time. For example, an orange is more sour after dessert than before, the odor of Bordeaux is stronger following the scent of cheese, a surf of constant temperature seems warm on a cold day and cold on a warm day, a room of medium illumination seems light on emerging from a dark room, and dark on entering from the bright out-of-doors. In simultaneous contrast, on the other hand, the effect is induced simultaneously and it is reciprocal with the inducing sensation. If, for instance, a sub-liminal sweet is placed on one side and a supra-liminal salt on the other side of the tongue, then the sweet becomes liminal and the salt is enhanced. The best known instances of simultaneous contrast occur between the eyes. If two narrow strips of gray paper are placed one on a black, the other on a white background, they appear lighter, but the latter much darker than the gray sheet (brightness-contrast). If, again, the same gray strips are placed the one on a well-saturated blue, the other on a good red background, and a sheet of tissue paper laid over all, each strip will be seen as yellow of poor chroma, the latter as a washed-out green (color-contrast). Vivid effects of color-contrast may also be seen in shadows, as, for example, the purple or violet shadows on the sunlit snow. The results of the experimental investigation of color-contrast have been formulated in the following laws: (1) The contrast-effect is always in the direction of the complementary color; blue induces yellow, red induces blue-green, black induces white. (2) Color-contrast is greatest when brightness-contrast has been eliminated. (3) The nearer together the contrasting surfaces, the greater is the contrast-effect. (4) The elimination of contours enhances the contrast-effect. (5) The more saturated the inducing color, the greater is the contrast-effect.

Two types of theory have been offered in explanation of contrast, the one physiological, the other psychological. Physiologically regarded, it may be said in general that successive contrast is the result of adaptation to the excitatory stimulus; an orange is more sour after dessert because the taste bulbs having become adapted to sweet respond without compensation to sour. In smell, the odors which contrast are antagonistic so that adaptation to the one leaves the other as it were in colder relief. In temperature, adaptation to an aerial cold seems to have correlated with it a "tuning" of the sense organs of warmth (in the area concerned) so that they respond to a stimulus of lower temperature; in the same way cold spots are "tuned" to a higher temperature of stimulus with adaptation to warmth. In vision, adaptation together with the negative after-image is sufficient to explain most cases of successive contrast. Adaptation fails, however, to explain cases of simultaneous contrast; the effect of adaptation always requires an interval of time, whereas simultaneous contrast is immediate. The case of the sub-liminal sweet noted above may be explained by the fact that the sensory nerves connected with the taste bulbs radiate to the two sides of the tongue; in the present state of our knowledge we can only guess that closely related areas of the cortex are thereby stimulated, and that attention to the sour facilitates the simultaneous arousal of the sweet. Simultaneous brightness and color-contrast has been most satisfactorily explained by Hering. This author supposes that the stimulation of a portion of the retina which involves an assimilation (or dissimilation) of a photo-chemical substance carries with it a simultaneous dissimilation (or assimilation) of the same substance in the contiguous unstimulated portion of the retina.

There are two psychological theories of importance. Helmholtz explained contrast as a deception of judgment. If, for example, a gray strip on a green background appears reddish, it is because it is seen as if through a green haze and the mind unconsciously inverts that if the strip is gray it must be inverted to compensate for the green. Except for an occasional textbook of physiology this theory has long since been given up; experiments may be devised which preclude the possibility of inference, and, furthermore, no explanation in
CONTRAT SOCIAL—CONTRERAS

terms of the unconscious is satisfactory to
to science. Wundt, in his early books, brought
contrast phenomena under his theory of rela-
tivity. (See WEBER’S LAW). He supposes that
the effect results from the fact that we apper-
cieve all sensory and affective experiences in
relation to each other. As against this theory
James has pointed out that the contrast-effect is
directly experienced, and it cannot by any logic
be made to depend upon an act of apperception.
Wundt, however, now recognizes the physio-
logical condition of contrast as a secondary
principle of explanation.

The occurrence of contrast phenomena in
feeling is doubtful. The opposition of affective
qualities is not, as some authors assume, like
that of color qualities. Pleasantness and un-
pleasantness are opposites in the sense that they
are mutually exclusive. A decrease of the one,
therefore, does not mean an increase of the
other, i.e., the change is in the direction of
indifference, of no feeling at all. It is true that
pleasantness and unpleasantness are logically
opposed, but there is no experimental evidence
of an enhancement of the one by the previous
experience of the other.

In space perception the size of objects and
length of lines often seem larger or smaller,
longer or shorter by virtue of the presence of
objects or lines whose size or length is logically
opposed. The illusion is not due to a contrast-
effect as is often alleged, but to some brain-
habit or disposition which conditions the per-
ception.

CONTRAT SOCIAL, konk’tra’ sō-sē-āl’, a
work by Jean Jacques Rousseau (q.v.), embody-
ing his political ideas and defending the sov-
erignty of the people. It was published in
1762 and was one of the powerful influences
affecting the leaders of the Revolution.

CONTRAVENTION, in French law, an
act done in violation of a legal obligation or
condition. It is most frequently applied in
Scottish law to any act done by an heir of
entail in opposition to the deed of entail, or to
the action founded on a breach of law-burrows.

CONTRAYEVRVA, konk-tra-yer’va (Span.
contrayerba, counter herb), the aromatic bitter-
ish rootstock of Dorstenia contrayerva, a
plant imported from tropical America, and
used as a tonic. The drug was once in much repute in low fevers, and was
considered efficacious against snake-bites whence
the name. See DORSTENIA.

CONTRERAS, konk-trǎ-rās, Hernando de,
Spanish adventurer: b. Spain about 1520; d.
Panama May 1550. He was the son of Rodrigo
de Contreras, governor of Nicaragua.

After the fall of his father, and the confisca-
tion of his property, Hernando and his brother,
Pedro, with a number of dissatisfied officers,
arranged a plot to seize Peru and Panama,
which the brothers claimed as inheritors of the
estate of their grandfather, Pedrarias. Her-
nando was to be king of the new realm, but
was never proclaimed, as the failure of his
attempt with two others made such an attempt
impossible. Panama was captured 20 April
1550, after several Church dignitaries had been
slain, and a large part of the royal treasure
stored in the city was taken. Hernando took a
considerable sum of the spoils, and was one of
the royal officers, leaving Pedro in command at
Panama. The citizens improved the oppor-
tunity to retake the city, and Hernando was
drowned shortly afterward. The other brother
was never again heard of.

CONTRERAS, Juan Senen de, Spanish
general: b. Madrid 1760; d. there 1826. He
entered the Spanish army in youth, in 1778 took
an active part in the Austrian campaign against
the Turks, and in 1795 commanded in the War
of Independence. While captain-general he
gallantly but unsuccessfully defended Tarragona
and was captured by the French. He was
imprisoned in the castle of Bouillon on the
Belgian frontier, but escaped in 1812, and two
years later returned to Spain. His narrative of
the siege of Tarragona formed the third volume
of Mémoires relatifs aux révolutions de France
et d’Espagne (1825).

CONTRERAS, Rodrigo de, Spanish
cavalier: b. Segovia, Spain, about 1495; d. Peru
sometime after 1557; the last date when he
was known to be living. He was appointed
 governor of Nicaragua in 1531, and sent an ex-
pedition into the interior, which discovered and
explored Lake Nicaragua. The expedition had
trouble with the adventurer, Robles, who tried
to seize the newly discovered country, but was
defeated. The administration of Contreras was
turbulent and marked by constant disputes with
the royal authorities and the dignitaries of the
Church. Finally he was formally charged with
various crimes and misdemeanors, found guilty,
driven from the country, and all his property
confiscated (1549). He vainly sought redress
from the Spanish government, and finally
returned to America, going to Peru, where he
was not heard of after 1557. For the attempt
of his sons to avenge their father’s alleged
wrongs, see CONTRERAS, HERNANDO DE.

CONTRERAS, Mexico, village about 12
miles southwest of the city of Mexico, the scene,
19–20 Aug. 1847, during the Mexican War, of
an important battle between a Mexican force
of 7,000 under General Valencia, supported by
another of 12,000 under General Santa Anna,
and a United States force of 4,500 under General
Scott. The Mexicans occupied a strong position
on high ground and fought for a time with great
gallantry, but, being attacked both in front and
rear at daylight on the 20th, finally gave way
and fled after having lost in killed and captur-
ted over 1,500.

CONTRERAS, Battle of (Mexican name,
Padierra), in the Mexican War, 20 Aug. 1847.
At Churubusco (q.v.), the main road south
from the city of Mexico is joined from the
southwest by another, running to the hills be-
beyond the hamlet of Contreras. This is about 12
miles from the city; a mile nearer the latter is
the hamlet of Padierra. The road to Mexico
City winds around the east flank of the ridge.
across the brook from Padierna and keeps on north, across four brooks to the important village of San Angel. The Mexican general, Valencia, with the "Veterans of the North," forming the right of Santa Anna's army, had made his headquarters at San Angel on the 17th; and he decided to occupy and fortify Peñón Cuauhtitlan, two miles southwest, to block the road to the capital skirting it. Powerful batteries were placed to command this and sweep the pedregal; and some 7,000 men were concentrated about the ridge, and facing Auzaldo and San Gerónimo. Santa Anna, apprehensive for his position on the main road, ordered Valencia to retire to Churubusco; but Valencia refused. On the 19th, Scott, at San Augustin, ordered a road leveled to Padierna; Twiggs and Pillow to check the enemy meanwhile. A fierce running fight with the Mexican troops ensued, and skirmishing continued. At 2.30 A.M. of the 20th, a dismal morning of cold, rain and fog, Smith and Riley moved southwest through the steep, gullied, slippery streets of San Gerónimo, and, unperceived, gained positions southwest of the ridge on the right flank of Valencia's lines. Meantime a strong diversion assaulted Padierna and along the rocks. The battle was won by a single impetuous onslaught of Riley's troops against Valencia's main batteries on the ridge, when the "Veterans of the North" broke and scattered like sheep. The battle was over in 17 minutes, and the Mexican army a routed mob, in face of a force numbering but a fraction of their own. Shields, who had taken Smith's place at San Gerónimo, marched rapidly to Auzaldo to cut off the retreat; but a portion of the army escaped in wild flight toward Churubusco along the San Angel road, while the rest plunged in disorder down the steep flanks of San Gerónimo, leaving all impediments behind. No more brilliant victory was won in the war. Scott had not over 4,500 men in sight, to Valencia's 7,000, and Santa Anna's 12,000 within supporting distance; and the natural and artificial defenses should have made the Mexican positions impregnable. The latter lost 700 killed and wounded, and 813 prisoners, including 88 officers, four of them generals; 22 brass cannon, vast quantities of small arms and ammunition, and many hundreds of pack-mules and horses. The American loss was 60 killed and wounded. This route contributed materially to the winning of Churubusco. Consult Wilcox, 'History of the Mexican War'; Wright, 'Life of Scott'; Scott, 'Autobiography.'

CONTRIBUTION, in law, the right of one person to exact from another his pro rata share of a common loss, as where one of two sureties discharges the entire obligation, he is entitled to secure from his cosurety his share of the amount. (See INDEMNITY; PRINCIPAL AND AGENT). In the law of war, contribution denotes the levy of money or supplies imposed by an invading upon the citizens of the territory occupied. See CONQUEST, RIGHT OF; TAXATION; TRIBUTE; WAR, and consult the authorities referred to under the last named.

CONTUMACY, kōntu′tə-mā′si, the offense of refusal or neglect of a party accused to appear or answer to a charge preferred against him in a court of justice, chiefly known in countries on the European continent. Actual contumacy is the refusal of a party actually before the court to obey some order of the court. Presumed contumacy is the act of refusing or declining any order of the court upon being cited. In civil cases a person in such case may be properly made liable to a decision against him for his neglect in not appearing to defend his rights; but by an extension of the principle to criminal cases persons are often sentenced, in their absence, to punishment in contumaciam, i.e., they are regarded as charged with the offense, but not convicted thereof.

CONTUSIONS, lesions of the body resulting from a blow struck by a blunt instrument without breaking of the skin or fracture of a bone. Contusions may involve the skin alone, or may produce some change in the deeper tissues. In contusions there is, as a rule, some rupture of blood vessels. This results in the extravasation of blood, which, if small in amount, causes minute spots called petechiae. When elongated in stripes such hemorrhages are called violes; or, when irregular and small, ecchymoses. When the hemorrhage is large and collected in one place, they are termed hematoma. Contusions, if very severe, may result in gangrene, hence all large contusions need prompt medical attendance, but small contusions may be treated with hot water in which there is some antiseptic, as a one-per-cent solution of carbolic acid; and if carefully handaged and kept from being infected, they usually recover quickly.

CONUS, a genus of gastropodous mollusks, the type of the family Conidae or cone-shells, so named from the form of the shell. They are found in the southern and tropical seas. The genus comprises several hundred species, some of them having very beautifully colored shells which are much prized by collectors. The rarest and finest of these is C. gloria-maris. All have a short, strong foot bearing a water-pore, two tentacles with eyes set on the outside at the end of a long tube, or siphon. They live in holes in rocks and in the crevices of coral-reefs, and their food consists mainly of other mollusks. Some of the species have a poisonous bite.

CONVALLARIA, the lily-of-the-valley, the typical genus of the tribe Convallarinae of the Liliaceae, or lily family. The order has about 23 genera, and 215 species, widely distributed. Nine of the genera are found in the American flora, among them: Asparagus, Clintonia, Polygonatum convallaria and Trilium. See LILY-OF-THE-VALLEY.

CONVECTION OF HEAT. See HEAT.

CONVENT (Lat. conventus), primarily the community of monks or nuns occupying a monastery, priory or other establishment of monastic or semi-monastic character. But the word is generally used to designate rather the establishment itself, if it is simply a cloister and not a considerable monastery or an abbey. The parts of a properly equipped conventual establishment are the church or chapel, including the choir, namely, that portion of the church in which the members assemble to recite or chant the psalms, etc., of the canonical hours; the chapter-house, an apartment in which the inmates assemble to deliberate or discuss com-
CONVENTICLE — CONVENTION

munity affairs; the cells, or separate quarters of the inmates; the refectory or dining-hall; the dormitory; the infirmary; the parlor for reception of visitors; the library; the treasury; the cloister, an enclosed space for recreation; and the crypt, the convent's place of burial. The word "cloister" is also used in the sense of convent; in that use cloister signifies a religious house access to which is restricted by the laws of the Church. In its popular sense the word is applied to an establishment containing a sodality of nuns, the male religious being denominated monks and their establishments monasteries. Convents are generally classed as strictly enclosed and unenclosed, but these divisions often overlap in function and are not mutually exclusive. The former represent the older type of convents to which women were attracted by a desire to save their own souls and those of others by prayer, penance, and mortification, while the latter refers to those which are devoted to active work along educational or social lines for the relief of others. Routine is prescribed; the bishop of the diocese has the inspection of the convent under his charge. In most orders the nuns are divided into choir sisters, who have religious duties only, and lay sisters who perform the manual labor of the convent. The first convent in England was erected at Folkestone in 630. The history of European convents follows the history of the monasteries. Consult Helyot, "Histoire des ordres religieux" (Paris 1792); Eckenstein, "Woman under Monasticism" (Cambridge 1896); Steele, "The Convents of Great Britain" (London 1902).

CONVENTICLE, a private assembly or meeting for the exercise of religion. The name was at first given to the private religious meetings of the early Church and then to a cabal of monks for the purpose of securing the election of a favorite as abbot. It was next applied to a form of approach to the religious assemblies of Wycliffe, the meetings of the English and Scottish nonconformists, and afterward applied to meetings of petty sects and dissenters generally. In strict propriety the word denotes an unlawful assembly, and cannot therefore be justly applied to the legal assembling of persons in places of worship licensed according to law. The Conventicle Act of 1664 outlawed all assemblies for religious purposes other than those of the Church of England. The penalty for repeated offenses was transportation.

CONVENTION, Political, an assemblage of delegates representing the members of a political party, whose leading function is to nominate the candidates of that party for elective offices. In the early years of the nation candidates were often nominated at mass meetings, but the growth of the country necessitated a change. Delegates were appointed by the local caucuses to confer with delegates from other caucuses in the city, county or district, with the object of making nominations for the next larger area. This method gained favor and early in the 19th century Pennsylvania adopted the county convention and Massachusetts and other States both the county and Congressional conventions. The legislative caucus performed many of the functions of the State convention for many years because of the difficulties of travel and communication over so large an area; the legislative caucus method also was used in the nomination of national candidates. As the Congressional caucus, however, was used for more than 25 years to choose the party candidates for President and Vice-President. During the campaigns of 1824 and 1828, owing to the failure of the Congressional nominating convention, the Democratic-Republican party held nominating conventions that were neither national nor systematically representative, and the first nominating convention that can be called national was held at Baltimore in 1831 by the Anti-Masonic party. Since that time the system has gradually developed into the present complicated but well-ordered system.

Minor Conventions.—First in order of the nominating conventions is the local primary, caucus or primary convention, called together by the party committee, and consisting of those voters affiliated with the party who reside in ward, precinct or township. This primary makes nominations to local offices and selects delegates to the nominating convention of the county or district. The county convention nominates candidates to county offices and sends delegates from among its members to a district convention which selects candidates for Congress and elects delegates to the State convention. In some States delegates to both district and State conventions are elected by the town primaries. The State convention nominates candidates for State offices and sends delegates-at-large to the national convention. In the Democratic party the State convention may select all the delegates and instruct them. The State convention formulates party policy within the State and decides questions of party regularity, though appeal may be made to the national convention. The basis of representation in the State convention is the party vote at the preceding election — whether Presidential or gubernatorial, whereas the membership of the national convention is not concerned with party strength.

Party Committees.—In early times the convention concerned itself only with the immediately succeeding campaign; it had a chairman, secretary, treasurer and other necessary officers, but the organization was purely temporary and had no permanency; on adjournment the organization lost its existence, and the next convention might be called either by the officers of the previous convention or by an informal self-appointed committee. Hence conventions adopted the plan of appointing permanent committees to act in their behalf during the interval between conventions. The Democratic convention of 1848 was the first to appoint a national committee but the committee's value was not generally recognized until after the Civil War. The national committee is now composed of one member from each State and Territory (chosen for four years or until the next national convention) and though subordinate to the convention exercises great authority — both executive and financial — and influence to control the convention and dominate its policies. It decides the place of meeting, arranges the seating of delegates, and, most important of all, selects the temporary chairman of the convention and the keynote of the campaign. It has then per-
formed its duties and on the opening of the convention is dissolved to make way for the appointment of a new committee, the members of which are in harmony with the Presidential candidate. The chairman of the new national committee, chosen by the President, who is the nominal head of his party, is both nominally and actually the head of the organization and is in close touch with the candidates. When the convention closes, the new national committee organizes at once and is usually divided into subcommittees, such as the executive committee, the finance committee, the committee on bureau of speakers, the committee on publicity to supervise the literature, press matter and distribution of public documents. Though not organically connected with State and local committees, the national committee in effect, through its State member, directs the campaign in every minor division. There is also the national Congressional committee, the organization of which differs in the two largest parties. The Republican committee consists of one member from each State and Territory represented in Congress (provided that State has a representative in Congress). He has instructed the members of both Houses. The Democratic committee is chosen at separate caucuses of the two Houses, nine members being appointed by the Senate and one member being appointed for each State and Territory represented in Congress. If a State has no Democratic representative in Congress, a prominent Democrat of that commonwealth is appointed to the committee. The Congressional committees have charge of the midterm elections when the two parties endeavor to elect a majority in Congress, either as an endorsement or a condemnation of the party which has previously elected the President. Subordinate to the national committees are the State central or State executive committees, varying in their machinery according to the section of the country. Outside of New England, where the town committee holds, the most important place, the county committee is almost universally the important one, but no district is too small to be used as a basis of party work, the Congressional, senatorial, judicial and school districts, and the city wards or precincts all having their share in the party organization. The State executive committee (consisting of as few as 13 members, or more than 100 members, as in Pennsylvania) may be named by the chief candidates of the party or may consist of representatives of Congressional or State senatorial districts and of counties.

The National Convention—Both national conventions are composed of two delegates from each Congressional district and four delegates-at-large from each State. Thus a national convention contains twice as many delegates as there are members of the House and Senate combined. Both the largest parties admit delegates from the Territories, varying as to numbers and privileges of voting. The State organization determines the method of electing delegates to the national convention. The Republicans prescribe that delegates shall be chosen in the same way that Congressmen from the same districts are nominated—either at primary elections or district conventions. The Democratic delegates may be selected by the State convention as a whole, by the delegates of each individual district or by each district at a district convention. Having assembled, the convention at its first session accepts the temporary officers nominated by the national committee and upon the roll call, by the temporary chairman, the delegates of each State and Territory select one of their number as a member of each of the four most important convention committees, by whom the permanent organization of the convention is effected. At the next session, on the acceptance of the report of the committee on credentials, the permanent chairman, vice-presidents and other officials are elected and the rules adopted, usually as suggested by the committee on rules and order of business. Democratic national conventions have always required a two-thirds vote for the nomination of President or Vice-President, but the other parties require only a simple majority. The Democrats also employ the "unit rule," under which a majority of the delegates from a State may cast the entire vote of the State even over the protest of the minority, whereas the Republicans allow delegates to vote as individuals even though the State convention may have instructed the delegates to vote as a single unit. The rules having been adopted, the committee on resolutions then presents the platform which may or may not be amended by the convention before acceptance. The nomination of candidates is the next and most important business, the rolling being called by States in alphabetical order, whereupon the delegates selected to place the candidates in nomination make their formal speeches. The balloting continues until one candidate receives the vote required to nominate, several days being consumed sometimes in reaching an agreement. Having completed the most important task for which they assembled, the delegates finish the work of the convention by electing a new national committee which, as previously stated, takes full charge of the campaign and remains in office until the next national convention has assembled. The direct primary (q.v.) has done much to rid the political parties of the obnoxious "boss" system by making the nominations more truly representative of the body of the voters. It has shown also that the convention system is not a necessity but is mainly useful for the formulation and promulgation of party principles.

CONVENTION OF 1787.—CONVENTIONS

CONVENTION OF 1787. See Constitution, Framing of the.

CONVENTIONS, Constitutional, in the United States. Conventions for the purpose of framing constitutions originated in the United States during the early years of the Revolution (1774-76) and the development of the methods employed may be divided into three phases: first, the framing of constitutions by the regular legislative bodies under direct authorization of the people; second, the performance of that function by a body separate and distinct from the regular legislature; and third, the submission of the proposed constitutions to popular approval before they become effective. The colonial legislative assemblies actively participated in the movement leading up to the Revolution; but as the royal governors (save in Rhode Island, Connecticut, Delaware and Pennsylvania) could adjourn, prorogue or dissolve these bodies, their replacement became necessary when the period of military opposition arrived. Hence provincial congresses or conventions sprang into existence during 1774-75, but as these were only temporary organizations, they recommended to New Hampshire (3 Nov. 1775) and to South Carolina (10 May 1776) that the people select representatives, who, if they deemed necessary, should establish a form of government to continue during the dispute with the mother country. Under this recommendation a number of constitutions were framed during 1776 to 1778. In eight instances (North and South Carolina, Georgia, Virginia, New Jersey and the continuation of the charters in Massachusetts, Rhode Island and Connecticut) the constitutions were adopted and promulgated by the legislative bodies without previous authority from or ratification by the people. In New Hampshire and Delaware in 1776, and in Georgia, New York and Vermont in 1777, the legislative bodies had been expressly authorized by popular vote to take such action, but the instruments enacted were not in any way submitted to the people. In Maryland, Pennsylvania and North Carolina in 1776, and in South Carolina in 1778, the legislatures which framed the constitutions received express authority from the people, and some time before enactment, copies were distributed so that the people might have an opportunity to object and suggest changes.

The principle that popular authority should be given before a constitution could be framed seems to have been well established and the feeling prevailed too that no constitution should be adopted until submitted to and approved by the people. Some of the first constitutions were informally submitted (Pennsylvania, Maryland, North and South Carolina), but the first instrument of government formally submitted to a referendum was the proposed Massachusetts constitution of 1778. The first constitutions framed by bodies separate and distinct from the regular legislatures—and the only ones so framed during the Revolutionary period—were those of New Hampshire and Massachusetts. The former colony delegated three members selected in 1778 and drafted a constitution in 1779, but on submission to the people it was rejected, as were two constitutions proposed by the second convention in 1781 and 1782, but the third constitution submitted by the second convention in 1783 was adopted. In 1777 a majority of the Massachusetts towns authorized the formation of a constitution by the general court, but the proposed instrument was rejected in 1778, largely because it had not been framed by a body appointed for that special purpose. Accordingly, a distinct convention was assembled and the constitution drafted by it was accepted in 1780.

Since 1784, with a few exceptions, constitutions have been framed or adopted by conventions chosen by the people for this special purpose. The Nebraska constitution of 1866, however, was framed by the territorial legislature and submitted to the people by that body. In Michigan the legislature provided for a special commission to prepare a new constitution but in 1874, when the instrument as drafted was submitted to popular vote, it was rejected. In Rhode Island a constitution was prepared in a similar manner but it was rejected in 1898 and 1899. In 1911 the Indiana legislature drafted a new constitution but the courts enjoined the legislature from submitting it to the people. Though more than 200 conventions have been held to frame state constitutions; the Massachusetts constitution of 1780 remained practically unchanged until the revision of 1917–18, though conventions were held in 1820-21 and 1853. Some States hold conventions more frequently than others; Virginia has held conventions in 1776, 1829-30, 1850-51, 1861, 1864, 1867-68 and 1901-02; and in 1776-77, 1801, 1821, 1845, 1867-68, 1894 and 1915 similar bodies met in New York; but in Minnesota no convention has assembled since the last constituted in 1857, and only two have been held in Indiana (1816 and 1850-51). The number of conventions in the Southern States is relatively larger owing to the secession conventions and the two sets of conventions called in these States during the Reconstruction period. For the history and characteristics of the State constitution see United States—The Formation of State Constitutions; United States—State Constitutions of the; Constitution, Framing of the; Constitution of the United States—Constitutional Amendments, History of; United States—The Federal Convention of 1787.

Constitutional conventions have been held in the various States in the following years, most of the instruments framed being adopted the same or the succeeding year, but in some cases constitutions were framed by bodies other than regularly constituted conventions (the word "not submitted" meaning that the constitution was put into operation without first submitting it to popular vote):

Alabama: 1819; 1861 (not submitted; secession convention); 1865 (not submitted; Reconstruction convention); 1875; 1901.

Arkansas: 1836 (not submitted); 1861 (not submitted; secession convention); 1864 (not submitted; Reconstruction convention); 1866; 1874.

California: 1849; 1878–79.

Colorado: 1876 (rejected); 1865 (ratified but State not admitted); 1875-76.

Connecticut: Operated under colonial charter of 1662 until many years after Revolution: 1818.

Delaware: 1776 (not submitted); 1792 (not submitted); 1831 (not submitted); 1852-53 (rejected); 1890.

Florida: 1838-39 (not submitted); 1861 (not submitted; secession convention); 1865 (not submitted; Reconstruction convention); 1868; 1885.
CONVENTIONS

GEORGIA: 1776 (temporary constitution proclaimed by Provincial Congress); 1776-77 (not submitted); 1778; 1779 (not submitted); 1785 (amendments, not submitted); 1786; 1787; 1788; 1789 (amendments, rejected); 1791 (amendments, rejected); 1801 (not submitted; succession convention); 1805 (not submitted; Reconstruction convention); 1861; 1865 (not submitted; Reconstruction convention); 1866-67; 1877.

IDAHO: 1889.

ILLINOIS: 1818 (not submitted); 1847; 1862 (rejected); 1869-70.

INDIANA: 1816 (not submitted); 1850-51 (revised in 1851; a draft for a referendum vote being submitted against its submission to the people).

IOWA: 1844 (rejected); 1846; 1857 (Amendments of 1900 were held to be unconstitutional and proposed and adopted.); 1855 (Topeka Convention); 1857 (Lecompton Constitution); 1858 (Missouri-Leavenworth Convention); 1859 (Wyandotte Constitution; constitution ratified by 1859, effective 1861).

KENTUCKY: 1792 (not submitted); 1799 (not submitted); 1840-50 (not submitted); 1890 (constitution was changed by a convention, not approved by people).

LOUISIANA: 1811-12; 1844-45; 1852; 1861 (not submitted; succession convention); 1864 (Reconstruction convention); 1865 (government organized under the constitution not recognized by Congress); 1869-77; 1879; 1898; 1913.

MARYLAND: 1776 (not submitted); 1850-51; 1861; 1875.

MICHIGAN: 1777-78 (rejected, without further definition of the territorial charter until 1800); 1779; 1780; 1834-35; 1857; 1861 (rejected); 1917 (amendments not submitted; 1865 (not submitted; succession convention); 1868 (rejected in 1868 but adopted in 1869); 1890 (not submitted).

MINNESOTA: 1857.

MISSOURI: 1812; 1813; 1832; 1861 (not submitted; succession convention); 1865 (not submitted; Reconstruction convention); 1866 (rejected in 1868 but adopted in 1869); 1890 (not submitted).

MISSOURI: 1820; 1845-46 (rejected); 1861-63 (not submitted; Union Convention); 1865; 1872.

MONTANA: 1889.

NEBRASKA: 1776 (drafted by committee and adopted by convention but not accepted by Congress until 1867); 1875.

NEVADA: 1863 (rejected); 1864.

NEW HAMPSHIRE: 1776-77 (not submitted); 1778-79 (rejected); 1781; 1783 (rejected); 1783; 1791-92; 1850 (amendments rejected); 1851; 1857; 1889; 1903; 1912.

NEW JERSEY: 1776 (rejected; Revolutionary Congress); 1844; constitutional commissions sat in 1873 and 1894.

NEW MEXICO: 1889-90 (rejected); 1910.

NEW YORK: 1776-77 (not submitted); 1851 (five amendments promulgated without submission); 1851; 1864; 1867-68 (rejected); 1894; 1915 (rejected).

NORTH CAROLINA: 1776 (not submitted); 1835 (amendments); 1861 (not submitted; succession convention); 1865 (not submitted; Reconstruction convention); 1866 (convention reassembled, proposed amendments rejected); 1868; 1875.

NORTH DAKOTA: 1889.

OHIO: 1802 (not submitted); 1850-51; 1873-74 (rejected); 1912 (34 out of 42 propositions adopted).

OKLAHOMA: 1905 (constitution proposed New State to be called Sequoyah); 1907.

OREGON.

PENNSYLVANIA: 1776 (not submitted; Revolutionary Congress); 1783-84 (council of censors met without action); 1785 (censorship without submission); 1837-38; 1872-73.

RHODE ISLAND: Operated under colonial charter of 1663 until 1842; 1824 (rejected); 1834 (abdiective); 1841-42 (People's Convention); 1841-42 (chart government convention).

SOUTH CAROLINA: 1776 (not submitted; proposed by Revolutionary convention); 1777-78 (put into effect by legislature without submission); 1790 (not submitted); 1860-61 (not submitted; succession convention); 1865 (not submitted; Reconstruction convention); 1868; 1895.

SOUTH DAKOTA: 1889.

TENNESSEE: In 1772 the Watauga Association adopted a constitution and in 1874 a constitution was put into operation in the State of Franklin but was not ratified at convention of 1783; 1796 (not submitted); 1834; 1861 (succession convention); 1865 (Reconstruction convention); 1870.

TEXAS: In 1777 a constitution was framed for Coahuila and Texas; in 1833 another was framed at San Felipe but not recognized by Mexico or put into operation; in 1836 a "Constitutional Convention" was framed and in 1839 a constitution of the Republic of Texas; 1845; 1861 (succession convention); 1866 (Reconstruction convention); 1868; 1875.

UTAH: 1895.

VERMONT: 1777 (not submitted); 1786; 1793; 1799; 1806 and 1813 (meetings of council of censors, abortive); 1822 and 1836 (deemed referred to conventions by council of censors and all but one rejected); 1836; 1843; 1850; 1857; 1870; 1880 (amendments proposed by Senate, council of censors having been abolished and adopted by people in 1883); 1890, 1900, 1910 and 1913 (amendments submitted but only 10 adopted at elections).

WISCONSIN: 1846 (rejected); 1847-48.

WYOMING: 1889.

Methods of Calling Conventions.—The only provisions for calling conventions to be found in the earlier State constitutions were contained in those of Pennsylvania (1776), Vermont (1777), Georgia (1777), Massachusetts (1778) and New Hampshire (1784). In Pennsylvania the people were to elect a council of censors every seventh year, on the consent of two-thirds of whom a convention might be called to amend such parts of the constitution as the council thought necessary, but any proposed amendments, additions or omissions of the legislature would be promulgated "at least six months before the day appointed for the election of such convention, for the previous consideration of the people, that they may have an opportunity of instructing their delegates in their sentiments." Only one meeting of this council was held and in 1789, after the constitutional requirements had been ignored in calling the convention of 1789, the council was abolished. Vermont made the same provision but the members of the council of censors were to be elected in a different manner. The Vermont council had called several constitutional conventions before being abolished in 1870. The Georgia constitution of 1777 provided that the legislature should call a convention if petitioned to do so by a majority of the voters of a majority of the counties, but the petitions must specify the desired amendments and in calling the convention the legislature must do likewise. In Massachusetts the desirability of revising the constitution was to be voted upon in 1795 and if two-thirds of the votes cast favored such revision, the general court was to call a constitutional convention, but as the vote was adverse the State never afterward had a constitutional provision for calling conventions. New Hampshire and Rhode Island are the only States where the attorney-general contends that such a convention is not only legal but is expressly authorized by the State constitution (1917 Mass. House Doc. 171, pp. 2-3). The New Hampshire constitution of 1784 provided for the calling of a convention within seven years upon a favorable popular vote and the constitution of 1792 contained a similar provision for a vote within each seven years thereafter. Seven of the Revolutionary constitutions which continued after 1784 made no provision for conventions and others recently adopted have omitted such provisions (Georgia, 1798; Connecticut, 1818; New York, 1822; Missouri, 1820; Rhode Island, 1842; Pennsylvania, 1790, 1838, 1873; Virginia, 1830, 1852, 1864; Vermont, 1870; Arkansas, 1868, 1874; Tennessee, 1834; Texas, 1868; Louisiana, 1845, 1851, 1864, 1866, 1879, 1898), though in States which possess no such constitutional authority it has been assumed that conventions may be called.
Dakota) make no provision whatever for calling conventions, but conventions may be called in these States by legislative action, and the legislature has power to determine whether the people shall have an opportunity to express their wishes by voting upon the subject. Judge Jameson calls attention to 27 conventions which have met without constitutional authority for their assembling (Arkansas, 1874; Connecticut, 1818; Georgia, 1831, 1839; Indiana, 1850; Louisiana, 1852, 1879; Massachusetts, 1853; Missouri, 1845, 1861, 1865; New Jersey, 1844; New York, 1801, 1821, 1846; North Carolina, 1835; Pennsylvania, 1837, 1872; Rhode Island, 1824, 1834, 1841, 1842; South Carolina, 1790; Tennessee, 1870; Texas, 1876; Virginia, 1829, 1850) and since he wrote there have been at least three cases of the same character—Mississippi in 1890, Louisiana in 1898 and Connecticut in 1902. To this list also should probably be added the conventions of Delaware, 1791 and 1852; Maryland, 1850; Massachusetts, 1820 and 1917–18; and Indiana, 1918. Under another class of constitutions, such as those of Maine and Georgia, the legislature is empowered to call conventions without first submitting to popular vote the question whether a convention shall be held. Among the conventions thus called were those of Connecticut (1818), Rhode Island (1824, 1834, 1841, 1842), New Jersey (1844), Missouri (1861, 1865), Arkansas (1874), North Carolina (1875), Louisiana (1879), Mississippi (1890) and the secession and reconstruction conventions. On the other hand, several legislatures, though bound by no constitutional provisions, submitted the question to the people; among such were the conventions of Massachusetts (1820, 1853), New York (1821, 1846), Virginia (1829, 1850), Maryland (1850), North Carolina (1835), Pennsylvania (1837, 1872), Missouri (1845), Louisiana (1852, 1898), Tennessee (1870), Texas (1875) and Connecticut (1902). A third plan, adopted by 32 States, requires popular approval before a convention can be called, but in 25 of these States (Alabama, California, Colorado, Delaware, Florida, Idaho, Illinois, Kansas, Kentucky, Minnesota, Missouri, Montana, Nebraska, Nevada, North Carolina, Oregon, South Carolina, South Dakota, Tennessee, Utah, Virginia, Washington, West Virginia, Wisconsin and Wyoming) the legislatures have the power to decide the proper time when the question of holding a convention shall be submitted to the people. Seven constitutions contain a provision that the question of calling a convention shall be voted upon by the people at regular intervals without reference to legislative action. New Hampshire requires a vote upon this question every 7 years; Iowa every 10 years; Michigan every 16 years; Maryland, New York and Ohio every 20 years; and Oklahoma, at least once every 20 years, though the legislature has discretionary power to submit the question more frequently. The legislatures of Iowa, Michigan, New York and Ohio may submit to the people the question of holding a convention at other times than those above specified. In States where a referendum is in vogue the legislatures have lost a large part of their control over the calling of conventions, since the people themselves may initiate and adopt a measure providing for the holding of a convention. These provisions have been adopted in the following States: Oregon (1902), Oklahoma (1907), Missouri and Michigan (1908), Arkansas and Colorado (1910), Arizona and California (1911), Nevada, Nebraska, New York, Ohio (1913) and North Dakota (1914), and in 1913 Michigan broadened and simplified the provision inserted by the convention of 1908. In Idaho, Maine, Montana, South Dakota, Utah and Washington also the people can initiate and adopt a measure providing for the holding of a convention and by referendum may veto any statute by which the legislature attempts to interfere with a convention.

In most cases legislative action is necessary after the people have voted in favor of a convention, since delegates must be elected and provision be made for the assembling of the convention, though in only eight States are such matters left entirely in the hands of the legislature; some of the constitutions expressly limit the number of delegates and regulate their appointment, method of election, etc. In Michigan, New York and Missouri, however, the convention assembles as a matter of course without legislative action, the constitutions themselves providing for the appointment and election of delegates and the assembling of the conventions. When Congress passes an act enabling a Territory to apply for admission as a State, such act contains a provision for the number and election of delegates to a convention for the purpose of framing the new State constitution. But if the Territorial legislature itself take the initiative in calling such a convention, with the ultimate object of applying for admission into the Union, provision for delegates, etc., is usually made by the Territorial legislative act. Respecting a national convention, Article V of the Constitution of the United States provides that "the Congress ... on the application of the legislatures of two thirds of the several States, shall call a convention for proposing amendments," thus imposing on that body no restrictions as to the conditions under which the convention shall be held.

Procedure of Constitutional Conventions.

—Conventions act under very few constitutional restrictions as regards their procedure, and in general have adopted their own rules, differing but slightly from those of other deliberative bodies. Though possible, few conventions attempt to perform their functions as a body, but usually divide the work among committees. The method of transacting business mainly in committee of the whole, with a few small committees to handle minor details, is apt to prove unsatisfactory unless the plan of the convention be quite complete before the meeting of the convention. The Federal convention of 1787 used the committee of the whole to a large extent, as did also the Pennsylvania convention of 1776. Some of the earlier constitutions were framed by a small committee which had been given full power to prepare and report a draft of a constitution to the whole convention. This method was adopted by the revolutionary conventions of Maryland, New York and Vermont in 1777, by those of New York and Vermont in 1777, by the Massachusetts general court in 1778, the Massachusetts convention of 1779-80, the Tennessee convention of 1796 and the California convention of 1849. But the usual practice in
modem times is for the convention to appoint
a number of committees among whom the sev-
eral sections of the constitution are distributed
for consideration and revision, after which such
sections are reported to the convention in
regular debate, where, with due regard to
phrases, methods of amendment, municipal gov-
ernment, rules, taxation, submission and ad-
dress, and miscellaneous. As a rule the mem-
ers of these committees are appointed by the
president of the convention. The Michigan
convention of 1908 employed the following pro-
cedure: After the convention had been or-
ganized, 28 standing committees were author-
ized, the members of which were appointed by
the president. The various propositions sub-
mittted by members were read and referred to
the proper committee, on being reported by
that committee were considered in committee of
the whole and when reported by the latter were
referred to a committee on arrangement and
phraseology. When this committee had reported
upon the proposals, they were put
upon their second reading and after this reading
were voted upon; if adopted the proposals
were again referred to the committee on ar-
angement and phraseology, whose action
monizing all the proposals adopted by the con-
vention, reported the complete revision as
agreed upon. The committee of the whole then
considered this revision section by section
and reported to the convention, which then
passed the revision to its third reading and
voted upon it by articles and as a whole. Thus
four different opportunities were presented for
the discussion and amendment of proposals,
and the committee on arrangement and phrase-
ology had the opportunity to revise the lan-
guage of each proposal after the committee of
the whole had agreed upon it and before it
was finally adopted; and as revised the propo-
sals were again sent to this committee to be
considered before they were finally adopted.

Submission of Constitutions to Popular
Vote.—Since 1840, with a few exceptions, the
States have followed the practice of submitting
constitutions to popular vote, but the practice
can hardly be said to have become fixed, since
only about one-half of the State constitutions
containing provisions for conventions require
that the constitutions framed by these conven-
tions be submitted to the people (California,
Colorado, Idaho, Illinois, Maryland, Michigan,
Missouri, Montana, Nebraska, New Hampshire,
New York, Ohio, Oklahoma, Utah, Washington,
West Virginia, Wyoming). Prior to 1874 the
only constitutions formally submitted to the
people were those of Massachusetts and New
Hampshire, though in Pennsylvania in 1790 and
in some of the other States a plan was pursued
which accomplished about the same purpose;
the Vermont constitution of 1786 (and also its
later amendments to 1870) and the Georgia
constitution of 1789 were ratified by special
bodies. Choice of securing on referenda or
express purpose. Constitutions were submitted for
popular approval by New Hampshire in 1792,
Connecticut in 1818, Maine in 1819, New York
in 1821 (being the first State outside of New
England to submit a constitution to the direct
vote of the people), Rhode Island in 1824
(this constitution being rejected), Virginia in
1829 (her second constitution), Georgia in 1833
and 1839, Tennessee in 1834, Michigan and
North Carolina in 1835, Pennsylvania in 1837-
38 and Florida in 1839, but the conventions of
Delaware in 1831, Mississippi in 1832 and
Arkansas in 1836 did not submit their work to
popular vote. Between 1840 and 1860 and from
1870 to 1890, almost the entire exception to the
constitutions framed by conventions were submitted to
the people for approval, but since 1890 the
practice has been varied. Prior to 1890 there
were 38 States, and since that time 10 others
have been added to the Union (North Dakota,
South Dakota, Montana and Washington in
1889; Idaho and Wyoming in 1890; Utah in
1896; Oklahoma in 1907; and New Mexico and
Arizona in 1912). Of the 38 States 12 have
held conventions to revise their fundamental
laws (Mississippi, 1890; Kentucky, 1890; New
York, 1894, 1915; South Carolina, 1895; Dela-
ware, 1897; Louisiana, 1898, 1913; Alabama,
1901; Virginia, 1901-02; Michigan, 1907-08;
Ohio, 1912; New Hampshire, 1889, 1902, 1912;
Massachusetts, 1917-18) and the others
succeeded in modifying its constitution with the
aid of a commission, while the amendments
adopted in Oregon and California since 1902
are so numerous and fundamental as to amount
virtually to revisions. States unsuccessfully
at tempted to revise their constitutions
(Rhode Island, 1898, 1899; Connecticut, 1902,
1907; Indiana, 1912; New York, 1915), and
referenda submitted to ascertain the popular
desire regarding the calling of conventions were
negatived in Maryland (1907), Iowa (1909
1910) and California, Indiana and South Da-
kota (1914), but Illinois, Indiana, Massachu-
setts, Nebraska and New Hampshire held con-
ventions in 1917 and 1918.

Of the constitutions adopted since 1890
seven have been submitted without reservation
—those of New York (1894), Utah (1895),
Alabama (1901), Oklahoma (1907), Michigan
(1908) and New Mexico and Arizona (1911),
though the submission of these was altered by
the people after the convention had approved it. The Indiana legislature of
1911 drafted a new constitution, but its sub-
mision to the people was enjoined by the
courts, and in November 1914 the voters de-
feated a proposal to submit a new constitution
to the people. Nevertheless the legis-
lature defied the popular mandate by passing
the act of 1917 for a convention in 1918. In
Ohio the constitution of 1851 was difficult of
amendment or revision owing to the necessity
of securing on referendum the approval of all
the electors voting at said election. Finally
a convention was authorized and held in 1912
and at a special election in September of that
year the convention submitted 42 separate prop-
sitions of which 34 were adopted. New Hampshire has no process of amending through the legislature, but every seven years submits a referendum in respect to the calling of a convention. The convention of 1889 submitted some amendments of which five were adopted; the convention of 1902 submitted 10 amendments of which six were adopted; and the convention of 1912 submitted 12 amendments of which only four were adopted. In Rhode Island any revision recommended must be approved by two elections. In 1888 a proposed revision made by a commission of 15 persons passed the legislature but was defeated at the polls; with a few changes it was repassed and resubmitted in June 1899 but was rejected by a larger vote. In 1912 another commission of nine persons was appointed to recommend another revision and made its report in 1915, which after being approved by two assemblies was voted upon in 1917. The Connecticut constitution makes no provision for a convention, but in 1901, after a referendum, the legis-
lature summoned a convention, the work of which was rejected at the polls in June 1902. In 1905 the legislature submitted a revised con-
stitution but this too was rejected in November 1907. In Vermont amendments have suffered at popular elections, two out of 23 submitted in 1880 being accepted, none of the nine offered in 1890 and none of the four offered in 1900 being passed, wherefore in 1908 a commission of five was appointed to propose amendments; eight were proposed in January 1910 and after acceptance by two successive assemblies were passed by the voters in 1913. After Louisiana promulgated its constitution in 1898 every ses-
sion of the legislature witnessed the introduc-
tion of numerous amendments until in 1913, owing to the necessity of making new arrange-
ments to fund the bonded debt of the State, a convention was called which added an article respecting the debt, incorporated previously adopted amendments into the constitution and promulgated, it without referendum. In 1912 North Carolina appointed a commission which in 1913 proposed 14 amendments to a special session of the legis-
lature but though that body accepted 10 of these they were rejected at the polls in November 1914, though the constitution was later amended in 1916.

In connection with the submission of consti-
tutions to popular approval, some attempts have been made either to enlarge or reduce the elector-
ate for the purpose of voting on such consti-
tutional changes. The legislature alone ex-
tended the electorate in New Jersey (1844) and Rhode Island (1841–42), but in 1821 this was done in New York with the aid of the electorate itself, while in Massachusetts in 1780 the con-
vention did the extending with the assent of both legislature and electorate. The conventions of Virginia (1830) and Illinois (1869) had only the power of the legislature, and the following conventions acted on their own initiative: Louisiana (1845, 1852), Michigan (1835), Texas (1845), Virginia (1851), West Virginia (1863), Tennessee (1834), Kansas (1859) and Arkansas (1868), the Tennessee and Arkansas conventions reducing the qualifications required by Reconstruction acts and by the conventions of Maryland (1864), Mis-
souri (1865) and New York (1867).

Constitutional Restrictions upon Conven-
tions.—Generally speaking, the only restrictions upon constitutional conventions are those ex-
pressly contained in the provisions of the State and Federal constitutions, or in the absence of such provisions, those implied in such constitu-
tions and those implied from the limited func-
tions of conventions. The existing constitu-
tional organization is not affected by a constitu-
tional convention since the latter acts under the restrictions either expressly or impliedly contained in the constitution in force at the time. Professor Dodd says that the convention 'is a regular organ of the State (although as a rule called only at long intervals)—neither sovereign nor subordinate to the legislature, but independent within its proper sphere. Under this view the legislature cannot bind the con-
vention as to what shall be placed in the consti-
tution or as to the exercise of its proper duties ... [which are] simply to propose a new constitution or to propose constitutional amendments to the people for approval; or in States where the submission of constitutions is not required, to frame and adopt a constitution if they think proper. Constitutional conventions should not be subject to con-
trol by legislative acts.' The new constitution does not become effective until promulgated by the convention, if such be the provisions of the existing constitution, or until ratified by the people, if this action be required. As an organ of the State and as a legislative body a conven-
tion must act in accordance with the provisions of the Federal Constitution regarding contracts, ex post facto laws and all other restrictions imposed upon the States by that instrument. If a State convention provide for the revision or framing of the organic law of the State by the calling of a convention, then such conven-
tion is impliedly restricted to that one act and the exercise of such powers only are neces-
sary to accomplish its object. If the State con-
stitution should make no provision for a con-
vention, then such convention acts under the existing constitution and accordingly the gov-
ernmental departments cannot be dissolved or replaced until the new constitution framed by the convention become effective. Hence it is to be presumed theoretically that a constitu-
tional convention is assembled for a limited and de
definite purpose and neither can nor does usurp the regular legislative, executive or judicial powers of the existing organs of government. (Consult, however, Hoar, R. S., 'Constitutional Conventions,' pp. 164–184.) Yet this has not always been the case, particularly as are now
early Revolutionary and during the Civil War
periods, notably in Missouri and the South-
ern States, though in the former period, as previ
ously stated, the conventions primarily were
provisional governments and the work of fram-
ing constitutions was only incidental. Analogous conditions obtained in Missouri in 1861–63 and in some of the other Southern States, so that the conventions were probably justified in acting beyond the limits of their regular duties. Some of the Reconstruction con-
ventions in South Carolina were called to frame organic laws and establish governments not only performed these duties but arrogated to themselves all the powers and functions of
the regular legislatures. Similarly the conventions of 1890 in Mississippi, of 1895 in South Carolina, of 1898 in Louisiana and of 1901 in Alabama they possessed power in excess of those connected with the framing of constitutions. In the South Carolina convention a motion was even made that there be no session of the legislature and that the convention should do its work. The legislative act for South Carolina of 1901 required that the new constitution be submitted at the April election of 1908, but the convention decided upon the following November, and by mandamus proceedings compelled the Secretary of State to recognize the convention's supremacy. In 1867 and 1894 the New York convention sat beyond the time fixed by the legislature, as did also the Alabama convention of 1901, but while the New York delegates received no extra compensation, the Alabama convention resolved that the pay of its members should continue after the time allotted until the completion of the work. But it would seem that a convention has no power to appropriate money, since in the constitutions the provisions that money shall be paid from the State treasury only upon a legislative appropriation. In a number of cases such actions have been questioned and have been held invalid by the courts, though other courts have upheld them. Consult Ashley, R. L., 'The American Federal State' (New York 1908); Bryce, James, 'The American Commonwealth' (rev. ed., ib. 1914); Borgardt, C., 'Adoption and Amendment of Constitutions in Europe and America' (trans. by C. D. Hazen, ib. 1895); Binney, C. C., 'Restrictions upon Local and Special Legislation in State Constitutions' (Philadelphia 1894); Dealey, J. Irving E. Rines, Author of 'History of the United States.'

CONVENTIONS, Revolutionary. Where the legal governments of countries have become the very grievances against which people rebel, the latter have no organ of expression save tumultuous or representative popular assemblies. The latter are usually called conventions. Thus, in England, the convention parliament of 1399 deposed Richard II and gave the crown to Henry IV; that of 1660, after the downfall of Richard Cromwell, proclaimed Charles II; that of 1669, after the flight of James II, proclaimed him abdicated and William III king. These were simply parliaments, except that there was no royal authority to call them. In Massachusetts, the convention of May 1689, at the same time as that in England, superseded the Andros government by one of the people. That of South Carolina in 1718, to form a provisional government in place of the proprietary government, is another instance. Of a similar character was the convention by which the first French Republic was declared in 1792, and under which the Revolution was carried on till the establishment of the Directory in 1795. In all these cases, the conventions were administrative bodies, governments pro tem. So during the Revolution, when the royal governors proclaimed the colonial assemblies dissolved, they were in the habit of reassembling as conventions, and they constituted the provincial governments until regular constitutions were in force, in which fact they themselves often framed and adopted. The later constitutional conventions, creatures of State law, and limited to the preparation of a plan of government to be afterward voted on, have nothing whatever in common with the above, and are in fact only enlarged consulting boards, representative enough to imply fairly the entire public feeling. Of the first sort were the nullification convention in South Carolina in 1832 (see COMPROMISE OF 1833), and the secession conventions of 1860 and 1861. See CONVENTIONS, CONSTITUTIONAL; UNITED STATES—STATE CONSTITUTIONS; VIRGINIA CONVENTIONS OF THE REVOLUTION.

CONVERGENCE. Cases often occur where two animals of different groups, with a different ancestry and affinities, but similar habits, so closely resemble each other that not only the ordinary observer, but the experienced naturalist, is deceived by their close resemblance. A familiar example is the whale, which so resembles a fish that by many it is even supposed to be one. Now, the whale is a mam-
mal, bringing forth its young alive, and suckling it. The cetaceans form an order by themselves. There are strong reasons for believing that they are the descendants of some group of land vertebrates which walked on all fours, but which, perhaps driven by competition, were forced to adopt marine life, and became wonderfully adapted to an aquatic life, during this process losing by disuse their hind limbs, while the front legs were converted into fins. From adaptation to the same medium, a fish and a whale have a similar shape and a strong superficial resemblance. The same is the case with certain extinct whale-like lizards, such as the ichthyosaurs. These, with the pleosaurus, are now supposed to have descended from some earlier four-footed terrestrial reptiles, which, becoming adapted to oceanic life, assumed a fish-like form.

Cases of convergence resulting from similar burrowing habits are seen in the Amphibia and reptiles. Certain amphibians (Caecilia) and several extinct Carboniferous forms, have lost their limbs by disuse; they are worm-like, from adopting the habits of earthworms. Among the lizards the glass-snake (Ophiopsamys) and a few other forms also have lost their legs in consequence of burrowing in the sand. There is a species (Bipes) in which a pair of legs are retained. Snakes have evidently descended from four-legged forms, the boa still retaining vestiges of the hind legs. It is not an easy matter to separate some of the legless lizards from small boa, owing to the convergence in their mode of life.

The thousands and tens of thousands of the boring larvae of insects, belonging to quite different groups, have strikingly similar forms owing to their similar habits; thus the headless and apodous maggots of flies resemble those of ants, wasps and bees. Among jumping mammals, the kangaroo, the jerboa and jumping mice have similar large muscular hind legs, with a reduced number of toes, although they belong to different sub-classes or orders. The kangaroo is a marsupial and we have marsupial or kangaroo rats and mice which can be separated only by an expert from ordinary rodents. The bear, the skunk and the beaver, the pouched wrens look like genuine weasels, and so on.

A multitude of other examples can be cited to illustrate the effects of convergent habits, or the influence of similar conditions of life, or adaptation to such and such surroundings. It is most probable that many, if not the large majority, of the cases of mimicry among butterflies and other insects generally attributed to the action of natural selection, are examples of convergence, resulting from exposure to similar physical conditions of light, temperature, etc., which have produced similar styles of coloration, outlines in their wings, etc.

While convergence is not in itself a primary factor of organic evolution, use and disuse are such factors, and convergence in habits or modes of life, resulting in use or disuse of parts, have had much to do with the evolution of such extremely specialized groups as the whales, the snakes, the pleosaurus and ichthyosaurs, as well as other minor groups of animals.

Convergence is of relatively rare occurrence in plants. However, the phenomenon of hetero-

spory in Pteridophytes is usually supposed to have originated separately in the several groups.

CONVERGENT SERIES. See SERIES.

CONVERSANO, kön-uer-sä'nô, Italy, a town in the province of Bari, on a hill, 20 miles southeast of the town of Bari and five miles from the Adriatic coast. It is in the diocese of Bari, and has a cathedral, a handsome cathedral of the 13th century, several convents, among them San Benedetto, a diocesan seminary, a hospital and a castle which belonged to the family of Accaviva. The district produces wine, oil, almonds, flax and cotton; and a good trade is carried on in these articles. The foundation of the town is attributed to the Etruscans. Pop. 15,112. Consult Simeon, S., "Il duomo di Conversano" (Trent 1896).

CONVERSATION, the oral interchange of ideas among two or more persons. It may be formal or informal, in the latter sense differing little in meaning from "speech or talk." In its formal sense it is sometimes spoken of as "polite conversation," and it may cover a wide range of topics. An art, the art of "polite conversation," may be said to have flourished in the courts and palaces of Italy from the Middle Ages onward, and in the salons of France during the 16th, 17th and 18th centuries. In England, in the 17th and 18th centuries, conversation was perhaps at its best. Some of the "polite conversa-
tions" of this period has been preserved in the form of "table talk," but some of these literature might be better described as "monologue."

CONVERSE, Florence, American writer: b. New Orleans, 30 April 1871. She was graduated at Wellesley College in 1893, and was a member of the editorial staff of The Churchman (New York), 1900-08, when she joined the editorial staff of the Atlantic Monthly. Author of "Diana Victrix," a novel (1897); "The Burden of Christopher" (1900); "Long Will, a romance" (1903); "The House of Prayer" (1908); "A Masque of Sibyls" (1910); "The Children of Light," a novel (1912); "The Story of Wellesley," a history of Wellesley College (1915). She is also editor of the "Lit-
tle Schoolmate Series," and has written short stories and poems which have appeared in the Atlantic Monthly, The Century and other mag-
azines.

CONVERSE, Frederick Shepherd, American composer: b. Newton, Mass., 5 Jan. 1844. He was educated at Harvard University and at the Royal Academy of Music, Munich. From 1899 to 1901 he was instructor in harmony in the New England Conservatory of Music. At Harvard he was instructor in music in 1901-04, and assistant professor 1904-07. His compositions include 'Sonata in A'; Suite for Piano'; 'Festival of Pan' (1904); 'Night and Day'; 'La belle dame sans merci'; 'Three Love Songs'; 'Two Songs for a Soprano Voice'; 'Quartet in A Minor'; 'Two Songs for Low Voice'; 'Silent Noon'; 'Laudate Dominum'; 'The Pipe of Desire'; 'The Sacrifice'; 'Job,' an oratorio; and 'Ormaid,' a symphonic poem.

CONVERSE, James Booth, American clergyman and author: b. Philadelphia, Pa., 8 April 1844; d. Morristown, Tenn., 31 Oct. 1914. He was graduated at Princeton, 1865, and at Union Theological Seminary, Va., 1870. He was ordained in the Presbyterian ministry in
CONVERSION — CONVEYANCING

1871. He edited the Christian Observer 1872-79, and the Christian Patriot 1890-95. He published 'A Summer Vacation Abroad' (1879); 'The Bible and Land,' an argument in favor of single tax (1889); 'Uncle Sam's Bible, or Bible Teaching Assay, Postorder 1891,' and 'Shall We Be No Poor?' (1906), and also hundreds of articles in newspapers and magazines.

CONVERSION, (1) In theology, is originally the acceptance of Christianity by heathens. It is also used generally for a change from one religion to another, or in a narrower sense for a complete change of attitude toward God, involving a deeper conviction of the ultimate religious and moral truths. Considerable difference of opinion exists within the Christian Church as to the true nature and causes of conversion, especially in the sense last described. The difficulties hinge mainly on the extent of man's cooperation with Divine Grace, and the precise connection between conversion and repentance. In all cases of conversion the criterion of its validity is generally taken to be the resultant change of a man's character as manifested in his mode of life and thought, in the abstention from sin and in devotion to good works.

(2) In logic.—In the syllogistic method it is often necessary in order to reduce the modes of the other figures to those of the first, to change the subject into attribute and the attribute into subject. This operation is called the conversion of propositions. In mathematical propositions the conversion is easily effected and the simplicity of the relations expressed renders evident the methods to be followed. The terms of an equation can be transposed without change, and the terms of an inequality by changing the sign; e. g., \( A > B \) becomes \( B < A \) and \( A > B \) becomes \( B > A \). In the qualitative propositions of logic the relations of the terms are more complex and the rules more precise. Here we have four kinds of propositions—the universal affirmative \( A \), the universal negative \( E \), the particular affirmative \( I \) and the particular negative \( O \). How are these propositions converted? A may present two cases, it may express a definition in which the attribute has exactly the same extension as the subject, and in the case the attribute can take the place of the subject without changing in any way the quantity of the proposition, e. g., All men are rational animals becomes all rational animals are men. This is an example of simple conversion. The universal affirmative \( A \) may also express the union of an attribute with a whole class of subjects without limiting this attribute to this class. In the conversion of such a proposition this indetermination of the attribute must be maintained, e. g., All men are rational animals are men. A is here converted by limitation or per accidens. The universal negative \( E \) always expresses the exclusion of an attribute without limit from an entire class of subjects; after conversion the proposition may consequently remain universal, thus, No man is a quadruped becomes by conversion No quadruped is man. Again we have here a case of simple conversion.

The particular affirmative \( I \) expresses that an attribute belongs only to a class of subjects named in the subject and in conversion this restriction must be maintained; thus, Some mammals live in water becomes some animals that live in water are mammals. The particular negative \( O \) cannot be converted by this simple transposition, for the sense would be altered altogether;—thus Some man is not just cannot be converted into Some one just is not man and a fortiori we may not convert a particular negative into a universal negative and say No one just is man. To convert a particular negative proposition therefore we must resort to a third mode of conversion and say, for example, Some one not just is not some one just and this mode of conversion is known as contraposition. We have, therefore, three kinds of conversion, simple, in which the quantity of the proposition converted remains the same as that of the proposition to be converted, limited or per accidens, in which the universal proposition to be converted is changed into a particular proposition, and lastly conversion by contraposition. In all cases the quality of the proposition must remain the same. The Scholastics expressed the laws of conversion in the following mnemonic verses:

PQuo Simpliciter convertitur, eva per accid. Allo per contr. Sic fit conversione tota.

Conv. (3) In common law, the wrongful assumption of dominion over the goods of another or others. The term conversion does not apply to the wrongful assumption of ownership of money or chattels real. Unauthorized destruction, sale or the use of the personal property of another constitutes conversion. There may be conversion when there is no wrong motive, as where an agent of A sells property believing it to belong to B when it really belonged to C. The wrongful taking may amount to larceny, to trespass or to a crime. Formerly the action for conversion was trover, but this has been abolished by statute both in Great Britain and the United States. The action is now called conversion. Usually the amount of damages recoverable is the value of the goods or the plaintiff's interest where he owns only a part. The plaintiff may either sue to recover the goods or he may claim damages. In the latter case titles to the goods vest in the defendant if the judgment is satisfied. The courts are divided as to whether the defendant may mitigate his damages by a tender of the goods to the plaintiff. (4) In equity, an assumption that personal property has been converted into real property or vice-versa when the owner has shown in a proper manner that such was his intention. This is in accord with the well-known maxim that equity regards as done what ought to have been done. Likewise land may be converted into purchase money by a contract to sell made by the owner. Such intention, however, must be clearly expressed by the owner. The subject is of great importance on account of the radically different disposition of realty and personally under inheritance and succession laws.

CONVERTER. See STEEL, BESSEMER PROCESS.

CONVERTIBLE GOVERNMENT NOTES. See CURRENCY.

CONVEYANCING, a term including both the science and the body of cases relating to the real estate from one person to another. In Hebrew times the modern form of transferring land was well known. In Rome property was
exchanged by ceremonial only until the reign of Justinian when a simple legal process was instituted. Sometimes the term is applied in a restricted sense to the cumbersome forms which the feudal system has rendered necessary to the transference and tenure of landed property. When left to shape itself by individual practice, without legislative intervention, there were several causes rendering such conveyancing cumbersome and complex. The theory of the feudal tenures and hierarchy remaining unchanged throughout the social revolution which had substantially abolished superiority and vassalage, and brought land out of feudality into commerce, the feudal ceremonies of the Middle Ages were necessarily retained, and they were adapted to fictions and explanations to modern exigencies. It seems strange that not many years have passed since in Scotland, when a parcel of land was bought and sold, a party of men certified, and went to the old form of feudal investiture by the delivery of so much earth and stone from the superior bailiff to the vassal's attorney, who took instruments and had the whole recorded at length by a notary of the empire. In England, from the royal patent of general system of registration known in Scotland, the complexities of conveyancing had become so inextricable, that one of the most approved forms of transferance was a fictitious suit and judgment of possession called a fine and recovery. To these various sources of complexity must be added the timidity of conveyancers, who, afraid to commit themselves by attempting to abbreviate or reconstruct the forms which they find in existence, repeat them with additions from time to time as new circumstances must be provided for. Consequently to keep conveyancing within rational bounds the legislature, both in England and the United States, has interfered from time to time, by sweeping away excesses, and providing brief and simple forms. All instruments under seal are spoken of as deeds, but the term deed is usually understood as applying to conveyances of land. Every person capable of holding lands (excepting idiots, persons of unsound mind, infants), who has personal estate or interest in lands, may alien such estate or interest at pleasure, subject to the restrictions and regulations prescribed by law. For a description of the method and procedure of modern conveyancing see Deed; Title-Deed; Title Registration; Title Insurance; Consult Brewster, 'Conveyance of Estates in Fee by Deed' (Indianapolis 1804); Greenwood, 'Manual of the Practices of Conveyancing' (London 1891); Hunter, 'The Dominion Conveyancer' (Toronto 1893).

CONVEYER, a mechanism for conveying something, as loose material, from one place and depositing it at another place distinguished in mechanics from a carier or elevator. Conveyers may be divided into four general classes: those that travel with endless chains or belts; those that travel along cableways or on a trussed support; those that operate by gravity; those that use a reciprocating surface to throw material forward. These mechanisms have come into very extended use during the past 30 years, being employed in large excavating operations and in handling coal, grain, cement, ore and similar material. Their manufacture is carried on by a score or more concerns in the United States. One of the simplest and earliest forms of conveyer consists of a pair of endless chains, connected at intervals with cross-pieces or scrapers. These are used for storage. At the centre of what is to be the pile of coal a pole is erected, and to the top of this one end is located a little above the ground level, near a steam engine or other motive power. As coal is dumped within the space the scrapers convey it upward toward the pole, and as the lower end of the conveyer may be moved to any point in the circle about the pole, coal dumped anywhere in the circle may be smoothed up and pushed toward the centre, until all lines in a symmetrical pile.

A common form of conveyer consists of a sheet iron trough through which travels a linked belt or chain device having cross strips or scoops. Any loose material dropped in the trough is carried forward, by the scoops, to the point where the linked belt bends for its return. The Hunt conveyer consists of a series of sheet iron buckets or small cars, hung between parallel lines of flat links, that constitute chains. The buckets swing and travel on the links placed about the centre of gravity, so that they always remain upright, no matter what is the inclination or route of the chains, until they reach a dumping or upsetting mechanism. The links have wheels that run on little tracks, so that the whole constitutes a miniature railway train. The cars or buckets will carry either liquid or dry material. This is called a noiseless conveyer, because the provisions for lubrication do away with all objectionable noise, the latter being a special nuisance with conveyers of the scraper type. The driving wheel of the Hunt conveyer has a series of large paddles, that engage with pins on the links, and provide a slow, but steady and powerful motion. Capacity is obtained by the size of the buckets and not by speed.

Bucket conveyers, more or less similar to those just described, are commonly employed to supply large boiler plants with coal, and to carry away the ashes. In plants located by a watercourse, or enabled to obtain water at the refinery, the coal is hoisted in grub-buckets direct from the hold of a vessel, and dumped into the buckets of a conveyer, which transports it to a large pocket or storage room located above the boilers. Thence the coal is fed through automatic stokers to the boilers. Running along below the boilers is another line of conveyer buckets that receive the ashes from the hoppers below the boilers and carry them out to a dumping place, which is often a large elevated hopper, from which large wagons can load by driving directly under it and opening a discharge gate. All large railway terminal stations have a coaling-house arranged somewhat on the plan described. The coal is conveyed to overhead storage by the conveyers and is dropped direct into the tenders as they come below. At the plant of the Philadelphia and Reading railroad in Philadelphia monobar conveyers are employed, having a conveying capacity of 120 tons of coal an hour, while the set used to carry away the ashes dumped by the locomotive has a capacity of 20 tons an hour. Nearly all this capacity is needed at times, as the plant is sometimes called upon to load as many as 12 locomotives at once. The monobar
CONVEYER

chains or belts normally deposit the material at the point where the chains or belts are curved over rollers or sprockets for return. For depositing the material at points along the route, various forms of tripers are manufactured, according to the nature of the conveyor and of the material handled. For handling a conveyor on route there are also in use numerous styles of fillers, many of them being simply spouts leading from hoppers, and others specially designed for the work they are to do.

The type of conveyor used on a cableway is radically different from the foregoing. A wheeled carrier is slung on a supporting rope, usually a steel wire rope, and from this cartier is hung the material to be conveyed. To the carrier is attached a rope, and a conveyor-engine at one end of the cableway pulls the load along to its destination. This is the system followed in coaling vessels at sea. The United States battleships are coaled in this manner during rough weather, the coal being readily carried aboard under these conditions at a rate of 20 tons an hour.

In excavating work, as the New York subway and the Chicago drainage canal, this type of conveyor is in constant use, owing to its economical construction and portability. The system is employed for handling sand, at glass works, etc.; for discharging cargo from a vessel to a shore where there is no wharf; for carrying material over rivers or rough land, as in new sections of country, where there are no good roads; for transporting the material used in building breakwaters and piers; in the building of dams and locks, and for a variety of purposes in connection with mines. A few conveyors have been built for permanent use, in which an overhead truss or bridge with a rail takes the place of the cableway.

The transporter-crane is an enormous structure resembling a gantry crane, having a large trussed framework or steel tower, which supports a long trussed arm that serves as a way for a car or carrier that does the conveying. This is useful in loading and unloading vessels at docks, and can be used to pass the merchandise completely over low buildings or other obstructions.

A spiral chute is often used to deliver sacks of material to a lower level by gravity. The inclination of the spiral invites friction which prevents the sacks from descending too rapidly. A perpendicular tube is sometimes used for a similar purpose by placing alternate inclines on the sides so that the sack or other object is thrown by gravity alternately to either side, and so descends at a sufficiently delayed speed to prevent its being damaged by the fall.

About 1910 a new type of conveyor appeared on the market, which permitted the transportation of loose material, as ashes, broken stone, etc., around a right angle. Nearly all other conveyors are restricted to a straight line of operations, subject only to slight variation in grade, or sometimes to swinging in the arc of a circle. The Zimmer conveyor, and others of its type, is a rectangular trough of wood or iron, with an oscillating mechanism for moving the bottom boards or sections of the trough. Power is applied to these bottom boards so as to reciprocate them slowly in a forward direction with a quick return. The slow forward motion not only advances the material in the
CONVICT LABOR

through, but raises it slightly, and before the material can fall the bottom is pulled down by a quick-acting spring to first position. The material is thus thrown forward by a series of slight jumps, so that it appears to move slowly or in a mass, and may be made to turn a right-angled corner or any other shorter sharp angle. The Norton and Marcus conveyors employ the same principle. See Excavator; TEL-PHRAEAGE. Consult Zimmer, 'Mechanical Handling and Storing of Goods' (1906).

CHARLES H. COCHRANE,
Author of 'Modern Industrial Progress.'

CONVICT LABOR. The introduction of industry into prison life, apart from its use to keep penitentiaries in good order and good repair, is a product of 19th century reforms. Isolated cases it is true occurred before. Mabillon, a Benedictine monk of the 17th century, urged a cellular system of imprisonment, labor in the cells and gardens where prisoners might rest after the day's work. In 1704 Pope Clement XI opened a prison at Rome, where the industrial feature proved successful in the case of boys. A famous prison built in Ghent in 1775 by Viscount Vilain XIV had a well-organized labor system, intended to benefit the prisoner and make him useful to the state. Two years afterward John Howard published his work on 'Prison Reform.' But in practice before the beginning of the 19th century, and well into it, labor was considered in a pell-mell fashion in making the possibility of severe punishment, an idea excellently typified by the Roman system of punishing the city slave by sending him to the country tred-mill, or by the terrible toil of the galley slave in Italy and France. This penal point of view was followed by the fiscal interest of the state and to a certain degree intermixed with it; the state will save, and if possible, make money by means of its use of the time and strength of the convict. Then the disciplinary interest became predominant; the convict will furnish us less trouble if we keep him at work. A further step is taken when the object of convict labor becomes moral and the prisoner is put to work to keep him from idleness, spring of so much vice, and to promote his ability to earn an honest livelihood upon his release. In the latest among these stages a distinct effort is made to furnish the convict with decent and pleasant work, and the old scheme of choosing the most revolting and dangerous, the most degrading and monotonous task has been done away with.

Unfortunately the evolution hinted at has not been completed, and traces of each of the ideals mentioned may still be found in the various systems of Europe and the United States. 'At hard labor,' for example, is still felt to be a degrading and aggravating addition to the sentence of detention. As far as actual business management is concerned there are two methods of convict labor. In the first, where the product or profits of labor is shared by the state with private individuals or firms, we may notice that this system is most closely characterized by their common names: the contract system, the piece-price system and the lease system. The second general class, 'systems under which convicts are worked wholly for the benefit of the state,' or its parts, again falls into three divisions, the public-account system, the state-use system and the ways and works system. Theoretically the price-piece system is best in the former case, as it keeps discipline in the hand of prison authorities and leaves business to the entrepreneurs; and it lacks the faults of the contract system, which to a degree interferes with regenerating influences by the very monotonous of highly specialized and largely divided industries. In the second class, the public accounts, in which goods were made in prison, under the control of regular prison officers, and were sold in a rather haphazard way, has bulked so largely in the public eye, by reason of the attacks made on it by the representatives of free labor (who overlook the fact that cheaper production is offset by slower production), that the other sub-classes have been overlooked. Of these systems the most popular is that which provides that all results of convict labor should be used by the state, and yet this as a system could equally well be attacked by labor unions, which naturally desire to supply state institutions as well as other sources of demand. Although it has but a limited field, the state-use system is growing; it is used in most of the northern States and is authorized by the Federal government for the Fort Leavenworth penitentiary. Another system is the State farm system, under which, as in several southern and some northern States, large plantations are purchased to be operated by the State with convict labor, part of the products being used to maintain the prisoners and the unused portions being sold in the public markets. In the North many of these farms are adjacent to the prisons so that they may be worked by the inmates. The State farm system has been in vogue in Massachusetts many years, and in some of the southern States they are highly profitable to the State. In favor of the system it may be said that the prisoners can be kept in permanent places; they are not exposed to public view; they may be instructed in the ways of becoming self-supporting; they have healthful outdoor life; and the system does not arouse a great amount of public ridicule.

The lease system calls for special notice. Its particular habitat is the South, where after the war a remodeling of the penitentiary system was demanded because of the addition of the negro factor to the problem, more than 90 per cent of convicts in most States being negroes. Both expense and the need of outdoor work on the part of the negro made impracticable the continued use of walled penitentiaries, which moreover would have been quite inadequate under new conditions. The lease system came into general use in the late forties, and felons were worked in coal and iron-mills, saw-mills and farms. A chief inspector had general charge, but the reparation, such as it was, than nominal, was upon the lessee and his inspectors and physicians. In many States this system gave rise to horrible abuses. In Georgia it was abolished in 1897 and the State camp system put in its place. The death rate dropped from over 7.4 per cent in four years, Pay was allowed the prisoner who volunteered to do extra work, and the more brutal forms of corporal punishment abolished. But even in Georgia the county chain gang, made up of minor offenders, under supervision of county
road commissioners, is still cruel and vicious. Worse than the county chain gang of Georgia, where only 45 per cent are hired to private individuals, is the system in which Alabama has followed its contract law of 1901, which was declared unconstitutional in 1903 by a United States Circuit Court judge, made possible the following scheme of pauperage: A minor offender and often a perfectly innocent person is taken on the convict lease system, from which the contractor offers to pay for a certain number of months' work. At the expiration of this period a new charge is trumped up, or the negro induced to escape, he is again tried and sent to the convict camp or fined for the benefit of the constable and his backers. The universal disapproval of this system in the South and the prompt action of the Federal authorities has led to the abolition of its worst features.

CONVOCATION, an assembly of the clergy of the Church of England, belonging either to the province of Canterbury or that of York, to consult on ecclesiastical matters. In both provinces the Convocation consists of two houses, an upper and a lower. In the former sit the bishops and in the latter the deans and archdeacons, along with the proctors, who represent the inferior clergy and the chapters of cathedral churches. In the Convocation of the province of York the usual practice has always been for all the members to sit in one house. Originally convocations were merely ecclesiastical councils that had no special privileges or recognized political status, but gradually they came to take the present form, being endowed with the right of passing canons, of determining their own taxation, etc. When thus formed into an assembly, having certain political as well as ecclesiastical functions, there was an early Convocation for all England, and this lasted down to the beginning of the 14th century, when the clergy of the two provinces began to meet in separate Convocations. The archbishop of each province has the right of summoning, if he cannot do so without the royal consent, nor can Convocation pass any canons without the same authority; and from its judicial proceedings there lies an appeal to the sovereign in council. In 1664 the practice of granting subsidies to the Crown, in which the right of self-taxation enjoyed by the clergy, was discontinued, and since that time their functions have been mostly formal. In the reigns of William III and Queen Anne the Convocation of the province of Canterbury recovered some degree of importance, but in 1717 that temporary influence was again lost, and from that year down to a recent period the practice was to prorogue the Convocation as soon as it had assembled. Since 1852, however, the Canterbury Convocation has met regularly two or three times a year for the transaction of business relating to the Church, and in 1861 it exercised its legislative power, the first time for a long series of years. On the opening of a new Parliament a new Convocation is summoned. If the Crown desires to refer any question to Convocation, letters of business are issued, directing that question to be taken into consideration. Other bodies in touch with the work of Convocation are the House of Laymen and the Representative Church Council, which, however, are without constitutional status in the Church of England.

The term Convocation is also applied to the legislative body of the University of Oxford, composed of all masters and fellows, and has the power of acceptance or rejection of statutes passed by the Hebdomadal Council and the Congregation. Consult Trevor, 'The Convocation of the Two Provinces: Their Origin, Constitution, and Forms of Proceeding' (London 1854); Lansbury, 'History of the Convocation of the Church of England' (London 1842).

CONVOLVULACEAE, kon-vol-vul-ah-se, or BINDWREEDS, an order of herbaceous or shrubby plants, usually twining, with plaited tubular corolla, imbricated calyx, alternate undivided or lobed and pinnatifid leaves; bell-shaped flowers, axillary or terminal; five stamens; and fruit with two or three cells. Many of the order contain a milky and resinous juice possessing purgative properties more or less drastic. Jalap is derived from the Ipomoea purga, and inhabitant of Mexico and the southern parts of the United States; and scammony (C. scammonia) is a resinous substance possessed of nearly the same properties as jalap. Some species of the order have tuberous and fleshy roots containing a farinaeous and saccharine principle which fits them for food for man and beast. Among these is Ipomoea batatas, the sweet potato, originally from India or South America, but now cultivated in all countries where it can stand the climate. C. scoparius and floridus yield by distillation an essential oil having a aromatic odor which has a bitter balsamic flavor. Their wood, when powdered, forms an agreeable snuff, and when burned is very fragrant. There are about 40 genera and 900 species widely distributed. The various species of Cucumis, the dodder (q.v.) or bindweeds, which are parasitic on
other plants and lack leaves and green color entirely are often considered as belonging to the family.

**CONVOLVULIN**, kòn-vɔlˈvɔ-lin, the purgative constituent of jalap (C₇H₄NO₇), obtained from the root by treatment with water and strong alcohol. The alcoholic extract is mixed with water, boiled with animal charcoal, filtered, evaporated and treated with ether as long as anything dissolves. Pure convolvulin is transparent and colorless, brittle at 212°F, fuses at a higher temperature to a clear liquid and is decomposed by strong heating. It is almost insoluble in water and quite so in ether, but soluble in alcohol. It has no taste or smell. In doses of two or three grains it is a powerful purgative, and in larger quantities is fatal to animals. By treatment with alkalis it is converted into convolvolinic acid, and by acida into convolvolinol (C₇H₄O₇) and glucose.

**CONVOLVLUS**, the typical genus of the natural order *Convolulacea* (q.v.), or morning-glory family, formerly known as bindweeds. There are about 150 species widely distributed in temperate and tropical climates, some 15 of which are found throughout the southern and western United States.

**CONVOY** (Fr. **convoyă**, "to accompany"). In nautical language, a fleet of merchantmen bound on a voyage to some particular port or general rendezvous under the protection of a ship or ships of war. The name is also given to the ship or ships appointed to conduct and defend them on their passage thereto. It is used of a wagon train under an escort of troops, and loosely for the escort itself.

**CONVULSIONISTS**, or **CONVULSIONARIES**, a sect of religious fanatics originating among the Jansenists of France about 1730. Three years previously a charitable and ascetic deacon of Paris, one Francis, died, and was buried in the cemetery of Saint Médard, in one of the suburbs of the capital. Reports of miracles wrought at his tomb spread among the people, and soon the cemetery was the scene of extraordinary manifestations. As the devotees approached the tomb many were seized with convulsions, or took to dancing and contortions, accompanied by shouts and other eccentric demonstrations. Some of their utterances were accounted as prophecies miraculously inspired by the venerated dead. Most of them were directed to the support of the Jansenist doctrines; but some of the fanatics, by denouncing the throne, and predicting its downfall as well as that of the Church, drew the attention of the government and the ecclesiastical authorities. The cemetery was ordered to be closed; but the same virtue seemed to be possessed by the tomb also inherent in earth surreptitiously obtained from it, and the manifestations continued. Imprisonment failed to stop them, but the fanaticism gradually declined.

The account of this sect was published by P. F. Mathieu, in Paris in 1864, entitled *Histoire des miracles et des Convulsions-Saint Médard.* Consult also Carré de Montgeron, "La vérité des miracles opérés à la sépulture de M. de Paris et autres apppellans" (3 vols., Paris 1737).

**CONVULSIONS.** A convolution is a violent involuntary contraction or series of contractions of the voluntary muscles. It occurs in many conditions, both functional and organic, namely, tetany, hysteria, epilepsy, tetanus (lock jaw), uremia, eclampsia and chorea (Saint Vitus dance), occurring most frequently in infants. The convolution may be local or general, tonic or clonic in character, and is due to a hypersensitive nervous system or to lowered excitability of the brain and the undeveloped power of inhibitory control. In children it may be reflexly due to teething, phimosis, rachitis, eating of indigestible articles of food, intestinal worms, injuries to the body, constipation, foreign bodies in the ear and nose, and fever from any cause or toxemia of any kind. Convulsions at the time of birth may be due to cerebral hemorrhage following a forceps delivery, or brain tumor, brain abscess and hydrocephalus.

Uremia is the result of kidney disease, as it is also eclampsia which occurs during the pregnant state. The convulsions are tonic and clonic in character, frequently occur without warning and in people apparently in good condition. The attack may come on at any time—the eyes become fixed at first and then roll from side to side, the convulsive movements first appear about the mouth, which begins to twitch and is drawn to one side, the entire face becoming distorted. They extend rapidly to the arms, the body, and then finally to the legs. The breathing is stertorous, the face congested and flushed, the patient foams at the mouth and often bites his tongue. During the convolution, which may last from a few seconds to a half hour, the patient is profoundly unconscious, and after the movements cease passes into a condition of coma which lasts for a longer or shorter period. The convulsions are frequently repeated.

Chorea occurs most frequently in children, and the convulsions or twitchings are of a clonic character and affect groups of muscles. The twitchings may be slight or very severe so as to interfere with speaking, locomotion and coherent voluntary bodily movements. It may affect one side of the body, as one arm and leg, when it is known as hemichorea, or it may affect both sides. The twitching movements are greatly exaggerated when the patient endeavors to perform a voluntary act. Consciousness is always present.

In epilepsy (q.v.) the convulsions resemble those described under uremia. There seems to be a regular order of movements followed out, preceded by aura, the patient becomes unconscious, froths at the mouth, bites his tongue, the pupils dilate and there is an involuntary passage of urine and feces. The convulsions last a few minutes, and when the patient is left in a semi-comatose condition, complains of headache, and then falls off into a restless sleep. The attacks also frequently occur at night while asleep.

Hysteria shows a great variety of manifestations. The convulsions may involve only the lower extremity or the head and neck. There is a condition known as hystero-epilepsy. There is no aura, the attacks are much prolonged and purposeful and tonic in character. The bladder, rectum, or vocal cords may not be disturbed. There is no complete loss of consciousness.
The patients seldom injure themselves, in fact they seem to protect themselves from injury. In children the convulsions usually begin suddenly, although they may be preceded by a rolling of the eyes, and by slight twitching of the muscles of the face. Unconsciousness soon supervenes, the eyes remain fixed and staring, the head is thrown backward, and the entire body stiffens out only to be followed by clonic contractions. There is a series of contractions and relaxations. The face assumes different expressions or grimaces, the teeth become set, there is a frothing at the mouth and the color of the face becomes dusky and cyanotic. The breathing is labored and heavy, urinarv and facial refrigeration may be said to be the most frequent manifestations of the disease. After going through several convulsions the child soon passes into a deep sleep and then awakens with an apparent interest in his surroundings. These convulsions usually indicate the approach of some serious disease, if not from convulsions. It is wise to consider them as a serious condition until the cause is discovered. The convulsion in the child is analogous to the child in the adult, it precedes such diseases as pneumonia, cerebrospinal meningitis, typhoid fever, and other fevers. The convulsion is a symptom and not a disease, and therefore it is never directly the cause of death.

As to treatment, it is of great importance to control the convulsion before trying to find out its cause. In children this is done by placing the child in a bath of hot water with mustard and keeping it there until the skin is reddened. If the convulsions persist, the child should be kept under the influence of chloroform until the convulsive tendency has disappeared. When the convulsion is controlled, search is then made for the cause. If the digestive tract is found to be at fault, the child is given a dose of castor oil, and a high rectal enema of soapuds is given as a matter of routine to empty the lower bowel. After the bowel is cleared and the child still shows a tendency toward convulsions, a rectal injection of 10 grains of sodium bromide and 3 grains of chlorate may be given for a child five years old. In very severe cases it is justifiable to give a hypodermic of morphia in proper dose. The room should be kept noiseless and an icebag placed to the head. It is always a good plan to examine the enema stool in search for intestinal parasites, foreign bodies or undigested particles or lumps of food. A child who is very nervous and is easily excited by physical impressions should be kept very quiet. Genital abnormalities should be properly treated, a child with a tight or adherent prepuce when circumcised becomes free from convulsions. Foreign bodies should be removed from the ears and nose. A child with rachitis should be built up, kept out of doors in the sun, and given the proper kind of food and tonics. Hydropoecphalus may be treated by tapping the ventricles of the brain through the anterior fontanella and so drain off some of the fluid or tap the spinal cord to drain it off that way and so relieve the incranial pressure. Anemia and malnutrition should be treated if found.

Convulsions due to tumors of the brain or brain abscess cannot be treated unless they be in a position accessible to the surgeon. Convolusions due to uraemia are very serious and need very urgent treatment; a mouth gag should be inserted into the mouth to prevent the patient from biting his tongue, blood letting is done from one of the veins at the bend of the elbow to lower the blood pressure and rid the system of a certain amount of toxins; usually 500 c.c. is withdrawn at one time, hot packs are given or the electric baker is placed over the patient to induce profuse perspiration, pilocarpine one-tenth grain by hypo is sometimes used but is not safe. In cases when the uterus is emptied as soon as and as rapidly as possible, using ether and oxygen as anesthetic; chloroform should never be used. Ether and oxygen are used to control the convulsions until the time for operation. A mouth gag is the first thing to be placed in the mouth. Veratrum viride, 5 minims by hypo every onehalf hour, is given to lower the blood pressure. Magnesium sulphate, a dram to the pint, is administered usually post-partum intra-venously and frequently repeated. In epilepsy the convulsions usually do not last long. Prevent the patient from injuring and biting his tongue. Loosen all his clothing and see that he lies in a well-padded place and away from solid objects. Chloroform is used if the convulsion is very severe. Epilepsy found to be due to depressed fracture of the skull is often cured of any future attacks when operated upon and a button of bone removed, the incranial pressure being thus relieved. In chorea, the child should be kept as quiet as possible, free from all mental and physical strain. Its food should be easily digested and nourishing; arsenic in the form of Fowler's solution is the best remedy. If traces of rheumatism are present it is combined with the salicylates. Bromides and chloral are given to quiet and control the spasmodic movements. Iron is also given as a tonic. In hysteria the best way to check the convulsion is by dashing a glass of cold water into the patient's face. A hypo of apomorphine, one-tenth grain, causes sickness of the stomach and immediately arrests the attack. A teaspoonful of aromatic spirits of ammonia may be given. Convulsions due to meningitis, tetanus, brain abscess and tumors of the brain are treated along general lines.

HENRY H. BEINFIELD, M.D.

CONWAY, Hugh. See FARGUS, FREDERICK JOHN.

CONWAY, Moncur Daniel, American clergyman and author: b. Stafford County, Va., 17 March 1832; d. New York 1907. He was graduated at Dickinson College in 1849, entered the Methodist ministry in 1850, and later studied at the Harvard Divinity School. He had become imbued with rationalistic ideas and attempted to preach them on his return to Virginia, but was obliged to leave the State. He became pastor of a Unitarian church in Washington, D. C., but was obliged to leave this charge, owing to his opposition to slavery. He secured another pastorate in Cincinnati, and while there wrote several volumes and edited the Dial. In this periodical and later in The Commonwealth of Boston he earnestly advocated emancipation, and in 1863 went to England to explain the cause of the Civil War. From 1863 to 1884 he was minister at South Place Chapel in London, England, and again, 1892-97. He returned to America near the
close of the century and made his home in New York. His published books include 'Tracts for To-day' (1857); 'The Rejected Stone' (1861); 'The Golden Hour' (1862); 'Testimonies Concerning Slavery' (1864); 'The Earthward Pilgrimage' (1870); 'Sacred Army' (1871); 'Idols and Ideas' (1874); 'Travels in South Kensington' (1875); 'Demonology and Devil Lore' (1879); 'The Wandering Jew' (1880); 'Thomas Carlyle' (1881); 'Emerson at Home and Abroad' (1882); 'George Washington and Mount Vernon'; 'Ommitted Chapters in History Different in the Life of Edmund Randolph' (1887); 'Pine and Palm;' a novel (1887); 'Life of Nathaniel Hawthorne' (1890); 'Prisons of Air,' a novel (1891); 'Life of Thomas Paine' (1892); 'Barons of the Potomac and the Rappahannock' (1892); 'Centenary History of South Place Chapel' (1893); 'Solomon and Solomon's Language' (1899); 'Autobiography' (1904); 'My Pilgrimage to the Wise Men of the East' (1906); 'Addresses and Reprints, 1850-1907;' (Boston 1909). He edited the 'Works of Thomas Paine' (1893-96).

CONWAY, Robert Seymour, English classical philologist: b. Stoke Newton, 1864. He was educated at Caius College, Cambridge. He was Fellow of Gonville and Caius College in 1889-94, classical lecturer in Newnham College, in 1893, 1894, and 1895, and professor of Latin, University College, Cardiff, Wales, in 1895. When he took the corresponding chair in Victoria University, Manchester. He wrote 'Vernon's Law in Italy' (1887); and 'Virgil, an Accidental Lecturer' (1903), 'collaborated in the translation of Brugmann's Comparative Grammar' (1888-95); 'The Restored Pronunciation of Greek and Latin' (1896); 'The Italian Dialects' (1897); 'Dialectorum Italicarum Exempla' (1898); 'The Pre-Hellenic Inscriptions of Praesos' (1903). He is a frequent contributor to classical periodicals.

CONWAY, Thomas, Irish soldier of fortune: b. Ireland, 27 Feb. 1733; d. about 1800. He was educated in France, and entering the army there became a colonel. He came to America in 1776, and was agent of the Continental Congress was appointed brigadier-general and subsequently inspector-general, with the rank of major-general. He intrigued to have Washington superseded by General Gates, and he and his associates were known as "Conway's Cabal." He resigned in 1778, went to France and was made governor of Pondicherry and the French settlements in Hindustan. In 1792 he was appointed commander of the Royalist forces in the south of France, but on the success of the Revolutionists fled from the country.

CONWAY, Sir William Martin, English art critic, explorer and mountaineer: b. Rochester, England, 1856. He was educated at Trinity College, Cambridge; professor of art at University College, Liverpool, 1885-88, and Slade professor of fine arts at Cambridge 1901-04. In 1892 he traveled extensively in the Himalayas and in the Alps 1894; he explored the interior of Spitzbergen in 1896-97; and the Bolivian Andes in 1896-98, as well as the glaciers of Tierra del Fuego. Among his peaks he has ascended are one in the Himalayas of 23,000 feet, and Aconcagua, Illimani and Sorata in the Andes. He was knighted in 1895, received a gold medal for mountain surveys at the Paris Exhibition in 1900, and the founder's medal of the Royal Geographical Society, 1905. He has published 'Woodcutters of the Netherlands in the 15th Century' (1884); 'The Artistic Development of Architecture in France' (1886); 'Early Flemish Artists' (1887); 'Literary Remains of Albrecht Dürer' (1889); 'Dawn of Art in the Ancient World' (1891); 'Climber's Guides to the Alps' (1890); 'Climbing and Exploration in the Karakoram-Himalayas' (1894); 'The Alps from End to End' (1895); 'The First Crossing of Spitzbergen' (1897); 'With Ski and Sledge over Arctic Glaciers' (1898); 'The Bolivian Andes' (1901); 'Aconcagua and Tierra del Fuego' (1902); 'Great Masters' (1904); 'Early Voyages to Spitzbergen' (1904); 'No Man's Land' (1906); 'The Sport of Collecting' (1904); 'The Crowd in Peace and War' (1915).

CONWAY, Ark., county-seat of Faulkner County, on the Saint Louis, Iron Mountain and Southern Railroad, about seven miles east of the bend of the Arkansas River at Searcy and 25 miles northeast of Little Rock in an air line. The town has an extensive trade in cotton, lumber, flour and cotton-seed oil, cotton compress, broom factory and excelsior works. It is lighted by electricity, and governed by a mayor and council. The educational advantages are among the best of any of the agricultural towns of the state. The Methodist Episcopal Church South maintains Hendrix College, established in 1884, Arkansas State Normal School and Central College. All are located there. The town was founded in 1871 and incorporated three years later. Pop. 2,794.

CONWAY, N. H., town in Carroll County, famous for the beauty of its natural scenery, which makes its villages among the most popular summer resorts in the White Mountain region. The town lies along the Saco River, on the Boston and Maine Railroad, about 75 miles north by west of Portsmouth. There are extensive granite quarries in the town and a few lumber mills,经营ing their services to a sawmill, box factory and canning interests. The waterworks are municipally owned. Pop. 3,413. Consult Eastman, 'East of the White Hills.'

CONWAY, or ABERCONWAY, Wales, town and parliamentary borough in the county of Conway, about 14 miles east-northeast of Bangor. It is picture-quesly situated on the left bank of the Conway River, and is surrounded by an old wall still in good preservation, 12 feet thick, fortified with towers and battlements. The old castle of Conway, erected toward the end of the 13th century by Edward I, is one of the most magnificent structures of the kind in England. It is one mile in circumference and was fenced with 21 round towers. Many parts of it are still entire, including the great hall, which is 130 feet long, 32 broad and 20 high. A suspension bridge was thrown over the river in 1385, and in 1848 another bridge was built by Robert Stephenson for the accommodation of the Chester and Holyhead Railway. It is a wrought-iron tubular bridge on the same principle as the Britannia bridge over the Menai Strait. Con-
way unites with Carnarvon, Bangor, Criccieth, Nevin and Pwllheli in returning one member to Parliament. Curfew is still rung in Conway. Pop. 5,242.

CONWAY, a river of Wales, rising from two head-streams, one in the southeast of the county of Carnarvon and the other in the southwest of the county of Denbigh, which unite about 15 miles south of Conway. At Conway it is half a mile broad at spring tides which rise here 21 to 24 feet. The united stream flows north, separating Carnarvon from Denbighshire, and falls into Beaumaris Bay after a course of from 25 to 30 miles. It is navigable to Llanrwst, or about 10 miles from its mouth. The Conway has been famous for its pearls since Roman times.

CONWAY CABAL, 1777-78, in American history: an intrigue headed by Horatio Gates, Charles Lee, Thomas Mifflin (then quarter-master-general) and James Lovell of Boston (Gates' confidant, and an unspurning confederate of Washington); with Thomas Conway as the chief subject to be displaced by Washington by Gates; and there were plenty of other ambitions which hoped to reap advancement in the overtum. It gained its momentum from that popular clamor for immediate success in the war. The faction, the meagerly-proven and the weak, the crying of ‘Gates or Washington’ by Gates—Washington as commander by contrasting the victories of the former at Saratoga with the almost contemporaneous reverses of the latter at Brandywine and Germantown. In November 1777 the Board of War was reconstituted: Gates was made President, with liberty to serve in the field at will—that is, put over Washington's head with power to supersede him; Mifflin was made a member of the Board of War and shortly afterward Conway was made inspector-general over Washington's emphatic advice to the contrary. A very petty series of letters maligning Washington was circulated, and other minor intrigues resulted. Then Gates undertook to send Lafayette on a senseless expedition to Canada, promising him abundant men and supplies; but he so utterly failed of providing either and the scheme was so disapproved by the public that it pricked the Gates bubble. Conway resigned conditionally: Gates and Mifflin were removed from the Board of War and Gates was assigned to the forts on the Hudson, with emphatic warning to report to Washington. The adherents or helpers of the cabal disclaimed all connection with it, and Conway shortly went to France. Consult Fiske, 'The American Revolution' (Vol. II, Boston 1893).

CONWELL, Russell Herman, American Baptist clergyman, university president and lecturer: b. Worthington, Mass., 15 Feb. 1842. He studied law at the Yale and Albany Law schools, and was an officer in the Federal army in the Civil War. He was immigration officer of Minnesota in Germany in 1867-68; foreign correspondent, the New York Tribune and Boston Traveler, 1868-70; and practised law in Boston 1870-79. He was ordained to the Baptist ministry in 1879; was pastor of Grace Baptist Church, Philadelphia, 1881-91; and has been pastor of the Baptist Temple since 1891. He founded Temple University in 1888 and is still its president. He founded the Samaritan Hospital in 1891. He has given his celebrated lecture, "Acres of Diamonds" over 5,000 times. He is a member of the Union League, Manufacturer's Club, New England Society and Yale Alumni. Among the books he has published are 'Life of Bayard Taylor,' 'Why the Chinese Emigrate' (1874); 'Woman and the Law' (1875); 'Life of C. H. Spurgeon' (1893); 'Acres of Diamonds' (1888); 'Present Successful Opportunities'; 'Lives of the Presidents' (1878); 'Life of James G. Blaine'; 'The New Day' (1902), etc.

CONY, or CONY, an old name for the rabbit; used also in the English version of the Bible as a translation of a Hebrew word probably meaning the Hyrax syriacus, a rabbit-like animal common in Syria and Palestine, inhabiting clefts of rocks.

CONYEARE, Frederick Cornwallis, English Orientalist: b. 1856. He was educated at Tonbridge School and at University College, Oxford, of which he became scholar in 1875 and Fellow and praeblocet in 1881. He was made a Fellow of the British Academy in 1903, an officer of the French Academy in 1906, and honorary doctor of theology at Giessen in 1907. In his special field, Armenian language and literature, he came to be recognized as probably the foremost authority of his time, and he wrote on religion and religious history. His published works include 'Ancient Armenian Texts of Aristotle' (1892); 'The Key of Truth, a Manual of the Paulician Church of Armenia' (1898); 'Roman Catholicism in International Politics' (1901); 'Rituale Armenorum' (1905); 'Old Armenian Texts of Revelation' (1906); 'Myth, Magic and Morals: a Study of Christian Origins' (1909); 'New Testament Criticism' (1910); 'The Historicity of Christ' (1914).

CONYEARE, John, English clergyman: b. Pinhoe, near Exeter, 31 Jan. 1692; d. Bath, 13 July 1755. He studied at Exeter College, Oxford, received orders, and was curate at Fetcham in 1717. He returned to Oxford in 1718, became successively tutor in his own college, preacher to his majesty at Whitehall, rector of Saint Clement's, Oxford, and in 1730 master of Exeter College. In 1732 he published his celebrated 'Defense of Revealed Religion,' in answer to Tindal's 'Christianity as Old as the Creation,' which was then in question. He was appointed dean of Christ Church, and in 1750 succeeded Butler as bishop of Bristol.

CONYEARE, William John, English clergyman: b. England, 1 Aug. 1815; d. Weybridge, Surrey, 1857. He published 'Perversion,' a religious novel (1856); and 'Essays Ecclesiastical and Social.' He was a notable writer for his joint authorship with Dean Howson of the popular 'The Life and Epistles of Saint Paul' (1851).

CONYERS, kön'ýərz, Ga., city and county seat of Rockdale County, 30 miles southeast of Atlanta on the Georgia Railroad. Cotton growing and granite quarrying are important industries. The city also has a cotton factory, an oil mill, bottling works and a flouring mill. The city owns the waterworks. Pop. 1,919.

CONZE, kön'zə, Alexander Christian Leopold, German archaeologist: b. Hanover 1831; d. 1914. He received his education at Göttingen and Berlin. From 1863 to 1869 he was professor of archaeology at Halle, from 1869 to 1877 at
COOCHE BEHAR—COOK

Vienna, and at Berlin from 1877 to 1887. He was made director of the Berlin Museum and in 1887 became general secretary of the German Archaeological Institute. His published works include studies on the Insele der thracischen Insel (1869); 'Archäologische Literatur schriften in Samothrake' (2 vols., Vienna 1875–80); 'Beiträge zur Geschichte der griechischen Plastik' (2d ed., Halle 1869); 'Die Ergebnisse der Ausgrabungen zu Pergamon' (Berlin 1880–83); 'Die Ausgrabungen zu Pergamon 1880–86' (Athens 1899); 'Die Kleinfunde aus Pergamon' (Berlin 1902).

COOCHE BEHAR, kooch bā-hār', or KUCH BEHAR, India, a native state and in political relation with the government of Bengal. It forms a level plain of triangular shape, intersected by numerous rivers which make a great part of it almost hopelessly waterlogged, and is entirely surrounded by British territory. The greater portion of the soil is fertile and well cultivated. Rice, jute and tobacco are the principal crops. The mean annual temperature is 78 degrees, and the rainfall 123 inches. It was at one time a part of the ancient kingdom of Kamarapu. British connection began in 1774. The chief town, Cooch Behar (pop. 11,000), contains some handsome public buildings and a splendid new palace of the Maharajah, and has a population of 9,535. Area of state 1,507 square miles. Pop. 593,000.

COODIES, Thé, in the political history of the United States, a nickname applied to those members of the Federalist party in New York who favored the War of 1812. It was derived from the fictitious name, Abimelech Coody, assumed by the leader of the faction, Gailen C. Verplanck (q.v.) when writing in the public prints. Consult Hammond, 'The History of Political Parties in the State of New York' (4th ed., Cooperstown 1846).

COOK, Albert John, American naturalist: b. Owosso, Mich., 30 Aug. 1842. He was graduated at Michigan Agricultural College 1862, and was professor of zoology and entomology there 1862–93, when he became professor of zoology at Pomona College, Claremont, Cal. In 1911 he was appointed State commissioner of horticulture for California. He was one of the first to make kerosene emulsion (1877), and to advocate and demonstrate the use of the arsenide as a specific against the codling moth (1880). He has published 'Injurious Insects of Michigan' (1873); 'Manual of the Apiary' (1876; 14th ed., 1886); 'Silos and Silage'; 'Maple Sugar and the Sugar Bush'; 'Birds of Michigan'; 'California Citrus Culture' (1913).

COOK, Albert Stanburrough, American scholar: b. Montville, N. J., 6 March 1853. He was graduated at Rutgers College 1872, and studied at Göttingen and Leipzig 1877–78, London and Jena 1881–82. He was professor of English at the University of California 1882–89, when he became professor of the same in Yale University. He organized the department of English at the Johns Hopkins University (1879–81); brought the University of California into close connection with the high schools of the State (1884–89); translated into English the first thoroughly scientific grammar of Old English; established a new standard of editing for Old English texts; laid a firm basis for the study of the Old Northumbrian dialect, the modern Scotch and Northern English; was instrumental in having the study of English texts, as distinct from reading and composition, made a national requirement for admission to college 1884; has specialized on the study of the Bible in English; has edited books on the criticism of poetry; was the first to edit a volume of Ginn's Athenæum and Albion series; and of Heath's Belles Lettres series, Old English division; founded the Concordance Society in 1906, of which he has ever since been president, and edited 'Concordance to Gray' (1908); 'Concordance to Beowulf' (1910); was president of the Modern Language Association of America 1897; has edited a series of 55 volumes, 'Yale Studies in English'; has established an approximate date for the two chief Runic monuments of Great Britain ('The Date of the Ruthwell and Bewcastle Crosses,' 1912); has published a 'Literary Middle English Reader' (1915); a translation of Sievers' 'Old English Grammar' (1885). His publications further include 'The Phonological Investigation of Old English' (1888); 'The Bible and English Prose Style' (1892); 'The Art of Poetry' (1892); 'First Book in Old English' (1893); 'The Artistic Ordering of Life' (1898); 'Biblical Quotations in Old English Prose Writers' (1904, 1913); 'Higher Study of English' (1906); 'Concordance to Beowulf' (1910) and has founded two prizes in poetry, one at Yale University and the other at the University of California.

COOK, Sir Edward Tyas, English journal-ist: b. Brighton, Sussex, 12 May 1857. He was educated at Winchester College and New College, Oxford, and was subsequently editor of the 'Pall Mall Gazette,' 1890–92; 'Westminster Gazette,' 1893–96; and the London Daily News, 1896–1901. He has published 'Popular Handbook to the National Gallery'; 'Studies in Ruskin'; 'Popular Handbook to the Tate Gallery'; 'Life of Ruskin' (1911); 'Homes and Haunts of Ruskin' (1912); 'Life of Florence Nightingale' (1913). He was knighted in 1912.

COOK, Eliza, English writer of verse: b. Southwark 1818; d. Wimbledon, Surrey, 24 Sept. 1889. She began at an early age to contribute articles to various periodicals, and her first volume of verse, which appeared in 1840, was very successful. In 1849 she published 'Eliza Cook's Journal,' which appeared weekly until 1854. She published 'New Echoes, and other Poems' (1864), and in the same year received a pension from the Civil List. By their simplicity of theme and treatment her poems obtained a large measure of popularity in England and America. Her most familiar poem is 'The Old Arm Chair.' A complete edition of her poetical works appeared in London in 1870 and in New York in 1882.

COOK, Francis Augustus, American naval officer: b. Northampton, Mass., 10 May 1843. He was graduated at Annapolis 1863, and served for two years with Farragut in the West Gulf squadron. He became lieutenant-commander 1868; commander 1881 and captain in 1886. During the Civil War he commanded the Brooklyn, the flagship of Commodore Schley's flying squadron, which took so conspicuous a part in the battle of Santiago, 3 July 1898, when Cervera's fleet was destroyed. He was relieved of sea duty after the war and
he was made master of the *Mercury*, which belonged to the squadron sent against Quebec, and performed the hazardous service of taking soundings in the river Saint Lawrence opposite the French encampment. He also made a chart of the river Saint Lawrence below Quebec in a very satisfactory manner. The charts and observations which he made of the coasts of Newfoundland and Labrador, published in 1776-78 and distinguished for their accuracy, induced him to the notice of the Royal Society.

This organization appointed him in 1768 to the command of a vessel destined to convey to the Pacific Ocean persons employed by government to make observations on the transit of Venus. He left Plymouth on 26 Aug. 1768, touched at Madeira and Rio de Janeiro and doubled Cape Horn. The transit of Venus, 3 June 1769, was advantageously observed at Tahiti; the neighboring islands were explored, and Cook then sailed for New Zealand. Six months were employed in examining the shores of the islands; after which he took his departure for Australia, the eastern coast of which he attentively surveyed as well as New South Wales. On his return in 1771 he was promoted to the rank of master and commander in the navy. An account of the voyage, drawn up by Dr. Hawkesworth, was speedily published, and a second expedition was planned to explore the Antarctic regions.

On this occasion two ships were employed the *Resolution*, of which Captain Cook had the command, and the *Adventure*, under Captain Furneaux. After proceeding as far south as the latitude of 71 degrees, where a barrier of ice opposed any further progress, discovering the island of New Georgia in lat. 54° S., and visiting Tahiti and other places, encircling over 20,000 leagues, Captain Cook returned to Great Britain in 1775. The captain had taken such excellent precautions for his crew that only one man had died. He communicated to the Royal Society a paper describing the regulations and remedies which he had adopted and was chosen a fellow of that body, and his experiments were rewarded by the Copley gold medal. Government rewarded him with the rank of post-captain in the navy, and the appointment of captain in Greenwich Hospital. The narrative of this voyage was drawn up by Captain Cook himself, and was published at London in 1777. In July 1776 he sailed on an expedition to ascertain whether any communication existed between the Atlantic and Pacific oceans in the Arctic regions. In this voyage he again commanded the *Resolution*, which was accompanied by the *Discovery*, and explored a considerable extent of the western coast of North America. He also discovered the Sandwich Islands, and to Hawaii, one of this group, he returned from his American survey to pass the winter of 1778. In February Captain Cook sailed for Kamchatka, but was compelled by an accident to put back to Hawaii. A boat having been stolen by one of the islanders, the captain went on shore to seize the king of Hawaii, and keep him as a hostage till the boat was restored. The people, however, were not so much insulted; their resistance brought on hostilities, and in attempting to reach his boat Captain Cook and some of his attendants became victims to the fury of the irritated islanders and were slain, 14 Feb. 1779. A complete ac-
count of this third voyage appeared in 1784.

The first two volumes were by Captain Cook himself, and the third by Capt. James King. A medal in commemoration of him was struck by order of the Royal Society; his eulogy was pronounced in the Florentine Academy and was made a prize subject by one of the French scientific societies. Consult Kippis, 'Life of Captain James Cook' (1806); Brace, 'Captain James Cook' (1800); Wharton, 'Captain Cook's Journal During His First Voyage Round the World' (1897); Syngue, 'Captain Cook's Voyages Round the World' (1897); Kitson, 'Captain James Cook' (1907).

COOK, John, Canadian clergyman and educator: b. Sanquhar, Scotland, 1805; d. Kingston, Ontario 1892. He was educated at Edinburgh University, was ordained to the Presbyterian ministry in 1835, and came to Canada in 1836, settling at Quebec. He aided in founding Queen's University, Kingston, and was its first chancellor. He was also one of the founders of Morrin College, Quebec, in 1862; and became its first principal. He actively supported Presbyterian union in Canada and in 1867 represented the moderator of the first general assembly.

COOK, John Francis, American negro educator: b. about 1785; d. Washington, D. C., 1855. In 1834 he became head of the Columbian Institute, a free school for negro children. Cook stands forth the most conspicuous figure of his race during the first half of the 19th century. His leadership was manifested both in religious matters and in secular affairs. He was one of the organizers of Union Bethel Church in 1838; was organizer and first pastor in 1841 of the Fifteenth Street Presbyterian Church; was one of the charter members of United Friendship Lodge of Odd Fellows. At his death the mantle of education fell to his two sons, who had gained their experience as his assistants at the Columbian Institute.

COOK, John Francis, American negro educator and civil administrator: b. Washington, D. C., 21 Sept. 1850; d. 1910. His early years were spent without special incident. After teaching for some years in the school established by his father, John Francis Cook, Sr. (q.v.), he taught for a brief period in New Orleans and until the outbreak of the Civil War. In 1867 he accepted a clerkship in the office of the collector of taxes in his native city. The next year he became a member of the board of aldermen and in 1868 was elected register of the city. In 1874 he was nominated to the collectorship of taxes by President Grant and confirmed by the Senate, a position held by him through the administrations of Grant, Hayes, Garfield and Arthur, until the accession of the Democratic party caused his resignation. In 1906 he was appointed a member of the local board of education. He also served as trustee of Howard University for 35 years.

COOK, Joseph, American lecturer and author: b. Tirodenora, N. Y., 26 Jan. 1838; d. there, 24 June 1901. He was graduated at Harvard and Andover Theological Seminary, and after three years preaching went to Europe in 1871, where he studied in Germany; and made a tour of the Mediterranean countries. In 1873 he began a series of 'Monday Lectures' in Boston, which, endeavoring to harmonize science and religion, and discussing social and industrial questions, was supported by his friends. In 1880 he began an extended lecturing tour around the world. In 1883 he returned to Boston and resumed his Monday lectures. In 1888 he founded a religious monthly called Our Day. Besides his lectures, he published a number of works on such subjects as 'Biology' (1877); 'Transcendentalism' (1877); 'Marriage' (1878); 'Heredity' (1879); 'Labor' (1880); 'Socialism' (1880); 'Occident' (1884); 'Oriental' (1886); 'The Higher Levels of Arbitration' (1900); 'New Defenses of the Lord's Day' (1900).

COOK, Melville Thurston, American botanist: b. Coffeen, Ill., 20 Sept. 1869. He was educated at De Pauw and Leland Stanford Junior universities, and took post-graduate work at the universities of Chicago and Ohio. In 1894-95 he was principal of the Vandalia (Ill.) high school, in 1895-97 instructor, and in 1897-1904 professor of biology at De Pauw University. He was chief of the department of plant pathology and economic entomology at the Estacion Central Agricola de Las Vegas, Cuba, in 1904-06, and plant pathologist at the Delaware agricultural experiment station, Newark, N. J., 1907-11, and since the latter year has been professor of plant pathology at Rutgers College and State plant pathologist of New Jersey. He has published 'Diseases of Tropical Plants' (1902), and many contributions to botanical journals.

COOK, Orator Fuller, American botanist: b. Clyde, N. Y., 28 May 1867. He was educated at Syracuse University, where he was in charge of the biology department in 1890-91. As agent of the New York Colonization Society he made explorations and investigations in Liberia in 1891-97, and he also served as professor of natural sciences in Liberia College during this same period and as president of the institution in 1896-97. In 1898 he became custodian and assistant curator of the United States National Museum. He had charge of plant importation by the United States Department of Agriculture from 1898 to 1900, when he took up the investigation of tropical agriculture. In 1904 he became professor of botany at Yale University. In 1915 he accompanied the Bingham expedition to Peru and investigated the plants used by the Incas. He is author of various articles and reports on Liberia and African colonization, Porto Rico, tropical agriculture, botany, zoology and evolution.

COOK, Stanley Arthur, English Orientalist: b. King's Lynn, 12 April 1873. He was educated at Gonville and Caius College, Cambridge, of which he became fellow and lecturer in Hebrew and Syriac. In 1896-1903 he was on the editorial staff of the 'Encyclopaedia Biblica'; in 1902 he became editor for the Palestine Exploration Fund; and he was the editorial adviser and a contributor on Old Testament and Semitic subjects to the 'Encyclopaedia Britannica.' He contributed to the 'Jewish Quarterly, the Expositor, etc., and published 'Glossary of Aramaic Inscriptions' (1898); 'The Laws of Moses and the Code of Hammurabi' (1903); 'Critical Notes on Old Testa-
ment History (1907); 'Religion of Ancient Palestine' (1908); 'I Esdras' (1912); 'The Study of Religions' (1914).

COOK, Theodore Andrea, English journalist and author: b. Exmouth, Devonshire, 28 May 1867. He was educated at Wadham College, Oxford, and was on the editorial staff of the Saint James's Gazette, 1897-1900, and has been editor-in-chief of The Field since 1910. He has published 'Old Touraine'; 'Rouen' in 'Medieval Towns Series'; 'Topogamnion at Saint Moritz'; 'A History of the English Turf'; 'An Anthology of Humorous Verse'; 'The Spiral in Nature and Art'; 'Turner's Water-Colors in the National Gallery'; 'Old Provence'; 'Twenty-five Great Houses of France'; 'The Germans by Themselves'; 'Kultur and Catastrophe'; etc.

COOK, Thomas, English excursion promoter: b. Melbourne, Derbyshire, 22 Nov. 1866; d. 19 July 1892. In the earlier portion of his career he was prominently identified with the temperance cause. Later he devoted himself to the work for which he became famous. On 5 July 1841 he began an excursion train between London and Overbury on the Midland Railway, England. This was the first publicly advertised excursion train in England. From this small beginning the enormous business of Thomas Cook & Son, Managers of Tours and Excursions (known as 'Cook's Excursions') was subsequently evolved. To John Mason Cook, son of the founder (b. January 1834; d. 4 March 1899), the present scope of the business is mainly due. The existing firm is composed of the three grandsons of the founder. To such an extent has the 'Cook's Excursions' business developed that the company now has agencies all over the globe, the head office for the United States being in New York.

COOK, Walter, American architect: b. New York, 23 July 1846. He was educated at Harvard University and received his professional training at the Royal Polytechnic School, Munich, and the Ecole des Beaux-Arts, Paris. In 1877 he returned to New York, becoming in succession a member of the firm of Babb, Cook and Willard; Babb, Cook and Welch; and Cook and Welch. He was a member of the jury for the 'New York Public Library and for the University of California, became consulting architect for the board of estimate and approbation, New York, and was a member of the New York art commission 1905-07. Among the buildings designed wholly or in part by him are the De Vinne Press building, office buildings for the New York Life Insurance Company, a residence for Andrew Carnegie, the Choir School at the cathedral of Saint John the Divine, the stadium and other buildings at the Pan-American Exposition, and a number of branch buildings for the New York Public Library. He is a member of the National Academy of Design and chevalier of the Legion of Honor.

COOK, William Wilson, American lawyer: b. Hillsdale, Mich., 16 April 1858. He was graduated from the University of Michigan 1881, and from its law department in 1882. He is general counsel for the Postal Telegraph Company, the Commercial Cable Company and the Commercial Pacific Cable Company. He has written 'Treatise on the Law of Stock and Stockholders as Applicable to Railroad, Banking, Insurance, etc., Corporations' (1887); 'Trusts: Their Character, Legality and Mode of Organization' (24 ed., 1888).

COOK, Mount, the highest peak of Australasia; is one of the southern Alps near the centre of the range, on the west side of the South Island of New Zealand. It is 12,349 feet high, is covered with perpetual snow (the snowline being 3,500 feet lower than in Switzerland), is difficult of access, and was scaled for the first time by the Rev. W. S. Green on 2 March 1882.

COOK INLET, Alaska, bay of the north Pacific Ocean, between the Alaskan and Kenai peninsulas, in lat. 59° and 61° 20' N. and long. 149° and 154° W. In shape long, narrow and crooked, its length is about 200 miles and its greatest breadth 60 miles. Sudden storms and tidal rips, due to high tides along the broken coast line, make navigation at the northern extremity somewhat dangerous. From November to May the northern port is locked in ice. It contains several islands, Augustine Island, with its volcano, Mount Saint Augustine, in violent eruption during 1883, being the largest. The coast scenery is grand, comprising active volcanoes, snow-clad mountains, glaciers and green hills. It was explored in 1778 by the navigator whose name it bears, in the hope of finding a passage to the Arctic Sea. It receives the waters of a number of rivers, chief of which is the Susitna River, coming from the north. Coal is found on its shores, along which are a number of small towns. Seldovia is the port of call for steamships.

COOK ISLANDS, New Zealand, archipelago of small islands in Polynesia, consisting of the islands of Raratonga, Mangaia, Atiu, Aitutaki, Mauke, Mitiaro and the Hervey group. They lie between 8° and 23° S. lat., 157° and 179° W. long. The total area is 138 square miles. The soil is generally fertile but water is scarce. The chief products are copra, coffee, pearl-shell, fruit, hats and caps and lime-juice. The trade for 1914 was imports $511,160, including $336,095 from New Zealand; exports $435,075, including $350,380 to New Zealand. The inhabitants are Polynesians of the Tonga-fiti migration, and are all converts to Christianity. The islands were discovered by James Cook in 1773-77; became a British protectorate in 1888, and in 1901 were annexed to the Dominion of New Zealand, with which there is monthly steam communication. Laws have been made since 1890 by a general legislature, and are administered by an executive council of which the Ariki, or native chiefs, are members. At Raratonga there is a British resident, whose approval is required for all enactments. The annual death-rate is higher than the birth-rate of the islands. Pop. 6,964.

COOK STRAIT, New Zealand, passage which separates North Island and South Island. Its greatest width is 90 miles. It was discovered by Captain Cook on his first voyage in 1769.

COOKE, George Frederick, English actor: b. Westminster, 17 April 1756; d. New York, 26 Feb. 1811. He made his first public appearance at Brentford in 1776; and in the period
between 1784 and 1800 became very popular in the English provinces and in Ireland, attaining a front rank as his profession. From 1801 to 1810 he played at Covent Garden, both in comedy and in tragedy, and rivaled Kemble in the public favor. His best characters were Richard, Shylock, Iago, Sir Giles Overreach and Sir Pertinax MacSycophant. In 1810 he went to the United States, and appeared before enthusiastic audiences in the chief cities. A monument marks his grave in Saint Paul's churchyard in New York city, erected in 1821 by Edmund Kean, who regarded Cooke as the greatest of actors. Consult Dunlap, 'Memoirs of Cooke' (London 1813).

COOKE, George Willis, American Unitarian clergyman and author: b. Comstock, Mich., 23 April 1848. He was educated at Olivet College, Michigan, studied for the Unitarian ministry at Meadville Theological School, and was ordained in 1872. He has since held Unitarian pastorates in Wisconsin, Michigan, Indiana and Massachusetts. After 1889 he devoted his time principally to lecturing and writing. Besides contributing much to the periodical press, including editorials to the Christian Socialist (he became a Socialist in 1902), he has published 'Ralph Wado Emerson, his Life and Writings' (1883); 'Life of George Elton' (1883); 'Poets and Problems'; 'The Clapboard Trees Parish, Dedham: a History' (1887); 'A Guide Book to the Poetic and Dramatic Works of Robert Browning' (1891); 'The Spiritual Life' (1893); 'Biography of John Sullivan Dwight' (1898); 'History of Unitarianism in America' (1903); Notes to the Riverside edition of the Works of Robert Browning (1899); 'An Historical and Biographical Introduction to The Dial' (1902); 'The Poets of Transcendentalism' (1902); 'Bibliographies of Lowell and Emerson' (1907); 'Woman in the Progress of Civilization' (1909); editor three volumes of Theodore Parker's Complete Works (1910).

COOKE, Grace MacGowan, American novelist: b. Grand Rapids, Ohio, 11 Sept. 1863. In 1894 she was married to the journalist of the Woman's Press Club. Her publications include 'Mistress Joy,' with Annie Booth McKinney (1901); 'Return: A Story of the Sea Islands,' with Alice MacGowan (1903); 'Hulda' (1904); 'A Gourd Fiddle' (1904); 'The Grapple' (1905); 'Their First Formal Call' (1905); 'Son Riley Rabbit and Little Girl' (1907); 'The Power and the Glory' (1910); 'The Doings of the Dollivers' (1910); 'The Joy Bringer' (1912); 'William and Bill' (1914); 'Sonny Bunny Rabbit and His Friends' (1915).

COOKE, Jay, American capitalist, known as the "Financier of the Rebellion": b. Sandusky, Ohio, 10 Aug. 1821; d. Ogontz, Pa., 16 Feb. 1905. He was educated in private schools. At the age of 13 he had entered mercantile life as a clerk in a Sandusky store, after displaying unusual ability as a bookkeeper. In 1835 he went to Saint Louis to engage in mercantile business. In 1838 he entered the banking house of E. W. Clark & Company in Philadelphia, and so rapidly mastered the intricacies of finance that before he became of age he was given power of attorney for the firm. Upon his retirement from that firm he was engaged in a general banking business until 1861, when he united with his brother-in-law under the name of Jay Cooke & Company. From 1861-65 his house acted as agent for the government in floating the Civil War bond issues to the extent of $2,500,000,000, including the $5-20 loan of $515,000,000 (February 1862), the 10-40 loan of $200,000,000 (March 1864), the 7-10 loan of $829,992,500 (June 1864 to March 1865), and others. These services he rendered to the nation for so small a commission there was practically no profit. A long period of successful operations followed the war, and then the firm became fiscal agents of the Northern Pacific Railway Company, advancing large sums of money on its bonds, but in the financial panic of 1873, being unable to realize a sufficient amount on the bonds to tide them over the trouble, on 18 September suspended business and eventually went into bankruptcy. The value of the bonds afterward greatly increased. Mr. Cooke not only regained his fortune, but paid his creditors both principal and interest, and the firm continued successfully. Consult Oberholtzer, E. F., 'Jay Cooke, financier of the Civil War' (Philadelphia 1908).

COOKE, Joseph Parsons, American chemist: b. Boston, 1827; d. 1904. He was graduated at Harvard in 1844, and soon afterward was appointed to the chair of chemistry and mineralogy there. In this capacity he conducted, in 1851, the study of chemistry at collegiate institutions, urging laboratory instruction, which before his time had not been introduced into the undergraduate course of American colleges. He introduced his pupil Theodore William Richards to the study of the atomic weights — a subject to which the latter made many signal contributions. The joint communication, by Cooke and Richards, on the relative values of the atomic weights of hydrogen and oxygen, was published in the 'Proceedings of the American Academy of Arts and Sciences' for 1857. Cooke's other publications include 'Chemical Problems and Reactions' (1853); 'Elements of Chemical Physics' (1860; 4th ed., 1886); 'Principles of the Chemistry of Philosophy' (1868; rev. ed., 1882); 'The New Chemistry' (1872, 1884); 'Michigan: a History of Governments' (1885; rev. ed., 1905); 'The Credentials of Science the Warrant of Faith' (1888).

COOKE, Mordecai Cubitt, English botanist: b. Horning, Norfolk, 1825; d. 1912. When a boy he was successively a draper's assistant, clerk in a law office and later a school teacher. He secured a position in the Indian Museum in 1860, and was transferred thence to the Kew Botanical Gardens in 1863. In 1893 he was awarded the Victoria medal of horticulture by the Royal Horticultural Society, and the Linnean gold medal by the Linnean Society. He published over 40 volumes, several of which deal with fungi, including 'Manual of Botanic Terms' (1869); 'Handbook of British Fungi' (1874); 'Mycographia' (6 vols., 1879); 'Illustrations of British Fungi' (8 vols., 1881); 'Introduction to the Study of Fungi' (1895); 'Mushrooms, Edible and Poisonous' (1903); 'Fungoid Fests of the Flower Gardens' (1906); 'Manual of Structural Botany' (1907).
COOKE—COKCERY

COOKE, Philip Saint George, American military officer: b. near Leesburg, Va., 13 June 1809; d. Detroit, Mich., 20 March 1895. He was graduated at West Point in 1827 and rose to the rank of brigadier-general. He was on the frontier for several years, and took part in the Black Hawk War of 1832. In the Mexican War he was in California in command of a battalion of Missouri volunteers and later commanded a regiment in the city of Mexico. After 1849 he was again on the frontier, took part in several expeditions against the Indians, commanded the Utah expedition of 1857-58 and was commander of the Department of Utah in 1860-61. In the Civil War he sided with the Union and greatly distinguished himself in the Peninsula campaign. He was brevetted major-general at the close of the war, commanded the Department of the Platte in 1866-67, the Department of the Cumberland in 1869-70, and the Department of the Lakes, 1870-73, when he retired. He was the author of works on tactics and of "Scenes and Adventures in the Army" (1856); "Conquest of New Mexico and California" (1878); "New Cavalry Tactics" (1894).

COOK, Richard Joseph, American Methodist Episcopal bishop: b. New York, 31 Jan. 1853. He was graduated at East Tennessee Wesleyan University in 1880. He entered the ministry in 1873, became professor of New Testament exegesis and historical theology in Grant University, with which institution he was connected until 1902. From 1891 to 1912 he was editor of the Methodist Advocate Journal, and book editor of the Methodist Episcopal Church. In 1912 he was chosen bishop of the Church. He was a close disciple of Dr. S. B. Farnam, the former bishop of the Methodist Episcopal Church in the British and Irish Wesleyan conference, England and Ireland 1906. He has published "Doctrine of the Resurrection" (1884); "Reasons for Church Creed" (1888); "Christianity and the Necessities of the Times" (1891); "The Historic Episcopate" (1896); "History of Ritual of M. E. Church" (1900); "Christian and the Critic" (1898); "Digest of Judicial Decisions of the General Conference of the M. E. Church"; (1907); "Touched by Thought in Religious Teachings" (1913) and contributions to religious periodicals.

COOKE, Rose (TERRY), American poet and story writer: b. West Hartford, Conn., 17 Feb. 1827; d. Pittsfield, Mass., 18 July 1892. She married Rollin H. Cooke in 1873. Her complete poems were published in 1888, 'The Two Villages' being her best known poem. Her short stories treat of New England rural life, her most acceptable work appearing originally in the Atlantic Monthly and other periodicals. Her published books include: 'Poems' (1860); 'Happy Dodd' (1878); 'Somebody's Neighbors' (1881); 'The Sphinx's Children and Other Peoples' (1886); 'Complete Poems' (1886); 'Steadfast' (1888); 'Huckleberries', a collection of short stories (1891).

COOKE, Sir William Fothergill, English electrician: b. Ealing, Middlesex, 1806; d. 25 June 1879. He served in the Indian army from 1826 to 1832 and, after studying medicine at Paris and Heidelberg, abandoned this for telegraphy, and in 1837 entered into partnership with Professor Wheatstone. After experiments on various railway lines, they patented the single needle apparatus in 1845. A dispute then ensued between the partners as to the part played by each in the achievement, and in 1879 they were finally reconciled. In 1846 Cooke formed a company, which paid $600,000 for the partners' earlier patents. Wheatstone was knighted in 1868 and Cooke in 1869.

COKCERY, the art of preparing food for eating. The savage does little or no cooking; he lives on roots, fruits, insects and raw flesh, and when he cannot procure food, he twists his belt tighter and tighter; the barbarian makes a fire and hunts and fishes, but still eats much of his food raw, or with the slight disintegration of fibre given it by the motion of his body as he carries the food on his steed. Neither cares he for variety, nor has any purpose in eating other than to satisfy hunger. With the development of agriculture came an increase in food supplies, in the use of fire in cooking and an advance in civilization; and with the development in man's social nature, eating ceased to be a mere grabbing game, and food was shared with friends,—and strangers also, for there were no public ins,—as an evidence of good will. Later, feasting was a part of all hospitality, and banquets in honor of the gods, of victory, or some special event, came to be considered the highest form of social physical enjoyment. As the ancients in times of prosperity sought the rarest foods (300 nightingales' tongues were often made into one pie), and served them in the most costly manner (whole cities being ruined, it is said, where Xerxes was entertained for two meals), so history repeats itself, and some modern hosts spare no labor or expense in setting before their guests the most unique concoction their chef can prepare, as the highest expression of good will. But they often have no concern as to the nutritive effect of their offering. The thoughtful person feels that extravagant cooking and riotous feasting are not necessary to true hospitality, nor to the genuine enjoyment of food. He has learned that the true reasons for cooking food are:

First, to have the time and energy needed to digest and assimilate unprepared food, to use in getting a living while developing his mental and moral nature.

Second, to facilitate mastication and digestion, by softening hard and tough substances, changing starch into dextrin, sugar into amel and connective tissue into gelatin, developing improved flavors and odors, and having at least a part of the food warm.

Third, to destroy parasites and disease germs.

Fourth, to keep foods which are perishable that he may enjoy them when out of season.

The cooking of food includes several important processes, not always considered, some of which call for the highest degree of intelligence; but too often cooking is regarded merely as a form of manual labor. Taking these in their natural order we have:

Selection.—This was once a question of mere environment; food nearest at hand being the *Hobson's choice* of the savage, as it now is of the very poor in...
many lands. Climate and non-intercourse with other nations limit choice, as invasion, travel and the internal facilities extend it. From the limited, but not always scanty fare of the Pilgrims, to the cosmopolitan markets of the present day, is a wonderful advance, and the modern American often yields unwisely to their temptations. Appetite guides us safely in this as in most of material things; when it has not been impaired by too great indulgence in improper food. To select from this vast supply, food sound in texture, free from adulteration, seasonable, not exorbitant in price, adopted to individual need, and suitable in quantity, needs no small amount of judgment in the buyer, who often must also be the cook.

Separation.—The removal of the inedible from the edible portions of food is important, for the thoroughness with which it is done has much to do with making food palatable. Perhaps in no other part of the work has there been greater improvement over the primitive methods, as man's idea of what is inedible takes him farther and farther away from the savage, some of whose methods are too repulsive to bear allusion. Our forbeares were entertained before the feast by the slaughtering of animals in their presence, but now the refined taste is offended by the sight of a fowl dressed for the table in his discarded feathers; or a bit of hull in a supposed-to-be coreless apple, or food served in inedible scooped-out skins.

Combination.—The union of various materials often produces a more palatable food than any one would give alone. Association, custom and appetite have much to do with deciding whether certain combinations are harmonious or otherwise. Saffron, tansy, asafetida, decayed fish powder and hosts of other strange flavorings do not appeal to us, although highly prized by other nations. Pies, supposed to be filled with delectable compounds, but out of which dwarfs sprang and danced, and blackbirds sang, pleased our ancestors; and surprise is still a pleasant element in cookery. But it is not pleasant to find the biscuit which was supposed to be sweet with the nutty flavor of the wheat redolent with alkali.

Literature is replete with legends of the accidental discovery of the improved flavor found in a bit of the forbidden flesh on the altar, of fish rescued from burning seaweed, of bread made lighter with a portion of left-over dough, and many others which led to new ways of preparing food. The most fanciful legend seems credible when we remember the many times in one's own experience when accident or necessity has led to new combinations. Scientific proportion, correct measurement, thorough mixing and sufficient judgment to allow for the "total depravity of inanimate things" are needed to ensure uniform results. So to blend materials that they will develop "what ingenious cooks the relish call" is the fundamental principle of cookery, for "all foods are tasteless till that makes them good." It is the undearable combinations of the odors from the different foods in the ovens and kitchens of many hotels and restaurants that makes the unsatisfied boarder long for home cooking.

The Belgians, Swiss and Austrians are said to be hallowed by the art of retaining in foods a high degree in each food its full essence, aroma and properties, so that each dish has no odor or flavor from another. It is said one of the Roman epicures had a separate cook and separate kitchen facilities for it. Too much time and thought are given to the making of new combinations merely to gratify the desire to excel one's neighbors in one's luncheon. This causes great nervous strain and physical fatigue, and imposes upon the guests a deal when it has not been impaired by too great indulgence in improper food.

Manipulation.—For the manual part of cookery, tools and utensils are needed, which if wisely selected will not oblige one to say with Tithocles,

Lend me I pray you, the sauce pan,
in which you boiled your beans.—Tithocles.

That cook is fortunate who has the strength and endurance needed for the back-and-arming parts of the work, and still more fortunate if she possesses the deftness of hand and keen sense perception of the culinary artist; for we cook by the senses of touch, smell and hearing, as truly as by sight and taste. And those for whom she cooks. He or she must be informed if she "knows how to apply heat (see Methods) in the way that food will yield the greatest amount of nutriment in the shape best fitted for the body to assimilate it, as otherwise much food will be wasted in the cooking and wasted in the body.

Decoration.—This is the last step in the manual part of cookery, but an important one, for "the imagination should be fed when we feed the body, they should both sit at the same table." Those who labor with the larger muscles are usually sufficiently hungry to eat whatever is clean and wholesome; but the non-hungry person, or one who works with the small muscles of the hands or eyes, needs the stimulus which the senses of sight, smell and taste send to the stomach, to arouse his sense of hunger. This class of persons increases as civilization advances. There are some foods which if one ate them blindfolded would satisfy the mouth and the stomach would not demur. The nose rebels at Camembert, but the mouth approves. The eye should not be pleased and the tongue offended, but all these "gate tenders of the stomach" should agree in approval, if we would derive the best effect from our food. The tendency of the modern cook to make superfluity of garnishing conceal both merit and defect in material is to be deplored. Simplicity in design, harmonious blending of color and material, enhancing rather than disguising the individuality of each dish, with the least expenditure of money and labor, are most to be desired, and make of this indeed a fine art.

To take some meat that some one else has bought And then to dress it tolerably, is What any cook can do. A perfect cook is quite another thing. For there are many admirable arts. And of all of these he must be thorough master. Who would excel in this. He first must have A smattering of painting and indigo. Many the sciences which he must learn Before he's fit to think of cookery.—Nichomachus.

Cookery as a Science.—But little thought was given to this aspect of cookery by the ancients; probably more among the Greeks than among the barbarian nations. The worship of Hygeia, the goddess of health, and lived on coarse foods, barley bread, oil and
wine. Wheat was called the "marrow of man" and "running, fatigue, hunger and thirst" were their seasonings. Cookery attained a high degree of development during the Attic Age. The following quotations show that the Greeks understood the qualifications of a cook, and the effect of heat and water on food; and the third hints that our kitchen maids of to-day were not the first cooks who hurried up the fire with oil.

His mind must comprehend all facts and circumstances; Where is the place and what the time for supper; What fish to buy and where to buy it.— Alexandreis.

Fish that are fat are pleasant to the palate, but heavy and difficult of digestion, therefore they are better cured or roasted, for by that process their fatty parts are got rid of. Oysters when boiled get rid of most of their saltiness which they refuse into the water which boils them, and this water is apt to disorder the stomach; but roasted oysters have all their evil properties removed by the fire.— Menoias.

Placing all my pans upon the fire, I soaked the sabbles well with oil, to raise a rapid heat.— Archidisc.

The cook held the life and honor of his master in his hands, so common was poisoning by food, honors and wealth were bestowed upon those who had ability, those from Sicily ranking highest.

It was not until chemistry had advanced to the position of an exact science, and had evolved methods of analysis for organic substances, that the nature of food constituents, the changes in the nutritive value of food brought about by cooking, and what becomes of food in the body, could be determined.

Although vast strides have been made since Count Rumford, an American, who lived in Europe the latter part of the 18th century, taught the world how to cook and was the first to note the changes in the nutritive value of food on a large scale, the insight and method of the scientist,—the science of cookery is yet in its infancy.

The Agricultural Department in Washington has done a fine work along the lines of scientific analysis and experiment in food values, and its bulletins, issued frequently and free to any one on application, supply the latest and most reliable information. Investigations have also been made by many of the most civilized nations into the best way of preparing food for the army and the inmates of prisons and hospitals. Chefs gain their knowledge of the art of cookery by apprenticeship to noted chefs, taking a long and thorough training in every branch of the work. Training in the home, by "mother's way," is all the teaching many skilful housekeepers have received, but this, combined with judgment and faculty, has produced much good work.

During the last half of the 19th century, schools for instruction in cookery were opened in England, the agricultural colleges of the Western States, in large cities. Here not only the art, but the scientific principles were taught, and the pupils included children from the mission schools, servants, housekeepers, young and old, college and medical students and ladies of wealth and leisure. The first outgrowth of this beginning was the establishment of schools for training of teachers of cookery, and later cooking was made a part of the regular course in the public schools. Boston led in this part of the work, and now at the beginning of the 20th century, there are but few States in the Union and but few European countries where cooking schools are not found in successful operation.

Literature.—Cooking and feasting have been the theme of brush and pen, of song and romance in all countries, and from the earliest days of book-making, cookery has had quite a literature of its own. The names of Archestratus, Herodotus, Homer, Apicius, Lucullus and many others are associated in the minds of the student with the cookery and banquets of the Greeks and Romans. To attempt to enumerate those who have helped in the development of modern Italian, French and English cookery would be to do injustice to many of whom limited space would prevent mention. If one were to ask for the catalogue of culinary literature in any large public library in America, it would be found to be quite a volume, so rapidly has the literature of cookery multiplied, since it has taken front rank among the arts and sciences.

It has been claimed that men are the only really good cooks, chiefly because they make it their business for life and strive to excel in the art, whereas women use it a means of support until marriage relieves them from its necessity. And Dr. Johnson said that "women could not write good cook books." Perhaps men are better fitted to be chefs in hotels and large establishments, and to work with and manage a great body of men, and from having no other duties they have had ample time and means to give the subject more study. But when we recall the many women who have always prepared good, wholesome (if not fancy) food for their large families,—those who have catered to institutions, and those who have done fine work in teaching the science of cookery in schools and by their books and lectures, we question the statement. The American cook book of the 20th century is not a mere compilation of untried and inaccurate recipes, it is not a record of only one person's experience, where much is left to judgment, nor of a style of living too extravagant for the average home; but it is an evolution from the best experience of all nations, a collection of exact formulae deduced from actual experiment, giving the results of the latest scientific research, and all presented in an entertaining way in the best literary style.

Evolution.—The evolution of cookery, as traced in food, would be something after this order: The first foods were natural; milk, wild fruits, and vegetables, flesh and fish, eggs and animal fats, honey and salt, oily seeds and beverages made from simple fermentation of fruit-juices and of milk. The second stage might be called one of cultivated and manufactured or combined foods: the cereals, grains and legumes were developed into bread, cakes, puddings and malted large cities. Here not only the art, but the scientific principles were taught, and the pupils included children from the mission schools, servants, housekeepers, young and old, college and medical students and ladies of wealth and leisure. The first outgrowth of this beginning was the establishment of schools for training of teachers of cookery, and later cooking was made a part of the regular course in the public schools. Boston led in this part of the work, and now at the beginning of the 20th century,
In tracing the evolution of cookery among different nations, we find it has had the customary rise and fall of all the arts; introducing variety, magnitude and indulgence with the growth and prosperity of each nation; its national characteristics always largely determined by climate and natural advantages, but varied by the condition, and the extent of its rulers and nobility, and the advance of civilization. Persia with her fruits, sweets, wines and her lavish display modified the simplicity of the Greeks; the luxury and extravagance of the Romans disappeared under the invasion of the Goths, who cared only for wild fruits, fowl, venison, horse flesh and curdled milk. During the Middle Ages the best cooking was done in the monasteries. They had ample means and their many fast days incited them to the invention of many disguises. In Italy during the Renaissance, cookery, with the other arts, became more refined, and France soon felt the influence, through the Medici. She had early learned economy through necessity from famine and the exactions of her rulers; her many revolutions compelled every peasant to learn to make something savory of weeds, acorns, snails, rats and other things which many nations reject. Modern French cookery dates from Louis XIV and attained great height under his successor. The nobility and even royalty spent much time concocting new dishes; Richelieu madé mayonnaise, and Bechamel the sauce bearing his name. The French made great use of meat essence as a dressing for meats, and it was considered a great improvement over the oil of the south and the animal fats of the north. Large amounts of meat, poultry and game were often used solely to secure a small amount of glaze with which to dress an entrée; this shows an extravagant as well as an economical side to French cookery. Under Napoleon French influence was widely extended and it is said he left a French chef in every land he invaded. There are more chefs from France in America than from any other country. Austria and Switzerland rank next to France in excellence of home cookery. England's love for pork began with the Saxon invasion, and though condemned by some of her colonists, it is now the mainstay of her laboring classes. The coarse tastes of the Danes were modified by the soups and stews of the Normans. Many of our culinary terms are of Norman origin, and the surnames Cook and Butler came from professionals in that time. After groaning for centuries under saddles and sirloins, England's tables became more simple, for after the Reformation rich cooking was considered popish. Although modified by the modern French, England is still the great meat-eating nation. The English do their culinary work at the table with their palate-scouring table sauces, but the French do theirs in their saucepans. Scotland with her barren hills lacked vegetables, but mutton, game and fish were abundant; her chiliepiee and baggs show the influence of France.

There are still a few distinctly American dishes, many of them borrowed from the Indians, some made from native products, but a large number are but modifications of the native habit of the earliest settlers. The Yankee's love for pie may be traced to the mother country, and for the doughnut to Holland. The Dutch left a strong impress on New York and the Germans in the middle States. Extravagance in methods, great waste of food and material and the indigestibility of some of our national dishes have been our defects, but a large part of genuine American cookery will compare favorably with that of other nations. Widening of rulers and nobility, and the advance of travel and wealth have changed our tastes in a measure, enabling many to have chefs from abroad who command very high salaries. We have gained much of value from China and Japan. France has done more than any other nation in teaching us economy and artistic effect, and the influence of Spain is apparent on our western coast and our new possessions. The advantage of this influx of foreign elements into our cuisine has been greatest in cities and among traveled classes. In remote country places and everywhere among native laboring communities, there is need of knowledge of some of the economical foreign methods. Cooking teachers find it wise to accept some of the suggestions from their teachers, and strain them to meet the present days, instead of insisting that our methods are always the best. No doubt many foreign nations would derive equal benefit and enjoyment from some of our dishes which are seldom seen there. The cultivated American of colonial descent, while loyal to the virtues of succotash and the four B's of Boston, which are similar in nature and food value to the tortilla and frijoles of Mexico and the lentils of Egypt, is learning what to accept and what to reject from the solid puddings, pastry, bread and meats of England; the spicy cakes, sour vegetables, sausages and delicatessen supplies of Germany; the complex soups, sauces, entrées, soufflés and artistic disguises of the French; the pungent Spanish and Turkish goat, the onion, Hungarian goulash and Turkish pilaf; the Italian palenta, risotto and macaroni; the hors d'oeuvres of Russia and Scandinavia, and the curries and fruits of the tropics; and from them all he is beginning to form a cuisine to bear his own individuality which may be characterized as truly American. He prefers on his meat the sauce of its own juices; he insists on having no doubt as to the identity of his veal and chicken; he has accepted the piquancy of the green salad with its soothing oil in place of the sweets of the pudding and the sharpness of his mother's pickles. The nutty Vienna roll has taken the place of the half-baked raised biscuit, and he finds the bit of cheese which is the main food of the Swiss or Holland peasant, with the fruits and nuts of the savage, a good substitute for the soggy pie of his aristocratic ancestor.

Evolution of Methods of Cookery.—It is sufficient for our purpose here to consider foods merely as animal and vegetable, as the type of the former, and starch of the latter, albumen requiring a low and starch a high temperature. (See Foon). Starch and albumen are frequently combined in natural food, and there may be a high degree of both present, but they must be digested by fluids of a different nature, one an alkaline and the other an acid. Therefore, how to cook them that each
may best do its work in the body is the problem of good cookery.

Heat.—Cooking means, to prepare by heat (Latin cuco), and in all its phases heat is the important factor. The heat of the sun causes plant food to grow and ripen; the heat of the living animal prepares its flesh and products for the higher animal, man; he applies artificial heat in cooking vegetable and animal foods, and after eating them, his own internal heat helps in the assimilation of the food into his body. The absence of heat sufficient to be called cold is essential to make many foods more palatable. Water is removed from some foods by concentration, and added to others for the solution of albumen and the hydration of starch. Air, for the expansion of various substances the development of improved flavors and the dissipation of disagreeable odors is essential, and care should be taken that it be purged out.

Fuel.—Heat for cooking purposes was obtained first by drying foods in the sun. Many kinds of flesh, fish and fruit are still prepared in this way. Then came the burning of wood, oil, coal, gas, coal oil and alcohol; the latest advance is the use of electricity, the expense of which has retarded its adoption, but its merits are great and its possibilities unlimited. Heat is applied to food in two ways: through hot air, as in broiling, roasting and baking; and through hot liquids, as in boiling, frying and their variations.

Broiling or Grilling is cooking by close contact with the fire. The primitive way was on the coals: the smoke and ashes may have led the barbarian to wind the meat round a stick and hold it over the fire, much as the Turks do now with their strips of mutton or kabobs. To save personal attention the meat was suspended from a stick; later it was cooked on bars of wood or iron, called a gridiron, hence our word grilling, and was turned when partly cooked. The modern improvement of this time-honored method is the wire broiler, used over red-hot charcoal, or under the gas flame, and frequent turning has been found to be the secret of success. When the fire bears the fibres, with a slight loss of outside substance, but it seals the juices inside and gives the richest possible flavor. "The gridiron is the thermometer of civilization." Roasting is simply the broiling of bread and other cooked starchy foods, in order to develop dextrin. It sometimes develops charcoal. Pan-broiling is cooking in a very hot dry pan, with sometimes the merest film of grease to prevent too great loss of substance by adhesion. The quick searing gives richness of taste as in direct broiling. It is a convenient way for the chaining dish and oil stove.

Put the anchovies in the heated pan and in a moment
They will begin to hiss and are done.—Archestratus.

Roasting is a modification of broiling, at a lower temperature, adapted to large pieces of meat and poultry, which, on account of their thickness, are placed at a greater distance from the fire after the first searing. Forty times the animal was dressed and hung at once over the fire; when the fire was made in a hole, sticks were laid across on which the animal rested; we call it a barbecue. After fires were built on the hearthstones and cooking was done inside, the meat was hung on a frame placed in front of the fire, and was turned and basted by the cook's attendants. This was the common way of cooking meat in the great baronial halls of England for many centuries and may still be seen in old country houses. The modern spit has its clock-work attachments, which turn the meat, dip up the gravy and pour it over at regular intervals. In warm countries but little roasting is done; and although once the only way in America, it is little used in hotels, and by those who have ranges with a special attachment for roasting, or who have revived the old custom on the hearth of their country kitchens; for there are many who still think the old Greek method greatly superior to the cooking of meat in the oven, which is commonly called roasting.

Many are the ways and many the recipes
For dressing a bare, but this is best of all.

To place before a set of hungry guests
A slice of roasted meat fresh from the spit,
Hot, seasoned only with plain salt, salt,
Not too much done. And do not you be vexed
At seeing blood fresh trickling from the meat,
But eat it eagerly. All other ways
Are quite superfluous, such as when cooks pour
A lot of sticky, clammy sauce upon it.—Archestratus.

Baking is cooking by the heat radiating from a hot oven. The principle is the same as in roasting and broiling, namely, a quick searing of the outer surface for the sake of the flavor and to retain the juices, then a lower temperature that the heat may reach the centre without burning the outside. If the oven is not hot, or water is used at first, the juices are drawn into the pan, enriching the gravy at the expense of the meat. Flesh which has tough connective tissue, cartilage and bone should be cooked a long time, and needs the solvent action of water, after the first browning. Baking renders watery vegetables drier and more savoury, develops new flavors in fruits and grains and changes some of the sugar in the crust of cake into caramel and the starch in the outside of bread into dextrin. Some forms of baking are so nearly allied to stewing that it is impossible to make a strict division, but there is a great difference in the flavor developed by the two methods. In baking, the temperature is the important point, varying from 212° to 400° for different articles. The oven thermometer is the evolution of the old-time "hand and try cake" methods. Baking was done first in the hot ashes, then in a hole in the ground—the primitive oven—where a fire was built on stones and after it had burned down to coals, food was laid in, either in clay pots, or wrapped in moist leaves, then covered with brush or leaves, and left to cook slowly for a long time. Bread-fruit in the South Sea Islands is baked in this way. Poundéd and moistened grains made into a thin batter were spread on hot stones by a dextrous sweep of the hand, baking almost instantly; this was the first bread; the process may be seen now among the Arizona Indians in making piki. Some one found it better to cover the oven permanently and have an opening at one end; this was the beginning of the brick oven.

At the hearth fires, a covered utensil to stand near or over the coals, and later the Dutch oven, answered for daily use; the great brick oven near the chimney soon followed, and here enough rye and Injun* bread, pies,
cookies, Indian meal pudding, and beans, were baked to last a large family through the week. The kitchen range is an evolution of an American invention about the beginning of the 19th century. In many European countries they still use tile and brick stoves without ovens, all of the baking being done outside the home. In America there are ovens of every size and location, from the tiny box fan in the gas burner or oil stove, the jacketed box of the Aladdin oven, which concentrates and utilizes all the heat from an oil lamp, the ventilated ovens of the coal and gas ranges, to the immense ovens of the large baking establishments, with their steam jets, revolving shelves and griddles and other contrivances for securing the right temperature and texture.

Frying is immersion in hot fat: from 345° to 400°. This is not boiling fat, as it is often called; it is the water in the food, or the fat, If new, which bubbles. Immersion implies depth enough to cover the articles, that the surface may be hardened before the fat can penetrate the food. A coating of egg and crumbs helps to moisten the surface to harden quickly and keep its shape. Some previously cooked foods are fried merely for the flavor and crispness of the crust. Frying has been called the "curse of American cookery," but it is the wearing out of it that merits condemnation. Tough meats and flour mixtures rank with soda, put into cold lard and left to stew andizzle until hard and soaked with burned grease, have been all too frequently a large part of the daily food on many American tables. It may have originated when it was so much an undertaking to "fire up" the brick oven, and the drafts prevented the food in the Dutch oven from getting beyond the palest tint of brown. But there are indications that the boiler, the Scotch bowl, and the stew pan, are taking the place of the spider. When at its best frying is not to be recommended for those with weak digestion, its only merit being its quickness, but this is gained at the expense of time in the last stage of the work, digestion. But little frying would be done if everyone had to fry his food and inhale the odors. Frying probably originated where olive-oil was in common use, and oil is still the general frying medium in countries bordering on the Mediterranean. There it is usually done well, for vegetable oil may be heated with less acrid odor than from animal fats. When a pure vegetable oil without odor can be procured at reasonable rates in America, and when housekeepers are willing to believe that it is more economical to fry in a large amount of fat at high temperature and drain the fried food thoroughly, than to let a smaller amount of fat be absorbed by the food, frying will be greatly improved.

Sautéeing is a French term meaning "to toss," or turn over. It is the common way to cook omelets, mushrooms and other foods which need merely to be browned on each side in a little fat, or stewed in hot butter and tossed about until cooked. Griddle Baking, sometimes called frying, is cooking on a griddle, with or without fat, but little if of iron. The griddle is shallow and would not hold fat. For waffles and fancy wafers the griddle is double and revolves over the fire. Boiling and Simmering, terms often applied to cooking in water, regardless of temperature, so long as it is on the fire. At the sea-level, water simmers, or bubbles gently below the surface at 185°, and boils, or bubbles all over the surface, at 212°. Density, weather and altitude vary the boiling point from more or less, but it is easier to make some cooks understand this, than to convince them that water cannot be made any hotter after it once boils all over, at least not in the ordinary kettle. The scientific term for the point at one side of the meat which will cook it perfectly, and some of the foreign peasants seem to have known it intuitively, but the average cook in our kitchens piles on the coal until the water "dances a jig," and then wonders that her meat is stringy and tasteless. The first knows that if she wishes good broth or stock, she must cut the meat small, put it into cold water and let the juices soak out, then heat this water to the simmering point. But the average cook never can remember when to use hot, when to use boiling and when to use cold water. The educated cook knows that rapid boiling is advisable for the first 5 or 10 minutes, to seal the juices inside in boiled meats, then 10 minutes, to seal the juice and time — also to cook the starch in grains and vegetables; and that after this, the water should only simmer else there will be great washing out of substance. She knows, too, that when particles of food are to be kept in motion, to prevent adhesion among themselves or to the kettle, as in cooking rice and macaroni, the rapid boiling may be continued that "the rice may dance about." But to the average mind the cooking of food in water is probably more or less guesswork, judging by the results.

Stewing is only another form of simmering. In making a soup a large amount of water is used, and in making a stew a small amount. In both, the cooking is continued a long time at a gentle heat. Tough meats are improved in flavor by the union with vegetables, spices and other seasonings. In the soup they are removed, if it is to be clear, but in the stew they are retained. When dumplings of biscuit dough are cooked as a cover for the stew, or shortcake is served around the stew, it becomes a pot pie.

Fricasseeing, meaning "to fry," is a combination of frying with stewing, by which a flavor like that in frying, or pan broiling, is obtained.

The term is sometimes used when no real browning is done, the simple warming, or stewing in butter at a low temperature, making it, according to some authorities, a fricassee. It is to be regretted that the desire for new names (thinking thereby to have a new dish) has almost obliterated the true meaning of many culinary terms; there seems to be no standard for nomenclature.

Braising is a combination of frying, stewing and baking, with vegetables, etc., formerly done in a stew-pan having a hollow cover, in which coals were put for the final browning. It is a common way in foreign lands, where ovens are not much used and fuel scanty, only a little fire is needed for the initial cooking, for stewing, and each half-burned bit carefully put out by water and laid aside for another time. Braising is now done in an earthen dish called a casserole, and foods a la casserole are becoming very popular in hotels. It may be done in a granite pan with a tight cover and finished.
in the oven. It is one of the most savory ways of cooking meat, game, and poultry.

Smothering, or Pot-roasting, is done by quick searing of meat in a little of its own fat, in the stew pan or pot, and then throwing in enough water to prevent burning, covering closely (formerly with a lid of dough when it was done in an iron pot before the fire), and cooking slowly in the stew of its own juices. It gives rich, undiluted gravy and very tender fibre; the best way to cook tough lean meat free from bone.

Steaming.—Real steaming is done chiefly in factories, or large establishments, where the steam is confined in boilers and superheated, and then conveyed through pipes to the kettle containing the food. Owing to the expansive force of steam it cannot be confined in an ordinary kettle, and many of our canned fruits, soups and vegetables are more successfully done there, than they could be at home. But we can cook some foods over, or surrounded by boiling water, and call it steaming. In the first way, the food is placed on a perforated pan above the water, the moist steam surrounds it, and in consequence of the heat, just enough heat is given to the food. In the second way, a double or farina boiler is used (or a pail inside a common kettle), the heat is conveyed by the steam or boiling water through the metal, and thence to the food, which is less hot than the water, as the metal has absorbed some of the heat. Steaming makes tough meat tender and moist, and enables us to cook vegetables and glutinous foods without the constant attention needed, if cooked over the fire, or in a little water. The Romans had a kind of double boiler, also the chafing dish, which is one variety, combined with a sautéing pan. Our grandmothers could cook a pot of hasty pudding without burning it; but with the advent of many more glutinous foods and the knowledge that many foods containing milk and eggs need a low temperature, a great variety of steamers and double boilers have come into use. Our grandmothers lived in their kitchens; it was but little work to cover the pot® while they spun or wove, and the great kettle of cider apple sauce seldom had even a hint of scorching. But the modern housewife aims to spend as little time as possible in her kitchen. When we have to, this class it as a laboratory, it may tempt (although it may not require) a longer sojourn.

Cooking in water was probably the last to be discovered of the primitive methods, for it could not have been done until water-tight utensils were made; there were, first, baskets, made by plaiting grasses, twigs and rushes; then bowls or troughs were made by burning out hollow places in a log. Stones were heated in the fire and plunged into the water in these basins, which thus steamed the food. Indians cook their acorn mush in this way, and the Alaskans use their canoes for boilers, heating the water with hot stones, when they boil the salmon for its oil. When clay was found to be learned, shells were broken, and then into pots with three legs, and thus had a fire-proof as well as water-tight utensil; and after this stewing came into general use. Jacob's savory venison was probably stewed. In spite of luxury, the old men in Greece preferred the black broth made of cuttle-fish.

Rome was raised on gruel, or pulse, made of barley and vegetables, and it is probable that stewing in some of its forms has been the method in most general use, among the masses of the people, who barely had enough water to prevent burning, covering closely (formerly with a lid of dough when it was done in an iron pot before the fire), and cooking slowly in the stew of its own juices. It gives rich, undiluted gravy and very tender fibre; the best way to cook tough lean meat free from bone.

Stewing is not advisable, as commonly done in America, where a large amount of fire must be kept in one of our immense ranges especially for this purpose, but when it can be done over just the small amount of fire or gas needed, it is undoubtedly the most economical and nutritious way of cooking the cheaper kinds of meat, fish and poultry, and it is capable of many variations. But the average American man of moderate means does not take kindly to cheap meat. In this "land of the free and equal," he aims to have as nice a cut of steak as his rich employer, and his helpless helpmate probably knows no other way to cook meat save in the omnipresent frying-pan, and has no knowledge of the principles of the Norwegian cooker. Americans, with the best vegetables in the world, have much to learn about the cooking of them. Too much water and too little cooking are the American faults: it is just enough heat, with just enough oil to prevent burning, and then a slow stewing in their own juices,—saving them generally, instead of throwing them out in the water,—is the better way for many vegetables. Our beverages, our soups, our steamed puddings, our candy and many other foods, are palatable or otherwise, according to our knowledge of cooking in water. A question asked by a lady in the early days of cooking-schools shows the lamentable ignorance of many women on this important subject: "How shall I know when the water boils?"

It is interesting to note that every primitive method has its counterpart now, not only among the barbarous people, but we find that persons of the highest civilization and refinement adopt some of them instinctively, when camping necessities suggest their use, or the satiated appetite craves simplicity. No foreign chef has produced anything finer than the trout and salmon of the river, or the steaks of the camp.
COOK'S EXCURSIONS — COOLIDGE

Special directions for cooking fruits and nuts, for making breads, cake, pastries, etc., as well as for preparing the foods enumerated above, can be found in American books and journals devoted to cookery. Every precaution should be taken to ensure cleanliness in the cooking of food, not only because one wishes to avoid filth, but also because unclean methods make possible the transmission of disease. In the United States and in other countries there is a growing effort to secure cleanliness in markets, food factories, bakeries, hotels, restaurants and other places where food is handled, prepared, sold and eaten. With this end in view legislation has been enacted in many places, providing for inspection and for punishment if the law is violated. See NUTRITION OF MAN.

MARY J. LINCOLN.

Author of ‘School Kitchen Text Book.’

COOK'S EXCURSIONS. See COOK, THOMAS.

COOKS PEAK. The highest summit of Cooks range in the northern part of Luma Country, New Mexico, 23 miles north, slightly east of Deming. A prominent landmark to travellers on the old Butterfield emigrant trail which crosses the range not far south. Consists of porphyry intruded in Paleozoic and Mesozoic rocks. Important mining district on its east and north slopes. Altitude 8,408 ft.

COOK'S VOYAGES. See COOK, JAMES.

COOKTOWN, Australia, town and port of Banks County, Queensland, at the mouth of the Endeavor River, 1,050 miles northwest of Brisbane, with which and with other ports it is connected by steamship service. It is connected by rail with Laura in the gold fields, 67 miles westward. November 12, 1770, Captain Cook was wrecked on the Endeavor in 1770 after he had gotten her off a reef outside, having thrown his guns overboard to keep the ship afloat. Search has failed to recover the guns, which have evidently been covered up by the strong coral growths of the vicinity. A monument to Captain Cook was unveiled in 1889. There are fine public buildings, an admirable hospital, churches, schools, etc. It is the main port for trade with New Guinea, and is the outlet for a sugar country and a rich mineral country. It has pearl fisheries, coffee and rice are grown nearby, tin and gold mined. Pop. 3,349.

COOLBRITH, Ina Dona, American librarian and poet: b. near Springfield, Ill., but while a young girl went to California, where she has since lived. She has been librarian of the Oakland Public Library (1874-94); Mercantile Library, San Francisco, 1898-1900; only woman member of Bohemian Club in latter city, 1900-06. She published ‘A Perfect Day and other Poems’ (1881); ‘The Singer of the Sea; Songs from the Golden Gate’ (1895); associated with Bret Harte in the Overland Monthly; contributor to leading journals East and West; honorable member Athenian and California Writers' Clubs (Oakland); Bohemian, Browning, Century and Sequoia Clubs (San Francisco); Arts and Crafts (Carmel by the Sea); Pacific Short Story Club (San José); president of the Pacific Coast Women's Press Association; president of: Panama-Pacific International Exposition Congress of Authors and Journalists 1915.

COOLEY, Leroy Clark. American physicist: b. Point Peninsula, N. Y., 7 Oct. 1833; d. Poughkeepsie, N. Y., 21 Sept. 1916. He was graduated at Union College 1858, taught physical science in New York State Normal College 1860-74, when he became professor of physics at Vassar College, remaining in this relation until 1907. He wrote several elementary text-books on natural philosophy, chemistry, etc., the most recent being ‘Beginner's Guide to Chemistry’ (1886); ‘Laboratory Studies in Chemistry’ (1894); ‘Student's Manual of Physics’ (1897).

COOLEY, Mortimer Elwyn. American engineer: b. Canandaigua, N. Y., 28 March 1855. He was graduated from the United States Naval Academy in 1878; in 1881 became professor of mechanical engineering and in 1904 dean of the department of engineering at the University of Michigan; was chief engineer in the United States navy during the Spanish-American War, and chief engineer officer of the Michigan Naval Brigade from 1895 to 1911. After 1900 he was known as an expert investigator and appraiser of public utilities through his work in appraising the railroad and public-service corporations of Michigan in 1900-01, 1903-05 and 1910-11, and through his municipal investigations in New York, Chicago, Boston and other cities. From 1907 to 1912 he was chairman of the Block Signal and Train Control Board of the Interstate Commerce Commission. He is a member of the American Society of Mechanical Engineers and many other learned bodies.

COOLEY, Thomas McIntyre. American jurist: b. Attica, N. Y., 6 Jan. 1824; d. Ann Arbor, Mich. 12 Sept. 1889. He was admitted to the bar in 1846 and became professor of law in the University of Michigan in 1859. He was elected justice of the Supreme Court of Michigan in 1864 and was chief justice of that State 1868-69, retiring from the bench in 1885. In 1881 he again became professor of law in the University of Michigan. His principal works are ‘A Treatise Upon Wrongs and Their Remedies’ (1878); ‘General Principles of Constitutional Law in the United States’ (1880); ‘Commentaries on the Constitution of the United States’ (1873); ‘Law of Taxation’ (1876); ‘Michigan’ in ‘American Commonwealth Series.’

COOLIDGE, Archibald Cary, American educator: b. Boston, Mass., 6 March 1866. He was educated at Harvard University, the University of Berlin, the Ecole des Sciences Politiques, Paris, and the University of Freiburg. He was acting secretary to the American legation at Saint Petersburg in 1890-91 and secretary to the American legation at Vienna in 1893. In 1893-99 he was instructor in history at Harvard, from 1899 to 1910 associate, and thereafter professor; in 1911 he also became
director of the university library. He was a member of the Taft party to the Philippine Islands in 1905–06, Harvard lecturer at various French universities (1907–08), a delegate to the Pan-American Scientific Congress at Santiago, Chile, in 1908–09. In 1913–14 he was American exchange professor at the University of Berlin. He is the author of "The United States as a World Power" (1908; French and German translations); "The Origins of the Triple Alliance" (1917).

COOLIDGE, Charles Allerton, American architect: b. Boston, Mass., 30 Nov. 1838. He was educated at Harvard University and the Massachusetts Institute of Technology, and was in the office of H. H. Richardson, architect, in Boston from 1882 until he became a member of the firm of Shepley, Rutan and Coolidge in 1886. From 1892 to 1900 he had charge of the Chicago office of the firm. Among the notable buildings planned by him are the Ames building, South Terminal station and the new Harvard Medical School buildings at Boston; the Chicago Public Library, Chicago Art Institute, the Law School and Commons of Chicago University and the new building for the Rockefeller Institute, New York. He is chevalier of the Legion of Honor and member of the Society of the Cincinnati.

COOLIDGE, Susan. See Woolsey, Sarah Chauncey.

COOLIDGE, Thomas Jefferson, American merchant and diplomat; b. Boston, Mass., 26 Aug. 1831. He was graduated at Harvard in 1850, began business as an East India merchant, but later became treasurer of the Amoskeag Manufacturing Company and closely identified with the New England cotton industry and large banking and railroad enterprises. He was president and is a director of the Chicago, Burlington and Quincy Railroad; an overseer of Harvard 1886–97; appointed Minister to France by President Cleveland 1892; and a member of the joint high commission to adjust disputes between the United States and Canada 1899.

COOLIE, a term commonly applied to unskilled laborers from India and China. The first coolie emigrants appear to have been Indian bondmen from Calcutta, called British Guiana, in 1839, soon after the abolition of slavery in that colony. As free negroes were found to be insufficient to perform the work that had previously been done by slave labor and the whites could not endure hard labor in a tropical climate, the planters had to look for recruits from other places than Africa. The Chinese coolie traffic was publicly recognized in 1844 when the British colony of Giana made provision for the encouragement of Chinese immigration. For a certain specified amount, generally about 17s a month, the coolies were bound for a term of years and after 10 years' service they were entitled to free passage back to their native country. The Chinese coolies were not entitled to this back-passage. To induce the Indian laborers to remain inducements were offered them, and many did remain. The coolies employed in Guiana, chiefly from India, were in 1891 in number 105,463. The first attempt to use people from India as coolies proved unsuccessful. Various abuses existed almost from the beginning, in the treatment of the laborers. The transport ships were crowded so that few survived the passage; the survivors were often sold, and many were on the verge of starvation. In 1889, by agreement, to work in the soil guano pits in Peru, where huge numbers perished. The Chinese Passengers' Act of 1885 put an end to the more abominable phases of the traffic. No British ship was allowed to sail on more than a week's voyage with more than 20 coolies on board, unless her master had complied with certain very stringent regulations. This ruling enabled the Portuguese to gain almost entire control of the trade. The abuses which had crept in made the trade almost as bad as the trade in African slaves. The legislature of Jamaica, in 1869, passed a law requiring more humane treatment from employers toward their coolies. Macao, the Portuguese port at the mouth of the Canton River, China, sent large numbers of Chinese coolies to Cuba and Peru and under conditions little short of absolute slavery, even kidnapping was practised with impunity. In 1886 the matter was made subject to an international conference, and improvements were made by agreements signed by China, France and Great Britain. By this agreement, the legalized coolie trade between the West Indies and China was abolished. In 1904, under a convention drawn up between China and the United Kingdom, over 50,000 Chinese laborers were engaged at work in the gold mines of Transvaal. To the Malay states and other parts of eastern Asia, there is an extensive yearly migration of Chinese coolies under contract. From Amoy alone, some 75,000 coolies emigrate yearly to Singapore and The Straits Settlements, whence they are drafted for labor purposes in every direction.

The first recorded attempt at coolie trade with India took place in 1834, when coolies were transported to Mauritius. The trade grew enormously, and all sorts of abuses existed, which were finally stopped by the Indian Emigration Act of 1883, under which contract is allowed to certain colonies only, where good treatment is assured, which includes provision for an agent residing in India under the supervision of the protector of emigrants; the informing of the coolies of the exact nature of the agreement; medical inspection of immigrants and depots; inspection and licensing of ships, etc. The British colonies to which coolies are now admitted are British Guiana, Jamaica, Mauritius, Trinidad, Saint Lucia, Saint Kitts, Saint Vincent, Grenada, Natal and Fiji; and also to the French Guadeloupe and Martinique as well as Dutch Guiana and the Danish Saint Croix. In 1909 there were 625,000 coolies in the British colonies. During the construction of the Uganda Railway large numbers of coolies were required and are imported, especially from the coast of West Africa. The tea estates and pearl fisheries of Ceylon and the harvesting in Burma attracted many laborers from Tamil. The name is also applied to the Chinese immigrants to the United States, many of whom came to the western shore of this country after the discovery of gold in California. The Chinese Exclusion Act of 1888 and the stringent laws against Chinese coolies were greatly limited the numbers of Chinese in this
COOLING—COOPER

country. (See Chinese Immigration). Consul Hope, J. L. A., In Quest of Coolies (1872); Jerrold, E., The Wit in His Rights and His Wrongs (1871); Grose, C. B., The Labour Ordinances (Georgetown 1890) and reports of the commissions.

COOLING, Velocity of, a body isolated in air or other gas, or in vacuo, and surrounded by air, if larger than itself, loses heat, by radiation in the last mentioned case, and in the former case partly by radiation and partly by convection. The rate at which its temperature decreases depends on a variety of circumstances,—on the nature of its surface, for example. But, other things remaining the same, the velocity of cooling is proportional to the excess of the temperature of the body in question above that of its surroundings. This is Newton's Law of Cooling.

The law of cooling has been verified by Dulong and Petit experimentally. A copper ball was suspended in the midst of a metallic chamber, round the outside of which water was kept flowing, in order to maintain a constant temperature. The copper ball was heated before being suspended in the chamber, and a thermometer was inserted in a hole in the ball, and so arranged that the stem, which was long, projected to the outside of the chamber and could be read there. The fall of the temperature of the ball during equal intervals of time was noted, and it was found to become less and less as the temperature of the ball gradually approached that of the walls of the surrounding chamber, the law of decrease being Newton's as stated above.

The following example will illustrate practically the meaning of this law: Suppose the temperature of the ball to be 20° higher than that of the enclosure at the beginning of the experiment, and that during the first five minutes it loses 1°, that is, one-twentieth or 5 per cent of the excess of temperature. During the next five minutes it will lose 5 per cent of the excess that remains, that is, of 19°. It will therefore lose 0.95°, or the temperature of the ball is now 19° above that of the enclosure. At the end of the next five minutes the difference of temperatures of the ball and enclosure will be 17.15°, and so on.

COOLING SYSTEMS. See Internal Combustion Engine.

COOMASSIE, koo-mas'se, or KUMASSI, Africa, capital of Ashanti, in West Africa. The houses, formed of stakes and wattle-work filled up with clay, and thatched with palm leaves, are often furnished with arcades and ornamented with painting and carved wood. Coomassie was captured in 1874 by the British, and again in 1896. In 1900 they took entire possession and it is now the seat of the British resident. It has a fort and a market-place. It was made a railroad terminal in 1903 and carries on an active trade with central Africa. Pop. 24,000.

COOPER, Anthony Ashley. See Shaftesbury.

COOPER, Sir Astley Paston, English surgeon: b. Brooke Hall, Norfolk, 23 Aug. 1768; d. London, 12 Feb. 1841. He studied medicine in Edinburgh and London and in 1791 visited Paris, where he attended the lectures of Desault and Chopart. In 1793 he was appointed professor of anatomy at Surgeon's Hall; in 1802 he received the Copley medal of the Royal Society and in 1813 became professor of comparative anatomy to the College of Surgeons, and in 1822 one of its court of examiners. In this year appeared his great work 'On Dislocations and Fractures of the Joints.' Having performed a slight operation (1804) he was created a baronet in 1821, after which his practice largely increased. In 1827 he was elected president of the Royal College of Surgeons. His 'Lectures on the Principles and Practice of Surgery' appeared in 1824-27; his 'Anatomy and Diseases of the Breast' was published (1829-40), and 'Anatomy of the Thyroid Gland' (1832). He was the first to attempt the tying of the carotid artery and the aorta. These operations were not successful in his hands, but pointed the way for further research. Consult his 'Life and Correspondence' (2 vols., London 1843).

COOPER, Charles Alfred, English journalist: b. Hull, 16 Sept. 1829; d. 1916. From 1876 to 1905 he was editor of the Edinburgh Scotsman. He was a contributor of 'Letters on South Africa' (1895); 'An Editor's Retrospect' (1896).

COOPER, Colin Campbell, American landscape painter: b. Philadelphia, Pa., 1856. He studied at the Philadelphia Academy of the Fine Arts and was a fellow of the Academies of Paris. After a year as teacher in Drexel Institute, Philadelphia, he settled in New York. He was one of the first to give expression to the distinctive beauty of American cities, with their skyscrapers and manifold activities. A close observer, he renders one, in his color and atmospheric effects, of the Impressionists. He also paints cathedrals and views of quaint German cities with feeling and charm. His best-known works are 'Broad Street, New York,' (Cincinnati Museum); 'The Blanton Building' (Dallas, Tex.); 'Quebec Cathedral' (Philadelphia Art Club); 'Procession of Bruges' (1906); 'Lotos Club, New York'; 'View of Pittsburgh'; 'Beauvais Cathedral' (1912); 'Be Aventour'; 'Cathedral of Siena' (1913). He was awarded silver and gold medals at the Panama-Pacific Exposition, San Francisco, in 1915 and has been the recipient of numerous other awards.

COOPER, Elwood, American horticulturist: b. Lancaster County, Pa., 24 May 1829. For 10 years he was engaged in business in Port-au-Prince, Hayti, but went to California in 1870 and devoted himself to fruit culture. He was the first manufacturer of olive oil in the United States, inventing special machinery for the purpose. He is also the inventor of machinery for hulling and pitting almonds, and for hulling and washing English walnuts. From 1885 to 1903 he was president of the California State Board of Horticulture, and for three years was president of Santa Barbara Agricultural Society. He has published 'Statistics of Trade with Hayti' (1868); 'Forest Culture and Eucalyptus Trees' (1876); 'Treatise on Olive Culture' (1882).

COOPER, Emma Lampert, American artist, wife of Colin Campbell Cooper: b. Nunda, N. Y. She was educated at Wells College and in Paris, Kever in Holland and Chase in New York. Her principal subjects are street scenes,
interiors and landscapes. For a time she taught painting in Rochester, N. Y. At the Chicago World’s Fair (1893) she received a medal for her work. The "Troubadour," Miss Alice, and another at the Atlanta Exposition (1895) for an oil painting, "Behind the Dunes." Others of her pictures are "Mother Claudius" (1890); "Picardy Hillside" (1897); "High Noon, Cape Cod"; "Switzerland"; "Graystone, Switzerland." "News of the Day"; "Canal at Lisieux." 

COOPER, Frederick Taber, American author and editor; b. New York, 27 May 1864. He was educated at Harvard and Columbia universities; was associate professor of Latin and Sanskrit at New York University 1895-1902, literary editor of the New York Commercial Advertiser 1896-1904, and editor of the Forum 1907-09. His writings include "History of the Nineteenth Century in Caricature" (with A. B. Maurice, 1904); "The Craftsmanship of Writing" (1911); "Some American Storytellers" (1911); "Some English Storytellers" (1912); a translation of Montessori's "Pedagogical Anthropology" (1913); "Thomas Alva Edison" (1914). 

COOPER, George Henry, American naval officer; b. Waterford, N. Y., 27 July 1821; d. Brooklyn, N. Y., 17 Nov. 1891. He entered the navy in 1837, became captain in 1867, commodore in 1874 and rear-admiral in 1881. He was on sea service for more than 25 years, and on shore or other duty for more than 18. In the Florida Seminole Indian War he served in co-operation with the army; during the Mexican War he led an assault against Point Isabel, was captured at Monterey, and after being exchanged took part in the attacks on Tabasco, Agua Fria, and Tuxpan; during the Civil War he commanded, among other vessels, the monitor Sangamon, which was on picket duty inside the Charleston roads. He was commander of the Norfolk navy yard (1867-69); of yard at Pensacola, Fla., 1874-78; and of the Brooklyn navy yard, and in command of the North Atlantic squadron from 1880 until his retirement, 27 July 1884. 

COOPER, Henry Ernest, Hawaiian politician; b. New Albany, Ind., 28 Aug. 1857. He was graduated at the Boston University Law School 1880; was admitted to the Suffolk County (Mass.) bar; and settled in Honolulu 1880. During the Hawaiian revolution of January 1893, he was chairman of the Committee of Safety, and on 17 Jan. 1893 read the proclamation abrogating monarchical government in the islands. He became a member of the advisory council in the provisional government; a Circuit Court judge 1893-95; Minister of Foreign Affairs 1895-99; acting President of the republic, January to March 1898, and has served as head of the departments of justice, public instruction, and interior, and as attorney-general 1899-1900. He retired in 1900 and now practices law in Honolulu. 

COOPER, James, American senator; b. Frederick County, Md., 8 May 1810; d. Camp Chase, Columbus, Ohio, 28 March 1863. He was graduated at Washington College, Pennsylvania, 1832, studied law and began practice at Gettysburg, Pa. He was elected to Congress 1838 and 1840; to the State legislature 1843-48; was attorney-general of Pennsylvania 1848, and elected a United States senator 1849. Subsequently he settled in his native town, and when the Civil War broke out took command of the Maryland volunteers, organized them into regiments, and on 17 May 1861 was made the brigadier-general. He was in command of Camp Chase at the time of his death. 

COOPER, James Fenimore: b. Burlington, N. J., 15 Sept. 1789; d. Cooperstown, N. Y., 14 Sept. 1851. His father, Judge William Cooper, removed in the year 1792 to Otsego Hall, where he was born a few years. His father died in 1794, leaving him in the hands of his private tutor, Thomas M. Cooper, with whom he resided until 1808. He was then sent to John Boyes, of Cooperstown, N. Y., where he remained until 1810, when he entered the Albany Academy. He was graduated at Yale College at 13. He neglected his studies so persistently that he was expelled in his third year. In 1806 he went to sea in a merchantman, and served in the navy in London and at Gibraltar, receiving a midshipman's commission in January 1808. He served for a time on board the schooner Eagle, and then with a construction party on Lake Ontario, where he saw a new aspect of frontier life and became familiar with the details of shipbuilding. In 1811 he resigned and married a daughter of John Peter De Lancey, who came of a conspicuous Tory family. Cooper's resignation from the navy on the eve of the War of 1812 was criticized as unpatriotic and influenced by his Tory connections. For the next nine years Cooper was engaged mainly in managing and improving his farm possessions, at first near Cooperstown, then in Westchester, with no discovered or suspected bent toward literature. Chancing to read a book of fiction that aroused his dislike, he professed himself able to produce a better, and being held half jocularly to the task, wrote "Precaution," published in 1820. It was only an indifferent novel, but it was praised by friends, and Cooper was drawn to give himself to authorship. In 1821 'The Spy' appeared, winning immediate popularity both in England and at home. Cooper's chance of success lay, not in graces of style, which he showed small disposition to cultivate, nor in imitation, but in his large knowledge of colonial and pioneer life and of the sea. 'The Spy' he had utilized his acquaintance with many details of the Revolutionary struggle, and with Westchester as "the neutral ground." His next work, 'The Pioneers' (1823), concerned itself with life and folk in the wilderness about Cooperstown, where he had been brought up, and which he introduced under the name of Templeton, as the centre of the action. It was the first of the "Leatherstocking Series." In 1824 he published 'The Pilot,' in which he first makes use of his knowledge of seafaring. Suggested by 'The Pirate' of Scott, it was written to show how much more might be made of expert nautical knowledge than Scott had been able to effect. It really created a new literature of the sea. In another year Cooper had completed 'Lionel Lincoln,' a painstaking novel of Boston and the Revolution, but never popular. This was followed (1836) by 'The Last of the Mohicans,' which became quickly famous, being translated widely into foreign tongues. Its popularity was mainly due to skilful handling of the Indian
characters, Uncas and Chingachgook, and still
endures. After quitting with 1826, Cooper spent seven
years in Europe, continuing his authorship, and
supplying much needed knowledge of men and
things. 'The Prairie,' 'The Red Rover,' 'The
Wept of Wish-ton-Wish' and 'The Water
Witch' continued the series begun before he
sailed. On account of distorted notions held
abroad concerning the people of his country,
Cooper wrote 'Notions of the Americans;
Picked up by a Traveling Bachelor'; but the
book failed of its purpose, edifying Americans
rather than enlightening Europeans. He wrote,
besides, three novels, 'The Bravo,' 'The
Heidenmayer' and 'The Headsman,' dealing with
continental scenes and characters, but their
American bias tended to lessen his popularity.
His manner of meddling with unpersonal mat-
ters got him into some trouble at this time. He
determined in consequence to write no more.
Coming back to America, near the close of
1833, he found the general crudeness of taste
and manners pronounced, after his foreign
stay, and he did not spare his critic-
sim. The result was greater unpopularity at
home than he had incurred abroad. His comb-
bative temper prompted his putting out the
satiric novel of 'The Monikins' (1835), which
had small effect. In the three years following
he published 'Sketches of Switzerland' and
'Gleanings in Europe,' in which he gives his
impressions of the Swiss, the French, the
English and the Italians, and renews his strictures
on foreign and domestic faults. The result was
increased bitterness and abuse. A dispute with
the people of Cooperstown, over his rights in
Myrtle Grove, on Otsego Lake, made matters
worse, for the press of the State took sides
against him, misrepresenting his motives and
spirit in the case. Relief was at length secured
from this sort of persecution; Cooper pursued
the chief offenders for libel, and won his suits.
In 1838 he published the two novels, 'Home-
ward Bound' and 'Home as Found,' and in the
next year 'The History of the Navy of the
United States,' a work long had in contempla-
tion, and received with fresh abuse from the
press. The resulting trouble was settled, by a
board of arbitration, in Cooper's favor. In 1840
he published 'The Deerslayer,' generally consid-
ered, with the preceding novel, the best of the Leather-
Stocking Tales, which include, with these, 'The
Last of the Mohicans,' 'The Prairie' and 'The
Pioneers.' Cooper's powers of description and
portraiture were now at their best. In 1842
'The Two Admirals' and 'Wing and Wing'
appeared, and in 1843 'Wyandotte' and 'Ned
Myers,' the latter being the true story of a
sailor's career of earlier years. In 1844 'Afloat
and Ashore' came out in two parts. Three antici-
pated novels 'Satanstoe' (1845), 'The
Chainbearer' and 'The Redskins' (1846) fol-
lowed; and in the last-named year 'Lives of
Distinguished American Naval Officers' appeared.
'The Crater' (1847); 'Jaco Tier' and
'Old Omega Opus' (1848); 'The Sea Lions'
(1849) and 'The Ways of the Hour' (1850),
all indifferent novels, complete the list of his
more considerable works. His death was at
Cooperstown, where he had lived mainly since
1833. Cooper was of a social temper until op-
position withdrew from him society. His judg-
ments, except in matters of tact and policy, were
generally acute and sound, and his integrity
was heroic. His conceptions of the Indian
character have been frequently disapproved, but
were the fruit of deliberate study. In spite of
the faults in style, he had splendid narrative
ability and the power of creating characters
which are clear and strong. He was a
Birch Natty Bumppo, Long Tom Coffin and his
Indian personalities are very noteworthy. His par-
cular value to the literature of his country
lies in the fact that he opened up the course of
the novels concerning the origin and heart of
America, and of novels of the prairies and the
sea. Balzac and Hugo gave him enthusiastic
praise. The standard biography is Lounsbury's
in 'American Men of Letters' series, which
also contains a full bibliography and an excel-
lent criticism. (See DEERSLAYER, THE; LAST
OF THE MOHICANS, THE; PATHFINDER, THE;
PILLOT, THE; SPY, THE). Consult also Clymer,'James
Fenimore Cooper' (1901); Richardson, 'Amari-
American Literature' (Vol. 1, New York 1895);

1900); Brownell, 'American Prose Masters'
(ib. 1909); Erskine, J., in 'Leading American
Novelists' (ib. 1910); Phillips, M. E., 'James
Fenimore Cooper' (ib. 1912); and essays by
Mark Twain, T. W. Higginson and Edward
Matthews.

L. A. SHEPARD
Professor of Literature, University of Nebraska.

COOPER, Lane, American educator: b. New Brunswic,
N. J., 14 Dec. 1875. He re-
ceived his education at Rutgers College, where he
was graduated in 1896, studying later at the
universities of Columbia, Yale, Berlin and
Leipzig, and the College de France. In 1902
he began his connection with Cornell University,
becoming instructor in English there in that
year, assistant professor in 1906 and full pro-
fessor in 1915. He has published 'The Prose
Poetry of Thomas De Quincey' (1902); 'The-
ories of Style' (1909); 'Literature for Engi-
eers' (1909); 'Manual of American Litera-
ture' (1909); 'The Power of the Eye in Cole-
ridge' (1910); 'Concordance to the Poems of
Wordsworth' (1911); 'Function of the Leader
in Scholarship' (1911); 'Aspects of Poetry' (1913);
'Methods and Aims in the Study of Literature'
(1915); 'A Concordance to Horace' (1916); (editor) 'The Greek Genius and Its In-
fuence' (New Haven 1917); and con-
tributions to philosophical and other periodicals.

COOPER, Myles, English loyalist: b. Eng-
land 1735; d. Edinburgh, Scotland, 1 May 1728.
He was the second president of King's College,
now Columbia University, New York. He
studied at Oxford, became fellow of Queen's
College in 1760, and in 1761 published a volume
of miscellaneous verses, free from all
artificality and classical imitations. In 1762
he became assistant to Dr. Johnson, president
of King's College, and after a year as professor
of moral philosophy, Cooper, then 28, was
elected president in May 1763, upon the resigna-
tion of Johnson. Cooper had a faculty of four members. Both discipline
and members rose during his administration,
and a medical school was added. From 1767
to 1771 Cooper was in England, and after his
return to America showed himself not only a
typical high-churchman and Tory, but the mas-

886
tter of a trenchant and sarcastic pen. He published "The American Querist" in 1774 and in the same year wrote "A Friendly Address to All Reasonable Americans on the Subject of Our Political Confusion," a pamphlet answered by Alexander Hamilton, then an undergraduate at King's, and by Maj.-Gen. Charles Lee, who rivaled Cooper in virulence. His "What Think Ye of Congress Now?" (1775) urged that Americans were not bound by the decrees of Congress, as that body had transcended the powers granted to it. In the same year he was forced to leave New York, narrowly escaping illness-treatment at the hands of a mob. His departure from America he described in a poem in the Gentleman's Magazine for July 1776. In England he received a parish in Berkshire after a short residence at Oxford, where he preached in 1776 a sermon entitled "National Humiliation and Repentance Recommended, and the Causes of the Present Rebellion in America Assigned," a violent attack on the English Whigs. During the last years of his life he was senior minister of the first Episcopal chapel in Edinburgh. John Trumbull, in McFingal, speaks of "punter Cooper's reverend head," and he seems to have been rather free and convivial habits. Among the men who were educated under him were Gouverneur Morris, Robert Livingston, Alexander Hamilton and John Jay. He was the prominent classical scholar of 18th century America.

COOPER, Peter, American manufacturer, inventor and philanthropist: b. New York, 12 Feb. 1791; d. there, 4 April 1883. His early education was of the scantiest description, and in boyhood he assisted his father in making hats, at 17 learning the trade of coachmaking. He subsequently invented a cloth-shearing machine and engaged in various occupations, finally settling upon the manufacture of glue, which he carried on for half a century. About 1830 he became interested in iron manufacture and in 1845 removed his iron business from New York to Trenton, N. J., and was the first to roll wrought iron beams for fire-proof structures. In 1880 he built from his own designs the first locomotive engine ever constructed in America. He was also interested in the canal system of his city, and, at a later date, in telegraphic communications, being president of several telegraph companies. He took an active share in the enterprise which resulted in laying the first Atlantic cable. In 1876 he was nominated for the presidency of the United States by the independent party, receiving nearly 100,000 votes at the autumn elections. In 1854 he established in New York the well-known Cooper Union (q.v.). He published "Political and Financial Opinions with an Autobiography" (1877); "Ideas for a Science of Good Government" (1883). Consult Carter, Peter Cooper" (in Century Magazine, New York 1883-84), and Raymond, Peter Cooper" (ib. 1901).

COOPER, Philip Henry, American naval officer: b. Camden, N. Y., 1844; d. 1912. He was graduated from the United States Naval Academy in 1863, served on the Constellation in the same year, and took part in the battle of Mobile Bay. From 1867 to 1869 he was an instructor at the Naval Academy; in 1870-71 he was connected with the Tehuantepec surveying expedition, and was superintendent of the Naval Academy from 1894 to 1898. He was commander of the Chicago during the Spanish-American War. He attained the grade of rear-admiral in 1902; and was commander-in-chief of the Asiatic station in 1904, in which year he retired.

COOPER, Susan Fenimore, American author: b. Scarsdale, N. Y., 1813; d. Cooperstown, N. Y., 31 Dec. 1894. She was the daughter of James Fenimore Cooper, and during the last years of her father's life was his secretary and amanuensis. She was author of "Rural Hours" (1850); "Fields Old and New" (1854); "The Shield: A Narrative"; "Mount Vernon to the Children of America" (1858); "Rhyme and Reason of Country Life"; etc.

COOPER, Theodore, American engineer: b. Cooper's Plains, N. Y., 12 Jan. 1839. He was graduated at Rensselaer Polytechnic Institute, Troy, N. Y., in 1858, entered the United States navy as engineer officer 1861-72, and was assistant professor at the Naval Academy 1865-68. In 1872 he assisted Capt. John Hubbard in the construction of the Saint Louis bridge, becoming, after its completion, engineer and superintendent in charge. Later he held important positions with the Delaware Bridge Company, Keystone Bridge Company and as assistant engineer in charge of the construction of the first New York elevated railroad. He was one of the five expert engineers appointed to determine the Hudson River bridge span. Until his retirement he was consulting engineer for the New York Public Library and for the Quebec bridge. He is an authority on all matters relating to iron and steel construction. He published "General Specifications for Iron and Steel Highways Bridges and Viaducts" (1885; 7th ed., rev., 1909) and "American Railroad Bridges" (1889).

COOPER, Thomas, American physician and politician: b. London, 22 Oct. 1759; d. South Carolina, 11 May 1840. He was educated at Oxford, studied law and medicine and was admitted to the bar. Entering into the political agitations of the period, he was sent by the democratic clubs of England to the elected clubs in France. In this latter country he took part with the Girondists, but perceiving their inevitable downfall escaped to England. Edmund Burke criticized with some severity the activities of Cooper and Watt in France, and provoked a caustic reply from the former, entitled "A Reply to Mr. Burke's Inj ductive against Mr. Cooper and Mr. Watt" (1792). Its circulation was prohibited by the British government. While in France he had learned the secret of making chlorine from common salt, and he now became a bleacher and calico printer in Manchester, but his business was unsuccessful. He next came to America, and uniting with the Democrats opposed with vivacity the administration of John Adams. For a violent newspaper attack on Adams in 1799, he was tried for a libel under the Sedition Act of 1800, and sentenced to six months' imprisonment and a fine of $400. The Democratic party coming into power, in 1806 he was a delegate to the business of a land commissioner on the part of the State of Pennsylvania with such energy as to triumph over difficulties with the Connecticut claimants in Luzerne County, but being ap-
pointed to the office of judge, became obnoxious to members of his own party, and was removed in 1811. He then successfully occupied the chair of chemistry in Dickinson College, in the University of Pennsylvania, and in Columbia College, S. C., of which last institution he became president in 1820, and in which he was also professor of chemistry and political economy. On his retirement in 1834, the revision of the constitution of the State was confided to him, and he died in the performance of this duty. Cooper was alike eminent for the versatility of his talent and the extent of his knowledge. He published in 1794, in London, a volume of 'Thoughts Concerning America'; in 1800 a collection of political essays; in 1812 a translation of the 'Institutes of Justinian'; in 1819 a work on 'Medical Jurisprudence'; in 1812-14 two of the five volumes entitled the 'Emporium of Arts and Sciences'; 'A Practical Treatise on Dyeing and Calico Printing' (1815); and in 1826 'Lectures on the Elements of Political Economy.'

**COOPER, Thomas**, English Charlatan and poet: b. Leicester, 20 March 1805; d. Lincoln, 15 July 1892. While a shoemaker's apprentice he studied assiduously, and in 1827 became a shoemaker in New York. In 1830 a Methodist preacher. In 1841 he prominently identified himself with the Chartist movement as a leader, was editor of the *Midland County Illuminator*, and was arrested in the following year on a charge of sedition. During his subsequent imprisonment for two years in Stafford he wrote a Spenserian poem entitled 'The Purgatory of Suicides' and some stories published under the title of 'Wise Saws and Modern Instances.' He lectured much as a free thinker in London and the provinces, but in 1855 he abandoned free-thinking and began lecturing on Christian evidences. His autobiography appeared in 1872, his 'Poetical Works' in 1878 and his 'Thoughts at Fourscore and Earlier' in 1885.

**COOPER, Thomas Sidney**, English landscape and cattle painter: b. Canterbury, 26 Sept. 1803; d. there, 7 Feb. 1902. He studied at the Royal Academy School, went to France in 1827, and settled for three years in Brussels, where he learned much from Verboeckhoven. In 1833 he exhibited at the Academy, and in 1837 was elected Royal Academician. He exhibited at the Royal Academy 67 years successively. Among his works are 'Mountains in Cumberland' (1841); 'Ettrick Shepherds' (1842); 'Cattle at Pasture' (1843); 'Summer Evening' (1846); 'Charge of the Household Brigade—Waterloo' (1847); 'Forderich Meadows—Sunset' (1850); 'Snowed up' (1867); 'Milking Time in the Meadows' (1869); 'Passing Shower' (1870); 'Children of the Mist' (1872); 'Monarch of the Meadows' (1873); 'There's no Place like Home' (1874); 'God's Acre' (1875); 'Maternal Affection' (1876); 'A Cool Retreat' (1877); 'Isaac's Substitute' (1880); 'Summer Evening in the Marshes' (1880); 'On Deal Common' (1880); 'Scape Goat' (1881); 'Summer Afternoon—A Scene in the Meadows' (1883); 'In the Rob Roy Country' (1883). In 1882 he presented a gallery of art to his native town, and in 1890 published an autobiography entitled 'My Life.' His work is neat and highly finished in character, but conventional and displays no sympathetic study of nature, but rather an excellent imitation.

**COOPER CREEK**, or BARCOO, called by the latter name chiefly in its upper course, the largest inland river in Australia. See *Australia*.

**COOPER RIVER**, a river of South Carolina, rising in the eastern part of Berkeley County, flowing across the county in a generally southerly course and emptying into Charleston Harbor. Although the river has a very short course, it is remarkable for its breadth. It forms, with the Ashley River, the peninsula upon which the city of Charleston is situated. See *South Carolina*.

**COOPER UNION, or COOPER INSTITUTE**, an institute founded in New York in 1854 by Peter Cooper. Its object is to provide free schools of art and science and free reading rooms and library for the working classes. The founder chose the word "Union" because he hoped that other liberal persons would unite with him in providing the means for carrying into effect his benevolent intentions. The Cooper Union building was selected as a location of the Third and Fourth avenues and cost $630,000. An endowment fund was created by the gift of $100,000 during Mr. Cooper's lifetime and another $100,000 was added by his will. The William Cooper memorial foundation was $340,000. The fund has received additional gifts from time to time from Edward Cooper and Abram S. Hewitt, and in 1899 Andrew Carnegie gave $300,000 and later $300,000 more. The increase of annual revenue amounting to $25,000 provided by the three is mentioned was intended for the purpose of establishing a day school and of enlarging the operations of the night classes by the addition of special instruction in chemical, electrical and thermodynamic knowledge. The expenditure made necessary by preparation for enlarging the work of the institute amounted to about $22,000 additional, which was contributed chiefly by Mr. Cooper and Mr. Hewitt. The courses in science include engineering, electricity, chemistry, physics, astronomy and mechanical drawing; and those of art include architectural, industrial and ornamental and free-hand drawing, clay modeling and painting. Instruction is given in music, English literature, wood engraving and pottery. The institute confers degrees in science and in civil, mechanical and electrical engineering. There are several scholarships. Additional advantages are offered by lecture courses, a museum, an art gallery and a library of 39,481 volumes, with a reading room containing current numbers of nearly 500 magazines and newspapers. The institute is divided into the following departments: Night School of Science, Day School of Science, Naval Architectural Class, Night Art Department, Woman's Art School, Stenography and Typewriting School, Telegraphy School, Eloquence Class, Oratory and Debate Class. The annual budget approximates $205,000; the income-producing endowment to about $3,000,000, and the total value of the endowment is about $4,000,000. The number of students in the several departments is about 4,000. The People's Institute, although holding its meetings in the Cooper Union building, is not a branch of the Cooper Institute.
COOPERAGE—CO-OPERATION

COOPERAGE, the art of making vessels of pieces of wood bound together by hoops. Such vessels were in use among the Romans at the period of the Christian era. The upright pieces for the sides of a barrel or cask are called staves. The swelling at the middle of the barrel, called the belly or bulge, is formed by skillfully shaping each stave broad in the middle and narrowed at the ends so as to form part of the required double conoid. A skillful cooper can work this curve so accurately that no further fitting or alterations may be needed when the staves are put together. The staves are made to meet at their inner edges and by driving the hoops very hard, the inner part is compressed till the slight gaping outside is closed, and thus slight inaccuracies of fitting are remedied. The bulging shape of barrel and cask seems only a fashion. It has been suggested that the purpose is only to make more difficult the cooper's trade. During the last few years a steady effort has been made to introduce perfectly cylindrical casks in their place; the room saved in packing cars, etc., being the strongest argument for the new shape, which could be made by much cheaper machinery.

There are several branches of cooperage. The wet or tight cooper makes vessels for holding liquids. The dry cooper does inferior work, such as barrels for containing dry goods, where an inferior degree of accuracy is sufficient. The white cooper makes churns, pails, etc., which for the most part have straight sides. The best work is made of oak, which must be thoroughly dried before being put together. Other woods employed are elm, pine, gum, beech and bass in the order named. In warm countries, the drying of the sun is sufficient, and casks are therefore mounted in summer only; but in the United States, artificial drying is commonly resorted to.

The hoops are hammered down from the narrow to the wide part of the cask, by means of a mallet striking a piece of wood held against the hoop. Iron hoops are sometimes put on hot, in order that their contraction on cooling may bind the work together. Most ingeniously constructed machinery is now generally used in barrel-making. Like most other processes of manufacture, the cooper's trade has changed in modern times, with the substitution of machinery for hand work. Barrel-making machinery may be divided into machines for the manufacture of staves, machines for manufacturing the hoops for setting up and finishing the barrel. Consult Wagner, 'Cooperation: A Treatise on Modern Shop-Methods and Practice' (Yonkers, N. Y. 1910); Newlin, 'Tests of Wooden Barrels,' in 'Bulletin of the United States Department of Agriculture,' No. 86 (1914). Statistical bulletins on tight and slack cooperage stock are compiled by the United States Census Bureau in co-operation with the Forest service of the Department of Agriculture and are published annually. Other bulletins from the Forest Service dealing with co-operation are issued from time to time.

CO-OPERATION, in modern parlance the association of people for the accomplishment of any desired end, especially the association of working people for the management of their industrial interests in store, workshop or other undertaking, and the equitable distribution of profits. The advantages of co-operation consist in the lower prices paid for the ordinary articles of life and of manufacture, the common use of capital, machines, buildings, water power and in common production. Instances of co-operative industry have been discovered among English miners and New England fishermen in the 17th century and among Greek sailors of the Levant. Co-operative societies established as early as 1777-95 are still in successful operation. The earliest in England was founded in 1844 at Mongewell, in Oxfordshire, by Shute Barrington, bishop of Durham. During the Owenite agitation, between 1820 and 1845, hundreds of co-operative societies rose up. Robert Owen (q.v.), failing to convert his brother manufacturers to the innovations he had introduced for the benefit of his operatives in his New Lanark mills, appealed to the government to adopt measures that would alleviate the poverty of the laboring masses, but without success. He therefore abandoned these efforts and turned to the task of establishing co-operative communities that would put his ideas into practice. One hundred and seventy shops had been organized under the Owen plan in 1830, but four years later most of these had ceased to exist.

The modern movement first took practical and permanent form with the formation of the Rochdale Society of Equitable Pioneers in 1844. The founders were 28 Lancashire weavers, nearly all Socialists of the Owen school and Chartists. The original capital was $140, slowly collected by subscription of two pence, and afterward three pence, a week. With this capital they opened a store for supplying themselves with provisions; but at first they had only flour, butter, sugar and oatmeal to sell. They limited the interest on shares to 5 per cent, and divided the profits among members in proportion to their purchases. When it was proposed to take out a license for the sale of tea and coffee the members did not pledge or subscribe amounts, but "promised to find" small amounts ranging from two pence to one pound, and the latter sum was actually the largest offered. A motion was made that members who would not trade with the store be paid off, but those who desired to see co-operation in the principle of freedom opposed the motion, and it was withdrawn. At the end of 13 years they had a membership of 1,850, a capital of $75,000 and their annual sales amounted to $400,000. This successful society with its organization and methods of conducting business became a model which was followed in many parts of England and abroad. In 1864 a wholesale society with annual sales amounting to over $200,000,000, with a membership of 1,512,399 and a capital of nearly $330,000,000 was established at Manchester, and in 1869 a second at Glasgow. They work in harmony and are practically one institution. The wholesale society is a federation of retail societies for the supply of goods to the various societies composing it, with purchasing and forwarding depots in England, the United States and on the Continent. It owns eight steamships. It has extensive productive works, boot and shoe factories, woolen cloth works, corn mills, etc. There is also a co-operative fire and life insurance society. Since the inception of the co-operative stores in Great Britain a business of $4,500,000,000 has been transacted and $300,000,000 in dividends paid to their mem-
people's banks in Germany were founded by Schulze-Deitersch, the probable date being 1851, Schulze-Deitersch traveling through Germany, adding works, etc. One of the most notable examples of that kind of co-operation that includes profit-sharing is the South Metropolitan Gas Company, whose receipts are shared with 3,000 employees. The Leeds Co-operative, Inc. is perhaps the most famous single experiment. It is evident that probably 1,000,000 families, or a sixth of the whole population of England, have their wants in whole or in part supplied by co-operative stores.

Building and loan associations (q.v.) are purely co-operative organizations, and existed in form in England as early as the latter part of the 18th century. The date generally assigned for their beginnings in that country is 1836, for that year Parliament adopted an act for their regulation. The Friendly societies are co-operative in reality, though not in name. In 1827 the first English paper for the propaganda of co-operation was established, entitled the Brighton Co-operative News. In 1871 the Co-operative News was established as the organ of the societies. Since 1869 annual congresses of co-operative societies have been held throughout England. The Congress of 1902 had 1,100 delegates, with reports for 1,604 societies, giving a membership of 1,919,535; a gain of $7,291,000 in shares, $2,574,474 in profits and $6,614,124 in investments. Nearly $45,000,000 was distributed to members during the year as cash dividends. The number of societies in 1901 was 1,537, with a membership of 2,661,799; the aggregate trade transacted was $557,913,895, with profits of $60,122,405. In the Australian colonies co-operation has made a marked advance. There are many Friendly societies there. In 1873 the Co-operative Union was consolidated, with a regular constitution. It is governed by a board of 12 members, representing the six sections into which the union is divided. There were 48 additional societies not reporting. The movement for co-operation in Ireland has lately shown a decided progress. There are in the island 232 co-operative dairy or creamery societies, 101 agricultural societies, 52 co-operative banks and 39 other organizations; total membership 40,000. Although in Great Britain co-operation has succeeded best in the form of distribution, that is, in co-operative stores for supplying the domestic wants of the workman's family, in continental Europe other phases of the movement have been more prominent.

In France co-operation began with the Revolution and then nation was one of the few in which the state has stepped in to aid associative ventures of this kind. Building contracts have been awarded co-operative industries by the government, and M. Waldeck-Rousseau's known friendliness to the principle has awakened encouragement among the members of the various societies. Co-operation in different modes of agriculture has achieved some success in France. In 1900 there were 2,500 co-operative societies, 1,491 being devoted to dairy and various undertakings. Twenty hundred and fifty workshops are operated according to this principle. Paris has a very large and successful society. In Germany and Italy the co-operative idea has led to the formation of many people's banks, furnishing mutual credit to workmen and also small tradesmen. The
number of its adherents is comparatively small.

In the United States co-operation has made comparatively slow progress. A co-operative store in Kingston, Mass., is said to be the oldest existing experiment on the Rochdale plan. It was opened in 1850, but it was not until 1864 that the movement became prominent. There were various co-operative associations formed in the late forties and the early fifties. A bulletin of the Department of Labor issued in 1866 states that "none survive." In Missouri, however, one or two still exist, among which is the Protective Union of Worcester, Mass., and the Central Union Association of New Bedford, Mass., organized respectively in 1847 and 1848. In 1886 co-operative business in New England included creameries, banks and building associations. A co-operative coo-perating association was established in Minneapolis in 1874. In 1882 the students of Harvard University formed a society for supplying themselves with books, stationery and other articles at a great success and has been imitated at Yale and other colleges. The co-operative creameries in certain of our northwestern States have achieved an astonishing measure of success. Minnesota probably leads in the number and value of creameries in the United States, though New England—Massachusetts notably—has many of them. In 1901 more than 50 Farmers' Co-operative Grain associations were formed in Kansas. The Co-operative Association of America, organized during the same year, in Lewiston, Me., was started with the purpose of developing a federation of various lines of business, beginning with a grocery. The profits are divided semi-annually among the co-oper-ators. In 1901-02 the association accumulated $250,000 and reported a business of $600,000. There are many co-operative communities in the United States, varying much in their methods and characteristics. They have been classified as communitistic, socialist and partially co-operative. So far as it has gone the co-operative movement has been a real and effectual training for the intelligence, business capacity and moral character of the workmen. It has taught thrift, foresight, self-control and the habit of harmonious combination for common ends. Experience seems to show that where articles are produced to order and not for the general market co-operative production may succeed, but that these enterprises fail when they are confronted with the difficulty of adjusting the supply to the variations of the market demands. The success of co-operation in certain agricultural processes is essentially an incident in the marketing of products and bears no close relation to productive co-operation properly so called.

Co-operative Banking. The idea of co-operative banking was conceived by Herman Schulze-Delitzsch and was first put into practice in 1849 at Eisenburg. Professor Schulze-Delitzsch put a great deal of his efforts to recruit a number of carpenters and shoemakers from usury and to obtain money for them at fair terms upon their joint and several liability for buying the raw materials needed in their trades. The success of this venture led to various plans for people's banks and credit societies, based on co-operation for encouraging thrift in their neighborhoods and for extending financial assistance to their members for productive or provident purposes.

What Co-operative Banking Means.—Co-operation is the voluntary union of persons for utilizing their faculties or resources, or a part of them, under their own management in some economic enterprise carried on upon an account common to all with a view to their individual through their mutual benefit. A bank to be co-operative must be composed of members having this same aim and be so organized that they shall control its management; participate in its profits and losses and have the exclusive use of its credit facilities. The bank may borrow and even receive deposits from outsiders, since these are ways of utilizing collective credit for the members' benefit. But it cannot lend to outsiders, because if it should allow them to use its funds or resources it would be extending benefit to persons who had no voice in the management nor responsibility for the losses. This would impair its co-operative character and make its members simply a group of capitalists seeking profit for themselves without regard to the best interests of others. The bank, however, may invest in market securities, to prevent its funds from lying idle. The banks are formed either as joint-stock companies, or associations issuing shares, or as associations not issuing shares. A joint-stock company has the objection that its capital stock is a specified and fixed amount and that share investments therein cannot be as a matter of law be
CO-OPERATIVE BANKING

withdrawn at a member's will nor ordinarily be canceled and returned by the bank upon his expulsion or retirement. This violates one of the essentials of co-operation, which requires that any action be voluntary and dissolvable by either of them. Moreover, it is prejudicial to members that desire to keep their money within reach in case of need, while it deters persons from joining who might wish to resort to the bank only for occasional or temporary purposes. Determination of voluntary objections may, of course, be removed by contract. But the arrangement is not entirely satisfactory, and no co-operative bank has ever been formed as a joint-stock company except where the laws on associations were lacking or defective.

The associational co-operative banks are bodies incorporated under general laws which authorize licenses or charters to be granted upon filing articles of agreement and voluntary dissolution or to must be paid upon subscribing with a few cheap and simple formalities. The first law was that enacted by Prussia in 1867. From this law and many others enacted in Europe, it may be gathered that an association must have no limit for the number of members, except that it shall not be less than one for incorporators; and, if the association issues shares, no limit must be set for the number of these beyond the amount that may be held by one member. The shares may be paid at once or by periodic installments and must be subject to withdrawal. So the fund thus obtained increases or decreases according to payments or withdrawals made on shares and to any change in the number of members or of outstanding shares. Hence it is variable; and since it belongs, not to the association itself, but to the contributing members and must be returned to them upon retirement or expulsion, it is altogether different from a fixed capital stock and is called "share capital." These are the points which distinguish an association from a joint-stock company.

The articles of agreement must set forth all the important facts of the organization and administration of the bank and the methods of managing it. The shareholders may decide among any alternative forms or features allowed by the law. The delimitation of area, qualifications as to membership and special terms for admission and expulsion are optional. Many a bank restricts its area, makes residence within that area, or some particular occupation, race or religion a condition of membership, and exacts fees on entrance and fines for withdrawals, defaults or derelictions. If shares are issued, only one kind is permitted and 10 per cent or more must be paid on subscription. The articles must prescribe the par value and the manner of payment and the number of shares that may be held by one member, and the vote required for a decision on questions determined by more or by less than a majority. Plural voting may be allowed in a bank with shares, but in a bank without shares a member never has more than one vote. The member's liability must also be defined. This lasts for two years or more after retirement, and may be any one of three kinds.

In a bank without shares the liability may be unlimited, i.e., its creditor may hold members personally liable and sue all or any of them; or it may be contributory, i.e., the bank or its receivers may levy equal assessments against all members and repeat the process down to the last one financially responsible, until all the bank's debts have been paid. A member who pays more than his equitable proportion has a right of recovery against other members. In a bank with shares the liability may also be unlimited or contributory, but usually it is limited and runs in favor, not of its creditors, but only of the bank and its receivers; they may call immediately all what yet remains of the share or assess any member on his share up to a specified multiple of its face value. In practice, the assessments are rarely made except equally against all. A member of an unlimited-liability bank is forbidden to belong to any other bank. A ratio must be fixed at which assets, together with members' liabilities, shall be maintained to the bank's outstanding debts. If assets fall below this ratio, bankruptcy proceedings must be started. The law must specify the percentage of the profits to be annually set aside for a reserve, and what shall be done with the reserve upon dissolution.

Administration.—The administration is composed entirely of members elected or subject to the vote of the members, or to the vote of a committee of supervisors, with power to set aside any act of the board and to suspend any director, officer or member. The size for these bodies varies under the different laws. No person may serve on both the board and the committee at the same time. Nor may credit be extended to any director, supervisor or officer, or upon his endorsement, without the consent of the members. A bank may have a finance committee. Officers are selected for one year. Directors and supervisors may be elected for three years, but then it is so arranged that the terms of one-third of the board and of the committee expire annually. They may be re-elected. Salaries or compensation may or may not be allowed. Official inspection and a periodical making and publishing of reports are required. Loans are made by the bank, or by the members, to purchase shares of stock of a loan and savings society or to extend commercial banking. It may include collective buying and selling for members. Loans must be amply secured, the endorsement of one or more members being the usual security. Real estate mortgages are rarely taken, except to protect endangered claims. Rebates or dividends may be distributed, but at least a portion of the annual profits must be placed in the reserve. This fund is indivisible and, in the event of dissolution, passes to the government or trustees to be held for some new bank in the same locality or for use in some public object of benefit to such locality. In a bank without shares, all the profits are turned over to the reserve.

Chief Purpose.—The chief purpose of co-operative banking is the organization of credit. This distinguishes it from the operations of loan and savings societies, the object of which is mainly to encourage thrift. Co-operative banks flourish only where their members are able to utilize in their own individual businesses the money and credit made available; and they succeed best when each business has a productive or creative character. In the cities the members are tradespeople, owners of shops
and stores, grocers, butchers, tailors, shoe-makers, fishermen with their own outfits, artisans and the like, together with skilled workmen and frugal and industrious persons seeking to save money or to strengthen their financial standing with a view to setting themselves up in business. In some instances, as in the case of dividend-paying, limited-liability form, of which there are two major types. The first is the Schulze-Delitsch bank, in which the shares are large — sometimes even $1,000 apiece — and a member is allowed only one vote. Officers are paid for their service. The other is the Lussatti bank, in which the shares are small — $10 or under — and plural voting is allowed with a maximum usually of 10 votes for a member. Service of officers is gratuitous. Both have all ordinary banking powers and are called "people's banks." Many have become large and a few have acquired numerous members and enormous assets. Urban people's banks not infrequently belong to leagues for promoting and safeguarding their general interests. They rarely combine for mutual financial assistance.

In the rural districts the co-operative banks admit to membership country-store merchants, blacksmiths, persons engaged in or connected with agricultural pursuits, school-teachers, priests, preachers, professors of agricultural colleges, agricultural government officials, agronomists and bankers along with the farmers. Often members not farmers are elected on their boards and committees. The banks, however, devote their funds exclusively to agriculture ways. and may come to help one another. Differently from urban banks, their tendency is to become parts of a system having three degrees of organization. The first degree is a local rural co-operative bank or a group of associations centring around such bank. The second degree is the regional or provincial unions, each with a central bank and central commercial and industrial associations. The third degree is the federation, with a bank and associations having a national scope. Usually the associations of the federation and its associations are elected by the unions, the officers of each union and its associations are elected by the adherents composing its various local groups, and the officers of the latter are elected by their individual members. The banks of the federation and of the unions of this system have shares, pay dividends and limit the liability. But in many instances the local banks impose unlimited liability, issue no shares and put all profits into the indivisible reserves.

These are called Raiffeisen societies in honor of Frederick William Henry Raiffeisen, whose ideas and work for the Prussian peasantry led to the formation of the first society of the kind in 1862 at Anhausen, and to the inauguration in 1869 at Heddesdorf of the rural co-operative credit movement which now embraces all German. The features already noted, a German Raiffeisen society confines its area to a rural section containing by preference not more than 2,000 inhabitants and so remains small. No entrance fees are charged. The members must profess some Christian faith and bind themselves to contribute to the society and use none but its facilities in their affairs. Directors, supervisors and officers, except the secretary-treasurer, must serve gratuitously.

The powers of a Raiffeisen society comprise buying, selling and supplying various agricultural needs, as well as receiving deposits and extending credit. Loans are subject to recall on four weeks' notice, and on this condition may be granted at long term for acquiring farms. The borrowed money must be used only for a specific productive purpose. The society must join the federation and obligate itself to do no business with the outside world, except through the federation's banks and associations. The affiliated society buys their shares and bonds with its excess funds. Thus it serves as a basic unit and financial support of the system in return for advantages obtained therefrom. It attracts members by enabling them to economize their resources.

**Laws Enacted.** — Following Massachusetts in 1909, laws were enacted on credit unions in New York in 1913; on credit unions in North Carolina in 1915; on co-operative banks and on credit unions in Oregon in 1913; on agricultural credit co-operative associations in the Philippine Islands in 1915; on credit unions in Rhode Island in 1914; on co-operative unions in South Carolina in 1915; on rural credit unions in Texas in 1913; on co-operative banks for personal credit in Utah in 1915; and on co-operative credit associations in Wisconsin in 1913. With the exception of the co-operative banks in Oregon, the associations authorized by these laws do not possess ordinary banking powers. None can carry out the principal of the principle of either Schulze-Delitsch, Lussatti or Raiffeisen. They are all intended rather for encouraging thrift and for granting loans on security other than real estate than for organizing credit or for supporting co-operative systems.

**COOPERIA,** koo-pur-ee-a, a genus of plants of the Amaranth family (Amaranthaceae), so named in honor of Joseph Cooper, a curator of the Botanical Society of London. They are low herbs with coated bulbs and narrow grass-like leaves, with flowers somewhat resembling the atamasco lily. There are two known species in the United States, native to the southwest, and Mexico. Drummond's Cooperia (C. Drummondii) grows on the prairies from Kansas.
through Louisiana to Texas, New Mexico and Mexico. The flower is very fragrant, and because of its habit of blooming at night or in the early evening it is known as the evening star. The giant fairy-flower (*C. pedunculato*) is a favorite for cultivation, as it thrives well in ordinary garden soil, and if placed in a root cellar in dry soil with an even temperature, will bloom again in the spring.

**COOPERSTOWN, N. Y.,** village and county-seat of Otsego County, at the outlet of Otsego Lake, and on the Delaware and Hudson Railroad, 90 miles west of Albany. It is noted for having been the residence of James Fenimore Cooper, the novelist. It has Thanksgiving Airport, a Union free school, knitting mills, national bank, a box factory and a cheese factory. This was once an old Indian town, but as early as 1769 was owned by George Croghan, and in 1785 was purchased by William Cooper, the father of James Fenimore Cooper. It is growing in popularity as a summer resort. It is in a hop-growing and farming region. Consult Halsey, "The Old New York Frontier" (New York 1901). Pop. 2,484. See Cooper, James Fenimore.

**CO-ORDINATES.** See Geometry; Geometry, Cartesian; Geometry, Elementary; Geometry, Line; Geometry, Modern Analytical.

**CO-ORDINATION.** (Lat. "arranging in order," "ranking together"); a physiological and psychological term, indicating the normal and harmonious operation of the muscles, especially the voluntary ones, in such actions as walking, motion of the arms and mastication. Co-ordination is dependent on the perfect and complete action of the sensory nerves, more especially those of the muscular sense and of the semi-circular canals (See Ear), of the cerebellum and of the motor nerves and upon the healthy condition and proper interrelation of the muscles concerned. Its failure is usually due to affections of the brain or spinal column and is styled ataxia (q.v.).

**COORG, koor, or KOOOG, British India, province bounded by Mysore on the east and north, and the districts of South Canara and Malabar on the west; area, 1,582 square miles. Its greatest length from north to south is 60 miles, and greatest breadth from east to west 40 miles. It has a rainfall of 133 inches annually. The country in general is extremely rugged and covered with forests, in some parts abounding in sandal and other valuable woods, but in others overrun with jungle, the resort of elephants and beasts of prey; climate is temperate and healthy; soil fertile and in many parts well cultivated, yielding in abundance rice of superior quality. Great numbers of cattle are reared. The growing of coffee is an important industry, the bulk of the product being exported to France. The manufactures are insignificant. The province was added to the British dominion in 1834. The capital is Mysore. The old fortifications are interesting. High ramparts and deep ditches are so arranged as to be most effective in checking the advance of an enemy. Pop. 174,976.

**COORNHERT, kön'hört, Dirck Volekerts-""sen, a Dutch scholar: b. Amsterdam 1522; d. Gouda 1590. In 1562 he became secretary of the city of Haarlem and opposed the Spanish power, until he was imprisoned for a short time, and on his release forced to flee to Cleves and Xanten. In 1572, when the Dutch successfully revolted against Spain, he was made state secretary of the States of Holland. He was a well-known theologian, an opponent of the orthodox Protestant party. By his poetical writings, as also by his elegant translations from Boccaccio and the classics, he earned the title of "restorer of the Dutch language." His poetical works include "Abrahams ryhmg" ("The Death of Abraham") and "Comedia van de blinde van Jericho" ("Comedy of the Blind Man of Jericho"). His prose works include "Zekedunst, dat is wellevens kunst" ("Ethics, that is, the Art of Right Living") which appeared in 1586, and deserves special mention. Consult Moorres, "D. V. Coornhert de Libertijn" (1887).

**COOS BAY, an indentation on the coast of Oregon in lat. 43° 45' N. in Coos County. It extends into the land about 10 miles and is only one mile in width, thus making it a safe harbor. Marshfield and Empire City are on Coos Bay.

**COOSA, koo'sá, RIVER, in Floyd County, in the northwestern part of Georgia, is formed by the junction of the Oostanaula and the Etowah rivers; it flows southwest into Alabama and about eight miles north of Montgomery it unites with the Tallapoosa River and forms the Alabama. Its length is about 350 miles. It is navigable for boats of light draft from its mouth to Wetumpka and from Greensport to Rome, Ga., and drains an area of 10,000 square miles.

**COOSY, koo'sè, or KUSI, a river of India, rising in Nepal and flowing first south-southeast to the British frontier, and then nearly due south to the Ganges. It is very rapid and difficult to navigate. It is noted for its destructive floods. Its total length is about 325 miles.

**COOT, a strictly aquatic bird of the genus Fulica, sub-family Fulicinae and family Rallidae, also called water-hens and crow-ducks. About 10 species are known, distributed throughout the world; but mostly in South America, which has six. The species of South Canara and Malabar is abundant throughout North America, breeding wherever found and resident in the South. Its appropriate habitat is shallow reedy ponds, and sluggish streams. The nest is a disorderly heap of reeds or similar material in or near the water, in a hollow of which 8 to 12 eggs, clay-colored, with brown spots, are deposited. The length of the bird is 14 to 16 inches, but the body is remarkably compressed, and the feet are nearly unique in the lobate webbing of the toes. The color is generally sooty slate, with the lower belly and some other parts white and the bill red at tip and base. The coot is much sought by gunners about the interior lakes. The European coot (*Fulica atra*) is a closely similar bird, slaty in color, with a bare patch on its head, whence the name bald coot; it is found throughout Europe and in Asia.

**COOTE, Sir Eyre, British military officer: b. County Limerick, Ireland, 1726; d. Madrid, 26 April 1783. He entered the army at an early age, and from 1754 to 1762 served in India. It was by his arguments that General Amherst was prevailed upon to risk the battle of Plassey, and for his services in this and other engagements, Coote was..."
in 1759 given the command of the newly raised 84th regiment. In this year he gained the great victory of Wandiwash; and his capture of Pondicherry in 1761 completed the downfall of the French in India. Coote returned to England, and was knighted in 1771. In 1779 he assumed the command-in-chief in India, with the rank of lieutenant-general, and in 1781 he routed Hyder Ali at Porto Novo.

**Copaiba** (Copaiba Langsdorffii) and other species of *Copaiba* are of recent origin, and are known as “spirit copals” because soluble in alcohol or turpentine.

**Copalchí Bark**, a bark resembling cascarilla bark in its properties, and produced by a shrub of the same genus, *Croton Pseudochinon*, native of Mexico and of Central America. The bark comes to Europe in quills a foot or two in length, and has a thin corky epidermis. Copalchi bark is much used as a substitute for cinchona in Mexico, where it goes by the name *Queña blanca*, and is imported, though not to a large extent, into Europe. It contains a minute proportion of a bitter alkaloidal resembling quinine, and is somewhat weaker than cascarilla bark.

**Coparcenary**, in law, partnership in inheritance; joint heirship, in which a heir is entitled to a distinct share of the benefits, while the property remains undivided. It commonly arises from the custom of dividing equally among coheirs the property of a man who dies intestate; but even in England, where the eldest son is usually sole heir, local custom may create coparcenary among male heirs.

**COPE, Charles West**, English painter; b. Leeds, 28 July 1811; d. Bournemouth, 21 Aug. 1890. He studied at the Royal Academy and in Italy, and first exhibited at the Academy in 1831. In 1843 he gained a prize of £30 for a picture, ‘The First Trial by Jury’; in 1844, by his fresco, the ‘Meeting of Jacob and Rachel,’ he secured the commission for one of six frescoes for the House of Lords, producing accordingly ‘Edward the Black Prince Receiving the Order of the Garter.’ Altogether he executed eight frescoes from English history of the 17th century for the House of Lords, while his other works were numerous, the subjects being historical, romantic or domestic. Amongst the most prominent of these are ‘Nereids’ (1836); ‘Cotter’s Saturday Night’ (1843); ‘Last Days of Wolsey’ (1848); ‘King Lear’ (1850); ‘Milton’s Dream’ (1850); ‘Pilgrim Fathers’ (1857); ‘Evening Prayer’ (1860); ‘Spring Flood’ (1863); ‘Shylock and Jessica’ (1867); ‘The Disciples at Emmaus’ (1868); ‘Yes or No?’ (1873); ‘Taming of the Shrew’ (1874); ‘Anne Page and Slender’ (1875); ‘Selecting Pictures for the Royal Academy Exhibition’ (1876); ‘Blanca’s Lovers’ (1877); and ‘Far Away Thoughts’ (1881). His etchings have also been much admired. He also illustrated the de luxe editions of Gray’s ‘Elegy’ (1847); Goldsmith’s ‘Poetical Works’ (1845); Thomson’s ‘Seasons,’ etc. He became A.R.A. in 1843 and R.A. in 1848. Consult Cope, C. H. ‘Reminiscences of C. W. Cope’ (London 1891).

**COPE, Edward Drinker**, American zoologist and palaeontologist; b. Philadelphia, Pa., 28 July 1840; d. there, 12 April 1897. Oliver Cope came to this country from Wiltshire, England, about 1687 and settled in the northern part of the State of Delaware. Oliver’s grandson, Caleb, a member of the Society of Friends, was burgess of Lancas-
ter, Pa., in 1776, and incurred the indignation of his fellow-townsmen for offering the hospitalities of his house to Captain (afterward Major) André and other British prisoners captured at Saint John's, Canada, by General Montgomery. Caleb's son, Thomas Pim Cope, settled in Philadelphia, and established the Cope press, which was the leading print shop in the city and Liverpool. Thomas Pim Cope's son Alfred married Hannah Edge and was the father of the subject of this sketch.

During the first seven years of Edward's life he was educated at home, and gave early proofs of a restless inquisitiveness and an accuracy of reasoning on what he had observed, very rare in so young a child. At 13 he entered the Friends' School at Westtown, Chester County, Pa. As a young man of 18 he announced to his family that he was to be a naturalist.

His father tried to make a farmer of him, and for this purpose gave him a farm near Coatesville, Pa. He learned much of the flora and fauna of the country at this time, and gradually developed the thought of settling down to this monotonous life. He longed to grapple with the larger problems of biology, and broadly hints in a letter of 1858:

"Dr. Leidy is getting up a great work on the comparative anatomy of..."

Such a work will be very useful to those who want to go to the bottom of nature's history; it is an interesting study, too, to notice the modifications in form, the degradations, substitutions, etc., among the internal organs and bones. The structure, forms and positions of the teeth, too, are interesting to notice, so invariably are they the index of the economy and the position in nature of the animal."

In 1859 he published his first paper on the "Primary Division of the Salamandridae." He became a member of the Academy of Natural Sciences of Philadelphia in 1861. He had had his wish to attend Leidy's lectures, and this same year he spent some time with Gill, Kenrick, Meek and Hallowell in the museums of the Smithsonian Institution at Washington. He greatly admired professors Henry, Baird and Arnold Guyot. He was astounded that Guyot believed in the resurrection of the body. He published 6 scientific papers in 1860: 9 in 1861; 7 in 1862; 4 in 1863; 3 in 1864; 10 in 1865; 11 in 1866. These were almost exclusively printed in the Proceedings of the Academy of Natural Sciences and were largely on herpetology. In 1866 he became a member of the American Philosophical Society, and thenceforward published largely in this society's proceedings. Altogether, counting his editorials in the American Naturalist, and five posthumous publications, his life yielded 1,281 separate papers on scientific subjects. The following statement of his work is taken from Prof. Henry F. Osborn's article in Science for 7 May 1897.

As early as 1868 he laid the foundations for five great lines of research on the following subjects: Fishes, Amphibians, Reptiles, Mammals and Phylum Reptilia. He unconsciously followed Lamarck in ascribing to conscious effort the adaptive changes in species, and this at the age of 28. In 1869 he struck the keynote of all his later evolution in the sentence, "Intelligent changes may be regarded as the originator of the fittest, while natural selection is the tribunal to which all the results of accelerated growth are submitted."

He accepted the term Neo-Lamarckism as properly describing his position, which was that, while very many specific characters are adaptive, few generic characters are so, but these latter are the results of the acceleration or retardation of one plan of development when that city and Liverpool. Thomas Pim Cope's son Alfred married Hannah Edge and was the father of the subject of this sketch.

During the first seven years of Edward's life he was educated at home, and gave early proofs of a restless inquisitiveness and an accuracy of reasoning on what he had observed, very rare in so young a child. In 1866 he became a member of the American Philosophical Society, and thenceforward published largely in this society's proceedings. Altogether, counting his editorials in the American Naturalist, and five posthumous publications, his life yielded 1,281 separate papers on scientific subjects. The following statement of his work is taken from Prof. Henry F. Osborn's article in Science for 7 May 1897.

As early as 1868 he laid the foundations for five great lines of research on the following subjects: Fishes, Amphibians, Reptiles, Mammals and Phylum Reptilia. He unconsciously followed Lamarck in ascribing to conscious effort the adaptive changes in species, and this at the age of 28. In 1869 he struck the keynote of all his later evolution in the sentence, "Intelligent changes may be regarded as the originator of the fittest, while natural selection is the tribunal to which all the results of accelerated growth are submitted."

He accepted the term Neo-Lamarckism as properly describing his position, which was that, while very many specific characters are adaptive, few generic characters are so, but these latter are the results of the acceleration or retardation of one plan of development when th...
tion in 1906. He has edited ‘Adams Primer on Teaching’ (1905); ‘The Aims of Religious Education’ (1906); ‘The Materials of Religious Education’ (1908) and is the author of ‘The Bonanza Bible Class’ (1904); ‘Sunday School Management’ (1905); ‘Hymns You Ought to Know’ (1905); ‘The Modern Sunday School in Principle and Practice’ (1909); ‘Levels of Living’ (1909); ‘The Friendly Life’ (1909); ‘The Efficient Layman’ (1910); ‘The Evolution of the Sunday School’ (1911); ‘Efficiency in the Sunday School’ (1912); ‘Religious Education in the Family’ (1915). He received the honorary degree of A.M. from Oberlin College in 1911, and that of D.D. from Washburn College in 1911.

COPE, Sir John, English general: d. 28 July 1760. Having been made a knight of the Bath, in 1742 he commanded the troops sent to the assistance of Maria Theresa. On the landing at Pikma, Charles Edward landed in 1745. Cope was appointed commander-in-chief of the government forces in Scotland. After a fruitless march to the Highlands, he returned with his troops by sea to Dunbar, and on 21 September was totally defeated at Prestonpans by the Scottish forces under Charles Edward Stuart. His defeat is celebrated in the Jacobite song, ‘Hey, Johnnie Cope, are Ye Waukin’ Yet?’ In 1732 he headed a committee which made a famous report on revenue funds and smuggling.

COPE, Thomas Pym, American merchant: b. Lancaster County, Va., 20 Aug. 1768; d. Philadelphia, Pa., 22 Nov. 1854. He began importing goods in his own vessels in 1807, and in 1821 established the first line of packets between Philadelphia and Liverpool. He was held in great respect by his fellow-townsmen, who elected him to many places of trust and honor. During the yellow fever epidemic of 1793 he stayed in the city to aid its victims, and during the smallpox outbreak in 1797 carried food to the houses of those taken with the disease, and in other ways cared for them. He was an executor of Stephen Girard’s will; secured the estate of Lemon Hill as a park for the city; and was active in the construction of the Pennsylvania Railroad. The introduction of the Philadelphia water supply from the Schuylkill, the completion of the Chesapeake and Delaware Canal, the construction of the Pennsylvania Railroad and the establishment of the Mercantile Library were largely due to his efforts. In 1807, he was elected to the State legislature.

COPE, an article of ecclesiastical vesture in the Roman Catholic Church. It is a voluminous coif, covering the ears, opening in front, and with a semi-circular cape or hood behind. It is usually of silk material, embroidered, or of cloth of gold. It is worn by the celebrant in certain functions, as processions and benedictions, and is not, like the chasuble (q.v.), reserved to priestly use; it is worn also in solemn processions by the clerics who attend the celebrant, and by the cantors in church services. See COSTUME, ECCLESIASTICAL.

COPECK (Russian, a lance), a Russian copper coin, so called from the impression of Saint George bearing a lance. It is the oldest form of coin in Russia and superseded furs as a medium of exchange. The coin is the hundredth part of a silver ruble, or about the eightieth part of a paper ruble. It varies in value from three-fifths to three-fourths of a cent. See COINS, FOREIGN, AMERICAN EQUIVALENT OF.

COPELAND, Edwin Bingham, American botanist; b. Monroe, Wis., 30 Sept. 1873. He was graduated at Leland Stanford Junior University in 1895, and also studied at the universities of Leipzig, Halle, Wisconsin and Chicago. In 1897-98 he was assistant professor of botany at Indiana University and held the same position in the University of West Virginia in 1899-1900. In 1901-03 he was instructor in botany at Leland Stanford University, he was botanist to the Philippine government, 1903-08; superintendent of the Philippine Agricultural School 1908-09 and dean of the College of Agriculture and professor of plant physiology in the University of the Philippines since 1909. He has written ‘Philippine Agriculture’ (1908); ‘The Coconut’ (1914); also some 100 articles on botanical research.

COPENHAGEN (*Merchants’ Haven*), Denmark, the capital, situated on the shore of the island of Zealand, in the sound, which is here about 12 miles broad; an outlying portion, Christianshavn, stands at the north end of the island of Amager or Amak, which is separated from Zealand by a narrow arm of the sea. The channel forms a fine large harbor, which is bridged over at two points to connect Christianshavn and the main part of the city. The fortifications on the land side have been removed since 1863; so that the city has now practically incorporated the suburbs Østerbro, Nørrebro, Vesterbro and Frederiksberg and occupying an area of 31 square miles. To counterbalance the expected injury to the city, commerce from the opening of the Baltic Canal, a great free port, free from customs dues, was constructed in 1890-94 to the north of the harbor. The business quarter stretches from the harbor in a northeasterly direction toward the principal and executive district of Nytorv, which forms the focus of the life of the city. Farther north and east of this point lies the aristocratic quarter, with the handsome Amalienborg Square and its royal and ministerial palaces; this district is bounded on the extreme north by the citadel and the adjoining public gardens and walks on the shores of the sound. Among its few buildings of historical interest or intrinsic beauty, the Metropolitan cathedral church, known as Vor Frue Kirke, rebuilt after the bombardment in 1807, possesses statues of Christ and the apostles and a baptismal font, designed and in part executed by Thorwaldsen. Trinitatis-kirke is remarkable for its round tower, which is ascended by a winding causeway instead of steps. Holmens-kirke contains interesting monuments to the great naval heroes, Juel and Tordenskjold. An English church, built at a cost of $49,000, was consecrated in 1857. The royal palace, called Christiansborg, was rebuilt between 1794 and 1828, but was never remarkable for architectural beauty. The principal part of the vast building was destroyed by fire in 1884, when many precious works of art were destroyed. Happily most of the pictures in its great art gallery were
COPENHAGEN—COPERNICAN SYSTEM

The castle of Rosenborg (1610-24), where the regalia are kept, contains interesting collections of objects of art; and the palace of Charlottenborg (1624) is now used as an academy of arts. Copenhagen is the centre, not only of Danish, but northern literature and art, and is the seat of a number of societies for the advancement of these in all their branches, among which are the Royal Society, founded in 1742; and the Royal Society of Northern Antiquaries, founded in 1825. A magnificent national theatre was built in 1874. The royal library contains over 600,000 volumes, besides great treasures of Sanskrit and other MSS. The Museum of Northern Antiquities in Frindsens Palais is unrivalled in its kind, having been made what it is mainly by Worsaae. The Thorvaldsen Museum, opened in 1846, consists of works of art by that sculptor himself, and others left by him to the Danish nation, for which a separate building has been erected. There are statues of several of the Danish kings, of Tycho Brahe and of the poets. The city is governed by a body of magistrates nominated by the king, and a municipal council of 42 members. About 50 per cent of the trade of Denmark passes through Copenhagen. The chief exports are grain, rape-seed, butter, cheese, meat, cattle, wool, hides, bones and grain-spirit. Porcelain, pianos, clocks, watches, mathematical instruments, textiles, chemicals, sugar, beer and tobacco are manufactured.

Copenhagen is the seat of a United States consul-general.

About the middle of the 12th century Copenhagen was but a fishing village, in the neighborhood of which Bishop Axel, or Absalon, built a castle. In 1254 the village obtained the privileges of a town, and in 1443 King Christopher made it the capital of the kingdom. It was several times attacked by the Hanseatic League, was besieged by the Swedes in the 17th century; was bombarded by the English, Dutch and Swedes in 1700; suffered grievously by fire in 1828, 1794 and 1795; witnessed a great sea-fight in its waters on 2 April 1801, when the English, under Sir Hyde Parker, with Nelson as his second in command, destroyed the Danish fleet; and, (to prevent the Danish fleet from falling into the power of Napoleon), was bombarded by the English from the 2nd to the 5th of September, 1807, when great destruction was wrought, both in houses and public buildings, and hundreds of persons lost their lives. Pop. with suburbs, 559,958. Consult 'Copenhagen, the Capital of Denmark' (1896); Nielsen, 'Denmarks Historie og Beskrivelse' (6 vols., 1887-92).

COPENHAGEN, University of, founded in 1478, by Christian I; destroyed during the civil wars; rebuilt by Christian III in 1539; destroyed by fire in 1728; rebuilt by Christian VI in 1732, and organized as at present in 1788. This is the only university in Denmark and one of the best in the northern part of Europe. It is supported partly by the government and partly by endowment; instruction is free to both sexes. In 1902 there were enrolled 3,000 pupils, and the library contained 400,000 volumes. It possesses also a large collection of Fine Arts, MSS, and another of Northern MSS. Connected with the university, which has five faculties, are a surgical academy, an observatory, a botanical garden, a zoological museum and a polytechnic institution.

COPERNICUS, an order of small Crustacea, characterized by the following aggregate of features: Animal consists of about 16 segments; limbs mostly two-branched; no carapace; development by the addition of new segments behind to a Nauplius larva. Except in the Branchiura, the simple eye of the Nauplius is the definite eye of the adult. Many widely different copepods are parasitic. The Branchiura are ectoparasites on various species of fish. The remaining copepods are divided into the Gymnoplea, in which the division between the front and hind portions of the body falls immediately in front of the genital openings, and behind the fifth thoracic feet, which are modified in the male into a copulatory organ, and the Podoplea, where the boundary falls in front of the fifth thoracic segment. The phosphorescence of the sea is largely due to certain small Gymnoplea. Certain of the Podoplea, forming the family Manastrellidae, have a very complicated development, for an amorphous parasitic stage intervenes, and the swimming Nauplius and a likewise free-swimming adult. Consult the article on the Crustacea by Smith and Weldon in volume IV of 'The Cambridge Natural History' (London 1899); the article on the Crustacea by W. Calman in Part VII; third fascicle in Sir Ray Lankester's 'A Treatise on Zoology' (London 1909); the article on the Crustacea in volume III of A. Sedgwick's 'A Student's Text-Book of Zoology' (London 1909).

COPERNICAN SYSTEM. The, an epoch-making reversal of man's ideas as to the place of the earth in the universe and the motions of the heavenly bodies, the full details of which were completed by Nicolaus Copernicus, a Polish astronomer, in the year 1530. Prior to the work of Copernicus, it was universally held that our earth is a fixed and immovable body, situated at the centre of the universe, about which all heavenly bodies, including the sun and the fixed stars, are in rotation. To account for the apparently complicated motions of the planets, which sometimes are retrograde and sometimes moving westward (or retrograding), it had been necessary to suppose that each planet is moving about the circumference of a small circle (called the 'Epicycle'), which in its turn is moving about a larger circular path around the sun. This older system, devised as early as 140 A.D. by Claudius Ptolemy (q.v.), an Egyptian astronomer, held its place as the true conception of the universe for upward of 14 centuries.

In the Copernican system it was clearly shown that the diurnal motion of the stars (their rising and setting) could be accounted for by assuming that the earth rotates on an axis with a uniform angular velocity, and further, that the complicated displacements of the planets among the stars could very nearly all be explained by the assumption that the earth and all of the other planets are revolving about the sun in circular orbits of which, however, the sun does not occupy the exact centre. The true paths, however (as we now know), are ellipses, and not exact circles. (See SOLAR SYSTEM). It was therefore necessary for Copernicus to retain in his system a few small
COPERNICUS—COPHA

"Epicyles" to account for certain small outstanding disagreements between the predicates and the observed motions. This new system of the heavens is accounted in the following words: "Copernicus, vir maximo ingenio, et quod in hoc exercitio magni momenti est, animo liber." In his celebrated work, dedicated to the Pope, Paul III, 'De Orbitum celestium Ratione,' (completed in 1530, although first published at Nuremberg 1543, folio; later editions appeared at Basel 1566, at Amsterdam 1617, at Warsaw in 1851, at Berlin in 1873), his system is developed.

Besides his principal work, we have also by him a work on trigonometry, 'De Lateribus et Angulis Triangulorum.' The first biography of Copernicus was written by the mathematician Gassendi (1654), and for 200 years this work served as the basis of all subsequent biographies of the great astronomer; but in more recent times the labors of Prowe and others have helped us to a better acquaintance with the facts of his life. Count Sierakowski erected a monument to his memory in Saint Anne's Church at Cracow, with this inscription: 'Nec sol, ne moveare' (Stand, Sun, do not move).

Thorwaldsen, one of the greatest sculptors of our time, executed a colossal statue of Copernicus for the city of Cracow, which is one of the noblest specimens of modern art. Another statue of him by F. Tieck has been erected in his native town. Consult Bertrand, 'Les fondateurs de l'Astronomie moderne' (Paris 1865); Bryant, 'History of Astronomy' (London 1907); Curtze, 'Nicolaus Copernicus' (Berlin 1899); Czyzak, 'Kopernik et ses travaux' (Paris 1847); Flammarion, 'Vie de Copernic' (ib. 1872); Gassendi, 'Vita Nicolai Copernici' (The Hague 1652); Muller, 'Nikolaus Copernicus der Alte monarch der neueren Astronomie' (Freiburg 1898); Prowe, 'Nicolaus Copernicus' (3 vols., Berlin 1884), the standard biography; Wolf, 'Geschichte der Astronomie' (Munich 1877); id., 'Handbuch der Astronomie, ihrer Geschichte und Literatur' (2 vols., Zürich 1893).

COPHA, a racially and linguistically distinct Indian family who first occupied extensive territory in California from far south to Mount Shasta in the north. The Cophan language was well developed and harmonious; but their political and social systems were little, if any, in advance of those of the other Indian races of California. There was considerable difference between the language (dialectically) and customs of the Cophas of the south and those of the north of California. Even the people of the 20 or more important villages of Cophas differed dialectically. There were two distinct branches of the Cophas or Copehan family, known as the Patwin and the Wintun. The Government Agricultural Commission appointed in the fifties to adjust the claims of the Indians and Mexican farmers to a small section of the Cophas then living on what is now known as Warner's Ranch near Los Angeles, in southern California, and their lands were sold without a hearing. They refused to leave their home, but in May 1901 the Supreme Court declared them white claimants. In May 1903 they were moved by the government to a fertile tract of land.
in the Valley of Pala, on the San Luis Rey, where they were subsequently joined by other members of the tribe.

COPHEUTA, an African king of legend and ballad verse who married the beggar maid, Penelopeh. Shakespeare in alluding to Copheuta calls the maid Zenelophon. There is a well-known poem by Tennyson on the subject, called the 'Beggar Maid', and the story is also told by Mauro Aragonio.

COPIAPO, có-pé-á-po', or SAN FRANCISCO DE LA SELVA, Chile, the capital of the province of Atacama, centre of an important mining district containing machine shops and smelting works. Silver and copper are the chief minerals obtained, but gold also is found. There is a railway connecting it with its port, Caldera. In 1819 and 1822 it was destroyed by earthquakes; and in 1851 it was again seriously damaged. The principal points of interest are the parish church; a bronze statue of Juan Trueby, the discoverer of the Chañarillo silver mines; and also a provincial high school, a mining school and a public library. Pop. about 12,000.

COPLAS DE MANRIQUE, có-plas de mán-ré-ké. This is the modest title of an elegiac poem by Jorge Manrique, (1446-79), generally considered the most eminently successful of the Spanish lyric poets of the 15th century. This success is due to the coplas, the more distinctive title of which is 'Coplas de Manrique por la muerte de su padre' ('Manrique's Couplets on the death of his father'). The elegy consists of about 500 lines divided into 42 coplas, or stanzas, in the old Spanish measure and manner, called redondillas con quebrados (quatrain with a short line in every third place). The poem was first published in 1492, 16 years after it was written, when Manrique's father, the Maestro de Santiago, died (1476), in whose honor it was composed. Spanish devotional poetry contains many exquisite gems, and the coplas are rightly placed among them. Grief for the death of his father has brought to the poet's mental vision a vista of the spiritual world, and a realization of the vanity of material things. The impression of time is ineffaceable. In 1833 appeared the remarkably fine English rendering by Longfellow, in which the versification, spirit and even wording of the original are followed as closely as possible. Besides its inherent quality, this poem is noteworthy in its independence of the three dominating poetic influences of the day, the artificial court verse, the Italian influence and that of the Renaissance.

There have been many editions of the Spanish text of the poem since the 1492 edition, notably the Madrid edition of 1799 with a gloss, contained in 'Proverbios de don Hilario López de Mendoza, Marqués de Santillana, y las coplas de don Jorge Manrique, todo con sus glosas, por D. Fermín Villalpando'; the critical edition published by R. Foulech Deibosc (Madrid 1902; Vol. XI of the 'Biblioteca hispanica'); other translations into foreign languages and commented versions. Many, if not all, of the cantares folkloricos have been gathered into anthologies. (Cf. J. D. M. Ford's 'A Spanish Anthology', Boston 1901, pp. 43-59). The entire text of the poem will be found in 'An-
his dramas in four volumes appeared (1873-86). Among his poems may be named 'Les intimités' (1868); 'Poèmes modernes' (1869); 'Un amour de Marie' (1876); 'Les exilés' (1876); 'Lesmois' (1877); 'Le naufrage' (1878). He has also published short stories including 'Le coupable' (1896), and 'La bonne souffrance' (1900) and a collection of essays 'MaÎtre André parle' (1906) and 'Lescure' (1913):

F. Coppée, l'homme, la vie et l'œuvre (Paris 1889); Gaubert, 'Français Coppée' (l. 1906); Druihlet, 'Un poète français: François Coppée,' (Paris 1902); Delmont, 'Trois illustres conquis de la foi: Coppée, Brunetière, Bourget' (1905).

COPPENS, Charles, American clergyman and educator: b. Turnhout, Belgium, 24 May 1835. He was educated at the Jesuit college, Turnhout, and the Jesuit scholasticates at Saint Louis, Mo., and Fordham, N. Y. In 1855 he entered the Society of Jesus, was ordained to the priesthood in 1865, and at various times was professor of the classical languages, of philosophy and the history of philosophy in the Jesuit colleges at Saint Louis, Cincinnati, Detroit, Omaha and Chicago. From 1891 to 1894 he was president of Saint Mary's College, Kansas, and in 1908 was appointed professor of literature at Saint Ignatius College (now Loyola University), Chicago. He is the author of 'Introduction to English Rhetoric' (1885); 'Oratorical Composition' (1886); 'Logic and Metaphysics' (1892); 'Moral Philosophy' (1896); 'Moral Principles and Medical Practice' (1898); 'The Living Church of the Living God' (1902); 'Systematic Study of the Catholic Religion' (1903); 'Protestantism, How it was Brought About' (1907); 'A Brief History of Philosophy' (1909); 'Who are the Jesuits?' (1911). He is a contributor to 'The Catholic Encyclopedia,' the American Ecclesiastical Review and various Catholic journals.

COPPER, a butterfly of the genus Chrysochode of the family Lycaenae. They are small, have the upper side of the wings some tint of copper-red or orange, frequently glossed with purple; the under side of the wings is marked with small spots and lines. The caterpillars are thick, most thick in the middle and with small heads. The genus is distributed over the temperate regions of both continents, 13 species inhabiting North America.

COPPER, a metallic element occurring abundantly in nature, and widely used in the arts, both in the pure state, and as an essential constituent of many alloys. It has been known from the earliest times, and is frequently mentioned by the ancient writers. Prehistoric weapons, tools and ornaments of copper, as well as domestic implements, remain in preservation to this day; and it has been commonly asserted that copper was known and used before iron, though some authorities consider the evidence of this to be inconclusive. The Romans obtained their best copper from Cyprus, and it was obtained over there, and for this reason the metal was known as Cyprium a., or Cyprian brass, a name that was later contracted to ‘cuprum and copper.’

Physical Properties.—Copper is red in color, and crystallizes in cubes, octahedra and other forms of the isometric system, twinned crystals being quite common. When in a finely divided condition it has a specific gravity of about 8.36; but the specific gravity of native copper is 8.94, and that of hammered or electrically deposited copper is about 8.90. It has a melting point of about 2000° F., and has a specific heat of about 0.093, and a coefficient of linear expansion of about 0.0000002, per Fahrenheit degree. Its tensile strength varies greatly, according to the physical condition of the metal. The following data are commonly used in engineering practice, as corresponding to the tensile strength in pounds, per square inch of sectional area: Cast copper, 19,000; sheet copper, 30,000; copper bolts, 30,000; copper wire, 60,000. The thermal conductivity of copper, at ordinary temperatures, is about 0.74 times that of silver. The specific electrical resistance of hard-drawn copper is 1.620 ohms, and that of annealed copper is 1.634 ohms. A wire of the metal that is one metre long and one millimeter in diameter has a resistance of 0.0206 ohms if hard drawn, and 0.020 if annealed. These data are for the pure metal, at the temperature of freezing water. The electrical resistance of copper increases by about 0.338 of its original value for each Centigrade degree of rise of temperature. The electrical resistance is also greatly increased by the presence of small percentages of iron, zinc, tin, phosphorus or arsenic, and hence great attention is paid to the purity of the copper that is intended for use in electrical conductors. Copper is very malleable and ductile, and may be drawn into small wire and hammered into exceedingly thin sheets. An alloy consisting of 11 parts of copper and 2 of zinc is even more malleable than copper itself, and may be hammered into foil comparable in appearance with gold-leaf, for which it is used as a substitute in certain kinds of work, under the name of Dutch metal. Copper becomes very soft and malleable when it is strongly heated and immediately immersed in cold water, its behavior under these circumstances being diametrically opposed to that of steel. It may be forged into any shape, but it will not bear more than a red heat, since it becomes brittle at higher temperatures. It does not oxidize readily under ordinary conditions, but becomes superficially tarnished with a coating of carbonate that resists the subsequent action of the oxygen of the air. Copper often gives off poor casts, because it causes the molten metal to absorb gases, and these, when given off again at the moment of solidification, make the casting porous. The castings are said to be much more sound when a small quantity of phosphorus is added to the molten metal—usually in the form of phosphor-copper. The large copper cylinders that are used in calico-printing are cast in molds, and are subsequently hammered under a steam-hammer until the metal is sound, and then turned down in a lathe until the surface is fine and free from defects.

Alloys.—Many alloys of copper are used in the arts, chiefly under the name of brasses or bronzes. Originally a brass was defined as an alloy of copper and zinc, and a bronze was defined as an alloy of copper and tin. This convention is still retained in a general way, but the same names are applied also, and very commonly, to numerous ternary alloys, containing copper, zinc and tin, which pass by insensible gradations from a twin brass to a true bronze, so that "brass" and "bronze" can no longer be
regarded as very definite terms. Alloys of copper with aluminum are called "bronzes," even when no tin is present. See Alloys; Brass; Bronze.

Chemistry.—The chemical symbol for copper is Cu (cuprum), and the atomic weight of the element is 63.5. Hg = 207.5. Performs two distinct series of salts, known respectively as "cuprous" and "cupric" compounds. In the cupric series the metal is a dyad, while in the cuprous series it enters into the ordinary formulae as though it were a monad. (See Chemistry.) Structural formulæ have been given, however, which indicate that the metal is really a dyad in both cases. The cupric series of salts embraces those compounds that are most familiar in the arts. Cupric oxide (known also as copper monoxide, or black oxide) is formed when metallic copper is heated in the presence of air. It may occur as a brownish-black amorphous powder, or in lustrous monoclinic crystals. Cuprous oxide is used by the laboratory for effecting the combustion of organic substances, the oxide being intimately mixed with the body to be oxidized, and the whole raised to a red heat, at which temperature the cupric oxide readily gives up its oxygen to either hydrogen or carbon. Cupric oxide (the formula of which is CuO) is soluble in acids, and yields, with them, salts which crystallize well. If a solution of any of these salts be made alkaline by the addition of a solution of common alkali, a light blue precipitate of cupric hydrate, Cu(OH)₂, is thrown down. Upon heating to 212° F., this part with a molecule of water and becomes reduced to the black oxide, CuO. If cupric hydrate be precipitated by adding the calculated quantity of sodium hydrate to a solution of copper sulphate, and the precipitate be washed and dissolved in ammonium hydrate, a blue solution is obtained, which is sometimes called "cupro-ammonium hydrouxine," and which possesses the singular power of dissolving cellulose (q.v.) without chemical change. When pure cupric oxide is desired, it is most conveniently prepared by heating cupric nitrate to redness. Cupric nitrate is readily prepared by dissolving metallic copper in nitric acid, or by crystallizing fromieves, containing the composition Cu₃(ONO₂)₂ + 6H₂O. Ordinary copper sulphate (cupric sulphate, or "blue vitriol") is manufactured in large quantities by dissolving scales of copper oxide (CuO) in sulphuric acid. It forms large blue triclinic crystals, which have the composition CuSO₄ + 5H₂O. The sulphate is used in calico-printing, and in the manufacture of various copper pigments such as Brunswick green and Scheele's green. Cupric chloride, CuCl₂, is formed by dissolving cupric oxide in hydrochloric acid, or by acting upon metallic copper by chlorine gas. It is soluble in alcohol or water, and forms acicular crystals having the formula CuCl₂ + 2H₂O. Cupric sulphide, Cu₂S, in the familiar black precipitate that is obtained when sulphuretted hydrogen gas is passed through an acid solution of a copper salt. (See Chemical Analysis.) Copper carbonate, CuCO₃, has not been prepared in the pure state, but a green precipitate having the formula Cu₂(OH)₂CO₃ is thrown down when carbonate of potassium or of sodium is added to a solution of a copper salt; this precipitate being identical in composition with the mineral malachite. Cuprous oxide, Cu₂O, or red oxide of copper, occurs native in red octahedral crystals, and it may also be prepared artificially by heating a mixture composed of equivalent parts of cupric oxide and finely divided metallic copper, or (more conveniently) by heating a mixture of cuprous oxide and ammonium carbonate, (NH₄)₂CO₃ over a Bunsen burner, until all the ammonia is expelled. It is a crystalline powder of a carmine color, melting at a strong red heat, and is used in glass manufacture for the production of a ruby color. The precipitation of this oxide from certain test-solutions is used as a test for the presence of sugar in urine. (See Uninary Analysis.) Cuprous oxide dissolves in various acids with the production of colorless salts, which are unstable, since they readily absorb oxygen and pass into the corresponding cupric salts. The most important cuprous salt is the chloride, which has the formula Cu₂Cl₂ and is formed by heating metallic copper to dull redness in the laboratory, or by dissolving a mixture of cupric oxide and metallic copper in hot hydrochloric acid. It is a white crystalline powder, insoluble in water or alcohol, or in dilute nitric or sulphuric acids, but dissolving in hot or cold hydrochloric acid. Its solution in either of these menstrua possesses the remarkable property of absorbing carbon monoxide gas. Copper may be detected in solution (1) by the formation of the blue hydrate of copper when a stream of sulphuretted hydrogen gas is passed through the acidified solution; (2) by the precipitation of the blue hydroxide, which blackens upon heating; (3) by the deep blue color that its salts give upon the addition of ammonia; and (4) by the precipitation of a red film of metallic copper when a clean, bright fragment of iron is immersed in the solution.

Physiological Action.—In medicine, salts of copper are used as astringents and as antiseptics, copper sulphate being the favorite salt. The soluble salts of copper are all exceedingly poisonous, and since the metal is very widely used in the arts, copper poisoning is quite common. In acute poisoning the symptoms are those of an asthagia in large doses. These usually develop in from 10 to 20 minutes, though they may be delayed as much as two or three hours. There is nausea and vomiting of bluish material, accompanied by a metallic taste in the mouth, and intense burning in the stomach and great abdominal tenderness. If all the copper is ejected by the emesis, the patient usually recovers. This is usually the case, but sometimes, when the dose is extremely large, vomiting is ineffectual. In addition to the symptoms already given, intense headache then develops, accompanied by great prostration and cramps, with small, rapid pulse and collapse; death sometimes following in from 4 to 12 hours, but more commonly after two to four days or more. Ordinarily that which occurs in nature, and in the Lake Superior district (Michigan), forms the chief ore. Chalcocite (Cu₂S) chalcopyrite (CuFeS₂), bornite (Cu₇As₅S₈), enargite (Cu₄AsS₄) covellite (CuS) tetrachloride (Cu₂Cl₄), and (2Cu₂CO₃·Cu(OH)₂), malachite [Cu₂CO₃·(OH)₂], chrysocolla (Cu₂SiO₃·2H₂O) and cuprite (Cu₂O), are all important ores.

Practically all our important copper deposits
are the result of heated waters related to volcanic activity. Typical contact metamorphic deposits are found in the Clifton-Morenci district of Arizona and in the limestone deposits of Bingham, Utah. Bisbee, Ariz., and Ely, Nev., are also classed with this type. The Butte, Mont., ores are typical volcanic, formed by hot waters. Globe, Bisbee and Clifton-Morenici all show typical replacement deposits in limestone. The Bingham camp in Utah is now noted for its enormous bodies of low grade disseminated ore, described as "bodies in wallrock," and Ray district of Arizona contain great disseminated deposits in Pre-Cambrian schists. The Lake Superior ores are chiefly native copper, occurring in the vesicular openings (amygdules) of lava flows, or replacing interbedded layers of conglomerate. As indicated above, one district may show several types of ore deposit. See Ore Deposits.

The greatest copper producing locality in the United States, and therefore in the world, is the Bingham, Utah, district. The ores there are confined to a comparatively small area lying north of Silverbow Creek, about two miles in length and one and one-half miles in width. Several of the mines now producing copper are grouped as Ely, the silver being replaced by copper at the depth of about 150 feet. This locality produced in 1816 349,500,000 pounds of copper, equivalent to 17.42 per cent of the entire output of the country. Inclusive of this amount the total production of this region since it was opened in 1868 has been 7,030,000,000 pounds — an output larger by more than 1,000,000,000 pounds than any other copper-yielding region known. The ore most common in this region, and which has supplied 75 per cent of the entire output, is chalcopyrite, or copper glance — a sulphide, carrying 29.8 per cent of metallic copper. This ore was originally pyrite, and has been altered by hot descending waters containing copper sulphate. About 20 per cent of the Butte copper production has been from enargite, a sulpharsenate of copper, carrying 48.67 per cent of the metal. About 4 per cent has been recovered from bornite, an altered chalcolite, carrying 63.3 per cent of copper. The remaining 15 per cent is supplied from covellite, chalcopirite and tetrahedrite.

Two other localities in the United States are eminent as producers of copper: the Keweenaw (Lake Superior) district of Michigan and the Bisbee district of Arizona. The former has a record of 6,029,777,200 pounds since its first production in 1845, practically all recovered as native copper. The Bisbee district began production in 1880, and its record stands at 2,219,556,000 pounds. Four other districts in Arizona have contributed to swell the grand total for the State to 5,767,668,935 pounds since the first mine within its borders was opened in 1873. The ores of Arizona are virtually the same as in Montana, the upper earth section being barren through alteration, and the lower 100-foot zone being the productive section. Chalcopyrite is the principal ore, altered in places to chalcocite and malaconite. See Superbenevolence defining. Mining the ore is but the preliminary step in the production of commercial copper. The crude ores must be smelted and the smelter product refined. The first treatment of the ore receives after being raised is concentration. This is a mechanical treatment with the object of eliminating as much as possible of the gangue or non-ore-bearing rock accompanying the ore. It makes use of the methods of hand-picking, wet and dry jigging tables and hydraulic separation. The ore then goes to the smelter.

The particular smelting process employed depends on the chemical constitution of the ore: that is, whether it is a sulphide, an oxide or native copper. With the sulphide ore the first operation is roasting, in order to oxidize the sulphur and iron present, and to volatilize the arsenic, bismuth and antimony. The roasted ore is then reduced in a blast furnace with anthracite coal, the product of this state being known as "mattes." This is again roasted and again passed through the blast furnace, the product being the impure copper known as "black copper." Oxide ore is reduced by mixing it with sulphide and then melting it for matte, as explained above. Native copper ore is smelted with anthracite and moved to a reverberatory furnace, with or without the addition of limestone flux. The product is crude metallic copper, which is often tapped directly into the refining furnace.

The metallic copper of various forms as it comes from the reducing furnaces contains as impurities some if not all of the following named minerals: iron, nickel, cobalt, lead, zinc, tin, arsenic, antimony, bismuth, sulphur, selenium and tellurium, besides a percentage of silver and gold. The object of the refining process is to remove to the utmost practicable limit all of these substances, and to turn out the metallic copper at least 99.8 per cent pure. The process of fire-refining is essentially an oxidizing process. It is, however, conducted at a degree of heat so high that such metallic impurities as arsenic, antimony and bismuth are volatilized. The other metals present are oxidized into dust and removed with the slag. The cuprous oxide (CO) held in solution in the metal is made into a small copper which is stable at the melting point of copper, is gradually reduced until only about one-half of 1 per cent remains, and this is left in the metal to make certain that no other metallic impurities present except in the form of harmless oxides.

The furnace used in fire-refining is of the reverberatory type. The more impure the metal the longer the treatment and the smaller the quantity which can be worked at one time. The "charge" of solid copper, in the form of cakes, is placed in the furnace basin by hand or by mechanical appliances, and the first or melting fire is set in the fire-box. If the copper is relatively pure it melts quickly; if impure "black" copper, it is much slower and may be hastened with an air blast. When the melting is complete the fire is drawn and a new, oxidizing fire built. As the slag forms it is constantly skimmed away and the clear metal exposed. Cuprous oxide is formed on the clear surface and is dissolved in the molten metal. The metallic impurities which have a stronger affinity for oxygen than has copper take up oxygen from the cuprous oxide and rise to the surface as slag. This operation is forwarded by forcing air into the molten metal through a tube, dipping well down below the surface. These pipes melt off in the great heat, but the iron is oxidized and rises to form part of the slag.
When the slag ceases to form, the melted copper retains about 6 per cent of cuprous oxide in solution. This proportion of cuprous oxide is reduced by the process of “poling” which consists of forcing poles of green timber, butt end first, into the mass of melted copper, and feeding them in as they burn away. A state of ebullition is excited by the vapors arising from the decomposition of carbonic oxide and hydrogen set free seize upon the oxygen of the cuprous oxide and the charcoal aids in the reduction. This operation is continued until a microscopic examination determines that the cuprous oxide is reduced to the correct proportion—from .5 to .7 per cent. If the poling is carried too far the other impurities give up their oxygen and resume their metallic state, and the entire mass of the copper has to be reoxidized to the 6 per cent content, and the poling done over again. When the copper has reached the proper constitution it is cast into ingots, ingot-bars, wire-bars or cakes.

The electrolytic method of refining copper is generally preferred in the United States, and nearly three-fourths of the total annual output is thus refined. This process is essentially electroplating. The anodes are of cast copper, about three feet square and one inch thick and weighing 475 pounds each. The cathodes are of pure electro-deposited copper, a little longer and wider than the anodes, and of one-sixteenth of an inch thick. The anodes are placed in the tank at from three to five inches apart; the longer distance for the more impure metal. A cathode is hung between each of two anodes and one at each end of the tank. The tanks are built of timber and lined with lead. They are two inches wider than the cathodes, allowing an inch of free electrolyte at each side. The tanks are usually about 10 feet long and hold from 20 to 30 pairs of anodes and cathodes, connected usually in multiple. Some few of the largest works, however, connect them in series. The electrolyte is a solution of copper sulphate in the proportion of 12 per cent, and acidulated with about 9 per cent of sulphuric acid. The copper content is held up to at least 3 per cent to prevent plating with arsenic where it is presented in the anode. The free sulphuric acid in the bath is limited to 12 per cent to avoid decomposition of the electrolyte and is held between 105° and 140° F. by means of steam coils. A continuous circulation of the electrolyte is necessary to prevent irregular deposition. The current ranges from 12 to 34 amperes per square foot of anode. The lower figures are adopted where arsenic is present. The voltage varies in different plants from 60 to 180. The time required to deposit the pure metal from the anode is about 20 days.

In 1916 there were active in the United States 13 refineries, nine of which employed the electrolytic method and five the furnace process on Lake Superior copper—one employing both methods. Their combined output for the year was 2,259,887,315 pounds, of which 1,950,255,629 pounds were electrolytic; 259,744,531 pounds were Lake and 39,337,155 pounds were casting and pig copper. Of the total refined product about 370,000,000 pounds were of foreign origin. In addition to this primary copper, the refineries handled secondary copper, producing from this source 768,526 pounds, to which were added 25,838,511 pounds of casting copper. A part of this also was foreign. Besides this output of metal the refineries also produced 55,622,345 pounds of blue vitriol, equivalent to 14,043,315 pounds of metallic copper.

Secondary Copper is the name given to the copper recovered by smelters and refineries from scrap metals, sweepings, skimmings and dross, as distinguished from the primary copper recovered from the ores. The production of secondary copper in the United States in 1916 was unprecedented, very large quantities of scrap from rolling mills and munition works finding their way to the secondary smelters. The record for the year shows a total of 140,000 short tons of copper and copper in alloys (exclusive of brass), and 300,000 short tons of brass containing about 70 per cent of copper, or about 210,000 tons—a grand total of 350,000 tons, valued at $196,320,000.

Commercial Copper.—In the American markets copper appears in three grades: electrolytic, Lake and casting copper. Both electrolytic and Lake grades test at least 99.8 pure. Electrolytic copper has a slightly higher degree of conductivity and a higher degree of endurance in bending and twisting tests, and is therefore preferred for electrical work. Casting copper is a fire-refined blister copper, testing sometimes as low as 98.5 per cent pure. It is unsuitable for electrical purposes on account of its high brass and sheet brass, but is available for making copper or brass castings. The principal forms in which copper is marketed are ingots about 3 by 3 by 9 inches, weighing about 17 pounds; ingot-bar, about 3 by 3 by 27 inches, weighing about 50 pounds; wire-bars, about 3/4 by 3/4 by 33 and up to 60 inches, and weighing from 85 to 250 pounds; and cakes, in round or square forms, ranging in diameter from 8 to 39 inches, and 14 by 17 inches up to 42 inches square, and from 1 1/2 to 8 inches in thickness. About one-third of the entire copper product of the country is used in making wire and electrical supplies and one-fourth in making brass.

Production.—The world’s smelter production of copper for the year 1916 amounted to 3,106,995,600 pounds (estimated in part), an increase of more than 31 per cent over the production of 1915, and almost exactly double the production of 1906. Of the grand total, the United States produced 568,124,884 pounds (62 per cent); Japan, 179,189,888 pounds (5.8 per cent); Chile, 157,474,578 pounds (5.1 per cent); Canada, 119,770,814 pounds (3.8 per cent); Mexico, 111,625,577 pounds (3.6 per cent); Spain and Portugal, 110,230,000 pounds (3.6 per cent).

In the United States the mine production in 1916 was 57,863,365 tons of copper ore, containing 2,005,875,312 pounds of metallic copper—an average of nearly 35 pounds per ton of ore. Not all of this was recovered (in 1917 and previous years, and this accounts for the variance with the figures given above for the United States under the world’s production. In 1,011 mines copper was the principal product, and these mines produced a total of 1,477,796,784 pounds. In 837 other mines copper was recovered as a by-product to the amount of 28,150,528 pounds.

Among the states, Arizona maintained first rank with the unprecedented output of 721,833,160 pounds (of the total 833,160 of the total of the output of the whole country, and an increase
of 60 per cent over her record yield of 1915. Montana held second rank, with 352,928,373 pounds. Michigan was third with 273,692,525 pounds; Utah fourth, with 240,275,222 pounds; Alaska fifth, with 119,981 pounds, and Nevada sixth, with 105,165,813 pounds. These five States with Alaska produced 93 per cent of the total copper output of the United States in 1916. The price of copper for the year averaged 24.38 cents per pound—as compared with 17.30 cents in 1915. The total value of the country's production was $474,238,000.

Imports and Exports.—In 1916 the United States imported a total of 462,315,580 pounds of copper, of which 258,927,315 pounds was in unrefined blocks, bars and pigs; 9,451,388 pounds in clippings and old metal and 84,611,320 pounds in refined plates, bars and rods. The remainder was the calculated copper content of ores (124,-878,905 pounds), concentrates (32,753,974 pounds), and matte and regulus (15,155,073 pounds), that in such form as could be processed was excluded. These importations came chiefly from Chile (121,342,981 pounds), Mexico (95,916,592 pounds), Canada (91,110,410 pounds), and Peru (77,672,763 pounds). The exports amounted to 789,759,317 pounds. Of the whole, 336,829,464 pounds went to France; 184,506,740 pounds to the United Kingdom, and 113,764,478 pounds to Italy.

COPPER: Discovery and Development. Copper in a metallic form occurs either alone or in connection with chemical combinations of the same metal, in many parts of the earth, notably in Peru, Chile and neighboring countries, in Alaska, in parts of South Australia and melanesia, in New Guinea, in Germany, in several of the United States and elsewhere. In few localities has it been found in quantities as large, or under circumstances as favorable for large mining operations, as in Lake Superior region. The attention of the early navigators to America, next to the finding of a northwest passage to Asia, was directed to the natural resources of the New World, and especially to its deposits of valuable minerals. Of early references to copper in North America, that of Ferrazavinedo, in Germany, is the first. He saw, on the coast of New England, beadstones of that metal in the ears of the natives. In 1553 Jacques Cartier, on his second voyage to the Saint Lawrence River, was told by the Indians that native copper—coppur rouge—by them called "caignetdaze," came from the Northwest, from the region known to them as Saguenay, and they gave to their chief, Donnacona, when he sailed for France with Cartier, a large knife of that metal.

In 1610 Champlain, on one of his excursions up the Saint Lawrence, is said to have been given a piece of copper a foot long, that was reported to have come from the bank of a river near a great lake. The Indians asserted that it was gathered in lumps, and, after having melted it, they spread it in sheets, smoothing it with stones.

On Champlain's map of 1632 we find in a lake northwest of Lake Huron an island marked "where there is a mine of copper." This might have been either Michipicoten Island or Isle Royale.

Sagard, who published his 'History of Canada' in 1636, wrote that Bruslé, one of Champlain's interpreters, showed him a "lingot" of copper which had come from a mine 80 or 100 leagues from the Hurons.

In 1660 Pierre Esprit Radisson, probably the first white man to explore the shores of Lake Superior, was led by an Indian companion to a place near the banks of a small stream that flows into the lake east of the Pictured Rocks, where he saw "many pieces of copper uncovered," and was told that a mountain near by was "nothing else." As is supposed the area of the copper-bearing rocks the copper was either "float" or had been hidden there by the Indians. Radisson was also told that an island at the end of Keweenaw Point (Manitou Island?) was "full of copper." In the Jesuit Relations of 1659-60 it is said that an Indian reported copper from Lake Superior in pieces as large as one's fist. In the Relations of 1666-68 Father Allouez reported pieces of true red copper from an island in Lake Superior, which, according to his description, was probably Isle Royale.

In the Relations of 1669-71 Father Dablon reports red copper from the Ontonagon River, concerning which he says opinions differed as to where it was actually found; and also from the end of Keweenaw Point—the latter place being an islet which appears to be six feet square, and is said to be all copper. This sound like the report made to Radisson, except that no size was given to Radisson's islands, whose distance from the mainland corresponds with that of Manitou Island. The Jesuit Fathers were also assured by the Indians that in the interior to the south of Lake Superior "mines" of copper were found in different places. This might possibly have some significance in connection with the so-called prehistoric miners, if the term mine had been used by the Jesuit Fathers with the meaning usually attached to it 40-day, as something in esse rather than in posite—a rock formation carrying a workable deposit of mineral, rather than an isolated mass, one that had been removed to a distance from the parent bed. We know that the term was used loosely by later writers, even in the first half of the 19th century. H. R. Schoolcraft in 1821, when referring to the celebrated copper mass on the Ontonagon River, speaks of it as a mine.

With the exception of the "islet" referred to by Dablon which was possibly a piece of mass copper projecting out of the water at a shallow spot near the shore, all of the copper found as late even as the latter half of the 18th century appears to have been "float," that is, masses of smaller or larger size that had been transported from their original beds, generally by glacial action. Indeed it is just this that probably explains the statement of Capt. Jonathan Carver in 1778 that the copper itself costs nothing.
The area of "boat" copper appears to have extended much beyond the territory immediately tributary to Lake Superior, for in 1700 Le Sueur speaks of pieces of it found near the mouth of the Chippewa River and another about four leagues above the mouth of the Saint Croix River, in Wisconsin. In later years similar finds have been reported as far south as Indiana and Illinois. But while Lake Superior was supposed to be the source of this copper we do not find any evidence that any white man—except, perhaps, Father Hennepin—had ever seen anything that could be called a copper mine (sic), as early as the time of Chateaugoux. The latter in his history of New France, published in 1744, says "It is certain that there has been discovered in several places a considerable quantity of this metal, without even being obliged to dig much." It is true that La Hontan early in the 18th century speaks of copper mines along Lake Superior, but he does not claim, like Hennepin, to have seen them. We also find many references to copper "mines" in the interior as reported by the Indians, who usually showed great reluctance to disclose their whereabouts to the white man.

Thus far the pieces of native copper found on Lake Superior were gathered on the edges of the islands and on the borders of the lake along the highways of navigation by canoe. It was not until 1765 that Alexander Henry, attracted by Indian reports of a large mass of copper, the one referred to by Dablon, visited the Ontonagon River and went up stream several miles above the junction of the east and west branches. He found, on a clay bank, at or near the edge of the stream, the copper mass, with some rock adhering to it through which ran small veins of copper. In 1771, revisiting the same place, he noticed also much copper bedded in stone, and left a party of miners there, "to make a trial on the hill, till we were better able to go to work on the solid rock." They dug 40 feet into the clay bank and found frequent masses of copper. All went well during the winter, but when spring came, the clay thawed and caved in, and the party left. In accounting for the above facts, Henry added that "The copper ores of Lake Superior can never be profitably sought for but for local consumption. The country must be cultivated, and peopled, before they can deserve notice." In a footnote to the above, having in mind the more roseate view then recently expressed by Alexander Mackenzie and earlier by Captain Carver, he adds, "The copper mines of Lake Superior have been more than once represented to the world in colors capable of enticing Designers; and the statement in the text will not have been uselessly made, if it should at any time serve as a beacon to the unwary." The fame of Henry's operations was probably spread abroad at this time, although his book was not published until 1809.

Henry's visit to the Ontonagon River marks the culmination of the efforts of two and a half centuries of search for the original source of the Lake Superior native copper—its location in what is known in that region of Visit as "the inland sea. It also marks the beginning of an industry that in spite of Henry's warning has grown to be one of the most important of the Northwest. Possibly the troubles that distracted the country during two wars, and the boundary disputes in the region of the Great Lakes, rather than the adverse sentiment caused by Alexander Henry's failure, kept back the development of this region. But the spirit of expansion which during the administration of Jefferson found expression in the expeditions of Lewis and Clark and of Pike later found an echo in Gov. Lewis Cass, at whose initiative and under whose personal leadership an expedition to the Northwest was effected in 1820, one of the objects of which was to investigate the copper "mines" of Lake Superior. Henry R. Schoolcraft accompanied this expedition as mineralogist. They visited the Ontonagon copper mass, which Schoolcraft recognized as having been removed from its original bed of "serpentine" rock; from which circumstance he inferred that there must be extensive "mines" in the vicinity.

In 1832 Schoolcraft, this time with Dr. Douglas Houghton as geologist to the party, again visited the Ontonagon River and the famous copper mass. On the way thither Dr. Houghton found copper embedded in the trap rocks on the western side of Keweenaw Point, and expressed the opinion that the "trap rock formation was the original source of the masses of copper," and that-copper would probably not be found in that region in any other rock than trap, which Dr. Houghton at that time had seen only on Keweenaw Point.

During 1832 and 1833 Dr. Houghton visited the south shore of Lake Superior three times. Five years later he was appointed State geologist of Michigan and before his death, in 1845, had carefully examined the copper-bearing formations, had ascertained their altitude and extent, had located a number of copper veins and had given to the world enough information to attract at once a large body of prospectors. The interest thus stimulated in the Michigan copper district soon led to the opening of some of its most famous mines. The success of this new industry, as predicted by Captain Carver, was soon assured by the building of the canal at Sault Sainte Marie, which afforded the products of upper Michigan cheap transportation from the wilderness to market.

**Geology.**—The "trap" rocks that constitute the greater part of the Lake Superior copper-bearing formations are a series of old lava flows. All around the western end of the lake through Michigan, Wisconsin and Minnesota, the trap beds extend for several miles in width, striking nearly parallel with the general trend of the shore line, and dipping always toward the lake, the dip being usually flatter near the shore than it is further back. Associated with these trap beds occur beds of reddish conglomerate or sandstone at different intervals, composed of the debris of the traps and associated more acid rocks.

On the extrusion and flow of lava which has been under pressure, the pent-up gases in it expand near the surface of the flow like the bubbles in a glass of champagne, and as the surface of the flow rapidly congeals, each gas bubble forms a cavity or amygdale. In the same manner portions of the lava beds, which are thus characteristic of the upper surface of the bed, though sometimes found at the bottom—also in cavities caused by chemical changes or by fractures, and occasionally in the conglomerates—are frequently found the
deposits of native copper that characterize these formations. At different angles to the strike of these beds fissure veins of later age are found, several of which, notably the Cliff, Phoenix and Central, proved also to be rich in copper, which in the Cliff mine carried with it a large amount of siderite, a large scale. These constitute minute flakes, or in more compact bodies from the size of a pin head or less to masses of 500 tons or more in weight, of shapes rounded like a boulder or branching irregularly through the poorer rock. A large mass of such a body occurred in the conglomerates, but in these beds individual boulders are often found entirely replaced by copper. In the early days of mining here it was the fissure veins that were sought and worked almost exclusively. They produced a large amount of mass in a small area of ground, and this could be made marketable without the expense of treatment in a stamp mill. By the time the fissure veins were beginning to show signs of exhaustion the amygdaloid deposit was already being worked on a large scale. The substitution of air drills for hand drills and of high explosives for black powder helped to confirm this promise. Meanwhile the discovery of the Calumet conglomerate with its wealth of mineral had been made. As work on the fissure veins was gradually being abandoned, the masses were in popular parlance grouped into two classes — amygdaloids and conglomerates. To-day, however, it is apparent that all so-called amygdaloid copper deposits are not properly so named and a further division is possible. Throughout the formations, especially along the upper surfaces of conglomerate beds, planes of weakness have existed along which there has been more or less movement of the overlying formations. These planes of weakness not infrequently coincide with the amygdaloidal upper portions of the trap beds, both in strike and dip, and shearing movements along them have fractured the rock to so great an extent as to form a veritable breccia, in which coppfer is at times disseminated in workable quantities. Indeed the copper often occupies the interstices in these breccia beds, while the amyguules of the rock composing the breccia are entirely filled with minerals other than copper. In a case of this kind the term “amygdaloid” deposit, if not confusing, is at least inexact.

Exploration.—The greater part of the area underlain by the copper-bearing formations of Lake Superior rise to an elevation of from 400 to 700 feet above the lake. Several ridges stand out above this general plateau whose summits show naked rock, and even in the lower ground there are some exposures of rock in place, but over a large area there is a heavy covering of ground — sand, gravel and boulders — which completely conceals the rock surface and renders difficult a successful search for mineral. When mining operations began on Keweenaw Point the attention of the early prospectors was attracted by grooved stone hammers, some of which weighed as much as 30 pounds, and by the side of shallow excavations that showed copper embedded in the rock. These traces of crude mining by a former generation evidently served as a guide to the early white miners in locating the most prominent deposits. The ridges naturally consist of the hardest rock — the massive trap beds that have resisted erosion better than the softer amygdaloids. By following these ridges the early prospectors located the fissure veins, and with them some quasi fissure veins that ran parallel with the formation and contained large masses of copper, rough prongs of which projected above the rock surface. A "conformable vein" or "amalgdoid deposit thus located would be followed for miles, until perhaps it disappeared beneath a covering of drift. Sometimes a large block of cupriferous rock would be found, whose angularity indicated its probable nearness to the parent bed. Surfacing the direction of the glacial movement the prospector would dig a series of trenches or costeans at right angles to the strike of the formation, on the side whence the glacial movement was supposed to have come. But here obtained, many of the early copper deposits were not recognized that Keweenaw Point had been the scene of glacial movements from at least two directions, and thus in one well-known instance explorations were vainly made in the wrong direction from the blocks of rich float-rock.

With the progress of geological investigation it was realized that the conglomerates interbedded with the traps and representing old sea beaches were more or less continuous around the ancient basin. Their character, it is true, does not remain constant from point to point, for this depends in a great measure upon the rocks that lay behind them during the process of their formation. They furnished reliable aid to correlation, however, and could be followed and recognized for long distances even across drift-covered areas. The lava beds, on the other hand, from their broad general similarity, usually were not safe guides. In some cases, however, even these could be identified over long distances by some marked peculiarity. If a workable copper deposit was known to exist near one of these conglomerates or near a recognizable trap bed, the latter was traced out and a pit or trench was then dug at a known distance from it equivalent to the unit thickness of that bed from the copper-bearing bed at the place where the latter was last seen, allowance being made for ascertainable changes in the dip of the formation between the two places. In this way the Baltic lode of the Champion Mine was located about three miles from the Baltic Mine, although in the intervening distance the strike of the formation had changed 34 degrees. By taking the great Greenstone ridge in Keweenaw County as a guide the position of the northward extension of the Kearsarge amygdaloid bed was in a similar manner approximately ascertained about six miles from the nearest point at which it had been previously opened. While trenching was in progress to uncover this bed, the recognition of an isolated outcrop of its footwall — a very characteristic rock — pointed more exactly to the location of the amygdaloid. Exact calculations are not always possible, for the dip of the beds from younger to older may change — commonly does change — and can sometimes be determined at any one place, in advance of mining. The diamond drill is often an important aid in cases.
like the above, where the thickness of the drift-covering makes trenching impossible or too expensive.

Development.—A mere deposit of mineral or an isolated mass is not necessarily synonymous with a "mine," as previously remarked. As now, frequently understood, a "mine" is a deposit sufficiently exploited to afford reasonable hopes that it can be worked at a profit. To ascertain whether a native deposit of copper in Michigan will pay requires a good deal of time and the expenditure of a large amount of money. Shafts must be sunk, generally, in the lode to test the latter continually in depth, and drifts must be driven from the surface, to show the lateral extent of the deposit, its uniformity and richness. If the rock mined carries from 1 to 2 per cent of fine copper, or from 20 to 40 pounds per ton, and the lode is 10 feet or more wide, the management knows that by mining on a large scale the costs can be brought down to a paying basis with copper at about 12 cents a pound. Some mines with wide deposits can make a handsome profit at the last named price. In the present literary stage of mining these factors must be ascertained before a permanent and economical plant can safely be installed. By neglecting this precaution several notable failures have been made and expensive plants erected only to be sold out later at a loss. In Michigan the copper deposits usually extend to great depths, some of the older mines being a mile deep vertically. Powerful hoisting engines and other machinery in proportion are ultimately necessary for this work. The permanent shaft can be sunk in the footwall so as to enable the removal of the maximum of copper-rock without endangering the shaft. The percentage of copper-rock that can be safely and cheaply mined often has an important bearing on the method of mining that is to be adopted. The shafts where possible follow the dip of the lode, thus avoiding the unnecessary mining of barren ground to reach the lode from the shaft, as would be the case if the latter were vertical. Shafts are now placed a thousand feet or more apart. The drifts from the shafts are driven along the lode from 85 to 150 feet apart, measured on the dip of the lode. From these shafts as starting points all of the lode matter possible is broken down from above by "stopping," as far as the next higher level, by various methods; sorted where possible, and the barren portions left in the mine or returned to it from the surface, as "filling" to support the hanging wall. The amount thus discarded will vary according to the nature of the deposit, up to 40 per cent of the total rock mined. In some cases the copper is so evenly disseminated through the rock that sorting is impracticable and all of the rock goes to the mill. The copper rock from the stopes is trammed by hand, or where the shafts are far enough apart, by mechanical power, to the nearest shaft, hoisted in the cars in a cage, or in skips of a capacity of two to eight tons, dumped on the surface in the upper part of the rock-house and here sometimes sorted again, or all of it delivered at once to the nearest mill. When crushed to small sizes; it is then transported to the stamp mill. The larger masses of copper mixed with rock are placed under a heavy hammer by which the rock is beaten off; the masses are then sent directly to the smelter. After going through the breakers the fine rock falls into large bins and is drawn off into railroad cars for transportation. To save expenses as many operations as possible are performed by gravity. A constant effort also is made to introduce labor saving mechanical devices both underground and on the surface.

Stamping.—The crushed copper-rock from the mine is sent to the stamp mill, which sooner or later forms part of the equipment of every permanent mining company. Nature seldom furnishes a place that combines all the essentials of a good stamp mill site. The principal of these is an abundant water supply, dumping-room for the waste products, sufficient elevation for handling the material by gravity through the different stages of the stamping process, accessibility by railroad and storage room for fuel. The absence of any one of these essentials adds materially to the cost of construction or to that of subsequent operation. Where possible, the side of a hill is selected near a body of water. A stream that will supply three and a half million gallons of water per day is great for a one-head mill with a capacity to stamp from 500 to 700 tons of malahydrate or 300 tons of conglomerate in 24 hours. If the stream can be dammed at an elevation sufficient to deliver its water by gravity at the mill about 40 feet above the point where the waste launders leave the latter, its water is utilized in that way. A dam built on a stream near the shore of Lake Superior, to serve two mills that have a daily stamping capacity of about 4,000 tons, cost about $250,000. To pump water from Lake Superior for a mill of nearly the same capacity costs between one and one and a half cents per ton of rock stamped, to which must be added interest and maintenance charges on a pumping plant that would cost nearly $100,000. To obtain water from Lake Superior requires a tunnel under the lake or a large pipe leading from the shore to a crib far enough out in the lake to avoid being choked by sand and other obstructions. This distance is usually about 1,000 feet.

Where the stamp mill cannot be built low enough to enable the rock cars to run from grade into the space above the rock bins, the cars must be hauled up one by one, by special haulage mechanism. Where the mill is built with the main lower floor but slightly elevated above the level of the dumping ground, the stamp-sand may eventually have to be carried long distances in launders and sometimes must also be lifted to the necessary height by immense sand wheels. Where mills have been built on the exposed shores of Lake Superior the waste sands are removed from time to time by storms, but if built on bays or sheltered places, the heaping up of the sand is likely to give trouble unless the waste launders from the mill are sufficiently elevated above lake level.

The function of the stamp mill is to crush the rock fine enough to be able to separate it from the copper and to recover a maximum amount of the latter. The copper rock from the mine is hauled from the storage bin at the back of the mill, which is of sufficient capacity to provide against slight delays incident to transportation. From the bottom of the bin the rock runs over a feed
COPPER

Smelting.—The product of the mine that goes directly to the smelter is in the form of masses, often several tons in weight. This mass of copper with the product of the stamp mill constitutes what is called "mineral." Large pieces of rock crushed in the breakers at the mine frequently contain the mineral mass collected from the rock as the latter goes into the stamp-heads and shipped to the smelter in barrels. This product is called "barrel work." Some pieces of copper as large as one's fist unavoidably get into the stamp-heads and these are taken out through the hydraulic discharges as described above and are shipped as "headings." The finer copper mixed with more or less rock is collected in different grades, the number of these being sometimes as many as six, but in modern practice being reduced to as few as two. The smallest of these grades are called "fines" and "slimes," of which many particles are often minute and light enough to float on a moderate current of water, and hence are difficult to save.

The impurities found with the product of the stamp mill are principally the "vein" rock, from which, owing to the intimate mixture of the copper and rock, the separation of the one from the other has been impossible, and impurities, such as iron, sulphur, arsenic, with traces of nickel and of some of the rarer elements. The function of the smelter is to remove the impurities and to leave the copper in a condition best fitted for the different uses to which it is to be put. These are principally: (1) For electrical purposes, as wire, where great conductivity is required; (2) for rolling into plates, where great tensile strength may be desired; and (3) for mixing with other metals to form alloys. The forms in which it leaves the smelter are indicative of these uses. They are respectively bars, cakes and ingots. When it is known that .07 of 1 per cent of arsenic in copper will reduce the conductivity of the latter to 75, and that arsenic is almost always present in copper ores, and to some extent also in native copper, the necessity of careful refining will be realized. Copper derived from copper ores generally contains enough impurities to render it unfit for electrical purposes unless it is refined electrolytically. For this purpose it is cast into plates called anodes. In the Lake Superior region the copper derived from the higher or younger formations of the copper-bearing series has generally been found to be pure enough on leaving the smelter to be used for wire (99.9 per cent fine and upwards), but the copper from the lower or older beds usually carries enough arsenic to render such a use impossible without further refinement. This copper, on the other hand, with the proper percentage of arsenic, is tougher and more desirable for some uses than the purer grade.

The mineral is treated first in a melting or reverberatory furnace, the flame passing from the fire-box over the copper under a low arched roof with a stream of air brought in from below. This is an oxidizing process and the slag that separates from the copper and is drawn off from the surface of the latter contains from 8 to 14 per cent of the metal, largely in the form of oxides, mixed with a large amount of the impurities. After the removal of the slag, charcoal is thrown on top of the melted copper and the liquid mass of the latter is agitated by
the insertion of green poles of hardwood ("poling"), the ignition of which and of the charcoal produces the carbon that takes up the oxygen in the copper, thus changing the action of the furnace from an oxidizing to a reducing process. This is often preceded by blowing a chamber of air preceding the molten copper. By dipping small buttons of the metal in a trial ladle from time to time, if the copper sets with a level surface the process of "poling" is complete. If the reduction is overdone, the charge must be remelted. When the copper is pouring, it is ladled or run out into moulds. The tendency of modern practice has been to increase the size of the melting furnace contingent upon the ability to keep the heat throughout of an even temperature. Some modern furnaces can take a charge of 100 tons at a heat. It has also been found advantageous instead of doing the refining in these large melting furnaces to run the copper from them into special refining furnaces. The fuel used in this latter operation is soft coal.

The slag derived from the reverberatory furnace is broken up and eventually taken to a blast furnace, otherwise called a cupola, where the action is reducing, and where the slag is remelted. This process is substantially the same as the process in the reverberatory furnace except that the copper being mixed with a large amount of slag, other substances such as limestone, iron or silica are added to form a proper mixture for refining and for the proper separation of the copper. The relative amounts of the several materials are ascertained in advance by analysis. All of the ingredients are mixed with anthracite coal, with or without coke, and to stimulate ignition a cold blast of air under compression is driven upwards through the mass. The copper falls out and is drawn off at the bottom of the furnace, containing even then a larger amount of impurities than the product of the first process; this copper should be refined separately. In practice, the slag-copper is poured into ingots or ingot-bars, but never into wire bars. It is sometimes specially branded.

The slag that is finally rejected contains about 7 of 1 per cent of copper and is usually distilled into the furnace and granulates it and carries it away in launders.

COPPER AND BRASS INDUSTRY.

The Naugatuck River has its sources in the hills of northwestern Connecticut and flows southward about 40 miles to its junction with the Housatonic River at Derby, taking its course through a narrow, winding valley. From Torrington, at the head of the valley, to Derby there is a fall of about 600 feet, and wherever the valley broadens to give room for a village or town, there are water privileges, and the power is utilized for manufacturing purposes. In this narrow valley, which contains a large population, evidence of thrift and prosperity is everywhere seen in the neat, comfortable homes of those engaged in industries by whose fine fuses are the employers. This is the seat of the brass-rolling industry of America. Many large corporations are here directly engaged in this business, producing about three-fourths of the total quantity of rolled brass manufactured in the United States, giving direct employment to 25,000 persons and indirectly to many thousands more. About one-half the total quantity of copper consumed in the mills of the United States is conveyed annually to the Naugatuck Valley for use in these manufacturing establishments.

Here were found the men of foresight, energy, skill, and capital, who have established and continued the industry which is carried on to the present day, and the products of which have made the Naugatuck Valley one of the most important in the country. The brass-rolling industry has reached a point where the plants are the most important in the country.
COPPER AND BRASS INDUSTRY

noteworthy fact that nearly all of the brass-mills outside of the State of Connecticut were constructed or are operated by Connecticut men. Israel Coe, a farmer of Connecticut, John Huntington, a programmer, and the Hon. G. Phelps, a capitalist of New York, and founder of the house of Phelps, Dodge & Company, were pioneers in brass manufacturing in this country, and in 1834 they built a brass-mill at Wolcottville, now Torrington, Conn. Previous to 1830 brass was imported, or manufactured here in a very primitive way. As early as 1811 James G. Moffett of New York rolled brass in small quantities, using for power a sweep actuated by oxen. In 1802 the manufacture of gilt buttons was begun in Connecticut by Abel Porter & Company. At that time these buttons were articles of fashionable use. To obtain brass for this purpose the mixture was cast in ingots at Waterbury and taken to Bradleyville, near Litchfield, Connecticut. There was an iron-mill driven by water power; here it was broken down and rolled into strips, and returned in a rough state to the button factory in Waterbury, where it was rolled thinner by being passed through a mill and then cold drawn. Spelter, which was import ed in large diameter, driven by horse power. The copper for brass-making was obtained from old boilers which had been used in distilleries and in sugar-making. This copper was cast into ingots and mixed with spelter, which was obtained from abroad. In 1808 Abel Porter & Company purchased the water power now owned by the Scovill Manufacturing Company at Waterbury, and soon afterward put in rolls suitable for brass. In a period of about 20 years they rolled brass, but it does not appear that their production was any more than enough to supply their own requirements. In 1830 the firm of Holmes, Hotchkiss, Brown & Elton established a mill and engaged in the manufacture of sheet brass at Waterbury. This was substantially the beginning of the sheet-brass business in America, although the metal, in small quantities, may have been occasionally supplied to consumers before that time by the firm of J. M. L. & W. H. Scovill and by Benedict & Coe of Waterbury.

There was at that time also a demand for brass kettles, which were manufactured in England by a process known as the "battery" process; that is, they were hammered into shape from metal blanks. The establishment of the mill at Torrington, at the head of the Naugatuck Valley, in 1834, was for the purpose of rolling brass for use in manufacturing these kettles and to supply the growing demand of the button factories. A small rolling-mill was built, with machinery imported from England, and Israel Holmes of Waterbury was engaged as manager of the mill. There was great difficulty in securing workmen competent to carry on the business. Mr. Holmes was sent to England and succeeded in procuring a few experienced men. He afterward made another trip abroad for the same purpose, but the English manufacturers, fearful of losing their American market and from hiring their men, and it was with great difficulty and some danger to himself that he succeeded in embarking a colony of workmen and their families, about 30 persons in all. These were landed at Philadelphia, taken in a schooner from there to Hartford, Conn., from which place they proceeded on foot through the woods, a distance of 25 miles, to Torrington.

From this small beginning, and with no end of difficulty and discouragement, the enterprise continued to grow. Connecticut copper company, and in 1840 Edwin Hodges of West Torrington started a mill for the purpose of making brass kettles and also for drawing brass wire. This seems to have been the first brass wire-drawing establishment in this country. It was located in Cotton Hollow, in the town of Torrington. The enterprise was unsuccessful and the mill was soon closed, with the loss of all the capital invested. In 1841 the original enterprise at Torrington was made into a stock company, with a capital of $56,000. It was named The Wolcottville Brass Company, and the incorporators were John Hungerford, Anson G. Phelps and Israel Coe. The records of this company for the first few years of its existence contain some interesting details. The copper used was imported from Chile, or was obtained in the form of old copper, which was collected from different places throughout the country. The price of copper was then $8 per pound. Spelter, which cost $8 per pound. The fuel used was mainly wood, but some Leshigh coal was procured, which cost, at Hartford, $8.43 per ton, to which was added the cost of transportation by teams from Hartford to Wolcottville. Firebrick for the furnaces cost $60 per 1,000. The manufactured product, in the form of rolled and sheet brass, was valued at 26c to 30c per pound. It was taken by teams either to Waterbury or 25 miles across a hilly country to Hartford, and from there shipped on sloops to New York. Upon the site of the works occupied by the Wolcottville Brass Company are to-day the factories of the Coe branch of The American Brass Company. The name of Anson G. Phelps is perpetuated by the city of Ansonia, the Ansonia branch of The American Brass Company and the Ansonia Clock Company, as well as by the firm of Phelps, Dodge & Company, Inc., which he founded; and the name of Israel Holmes appears in the title of the corporation of Holmes, Booth & Haydens, of Waterbury.

The decade from 1840 to 1850 saw the birth of many of the prominent brass manufacturing corporations of the present day. In 1848 a joint-stock company at Waterbury was organized under the title of the Benedict & Burnham Manufacturing Company, with a paid-up capital of $100,000. Aaron Benedict was president and treasurer and John S. Mitchell secretary. Mr. Aaron Benedict continued at the head of the company until his death in 1873.

The Waterbury Brass Company began business in 1845 with a capital of $40,000. Among the incorporators were John P. Elton, Lyman W. Coe, Israel Holmes and Hobart V. Welton.

In 1849 the Naugatuck Railroad was completed and the product of the valley mills was thereafter shipped by rail to tidewater at Bridgeport.

In 1849 Thomas Wallace and his sons, John, William and Thomas, began the business of wire drawing at Birmingham, Conn. Their cash capital was $500. Their knowledge of their trade enabled them to increase their business and in a few years they built a factory at Ansonia, which has been greatly enlarged and
COPPER AND BRASS INDUSTRY

is now owned and operated by the Coe branch of The American Brass Company.

The Scovill Manufacturing Company of Waterbury succeeded the firm of J. M. Leary & W. H. Scovell and was incorporated in 1850 with a capital of $200,000, which has since been increased to $5,000,000. They now manufacture brass, German silver, etc., and are extensive remanufacturers of metal.

The Coe Brass Manufacturing Company of Torrington, Conn, was founded by Lyman W. Coe in 1863, and succeeded the Wolcottville Brass Company. Lyman W. Coe, the son of Israel Coe, was the president of the corporation, which began business with a capital of $100,000. Their capital has been increased from time to time and they are now merged in The American Brass Company.

In 1844 Anson G. Phelps purchased extensive lands in the vicinity of what is now the city of Ansonia, which was founded by him and named in his honor. He constructed a dam across the Naugatuck River, a canal, large reservoirs for water power and built a mill for rolling copper. The firm of Phelps, Dodge & Company had for some years prior to 1844 operated a copper rolling mill in Ansonia, Conn. The water privilege at Ansonia is now owned and operated by the Ansonia Land and Water-Power Company and is the source of water power for the city of Ansonia. Mr. Phelps brought from the Wolcottville works J. H. Bartolomew and C. C. Swan, who managed the business at Ansonia under the name of the Ansonia Brass and Battery Company, the term "battery" being indicative of the process by which brass kettles were hammered from metal blanks. This method of making kettles was in use until 1851, when it gave place to a patented process for spinning kettles from circular blanks of metal. The business of the Ansonia Brass and Battery Company was conducted by the firm of Phelps, Dodge & Company of New York. A brass-mill was built, and later a wire-mill. The company afterward engaged in the manufacture of clocks. In 1869 this manufacturing enterprise was incorporated under the name of the Ansonia Brass and Copper Company. In 1877 the manufacture and sale of clocks had increased to such an extent that it was decided to form a new joint-stock corporation under the name of The Ansonia Clock Company, which began business on 1 Jan. 1878. The location of this company’s business was transferred to Brooklyn, N.Y., where large factories have been erected and are now in operation, producing clocks and watches which are marketed in every part of the world.

Taking into account the capital employed and the magnitude of its operations in brass and copper this company is the most important brass manufacturing enterprise in the world and the largest single consumer of copper, giving employment to about 15,000 persons.

During many years brass manufacturing was conducted on a very small scale, and, although the methods pursued at the present day are substantially the same as at the beginning, great progress has been made in cheapening these methods and improving the quality of the articles manufactured. It is stated that in 1830 it was customary for the manufacturers at Waterbury to appoint a committee to make the long journey to Baltimore for the purpose of purchasing copper for the season’s supply. At that time the purchase of 500,000 pounds of copper was sufficient for a year’s supply for these manufacturers. At present that quantity would not supply the demand of the Naugatuck Valley for one day.

Copper and spelter being the metals from which brass is made, a brief account of the sources of supply from which these materials are obtained will throw some light upon the development of the business of brass and copper rolling. The first copper mine worked in the United States was the Simsbury mine at Granby, in Connecticut. The record of this mine extends back to the year 1705. It was worked until 1770, but was not profitable, and only a small quantity of ore was taken out. During the War of the Revolution it was used as a prison. About the year 1779 the Schuyler mine, near Belleville, N. J., was opened and became one of a number of small mines which were worked in that section of the country for a series of years following. The Gap mine, in Lancaster, Pa., was started in 1732. The production of copper from all these openings, however, was of very little commercial importance, and until the Lake Superior region became a source of supply, the consumers of copper in the United States had to procure their raw material in Chile. It was brought to this country in the form of pigs, and refined near Boston, Baltimore and at other points along the coast. In 1844 the Cliff mine, near Eagle River, Lake Superior, was opened, and in 1845 regular records of production were begun. The great development of copper mining at Lake Superior soon placed the United States in the front ranks of the copper-producing countries of the world, and the product of these mines, being of a quality much finer than the copper produced abroad, naturally took the place of the foreign product for home consumption. Copper production in the United States from 1845 to 1880 kept pace with home consumption, a comparatively small quantity being exported up to the last-named period, so that the record of the copper produced in the United States between the periods indicated would indicate the progress made in manufactures of brass and copper. Beginning in 1845 with a product of 100 tons (which was much less than the quantity required for home consumption), the record for periods of 20 years is as follows: 1860, 7,000 tons; 1870, 12,600 tons; 1880, 27,000 tons; 1890, 130,000 tons; 1900, 303,000 tons. In 1917 production reached 970,000 tons, valued at $540,000,000.

Comparatively little fine copper was imported to the United States after 1860. In 1879 the
COPPER AND BRASS INDUSTRY

Lake Superior region furnished about 83 per cent of the total quantity of copper produced here, but after 1880 the opening of the copper-mining regions of Arizona and Montana increased the output largely for use in the producing states required for domestic use. A heavy exportation at once followed, and this country became one of the world's great sources of supply.

The Lake Superior district includes the first notable deposits of copper discovered on the American continent. This district was the greatest producer for half a century; the product is still very large, the Michigan output in 1915 being 158,000,000 pounds. The copper found there is remarkably pure, and is called Lake copper, being marketed without electrolytic refining as is necessary with most coppers. The Rocky Mountain copper deposits became of commercial importance about 1868, when the Butte development got under way. Three great fields have opened up in the Rockies, outdistancing the great Lake deposits. In 1913, the Arizona production was 404,000,000 pounds, or the equivalent of the entire world's production in 1890. The same year Montana produced 286,000,000, or more than the United States total of 1890. The other large producing States were Michigan, 158,000,000; Utah, 132,000,000; Nevada, 85,000,000; New Mexico, 50,000,000; California, 32,000,000; the year's total for the United States being 1,224,484,098 pounds. In 1917 Arizona produced about 710,000,000 pounds; Montana, 370,000,000 pounds; Michigan, 272,000,000 pounds; Utah, 240,000,000; Alaska, 145,000,000; Nevada, 103,000,000; New Mexico, 100,000,000; California, 65,000,000; and Tennessee, 21,000,000.

As measured by districts, the Butte smelters, which began in 1868, have been the world's largest producers of copper; the entire product to 1915 being 6,177,800,000 pounds; the Lake Superior district, which has produced since 1845, yielded a total to 1915 of 5,360,995,000 pounds; next comes the Bisbee, Ariz., district, opened in 1880, with 1,710,300,000, and the Moreno-Mexia district, also of Arizona, with 1,104,200,000. These are the four greatest copper districts of the world.

The quantity of copper produced in the United States is reported by the United States Geological Survey to be as follows:

The consumption of new copper in the United States in 1915 is estimated to have been 1,043,461,982 pounds, to which may be added old copper from sundry sources such as old copper and brass, scrap, etc., estimated to be 392,274,000 pounds, making about 1,435,000,000 pounds of new and old copper available for use during the year. This estimate includes at least 150,000,000 pounds of copper produced by remelting scrap accumulated in the process of manufacturing copper and brass articles. The apparent domestic consumption of new copper in 1914 was 640,445,000 pounds.

A fair estimate of the average price of copper in the United States from 1845 to 1859 is 20 cents per pound. From 1859 to 1876 the yearly average price of copper varied from 20½ cents to 32 cents per pound, with the exception that in the years 1864 and 1865 the price was advanced, so that in 1865 the price was 34½ cents. Lake Superior copper was 46¾ cents per pound and in 1866 36¾ cents. After 1876 there was a gradual decline in the yearly average price, which was 18¾ cents in 1877 and 11¾ cents in 1887. In 1894 the price touched 9 cents per pound, which is the lowest point recorded.

In 1899 the increased demand for copper in the United States and abroad was the cause of a rapid advance in the price of the metal, which sold as high as 18 cents per pound. The large exports (159,000 tons in the year 1900), and the steady increase in the demand for home consumption, kept the price between 16 and 17 cents until December 1901.

In the fall of 1901 it became known that a considerable stock of unsold grades of material accumulated in the hands of one of the largest of the producing mining companies. Meanwhile, owing to decreased consumption abroad, the exports of copper had fallen off at the rate of about 65,000 tons per annum (the total quantity exported in 1901 being 81,000 tons). Toward the end of the year there was a sharp decline in the London market, followed by a series of reductions in the price of copper in New York, which, emanating from one source, brought the price, within a period of 30 days, from 16½ cents down to 11½ cents per pound. The first effect of this action was to check consumption, but when it was known that copper could be bought for forward delivery at 11 cents per pound, the demand for manufactured copper increased to such an extent that large buying of the raw material followed and the price of copper quickly advanced to 12½ cents. The average price of Lake copper during 1902 was 11¼ cents, and in 1903 about 13½. The average price obtained by the Lake Superior mines for copper during 30 years previous to 1903 was about 12½ cents. From 1903 to 1913 the average price of electrolytic copper was about 15 cents per pound. In 1916 and 1917 it was slightly above 27 cents per pound.

Since we became great exporters of copper, the price of this metal in the United States has been nearly at a parity with the price in Europe. With increased production the cost of mining has been greatly reduced, while improvements in metallurgy and methods of electrolytic extraction have brought into the market great quantities of copper suitable for the finest work from sources which formerly furnished only coarse and ordinary grades. In former years the tariff upon copper affected the price of the raw material in this country, often enabling the mining companies to obtain from the consumer at home a higher rate than that which ruled abroad. The price of copper in this country was sometimes sustained by arrangement between the mining companies, who would market the copper here at a fixed price and ship their surplus product abroad at a considerably lower rate. The American brass manufacturer was thus confined to a home market for his product, and the statement that, in certain cases, he succeeded in taking large foreign contracts for brass, with the disadvantage of having to pay a higher price.
than his competitor abroad, not only for his raw material but for his labor and supplies, is the best possible tribute to the excellent quality of his work. Ingot copper was admitted to this country, duty free, until the act of 30 July 1846, when a duty of 5 per cent was imposed. The act of 3 March 1857 restored copper to the free list. Subsequently, duties were imposed upon copper: in 1861 of two cents per pound, and after that of from two and a half to five cents per pound. The McKinley Bill made the duty one and a quarter cents per pound, and at present ingot copper is on the free list.

The first refined spelter produced in this country was made in the year 1856, at Bethlehem, Pa., from ores mined there, and it was sent to the government arsenal at Washington. Up to 1865 or 1866 the spelter used by brass manufacturers was imported from Germany and Belgium. In 1867 the Missouri Zinc Company, at Carondelet, Mo., began to make spelter from Wisconsin ores. The first year they made about 1,800 tons; the next year about 2,500 tons. This was spelter from the United States. In 1869 the first zinc ores were discovered in southwestern Missouri, and since then the development of the zinc industry has been constantly increasing. The output of the year 1903 was 157,900 short tons of metallic zinc or spelter. The production and consumption of spelter in the United States in 1914 and 1915 is estimated by the United States Geological Survey to be as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Short Tons</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1914</td>
<td>353,449</td>
<td>$36,414,000</td>
</tr>
<tr>
<td>1915</td>
<td>409,019</td>
<td>121,401,000</td>
</tr>
</tbody>
</table>

The apparent consumption of spelter was 259,125 short tons in 1914 and 354,382 short tons in 1915. The abnormal demand for high-grade spelter in 1915, for use in the manufacture of brass for ammunition exported to Europe, caused an unprecedented advance in the price of the metal which ranged from 6 to 25 cents per pound. The average selling price for prime water spelter was about 12 cents per pound but sales of some of the higher grades were made at more than double that price. The number of retorts at zinc smelters increased from 115,114 at the close of 1914 to 156,558 at the close of 1915. As late as the end of 1916 the spelter producing capacity of the country was about 900,000 tons. American brass manufacturers have used domestic spelter almost exclusively for the past 30 years, the quality of the American product being superior to that of the foreign article. One of the finest grades of spelter is produced in New Jersey and is sold at a high price. At no time within the past 30 years has spelter been admitted to the United States free of duty. The duty on the McKinley Bill was one and a half cents per pound. Subsequently it was made one cent per pound and the duty at present is 15 per cent ad valorem.

On 13 Jan. 1801, Paul Revere, of Revolutionary fame, wrote to a friend in London, requesting him to go down to Maldenhead, where the rolling machinery was manufactured, and ascertain the price of a pair of rolls 9 inches in diameter and 20 inches long, for making sheet copper. Colonel Revere was a silversmith, and had previously coworked with Benjamin Stoddard, Secretary of the Navy, upon the subject of copper rolling. It is not known whether or not these rolls were procured at that time, but in January 1801, Colonel Revere purchased an old powder-mill at Canton, Mass., where he began the production of sheet copper. The business has been carried on continuously since that time, and is now incorporated under the name of the Revere Copper Company. Among the names of those who have carried on this enterprise are Joseph A. Revere, James Davis, John Revere and S. T. Snow. This company was finally consolidated with the Taunton-New Bedford Copper Company.

In 1812 the Soho Copper Company was established in Belleville, N. J., where there is a good water power and water transportation by canal and the Passaic River. The originator of this enterprise was Harmon Hendricks, the son of Uriah Hendricks, who was an importer of copper and metals. Some of the buildings were of brick, roofed with tiles imported from Europe. The rolling-mill was of wood and contained one pair of breaking-down rolls, one pair of sheet rolls and one pair of bolt rolls, all of which were imported from England. The plant and machinery cost $50,000, and were intended for the purpose of furnishing the United States government with heavy copper sheets for boilers and bolts for shipbuilding, during the War of 1812. This business was continued from father to son in a direct-line, until it is now in the hands of the fourth and fifth generations, and is known as the "Belleville Copper Rolling Mills," operated by Hendricks Brothers. In the year 1813 ingot copper sold for 18½ cents per pound and the price of copper sheets was 39 cents per pound.

The Gunpowder Copper Works were built in 1817 on the Gunpowder River, 10 miles from Baltimore, by Levi Rollingsworth. Water power was used in manufacturing. In 1866 the rolling-mill was transferred to Canton. It is now operated by the Baltimore Copper Smelting & Rolling Company, who are engaged in smelting and in the manufacture of blue vitriol and sub. The manufacture of yellow metal for sheathing vessels was the subject of a patent by H. F. Munetz, of Birmingham, England, about the year 1840. This mixture, which contains a large proportion of copper, is manufactured by the British iron foundries, and when hot, being cheaper than copper, naturally came largely into use for ship sheathing. It was first made in this country by the Revere Copper Company, within a year or two after its production in England. Later, it was made by the Taunton Copper Manufacturing Company, the New Bedford Copper Company and the Bridge-water Iron Company. The decline of American ship-building, and legislation permitting American vessels engaged in foreign trade to use the foreign metal without payment of duty, have greatly decreased the demand for yellow metal in the United States.

The causes that have tended to localize the manufacture of sheet brass do not affect the rolling of copper. The makers of sheet copper usually do not remanufacture their product. So that, while most of the brass-mills are located in Connecticut, the copper-mills are distributed throughout the country: in Massachusetts, Connecticut, New York, New Jersey, Pennsylvania, and elsewhere.

The manufacture of seamless tubes of brass and copper is an important part of the brass
business. These tubes are made in the Naugacuck Valley by The American Brass Company and also by the American Seamless Tube Company of Boston, and by other manufacturers. Early in 1848, Joseph Cotton, Joseph H. Cotton, William E. Coffin, Holmes Hinckley and Daniel F. Child, all of Boston, despatched to England an engineer, Joseph Fox, to learn how to make seamless brass tubes, paying a large sum to Messrs. Green and Alston, the English patentees, for the instruction of Mr. Fox, and the right to make tubes by their process in the United States. Previous to that time all copper and brass tubes for use in locomotive and marine boilers and for the hundreds of other uses to which tubes were put, were brazed: that is, made of strips of metal put in a rounded form and their edges brazed together. In 1850 the gentlemen before named organized a corporation called the American Tube Works, of Boston, and began the manufacture of seamless drawn brass tubes. Such tubes have taken the place of the brazed tubes in all cases where steam, or other high pressures are involved.

There are no public records correctly showing the present condition of the brass and copper industry in America. Figures can only be obtained by personal application to the manufacturers. The following details, showing the state of the business in the year 1903, are taken from information furnished by 20 of the largest corporations, and include the entire business of the country in rolled brass, copper, tube and wire. In a few instances, where information was refused, an estimate of the business has been made, but this does not exceed 13 per cent of the total.

The nominal capital invested was $17,000,000, but the amount of the actual investment was about $29,000,000.

The average number of persons employed was 16,000.

The annual consumption of copper was 300,000,000 pounds.

The annual consumption of spelter was 43,500,000 pounds.

The value of the annual product was $73,700,000.

If the foregoing figures were doubled they would fall short of the amount invested and the entire business in 1905. This increased volume of business is mainly supplied by extension of previously existing plants, but some corporations of more recent origin have come into prominence, notably the Buffalo Copper and Brass Rolling Mills of Buffalo, N. Y.

Brass founders or manufacturers of articles of cast brass are not included in the foregoing figures. That is a separate branch of business, and it is carried on by a great number of foundries in the United States, consuming a large quantity of ingot copper and old metal. Many manufacturing concerns, also, have their own foundries, where metal is cast, to be used in their various departments.

Early in the year 1915 it became evident that a large quantity of copper and spelter would be required by the mills of this and other States, for use in the manufacture of ammunition for the warring nations of Europe, and the price of these metals rapidly advanced until, in 1916, copper was quoted at 34 cents per pound and spelter at from 18 to 30 cents according to the quality of the metal and the time of delivery, the highest price being paid for immediate requirements. Brass rolling-mills running day and night were unable to supply the demand for brass; existing mills increased their facilities; new mills were started; old and disused mills were put in operation; wages were advanced; labor became scarce and serious strikes occurred, for the first time in the history of the business. Brass rolling became very profitable and the shares of corporations engaged in that business doubled in value within a year.

In brass rolling-mills the copper is received in the form of ingots and the spelter in the form of plates which are broken when required for use. The copper is melted in crucibles and the spelter is then added in the proportion required, the standard mixture being about two parts copper to one part spelter. This mixture and those containing a higher percentage of copper are rolled and worked when cold. The combination of 60 pounds of copper with 40 pounds of spelter is known as yellow metal and is usually rolled while hot into sheets and rods. The melted brass is poured into sectional molds from which when cooled it is taken in the form of slabs, approximately of the width required for the finished product. These slabs are then reduced and elongated by passing through rolls of chilled iron. Frequent annealing is required between the successive passes and the oxide forming upon the surface of the metal in the process of annealing is removed by baths of dilute sulphuric acid. Brass rods are drawn from round bars by successive passes through dies on draw-benches. Brass wire is produced by drawing the metal through a succession of dies by means of revolving drums on which the wire is coiled. Seamless brass and copper tubes are usually cast in hollow form round a core and finished on draw-benches by drawing through dies over mandrels. Another process consists of piercing a bar of metal by a steel mandrel over which the metal is drawn by the action of conical rolls revolving at a high speed; the shell thus formed is then drawn into a tube in the ordinary manner. Brass rods and tubes of intricate shape are formed by a process of extrusion by means of which the metal, after being heated to a temperature of about 1,000° F, is placed in a cylindrical container at one end of which is the die and, upon pressure being applied at the opposite end by means of a hydraulic ram, the metal, which is in plastic condition, is forced through the die, issuing therefrom as rods or tubes of the required section and of a length governed by the quantity of metal placed in the container. In this way metallic sections are produced in complex designs with re-entering angles which it would be impossible to roll or draw. An admixture of brass and nickel produces the white metal known as German silver, used in the manufacture of spoons, forks and other articles which, when plated, have the appearance of silverware. Sheet copper and copper rods are rolled at a red heat from cast plates and bars and, when a fine surface is required, they are filed for cold drawing. In the rolling of brass and copper the accumulation of clean scrap metal is remelted and used.

Alfred A. Cowles,
Late Vice-President of The American Brass Company.
COPPER CLIFF, Canada, a town in the Sudbury district of Ontario, on the Sault Sainte Marie section of the Canadian Pacific Railway, four miles west of Sudbury. The neighborhood is rich in copper and nickel. An electric railway now connects with Sudbury. Pop. 3,082.

COPPERAS, the commercial name for ferric sulphate, or green vitriol. (See Iron.) Its formula is FeSO₄·7H₂O. Copperas occurs naturally as the mineral melaniterite (q.v.), commonly in connection with deposits of pyrites, from which it is derived by oxidation.

COPPER, or ATNA, RIVER, a stream in Alaska, rising in the neighborhood of Mount Wrangell, flowing in a generally southerly direction west of that mountain, and emptying into the Gulf of Alaska about 30 miles west of Chilkat. The length of the river is a little over 300 miles. Its name is due to the alleged fact that its waters hold copper in solution. Its basin has an area of about 23,000 square miles. Its course reveals a reverse topography, for the river begins in a mountainous region, its upper course lies through a broad plain, while its lower course carries it through the Chugach Mountains. Consult Mendenhall, 'Geology of the Central Copper River Region, Alaska' (in United States Geological Survey, House Document No. 197, Washington 1905).

COPPERFIELD, David. See David Copperfield.

COPPERHEAD (Anaxistodon contortrix), the most widely distributed, and in many places the most abundant of the venomous snakes occurring in the eastern United States. It belongs to the family Crotalidae (q.v.), but with the water moccasin belongs to a genus (Anaxistodon), distinguished from the rattlesnakes by the absence of rattles, while the copperhead is peculiar in the presence of a small additional plate between the eye and nostril. The copperhead seldom exceeds a length of three feet. It is brown, with a series of dark blotches on the back, and the triangular head is a brassy red, from which circumstance it takes its name, while the white color of the interior of the mouth has given rise to another of its names, that of cottonmouth, also applied to the water moccasin. It is sometimes called the red viper. Like other poisonous snakes the copperhead has been exterminated in the thickly settled parts of the northern States, but is still abundant in unsettled regions and in the South. It is partial both to the neighborhood of water and to dry rocky hills and, owing to its activity, its silent approach and its irascible temper, is justly feared by man and the lower animals, including non-venomous snakes. Some of the latter, as the blacksnake, will, however, attack and eat it. The customary food of the copperhead consists of small birds and mammals. About seven or eight years are produced at a time, this snake being viviparous; it is said that when pregnant a large number of females will sometimes twine themselves together, whence the epithet "enatrix," in a popular sense. Like the copperhead, as well as many harmless American snakes, is sometimes called an adder or viper, though in common with all related poisonous serpents of North America, it differs from the true vipers in the presence of the preorbital sensory pit.

In England adder is the name applied to the only native venomous serpent, the Pituos berus.

COPPERHEADS, a name applied in 1862 and throughout the Civil War to members of the Democratic party in the northern States who violently opposed the prosecution of the War. They were not necessarily in sympathy with the South, but in all events they held that the Confederacy could never be conquered, and that the attempt to coerce the seceding States was hopeless and illegal. The name was generally indicative of a treacherous character, and was a reference to the habit of the copperhead snake, which strikes without warning. Another explanation of the name is that it came from the button cut out of a copper cent, on which in 1868 was the head of the Goddess of Liberty, won by the opponents of the war. The most prominent and obnoxious of the copperheads was Clement L. Vallandigham (q.v.).

COPPERMINE RIVER, in Canada, near Coppermine Mountain. It has its source in Point Lake and flows into Coronation Gulf, an arm of the Arctic Ocean, near Duke of York's Archipelago, lat. 68° N., long. 116° W. Its length is about 325 miles; but the large number of waterfalls along its course render it useless for any travel except by light canoes.

COPPAGE. See Copse.

COPPIN, Fanny Muriel Jackson, American negro educator: b. Washington, D.C., 1846; d. Philadelphia, 21 Jan. 1913. She was born in slavery and her freedom was purchased by an aunt when Fanny was about 12 years of age. At 15 she went to Newport, entered the service of the Calvert family, and in her spare time managed to acquire the rudiments of an education. Later she entered Oberlin College, and was the first colored woman in the United States to graduate from a recognized college. She taught a class in the preparatory department at Oberlin with conspicuous success and soon after the outbreak of the Civil War was called to the Institute for Colored Youth in Philadelphia, of which she became director in 1869. For 35 years her career in Philadelphia was one of intense activity, both in the unselfish ability as an educator and distinction as a leader in every good cause for the promotion of the betterment of the colored people of her city and the country at large. She organized the Colored Woman's Exchange, and an Industrial School as well. In 1888 she visited England to attend the missionary Congress and there most eloquently pleaded her cause. In 1881 she married the Rev. Levi J. Coppin, who in 1900 was elected bishop and assigned to work in South Africa. She re¬

COPPINGER, John Joseph, American military officer: b. Ireland, Nov. 17, 1834; d. 1909. After the completion of his military education in Ireland he went to Rome, serving in the papal army as aide-de-camp. He came to the United States in 1861 and was given a commission in the Union army, rising to the rank of brigadier-general in the regular army in 1895. In the
war with Spain, as major general of volunteers, he commanded the 4th Army Corps in Porto Rico. He married Alice, daughter of the late James G. Blaine (q.v.). He was retired in 1898.

COPRA, the dried kernel of the coconut, from which the oil has not yet been expressed, is a considerable article of commerce in some tropical regions. Samoa and the Fiji Islands export more than 10,000 tons annually. Tahiti about 2,000 and Ceylon 3,000 tons. From it coconut oil and cocoa butter are manufactured, and the residue after expression is an excellent fodder, with many of the nutritive properties of cottonseed oil cake. Copra, either sun-dried or kiln-dried, contains 50-65 per cent of oil, while hot air dried may run as much as 74 per cent.

COPROLITES, the term originally applied to the fossil excrements of extinct animals, especially fishes and reptiles, found most abundantly in the llanos, green sand and Suffolk clays of Great Britain, is the collective name of fossilized animal droppings. As such it has afforded to Champollion, Dr. Young and others the key to the interpretation of the Egyptian hieroglyphic inscriptions. At the time of the introduction of Christianity among the Copts the hieroglyphic, hieratic and demotic modes of writing previously in use in Egypt were abandoned, and the Greek alphabet was adopted, with the addition of six characters of the demotic alphabet, which were retained because the equivalents to them were wanting in the Greek alphabet. These six letters represented kh, h, f, the English j and two forms of sh. By the time that this change was made the Coptic language was no longer the same with the ancient sacred language, but had adopted a number of words from the vernacular language which was spoken in Egypt alongside of the former, besides a large number of others from the Greek, the Latin, the Arabic and other sources. It still remained, however, essentially Egyptian. The Coptic language is monosyllabic in character. All its radical forms are monosyllables, and whenever a polysyllabic word is met with it may be at once affirmed that the word is either a derivative or a compound. As a rule the radicals are capable of certain modifications according to the soil and climate, from 12 to 30 years; and after paying all expenses it often yields from $150 to $250 per acre in barn used for tanning and in wood convertible into wheel-spokes, or applicable to other purposes. The stems, cut over the ground, are carefully dressed and rounded, so as to prevent them from rotting; in a short time a number of shoots appear, all of which are thinned away except three or four of the most promising, which are left to grow till they again become fit for another cutting. When plantations are extensive, the method usually followed is not to allow all the copse to come to maturity at the same time, but to divide it into a number of sections and to cut one of them annually, so as to avoid a wasted year in regularity, and not infrequently to as large an amount as an equal quantity of land under cultivation. For instance, a copse of 100 acres, on the assumption that it may be profitably cut after 20 years' growth, is divided into 20 sections, or 5 acres each. By cutting only one of these sections annually a perpetual succession of cuttings is obtained, yielding, on the most moderate calculation, a clear income of at least $500 per annum. The proprietors of many of the rocky glens of Great Britain, by pursuing this method, have materially increased the value of their estates. The other kinds of wood commonly used for copse are chestnut, which, from its durability, even when partly covered with earth, is valuable for posts, etc.; ash, preferred for all purposes where strength and elasticity are required; and hazel, admirably adapted for barrel hoops, and in great demand for crates in the vicinity of potteries. The willow, well known for its uses in basket-making, being cut down regularly after every year's growth, scarcely falls under the head of copse. In some continental countries the copse is the source of the whole fuel supply.

COPTRIC LANGUAGES, the language formerly spoken by the Copts or Egyptian Christians and regarded as the direct descendant of the ancient sacred language of the Egyptians, as it has so often been referred to in the Christian text of the Copts, as it has been used by them in the past, and as it is now used in the Coptic Church. It is a language that is essentially Egyptian. The Coptic language is monosyllabic in character. All its radical forms are monosyllables, and whenever a polysyllabic word is met with it may be at once affirmed that the word is either a derivative or a compound. As a rule the radicals are capable of certain modifications according to the soil and climate, from 12 to 30 years; and after paying all expenses it often yields from $150 to $250 per acre in barn used for tanning and in wood convertible into wheel-spokes, or applicable to other purposes. The stems, cut over the ground, are carefully dressed and rounded, so as to prevent them from rotting; in a short time a number of shoots appear, all of which are thinned away except three or four of the most promising, which are left to grow till they again become fit for another cutting. When plantations are extensive, the method usually followed is not to allow all the copse to come to maturity at the same time, but to divide it into a number of sections and to cut one of them annually, so as to avoid a wasted year in regularity, and not infrequently to as large an amount as an equal quantity of land under cultivation. For instance, a copse of 100 acres, on the assumption that it may be profitably cut after 20 years' growth, is divided into 20 sections, or 5 acres each. By cutting only one of these sections annually a perpetual succession of cuttings is obtained, yielding, on the most moderate calculation, a clear income of at least $500 per annum. The proprietors of many of the rocky glens of Great Britain, by pursuing this method, have materially increased the value of their estates. The other kinds of wood commonly used for copse are chestnut, which, from its durability, even when partly covered with earth, is valuable for posts, etc.; ash, preferred for all purposes where strength and elasticity are required; and hazel, admirably adapted for barrel hoops, and in great demand for crates in the vicinity of potteries. The willow, well known for its uses in basket-making, being cut down regularly after every year's growth, scarcely falls under the head of copse. In some continental countries the copse is the source of the whole fuel supply.
The Coptic language is divided into three dialects—the Theban, which was spoken in Upper Egypt, and which is the best preserved of the three; the Memphitic, or Coptic, strictly so called, which was spoken in Lower Egypt; and the Bashmuric, which was spoken in the Delta. Of the last the literary remains are very scanty, but it is that which comes nearest to the hieroglyphic language of the ancient Egyptians. After the Arabian conquest of Egypt the Coptic language gradually ceased to be spoken, and as early as the 10th century it was no longer in use in Lower Egypt, except in their church liturgies; in Upper Egypt, however, it maintained itself for some centuries longer, but here also it was at last obliged to give way to the Arabic. The theological writings in use among the Coptic Christians, however, are still written in the Coptic language, but an Arabic translation always accompanies them. In the schools the children learn the Gospels and the epistles of the New Testament in Coptic as well as Arabic, but they are no longer taught the former language grammatically. In the various libraries of Europe there are numerous Coptic manuscripts, but most of them are of little interest. The Coptic literature is almost entirely of a religious character, the works written in it comprising portions of the Old Testament, the Acts, sermons and homilies, martyrlogies, etc. Translations of the Pentateuch and some other books of the Old Testament and of the Gospels into Coptic have been published at Rome. One of the most valuable discoveries of Coptic literature—practically the whole library of the old Coptic monastery of Saint Michael in the Egyptian Fayyûm, was acquired by the late J. Pierpont Morgan in 1911, and placed by him in the J. Pierpont Morgan Library in New York city. It consisted of 50 volumes, and these are being edited for publication by Professor Hyornat of the Catholic University of Washington. The larger part consists of manuscripts of books of the Bible of the 2d century of our era, and the remainder of liturgical books and treatises by the old monks of Alexandria. These are the oldest manuscripts known, and the fine bindings are the choicest and oldest existing in any library. Materials for the study of the Coptic language will be found in the grammars of Schwartz (Berlin 1850), Uhlemann (Leipzig 1854), and Stern (Leipzig 1880), and the dictionaries of Peyron (Turin 1835, still considered the best) and Parthey (Berlin 1844).

**Coptine**, a colorless alkaloid which is said to have been found together with berberine in the root of *Coptis trifolia*. Coptine dissolves in sulphuric acid, the solution becoming purple-red when heated; it gives a crystalline precipitate with a solution of mercuric potassium iodide.

**Coptis**, a genus of low herbs of the crow-foot family (*Ranunculaceae*). It comprises about nine species occurring in the cooler parts of the northern temperate zone. Four species are found in America, three of them on the Pacific Coast. *C. trifolia*, gold-thread or canker-root, grows in bogs and wetland from Newfoundland to Maryland, and westward and north to Minnesota, British Columbia and Alaska. Its common name of canker-root is given to it because of its use in household medicine as a salve for cankerous fissions of the mouth in children. A yellow dye is extracted from the slender yellow root stock. *C. teeta* is used in India as a tonic.

**Copts**, a name given to the schismatic Christians of Egypt who are of the Monophysite sect, similar in belief with the Jacobites of Asia. The Monophysites were followers of Dioscorus, patriarch of Alexandria, who was deposed by the Council of Chalcedon in 451, because he maintained there was only one nature in Christ. The Copts were of pure Egyptian blood, and at first were more numerous than their adversaries, the Melkites, who were Greeks in origin and believers in Christ as taught by the Church. Officials who were considered orthodox were sent from Constantinople to govern Egypt, and many of the Copts fled to Upper Egypt and some went to the Arabs. So incensed were they with their rulers that when an opportunity occurred, they betrayed their country to the Saracens, who drove the Greeks and Romans out of the land. But the Copts soon found that their privileges would be of little avail, and their wealth, numbers and respectability rapidly declined, and though rarely intermarrying with their conquerors, and preserving their features, manners and religion unaltered, they soon lost their language, which had resisted the influence of a Grecian court for so many ages. In person and features the Copts differ much from the other natives of Egypt, and are evidently a distinct race. According to the younger Champollion they are the result of a mixture of all the different races that have ruled over Egypt. Reduced by a long course of oppression and misrule to a state of almost degradation, their number and national character have declined; their number was estimated in 1907 at 706,322. Their costume resembles that of the Moslems, but they are in the habit of wearing a black turban for distinction's sake. They also commonly wear a black or dark-colored outer robe. In their general customs there is little to distinguish them from the other inhabitants of the country. They are chiefly employed as clerks, secretaries, etc. The women go out with veiled faces, like the other females of the country. They have numerous schools for their male children, but very few of the females are taught to read. In doctrine they are wholly with the Roman Catholic Church, except on the one point which caused the separation—the two natures in Christ. They celebrate mass in the old Coptic language, as with them now the Arabic is the common tongue. Their supreme head is the Monophysite patriarch of Alexandria, who is chosen from among the monks; then come the bishops, priests, deacons, inferior clergy and monks. The priests may be married according to the Eastern discipline, and as a rule the more by way of support from their congregations, they are generally engaged in the ordinary occupations of the place in which they live. (See Jacobite Christians; Melchites). They have four seasons of fasting, all of which are scrupulously observed. They celebrate Easter five days earlier than that observed by the Roman Catholic Church. The doctrine of the sacraments does not vary from that of the Latin
COPY — COPYING

Church, but they have a peculiar ritual in the administration of the sacrament of extreme unction, which they give with the sacrament of penance, even when there is no bodily illness, to heal the disease of the soul. The curious custom exists of blessing the bathing water stored in large tanks; and to appease or please the Maching malums, they have adopted this circumcision. Within recent years a large body of the Copts made corporate reunion with the Roman Catholic Church, and there is a Catholic Vicar Apostolic of the Coptic rite for the Copts of Egypt.

The Coptic language flourished from the 3rd to the 16th century, but is now extinct as a vernacular. It is of great linguistic importance because of its descent from the Ancient Egyptian. Its literature is of little importance; it borrowed extensively from Greek and Latin but is free from any admixture of Arabic. It was divided into five principal dialects — the Sahidic and Achmimic in Upper Egypt, the Boheiric and Memphitic in Lower Egypt, and the Fayumic, or so-called Bashmuri in Central Egypt. The Sahidic is the liturgical dialect of the Coptic Church and in it is contained by far the greater amount of the Coptic literature extant.

COPY (Lat. copia, abundance). (1) In ancient times, when the art of printing in its improved form was unknown, the copist was a much esteemed person, and manuscript was multiplied by the laborious process of writing by hand. Some of the Roman slaves were copyists. From the early centuries of Christianity through the Middle Ages, and until the art of printing became popular, there were in each monastery certain monks who were copyists. Their whole time was occupied with transcribing manuscripts of the Bible and the writings of the fathers and doctors; but their chief care was the making of copies of the Bible. Often days were spent upon ornamenting an initial letter or in decorating the names of the Deity. The elevation of the Coptic classically written in the present form, and of ancient classics in general, is due to the faithful work of the old copyists. Copies of books in those days were of great value, often they were carried under guard from place to place when the owner was traveling, and the copy of the Bible was usually chained in the parish church.

(2) The matter, whether in print or manuscript, sent to the printer to be typeset, or the exact reproduction of a work of art made by one other than the original artist; a copy made by the original artist is called a replica; a copy of a statue or other piece of sculpture, taken from a mold, is called a cast.

COPYHOLD, in English and Irish law, a tenure of estate by copy of court roll, or a tenure for which the tenant has not received except the rolls made by the steward of the lord's court. Copyhold property cannot be now created, for the foundation on which it rests is, that the property has been possessed time out of mind, by copy of court roll, and that the tenements are within the manor. The method of conveyance of such property is by surrender and admittance, i.e., the holder surrenders it to the lord of the manor, whose steward, on receiving a fee, transfers the copyhold to the person in question, who again swears fealty. The heirs must pay the fee of admittance in order to retain the property. Copyhold land may be converted into freehold by agreement between the lord and the occupants; and the lord or tenant may, by paying a fine, lease an annual rent (the amount to be fixed by commissioners), compel the enfranchisement of the copyhold. Copyhold does not exist in the United States. Consult Scriven, *Treatise on Copyhold, Customary Freehold,* etc. (7th ed., 1896).

COPYING, a term in general use for a great many different processes, which may be described generally as the reproduction, usually either on an enlarged or reduced scale, of any drawing, map or other work of art. A few of the methods employed may be shortly described. If the copy is to be the same size as the original, the easiest way is to trace it. A piece of tracing-paper is put over the drawing, and the principal lines gone over with pencil. The back of the tracing is then rubbed with black lead or reddle, and put on the paper on which the copy is to be made; the traced lines are gone over with a hard point, and thus indicated on the paper. Guided by the traced lines, the copy can then be drawn in. When the copy is required of a different size from the original, the simplest way is to sketch it by hand and enlarge or reduce, where more mechanical accuracy is required, the method of squares is very useful. The original is covered with squares of any convenient size by pencil lines or threads or by tracing paper ruled off in squares; a piece of paper for the copy is prepared with a corresponding number of squares, of a smaller or larger size, according as the copy is wanted smaller or larger. These squares must bear the same proportion to the squares on the original as the copy is to bear to the original. It is then an comparatively easy matter to copy in each square the part of the original in the corresponding square. To avoid confusion if the squares are small, it is well to number them along each side of the drawing. Any drawing, drawing principally of straight lines, such as a plan, can be conveniently reduced by constructing a scale to suit the reduced size required. The lines of the original are measured by its scale, and the same proportion of the smaller scale gives the necessary measurement. The pantograph is another means of making a reduction or enlargement,
COPYING MACHINE — COPYRIGHT

but is very seldom used now. It is only ac-
curate in a general way. Perhaps the simplest
and most exact method is to get the original
photographed to the required size; the copy
can then be traced on to clean paper as already
described.

The copying of letters and other docu-
ments for commercial purposes is usually done
by means of the ordinary copying-press, which
is so familiar in every counting-house as to
need no detailed description. A letter written
with a specially prepared ink is transferred to
another piece of paper by means of damp and
pressure. Common ink thickened with a little
sugar will serve as copying ink. Many modifi-
cations of this arrangement have been devised
for producing a number of copies of circulars,
etc., from one written copy, and are known as
"graphs." A document written with the ink
prepared for the purpose is transferred by pres-
sure with the hand to a gelatinous slab, from
which as many as 50 or 60 copies, more or less
direct, can be transfected by rubbing with
the hand. A very useful method of manifold
writing is largely employed in telegraphic news
work, and for duplicating invoices by retail
tradesmen. Carbonized paper is put between
two, three or more sheets of thin paper, and
thus whatever is written on the top sheet with
a hard pencil is duplicated on the others.
When an indefinite number of copies or any
drawing or other subject is required, there are
many printing processes which may be em-
ployed. Letters or circulars, if written with
lithographic ink, can be transferred to stone,
and any number printed. Engineers' or archi-
tects' drawings, or any other drawing executed
in line, can be very successfully reproduced in
any size by the photo-lithographic process,
which depends on the action of light on citrate
of iron and prussiate of potash. (See PHO-
tography.) If required for block or letterpress
printing, then any of the zincotype processes
may be employed. By this process, also, plates
to reprint steel-engravings can be produced
from the original print. For reproducing
drawings executed otherwise than in line, pho-
tographs from nature, or paintings, there are
many other processes.

COPYING MACHINE, any one of a
number of contrivances by which one or more
copies of a letter or other document may be
made. Perhaps the best known is the copying-
press. The letter is written with "copying ink,"
a writing fluid containing some gummy sub-
stance which prevents the ink from soaking
into the paper. A sheet of bifolious tissue
paper moistened with water is placed over it,
and the letter is laid on the face of the writing, a sheet of
oiled paper is laid on the tissue paper and the
letter is placed between boards and put into a
press, the platen of which is screwed down
tightly. A few seconds' contact of the damp
tissue paper with the writing transfers sufficient
of the ink from the original to the tissue to
make a perfect copy. A number of letters simi-
larly treated may be copied by one operation
of the press, and by the use of very thin tissue
and longer impression three or four good copies
of the original may be made. Among copying
processes are many that are perhaps rather
methods of reproduction in bulk instead of
copying in a more limited way, being somewhat
akin to printing. Among these are lithography
(q.v.) and the mimeographic process. The
mimeograph consists of a stylus, moving over a
sheet of tissue paper, coated on one side with
some sensitive material. This paper is placed
below a steel plate, upon the surface of which
are cut intersecting corrugations. When the stylus
is moved over the paper, it presses the latter
down on the corrugations and these pierce the
paper along the line of writing. The paper is
then placed on the perforated cylinder, and ink
is forced through the perforations of the cylinder
and paper is fed to the cylinder, as in any small
printing press. The ink coming through the
perforated line on the special paper makes a
print on the sheets of paper fed to the cylinder
and an indefinite number of copies may be
struck off. The paper film is also adapted so
that it may be placed on an ordinary typewriter,
the ink ribbon of the latter is removed and the
stencil is cut by the type bars operated in the
ordinary manner. The stencil is then placed on
the printing cylinder and copies made in the
manner described above for the stencil cut by
the stylus.

COPYRIGHT, the exclusive right of prop-
erty in any intellectual production; the protec-
tion afforded by the law for a limited number
of years to the originator of any written or
printed composition or work of art, or to his
heirs and assigns, whereby persons unauthorized
are prevented from multiplying and selling
copies, or, in case of dramatic works, from
representing them on the stage. Such rights
were claimed by authors before the introduction
of printing. After the invention of the printing
press, the right to publish books became the
subject of licenses and patents. In Chambers'
Domestic Annals of Scotland," under date of
9 Nov. 1699, may be seen a warrant of the
Privy Council authorizing George Mossman,
stationer in Edinburgh,—

"to print and sell the works of the learned Mr. George
Buchanan, in one volume in folio, or by parts in lesser
volumes, and forbidding all others to print, import, or sell
the whole or any part thereof. For reproducing
drawings executed otherwise than in line, photo-
tographs from nature, or paintings, there are
many other processes.

Similar privileges were granted in England;
but all such monopolies were regarded with
suspicion by common lawyers. The common law
affords a certain measure of protection to works
unpublished or published only for a limited
pose. The writer of a letter, for example, trans-
fers his property in it to the receiver; but the
receiver has no right to print it for sale or dis-
tribution without the writer's consent. The
copyright in published works is the creation of
statute; the first copyright act was passed in
1709; and by virtue of its provisions authors
acquired the sole liberty of printing their books
during a term of 14 years from first publication,
and, if the author should be living at the end of
that time, during a further term of 4 years.

While this act was in force, Thomson sold
the copyright of his poems to Millar, a London
bookseller. Millar claimed the right to prevent
the issue of reprints by Donaldson (of Edin-
burgh) and others, even after the statutory term
had expired, on the ground that an author had
at common law, the sole right of printing his
works. Out of this dispute arose the famous
cases of Millar v. Taylor, and Donaldson v.
Beckett, which led to a remarkable difference of
opinion among the judges. The House of Lords decided that if any common-law right existed it had been taken away by statute.

At the union with Ireland, the copyright act was extended to that country, and the trade in cheap editions printed in Dublin and secretly imported into Great Britain came to an end. In 1814 the term of copyright was extended to 28 years, and the residue of the author's life if he were living at the end of the term. The improvement in the period of protection at the beginning of the 19th century, and especially the popularity attained by the works of Scott and Byron, greatly increased the market value of copyright, and ultimately led to further legislation in the interest of authors and publishers. The basis of the existing law is the copyright act of 1842, commonly known as Talfourd's Act, or Lord Mahon's Act. Macaulay's speech in the House of Commons on the second reading of this measure is one of his most successful parliamentary efforts. In Great Britain the term of copyright in a book is 42 years, or the life of the author and seven years, whichever of the two terms is the longer. No copyright can be enjoyed in seditious or immoral publications, and books on the United Kingdom. Articles contributed to encyclopedias and periodicals and books published in parts or series belong to the proprietor; but he may not publish them separately without the writer's consent, and after 28 years the copyright reverts to the author. Dramas and musical pieces, if first published in book-form, are subject to the same rules as books; but if they are performed in public before appearing in print the author retains the sole right of permitting them to be presented during the term of copyright; and this right is distinct from the copyright he acquires if his drama or piece is published as a book. By an act of 1882 the proprietor of a piece of music, desiring to reserve the right of performance, must give notice to that effect on the cover. Verses may not be taken from a copyright work and set to music for sale, without permission. A novel may be dramatized without the author's permission; but if copies of the drama are published containing portions of the novel, the author of the adaptation is liable to an action. The right to dramatize can be exercised only with precautions which must greatly restrict it in practice.

Copyright in engravings, maps, etc., is secured by several acts; the term is 28 years. Each plate and print must bear the name of the proprietor. Copyright in paintings, drawings and photographs is secured to the artist during his life and seven years after, by an act of 1842. In 1874 the Canadian Copyright Act enabled a British author to obtain copyright in Canada for 28 years, provided his work be published in the colony. This right is concurrent with and in addition to the rights given by the Imperial Act of 1842.

Prior to the enactment of the first Federal Copyright Law, the various States of the Union had individual copyright laws, having in view the same general purposes, expressed in the Federal Act, that is to secure to authors or publishers of new books the copyright of such books, and for the encouragement of literature and genius, which laws, generally speaking, followed a resolution of the United States Congress passed 2 May 1783, recommending that the several States secure to the authors and publishers of books and publications the exclusive benefits derived from the sale of such publications for a limited period. By virtue of the authority of the Constitution of the United States 17 Sept. 1787, Art. 1, Sec. 8: "The Congress shall have power to promote the progress of science and useful arts, by securing for limited times to authors and individuals, exclusive right to their respective writings and discoveries."

The act of 1790 made it possible to secure copyright protection for copies of maps, charts and books, and by an act of 29 April 1902, the benefits of copyright were extended to the arts of designing, engraving and etching, historical and other prints, and there have been many subsequent acts enlarging the scope of the copyright act, and providing for reciprocal protection of copyright matter, with various foreign countries.

Under the authority of the Constitution, as above mentioned, Congress, on 4 March 1909, passed an act to amend and consolidate the previous acts respecting copyright. This act of 1909 was amended 28 Aug. 1912, 2 March 1913, 28 March 1914, which acts are now in force, and upon complying with their various provisions, the exclusive right to print, reprint, publish, copy and vend the copyright work, to translate the copyrighted work into other languages, or dialects, to make other versions of it if it be a literary work, and to dramatize it if it be a non-dramatic work; to convert it into a novel or other non-dramatic work, if it be a drama, to arrange it or adapt it if it be a musical work; to complete, execute and finish it if it be a model or a design for a work of art; to deliver or authorize the delivery of the copyrighted work in public for profit, if it be a lecture, sermon, address or similar production; to perform or present the copyrighted work publicly, if it be a drama, or if it be a dramatic work, and not reproduced in copies for sale; to vend any manuscript, or any record whatsoever thereof; to make or to procure the making of any transcription or record thereof by or from which, in whole or in part, it may be made, or by any method be exhibited, performed, represented, produced or reproduced; and to exhibit, perform, represent, produce or reproduce it in any manner or by any method whatsoever, and to perform the copyright work publicly for profit if it be a musical composition, and for the purpose of public performance for profit; or to print, reprint, publish, copy and vend any arrangement or setting of it or of the melody of it in any system of notation or any form of record, in which the thought of an author may be recorded, and from which it may, be read or reproduced.

Books, including composite and cyclopaedia works, directories, gazetteers and other compositions, periodicals, newspapers, lectures, sermons, addresses (prepared for oral delivery), dramatic or dramatico-musical compositions, maps, works of art, models or designs for works of art, reproductions of a work of art, drawings or plastic works of a scientific or technical character, photographs, prints and reductions, motion picture photoplays, motion pictures other than photoplays, are by acts of 1909, 24 Aug. 1912, 2 March 1913 and 28
March 1914, made the subject matter of copyright protection.

Prior copyright laws required samples of the object upon which copyright protection was sought, to be marked with copyright notice and filed with the Librarian of Congress, before publication. The Copyright Act of 1909 permits publication of the matter for which copyright is claimed prior to filing with the Register of Copyrights at Washington, D.C. No copyright is valid unless *Notice* of the claim is given in some manner upon the article or object in which copyright protection is sought. Publication by a person entitled to the benefits of the act, with the copyright notice thereon, *secures* to such person the copyright, and the notice must be affixed to each copy published or offered for sale in the United States by the proprietor, or with his authority, except in case of books seeking *ad interim* protection. The copyright proprietor may obtain registration of his claim to copyright, after publication with the notice on the title page. Registration with the Register of Copyrights two complete copies of the best edition then published, except in the case where the work is by an author who is a citizen or a subject of a foreign state or national, who has published in a foreign country, in which case one complete copy of the best edition then published in the foreign country may be filed. Should the copyright proprietor after publication with notice fail to file the necessary copies with the Register promptly, the Register may, at any time after publication of the work, upon actual notice, require the copies to be deposited, and if the demand is made and not complied with within three months from any part of the United States except an outlying territorial possession of the United States, or within six months from any outlying territorial possession of the United States, or from any foreign country, the proprietor of the copyright will be liable to a fine of $100 and to pay to the Librarian of Congress twice the amount of the retail price of the best edition of the work, and the copyright shall become void.

Books, including composite and cyclopedic works, directories, gazetteers and other compilations, periodicals, which include newspapers, except the original issue, if such issue is foreign origin, or in foreign language other than English, must be printed from type set within the limits of the United States, or from plates made within the limits of the United States, and if the text is produced by a lithographic process or photoengraving process, the processes must be performed within the limits of the United States, and the printing and binding must be done in the United States. These requirements extend to illustrations in books and illustrations produced by lithographic process or photoengraving process and to separate lithographs or photoengravings, except where the subjects represented are located in a foreign country, and illustrate a scientific work, or reproduce a work of art. These requirements do not apply to works in raised characters for the use of the blind, or to books of foreign origin in other than the English language.

Upon filing application for copyright a fee of is. is paid, for which and for an entry of the copyright and issues to the proprietor or claimant a certificate of registration under seal. Where the copyright protection is sought on photographs, and where no certificate is required or demanded by the applicant, a fee of 50 cents is charged.

Copyright protection endures for 28 years from the date of first publication, and a renewal term of 28 years may be had upon application for an extension, made within one year prior to the expiration of the original term of copyright, and this right of renewal not only applies to the author himself, but to the widow, widower or children of the author, if the author be deceased, or any other person or persons for whom the author, or the author's heirs, or executors or others, or children be not living, then to the author's executors, and in the absence of a will, the next of kin to the author is entitled to the re- newal and extension of a copyright under the same provisions as to filing application for renewal that characterizes the original application.

If the owner of a copyright has complied, with all of the requirements of the law, in obtaining the copyright and has a certificate of registration, he may bring suit for infringement of the copyright, the remedy being in the way of an injunction restraining such infringement and damages which have been suffered by the copyright proprietor due to the infringement, as well as all profits which shall have made, for such infringement, or in lieu of actual damages and profits, the court may assess such damages as it may think the infringement warrants.

No action for copyright infringement can be maintained until the copyright protection is completed by the issuance of a certificate of registration, and the claimant must have marked or given notice of claim of copyright in the manner prescribed by the law.

The notice of copyright required, if the work be a printed literary, musical or dramatic work, is *Copyright* or abbreviated *Copr.* accompanied by the name of the copyright proprietor, and the notice must include also the year in which the copyright was secured by publication, or when it was first published. Certain subject matter of copyright productions, maps, works of art, models or designs for works of art, reproductions of work of art, drawings or plastic works of a scientific character, photographs, or book of foreign origin, or in foreign language other than English, must be marked with the letter *©* enclosed within a circle, thus —-©— accompanied by the initials, monograms, mark or symbol of the copyright proprietor, provided that on some accessible portion of such copies of the margin, back, permanent base, pedestal or of the substance on which such copy shall be mounted, the name of the copyright proprietor appear, except in cases where a copyright subsisted when the act of 1909 went into force, or July 1909, in which cases the notices prescribed by prior acts are sufficient.

What is called *ad interim* protection may be obtained for a book published abroad in the English language or before publication in this country by deposit of one complete copy of the foreign edition in the copyright office in the United States at Washington, not later than 30 days after its publication abroad, with request for reservation of the name and nationality of the author and of the copyright proprietor and of the date of publication of the book, and such protection will endure for 30 years after the deposit in the American office.
and if an authorized edition of such book is published within the United States within the 30-day period, the copyright may be assigned, granted or mortgaged by an instrument in writing signed by the proprietor of the copyright, or may be bequeathed by will, but where an assignment is made, it must be recorded in the copyright office within three months after its execution in the United States or within six months after its execution outside of the limits of the United States, otherwise it will be void as against any subsequent purchaser or mortgagee for valuable consideration without notice, whose assignment has been duly recorded. Under the copyright act, original jurisdiction is given the District Courts of the United States and the District Court of any territory and the Supreme Court of the District of Columbia and the District Court of Alaska. Hawaii, and the Courts of First Instance of the Philippine Islands. Where the article to be copyrighted comes properly under the head of "Label" or "Print" which comprises artistic matter, for use upon merchandise or for advertising merchandise, it is registrable in the United States Patent Office by complying with certain rules and regulations made by the Commissioner of Patents, but the label or print must have upon it, when first published, the copyright notice as prescribed by the copyright act. The authority for this Patent Office registration is contained in the act of 18 June 1874, relating to the registration of prints and labels, and section 3 of the act is not repealed by the copyright act of 4 March 1909, or any acts in the interim between 18 June 1874 and 1909, and it provides that no prints or labels designed for use on any other articles of manufacture shall be entered under the copyright law, but may be registered in the Patent Office.

Until 1891, copyright could be acquired only by a citizen of, or permanent residence in, the United States. British and other authors had much reason to complain of this state of the law, and it was opposed by having to compete with cheap, unauthorized reprints of foreign works, but this condition no longer exists, and there is in most instances a very good understanding between the United States and foreign nations in copyright matters.

Foreign Works.—There was at one time an understanding that the American publisher who first placed a British work on the market obtained copyright by courtesy; and considerable sums were paid for "advance sheets" in order to obtain this advantage, but the "courtesy of the trade" came to be disregarded. In December 1887, the convention of Bern brought nearly all the states of Europe into copyright relations with one another. This was the most important convention in the world's literary dealings, for it secured an almost universal recognition of the rights of authors.

The rights of citizens or subjects of foreign nations to copyright in the United States may be extended by presidential proclamations, and now Americans can secure copyright in all foreign countries with which we have reciprocal copyright arrangements, and in consequence a citizen or subject of a foreign state or nation may obtain copyright protection for any copyrightable matter when such alien is domiciled within the United States and his work is published for the first time in the United States, or, as just suggested, when the foreign state or nation of which such author or proprietor is a citizen or a subject grants, either by treaty, convention, agreement or law, to citizens of the United States the benefits of copyright on substantially the same basis as to its own citizens, or copyright protection substantially equal to the protection secured to such foreign author under the United States act, by treaty, or when such foreign state or nation is a party to an international agreement which provides for reciprocity in the granting of copyright, by the term of which agreement the United States may, at its pleasure, become a party thereto.

Presidential proclamations have been issued upon this basis permitting citizens or subjects of the following foreign states and nations to obtain copyright protection in the United States: Canada, Great Britain and British possessions, France, Belgium, Germany, Luxembourg, Sweden, Switzerland, Italy, Greece, Tunisia, Hungary, Denmark, Portugal, Spain, Netherlands and possessions, Norway, Japan, China, Korea, Austria, Mexico, Costa Rica, Cuba, Guatemala, Salvador, Honduras, Nicaragua, Argentine Republic, Brazil, Dominican Republic, Panama, Ecuador, Bolivia and New Zealand. For an American citizen to secure copyright in Great Britain the title should be entered at Stationers' Hall, London, the fee for which is five shillings sterling, and five shillings additional if a certified copy of entry is required. The work must be published in Great Britain or in her dominions simultaneously with its publication in the United States, and five copies of the publication are required, one for the British Museum and four on demand of the Company of Stationers for four other libraries. Copyright may be secured in France by a foreigner by depositing two copies of the publication at the Ministry of the Interior at Paris. No fee or entry title is required. To secure copyright in Belgium a foreigner may register his work at the Departement de l'Agriulture, Commerce and Public Works at Brussels. The term is the life of the author and 50 years after death except in cases of foreign authors, then the term is limited not to exceed that granted in the home country. In Switzerland register of title at the Department of Commerce and Industry at Bern is optional, not obligatory; fee two francs. If registered, deposit of one copy is required. The term is the life of the author and 30 years after death. Works published by corporate body 30 years from publication. Photographs five years from registration. Copyright in Canada is to be registered with the Minister of Agriculture at Ottawa; fee $1 for registry and 50 cents for certificate, and the work must be published in Canada and two copies deposited. The term is 28 years with renewal of 14 years or 42 years in all.

In Greece the period during which an author can hold a copyright is restricted to 15 years. The Swiss grant copyright during the life of the author or his heirs, and for 50 years after the date of publication of his work. In Brazil, the term of copyright is 50 years from publication.
COP YRIGHT

The difficulties have chiefly arisen from the importation into Canada from the United States of reprints of British works sold at low prices, and which it has been practically almost impossible to restrain. When these were so imported by American publishers under agreement with the British author, the Canadian publisher and printer saw themselves constantly deprived of business which they considered should be theirs, as no reciprocity was permitted them by the United States. Their mouthpiece was the Canadian Copyright Association and their agitation was continuous. The refusal of the United States to enter the Bern Convention was an important incident in the history of the trouble, although more recent United States legislation protects the British author to a certain extent. The Canadian author also has found it necessary to watch copyright legislation and raise some complaints. At present any author domiciled in the Empire, or in any country having an international copyright treaty with the United Kingdom, may obtain copyright in Canada for 28 years (renewable for 14 years by the author, his widow or children) of any book, map, chart, musical composition or any original painting, drawing, statue, sculpture or photograph, any print or engraving of an original design, or any translation of a literary work; but no exclusive right can be obtained to illustrate a piece of scenery or an object. The work must be printed and published, reprinted and republished or produced or reproduced in Canada. The copyright lapses with the expiration of foreign copyright. British copyrighted works may be copyrighted when printed and published, or reprinted or republished in Canada, and may also be imported notwithstanding Canadian copyright. Works published in separate articles of a periodical may be temporarily copyrighted but the complete work must also be registered when published. Anonymous works may be registered in the publisher's name. The registration is granted on delivery of three copies of the work to the Department of Agriculture (Copyright Branch). Ottawa, immediately on publication in Canada, and the issued work is to bear copyright notice in due form. A copy must also be sent to the Library of Parliament, Ottawa, and one to the British Museum, London. An interim copyright may be obtained, but becomes void unless the work is printed in Canada within one month after first publication elsewhere. All communications are addressed to "The Minister of Agriculture (Copyright Branch), Ottawa," from whom copies of the act and regulations may be obtained on request.

Any publication of an original manuscript without consent of author or proprietor entails liability for damages, unless the work is already printed in Canada or elsewhere. If the copyright is not registered out of print, the proprietor may, after a complaint made to the proprietor, and his neglecting to provide a remedy, grant licenses to others to publish, and may fix the royalty.

Foreign magazines and newspapers, containing British copyright works, may be imported, if the publication is with the author's consent, or under the copyright law of the country from which they come. Volumes of collections containing in part literary matter or music copy-
righted in Canada cannot be imported except from the United Kingdom.

William Douw Lighthall, Fellow Royal Society, Canada.

Coquelin, kō-kān', Benoît Constant, French actor: b. Boulogne, 23 Jan. 1841; d. France, 26 Jan. 1909. He is known as Coquelin Ainé, to distinguish him from his younger brother, Coquelin Cadet. He early gave promise of great dramatic ability. He was admitted to the Paris Conservatoire in 1859, the following year took the second prize for comedy, and made his début on the stage of the Théâtre Français, 7 Dec. 1860, as Gros-René in 'Le dépit amoureux.' Later he appeared with great success in 'Le Mariage de Figaro,' 'Le malade imaginaire,' 'Le misanthrope,' 'Le barbier de Seville,' and other pieces in the classical repertoire. His versatility was considered remarkable, as he was no less effective in modern plays, and he speedily became a popular favorite. He was elected a sociétaire of the Théâtre Français in 1864, but in 1886 he retired and made an extensive tour abroad. He made his first visit to America in 1888. About the end of 1889 he rejoined the Théâtre Français company and remained with it until 1892. In 1893-94 he again appeared in the United States. Upon his return to Paris he formed an engagement with the Renaissance Theatre, which led to a lawsuit with the Comédie Française in which Coquelin was condemned to pay damages. In 1900-01 he visited America again, in company with Sarah Bernhardt (q.v.), to whose Duke de Reichstadt he played Flambeau in Rostand's 'L'Aiglon.' Among the many characters created by M. Coquelin in later years are those of Labussière in 'Thermidor,' Cyrano de Bergerac in Rostand's play of that name, and Napoleon in 'More than Queen.' He was without a rival among his contemporaries. His versatility and mastery of technique were unequaled. He excelled in the Northern roles; but following the footsteps of his brother went to Paris in 1864 and entered the Conservatoire, to make a career upon the stage. He was graduated three years later with the first prize in comedy and made his début at the Odéon. In 1868 he became associated with his brother at the Théâtre Français, and continued there until 1875, playing in all the well-known classical comedies. He took an engagement at the Variétés in 1875, but returned to the Théâtre Français in the following year, shortly after which he joined a member of the company. He created the parts in 'Le sphinx,' 'L'Ami Fritz,' 'Les corbeaux,' 'Denise' and 'L'Héritière.' M. Coquelin, Cadet, as he was called, to distinguish him from his greater brother, was the author of numerous monologues, to the success of which he owed most of his reputation, and his rendering of them gained him great popularity in Paris. Under the nom-de-plume of Pirouette he published 'Le livre des convalescents' (1880); 'Le monologue moderne' (1881); 'Pariboles' (1882); 'Le rire' (1887); 'Pirouettes' (1888), etc.

Coquelin, Jean, French actor: b. 1 Dec. 1865. He is a son of B. C. Coquelin (q.v.), and adopting his father's rôles appeared at the Comédie Française for the first time, 20 Nov. 1890. In 1897 at the Porte-Saint-Martin he created the rôle of Raguenau in 'Cyrano de Bergerac.' Other famous rôles were Lubin in 'Thermidor;' Verdelet in 'Le gendre de M. Poirier' and Talleyrand in 'Plus que reine' (1899).

Coquerel, kō'krrěl', Athanase Josué, French Protestant clergyman: b. Amsterdam, 16 June 1820; d. Fismes, Marne, France, 24 July 1875. He was a son of A. L. C. Coquerel, and was the author of 'Jean Calas et sa famille' (1858) 'Libres études' (1867); 'Les Beaux-Arts en Italie' (1857), etc. He was widely known as an eloquent preacher, and was long a leader of the liberal Protestant party in France. Consult Stroehlin, 'Athanase Coquerel, fils' (2 vols., Paris 1886).

Côquila Nut (Sp. coquilo, 'little coconut'), the seed of the piassava or piassaba palm, Atalaia farnfera, one of the coconut group, a native of Brazil. The nuts are three or four inches long, oval, of a rich brown color and very hard, and are used in turnery for making umbrella handles, etc. They are known as vegetable ivory. The imports of the United States, which were valued at about $10,000 in 1913 and amounted to in the neighborhood of 30,000,000 pounds, are mainly from Ecuador, Colombia and Panama. Vegetable ivory is coming into increased use. See Artaele. Coquimbo, kō-kěm'bŏ, Chile, a province situated in the northern part of the republic, between the provinces of Atacama and Aconcagua. Area 14,098 square miles. It is divided into the departments of Serena, Elqui, Coquimbo, Illapel, Ovalle and Combarbalá. The principal towns are La Serena, the capital (pop. 17,578); Coquimbo, the principal seaport of the province, which is one-half hour by rail from the capital, and has 12,106 inhabitants; Ovalle (5,500); Elqui (2,500); Illapel and Combarbalá. Gold, silver, copper, iron, quicksilver, lapis lazuli and lime are found. There are four large copper-smelting works, besides several others for silver and gold ore. Natural pasturage is abundant. Agricultural products in excess of the needs of the province are exported in considerable quantities. Vineyards are located near the mountain range and wines and brandies are produced in large quantities, the proceeds of which are used in the support of the public schools and the government and one
COQUINA, kō-ke'na, a porous rock found in Florida, where it is used for building purposes. It is composed of the broken shells of sea animals and coral cemented together.

COR ANGLAIS, kör an-glah' (Fr. "English horn"), a wind instrument of the reed kind, similar to the oboe, and possessing a compass of like extent but of lower pitch. Its compass is from E in the bass to B flat above the treble staff. In Bach's works it appears as the Oboe di Caccia. Its effective wailing tone has caused it to be used by modern composers.

CORACIFORMES, an order of birds comprising a somewhat miscellaneous group, formerly designated as "picarian." Nearly all are arboreal, and are characterized by comparatively short and weak legs, and by usually nesting in holes. They include the rollers, nightjars, oropendolas, bee-eaters, hornbills, etc. (Coraciidae); the owls (Strigidae); the nightjars (Caprimulgidae); the swifts (Apodidae); the mouse-birds (Coliidae); the trogons (Trogonidae); and the woodpeckers (Picidae). See Ornithology.

CORACLE, kör-ə-kal, or CURRACH (Ir. curach; W. corc), a kind of ancient boat, constructed with a frame or body of wicker-work, and still in use among Welsh fishermen and on the Irish lakes. It is covered by skins, oil-cloth, etc., which are removed when out of use. It is of oval form, and generally contains but one man, who, on reaching the shore, shoulders his coracle, and deposits it in a place of safety, or carries it perhaps where he may again make use of it. Caesar (De Bello Civili, I, 54) describes coracles which he made after the British manner, for use in Spain. The coracle or currach is mentioned in the lives of Saint Patrick, Saint Columba and in accounts of travels made by Scots and Picts.

CORACOID, kōr'-ə-koid (Gr. "crow-shaped," that is, like a crow's bill), an important paired-bone in the breast-girdle, forming, along with the scapula, the articulation for the forelimb, and always lying ventrally. In the lower fishes the entire girdle is cartilaginous. In the bony fishes distinct coracoids first appear. They are well seen in Amphibia and in all reptiles except snakes, and are very large and strong in birds; but they become mere processes of the scapula in mammals. They very often exhibit a special anterior portion known as the precoracoid.

CORAL AND CORAL ISLANDS, the solid support or skeleton of the coral polyps. (See Polyps.) It was formerly supposed that the coral was a calcified portion of the soft parts of the animal, but this has been disproved. Recently Bourne has proved by examination that the skeleton is formed as a secretion by certain cells and that there is no deposition of crystalline carbonate of lime in the actual cells. The calcareous septa or partitions are deposited by the soft septa of the animal in the radial chambers. The coral particles begin to be deposited in the embryo polyp before it becomes fixed to the bottom. In the very young polyp of the Mediterranean Astrea, as soon as it becomes stationary 12 calcareous partitions are deposited, and finally become jointed to the external walls (theca) of the coral, forming a groundwork or pedestal, on which the young polyp rests, as if on a limestone foundation. If isolated needles or rods of lime are distributed beneath the outer layers of the polyp-stock, the latter becomes bony or leathery and more or less flexible, as in the alcyonarian polyps. The entire skeletal mass is called the corallium or coral-stock. In the common red coral (Corallium rubrum) of the Mediterranean, the solid unjointed coral-stock has a thin cortical layer of spicules in which the polyps are retractile.

Coral-like masses, encrusting reefs, are also formed by the animals of the hydroid millepore, which may be composed of the multinucleate minute cells or openings, much smaller than those of any genuine coral polyp. See Millepore.

The simpler, most primitive corals, are cup-shaped, forming a single calice or corallite containing but one polyp, as in the early Paleozoic cup-corals, and the existing species of Flabellum, Caryophyllia and Deltocyathus, which live buried in the mud in deep cold water in all seas, from Greenland to the tropics.

Microscopic Structure of Coral.—There are two kinds. In the aporetic or poreless corals such as Flabellum, Astrea and the like, the coral-stock is throughout its mass solid and stony. In the perforate kinds, such as Madrepora, all parts of the corallium, including the connecting ceenchym, or common calcareous stock or stem, has a structure like a meshwork, consisting of delicate rods of carbonate of lime so united as to leave interstices, which in the living coral are traversed by a network of interlacing tubes, representing the ceenosarc.

Rate of Growth of Corals.—Little is known regarding the rapidity of growth in corals. A specimen of Mammithina rhabrithina, measuring a foot in diameter and four inches thick in the most convex part, was taken from a block of concrete at Fort Jefferson, Tortugas, which had been in the water only 20 years. Hunt calculated that the average growth of a Madrepora observed by him at Key West was half an inch a year. Verrill states that a Madrepora found growing on the wreck of the ship Severn grew to a height of 16 feet in 64 years, or at the rate of three inches a year. See Polys.

Coral Islands.—The reef-building corals are the Madrepora and Mammithina, the latter dome shaped and massive. They are confined to waters in which through the coldest winter months the temperature does not fall below 68° F., though usually the water is warmer than this, the mean annual temperature of the north Pacific being about 73.5° F., and of the south Pacific 70° F. Coral reefs are abundant in the West Indies and occur on the coast of Brazil as far south as Cape Frio, but still more so on the coast of Europe and Africa and the two Americas. In depth reef-building species do not occur below 15 to 20 fathoms. Coral reefs are
divided into fringing, barrier and circular reefs, or atolls. Fringing reefs encrust the shores on which they grow. Barrier reefs have a lagoon between the reef and the seaward land. A fringing reef may ultimately become a barrier reef either by a sinking of the land and the successive upbuilding of the seaward face of the reef, or by gradual dying of the coral polyps next to the land where they do not get enough fresh water and food, the stony skeleton being redisolved while the outer part of the reef continues to grow. Atolls are roughly circular, with a central lagoon, with or without central islands. Contrary to the views of Darwin and Dana, it has been found by A. Agassiz that modern coral reefs form as a rule but a thin crust, those of Florida not more than from 50 to 75 feet in thickness; yet Tertiary reefs and those geologically older may be much thicker. According to Darwin and Dana atolls were supposed to have been formed on submarine banks over a subsiding sea-bottom, first starting as a fringing reef about an island or slightly submerged peak. After they had grown to the size of a lagoon the inner face of the reef could not get food, and ceased to grow. As the island or peak gradually sank, the outer face of the reef grew up in a ring. Owing to the observation of Semper, Agassiz and others, it is now evident that atolls may be deposited under any conditions, whether the sea-bottom be stationary, rising or subsiding. We will, however, have to hold on to the Darwin subsidence theory to account for coral reefs over about 100 feet in thickness, since corals do not grow at greater depths than this. From his prolonged explorations in the West Indies and the Pacific Ocean, A. Agassiz concludes that the barrier reefs of Fiji, the Hawaiian Islands and the West Indies usually flank volcanic islands and are underlaid by volcanic rocks. Those of New Caledonia, Australia, Florida, Honduras and the Bahamas are underlaid by outliers of the adjoining land-masses, which crop out as islands and atolls in the outer edge of the barrier reefs. Some of the barrier reefs of the Society, Fiji and of the Carolines, show that the wide and deep lagoons, separating them from the main lands, have been formed by erosion, from a broad, fringing reef, as explained above.

The reef-flats and outer reefs flanking elevated islands are partly barrier and partly fringing reefs. We may, says Agassiz, trace the passage of elevated plateaus like Guam, Tonga and some of the Fiji islands, which are partly volcanic and partly limestone, to atolls where only a small islet or a larger island of either limestone or volcanic rock is left to indicate its origin. Atolls also may be formed upon the denuded rim of a submerged volcanic crater, as in certain of the Pitos (Tutuia and Trombia), and as in some of the volcanoes east of Tonga.

As to the origin of atolls by subsidence, we really have few data to support the Darwinian theory. Agassiz claims that throughout the Pacific, Indian Ocean and West Indies "the most positive evidence exists of a moderate, recent elevation of the coral reefs." This is shown by the ridges, pinnacles and undermined remnants of Tec, or modern atolls, which are limestone formed recently beneath the sea, but now above sea-level, proving very recent uplift. The existence of honeycombed pinnacles of limestone within the lagoons of atolls, as shoals, islands or islets, shows the extent of the solvent action of the sea upon lagoon areas, and may formerly a greater extension than at the present day. The Maldivian plateau with its thousands of small atolls, rings or lagoon reefs, rising from a depth varying from 20 to 30 fathoms, is overwhelming testimony, says Agassiz, that atolls may rise from a plateau of suitable depth, wherever and however it may have been formed, and whatever may be its geological structure. In the regions examined by Agassiz the modern reef-rock is of every moderate thickness, being within the limit of depth at which reef-builders begin to grow and within which the land rams of atolls or of barrier reefs are affected by mechanical causes.

Why no coral reefs exist on the western coasts of the two Americas, and their absence at other points, is explained by Agassiz as due to the steepness of their shores and to the absence or to the crumbling nature of their submarine foundations or platforms. Coral reefs also cannot grow off the tops of cliff-surfaces of elevated, coraliferous limestone islands.

The proof of the supposed great thickness of coral reefs, to account for which Darwin invoked subsidence, will be ascertained by boring. Thus far the evidence tends to show that the coral beds are not continuous. At Honolulu they contained several beds of volcanic ash, etc. In the Fiji Islands, shell limestones were interstratified with coral rock. The great areas of subsidences postulated by Darwin and by Dana have been shown to be areas of elevation. The deepest depressions or "deepsea" in the Pacific, judging by the Challenger maps, are in regions where there are no coral reefs or atolls.

Bibliography.—The literature of the subject is extensive. The classic works are J. D. Dana's magnificent folio in the series of reports of the Wilkes Exploring Expedition, and his more popular volume, 'Corals and Coral Islands' (revised edition, New York 1890); and Darwin's 'Structure and Distribution of Coral Islands' (London, 3d ed., with notes by Bumey, New York 1899). Murray's paper on corals and reef-structures in the 'Proceedings' of the Royal Society of Edinburgh, Vols. X (1880) and XVII (1891) are highly important. The Agassiz, father and son, directed much attention to this subject, and Alexander Agassiz in particular has added greatly to information in his 'Visit to the Great Barrier Reef of Australia' (Cambridge, Mass., 1888). The illustrated works of Saville Kent on the Australian reefs should also be remembered, as well as Heiprin's on those of Bermuda. For structure and classification consult Bourne's account of the Anthozoa in Lankester's 'Treatise on Zoology' (London 1900); and for fossil corals consult Zittel-Eastman, 'Text-book of Palaeontology' (New York 1900), and the great 'Monographie des polyplors fossiles des terrains paléozoiques' of Milne-Edwards and Haimé, issued in Paris in 1851; also Hickson, 'Colen-terata' (in Cambridge Natural History, Vol. I, London 1906). See Barrier Reef, THE GREAT.

CORAL FISHES, a name given to several fishes of different genera belonging to the Chetodonidae. They are found in all tropical
seas, especially about coral reefs, and are all brilliantly colored. The most important is the 
Hokulii, the "emperor of Japan," which measures about 15 inches in length and is the most esteemed of all the Indo-Pacific fishes.

CORAL ISLANDS. See Coral.

CORAL SEA, part of the Pacific Ocean northeast of Australia and between it and the 
North American Continent. It lies between the parallel of 25° S. and Torres Strait. The numerous 
coral islands fringing the northeast of Australia and other islands washed by this sea give it its 
name. In 1874 the Challenger, when making soundings in these waters, found the Coral Sea, 
in some places, to be 14,700 feet deep. The coral growths of the great barrier reef lie 
along its western boundary.

CORAL SNAKE, a small venomous colu-
broid snake of the same family (Elapidae) as 
the cobra. The typical genus (Elaphe) is a 
strictly American. The usual color is rich 
red with black and yellow transverse bands, 
making these among the most brilliantly colored 
of snakes. Owing to the position of the poison-
fangs and the small size of the mouth they are, 
although venomous, usually unable to injure 
man. One species, the harlequin or bead snake 
(E. fuscus), occurs in the southern United 
States as far north at least as Virginia. It is 
a beautiful snake, about two feet or more long, 
and is less feared than it should be. Most of 
the remaining species, including the typical E. 
coralimus, are confined to tropical South America 
and the West Indies.

CORAL TREE, leguminous plants of the 
genus Erythrina, which has about 50 species. 
They are shrubs or trees with trifoliate leaves 
and racemes of scarlet flowers. The long pods 
enclose bright red seeds. They are mostly tropi-
cal, natives of America, Africa and India. One 
species (E. herbacea) is common throughout the 
southeastern United States, and two more are 
found in Florida. The plants are much culti-
vated in greenhouses. (E. indica) is said to have been stolen by Krishna, 
the Hindu deity, from the gardens of paradise. 
This is a spiny plant, and is planted for hedges. 
This species and E. caffra (the kaffir-boom of 
Africa) furnish soft light wood valuable for 
various purposes.

CORALLINE, kér’s-lín, a term popularly 
applied to sea-weeds with rigid calcareous fronds 
and also to certain of the zoophytes. The cora-
line algae are mostly purple and gradually grow 
paler and whiter as the season advances. Their 
habitat is commonly pebbly rocks, to which they 
cling fast. Corallina officinalis has been em-
ployed as a vermifuge.

CORALLINE, or PÆONINE, an orange-
red color prepared by the action of ammonia, at 
about 300° F., upon rosolic acid, or upon the 
washed residue of the action of a mixture of 
sulphuric, oxalic and carbolic acids. It dif-
fers from magenta in both its tint and its per-
manency, not being affected by light or by 
alkalis; but, on the other hand, fabrics dyed 
with it are readily turned yellow by acids. It 
is insoluble in water, but dissolves in alcohol 
and water. In which coagulated milk is treated 
with soda and a large quantity of water, and 
tartaric acid added, is employed for dyeing silk.

It is also printed upon cotton by means of 
albumen. The use of this dye has been much 
restricted on account of its alleged poisonous 
properties.

CORAM, Thomas, English philanthropist: 
b. Lyme Regis, Dorsetshire, about 1668; d. Lon-
don, 29 March 1751. He was bred a seaman, 
and rose to be a merchant captain. In 1694 
he settled in Taunton, Mass., and engaged in 
benevolence work among the Indians. A few years 
after he returned to sea, and settled in London, 
after suffering shipwreck off Cuxhaven in 1719. 
In London he interested himself in the settle-
ment of Georgia, and in planting English 
artists in Nova Scotia; but soon his long agita-
tion for the foundation of a foundling 
hospital in London, which was at length opened 
in 1740. Coram’s portrait was painted by 
Hogarth, a warm patron of his scheme. More 
thoughtful for others than for himself, Coram 
settled in poverty, from which he was relieved 
in 1745 by an annuity contributed by his friends.

CORANACH, kör’-ä-näk, or CORANACH, 
a dirge or lamentation for the dead formerly 
customary among the Celts of Scotland and 
Ireland. The coranach is commonly known in 
Ireland as the caoine (Ir. keen), a song of 
mourning for the dead. This funeral song, or 
dirge, was usually sung by professionals who 
had power to improvise and who told of the 
pedigree, worth, deeds and death of the 
decesed. In Scotland the weird, mournful notes 
of the bagpipes added sadness. The custom of 
having the caoine or coranach at wakes and 
funerals has fallen into disuse in both Ireland 
and Scotland. Frequent mention of the custom 
may be found in the writings of Sir Walter Scott, 
Lover, Davis and others. Crocker, Crofton, ‘Researches in the South of 
Ireland’; Jamieson, ‘Etymological Dictionary of the Scottish Language’ (revised by Long-
muir and Donaldson, Vol. 1, p. 494, under 
‘Coranich,’ Paisley 1879).

CORANDAGOS, kör-rän-dä-gos. IS-
LANDS, an Indian group of islands lying off 
the northeastern coast of Palawan. The group 
consists of two islands, Corandagas and Da-
langamen, and three islets. The inhabitants, of 
Malayan race, are mostly engaged in fishing and 
in the search for edible birds’ nests. Pop. about 
300.

CORATO, kör-rát’6, Italy, city in Apulia, 
about 50 miles southeast of Foggia. The modern 
city is of little importance, the chief indus-
tries being cattle raising and the manufacture 
of leather and tanner. Near the city are 
the ruins of the famous Castel del Monte, built by 
Frederick II, which is one of the most beautiful 
of the architectural remains of the Middle Ages 
in Italy. The general plan is a vast octagon, 
with eight hexagonal towers. The windows are 
pointed and round arched, and the vaulted halls 
are supported by triple shafts of marble. It is 
the chief attraction of the city. Pop. 45,307.

CORBAN, kör’ ban, a term used by the 
Jews to signify a thing given to the Deity. 
(Lev. ii, 4, 12, 13, etc.) Such an object was 
sacred and set apart from profane use. It 
was often used to designate an obligation to God 
and has reference to the Talmudic formula, by 
which, under pretense of dedicating a thing to 
God, a person might prohibit the use of it by
another person. Thus a son might declare his property as corban and avoid the obligation of using it for the support or need of a parent.

CORBEIL, kôrd-bā'yě, France, a town in northern France, in the department of Seine-et-Oise, at the junction of the Essonne with the Seine, 18 m. E.S.E. of Paris. It has various manufactures, chiefly of paper, clocks, cotton and linen; and there are large grain-mills and a copper-foundry in the town. Pop. 10,746.

CORBEL, kôrd-běl, in architecture, a piece of stone, wood or iron projecting from the vertical face of a wall, to support some superincumbent object. Corbels are of a great variety of forms, and are ornamented in many ways. They are of frequent occurrence in pointed architecture, forming the supports of the beams of floors and of roofs, the machicolations of a fortress, the labels of doors and windows, etc. A cornice supported by a series of corbels is styled a corbel table. Similar contrivances are the bracket and cantilever (q.v.).

CORBETT, Julian Stafford, English lawyer and author: b. Surrey, 12 Nov. 1854. He was educated at Marlborough and Trinity College, Cambridge, and was called to the bar in the Middle Temple in 1877. He practised his profession until 1882 and has since given his attention to literary pursuits. He has published 'A Business in Great Waters'; lives of Monk and Drake in 'English Men of Action'; series; 'Drake and the Tudor Navy'; 'The Successors of Drake'; 'England in the Mediterranean'; 'England in the Seven Years' War'; 'The Campaign of Trafalgar'; 'Some Principles of Maritime Strategy'; 'The Spencer Papers.'

CORBETT, Lee Cleveland, American horticulturist: b. Watkins, N. Y., 21 Oct. 1867. He was educated at Cornell University, where from 1891 to 1893 he was assistant horticulturist. He was professor of horticulture and forestry at the South Dakota Agricultural College in 1893-94, the West Virginia University from 1895 to 1901, and then he became horticulturist in the United States Department of Agriculture. His publications include 'Garden Farming' (1913); 'Intensive Agriculture' (1913); and the following experiment station bulletins: 'Pruning' (1903); 'Cranberry Culture' (1903); 'The School Garden' (1904); 'Tomatoes' (1905); 'Raspberries' (1905); 'Beans' (1907); 'Cabbages' (1911); 'Ice Houses' (1911); 'Tomato Growing as Club Work in the North and West' (1913).

CORBIE STEPS, CORBEL STEPS, or CROW STEPS, steps into which the sides of gables from the eaves to the apex are broken. They form a common feature in Scottish architecture, into which they were probably introduced from France. They are also to be seen in many old houses in Holland, Flanders and Germany, where they are even more general, especially in the north.

CORBIN, Caroline Fairfield, American writer: b. Pomfret, Conn., 9 Nov. 1835; married C. K. Corbin of Chicago, 1861. She has published the following books: 'Isle of the Mist' (1865); 'The Came of It!' (1860); 'Rebecca, or Woman's Secret' (1866); 'His Marriage Vow' (1874); 'Belle and the Boys' (1879); 'Letters from a Chimney Corner' (1886); 'A Woman's Philosophy of Love' (1892).

CORBIN, Henry Clark, American soldier: b. Clermont County, Ohio, 15 Sept. 1842; d. New York, 8 Sept. 1909. He studied law, and entered the Union army as second lieutenant in the 83d Ohio Volunteer Infantry, 28 July 1862; but before the organization was completed he was assigned to his 79th Ohio Volunteer Infantry, serving therein as second and first lieutenant, respectively, until 14 Nov. 1863, when he was appointed major of the 14th U. S. Colored Infantry. In the following year (4 March 1864) he was promoted to lieutenant-colonel, and 23 Sept. 1865, made colonel of the 14th United States Colored Infantry. He was honorably discharged from the volunteer service 26 March 1866, with the brevet of brigadier-general, which honorary rank was bestowed upon him in recognition of his faithful services.

In 1866, upon the muster-out of the volunteer army, and upon the recommendation of his military commanders, he was commissioned (11 May 1866) second lieutenant in the regular army. He was appointed to a staff-line 31 Dec. 1866, and from that year to 1876 he was continually in command of his company on the Western frontier in campaigns against hostile Indians.

He was appointed to the adjutant-general's department 16 June 1889, and served therein nine years in the grade of major, seven years in the grade of lieutenant-colonel and two years in the grade of colonel; and was, when appointed brigadier-general and adjutant-general of the army (25 Feb. 1898), the senior in the corps; having served on the staffs of Generals Hunt, Schofield, Terry, Crook, Miles (with whom he participated in the Sioux Indian campaign), McCook, Ruger, Merritt, and in 1891 conducted a successful campaign against the Moqui Indians in Arizona Territory.

During the Spanish-American War, General Corbin was brought into close relations with President McKinley and was by him consulted upon all questions of policy relating to military affairs; and in addition to his duties as adjutant-general of the army he superintended the organization of 250,000 soldiers, and within six months the muster-out of 100,000. Subsequently 35,000 additional volunteer forces were mustered, equipped and made effective for the Philippine service, and they in turn disbanded— the regular army having been increased during this period to three-fold its former strength. In recognition of his services and of the part which he took in the war, the Congress of the United States conferred upon him the rank of major-general and adjutant-general in the army of the United States. He was in command of the Division of the Philippines in 1904-06, when he was made a lieutenant-general, and retired.

CORBIN, John, American dramatic critic, writer, son of Caroline F. Corbin (q.v.): b. Chicago, Ill., 2 May 1870. He was educated at Harvard University, and at Balliol College, Oxford. From 1897 to 1900 he was assistant editor of Harper's Magazine; was member of the editorial staff of the Encyclopedia Britannica 1900-02; in 1902 he wrote the dramatic notices of the New York Times, and in 1905-08 those of the New York Sun. From 1908 to 1910
he was literary manager of the New Theatre, devoted the short life of which his efforts contributed much toward notably artistic productions. Since 1912 he is secretary of the Drama Society. Besides magazine stories and articles on the drama, he is author of 'The Elizabethan Hamlet' (1905); 'Schoolboy Life in England' (1906); 'An American at Oxford' (1902); 'A New Portrait of Shakespeare' (1903); 'The First Loves of Perilla' (1903); 'The Cave Man' (1907); 'Which College for the Boy?' (1908); 'Husband and the Forbidden Guests' (1910); 'The Edge' (1915).

CORBIN, Ky., city in Whitley County, 80 miles southeast of Lexington, on the Louisville and Nashville Railroad. It contains large railroad-repair shops, a wood working factory and some coal mines. The waterworks are the property of the municipality. A Catholic academy is the principal educational institution. Pop. 2,589.

CORBOULD, kôr'bôld, Edward Henry, English water-color painter: b. London, 5 Dec. 1813; d. 18 Jan, 1905. He was a member of the Institute of Painters in Water Colors, and teacher of drawing and painting to the children of Queen Victoria, 1851-72, who acquired many of his more noteworthy productions, which were chiefly water colors. He also attained celebrity as a book illustrator.

CORCHORUS, kôr'kô-rús, a genus of the linden family (Tiliaceae). There are about 35 species, mostly herbs or small shrubs, natives of Europe and Asia, and diffused in warm and tropical regions. The leaves of C. olitorius are used in Egypt and adjacent countries as a pot herb. From the fact that the Jews thus employ them they are sometimes called Jews' mallow. More important, however, is C. capsularis, which has long been cultivated for its fibre in China for Chinese hemp, also in India and other Eastern countries for making fish lines and nets, gunny bags, rice bags and matting, a coarse kind of linen-like cloth. This and the former species have much more recently been used to furnish jute (q.v.). The negroes in the West Indies use C. nilagruus to make coarse brooms and with its leaves as a substitute for tea. The 'Japanese shrub, erroneously called C. japonicus by gardeners, is a common garden plant on account of its pretty double yellow flowers.

CORCORAN, William Wilson, American banker and philanthropist: b. Georgetown, D. C., 27 Dec. 1798; d. Washington, D. C., 24 Feb. 1888. He was educated at Georgetown College and established himself in the banking business in Washington in 1837. He became very wealthy and was widely known for his charities and gifts to the public. In 1847 he gave the Oak Grove Cemetery property to Georgetown, founded the Louise Home for Indigent Women in Washington in 1870, and gave to the city of Washington the famous art collection known as the Corcoran Gallery of Art. When he was ninety-six and it was no longer possible for him to live in comfortable surroundings, the Corcoran Gallery of Art was erected and dedicated to him. The collection contains many masterpieces and is housed in a marble building designed by Ernest Flagg and erected 1894-97. The collection contains fine specimens of early American painters, an admirable collection of Barye's bronze statuettes, the well-known 'Grey Slave' by Hiram Powers. A free school of art is connected with the institution and biennial exhibitions of contemporary American painting contribute greatly to its usefulness. Consult Henderson, 'The Art Treasures of Washington.'

CORCORAN ART GALLERY. See CORCORAN, WILLIAM WILSON.

CORYRA, kôr-sîrâ. See CORFU.

CORD-GRASS, or MARSH-GRASS (Spartina), a genus of perennial grasses containing several species, widely dispersed in America, Europe and Africa. They are often maritime; with creeping rootstocks, simple stems and long tough leaves. The spikelets carry one flower, which has unequal glumes. Fresh-water cord-grass (S. michauxiana) is found along river banks, lake shores and brackish coast marshes over the northern part of the United States. It is grown for binding sand and river banks, and when cut early makes fair but coarse hay. It has been used successfully for making twine and paper. It is also used for thatch. Fox-grass (S. paucis) is rather slender and somewhat wiry, and is abundant on salt marshes; with black grass (Juncus gerardii) it furnishes most of the salt marsh hay produced. It is used for packing glassware, etc. Creek-sedge, thatch, or salt marsh-grass (S. glabra) grows along ditches and creeks of the Atlantic and Pacific coasts. It flowers from July to October, and is used for making ropes. When young it is eaten by stock.

CORDAGE. This is the general name for all manufactures of string, twine, cord, lines, rope, hawser and cables made of twisted fibres. Fibres are first combed out or drawn into parallel position, and then a few are twisted together forming yarn or thread. Two or more yarns twisted together oppositely form a strand. Two or three small strands twisted form string or twine. A thick string is termed a cord, and three or more cords laid together form a rope. There is no fixed and accepted definition of the terms cord and rope, however. Some manufacturers use the word rope for all diameters of an inch or more, and some begin at the half inch. The public speak of a half-inch clothesline, and the mariner calls small ropes lines. It therefore appears that small ropes are called cords and lines indiscriminately. The manner of twisting the cords to form a rope determines the lay. Three ropes are laid together to form a hawser and three hawsers a cable. The common lay consists of three strands or cords, but a shroud-laid rope has a core about which three other strands are laid. Binder twine is made with a right-hand twist, but rope-yarn requires both right-hand and left-hand twists. Ropes have to be lubricated to keep them from wearing out by their own internal friction, and also to keep out the moisture which would invite rot. Sometimes tallow or graphite with fish-oil is used, but tar is the cheap and common lubricant. In making tarred rope the yarn is unwound from bobbins to copperers, and the rope is then dipped in hot tar, being then passed between rollers to squeeze out the excess of tar and spread it uniformly. Where nine-thread and larger yarn is used the tarring is usually deferred, being applied in the completed rope. Where the rope is made to order it is not part of the cordage industry. (See TEFLONAGE.) Although rope-making constituted one of the most important branches of business from the
CORDAGE

earliest days of the American colonies, like almost all the local manufactories, it was many years before it began to develop sufficient strength to enable it to be regarded as an industry. The first rope-walk in America was constructed at Boston by John Harrison in 1642, just 12 years after the town had been founded, and prior to this time, all such products that had been required in the making of rigging and tackle had been bought direct from England by the captains of the various vessels, or were imported into this country for sale. In fact, it was not until the Boston shipbuilders had commenced the construction of the 160-ton TRIAL that the several advantages to be derived from a local rope-walk were fully appreciated, and it was at its instigation that Harrison, a Salisbury rope-maker, was invited to come to Boston, where he set up his “rope-field,” 10 feet 10 inches wide, on the lawn adjoining his house on Purchase street, at the foot of Summer street. At this time such work was done out of doors. Posts large enough to permit of the making of the largest sizes of rope then in use were firmly fixed in the ground in the open air; the cordage was suspended and the ropes made.

Harrison’s coming to Boston had been largely due to the fact that he was assured that he should have a monopoly of the business for a term of 21 years, and when, at the end of that time, the town officials gave permission to a John Heyman to “set up posts,” the fact that the latter was restrained in business to the “libertie only to make fishing lines,” did not prevent the older rope-maker from protesting against what he considered the invasion of his rights. Accordingly Heyman’s license was revoked, and Harrison had everything his own way up to the day of his death.

With the “original” rope-maker dead, however, the business began to extend its influence into other parts of the town. Rope-walks multiplied in number most rapidly in the West and North Ends, until there were finally no less than 14 of them. In 1793, an additional impetus was given to the business by the action of the general court in granting a bounty for American-made rope. On 30 July 1794, the date of the great fire, seven rope-walks were destroyed, and the selectmen, who had been flooded with protests from citizens who objected to this business being carried on in the heart of the town, refused to grant further licenses except upon the low lands west of the Common. As the result, six large rope walks were immediately constructed at that point. They ranged from 20 to 24 feet in width and were each about 900 feet in length. Destroyed by fire in 1806, five of them were rebuilt, only to be burned again in 1819. During the first year of the mayoralty of the elder Quincy, the walks were removed still further out of town for the purpose of improving the neighborhood around the Common, but by the latter part of the 18th century the industry had assumed such proportions that it was generally admitted that “the men employed in the work outnumbers any other class of mechanics in Boston.” At this time the work in the rope-walks was performed by hand, the method having been described by Longfellow in his poem, “The Rope-walk.” The twisting of the fibres was accomplished by a man who walked backward down the walk, spinning from the hemp which was strung around his waist. The twist was imparted to the rope by a wheel, which was at first turned by a boy, although this purpose was later accomplished by the use of horse, or even water power.

It was not to Boston alone that the early industry of rope-making was confined, however. Nantucket, in the old days of her prosperity, had three large rope-walks, all of which long since disappeared; there was one at Castine, Me., one at Portland, Me., and several in other parts of the country, including one on Broadway, New York. In 1810 there were 173 rope-walks in the United States. The large business which is now conducted on the Pacific Coast was instituted by A. L. Tubbs of California, sometime in the fifties, who purchased the machinery of one of the old Boston plants and shipped it to California, where two or three large factories now stand as monuments to his enterprise.

Prior to about 1850, nearly all the spun yarns used in the making of cordage were imported by the American manufacturers. As such yarns were the product of Russian serf labor, they could be brought into the country and sold for less money than similar yarns could be produced in America, so it was not until the introduction of improved machinery reduced the cost of local manufacture that the importation of this raw material ceased.

The modern factory system began to take the place of the more crude and primitive methods of making rope soon after 1830, and from that time until 1850 the conflict between the two modes of manufacture was waged with considerable bitterness. By the new system it was possible to spin a rope several thousand feet long upon an upright apparatus that occupied but a few feet square, the necessary twist being imparted by a rapidly rotating machinery which was not unlike that which is used in cotton and woolen mills. At the same time, while its cost was cheaper, the factory-made product was not an entire success. There were purposes for which the rope made by the rope-walk method was far superior, and the makers of the old-fashioned article used the words “patent cordage” to disparage the factory-made product. As time passed, however, the invention of improved machinery tended to put an end to such rivalry. The most important inventions are those of John Good, of New York. It was his spreaders and breakers that did away with the use of lappers, and his nipper and regulator on spinning-machines that gave such universal satisfaction until the perfection of the “preparation machinery.” Evolved methods that superseded his process.

The rope-forming machine has a gage-plate through which the threads pass, a capstan on which the first cord is twisted, a right-and-left-hand screw to guide the cord back and forth on the winding-reel, and the necessary driving mechanism. It delivers accurately twisted strands or cords which go to the laying machine. This draws in the cords, with a tension-regulating device, twists them by means of a capstan, and winds them on a large reel. Ropes are commonly marketed in coils of 1,200 feet length. A 10,000 foot rope has been made without a single splice.

Cotton is used for making string, and some cord and rope. It makes a neat white string
that can be readily dyed. It is a useful material for bands, as in cotton spinning, but cotton rope costs more and is less durable than hemp. The fibre used in the manufacture of cordage is of either imported Manila fibre or sisal (Mexican hemp). The Manila hemp is from the herb Musa textilis of the banana family. Sisal is from the Agave Iseli, of Yucatan and Mexico. The best hemp fibres are 6 to 12 feet long, and test ropes of 1 1/4 inches diameter have been made to withstand a tensile strain of 50,000 pounds. The twisting has to be done scientifically not to weaken the fibre. In modern practice the strands are often flattened so that they will lie closely in the rope or cable.

It was the invention of the self-binding harvester that played an important part in furthering the interests of the industry, and, about 1876, the mills of the country began to increase their size and output to a noticeable degree. Among the most prominent factories started prior to or during that period, one may mention the establishment of Sewall, Day & Company, of Providence, Rhode Island; C. F. Boston; J. Nickerson & Company, of Boston; Weaver, Filter & Company, of Philadelphia, afterward, as at the present time, Edwin H. Filter & Company; the Plymouth Cordage Company; of Plymouth, Mass.; the Hingham Cordage Company, of Hingham, Mass.; the New Bedford Cordage Company, of New Bedford, Mass.; Baumgardner, Woodward & Company, of Philadelphia; J. T. Donnell & Company, of Bath, Me.; William Wall & Sons, of New York; Lorraine Waterbury & Company, of New York; Tucker, Carter & Company, of New York; the Elizabethport Steam Cordage Company, of New York; Thomas Jackson & Sons, of Easton, Pa.; J. Rinek's Sons, of Easton, Pa.; and John Bonte & Sons, of Cincinnati.

As may be seen from the above list, the cordage industry, even in those comparatively recent times, was largely confined to towns either on the coast or in close proximity to the seaports, for those were the days when the great demand for cordage was for export purposes, or for the direct use of ships temporarily located at the American ports. Later, such factors as the decline in American shipping; the substitution of wire for hemp standing rigging, and the increased demand for binder twine, so altered the conditions of the industry that the location of factories became a matter of secondary importance. Thus, they began to multiply in the interior, especially in the Middle West, such cities as Akron, Peoria, Xenia and Miamisburg becoming great centres for the industry.

In 1843 the total quantity of manila hemp that was manufactured in the United States amounted to only 27,820 bales, or 7,511,400 pounds. To realize the ridiculously small proportions of such a product, it is only necessary to remember that any one of several of the large mills in this country could now manufacture the same quantity of hemp in less than 50 days, by running day and night, or that a similar quantity of hemp could now be brought down from the Philippines in the same length of time by the use of two steamers. So rapidly did the industry expand, however, that, by 1863 it had increased in size to not less than five times, while the period of the Civil War created such a demand for cordage that the factories in the North were utterly unable to comply with it. The profits of one Eastern factory alone, during that period, amounted to more than $1,000,000. This was an exceptional case, for everywhere manufacturers were fairly inundated with orders that they simply could not fill. It was about 1860 that the first sisal hemp was imported into the United States. Purely an experiment in the beginning, less than 200 tons having been used during the first year, the product was so favorably received by the trade that it soon became one of the great factors in the cordage industry, a fact which fully accounts for the rapid increase in importations from the pastry 200 tons to the amount of our present imports, a quantity that is greatly in excess of 80,000 tons.

During these years no action had ever been taken to regulate the price of cordage. Business had extended until the American product was accounted a factor in almost every part of the world. To meet these ever-widening demands, factories had increased, both in number and in the importance of their output, but with little effort toward the control of the product. As the result certain abuses had come to prevail among the firms engaged in the business, and it was to meet this situation and better, if possible, the condition of affairs, that the first meeting of the cordage manufacturers was held early in 1861. The result of this meeting was an agreement, which was perfected and signed, on 23 February. Thereafter weekly meetings were held by the manufacturers, at which trade conditions were not only discussed, but any complaints were considered, and regulations were effected respecting the standard of prices. From time to time the agreement of 1861 was amended, and in July 1874 a complete revision was adopted, the manufacturers pledging themselves, "as men of honor and integrity, faithfully to observe all its provisions. In April 1875 a still stronger agreement was made, but as complaints about underselling were still made, and as, in the absence of any specified penalty, it was necessary to accept any reasonable excuses, the manufacturers finally decided to adopt what has since been known as the "pool system." According to this system, which went into operation 1 Jan. 1878, the business of the country was divided among the various manufacturers according to their proportions. When the business of either of these concerns in any one month exceeded the proportion which had been assigned to it, it was compelled to pay a certain amount per pound on the excess to the treasurer of the "pool," while the concern that fell behind in the specified production received a gratuity to a corresponding extent. The novelty of the plan acted in its favor for a time, and, although it did not entirely put a stop to the custom of cutting prices, it worked so well that the scheme was continued from year to year. The percentages ranged from 11 3/4 to 1 per cent.

In January 1880 the amount of the pool was reduced, by stages, from 2 to 3/4 of a cent per pound, and in January 1881 it was abolished altogether. About the same time the same objections had become so unsatisfactory that it was found necessary to re-establish it, and, on 28 June, new proportions were agreed upon. These remained in force for a period of three years, when the new concerns that had been formed were taken into the
"pool," and after much labor, a new adjustment of proportions was accepted in July 1883, remaining in existence until April 1887, when it was dissolved.

The history of the National Cordage Company, the next attempt to associate the various cordage manufacturers, dates from 1 Aug. 1887, when four of the leading New York concerns formed themselves into a trust.* Their aim was to control the price of manila and sisal hemp, but the effort was a failure. In January 1890, an attempt was made to compel other manufacturers to join their organization. As none of those who complied with these demands knew the terms which had been made with his neighbor, a condition of distrust was engendered which finally, 4 May 1893, drove the corporation into the hands of a receiver, in spite of the fact that it had paid 8 per cent dividends on its preferred stock since 1891, and from 9 to 10½ per cent on its common, the last dividend being declared on both only three days before the failure.

As the result of the reorganization the United States Cordage Company was formed, but as this corporation was also unsuccessful in its schemes to monopolize the purchase of raw material, the factories which had been purchased by the National Cordage Company went back into the market. Some of them were purchased by their former owners or their representatives; others went into new hands.

An unusual factor in the cordage trade was represented by the binder twine situation. In the spring of 1895, there was a considerable doubt as to the success of the twine, the cordage houses made it for the manufacture of harvesting machinery at a profit of several cents a pound. When the market position of this produce was established, the harvest-machine makers began to manufacture their own twine, and while this was done at a third of its original cost, the loss of these contracts was a serious setback to the cordage industry. According to the United States census of manufactures for 1914, the total number of establishments engaged in the manufacture of cordage and twines was 103. Their output for that year amounted to 487,443,356 pounds of rope and binder twine, valued at $43,085,517; cotton rope, 13,244,198 pounds, valued at $2,539,960; and other twine, 105,249,677 pounds, valued at $13,996,522—a total value of $59,621,945.

The output of twine, other than binder twine, was valued at $13,996,522, an increase of 56.7 per cent since 1909. This value comprises that of twine made from cotton, jute, hemp, flax and other materials. The output of cotton twine in 1914 was 17,927,286 pounds, valued at $3,472,056, representing a decrease of 12.2 per cent in quantity and 1.3 per cent in value as compared with the 1909 figures. Of jute twine the 1914 production—55,282,159 pounds, valued at $5,268,357—showed an increase during the five-year period amounting to 55.7 per cent in quantity and 100 per cent in value. Hemp twine showed a decrease in the period in quantity and 45.1 per cent in value, and flax twine an increase of 33.3 per cent in quantity and 26.6 per cent in value. The output of other twines, including those made from mixed materials, increased 110.7 per cent in quantity and 179.9 per cent in value.

Of the total value of products in 1914, $83,228,424, that of rope and binder twine represented 54.8 per cent. Exclusive of cotton rope the output of these products increased from 411,443,281 pounds valued at $30,918,663 in 1909 to 487,443,356 pounds, valued at $43,085,517, in 1914, or by 18.5 per cent in quantity and 39.4 per cent in value.

The production of cotton rope and twine, above given, does not represent the entire output of these commodities, a considerable quantity having been made by establishments classified in the cotton manufacturing industries. The combined production of ropes and twines from cotton and cotton yarns amounted in 1914 to 49,972,017 pounds, valued at $9,695,310, representing a decrease of 14.6 per cent in quantity and 4.1 per cent in value as compared with the 1909 output. The aggregate production of ropes and twines of all kinds, in all industries, however, increased during the five-year period from 525,340,375 pounds, valued at $66,446,785, to 624,737,764 pounds, valued at $63,303,293, or by 18.9 per cent in quantity and 36.3 per cent in value. The materials represented by the 1914 total comprised Manila hemp, New Zealand hemp, Hennequin (sisal from Jamaica and Cuba), sisal (from Africa, the Bahamas, Hawaii and Java) and all other hard fibers taken as a group. The soft fibres comprised jute, jute butts, flax and flax tow, hemp and hemp tow and others.

CORDAITALES (from the genus Corda- sii, named in honor of A. J. Corda), an extinct great group of naked seeded and primitive gymnospermous plants, resembling in certain respects the cycads and cycadeoids, ginkgo, especially the yews among conifers, and the araucarias. The Cordaitales are the most ancient of well-known seed-plants. They must have evolved in the Silurian or earlier; in the Devonian they formed the world's first great forests; throughout the Carboniferous they remained cosmopolitan elements of climax forests; while in the Permian they declined, and the record closes in the Liias. In North America large and finely silicified trunks occur in Canada, Ohio, Indiana, Oklahoma and elsewhere. Some of the sections of petrified trunks from the Black Shale (upper Devonian) of Indiana are two inches in diameter by 20 feet long, and indicate stately forest trees from 100 to 150 feet high. In portions of the Cordaites shale of New Brunswick the leaves often occur packed in layers like those of modern forests. The group appears to have culminated in the upper Carboniferous coal-swamp forests. There the stems and leaves with a great variety of staminate fruits and seeds are especially abundant. The most noteworthy Cordaitales specimens are the silicified leaves, with microscopic structure preserved from the "black flints* of the Coal Measures of Grande Croix, France. Study of this material, together with various trunks, casts and imprints, has revealed, nearly all the important structures of these long-extinct plants.

The Cordaitales were mostly tall and rather slender trees with columnar trunks which only branched freely near their summits. The leaves were usually large and spirally inserted. In foliage and habitus various forms were much like Dammara, the New Zealand Kauri pine
On the basis of wood structure classification is likewise provisional, since studies of entire stems are seldom or never possible to carry out. Three more or less overlapping divisions are also distinguished by Scott. (1)

The Poroxyloce were far the most fern-like. The stems were slender, only a few centimeters in diameter. They had long internodes and a double leaf trace bundle as in Lyginoptera, from which they mainly differ in their lack of centrifugal primary xylem. The petioles are known, and the bi-lateral seeds called Rhabdocarpus appear to belong here. (2) The Pityee include Pitys (with three species from the lower Carboniferous of southern Scotland), Archaroptery of the Waverly-shale of Kentucky, and Callixylon. A very fine stem of the latter from the Indiana Devonian is called Callixylon Oweni, and a related species is Russian. This group is only known from the pith and wood. The trees reached large size, but still retained mesarch strands of primary xylem traversing the medulla next the secondary wood. They are thus of great interest as forms intermediate

---

**Fig. 1** — *Dorycordaites* as first restored by Renauldt. Numerous catkin-like inflorescences are interspersed among the lanceolate leaves. The usual habit was much taller. Bark not shown. × 14.

**Fig. 2** — Large leaf simple-stemmed Cordaitalean with prolonged fertile axis. × 3/4. From Dawson.

**Fig. 3** — Cordaites lingulatus. Group of attached leaves. After Grand 'Eury. (Reduced.)
between the fern-like Poroxylea and typical Cordaitaeas. (3) The Cordaitaeas are the most advanced type and the greatest forest makers. Some reached 100 ft in height and three feet in diameter. The stems still more closely resemble Araucaria in structure, the elements of the wood all being radially arranged. No distinction between primary and secondary wood appears in the transverse section. The strands of "old cryptogamic wood," characteristic of the preceding divisions, are lost. In the radial section narrow spiral elements of the protoxylem next the broad discoid pit are succeeded by wider spiral tracheides, many rows of scalariform elements, and lastly the pitted tracheides forming the bulk of the wood. The piths of this wood are generally in two or more densely crowded rows. Their alternation tends to produce hexagonal outlines, though isolated pits retain their circular form. The pore is usually an oblique slit, and the crossed slits of appressed facing pits are highly characteristic. The medullary rays are thin, mostly one cell thick. The secondary wood is thus quite indistinguishable from that of Araucaria. The phloem is radial, the cortex parenchymatous and provided with secretory sacs. The outgoing leaf traces are double, as in Araucaria, Ginkgo and various primitive gymnospermous forms. There was a thick bark, recalling that of Araucaria. As in that modern type there are diarch roots with spiral protoxylem and the scalariform tracheides, followed by the secondary pitted wood. Triarch and tetrarch roots of similar structure are known. The very large cycad-like pith of all these stems appears to owe its discoid structure to tension during growth; but this feature may be seen in various modern plants such as the hickory and the walnut. Growth rings of the discontinuous or Araucarian type may occur. Amongst forms structurally antecedent to the three foregoing groups, and more fern and cycad-like may be mentioned the stems classed as the Calamopityea with petiolar known as Kalymma. Well-conserved forms of these occur in the Waverly of Kentucky at the close of Devonian time. The leaves of some Cordaitaleas are conspicuously parallel veined with repeated dichotomy in all but the narrowest grass-like forms. Anatomically they are very similar to the single pinnules of either the cycads or the cycadeoids. As in the latter, the structure is well known from silicified specimens. The bundles are usually described as of the mesarch type, but the centrifugal xylem may fail. Each is surrounded by a strong sheath, usually connected with heavily developed hypodermal sclerenchyma. Interwinding strands of the latter tissue may give to the leaf secondary venation.

Fructification.—The knowledge of the floral morphology of the Cordaitales now constitutes one of the most interesting chapters of paleobotany. It largely rests on the labors of directly Eury and Renaut. The latter having been so fortunate as to find silicified strobili of both sexes of certain species preserved in astonishing detail in the siliceous fragments or nodules of Grande Croix. Both male and female flowers, as well as seeds, have often been found directly Eury and Renaut. As in Ginkgo the cycads and the cycadeoids. An actual stage in pollination is thus seen. It is of fundamental importance a highly interesting group of prothallial cells. This group is theoretically a transition stage between Pteridophytes and Spermatophytes. An extraordinary instance is recorded. In a seed of Cordaites euryi the outer integument is partly broken away, the mucilagin being left standing free. In its upper end the pollen chamber contains the pollen grains as in Ginkgo and the cycads. An actual stage in pollination is thus seen. It is of fundamental importance.
that the pollen grains found in the nucellar canal are larger than those in the sporangia, and their group of internal cells more developed; while grains found free in the matrix exhibit an intermediate condition. Evidently the pollen grains continued to grow after their discharge from the anther, and especially after entrance into the pollen chamber. Such a condition is one of the most readily thinkable later stages in the evolution of heterospory and seeds from sexual spore-producing dichotomous free prothallia. The presence of free swimming spermatozoids is surmised.

The seed-bearing spikes are of varied form; in some, solitary ovules accompanied by a few bracts are inserted directly on the axis (Fig. 6); in others this arrangement appears to be compounded, the lateral catkins each containing several ovules and in their younger stages much resembling the staminate forms. Each ovule was thus borne on a short axillary shoot as in *Taxus* or *Ginkgo*. In such forms basal stamens may earlier have been present, forming a *Tumbo*-like fruit (Fig. 5). While homology with other gymnosperms is not very close, it is evident that this open type of inflorescence was capable of undergoing change in the direction of modern forms of compaction and reduction. Undoubtedly Cordaitcean seeds (those found attached) are mostly cordate, and flat or platyspermic. The winged seeds about a centimetre long called *Samaropsis* (Fig. 7) were attributed by Grand 'Eury to the genus *Dorycordsites* seen in the restoration Fig. 1. Others reach five or more centimetres in length, and owing to their size, heavy angles, and thick testa, are also fossils of striking conservatism. But there is no gap either of structure or of form separating such seeds from the larger radiosymmetric types abundant in the Paleozoic. In general the Cor-daitcean testa is more or less distinctly triple-layered, if the sclerotic testa tissue separating the outer fleshy sarcotesta from the inner flesh be called a layer. The chalazal bundle may give off branches into both the inner border of the sarcotesta and the nucellus. In a form called *Cycadinosperms angustodunensis* the archegonia are plainly present, but embryonic structures have never been observed in such seeds. They are scarcely separable from those of the quasi-ferns and greatly resemble the seeds of modern cycads. The seeds of the cycadeoids, owing to reduction, present a far less visible similarity.

The Cordaites derive a unique significance from their age and primitive characters, so manifestly important in our conception of the manner and course of plant evolution. Botanists have been inclined to believe that the Cordaitalean and Cycadalean groups had a common filicalean ancestry, and that from the Cordaitales have been derived the Ginkgoales, the Coniferales and probably the Gnetales. Some would go further and place the Cordaitales in a position ancestral to angiosperms as well. Carruthers is about equally divided between a Cordaitalean and an Equisetalean derivation of *Araucaria*. Recent investigation calls these theories of descent more in question. It is now recognized that fossil types are seldom the true antecedents of later forms. Most fossil plants represent terminal climax constituents in the floras of the past; while the extent of homoplasy and parallelism yet remains to be measured. Certainly increasing knowledge of the Cordaites will show them to be more varied than as yet conceived, and in any case their discovery must be regarded as one of the great triumphs of paleobotany.

G. R. WIELAND,
Lecturer in Paleobotany, Yale University.

**CORDAY D'ARMANS,** kör-dā dār-mān,
Marie Anne Charlotte, French revolutionist: b. Saint Saturnin, near Séz, Normandy, 27 July 1768; d. Paris, 17 July 1793. She had passed her early years in a convent and had read Plutarch, Rousseau, Raynal, and Voltaire. Her lover was accused by Marat as a conspirator against the republic, and assassinated by villains hired for that purpose. This excited
Charlotte Corday to revenge. History had inspired her with a deep-rooted hatred against all opponents of the Marat, and at the same time it was constantly quarreling with the Jacobin Club. The leading events of the reign of terror may be traced to the conflict of the two clubs, and chiefly to the influence of the Cordeliers, of whom Marat and Danton were the ruling spirits. Anacharsis Cloots was also one of the members. At the time the club was in its zenith, Camille Desmoulins edited a popular journal in connection with it, under the name of Le vieux Cordelier, without, however, identifying himself completely with the politics of the formidable club. They were the first to demand a republic, insisting on "Liberty, Equality and Fraternity." After the execution of Danton, Hébert and Chaumette, the club declined in influence, and was closed by the law of 6 Fructidor, or 23 Aug. 1795, which dissolved all the political clubs of France. Consult Bougeart, 'Projet d'organisation des Cordeliers' (Paris 1870); also 'Les Cordeliers, documents pour servir à l'histoire de la Révolution' (Caen 1891).

CORDER, kör-dyá, Henri, American educator: b. New Orleans, La., 8 Aug. 1849. He was educated in Paris; has been successively secretary of the Chinese Educational Mission, professor at the School of Political Sciences, Paris, and at the School of Oriental Languages, Paris. He is a member of the Council of the Asiatic Society and honorary member of the Royal Asiatic Society, is president of the Société de Bibliographie, member of the Institut de France and Chinese man of letters.

He has published 'Catalogue of the Library of the North China Branch of the Royal Asiatic Society' (1872); 'Narrative of Recent Events in Tong-kung' (1875); 'Bibliotheca Sinica: Dictionnaire bibliographique des ouvrages relatifs à l'Empire Chinois' (2 vols., 1881-85; Suppl., 2 vols., 1895; 2d ed., 4 vols., 1904-08); 'Les voyages en Asie au XIVe siècle du bienheureux frère Odoric de Pordenone' (1891); 'Histoire des relations de la Chine avec les Puissances Occidentales' (3 vols., 1892); 'L'Expedition de Chine de 1857-58' (1905); 'L'Expedition de Chine de 1860' (1906); 'La Chine en France au XVIIe siècle' (1910); 'Bibliotheca Indo-Sinica' (1913-). He edited the third edition of Yule, 'The Book of Ser Marco Polo' (2 vols., 1903), and the same author's 'Cathay and the Way Thither' (1913). Since 1890 he has edited Tsung Pao, a review of Oriental affairs.

CORDERITE, a name formerly given to the mineral ilolite (q.v.), in honor of Cordier, a French geologist.

CORDILLERAS, a name from the Spanish for a mountain chain or ridge, formerly applied to any lofty and straight areas of land, but now specifically to chains, ranges or ridges of mountains, and especially to such of these elevations as are long and continuous. It is used particularly in physical geography, though in geology also it is sometimes applied to mountain systems at or near the coasts or borders of continents. The name was first given by the Spaniards to the chains of the Andes in South America and was extended to their northern continuation through Central America and Mexico, and finally to the
entire mountain systems stretching up the western coast of the United States, British Columbia and Alaska, and spreading eastward to include the Rocky Mountains (q.v.). This portion of the continent geographers have come to call the Cordilleran region of North America, designating the corresponding elevations of South America under the old name of Andes. This covers in the United States the whole western mountain portion of the country, including the Sierra Nevada, the Coast Range, the Cascade Range, and extending to and embracing the Rocky Mountains, as well as all the great mountain ranges and the moun-
tains of the western coast. Included within this Cordilleran region are mountain systems many of whose lesser chains, in length and elevation, equal some of the famous ranges of Europe.

CORDITE, a smokeless powder employed by the English government. It was invented in 1889 by Sir Frederick Abel and Prof. James Dewar, and originally consisted of a mixture of nitro-glycerine 58 parts, nitrocellulose 37 parts, and 5 parts of a known substance, the bentonite used as a drying agent. It was found that the nitrocellulose, 80 of nitrocellulose and 12 of acetone, could not be mixed in the right proportion to form a homogeneous powder. The present proportion is 60 of nitro-glycerine, 15 of nitrocellulose, and 25 of acetone. It is a mixture of various nitrocellulose nitrates, insoluble and soluble. The ratio of the two is such that the powder will not burst when ignited by an electric spark. The powder is used in the manufacture of smokeless powder.

CÓRDOBA, kör'dō-bá, Fernando Fernandez de, Spanish general and statesman: b. Madrid 1792; d. 1883. He entered the military service in 1810, and was rapidly promoted during the war with Napoleon. In 1847 he officiated for a short time as Minister of War; and was appointed inspecting general of the infantry. On 8 March 1850 he was made captain-general of New Castle; in the following year to the same position in Cuba, and in 1853 general-in-

chief of the cavalry. Immediately after the outbreak of the revolution of 1854, he was called upon by the queen to form a new cabinet. This he declined, but he ordered his soldiers to fire upon the insurgents, and when the latter proved too strong for him, he retired to France. In 1856 he returned to Spain, and was reinstated in his position of general, and 10 years later was active in the revolution which drove Queen Isabella from the throne. He was captain-
general of Cuba for the second time in 1870.

CÓRDOBA, Francisco Hernandez de, Spanish soldier and explorer. See HERNÁNDEZ DE CÓRDOBA, FRANCISCO.

CÓRDOBA, José Maria, South American general: b. Antioquia, Colombia, about 1797; d. 17 Oct. 1829. At the age of 16 he left his father, who belonged to the Spanish party, and joined a band of guerrillas, among whom he soon became noted for his intrepidity in contests with the Spaniards. At the battle of Boyaca, 8 Aug. 1819, he won the rank of colonel. Not long after he was appointed general, and distinguished himself at the battle of Ayacucho, after which he was made general of division on the field. In September 1828 he became head of the War Department of the republic of Co-
lombia, under Bolivar, but, a year afterward, revolted against him. He found but few ad-
herents, however, and being attacked, 17 Octo-
ber, by a force greatly superior to his own, was slain with the most of his followers.

CÓRDOBA, Luis Fernandez de, Spanish general: b. Cadiz 1799; d. Lisbon, 29 April 1840. He took a prominent part in the movement of 1820 as a constitutionalist, and in that of 7 July 1822 as an absolutist. He officiated afterward on diplomatic missions abroad, and eventually deserting the forlorn cause of Don Carlos, espoused that of Christina and Isabel, took a distinguished part in the battle of Mendigorría, was appointed commander-in-chief of the Christians as successor of Valdez, but un-
able to finish the war, was driven from office after the movement of 1836, and fled to France, whence he soon returned to Spain. He now conspired with the party of Narvaez against Espartero, but retired to Portugal when the latter came into power.

CÓRDOBA, Pedro de, Spanish Dominican missionary: b. 1483; d. Santo Domingo, 28 June 1525. He was vicar of the first Dominican colony in Hispaniola in 1510, preached against Indian slavery and endeavored to have laws framed for the protection of the Indians. His efforts in behalf of the Indians were successful to the extent that he drew the attention of the Spanish court to the evils going on in the government of the Spanish colonies in the New World; but the influence of the adventurers who swarmed into the country shortly after the discovery of America and the capacity of the representatives of the Crown and of the land holders finally brought his work to naught; and the Indians in Hispaniola and neighboring islands soon became practically extinct.

CÓRDOVA, or CORDOVA, Argentine Republic, a province next in size to that of Buenos Aires, bounded on the north by Santo

tiago del Estero, on the east by Santa Fe, on the south by Buenos Aires and the territorial government of Pampa Central, and on the west by the province of San Juan and Catamarca. Area 54,000 square miles. Its northwestern portion is mountainous, and rich
in minerals. Copper, silver, gold, lime, marble, graphite and salt are found. The central and eastern regions lie in a great plain watered by the rivers Cuarto, Segundo, Primero, Dulce, etc., with the lake called Mar Chiquita; and here agricultural and grazing industries are carried on. Cattle, horses and mules are bred in the south; wheat and fruits are raised along the river courses; there are large flocks of sheep and goats in the centre and north. Besides wheat and fruits, the principal crops are maize, lucerne, barley, sweet potatoes and white potatoes. Of the total productions, about one-half, in value, are pastoral, one-third agricultural. The mining industry is as yet comparatively undeveloped. Manufactures are flour, lime and cement, bricks, hides and leather, beer, wine and alcohol, boots and shoes, cut wood, vermicelli, gold embroideries, butter and cheese, cut stone, belts, candles and soap, artificial ice, etc. Principal railway centres are the capital city, Córdoba (q.v.), Villa María and Villa Nueva. Under the constitution of the republic dated 25 Sept. 1860 the province has its own constitution, framed upon the basis of a republican representative system of government, and in harmony with the principles, declarations, and guaranties of the national constitution: the provincial constitution relating to the administration of justice, the administration of the local government, and primary instruction. Upon these conditions the federal government guarantees to each province the exercise and enjoyment of its own constitutions. The provinces have their own local institutions and laws; they elect their governors, legislators, and provincial functionaries of all classes, without the intervention of the federal government. The province is represented in the national legislature by two senators, elected by the provincial legislature, and by deputies elected directly by the people. Each province is for this purpose considered as an electoral district, and the election is by a plurality of votes in the proportion of one deputy to each 20,000 inhabitants, or fraction of that number not less than 10,000. Population of the province approximately 625,000.

CÓRDOBA, Argentine Republic, the capital of the province of the same name, situated on the right bank of the Rio Primero, 432 miles from Buenos Aires, at the junction of five railways. It is one of the progressive inland cities, having adopted many of the modern improvements, such as electric light, running water, street railways, sewers and excellent pavements. Its university, founded in 1813; astronomical observatory, established 1871; National Academy of Science; National Meteorological Institute; national college, normal schools and elementary schools, have made it well known as an educational centre. Railway communications were established in 1868. The first national fair was held here in 1871. A score of newspapers and reviews are published in the city. In size it is the third city of the republic. There are fine public buildings and private residences, and attractive parks. It was founded in 1583, and its university is in point of age second only to that at Lima among the South American universities. Pop. 100,000.

CÓRDOBA, Mexico, a town on the Mexican Railway, 66 miles west of Vera Cruz, in a fruitful valley 3,045 feet above the sea. It has manufactories of woolen and cotton goods and is surrounded by rich coffee plantations. Pop. 9,000.

CÓRDOBA, Spain, a town and capital of the province of Córdoba, situated on the Guadalquivir, in Lower Andalusia. It is built on a gentle declivity of a chain of mountains, forms an oblong quadrangle and is surrounded with walls and lofty towers. A part of the town is of Roman, a part of Moorish origin; many of the buildings are in ruins, and a number of gardens occupy a great part of the inhabited space. The streets are narrow, crooked and dirty; the plaza mayor, the principal marketplace, however, is distinguished for its size, its regularity and the beauty of the colonnade by which it is surrounded. The remains of the residence of the Moorish kings now form a part of the archbishop's palace. The cathedral is a splendid building, originally a mosque, erected in the 8th century by King Abd-er-Rahman I. The mosque of Córdoba is, in the words of Gautier, "a monument unique in the world, and novel even for travellers who have a fortune to admire the wonders of Moorish architecture at Granada or Seville." It is 370 feet in length, 425 in breadth and has a bell tower 300 feet high. It was at one time the second largest sacred building of Islam, and is the most magnificent Mohammedan temple in Europe. It is surrounded by a wall supported by strong buttresses. Other points of interest are the Campo Santo, the site of Christian martyrdoms, and the chapel of the Hospital de Cardinal, once part of a mosque. From the 9th to the 12th centuries Córdoba was a great centre of trade; the leather exclusively manufactured there (cordovan) was exported in all directions. At what period the Romans laid the foundation of the town (Colonia Patricia, afterward Corduba) is not known. In 572 it was conquered by the Goths. During the reign of the dynasty of the Ommiades it was the capital of Arabian Spain; and afterward it became the residence of the powerful caliphs of the East, the sacred city of the Moors and the centre of Mohammedan worship and of Arabian splendor and science. At that time the city is said to have been about 15 miles in circuit and to have possessed a population of 1,000,000. In 1248 it fell an easy prey to Ferdinand III of Castile. In 1808 it was pillaged by the French, who captured it again under Soult in 1810. Pop. 65,200. The province of Córdoba includes the fertile and beautiful valley of the Guadalquivir and the snow-covered mountains of Sierra Morena. The area of the province is 5,298 square miles and the population about 460,000.

CORDON, in a military sense, troops so composed as to preserve an uninterrupted line of communication, to protect, for instance, a country from hostile invasion; also a similar line intended to protect a place from contagious diseases. In the latter sense it is called a cordon sanitaire. The word "cordon" also means, in fortification, the coping of the escarp or inner wall of the ditch. It is usually rounded in front and projects one foot over the masonry.

In horticulture, cordon is a system applied to a system of training fruit trees. The trees are dwarfed by training and pruning to one or two stems which extend horizontally or
obliquely, and from which the fruit-bearing spurs are developed. The objects sought are economic spurs and increased size and improved quality of fruit. The system is in little use in America, where land is cheap, but in Europe it is very popular. It is best adapted to such trees as pears and apples, which naturally bear their fruits upon spurs.

CORDON BLEU, kór’-dón’ blé, a knight of the ancient French Order of the Holy Ghost, at one time the most aristocratic order in the kingdom, whose decoration was attached to a blue ribbon or baldric. The knights frequently met in club form, and were noted for their excellent dinners, whence the term came to be applied to a cook of superior skill.

CORDON GRAND, grôn, a term applied to a member of any grade of the French Legion of Honor, because the cross of the order is always suspended from a broad ribbon.

CORDOVA, Francisco Hernandez de, Spanish navigator: b. in the latter part of the 15th century; d. Cuba 1517. He was the discoverer of Yucatan, which he visited in 1517, and had several encounters with the natives. He lost some of his men, and two were taken prisoners and carried up the country. Shortly after his return to Cuba he died; but the account he gave of his discoveries led to a new expedition under Juan de Grijalva, to whom was subsequently assigned the honor of the discovery.

CORDOVA, Pedro de, chronicler, historian: b. Concepcion, 1692; d. there after 1770. He served in the Chilian army in Araucania and was alcalde of his native place about 1740. He wrote a 'Historia de Chile,' which includes an account of the settlement of the country up to 1717. In 1739, by order of President Velasco, he founded Los Angeles, the capital of Araucania. The manuscript of the work was preserved at Madrid. It has been published in the 'Coleccion de historiadores de Chile.'

CORDOVA, Ala., town in Walker County, 30 miles north of West Birmingham, on the San Luis, San Francisco and Southern railroads. The principal industries are the manufacture of cotton and coal-mining. The Cordova bank has resources of about $50,000; and there is a school accommodating 500. The government is in the hands of a mayor and alderman. Pop. 3,000.

CORDOVA, See CORDOBA.

CORDOVAN, a fine leather which took its name from the Spanish city of Cordova, where it was manufactured in large quantities. It was also called cordwain. The modern application of the term is to a grain leather from the beat and strongest portions of a horsehide and used for heavy boots, as for walking or hunting.

CORDURY, a ribbed cotton fabric, woven with a pile which is cut so as to leave the surface ridged in the direction of the warp. See FUSTIAN; VELVET.

CORDWOOD, wood, especially firewood, cut in lengths of 4 feet and piled in an oblong stack 8 feet long and 4 feet high. The cubical content of 128 feet is the standard for determining the prices of sale or of labor on the material.

CORDYCEPS, kór’-di-séps, a genus of its fungi, some of which are found parasitic on other fungi, while others are remarkable for growing upon the larvae of insects, which they latterly kill. It grows very freely over a wide area, and in different countries 28 species have been found.

COREA, kör’-rē’a. See KOREA.

COREAL, kör’-ē-al, Francisco, the name affixed to the 'Voyage aux Indes occidentales,' which was issued in Paris 1727. Its author asserted that he was born in Carthagena, Spain, in 1648 and had traveled extensively through Florida, Mexico and South America. The book abounds in errors and is probably a compilation. The work passed through several editions, one of the most important of these being published in Brussels in 1730.

COREONUS, kör’-ē-nōn, a genus of abdominal fishes, family Siluridae. The teeth are very small or wanting, the scales large and the height or front of the first dorsal as great or greater than its breadth. The genus is common in European waters and unusually large varieties are found in the rivers of Siberia. The most representative is Coreonus clupeiformis, the whitefish. They inhabit clear lakes.

CORELLI, Marie, English novelist: b. Italy 1864. In infancy she was adopted by Charles Mackay, the poet. She was educated in London, and on beginning her literary career adopted as a pen name that which subsequently became her legal name. She has published 'A Romance of Two Worlds' (1886); 'Venetta' (1886); 'Thelma' (1887); 'Ardath, the Story of a Dead Self' (1889); 'Wormwood'; 'The Soul of Lilith' (1892); 'Barabas' (1893); 'The Silence of the Maharajah' (1895); 'The Sorrows of Satan' (1895); 'Camoes' (1896); 'The Mighty Atom' (1896); 'The Murder of Delicia' (1896); 'Ziska' (1897); 'Jane' (1897); 'The Master Christian' (1900); 'Boj' (1900); 'Temporal Power' (1902); 'God's Good Man' (1904); 'The Treasure of Heaven' (1906); 'Holy Orders' (1908); 'The Devil's Motor' (1910); 'The Life Everlasting' (1911); 'Innocent, Her Fancy and His Fact' (1914).

CORETTYN, kör’-ten-in, a river of South America, separating British and French Guiana, and flowing into the Atlantic. It has a course of about 400 miles, and is navigable below the Great Cataracts in lat. 4° 20' N.

COREOPSIS, kör’-ē-op’-sĭs, a genus of annual and perennial herbs of the family Asteraceae. Nearly all the species are natives of eastern North America. The flowers, generally yellow, flowers in heads, and are widely cultivated in gardens. They are of easiest culture, being grown from seeds sown in a hot-bed and transplanted to any ordinary garden soil where they will blossom freely with little attention beyond keeping the ground free from weeds.

COREY, William Ellis, American capitalist: b. Braddock, Pa., 4 May 1866. He was educated at Duft's College, Pittsburgh. When 16 years old, he entered the chemical laboratory of the Edgar Thomson Steel Works, and five years later he went into the Homestead Steel Works, where, in 1889, he became superin-
CORFE CASTLE, a castle in Dorsetshire, England, now in ruins, standing a little north of a small town, to which it gives its name, and with which it is connected by a bridge of four arches. It was built by King Edgar in the 10th century and at its gates his son Edward the Martyr was murdered in 979. It was the occasional residence of King John, and was for some time the prison of Edward II. During the great civil war it was heroically defended against the parliamentarian forces by Lady Bankes. It was subsequently taken by Fairfax through the treachery of an officer of the garrison, when it was demolished, 1646. Consult Hind, 'History and Description of Corfe Castle' (London and Bournemouth 1883).

CORFIELD William Henry, English sanitarian: b. Shrewsbury, England, 14 Dec. 1843; d. Marstrand, Sweden, 26 Aug. 1903. He was educated at University College, London, and in the medical schools of Paris and Lyons, and was the first professor of hygiene appointed in University College, London. He published 'A Digest of Facts Relating to the Treatment and Utilization of Sewage' (1870); 'Lectures on Water Supply, Sewerage and Sewage Utilization' (1872); 'Laws of Health' (9th ed., 1890); 'Dwelling Houses: Their Sanitary Construction and Arrangements' (4th ed., 1888); 'Disease and Defective House Sanitation' (1896).

CORFU, kör-fú (anciently Corcysa), Greece, island in the Mediterranean, the most northerly and the largest of the Ionian Islands, at the mouth of the Adriatic, near the coast of Albania, about 40 miles long, and from 15 to 20 wide; square miles, 431. The surface rises in the north at one point to the height of 3,000 feet, but the south portion is low. The scenery is beautiful, and the climate is pleasant and healthful, save for malaria in the centre and in the south, and the soil is fertile. Oranges, citrons, grapes, honey, wax, olives and oil are abundant. Salt is also produced in some quantity. The ancient name of the island was Drepane. A Corinthian colony settled in the island in the 8th century B.C., taking it from the Illyrian inhabitants. Corcyra's quarrel with Corinth was one of the immediate causes of the Peloponnesian War. The Venetians possessed Corfu from 1366 to 1797, making it a Christian bulwark against the Turks. The British held it from 1815 to 1864. Pop. 99,571. Corfu, the capital, is finely situated on the eastern coast on a promontory which terminates in a huge isolated rock crowned by the citadel; the streets are Italian in style. The chief edifices are the cathedral, government palace and Ionian Academy. There is a good harbor and considerable trade. It is the seat of a Greek archbishop and of a Catholic bishop. Consult Riemann, 'Corfu' (Paris 1879); Patrich, 'Die Insel Korfu' (Gotha 1887); Schmidt, 'Korkyraische Studien' (Leipzig 1890). Pop. 28,254.

CORIANDER, a plant, Coriandrum sativum, of the parsley family, native of southern Europe but sometimes established as a weed in North America. It is an annual with finely divided leaves and small white flowers. It is commonly cultivated for the *seeds* (*fruits*), which are used in flavouring pastries, confectionery and liquors.

CORIGLIANO CALABRO, kō-rē-lē-lyānō ka-lā-brō, Italy, city in the province of Cosenza, four miles from the Gulf of Taranto or 18 miles southwest of Taranto. It has a castle and an aqueduct, and markets a high quality of manna from the ash trees of the surrounding country, as well as some oil. It was destroyed in 1806 by the French. Pop. 16,388.

CORINNA, Greek lyric poetess of Tanagra, in Boeotia. She was contemporary with Pindar, whom she is said to have conquered five times at musical contests, and therefore her image crowned with the chaplet of victory was placed in the gymnasion of Tanagra. According to Pausanias, who relates this fact, she was so beautiful that he cited she may have influenced in some degree the opinion of the judges. Of the numerous poems which the ancients ascribed to her, only a few fragments have come down to us. Her poems were all in the Boeotian dialect. They have been collected by Bergk in 'Poetae Lyrici Graeci' (4th ed., 1878), and by Schneidewin in 'Delectus Poetarum Graecorum' (1839). Madame de Staël has given the name of Corinne to the heroine of one of her novels. In 1907 a papyrus was found of the 2nd century A.D. on which were considerable remains of two poems attributed to Corinna. Consult 'The Year's Work in Classical Studies' (1907); Edmonds, 'New Fragments of Corinna' (1910).

CORINNE. 'Corinne' (1806) was the crowning point of Madame de Staël's literary career. In it her ideals find their most complete expression. By it, pre-eminently, and by her 'Germany,' in the words of Faguet, "she sowed the century with fertile ideas and gave French poetry as it were a new soul." It is a book of self-interpretation. The heroine is herself, and is the only living picture like the story whose plot, though easy and graceful, is of no special value. Corinne, of mingled Italian and English blood, has gone from England to Rome to seek psychic emancipation in a freer artistic life than English conventions admitted. With admirable art the spirit of the two nations is contrasted, unreckoning idealism with self-satisfied calculation, passion with cant, nature with respectability, fame with wealth and ease. To Corinne as to Coleridge, all thoughts, passions, delights are but ministers of love. Glory without love is only "the bright shroud of happiness," conscious intellectual superiority rather a hardship than a boon. Yet a vision of happiness seemed always beckoning her on; and this vision made of 'Corinne,' for a whole generation of romantic spirits, a story of generous passion and of ideal love, none the less because the heroine dies at last, abandoning her dignity to her love, a victim to social conventionality. Here a new range of emotions gained recognition in the fiction of fiction. The artistic and musical novels of the next generation, the Teverino's and the Consuelo's, had in 'Corinne' their inspiration and exemplar. It showed, too, as no novel before it had done,
CORINTH

how description of nature might be made to reflect and interpret the psychic moods of its characters. There are four English translations.

Benjamin W. Wells,

CORINTH, Greece, a celebrated city upon the isthmus of the same name. It was renowned for the cities of Greece, commanded by its advantageous position a most important transit trade, and possessed all the splendor which wealth and luxury could create; while its citadel, the Acrocorinthus, rendered it one of the strongest fortresses of Greece. Only a few ruins remain to attest its ancient magnificence. Of the three ancient harbors the western harbor, Lechaæum, on the Gulf of Corinth, is choked with sand, as is the eastern harbor, Kekhries (ancient Cenchreae), on the Saronic Gulf. These were anciently the chief harbors of Corinth. The shallow harbor Schemos, now Kalamaki, at the eastern entrance of the canal across the isthmus, is used to some extent. There is still a wretched village on the site of ancient Corinth. The American School of Classical studies at Athens began excavations in 1896 on the site of ancient Corinth. Few works of art were found, but the sites of the theatre, the fountains of Pyrene and Glaucia, the road to Lechaæum, the Propylea and the Agora were determined. In this way a basis was furnished for identifying the topography of the ancient city from the detailed description given by Pausanias. New Corinth (Nea Korinthos) stands about three miles to the northeast on the coast of the gulf, on the railway from Athens to Patras. It is a small town built since 1858, is the capital of the eparchy of Argolis and Corinth, and the seat of an archbishop. It has a harbor and custom-house. Oil, corn, currants, honey and silk are among its principal exports. The Corinth Ship Canal was opened in 1893, and has greatly aided the prosperity of the city. Pop. 5,340.

In ancient Corinth great exchange of Asiatic and Italian goods took place. The duty paid on these goods afforded a great revenue to the state; and the citizens accumulated such wealth, that Corinth became one of the most magnificent, but at the same time most voluptuous, cities of Greece. Aphrodite was the goddess of the city and courtiers, and her priestesses, to whom recourse was often had, that they might implore the protection of the goddess in times of public danger; and a certain number of new priestesses were consecrated to her at the commencement of important enterprises. Isis and several other females of the same profession were distinguished by their great accomplishments and beauty, and the high price which they set on their charms; hence the old proverb, Non civites homini contingit dare Corinthum, that is, "It isn't everyone that can afford to go to Corinth." The virtuous women celebrated a feast to Aphrodite apart from the others.

The mythical Sisyphus was the founder of the Eolian dynasty, which is represented as the first that ruled in Corinth. It was conquered by the Dorians, and again restored by an oligarchy called the Baccides, in whose time the colonies of Syracuse and Corcyra were founded. This was overthrown by Cypselus in 657 B.C. Periander was the next ruler. Corinth took a prominent part in the development of Greek colonization and was long a great naval power. In the sequel Corinth became the head of the Achaean League, and was conquered and destroyed by the Consul Mummius, 146 B.C. Julius Caesar, about a hundred years later, rebuilt it; but its commerce could not be restored; the productions of the East now took the road to Rome. A Christian community sprang up in the city under Paul's ministrations, and to it he addressed two letters. The Venetians received the place from a Greek emperor; Mohammed II took it from them in 1458; the Venetians recovered it in 1667, and fortified the Acrocorinthus again; but the Turks, under Ali Comourgi, celebrated in Byron's 'Sieg des Friedens,' took it in 1715, and retained it until Greece became independent. It was reduced to ashes during the Revolutionary War, and again ruined by an earthquake in 1856. Against any enemy invading the Morea from the north, Corinth and its citadel were formerly of the highest military importance, and as a fortified post it continued of importance to modern times. But by the present Greek government it has been neglected, E. Curtius, P. Paukens, Gotha (1852); Willich, 'Beiträge zur inneren Geschichte des alten Korinth' (1841); id., 'Geschichte Korinths von den Perserkriegen bis zum dreizeitjährigen Frieden' (ib. 1847). For a popular account, consult Richardson, Century Magazine (New York 1899) and Cooley, in Records of the Past (Vol. I, Washington 1902).

CORINTH, N. Y., a town in the Adirondack Mountains, 17 miles from Saratoga on the Hudson River. The Adirondack branch of the Delaware and Hudson Railroad connects with the town. The principal industries are the manufacture of paper and pulp, gloves and shirts. There are three schools, a national bank and a town-hall. Pop. 3,500.

CORINTH, Advance on (30 April–30 May 1862), and Battle of (3–4 Oct. 1862). Corinth, Miss., an important strategic point, was early occupied by the Confederates. It was the objective point of General Halleck's campaign, for which, early in April 1862, he was concentrating Grant's and Buell's armies at Pittsburg Landing, on the Tennessee River. On 3 April Gen. A. Sidney Johnston marched from Corinth with 40,000 men to strike and crush Grant before Buell could join him; surprised him on the morning of the sixth, at Shiloh; and after a severe fight drove him back to the river, where he was joined by Buell's advance division. Johnston was killed during the battle, and was succeeded by General Beauregard. Grant and Buell renewed the battle on the seventh; Beauregard was defeated, and led his army back to Corinth, having lost 10,000 men. Gen. John Halleck joined the army at Shiloh, 11 April, assumed command, drew reinforcements from every direction, and at the end of the month had 110,000 men. Grant was second in command. On 30 April the movement began on Corinth, 27 miles distant, held by Beauregard with about 50,000 men. The army had been reinforced. Early in May Halleck began to throw up elaborate works. It was a siege from start to finish, the army entrenching from the Tennessee River to Corinth. On 9 May occurred an engagement in which the
CORINTH—CORINTHIANS

regard) (Vol. II); Force, "From Fort Henry to Corinth."—E.A. CARMAN.

CORINTH, Gulf of, a beautiful inlet of the Mediterranean, about 80 miles long, between the Peloponnesus and northern Greece, having the Isthmus of Corinth closing it in on the east. It is better known as the Gulf of Lepanto. See LEPANTO, BATTLE OF.

CORINTH, Isthmus of, an isthmus connecting the Morea (Peloponnesus) with northern Greece. It varies in width from four to eight miles. A canal, about four miles long, was constructed across the isthmus in 1882–93, which enables vessels to pass from the Adriatic without rounding Cape Matapan. See CANALS; SHIP CANALS.

CORINTHIAN ORDER, that order of Grecian architecture of which the most characteristic feature is the capital of the column, which is adorned with beautifully carved Acanthus leaves, but varies considerably in minor details. The column is generally fluted, with a fillet between the flutings, and stands upon a base. The entablature is variously decorated, especially the cornice; the frieze may be quite plain, or sculptured with foliage and animals. The Corinthian order was not very common in Greece before the time of Alexander the Great. Among the Romans it was much employed.

CORINTHIANS, Epistles of Paul to the. These New Testament letters form only a part of the correspondence known to have passed between the apostle Paul and the church of Corinth. The circumstances that called them forth and dictated their contents were of crucial importance in the early life of that church and the letters can be studied to best advantage in the light of these circumstances. It was probably early in the year 50 A.D. that Paul the missionary and apostle arrived in Corinth, the largest, wealthiest and most dissolute city of Greece and the capital of the Roman province of Achaia. Here the missionary efforts of Paul and his companions soon resulted in the formation of a flourishing Christian church in whose membership all classes of this truly cosmopolitan city were represented, although the majority were of lowly station (cf. Acts xviii, 1 ff.; 1 Cor. i, 26 f.). Paul remained with the infant church about a year and a half, leaving in the fall of 51 A.D. soon after the arrival of the new proconsul Gallio (Acts xviii, 12-18). Some time after Paul's departure Apollos, an eloquent Alexandrian Jewish-Christian visited Corinth and lent his effective aid in building up the church there (Acts xviii, 24; xix, 1). After Apollos' return to Ephesus, the church of Corinth began to be disturbed by various troubles, all due generally to the fact that the membership was quite varied in character, comprising many whose experience of Christianity was brief or only superficial. Party-strife broke out (1 Cor. i, 11 ff.). Paul's apostolic authority was even questioned by some (1 Cor. iv), and one or more cases of immorality had occurred with no censure from the church as a whole (1 Cor. v). In addition confusion of thought regarding various matters of Christian faith and practice was becoming apparent. Meanwhile Paul was at Ephesus (52-54 A.D.) busily engaged in developing a large and far-reaching
missionary movement from that metropolis as a centre.

Paul was also engaged in this work, and apparently all unmindful of the troubles developing in the Corinthian church, Paul sent Titus, one of his most trusted assistants, from Ephesus to Corinth to lay before the church there his plan to collect from his Gentile churches a substantial sum of money for the poor Christian brethren of the old mother-church of Jerusalem (2 Cor. viii, 6, 10 f., 16 ff.; ix, 1 ff.). Titus was well received at Corinth and the church readily promised to contribute to the proposed collection. It is likely, however, that Titus noticed that all was not well with the church and so reported to Paul on his return to Ephesus. This moved Paul to write a letter, now lost, to the Corinthian church in which he urged them to take prompt measures in regard to the case or cases of immorality in their midst (cf. 1 Cor. v, 9). The effect of the letter was, however, to arouse a spirit of bitter hostility against Paul on the part of the guilty ones and their friends, who now began to spread malicious reports concerning Paul. Even the headship of the church, many of whom had been converted after Paul's departure and therefore had had no personal contact with him. This letter was written sometime in 53 A.D., upwards of two years after Paul had left Corinth.

All unaware of the extent of the disaffection toward himself Paul had also arranged to have Timothy, one of his missionary co-workers, call at Corinth in the course of an extended visitation of the churches of Macedonia and Achaia (cf. 2 Cor. xvi, 10 f.). But before he arrived at Corinth a deputation of leading members of the church there, bearing with them also a letter from some portion of the membership of the church, had left Corinth for Ephesus to inform Paul of the whole situation and get the benefit of his counsel (1 Cor. xvi, 17 f.; vii, 1). On the basis of all the information he now possessed from these and other sources (cf. 1 Cor. i, 11) Paul wrote the letter now known as the First Epistle to the Corinthians (in reality the second letter he is known to have written this church) in which he sought to deal fully with all the more important problems then facing the church of Corinth. In all probability Paul sent this letter by the deputation on their return. The letter was probably written approximatively as late in the year 53 A.D. When Paul wrote 1 Corinthians he felt that he possessed the confidence and affection of the church-membership as a whole, although he was aware that the attitude of some was not cordial and that it was necessary to speak plainly in rebuking certain errors in which the church as a whole shared. Like most of Paul's letters this is a letter, not a treatise, a message directed toward a concrete situation, dealing with the actual problems of the day and intended to be read and understood by the plain, and not especially learned people of the church as then constituted. Read as such a message it is full of living interest, but if read as an abstract discourse to treatise it cannot fail of being misunderstood.

After the usual introductory section (i, 1-9) Paul first devotes his attention to the party-strife in the church (i, 10-iv, 21). In dealing with this he points out that the church is tithed to the church of Christ, not of Paul or of Peter or of any other individual, and being founded upon the message of the Cross it is not based on a theory emanating from merely human wisdom, hence all party-strife and boasting is entirely out of place. His argument throughout was intended to counteract the tendency, evidently present in the church, to view the Christian faith as the product of human wisdom or theory and not as something revealed to man in his ignorance to save him. Paul passes next to advice and rebuke in reference to the offenses against Christian morality of which some had been guilty (v-vi). Then, in answer probably to written questions brought by the delegation, he discusses various aspects of the question of marriage (vii, 1-40) and also the important question as to how a Christian should regard the eating of meat that had been, in one way or another, offered to an idol (viii, 1-ix, 1). Paul's argument here involved reference to several related questions, especially the expediency of yielding one's rights in consideration of others less firmly established in the faith. Then Paul takes up the large question of the conduct of the members of the church, how they spent their time. He has been criticized for services of the church, criticizing the church's conduct in three particulars, (1) that some of the women prayed in public with head unveiled (xi, 2-16), (2) that there was unbecoming disorder in the observance of the Lord's Supper (xi, 17-34), and (3) that there was an unwise and unedifying use of their various spiritual gifts (xii, 1-xiv, 40). The beautiful description of love as the way (ch. xiii) is an integral part of this discussion. Finally, the mooted question of the nature of the resurrection body is taken up and answered at length (ch. xv). The remainder of the letter is devoted to information as to his plans and other personal matters.

It is possible that it was while Paul was writing this splendid letter that Timothy arrived in Corinth only to find that the opposition to Paul in the church there had reached a violent stage. For the moment it seemed as though the church had turned completely against him and that his influence over it was entirely lost. Timothy could do nothing and returned to Paul with a most discouraging report, reaching Ephesus after 1 Corinthians had been sent. Apparently also the return of the delegation with the message contained in this letter was, for the fixed destination, of no effect. In consequence of Timothy's report Paul at once made a hasty, but painful and ineffectual visit to his rebellious church, returning to Ephesus in great sorrow and anxiety, although not altogether hopeless (2 Cor. xii, 14, xiii, 1 f.). He then now went back to Corinth, whose earlier mission to Corinth had been so successful, sending him with a letter, written in great sorrow of remonstrance and appeal. The greater part of this letter is probably preserved in the later portion of the so-called Second Epistle to the Corinthians, namely in 2 Cor. x-xiii, 10. Such seems to be the only satisfactory solution of the remarkable difference between 2 Cor. i-ix, so full of joyful confidence and thanksgiving and chapters x-xiii, so full of pain, anxiety, apology and explanation. It is this sorrowful letter that is referred to in 2 Cor. ii, 3 f. and vii, 8-12. It was written probably early in 54 A.D. about the time of the disturbance in Ephesus caused by Demetrius the silversmith (ch. xix, 21). This brief letter Paul first replied to the charge that
he was weak and forceless (1, 1-18), then defended himself for his apparent self-glorification, pleading his special relation to them and showing that he was only glorifying in his weakness for it was in reality God's power and not his own that he had in him (xi, 1-10). He was compelled thus to speak (xi, 11-18) and when he should come to them again, the third time, they would know how strong his position was (xii, 19-23).

Soon after Titus' departure for Corinth with this message Paul closed his work in Ephesus (June 54 A.D.) in order to make a tour of his Macedonian churches and then to pay a visit to Corinth in case conditions there became more favorable. It was probably at Philippi that Titus rejoined Paul, who had been anxiously impatient to hear from him (cf. 2 Cor. ii, 12), and brought the cheering and comforting news that the church of Corinth had repented of its errors and disorders and was fully prepared to follow the Apostle's advice and would be glad to see him again. Out of great joy and thankfulness Paul wrote the Third Epistle to the Corinthians, which we possess as 2 Cor. v-ix. The greater part of this letter (chs. i-vii) is devoted to the happy subject of the reconciliation that had been brought about through the efforts of Titus. These chapters do not reveal any carefully worked out plan. They are profoundly emotional and personal rather than deliberately didactic. For example, the thread of thought at i, 13 is suddenly broken off, as the full significance of Titus' success impressed itself on Paul, not to be resumed until vii, 5. But in spite of this lack of logical sequence these chapters are among the richest in spiritual truth of all the Pauline letters. Here the heart of the great apostle is laid bare and the depth and sincerity of his spiritual experience is disclosed. The latter part of the letter (chs. viii and ix) is devoted to urging the Corinthians to contribute promptly and heartily to the collection for the poor saints in Jerusalem. They had promised to do this the year previous and now, as he was sending Titus back to them with this letter, he urges them to have it all ready for him (Paul) to take it with him to Jerusalem as soon as possible after his expected visit to Corinth, which expedition was realized as we learn from Acts xx, 2.

It should be said that the view adopted above as to the composite character of 2 Corinthians is not as yet generally accepted although it is receiving increasing support. To the writer it is the only theory that satisfactorily explains the references in 2 Cor. ii, 3 f. and vii, 8-12 to a sorrowful letter and also the marked difference in tone between 2 Cor. i-iix and x-xiii.

CORINTHIANS, Third Epistle of, an apocryphal epistle or letter, which like one said to have been sent from the Corinthians to Saint Paul, were both in Armenian. Apocryphal letters or epistles made their appearance at a very early period after the death of the apostles. See APOCRYPHA.

CORINTO, ko-réntó, Nicaragua, in the department of Chinandega, and the principal port of entry on the Pacific coast of the republic. A railroad, owned and operated by the government, connects it with Momotombo, at the head of Lake Managua, a distance of 58 miles. There are four regular lines of steamships that touch at Corinto, carrying passengers, mail and general cargo, and navigating the Pacific from North to South America. Owing to the intense heat and unhealthfulness of the place, very few people live there, except the government employees, steamship agents, and those employed on the railroad and wharves. A 'convention of peace and compulsory arbitration' was signed here 20 Jan. 1902, by plenipotentiaries of the governments of Nicaragua, Costa Rica, Salvador and Honduras. It is the residence of a United States vice-consul.

CORIOLANUS, Gaius Marcius, Roman hero, called Coriolanus because of Coriolanus, the capital of the kingdom of the Volsci, was taken alone solely by his exertions. Coriolanus became very unpopular when, during the famine which prevailed in Rome 490 B.C., he proposed to distribute the provisions obtained from Sicily among the plebeians only on condition that they would agree that the tribuneship should be abolished. Banished for this cause, Coriolanus, resolved to revenge himself upon his country, went to the Volsci and prevailed upon them to go to war with Rome before the expiration of the truce. He himself was joined with Attius Tullius in the command of their army, which immediately took the cities of Latium, and the Volscian camp was pitched in sight of Rome before troops could be raised for the defense of the city. The envoys sent by the Senate returned with the answer, that Rome could not purchase peace only by the surrender of the territory taken from the Volsci. A company of Roman matrons, headed by Veturia, the mother, and Volumnia, the wife of Coriolanus, at length subduced his resolution and he withdrew his army, and lived among the Volsci until his death. On the spot where he yielded to his mother's words a temple was dedicated to Fortuna Muliebris and Valeria was its first priestess. Shakespeare, in his play of 'Coriolanus,' calls the hero's wife Virgilia, his mother Volumnia and the Volscian leader Tullus Aufidius. Consult Smith, 'Dictionary of Greek and Roman Biography and Mythology.'

CORIOLANUS, probably the latest of Shakespeare's Roman plays, dates from about 1609. Like Julius Caesar and Antony and Cleopatra, its plot is derived from Sir Thomas
North's translation of Plutarch's 'Lives' (first published in 1579), of which it makes on the whole an even closer use than the other two plays. About 550 lines of North's 'Life of Coriolanus' are woven into the drama, often — as in the case of the hero's great speech to Auffridus at Antium (IV, v, 71 ff.) and Volumnius at the Roman Senate (V, iii, 94 ff.) — with only the slightest verbal change. If the accepted date, as given above, is correct, 'Coriolanus' may be presumed to be the last of all Shakespeare's tragedies. It was not printed before the appearance of the first folio in 1623, and there occupies the first place in the group of tragedies, a position analogous to that of 'The Tempest' at the head of the comedies. It is one of the longest of Shakespeare's plays (only 'Richard III', 'Hamlet', and 'Cymbeline' cover a greater number of pages in the folio), and it is one of the most thoughtful. Without essentially changing Plutarch's story, Shakespeare has vastly elaborated the basic theme of the conflict between plebeian and patrician, with the result that this play remains his most ambitious effort at interpreting social theory. Like Plutarch, and like the Elizabethans generally, Shakespeare sympathizes with the claims of the aristocrat in the commonwealth, but he here reflects more justly than elsewhere both the force and weakness of democracy. This aspect of the play has naturally tempted discussion. In one of his most characteristic and provocative essays ('Characters of Shakespeare's Plays', 1817) William Hazlitt expounded 'Coriolanus' as an illustration of the uncompromising aristocracy of poetry. On the stage, 'Coriolanus' has had an eventful history. During the latter part of the 17th and through the 18th century various revised versions held the stage. The 19th century saw the gradual restoration of the original text. John Philip Kemble was famous in the play, along with his sister, Mrs. Siddons, and selected it for his farewell performance in 1807. The American actor Edwin Forrest similarly chose the rôle of Coriolanus as that in which to be immortalized in a statue.

**Tucker Brooke, Assistant Professor of English, Yale University.**

**CORK, First Earl of.** See Boyle, Richard.

**CORK, Ireland, a maritime county, province of Munster, having Saint George's Channel south, County Limerick north, Kerry west, Waterford and Tipperary east. Extreme length, east to west, 110 miles; extreme breadth, 70 miles; area, 2,890 square miles. The coast is indented with numerous bays and inlets, of which the more important are the bays of Bantry, Dunmanus, Long Island, and Clonskilly, Kinalse and Cork harbors, and is serrated with headlands and promontories. Off the coast lie the islands of Clear, Whiddy, Dursey, Bear and several smaller. The county is watered by the Bandon, Lee and Blackwater, and numerous smaller streams. The county is rich in coal, limestone and sandstone, and some iron is mined. Pop. about 400,000.

**Cork, Ireland, city, capital of the county of Cork, situated on the river Lee, 15 miles from the sea and 165 miles southwest of Dublin. Besides an upper harbor at the city itself, and quays 4 miles in length, there is a lower harbor at Queenstown, 11 miles below. The entrance, deep and narrow, is strongly fortified on each side. Cork is the third city in Ireland, and exports great quantities of grain, butter, bacon, eggs and live stock. The principal industries are tanning, distilling, brewing and the making of tweeds and linens. There are also iron foundries and yards for the building of iron ships. Cork's principal buildings are the Protestant and Roman Catholic cathedrals, exchange, custom-house, chamber of commerce, courthouse, Queen's College, etc. There is a naval dockyard at Haulbowline, an island within Cork harbor. Cork dates from a religious settlement in 622 and from a Danish trading settlement of the 11th century. Pop. municipal borough, 80,124; parliamentary borough, 104,496.

**Cork, the external bark of a species of oak (Quercus suber) which grows in Spain, Portugal, France, Italy, Tunisia, Algeria and Morocco, and is distinguished by the cellular texture of its bark, and the leaves being evergreen, oblong, somewhat oval, downy underneath and waved. The area over which the culture extends is about as follows: Portugal, 600,000 hectares; Spain, 300,000 ha.; Italy, 80,000 ha.; France and her African possessions, 661,000 ha., of which 426,000 are in Algiers and 82,000 in Tunis. The cork oak grows in forests in the company mostly of firs and evergreen oaks, but in a part of Tunis there are forests consisting entirely of cork oaks. The bark of these Tunisian forests is said to be of an extraordinarily excellent kind. France, Great Britain, Germany and the United States receive about 85 per cent of the total production of cork. Germany, Russia and the United States have no prohibitory duties on importation of cork and cork goods, and admit the material free or with only a trifling impost. Great Britain also permits the free entry of cork and draws most of its supplies from France, Spain and Portugal. The last named takes the chief place in cork productions, producing nearly one-half of the total growth of the bark — about 450,000 quintals per million produced. The greater part of this — perhaps three-fourths — is the crude bark, while the remainder is in manufactured stoppers. Spain exports only manufactured wares. In the collecting of cork it is customary to insert a knife at certain distances, in a perpendicular direction from the top of the tree-trunk to the bottom; and to make two incisions across, one near the top and the other near the bottom of the trunk. For the purpose of stripping off the bark, a curved knife with a handle at each end is used. Sometimes it is stripped in pieces the whole length, and sometimes in shorter pieces, cross cuts being made at certain intervals. In some instances, after the perpendicular and transverse incisions are made, the cork is left upon the trees until, by the growth of the new bark beneath, it becomes sufficiently loose to be removed by the hand. After the pieces are detached, they are soaked in water, and when nearly dry are placed over a fire and are charred, which blackens their external surface. By the latter operation they are rendered smooth, and all the smaller blemishes are thereby concealed; the larger holes and cracks are filled up by the introduction of soot and dirt. They are then loaded on carts for shipment, and subsequently are dried and stacked, or packed in
CORKITE—CORN

bales for exportation. In the course of eight or nine years the same tree will yield another supply of bark. The quality of the cork improves with each successive stripping; and the trees continue to live and thrive under the operation for 150 years and upwards. The tree is an evergreen species of oak. It reaches its height by about 30 feet. The outer layer of bark by annual additions from within gradually becomes a thick soft homogeneous mass, possessing those compressible and elastic properties upon which the economic value of the material chiefly depends. The first stripping takes place when the trees are from 15 to 20 years of age. This first yield is woody in texture, and is useful only as a tanning substance, or for forming rustic work in fermeries, etc.

The uses of cork were well known to the ancients, and were nearly the same as those to which it is applied by us. Its elasticity renders it peculiarly serviceable for the stopping of vessels of different kinds, and thus preventing either the liquids therein contained from running out, or the external air from passing in. This is the general use of cork in the manufacture of bottles, which is generally considered to have been introduced about the 15th century.

The practice of employing this substance for jackets to assist in swimming is very ancient, and it has been applied in various ways toward the preservation of life when endangered by shipwreck. The cork jacket, used to preserve the lives of persons in danger of drowning, may be constructed as follows: Pieces of cork about three inches long by two inches wide, and the usual thickness of the bark, are enclosed between two pieces of strong cloth or canvas, and formed like a jacket, without sleeves; the pieces of cloth are sewed together round each piece of cork, to keep them in their proper situation; the lower part of the jacket about the hips is made wide enough to give freedom to the thighs in swimming; and the whole is made sufficiently large to fit a stout man, and is secured to the body by two or three strong straps sewed far back on each side, and tied before; the straps being thus placed to enable any wearer to tighten it to his own convenience.

The floats of nets used for fishing are frequently made of cork. Pieces fastened together make buoys, which afford direction for vessels in harbors, rivers and other places. In some parts of Spain it is customary to line the walls of houses with cork, which renders them warm and prevents the admission of moisture. On account of its lightness cork is used in making artificial legs; and from its being impervious to water it is sometimes placed between the soles of shoes to keep out moisture.

In the cutting of corks (when they are made by hand, and not, as is now generally the case, by machinery), the only tool employed is a very broad, thin and sharp knife; and as the cork tends very much to blunt this, it is sharpened on a board by one whet or stroke on each side after every cut, and now and then upon a common whetstone. The corks for bottles are cut lengthwise of the bark, and consequently the pores lie across. Bungs and corks of large size are cut in a contrary direction: the pores in these are therefore downward — a circumstance which renders them more moisture-impervious than the others. The various sizes of cork are used for making Spanish black, and largely in the manufacture of linoleum and similar goods. The United States imports unmanufactured cork annually to the value of over $3,000,000, and manufactured cork to the value of $2,500,000 approximately.

CORKITE, a lead ore of minor importance consisting of phosphate and arsenate of lead and ferric sulphate. It occurs in ores of Beaver County, Utah.

CORLEONE, kör-lā-ô'na, Sicily, town in the province of Palermo, about 22 miles south of the city of Palermo, near the source of the Belici. It is well built, has several churches and convents, a prison, royal college and some other public edifices. The inhabitants are principally engaged in agriculture. The ancient Korilium was founded by the Saracens and colonized with Lombards by Frederick II in 1237. Pop. 19,072.

CORLISS, George Henry, American inventor: b. Easton, N. Y., 2 June 1817; d. Providence, R. I., 21 Feb. 1888. The construction of stationary steam engines was revolutionized by his improvements and a single cylinder of a size of 12 by 27 inches not only enabled him to move all the machinery in the central hall of the exposition of 1867.

CORLISS ENGINE. See STEAM AND STEAM ENGINE.

CORM, or CORMUS, in botany, the dilated base of the stems of some plants, as the crocus, cyclamen, etc. It is commonly called bulb or root tuber, but is actually neither.

CORMON, kör-mōn, Fernand, French painter: b. Paris, 22 Dec. 1845. He studied under Cabanel, Froment and others, and in 1875 he received the Prix de Salon; in 1887 a medal of honor at the Salon of that year; in 1889 the Grand prize at the Paris Exposition, and became an officer in the Legion of Honor. His best-known works are 'The Stone Age' (1884); 'The Victors of Salamis' (1887); other works of his are 'Cain' (1880), and 'The Raising of the Daughter of Jairus.' A series of archaeological subjects, probably, has been injurious to his reputation of human development from prehistoric times gave him celebrity, and his portraits have given him a high reputation in that branch of art.

CORMORAN, a Cornish giant in the nursery tale 'Jack, the Giant-killer.'

CORN (from French corne, from Lat. cornu, a horn, from its horny nature), a hardened and thickened portion of cuticle produced by pressure. Corns are generally found on the outside of the toes, but sometimes between them, on the sides of the foot, or even on the ball. They gradually penetrate deeper into the parts, and sometimes occasion extreme pain. No part of the human body, probably, has been injured so much by our injudicious mode of dress as the feet, which have become, in general, deformed. To this general deformity of the foot belong the corns, produced by the absurd forms of our shoes and boots. They appear at first as small dark points in the hardened skin, and in this state stimulants or escharotics, nitrate of silver (lunar caustic), are recommended. The corn is to be wet and rubbed with a pencil of the caustic every evening. It is well to have the skin previous to the soaking. If the corn has attained a large size removal by a cutting or ligature will be proper. In all cases
of cutting corns very great precaution is to be observed. The feet ought always to be bathed previously. Mortification has, in many instances, resulted from the neglect of this precaution, and from cutting too deep. An efficacious remedy for corns is the application of glacial acetic acid night and morning. This acid has a decided effect on the epidermis, of which corns are a hypertrophy. Salicylic acid is also an excellent application. A simple and generally very efficacious means of alleviating the pain caused by corns and removing the cause for their growth is the application of a thick adhesive plaster, in the centre of which a hole has been made for the reception of the projecting part.

CORN, grain, such as wheat and barley; maize, or Indian corn; also the plants that yield grain; breadstuff. This is a generic term for all kinds of grain used for making bread, and is applied specifically to the principal breadstuff; in England to wheat, in the United States to Indian corn or maize, and in Scotland frequently to oats. The word is Anglo-Saxon, and occurs in similar forms in the other Teutonic tongues. The words corn and maize are said to have been used in ancient times as at present, having a different meaning in different countries.

Indian corn, also called maize, is an endogenous plant that grows luxuriantly in warm temperate climates. It belongs to the tribe of Phaloidae of the order of Gramineae, or grasses. It is known in botanical science by the name Zea mays. The flowers are non-mecine; the male flowers forming a loose panicle at the top of the culm; the female flowers in axillary spires, enclosed in large, tough spathes, from which only the extremely long styles—in the common species, six to eight inches in length—hang out like tufts of feathers or silken tassels. The grains are large, roundish, compressed, naked and arranged in parallel rows along the upright axis of the spike. The long parallel-veined leaves and the stalks are often used as fodder. The common Indian corn is generally believed to be a native of the warmer parts of America, where it was cultivated by the aborigines before the discovery of the continent by Columbus; but a representation of the plant found in an ancient Chinese book in the royal library in Paris, and the alleged discovery of some grains of it in the cellars of ancient houses in Athens, have led some to suppose that it is a native also of the East, and has, from a very early period, been cultivated there, and even that it is the *corn* of Scripture; although, on this supposition, it is not easy to account for the subsequent neglect of it until after the discovery of America, since which the spread of its cultivation in the old world has taken place with a rapidity such as might be expected from its great productiveness and other valuable qualities. Columbus himself took it to Spain. When first introduced into Europe, many supposed it was brought from Asia, and it was as frequently known as Turkey corn, Turkey wheat.

Sweet corn is any one of the starch corns, flint, dent or flour corn, that has lost its faculty of converting sugars into starches. It is grown chiefly as a vegetable for table use, although the kernels are often harvested as forage for stock. Its culture is most extensive in the vicinity of large cities, where it is grown as a truck crop and in certain regions where it is grown as a feeding corn. The principal canning variety is a late corn, Stowell Evergreen. Country Gentleman is also used to a large extent among the canners. In Maine, a corn known as Clark's is used for canning. Hickox and Trucker's Favorite are the principal canning varieties in other regions. In the suburban truck gardens the custom is either to plant early and late corn, or one high-class variety every two weeks. Cory, Crosby, Quincy Market, Country Gentleman and Stowell Evergreen are often planted in the order named. According to the latest census the number of farms growing sweet corn in the United States was 48,514, the number of acres 178,224, the value of the product $5,936,419. New York had 6,586 farms producing sweet corn to the value of $942,023. Pennsylvania was second with 4,896 farms. Illinois had the second place in number of acres, with 19,976 acres and second in value of product, which was valued at $538,746. Ohio, Maryland and New Jersey are next in importance in the canning industry. The canning industry flourishes in Illinois, Indiana, Iowa, Maine, Maryland, New York and Ohio. In 1915 the amount of Indian corn produced in the United States was 3,054,535,000 bushels (final estimate. 1st December), and in Argentina in 1914 it was 2,672,500,000 bushels. Argentina in 1914 produced 204,562,000; Mexico, 190,000,000; Romania, 110,230,000; Italy, 105,000,000 bushels. Estimate for the maize crop of the world, 4-000,000,000 to 4,500,000,000 bushels.

CORN CLUBS, organizations promoted in 1916 in the rural districts of the United States, for the purpose of arousing interest in the scientific culture of corn and other agricultural products among the country boys and girls; and to supply wholesome recreational activity for the rural youth. These clubs were founded in connection with the general movement for rural recreation.

CORN-COCKLE (Agrostemma githago), a plant of the pink family (Sileneae). It is an annual, pubescent, often branching herb, from one to three feet tall, distinguished by its large purple flower. Though a native of Europe and western Asia, it is now found in most temperate regions, frequenting grain-fields and waste places. When its seeds become mixed with those of the grain, and are ground with them, it is said to effect and render the grain unwholesome; thus it requires to be separated from the grain by a special kind of sieve. In Germany the seed when ripe and dried is called schwartz-kümmel (black cumin), and is sold for medicinal and domestic purposes.

CORN-CRAKE (that is, *corn crow*, because of its cry), the common name in England of a small rail (Crex porphaena) which frequents meadow lands throughout Europe; also called landrail. The name crake is applied to various other birds of the family Rallidae, which differ from the typical rails in having a shorter beak. In the United States the common rail (Porzana carolina) and allied species are occasionally so called. They are secretive birds, abundant in reedy swamps, and are much sought by gunners in the fall of the year.

CORN CULTURE. The profitable production of corn depends upon: (1) fertility of
soil; (2) conditions of climate; (3) quality of seed; (4) methods of cultivation.

Fertility of soil is the first and most important of these conditions. Three elements, nitrogen, phosphorus and potassium, are important constituents of soil fertility, and the one which is usually lacking in quantity in the soil's composition, or become quickly exhausted by continuous cropping without proper rotation of crops or application of manures. In those regions where corn is most extensively grown as in the Mississippi Valley of the United States, the fertility of the virgin soils seemed almost unlimited to the pioneer farmers, who in many instances grew corn after crop of corn, selling the product off the land without apparently diminishing the productiveness of the soil. However, after a half century of such practice, it has been found that the soil has been exhausted by this system of farming. The depleted soils are found to have an insufficient supply of the important elements necessary to restore fertility, and it becomes necessary to resupply them directly in the form of commercial fertilizers, or indirectly, through the use of barnyard or other like manures, or by the growing of green manure crops.

Methods of Restoring or Maintaining the Fertility. — There are several methods which are practised with economical results in the corn belt of restoring exhausted corn lands to a fertile condition, and of keeping up the fertility of such soil under cultivation. It will be impossible to treat of many of them in detail here, so that only a few of the principal plans will be outlined.

Commercial Fertilizers.—The use of commercial fertilizers for corn land is limited to those soils which are lacking in one or more constituents of plant food which can be bought in the market, either alone or in combination, at a reasonable cost, usually nitrogen, phosphorus, potassium or lime. Their general use is limited from the fact that the cost of supplying them in this way is so great that the returns in crops like corn do not usually justify the outlay. Nitrogen, phosphorus and potassium now bring a high price per pound, when purchased in artificial fertilizers. From the fact that the cost of these manures is so great it would be unprofitable to use them for the growing of a crop without having as a basis a soil naturally sufficiently supplied with one or more of these elements. In some cases it may be advisable to apply one or more of these constituents to correct some unusual soil condition, but the large areas which are naturally rich in all necessary elements of plant food for corn, and adapted in all conditions for growing corn, preclude their general use for this purpose by the corn growers of the United States.

Barnyard Manure.—Barnyard manure contains a large supply of plant food, and when applied to the soil not only increases its fertility but improves the mechanical condition, or tilth, as well. The large amount of straw and vegetable matter in its composition, when decomposed and assimilated by the soil, improves its condition for corn crops. In fact it has come to be a generally followed practice among our most progressive farmers, not only to enrich the soil to live stock, carefully conserving the manure for application to the soil. In such cases, the best plan seems to be to compost the manure, and after it has become well-rotted, to spread it on the field while the soil is frozen in winter, plowing it under to a good depth in the spring. This practice can be followed only where local conditions permit. On soils that leach or are carried off by rain it is necessary to apply the manure at the times when it will not be washed off the soil by winter or spring rains, or wasted from other causes. In such cases, the manure may be spread on grass lands or pastures in the spring or summer, the field being plowed for corn the following autumn or spring. About 10 tons of well-rotted manure per acre is considered a sufficient application for ordinary corn land.

Green Manure Crops.—The most important method of maintaining the soil's fertility is by the use of green manure crops, such as clover, cowpeas, soy beans and alfalfa. These crops add to the supply of nitrogen in the soil under favorable conditions and when plowed under improve its tilth. They constitute a valuable feed for live stock. The addition to the plant food supply of the soil by the growth of leguminous crops is accomplished in two ways: Firstly, by the presence and growth of certain organisms peculiar to these crops, inducing the development of bacteria. These organisms have the power of drawing upon the free and unavailable nitrogen of the atmosphere and converting it into an available and useful condition for plant food. Secondly, from the fact that these crops root deeply as a rule, drawing upon plant food in the soil, which is not in position for use by ordinary crops. This food is assimilated by the plants, so that when the crop is plowed under the decomposition of the roots and stems leaves this plant food where it can be gotten at and used by corn or other plants.

Cowpeas and soy beans are leguminous crops, introduced into this country recently from Asia, and are coming to be grown on a large scale as green manure crops for the preparation of the land for corn.

In summing up the important points as regards the condition of the soil for corn, it may be said that continuous cropping without rotation or manuring is a land use that is harmful in the exhaustion of the fertility of the land to such an extent as to render it an expensive process to bring it back to a state of productiveness. Commercial fertilizers are expensive agents for maintaining the food supply for corn, and cannot be successfully used except for local or peculiar conditions or for the correction of some unusual occurrence, as the acidity of certain bog soils, or the small alkaline areas in the fields in certain sections of the Middle West. The most successful and practical plan adapted to most conditions seems to be a rotation of corn with some legume, preferably one which can be used to supplement corn as a ration for live stock, and the feeding of all crops followed by the return to the soil of the plant food in the shape of composted manure.

Climate.—Zea mays originated in all probability in Mexico. From Mexico it was carried north by the Indians by means of barter and trade, so that when the early explorers of America visited the shores now occupied by the United States they found considerable areas under a crude system of corn cultivation by the
Indian tribes. Upon the development of the vast sections of the Mississippi Valley corn became the principal crop, and is now recognized as the leading American cereal. From America this crop has been carried to all continents of the world, and is grown to a greater or less extent in most of the leading countries, especially in those in which the climate and soil conditions are similar to those of our Mississippi Valley region. Corn flourishes best in those sections having an annual rainfall of about 30 inches, or an artificial supply by irrigation, and a season of about 120 days for the maturing of the larger types. The crop seems to reach its best development in the temperate regions, where a part of the season, the time of greatest growth, has warm days and nights. Under such conditions the plants grow with great rapidity. Corn readily responds to climatic conditions; namely, by taking a late variety to a region of short seasons, an early variety can be developed by selection, and vice versa. Most of this result is due to the races of corn, which vary greatly in their characteristics, due to the adaptation to climatic conditions. It is not a good policy suddenly to remove a race suited to a peculiar set of conditions to very different conditions. Under such circumstances the strain may fail to thrive or may develop some quality detrimental to its value. It is probable that by selection races may be improved for any given corn region, and that by continued breeding and selection, these races may be further improved without resource to the importation of seed from other sections. However, it seems that there are certain conditions in which corn naturally reaches its highest and fullest development, and it is probable that in those sections most advance will be made in the permanent improvement of corn. It may be advisable for corn-growing sections not specially suited for corn growing occasionally to secure a small supply of breeding seed from the best corn regions, which after a few years' growth will have become suited to the new conditions and may have a better type than those which have been grown in the less favorable localities.

One of the important things which has been developed for the most part, in so far as climatic conditions are concerned in corn culture, is the systematic comparison of different races from different regions, in order to find those races which are the best naturally suited to local conditions. It is probable that before breeding is begun, it would be advisable to make such a test in order to determine the best breeding stock for permanent improvement.

Quality of Seed.—There are a number of races of dent corn (Zea mays var.) which for the most part are the result of the selection of sports or striking variations. The individuals of these races are not uniform, and from the fact that corn is normally cross fertilized, a pure race frequently becomes mixed with other races. In fact there are practically no pure races under normal cultivation, and owing to the difficulty of maintaining the pure type, little attention has been given to systematically breeding these races. As a rule the seed corn used for planting the crop of the world is subject to the selection of the seed dealer. Considerable fraud has been practiced by unscrupulous seed dealers in the past, who, in order to humbug the public, bought up ordinary corn, gave it a fancy name, advertised it widely without careful tests and, through extravagant claims for its productiveness, obtained a wide sale, with consequent loss to the farmers buying the seed, but with considerable financial gain to themselves.

Pioneer Corn Breeders.—Previous to 1900, little was done in the way of the systematic improvement of corn. A few men early in the last century realized the value of carefully selected seed, and began to select their corn with reference to some type particularly desirable to them. One of these men was James Leaming, of Wilmington, Ohio, who began the selection of the ordinary yellow corn of the Miami Valley for larger and heavier ears. His idea was to secure ears with small cobs, deep grains well filled over the tips and butts, which would mature under his conditions of soil and climate. In order to get early maturity he naturally selected a rather tapering type of ear. This seed was grown in the fall, winter, and all irregular kernels, such as tip and base kernels, were discarded before planting. Mr. Leaming began this work about 1815 and continued the selection of this type of seed for more than half a century, keeping the race as pure as possible. Some of the pioneers of Illinois, Iowa and other Western States carried seed of this race with them from Ohio to their new homes. It was found that under the very favorable conditions of the Mississippi Valley this race improved in size of ear, depth of kernel and productiveness. Naturally, it was carried over a large territory and during the past few years has been the subject of considerable attention by corn breeders who have effected further and marked improvement in the feeding quality and yielding power. The Improved Leaming strains of to-day bear little resemblance to the original Ohio stock, and are living evidences of the possibilities in careful selection of seed corn.

Another pioneer in the work of the improvement of corn and the establishment of new races was James Riley, of Thorntown, Ind. Mr. Riley began the selection of the ordinary white corn of his community about the middle of the last century. He was the first to select the selection of large, well-developed ears for seed, and the weeding out of barren stalks before pollination, a large-eared, uniform type of corn could be secured. By persistent planting of such seed ears in isolated fields, preventing mixture with other types, he achieved success in this work, and produced a race called the Boone County White, which stands foremost among all races of white corn grown in the corn belt. Other races were produced by Mr. Riley, among them a yellow type, which he called Riley's Favorite. The production of this race is interesting because it illustrates the development of new types by crossing, and fixing of type by hybrid selection. He crossed a large and late Southern race of yellow corn on a small, early maturing, Northern yellow race, his aim being to secure a new race having a medium or large ear and early maturity. He accomplished this object successfully, and the Riley's Favorite is now largely grown in northern parts of the corn belt.

Improved Races are Most Productive.—The results of these systems of selection are
1. Wedge-shaped kernel. A desirable type
2. Square kernel. Undesirable type
3. Round kernel. Most undesirable type
4. Well-filled butt of ear. A desirable type
5. Medium-filled butt of ear. An undesirable type
6. Poorly-filled butt of ear. Most undesirable type
7. Cylindrical ear with straight rows of uniform kernels
8. Cylindrical ear with straight rows of uniform kernels
9. Nos. 7, 8, and 9 illustrate a desirable kind of selection of uniform ears
10. Well-filled tip of ear. A desirable type
11. Partly uncovered tip. Undesirable type
12. Most undesirable type of tip of ear, poorly filled with irregular and small kernels
shown by the comparative tests of races of corn at the Illinois and other State agricultural experiment stations. It has been found that during a series of 10 years’ tests of comparative yields per acre, the Leaming and Boone County White varieties of corn have consistently and on the average, for 10 years, exceeded all other races. In fact, it has been shown that under widely different conditions these two races have yielded more than double the amount of the ordinary types of corn. It has further been shown that corn growers who have selected these races for feeding purposes have naturally selected the types which were most beneficial for feeding purposes, and have developed strains which have a chemical composition better suited for feeding than the ordinary races of corn now grown in any region.

The benefits of improved seed corn are that larger returns are secured with the same effort required to produce ordinary and smaller yields. It does not cost any more to grow a race of higher average possible yield per acre, or a small increase in the proportion of protein for feeding purposes, or of oil and starch for manufacturing purposes, than to grow the ordinary types of corn. Taking into account the large area devoted to corn in the United States, even a slight increase in yield per acre, or a small improvement in quality, means an enormous increase in the profit from breeding. The past few years have demonstrated the practicability of such improvement beyond a doubt, and the results obtained on the farms and by experiment stations have attracted world-wide attention.

**Corn Breeders’ Association.**—The organization of the Illinois Seed Corn Breeders’ Association, in June 1900, marked the beginning of a widespread attempt to put corn breeding on a similar basis to that of live stock breeding. In fact, it has been found that corn breeding follows the same general laws as the breeding of animals. In other words, corn can be bred like cattle. This organization was founded by a few men, extensive growers of corn, and in most cases, noted breeders of live stock, who resolved to begin a careful selection of their own seed for planting, and if favorable results were obtained to offer such seed for general planting. Care was taken to suit the development of the races they selected for breeding. All seed sent out by members of the Association was carefully inspected by an officer of the State Experiment Station, tested for vitality, and examined for uniformity, trueness to type and freedom from mixture with other types of corn. All seed sold was sent out in the ear so that the man who purchased the seed could see for himself the type and character of the seed sent to him. The success of the plan was so great that other States at once followed the lead of this organization, and at present Iowa, Kansas, Nebraska, Indiana and Maryland have corn breeders’ associations, comprised of men who are systematically selecting their corn, for the most part in co-operation with the State Experiment Station. By means of such organized efforts, States have appropriated large sums of money for further experiments in corn breeding and culture so that progress is being made in this work at a rapid rate and valuable results are obtained of wide application and importance.

**Some Standard Races of Corn.**—The Illinois Seed Corn Breeders’ Association recognizes eight distinct races of corn, which are the basis for the development of many strains produced by individual breeders. These races, date of beginning selection, originators and place of origin are as follows:

- **Boone County White,** 1876, James Riley, Thornwood, Ind.
- **Silver Mine,** 1890, J. H. Beagley, Sibley, Ill.
- **White Superior,** 1880, P. R. Sperry, Monmouth, Ill.
- **Leaming,** 1826, J. S. Leaming, Wilmington, Ohio.
- **Reid’s Yellow Dent,** 1846, J. L. Reid, Delavan, Ill.
- **Golden Eagle,** 1871, H. B. Perry, Toulon, Ill.
- **Riley’s Favorite,** 1885, James Riley, Thornwood, Ind.
- **Pride of the North,** about 1890, F. A. Warner, Sibley, Ill.

From the growing of these races under widely varying conditions, and the effect of selection by individual growers, it is very difficult to say which race is the best. With this in mind, a great many strains have been developed, which in time will probably come to be recognized as distinct races. New races will probably spring up as a result of the selection of naturally prepotent individuals whose productive efficiency is great enough to impress distinct characteristics upon the offspring and create new and dominant types. An illustration of this method of origin of new and dominant races from striking individuals is found in the history of the Silver Mine race. According to the statement of the originator it sprung from a single ear, which was of such perfection that it attracted this grower’s attention among an exhibit of several thousand ears of corn. This ear was carefully planted in an isolated patch and the crop carefully harvested and planted the next season in isolated fields. From this source the seed was obtained for the first general distribution, which has been followed by breeding experiments, and breeders taking up the race for continued improvement by selection.

One further result of the organization of corn breeders’ associations has been the holding of exhibits of samples of corn selected by men who compete for certain prizes. In several instances the number of samples brought together in such exhibits has exceeded several thousand, and in one or two instances the number of samples of 10 ears each has reached 10,000. The effect of such exhibits has been to awaken a wide general interest in improved types of corn and the methods and standards for judging these samples. During the past 10 years score cards and standards of perfection have been devised, which by continued revision have been developed to a state of great usefulness. The use of the score card is to compare, on a uniform basis, individual samples of a given race of corn. Owing to the fact that in the production of races for different purposes, and for different conditions, characteristic differences in shape, size and other qualities have been developed, it has become necessary to have a standard for each of the established races.

In order to show some of the characteristics which go to make up a type, which are considered in the study of a race, the following table of characteristics of seven leading races of corn is presented.

**Vitality of Seed.**—One of the most important factors entering into the production of the corn crop is the vitality of seed. In planting the ears in individual rows or plats, one of the most notable facts which strike the observer is the great irregularity of size of plants in the different rows. One row, for instance, will be on the average a foot higher than the adjoining row and so on throughout the entire field. This irregularity in growth and finally in productiveness was not shown in the seed ears, because in most cases the seed ears were so carefully selected for uniformity that they were absolutely alike to the casual observer. This difference in vigor of growth is due, in great measure at least, to differences in the vitality of the seed. This vitality means the life of the seed, which is affected by age, storage, heredity and many other factors. The degree of vitality by the seed ear can be partially measured before the seed is used for planting. No absolute measure can be made of the value of the seed ear, but a comparatively accurate idea may be gained of the vitality by means of the germination test. We believe that the kernels in the individual ear are considerably alike in composition and in vitality, in fact in all general characteristics. It has been found that there is a slight variation between the individual kernels in the ear, but that this variation is not as great as the variation between different ears; so that by testing the vitality of the individual ears the most vigorous may be picked out for planting the breeding field. This test can be made by taking out three kernels from near the tip, three from near the middle and three from near the butt of every ear. In cases where possible, it is more desirable to shell off two rows of kernels from each ear and test all of the kernels in each row. The kernels should be planted in moist sand, point down, or laid between layers of moist cloth. In this moist condition, and under a temperature of about 70° F., 95 per cent of the kernels should sprout inside of three days, and should have sprouts one inch long at the end of five days. If the seed germinates more slowly than this standard it is an indication of weakened vitality. In other words, the time required for germination is the indication of the degree of vitality. Weak seed of slow germination should be discarded, as it results in a poor stand, the most frequent cause of loss of profits to the grower.

**Effect of Methods of Storing Seed Corn.**—The usual practice among corn growers is to select the seed corn out of the general crib, in the spring just before time for planting. In some instances, especially during years unfavorable for the maturing of the corn crop, it has been found that such seed was weak in vitality and only a partial stand was secured. In fact, it has been found that seed corn containing a high per cent of moisture is most easily affected by cold weather, while well-dried seed is capable of withstanding cold with the least possible loss of vitality. The amount of moisture in seed
varies with the conditions of maturity, immature seed containing an unusually large amount of water, while fully matured seed contains a low per cent of moisture. The dryness of the seed when harvested does not always indicate the amount of water contained, as corn absorbs moisture from humid atmospheres, and imparts it to dry air.

Methods of Cultivation.—The methods of corn cultivation vary with the conditions of soil and climate. No definite rules can be laid down for all conditions, in fact, every corn grower must determine for himself the best methods suited to his peculiar conditions. However, there are certain general principles of plant growth which hold true under all conditions, and it will be the object of this discussion to point out the practical application of some of these principles.

Methods of Preparing the Seed Bed.—The methods of preparing the seed bed for corn can best be illustrated by the results of an experiment to test this point, conducted by the Illinois Agricultural Experiment Station, during the season of 1903. The experiment resulted as follows:

**EFFECT OF PREPARING THE SEED BED.** (Yield in bushels per acre.)

*By drag is meant the implement made of boards or timbers which is used for smoothing the surface of the seed bed and to crush lumps of earth.

This table and general experience goes to show that in many seasons it pays to disc or stir the land before plowing, plowing to a depth depending upon the nature of the soil, and keeping the land stirred until the time of planting. This constant stirring of the soil breaks up the capillarity and prevents the surface soil moisture, at the same time getting the seed bed in good mechanical condition for the reception of the seed.

Conservation of Soil Moisture.—In the first place it is necessary to supply the corn crop with a large supply of water for growth. It has been estimated, by careful experiments, that for every pound of dry matter produced the plant uses 300 or more pounds of water. When one considers the great yield of the corn crop in large areas and the necessary amount of water to produce this yield, it can easily be seen how important the conservation of soil moisture becomes. The moisture in the soil escapes by capillarity and by drainage. In order to prevent the loss by capillarity, it is necessary to break up the soil condition which conduces to capillary action. This is practically accomplished by plowing and continued stirring of the surface of the plowed land during dry periods, or by the use of the disc. The loss of water by washing or drainage is prevented as far as possible by bringing the land into such condition as readily to take up and hold the rainfall and all moisture that falls upon it. This latter plan is accomplished by sub-soiling, deep plowing at the proper season, growing of such crops as clover, cowpeas, etc., in the rotation, and the addition of humus to the soil, as by plowing under corn stalks, straw, barnyard manure, or other means. When the soil is in good condition and rich in plant food, it is probably in the best possible condition to retain the soil moisture for the use of the corn plant.

Thickness of Planting.—The thickness of planting best suited to give the most profitable results will depend upon the race of corn, the nature of the soil, the character of climate, the purpose for which the crop is produced and other factors. However, if yield alone is considered, the following table gives the most reliable data yet obtained on this point:

**EFFECT OF THICKNESS OF PLANTING.** (Yield in bushels per acre.)

This table indicates that which has been found to be true under general conditions that four to five stalks on good corn land with ordinary seed will give the largest yield, but where machinery is not used in harvesting it is probably more desirable to leave three stalks. With three stalks bearing large ears, less difficulty and expense will be found in harvesting than with more stalks producing small ears.

Hills v. Drills.—There are two general systems of arranging the seed in the row generally followed, first grouping from two to five kernels in hills some distance apart, second, drilling the seed one seed in a place, along the row closely together. The practice of drilling seed corn was the early method of planting employed by pioneer farmers. In the new countries, which were comparatively free from noxious weeds, it was not found necessary or practicable to cultivate the corn fields as carefully as is now the case in the more fully developed sections. The farmers wished to secure the largest possible yield, and so drilled their seed corn in such a manner as to secure an unusually large number of stalks in the row. As a result large yields of small ears were obtained. Upon the further development of these communities, foreign weeds were introduced and with the lessened fertility of the soil, due to continuous cropping, more careful methods of cultivation became necessary. Consequently, the corn for the most part came to be planted in hills, admitting of cross cultivation, and frequent stirring of the soil keeping the surface comparatively level. In tests of the two systems, equal numbers of stalks being retained in the hilled and drilled rows, there has been found to be little difference in the yield per acre.

Lister v. Planter.—In some sections, particularly in the States of Kansas and Nebraska, the seed corn is planted with listers. A lister is a plow and planter combined, which opens a
furrow, drills the seed corn in this furrow and covers the seed at the same time. It is therefore the means of planting large areas in a comparatively short time and at a small expense. From the extensive use of the lister in these regions, with apparently good results, the practice has spread to other States where it is now under trial. Experience has suggested certain modifications of the original simple plan, one of which is to plow the land early in the spring, and when ready to plant, to use the lister instead of the ordinary methods of preparation of the seed bed and planter. Another method is to open up furrows through the fields with the lister, very early in the spring, without planting, then later list again, opening new furrows between the first ones in which the seed is drilled. It has been found that in these older districts this method is not so successful as the plowing of the land and thorough preparation of the seed bed. It corresponds to planting the seed in a dead furrow. Where it is necessary to plant the seed in the ground to get moisture for germination, it is probable that this system may be valuable. On sandy soils it will probably succeed, while in the heavier clay or clay loam soils it does not give the best results.

Root Injury During Cultivation.—The vital principle of cultivation of the growing corn plant is that the plants be allowed to grow undisturbed and without competition of other plants, with sufficient stirring of the surface soil to prevent the rapid evaporation of soil moisture. In an experiment with pruning or cutting off the roots of the corn plant at the Illinois Agricultural Experiment Station striking results followed such injury.

**EFFECT OF ROOT PRUNING ON CORN. AVERAGE OF THREE YEARS’ TESTS.**

It can be readily seen without further explanation that injury to the roots interferes in the plant’s development and reduces the yield.

**Depths and Systems of Cultivation.—** The cultivation of the growing crop presents many problems differing according to the conditions of soil and climate. The general results of four years of tests of different methods of cultivation, indicating in a general way the effect of different systems in the corn belt, is summarized in the following table. There was found in these experiments a close correlation between the theory of cultivation and the results obtained by following out the methods suggested by the foregoing discussion.

The results of the above trials indicate that all competition with weeds must be prevented, from the fact that they live upon the same elements of fertility as the corn plants, and in this way reduce the yield of the corn crop. Deep cultivation injures the roots of the corn plant and reduces the yield. Shallow, frequent cultivation, removing the weeds, keeping a soil mulch on the surface of the soil, gives the best results. This conclusion agrees in general with the facts of ordinary practice in well-drained and fertile soils. In very weedy fields, undrained and in poor condition, it may be necessary to cultivate deeply in order to destroy the weeds, open the soil to the air and sunshine and allow the excessive water to drain off.

In summing up the important facts of cultivation, the following points should be emphasized:

1. The preparation of the seed bed should be such as to best conserve soil moisture, and obtain the most favorable mechanical soil condition.
2. The cultivation of the growing crop should be such as to avoid all root injury, maintaining a loose surface soil mulch, and preventing the presence of all weeds or competitors.
3. The method of planting and caring for the crop will depend upon local conditions to such an extent that it is necessary for every grower to make a thorough study of his peculiar conditions of soil and climate in relation to his methods of cultivation.
4. The conditions of growth for the corn crop are moisture, heat, light and plant food. The supplying of the conditions in the most favorable manner to the corn plants is the business of the grower and will have the largest profitable returns. Corn is more easily protected from its animal and insect enemies than most of the important crops. Of those insects that attack the roots and larvae all are gotten rid of by rotation. Fall plowing dispose in great part of the cutworm. For ear rot the sole remedy appears to be the gathering up and burning of all affected material. Consult Montgomery, ‘Corn Crops’ (New York 1913); Bowman and Crossley, ‘Corn’ (Waterloo, Iowa, 1911).

**CORN INSECT-PESTS.** The principal enemies of corn are the bollworm (q.v.), chinch-bug, cut-worms and certain caterpillars which bore in the stalks. In the Central and Southern States, notably in Kentucky and in southern Illinois, the cotton-boll worm in certain years has attacked the corn in the ear, eating the silk and afterward devouring the terminal kernels, hiding within the husk. Whole fields have thus suffered in these States, where there are two broods of the worm, the early and also the late corn suffering the worst.

Cut-worms.—These caterpillars are the most insidious pests in fields when the young corn begins to sprout. One species out of many is called the corn cut-worm. It is the young of the Clandestine moth (Noctua clamentia). While the fully grown caterpillar has not been described, the young are more or less distinctly marked above with pale and dark stripes, and are uniformly paler below. When first hatched they feed on the corn, descending, when bough, into the ground on the approach of severe frosts, and reappearing in the spring and
then beginning to grow again, attaining their full size and pupating before the middle of July, often much earlier, so that in the New England States the moth is seen from the middle of June to the middle or end of August, during which time it lays its eggs. Remedies: before planting, the seed corn should be soaked in copperas water, and late in the autumn corn land should be plowed deeply, so as to turn up the half-grown worms, and expose them to the winter cold and to the attacks of insect-eating birds. A more inside destructive to corn is the chinch-bug (q.v.) which punctures the leaves, sucking the sap. It appears early in June, and there is a summer and winter brood, the adults hibernating in the stubble. (See WHEAT-INSECT PESTS.) Several caterpillars live at the expense of corn, among them being the larva of the io moth, a great green worm, with poisonous spines, also the fuzzy larva of a moth (Arctia arge). Other pests are the larvae of many beetles, the corn root-worm, which is the larva of a beetle, and is only serious in land which has been planted in corn for several years, and the root-louse, an aphid.

CORN LAWS, regulations of the grain-trade and breadstuffs, a former system of legislation in England, part of the general economic policy of the country, lays restrictions of various kinds of grain; affecting the internal corn trade and speculative dealings; the assize of bread; the export of corn; the conflict between arable and pasture land; and the danger rural depopulation. The system of corn laws thus covered a much wider field than is indicated by import duties, these being but part of a much wider system dealing with allied questions of more importance, and which under changing circumstances are of recurrent interest. The corn laws originated in the reign of Edward III, and ended only with the repeal of the import duties in 1846, their repeal being only part of a great movement in the direction of free trade. As affecting the interests of the consumer, the earliest corn laws were intended to prevent the exaction of monopoly prices and to check speculation. Export of corn was regulated to secure cheapness and plenty at home; the bounty was defended on the same ground; the duties on imports were remitted or reduced in dear years, and sometimes bounties were given on imports. Up to 1815 the corn laws had little effect on prices, but after that year they raised to some extent the average price, and increased fluctuations beyond what would otherwise have been the case. The purchasers interested in the corn laws were the landowners, the farmers and the laborers. In the Tudor period direct legislation was attempted to restrict sheep farming and to promote corn-growing. From the 17th century the belief was general that the best sign of national progress was a rise in rent, and it was supposed that anything that raised rent increased progress. These views were held by unbiased, impartial writers. Corn laws that raised rents were also supposed to benefit the nation. At the close of the 18th century the interests of landlords and consumers began to be opposed and the divergence increased till the repeal. The farmers suffered from the greater fluctuations, but there was great progress in agriculture owing to other causes. Wages were low, and especially during the Napoleonic wars, while rents rose greatly, real wages fell. The low wages can only be partly ascribed to the effect of the corn laws, originated from the point of view of the interests of the state and of general public policy, the early corn laws involved the same idea as the usury laws. The

skinned grubs of snapping-beetles (Elater) often ruin to a lamentable degree the roots of corn. They are hard to eradicate, but may be caught by placing slices of potato, turnip or apple in the beds and examining the undersides every morning. Another inside destructive to corn is the chinch-bug (q.v.) which punctures the leaves, sucking the sap. It appears early in June, and there is a summer and winter brood, the adults hibernating in the stubble. (See WHEAT-INSECT PESTS.) Several caterpillars live at the expense of corn, among them being the larva of the io moth, a great green worm, with poisonous spines, also the fuzzy larva of a moth (Arctia arge). Other pests are the larvae of many beetles, the corn root-worm, which is the larva of a beetle, and is only serious in land which has been planted in corn for several years, and the root-louse, an aphid.

CORN LAWS, regulations of the grain-trade and breadstuffs, a former system of legislation in England, part of the general economic policy of the country, lays restrictions of various kinds of grain; affecting the internal corn trade and speculative dealings; the assize of bread; the export of corn; the conflict between arable and pasture land; and the danger rural depopulation. The system of corn laws thus covered a much wider field than is indicated by import duties, these being but part of a much wider system dealing with allied questions of more importance, and which under changing circumstances are of recurrent interest. The

CORN LAWS, regulations of the grain-trade and breadstuffs, a former system of legislation in England, part of the general economic policy of the country, lays restrictions of various kinds of grain; affecting the internal corn trade and speculative dealings; the assize of bread; the export of corn; the conflict between arable and pasture land; and the danger rural depopulation. The system of corn laws thus covered a much wider field than is indicated by import duties, these being but part of a much wider system dealing with allied questions of more importance, and which under changing circumstances are of recurrent interest. The corn laws originated in the reign of Edward III, and ended only with the repeal of the import duties in 1846, their repeal being only part of a great movement in the direction of free trade. As affecting the interests of the consumer, the earliest corn laws were intended to prevent the exaction of monopoly prices and to check speculation. Export of corn was regulated to secure cheapness and plenty at home; the bounty was defended on the same ground; the duties on imports were remitted or reduced in dear years, and sometimes bounties were given on imports. Up to 1815 the corn laws had little effect on prices, but after that year they raised to some extent the average price, and increased fluctuations beyond what would otherwise have been the case. The purchasers interested in the corn laws were the landowners, the farmers and the laborers. In the Tudor period direct legislation was attempted to restrict sheep farming and to promote corn-growing. From the 17th century the belief was general that the best sign of national progress was a rise in rent, and it was supposed that anything that raised rent increased progress. These views were held by unbiased, impartial writers. Corn laws that raised rents were also supposed to benefit the nation. At the close of the 18th century the interests of landlords and consumers began to be opposed and the divergence increased till the repeal. The farmers suffered from the greater fluctuations, but there was great progress in agriculture owing to other causes. Wages were low, and especially during the Napoleonic wars, while rents rose greatly, real wages fell. The low wages can only be partly ascribed to the effect of the corn laws, originated from the point of view of the interests of the state and of general public policy, the early corn laws involved the same idea as the usury laws. The
governmental power in regulating foreign trade in corn gave rise to constitutional struggle. Exports were encouraged to promote the mercantile marine and in that way naval power. The revenue from the import duties was considered of secondary importance till just before the repeal. Stress was laid on the advantages of a large rural population and of national independence as regards food supplies. The duties were essentially protective and must be regarded as part of a wider system. The repeal was only part of the general movement towards greater freedom of trade, which began with the petition of the merchants in 1820, and was not completed till 1860. Preferences were granted by the British colonies, also as part of the general policy. At the time of the repeal there was much exaggeration as to the past effects of the corn laws on prices, and also as regards the monopolistic spirit of the landowners. Although the landowners had been the dominant opinion and class for centuries, the greater part of the corn laws had been designed in the interest of the nation as understood at the time. In the 19th century the only part of the system that remained effective was the protective import duties; they had become hurtful to the consumer and trade in general, and if retained would have done still more harm. The whole history of the corn laws is a good example of the negative argument for free trade. Protection to agriculture could only be restored by reverting to old ideas which would now be still more difficult of accomplishment, as conditions have become so much more complex. The best means of securing a sufficient and steady supply of breadstuffs has always been a subject of great diversity of opinion, and the practice of governments has varied much at different times. The theory urged by Adam Smith, and now adopted in Great Britain and generally followed in the United States, is that the government should do absolutely nothing in the matter, on the ground that farmers and merchants, if unchecked, will always form correct views of their own interest, and that their interest will coincide with that of the community. This theory is supported by a large view of the facts. In ancient times famines were much more frequent than they are now, because commerce was more restricted, less regular and extensive, and subject to more frequent obstructions. A free communication between different countries, by which the abundance of the one may be brought to supply the want of the other, has proved the best security against the want of necessaries and even of comforts and luxuries.

The Athenians had laws prohibiting the exportation of corn and requiring merchants who loaded their vessels with it in foreign ports to bring their cargoes to Athens. The public provision and distribution of corn was an important branch of administration at Rome, and very intimately connected with the public tranquillity. The regulation of the supply of corn and the trade in the article have been a fruitful subject of legislation in modern Europe. But it is to be observed that the public solicitude and current of legislation take this direction only in populous countries, or at least those in which the population presses hard upon the means of domestic production of breadstuffs; for countries of which the staple export is corn need to take no measures for securing a supply. In agricultural countries the object of solicitude is to supply the want of arts and manufactures, as in populous and highly improved countries it is to supply the want of food.

But that object has been very various, and some of them contradictory; for as in Athens so in England, at one period the laws prohibited the exportation of corn; whereas at another period, and for a very long one in the latter country, a bounty was given on the exportation; and both these laws had the same object, namely, the adequate and steady supply of the article. (See CORNER; FREE TRADE.)

CORN-SALAD, called also lamb's lettuce, a genus of the valerian family (Valerianaceae). There are about 50 species natives of the northern hemisphere, most abundant in the Mediterranean region. Between 10 and 15 species occur in the western parts of the United States, some of which are natives. The plant is a humble annual weed, which is used as a spring salad, especially in France and Germany. The commonest species is V. oitorea, which is naturalized in the United States, and often called fetticus, white pot-herb and milk-grass. It is found in waste places and moist grassed soil from April to July. Corn-salad is cultivated in much the same way as spinach, and is much used for the same purpose as ergot (q.v.).

CORN-SMUT, a hemibasidal parasitic fungus (Ustilago zeai), affecting the corn. It causes extensive malformation of the corn, but rarely injures any large part of the crop. As an agricultural scourge corn smut has an unsavory reputation. In medicine it has been used for much the same purpose as ergot (q.v.), but its physiological action is very slight.

CORN SNAKE, a handsome colubrine serpent (Coluber guttatus) of the United States, also called red chicken snake, scarlet racer, house-snake and mouse snake. It is a near ally of the blacksnakes (q.v.) and has in general the size, habits and temperament of those vigorous reptiles. Its ground color is pale yellow. "On the back is a series of large crimson saddles narrowly bordered with black . . . On each side of the body is a smaller series of similar blotches, and beneath this a yet smaller series." The abdomen is white with large black squares and the lips are whitish. Although it climbs trees in search of young birds, catches ground birds and sometimes raids the poultry-yard, it feeds chiefly on small rodents and takes its name from being so frequently seen in cornfields, where mice gather to feed on the grain. On the whole, therefore, it is beneficial and ought not to be killed except when it persistently threatens the farmer's chickens. Consult Ditmars, 'The Reptile Book' (New York 1907).

CORNACEE, kör-nä'zē-ē, the dogwood family, a family of plants allied to the Umbelliferae (q.v.), and containing about 16 genera and 85 species, chiefly natives of the north temperate zone. Some species produced edible fruits;
some are valuable for the medicinal virtues of their bark, and others are cultivated as ornamental plants. See Dogwood, Tupeilo.

CORNARO, kor-nà'ro, Ludovico, Venetian nobleman: b. 1467; d. Padua 1566. From the 25th to the 40th year of his age he was afflicted with a disordered stomach, with the gout and with slow fevers, till at length he gave up the use of medicine and accustomed himself to extreme frugality in his diet. The beneficial effects of this he relates in his book entitled Discorsi della vita sobria (The Advantages of a Temperate Life) (1558, the English translation of which has passed through over 30 editions). Cornaro's precepts are not applicable in their full extent to every constitution; but his general rules will always be correct. His diseases vanished and gave place to a vigorous health and tranquillity of spirits, to which he had hitherto been an entire stranger. He wrote three additional treatises on the same subject. His work on the Birth and Death of Man, composed a few years before his death, he says of himself, I am now as healthy as any person of 25 years of age. I write daily seven or eight hours, and the rest of the time I occupy in walking, conversing and occasionally in attending concerts. I am happy and relish everything that I eat. My imagination is lively, my memory tenacious; my judgment good, and what is most remarkable in a person of my advanced age, my voice is strong and harmonious.

CORNUBY, Edward Hyde, Lord, 3d Earl of Clarendon, English colonial governor; b. 1601; d. London, 1 April 1723. He was the son of the 2d Earl of Clarendon and sat in Parliament for Wiltsire from 1665 to 1695 and for Christchurch from 1695 to 1701. He was one of the first officers of his household troops to desert from the service of King James II to the Prince of Orange in 1688. In return he was made governor of New York, where he arrived 3 May 1702. He was confirmed in his office by Queen Anne, and in the same year was also made first royal governor of New Jersey. His rapaciousness, bigotry, incapacity for administration and dissolute habits made him very unpopular. In New York the people became exasperated by his gratuitous appropriation of public funds and his attempts to control the legislature. The legislatures of both colonies finally passed lists of grievances which resulted in Cornbury's removal from office in 1708. He was at once thrown into prison in New York, his creditors and remained there until he became Earl of Clarendon in 1709, when he was enabled to pay his debts and return to England. He was made a privy councillor in 1711 and envoy to Finland in 1714. In Smith's History of the Late Province of New York (New York 1830) he is spoken of as follows: We never had a governor so universally detested, nor one who so richly deserves the public abhorrence. Consult Wilson, Memorial History of New York (New York 1893) and Gordon, History of New Jersey (Trenton 1834).

CORCRACKER STATE, a nickname of Kentucky, whose people are often called Corcrackers.

CORNEA (Lat. hornie, hornlike), the transparent concavo-convex disc which forms the anterior fifth of the globe of the eye, fitted accurately into the sclerotic or fibrous coat forming the posterior four-fifths of the organ. It is a segment of a smaller sphere than the sclerotic, and is from seven to eight lines in diameter; the greatest diameter being the transverse. Its anterior convex surface is covered by a continuation of the conjunctival epithelium, and its posterior concave surface is lined also with delicate pavement epithelium, which is in contact with the stroma. Its 'Medea,' and supposed by some to be concerned in the secretion of this fluid. The degree of convexity varies, being usually greatest in children and near-sighted persons. Its circumference is described as fitting into the sclerotic like a watch crystal into its frame. Its principal thickness, which is nearly the same at all points, is made up of about 60 layers of soft indistinct fibres, continuous with and similar to those of the sclerotic, connected together by delicate areolar tissue; these may be separated by maceration. Behind the cornea proper is an elastic transparent lamina called the membrane of Demours, which serves to maintain the corneal curvature. No vessels have been traced beyond the very edge of the cornea, although a thin layer of nutriment in the form of lymph. A superficial and a deep series of vessels surround the cornea, anastomosing freely around its margin; the superficial vessels are continuous with those of the conjunctiva, and the deep with the short ciliary arteries. In diseased conditions both sets of vessels may be prolonged into its substance. No nerves have been traced into the cornea. Its diseases are many, frequent and dangerous to vision; from its exposed situation, it is liable to suffer from blows, cuts and the introduction of foreign substances. It is often inflamed in various ophthalmic diseases, resulting in opacity, ulceration, increased vascularity, softening and rupture from gangrene; these affection are tedious and difficult to cure, are often painful and generally leave the patient with more or less obstruction of the power of vision, if they do not destroy the eye itself. In old persons, the circumference of the cornea often presents a whitish zone, a line or two wide, the result of the deposition of fat, and not interfering with vision. The convexity of the cornea in aquatic and amphibious animals is slight, and sometimes almost lacking.

CORNEILLE, kor-nà-yé, Pierre, French dramatist; b. Rouen, 6 June 1606; d. Paris, 1 Oct. 1684. He began his dramatic career with comedy. His first piece was Mélie, played in 1629. It was followed from 1632 to 1636 by Citadre, La Veue, La Galerie du Palais, La Suivante, La Place Royale, L'Illusion Comique, which had great success. Being more natural and more vigorous in style than the dramas which then held the stage, they announced the approach of a reformer endowed with talents of a higher order, and as such he was recognized even by his rivals. Mélie, produced in 1635, and imitated from Seneca, was the first indication of his talent for tragedy. His next work was Le Cid, which raised his fame at one bound to its highest pinnacle. It has been translated into many languages, but scarcely bears out its reputation. The popularity of the play was unbounded. But its enemies were stimulated by the hatred of Cardinal Richelieu for its author. Corneille had been appointed as one of five authors to whom Riche-
lieu entrusted the writing out of plays from plots furnished by himself, but he had been guilty of condemning the plot of a comedy committed to him, and the offense was unpardonable. Richelieu stimulated Chapelain to write a critique on behalf of the Academy. The critique was moderate, and while condemning the plot, admitted freely the merits of the author. It is printed in some editions of Molière's works under the title, 'Sentiments de l'Académie Française sur la Tragi-Comédie du Cid.'

Among other accusations brought against Corneille was want of originality. This led to his selecting as his next subject Horace (not the poet, but the Horatius of early Roman history), which is perhaps the work in which he shows the greatest invention, and is one of the most admired of his productions. It appeared in 1639; the same year appeared 'Cinna,' which, according to Voltaire, was the chef-d'œuvre of Corneille; and in 1640 the 'Polyeucte,' which other critics have styled the most original, the most touching and the most sublime work of the author, the chef-d'œuvre at once of Christiandom and of the French theatre. There is one flaw in this work which its admirers do not seem to have noticed. The poet so far mistakes the spirit of the Christian religion as to make Polyeucte, a convert under the Roman Emperors (as St. Philip was under the Emperor Constantine), bring on himself by refusing to sacrifice to the altar on which the priest is sacrificing. 'Pompée,' an inferior piece, appeared in 1641, and in 1642 'Le Menteur,' the greatest of Corneille's comedies, imitated, like the 'Cid,' from the Spanish Foote, has produced an English version of it called 'The Liar.'

From this time the success of Corneille as a dramatist steadily declined and many of his numerous works, in spite of the fame of their author, never acquired celebrity. On the merits of others the utmost diversity of opinion has prevailed, the same work being the subject of extravagant eulogy and unqualified condemnation. 'Rodogune,' 'Hercules,' 'Don Sanche' and 'Nicoméde' are among the best works of his second period, 1645-52. 'Rodogune' was his own favorite production. Some critics speak highly of it; others condemn it as showing marked indications of decline. From 1653-59 he gave up writing for the stage and employed his genius in producing a poetical translation of the 'De Imitatione Christi.' In the latter year he was induced to return to the drama and persevered 15 years amid declining success in producing pieces generally inferior to his earlier works. 'Œdipe' (1659) and 'Sertorius' (1662) are the best works of this period. 'Tite et Bérénice' (1670) was a rival production to the Bérénice of Racine, the subject being prescribed to both poets by the Princess Henriette; but Racine's poem was a success, that of Corneille a failure. His last pieces, 'Pulchérie' (1672), 'Suréna' (1674), were the weakest as well as the last. He had been chosen a member of the Académie Française in 1647, and was dean of the Academy when he died in 1684. His remains lie in the Pantheon, from where elegies, sonnets, epistles, etc., under the title of 'Poésies Diverses,' and also in prose three discourses, 'Sur le Poème dramatique'; 'Sur la tragédie'; and 'Sur les trois unités.' Voltaire has remarked that Corneille was the first dramatist who made the sentiment of admiration the basis of tragedy instead of terror or pity.

The admirers of Corneille gave him the strongest praise for the quality, sublimity. This is a quality not easily defined, and in straining after it it is only too easy to fall into faults very much opposed to sublimity. The faults found with Corneille in his weaker productions are precisely such as might be produced by such an effort, declamation, inflation, abuses of sentences and great words. His versification is less accurate and polished than that of Racine, as when he began to write the language was less formed, and his own taste in this respect probably less fastidious. There may also be observed in Corneille's delineation of character a straining after a heroic ideal, rather than a true and profound analysis of the real springs of human sentiment and emotion, in which alone an inexhaustible fund of dramatic action is to be found. He was, like Racine, strongly impressed with religious convictions, and extremely scrupulous in his writings. He had a high idea of his own powers, but was deficient in scientific tact. In conversational ability to such an extent that it is said he did not express himself grammatically. When reproached for his carefulness in cultivating the graces of society, he would reply, 'Je suis toujours Pierre Corneille.' The best edition of Corneille is that by Marty-Laveaux (12 vols., 1862-68). Consult Le Verdier and Pelay, 'Additions à la bibliographie Corneillienne' (1908); Picot, 'Bibliographie Corneillienne' (Paris 1885). Consult also Brunetière, 'Époques du théâtre français' (ib. 1892); Faget, 'Propos de Théâtre' (3 vols., Paris 1906); Guizot, 'Corneille et son temps' (7th ed., ib. 1880); Huszar, 'Pierre Corneille et le théâtre espagnol' (ib. 1903); Canfield, 'Corneille and Racine in England' (New York 1904); Lanson, 'Corneille' (Paris 1888); Lemaître, 'Corneille et la poétique d'Aristote' (ib. 1888); Raab, 'Pierre Corneille in deutschen Übersetzungen' (Heidelberg 1911); Wendt, 'Pierre Corneille und Jean Rotrou' (Leipzig 1911).

CORNEILLE, Thomas. French dramatist, brother of the preceding; b. Rouen, 20 Aug. 1625; d. Andelys, 8 Dec. 1709. He lived in the most friendly union with his brother till the death of the latter. They had married two sisters, lived in the same house without any division of means, and were remarkable for the conformity of their tastes. His first comedy, 'Les engagements du hasard,' appeared in 1647 and was successful. The number of his dramatic works is 42; yet most of them are now little known. His comedies, however, at the time of their appearance were received with greater interest, if possible, than those of the great Corneille, in imitation of whom Thomas applied himself to tragedy; and his 'Timocrate' (1656) was received with such continual applause that the actors, weary of repeating it, entrenched the audience, from which the representations of something else, otherwise they would forget all their other pieces. Since that time it has not been brought upon the boards at all. 'Camma,' in 1661, produced an equal sensation. The spectators thronged in such numbers as with the boards at least scarcely room enough was left for the perform-
ers. His best tragedy is 'Ariane' (1672). 'Le Comte d'Essex' (1678) has also retained some celebrity, although marred by the ignorance it displays of English manners and history. "L'Inconnu," a heroic comedy, appeared in 1682. In 1677 he versified 'Le Festin de Pierre' at the request of the widow of Molière, and until recently, when the prose of Molière superseded it, it was always represented in his version. He was a dramatist of the second rank, laborious but wanting in originality, yet not without considerable resources. In 1685 he succeeded his brother in the French Academy by a unanimous vote. His "Works" were edited by Thierry (Paris 1881). Consult Reynier, 'Thomas Corneille, sa vie et son théâtre' (Paris 1893) and Alfred de Vigny, 'Fragment inédits de critique sur Pierre et Thomas Corneille' (1905).

**CORNEIL (Lat. cornu, horn, from the hard, horn-like wood), a shrub belonging to the genus *Cornus*, about 20 distinct species, native of northern latitude, temperate climate. Flowers generally small, four parted, ovary inferior, two- or three-celled; fruit fleshy and edible in some species, especially those in Europe. The so-called "flowers" are really clusters of flowers surrounded by large bracts. The cornelian, *C. mas*, one of the species, is the cornelian, the only member of the genus known as the cornel, bears small greenish flowers; the fruit is acid and edible. The dogwood of the eastern part of the United States is the *Cornus florida*, a small tree which in May and June is covered with large white or pinkish flowers; the wood of which has a fine fibre and is very hard. The bark is sometimes used as a tonic. *C. canadensis*, the dwarf cornel or bunchberry, of woods in the northern part of the United States, is a low herb which bears a close clust of flowers that ripen into red, fleshy but scarcely edible berries. In North America there are about 18 well-known species. See Dogwood.

**CORNELIA, Roman matron, the daughter of Scipio Africanus the elder. She married Tiberius Sempronius Gracchus, censor 169 B.C., by whom she had five daughters and two sons. After the death of her husband, she devoted herself entirely to their education. Of the five children, only three survived the childhood, her daughter, married to Scipio Africanus the younger, and her two sons. Cornelia was highly educated and united the severe virtues of the old Roman matron with the refinement which then began to prevail in the upper class society of Rome. She bore the death of her sons with magnanimity, and afterward retired to Misenum, where she spent the remainder of her life. She exercised unbounded hospitality, and was constantly surrounded by men of letters. The Roman people erected a statue to her with the inscription: "Cornelia, Mother of the Gracchi," the base of which, with the inscription, is now in the Capitoline Museum at Rome.

**CORNELIAN, or CARNELIAN (Fr. cornaline, from Lat. cornu, "horn"), a precious stone varying from a light and fleshy red, opaque and semi-transparent, with and without veins, to a bright red or yellow, approaching the ruby, from which they are, however, known by sure distinctive marks. It consists of silica along with minute quantities of the oxides of iron, aluminum, and some times of other metals, and is actually a variety of chalcedony. It is much used for seals, bracelets, necklaces and other articles of minute gem sculpture; appended to watches, ornaments now in little use. It was, according to Pliny, by the name of *sarda*, from being found originally in Sardinia. The number of the cornellians that were engraved by the ancients and have reached our times is very considerable and nearly equal to that of all the other kinds of gems with which we are acquainted. Pliny thinks they were clarified by being steeped in the honey of Corsica. The national collection at Paris and the British Museum of London have many beautiful engraved cornellians. Many of the latter were found in the field of Cannus in Apulia, where Hannibal defeated the Romans.

**CORNELIS, cůr-ně-lís, Cornelius, Dutch painter: b. Haarlem 1562; d. 1638. He studied with Peter Aertsen the younger, and afterward worked at Antwerp under Peter Forbus and Giles Conguet. In 1583 he returned to Haarlem, where his great painting—the "Company of Arquebusiers"—established his reputation. Deschamps called it a collection of figures sketched by the "Genius of History." It is thought that van Mander, in his "Eenighe van schilderaren," was influenced by this picture. In 1595, with Charles van Mander, he instituted an academy for painting at Haarlem. His numerous pictures are rarely to be bought, on account of the great value which the Flemings set upon them. Corneils painted great religious and historical subjects, portraits, flowers and especially subjects from ancient mythology. His drawing is admirable. He is a true imitator of nature, and his coloring is always lively and agreeable, although those done in the Italian style are full of mannerisms and affectations. In his two large, paintings of the 'Massacre of the Inno cents' in Amsterdam and The Hague, he displays great skill in foreshortening. Consult Wedekind, ‘Cornelis Cornelisz van Haarlem’ (Leipzig 1911).

**CORNELIUS, a centurion of the Italic cohort, whose conversion at Cesarea is related in Acts x. His name would indicate that he was either a member of the distinguished gens Cornelia, or a descendant of one of its freedmen. He is reckoned by Julian the Apos tate as one of the few persons of distinction who embraced Christianity. The cohort in which he was centurion was probably Cohors II Italica civitatem Romanorum, which a recently discovered inscription proves to have been stationed in Syria before 69 A.D. The description of Cornelius as "a religious man, and fearing God ..." would indicate that he was one of the "proselytes of the gate" who worshipped the one true God and observed in great part the Mosaic law, but who were not formally affiliated to the Jews by circumcision. That he was not a full proselyte is attested by the opposition that developed to his admission to the Christian Church. His baptism is an important event in Christian history as he was the first uncircumcised Gentile admitted to the new Church with the obligation of subjection to ceremonial law of the Jews. Disapproval of his admission by the Jewish Christians of Jerusalem is narrated in Acts xi, 2, 3, and the cessation of that opposition through the influence of Peter.
in xi, 4-18, the matter being finally settled at the Council of Jerusalem (Acts xv). Consult Baronius, 'Annales,' ad ann. 41, n. 2; 'Acta Sanctorum,' Feb. 1, 27; 7, Feb. 5; Romney, 'Cornelius and the Icatical Cohort' (in The Expositor, 1896).

CORNELIUS, Pope and martyr. He succeeded Fabian on 4 June 251 and according to the Liberian catalogue resigned after 2 years, 3 months and 10 days. Fabian, his predecessor, had suffered martyrdom in the persecution of Decius in January 250. By March of the following year rivalns had appeared against the emperor and his absence from Rome caused the persecution to slacken; 16 bishops assembled in Rome and Cornelius was elected. A few weeks later the Roman priest, Novatian, made himself anti-pope, being more acceptable to those who opposed Cornelius because of the latter's leniency toward the lapsi. In October 251 Cornelius convened a numerous council at Rome, which confirmed his election. He did not enjoy his honor long, for he was banished by Gallus to Centumcellae (Civitá Vecchia), where he died, or, according to some accounts, suffered martyrdom, 14 Sept. 253. Ten of Cornelius' letters are directed to Cornelius and there are extant two genuine letters of Cornelius to Saint Cyprian. Besides these Cornelius wrote a long letter to Fabian concerning the character and conduct of Novatian, considerable extracts from which are preserved in Church History. Consult Benson, 'Cyprian' (London 1897); Mercati, 'D'alcuni nuovi sussidi per la critica del testo di S. Cipriano' (Rome 1889), and 'Acta Sanctorum' for 14 September.

CORNEILUS, kór-ná'lé-oo, Karl Sebastian, German physicist: b. Ronshausen, Lower Hesse, 1811; d. 1866. He studied at Göttingen and at Marburg, giving special attention to the exact sciences. After 1851 and until his death he was professor of physics and physiography at Halle. He published 'Die Lehre von der Elektricität und dem Magnetismus' (1855); 'Theorie des Sehens und räumlichen Vorstellens vom physikalischen, physiologischen, und psychologischen Standpunkte aus betrachtet' (1861); 'Meteorologie' (1864); 'Über die Bedeutung des Kausalzins in der Naturwissenschaft' (1867); 'Über die Entstehung der Welt' (1870); 'Über die Wechselwirkung zwischen Leib und Seele' (1880); 'Grundriss der physikalischen Geographie' (6th ed., 1886); 'Abhandlungen zur Naturwissenschaft und Psychologie' (1887).

CORNELIUS, Peter, German composer: b. Mayence, 24 Dec. 1824; d. 26 Oct. 1874. He studied for the stage and meeting with little success, devoted himself to music. He was intimate with Liszt who brought out his opera, 'The Barber of Bagdad,' at Weimar in 1855. He went to Vienna and there also wrote his second opera, 'The Cid,' which was produced at Weimar in 1865. He became a great admirer of Wagner, and was for a time a professor at the Munich Königliche Musikschule. He began the opera 'Gunild' in 1869, and it was finished from sketches after his death by his pupil, C. Hoffbauer. 'The Barber of Bagdad' is his masterpiece. It was re-scored by Mottl and Levi and produced in Munich in 1885. It had a great success and is to-day in the repertoire of every German opera house. It was produced in New York in 1890. Other works by Cornelius are his 69 songs for one voice which were published in 1897; and a volume on music and was also a poet of distinctive merit. His music is noted for its nobility, power of characterization and tone refinement. His complete works were issued by Brentkamp and Härkel (5 vols., 1905), and his literary works and letters (4 vols., 1905). See Wust, S., 'Peter Cornelius' (Leipzig 1904), and Sulger-Gebing, E., 'Peter Cornelius als Mensch und Dichter' (Munich 1908).

CORNELIUS, Peter Von, German painter: b. Düsseldorf, 23 Sept. 1783; d. 7 March 1867. He early exhibited a taste for art, and accustomed himself to copy from memory the works of Raphael and other masters. He thus acquired an early proficiency, and at 19 was entrusted with the painting of the cupola of the church of Neuss, near Düsseldorf. It was executed in chiaroscuro, in figures of colossal size, and showed already the grandeur of conception by which he was afterward distinguished. He soon after removed to Frankfort, where in 1810 he commenced a series of designs illustrative of the Prussian counsel-general, commissioned some members of this school to paint his villa. Cornelius executed two frescoes for this purpose—'Joseph Interpreting the Chief Butler's Dream' and 'Joseph Recognizing His Brethren.' He afterward began a series of frescoes from the 'Divina Commedia' for the Marquis Massini, but left it unfinished in consequence of receiving in a commission to execute the frescoes in the Glyptothek, then newly erected at Munich. The designs for the villa of Massini, though never painted, were engraved by Schoefer, and another series, illustrative of the 'Nibelungen Lied,' were engraved by Amstler and Lips. Before leaving Rome (1819) Cornelius had been appointed director of the Academy at Düsseldorf. His first work was to organize the Academy, and then to give his whole attention to the painting of the Glyptothek, which demanded a constant residence at Munich. He resigned the directorship after a short time, and received in 1825 that of the Academy of Munich. Simultaneously with the Glyptothek he undertook the painting with frescoes of the Ludwigs-Kirche. In these two great works he was assisted by his Munich pupils. Many of the cartoons prepared by him were painted under his superintendence by Zimmermann, Schott- hauer and others. In the Glyptothek two large halls were entrusted to him to decorate. In the one, called the Hall of Heroes, he gave a representation of the events of the Iliad; in the other, named the Hall of the Gods, he symbolized the Grecian mythology. In the Ludwigs-Kirche the greatest painting in size and importance was the 'Last Judgment,' of which one critic says that it is without a rival in Europe. Another critic says another that it is enough to say of it that in it Michelangelo is both imitated and disregarded. Cornelius also painted at Munich the Finakothen, a picture gallery for which, with
the assistance of his pupils, he executed an extensive series of frescoes representing the history of painting. In 1841 he was invited to Berlin by Frederick William IV, who entrusted him with the painting of the royal mausoleum or Campo Santo. The most celebrated cartoon in this series is the 'Four Riders of the Apocalypse.' The series consists of 12 paintings, which have been engraved. He was admitted a foreign member of the Institute of France in 1838 and a member of the Academy of Berlin in 1841. His advice and assistance were widely sought and he executed or superintended various works besides those enumerated.

On his merits as an artist there are the widest diversities of opinion according to the sympathies of those by whom he is appreciated. Cornelius was a true representative of modern German thought in his highest phases. He introduced into art a metaphysical and subjective element which in the hands of so competent an interpreter could not but be productive of great results, but which is equally open to the severest criticism. He was the founder of a school and threw new life into German art the mere enumeration of his great undertakings is sufficient to prove. Even his admirers, however, admit certain faults in his execution, and it would seem that in aiming at grandeur he too often failed to be natural. In seeking to develop his leading idea he subordinates details to an extent which amounts to sacrificing them, and that idea is often admittedly recondite, and requires learning and study to appreciate it. Still his admirers insist that his merits are such in the grandeur and beauty of his designs and the elevation of the tone of his execution as to overwhelm all faults of detail; but there are not wanting detractors who say that his excellences, whatever they may be, do not belong to the region of art, and that it is necessary to go outside of it into that of metaphysics to be able to appreciate them. Consult Dohme, 'Kunst und Künstler des neunzehnten Jahrhunderts' (Leipzig, 1878); 'Künstlermonographien' (Bielefeld 1906); Grimm, 'Neun Essays' (Berlin 1865); Koch, 'Peter Von Cornelius' (Stuttgart 1905); Von Wolzogen, 'Peter von Cornelius' (Berlin 1857); Riegel, 'Cornelius, der Meister der deutscher Malerei' (ib. 1870); Förrster, 'Peter von Cornelius: ein Gedenkbuch' (1874); Muther, 'History of Modern Painting' (Vol. I, English trans., London 1895).

CORNELIUS NEPOS — See NePOS.

CORNELL, Alonzo Barton, American capitalist and politician: b. Ithaca, N. Y., 22 Jan. 1832; d. 15 Oct. 1904. He was a son of Ezra Cornell (q.v.), and his early life was spent as a telegraph operator and manager in Cleveland and New York. He was defeated as Republican candidate for lieutenant-governor in 1868; was chairman of the New York State Republican Committee 1870-78; surveyor of coterminous New York, 1861-63; member of the New York State assembly 1873; and naval officer of the port of New York 1876-78. During Cornell's occupancy of the latter office, President Hayes issued his famous order requiring office holders to refrain from politics. In spite of this warning, Mr. Cornwall proceeded with the formation of the Rochester State Commit-tee, called the Rochester convention to order, and as a consequence lost his office, July 1878. In 1879 he was elected governor by the Republican, and served until 1 Jan. 1883, since which time he devoted himself to the care of his large financial interests. He wrote 'True and Firm: Biography of Ezra Cornell, Founder of the Cornell University: a Filial Tribute' (1884).

CORNELL, Ezra, American capitalist and philanthropist: b. Westchester Landing, N. Y., 11 Jan. 1807; d. Ithaca, N. Y., 9 Dec. 1874. He was of Quaker parentage and in 1819 removed with his father, a potter by trade, to De Ruyter, N. Y. His early education was scanty, and for a time he assisted his father in farming and in making pottery, meanwhile teaching in a district school. He also learned the trade of carpenter, worked as a mechanic at Homer, N. Y., and from 1828 to 1838 was manager of a flour mill at Ithaca. He was afterward engaged in a lumber business with his brother, but in 1842, when telegraph lines were first being put in operation, he became interested in the construction of a telegraph line from Baltimore to Washington. He invented a machine for laying the wires underground and was in charge of the work. This method failed, owing to defective insulation, and Cornell's suggestion that the wires should be strung on poles was adopted. He then devoted himself to telegraph line construction and became one of the founders of telegraph companies, and was one of the founders of the Western Union Telegraph Company in 1855. He accumulated a large fortune and in 1858 retired to a farm at Ithaca, N. Y. He was a member of the first Republican National Convention of 1856, was a member of the State assembly in 1862-63, and of the State senate 1864-67. He is best known as the founder of Cornell University, which he liberally endowed and for which he secured special legislation at Albany. He also founded a public library at Ithaca. Consult 'The Life of Ezra Cornell,' by his son, Alonzo Barton Cornell (New York 1884).

CORNELL COLLEGE, a coeducational institution in Mount Vernon, Iowa; organized as a college in 1857, under the auspices of the Methodist Episcopal Church. It is an academic department and a department of civil engineering. The degrees are B.A., B.S. and B.S. in C.E. The enrolment is about 750 and the faculty numbers 41. Besides the college proper, the organization includes an academy, a conservatory of music, a school of art and a school of oratory. The principal buildings of the college are the library and college, science, chapel, Bowman and conservatory halls. The endowed income amounts to about $11,000,000 and the annual income to about $60,000. The library contains about 39,000 volumes.

CORNELL UNIVERSITY, at Ithaca, N. Y., owes its origin primarily to the Land Grant Act of 1862, 1, 7 donating public lands to the several States and Territories which may provide colleges for the benefit of agriculture and the mechanic arts. 2 Under this act New York received as its portion 989,920 acres of land. The institution established was named in honor of Ezra Cornell (q.v.), who offered to give 500,000 with which to erect its buildings (the terms of the land grant restricted in the use of its proceeds for that particular purpose), on condition that it should be located at Ithaca. The university was incorporated in
1865. The number of students (412) who registered at the opening was highly satisfactory. The liberal admission policy, with or without written application, and the freedom against possible control or undue influence by any religious denomination; the nature of the entrance requirements; the promise of opportunities to pursue lines of study not found in other schools then existing; the location, free from the distractions of a large city; the cost of tuition; and other features combined to attract students to the new school. Yet, encouraging as was the beginning the university for the next four years had much difficulty in maintaining its existence. The State's land scrip, which was expected to bring not less than $10 an acre, was being sold for only 50 cents an acre, when Ezra Cornell, believing that the land would increase in value, purchased all the scrip, which had not been otherwise disposed of, and bought over 500,000 acres of excellent timber lands in Wisconsin, which before his death he transferred, with full title and control, to the university. But not before 1882 were any of these lands sold for amounts sufficient materially to aid the institution, and the sum of $2,853,480 was realized from the sale of 140,000 acres. Later other lands were sold at fair prices, making in all from the land grant lands a net profit of about $6,500,000.

Besides Ezra Cornell's endowment, the university received large gifts from Henry W. Sage, for a women's dormitory, a chapel, a library building and a book endowment fund, a school of philosophy, a museum of ethnology, etc., all generously endowed; a donation from John McGraw for a building devoted to zoological and scientific laboratories; from Hiram Sibley for a college of mechanical engineering and mechanical arts; from Andrew D. White a priceless historical library; from Dean Sage a fund for supplying the college pulpit, etc. The university is also indebted to A. S. Barnes for a Christian Association building; to William H. Sage for the chapel enlargement and organ, the purchase of the great Zarncke library, a stone bridge, and in conjunction with Dean Sage, an endowed infirmary for sick students; to Dean Sage for Stimson Hall; to John D. Rockefeller for Rockefeller Hall of Physics; to Willard Fiske for a library fund of about a half million dollars; to Oliver H. Payne for the Cornell Medical College in New York city, and to others for valuable gifts. The total property valuation of Cornell University in 1915 was $22,786,051.73. The total invested funds were $14,051,115.33; total income for 1915, $3,139,530.38, of which $2,026,632.06 represented benefactions. Grounds, buildings, equipment and other property of the university in 1915 were $8,534,157.48. The library comprises 400,000 volumes. In all, 16,698 degrees had been granted and there were about 14,500 living graduates.

The broad scope and many-sidedness of the university is based on Ezra Cornell's proposition, "I would found an institution where any person can find instruction in any subject," in which the more specific purpose of the national university is conformed to the practical needs of the age. The university annually grants free tuition to about 600 students of New York State, apportioned by assembly districts; also to New York State students in agriculture, and to New York State students in architecture, which guards the public interest.

Cornell University occupies in the United States a middle ground between the institutions of private or chiefly private foundations, with independent corporate existence, and the State universities supported and controlled by the States. The government of the State of New York is represented in Cornell University by ex officio members on the board of trustees. Its constitution has undergone many changes, as well of internal arrangement as of outward expansion. Its present organization is as follows: 1. Graduate department. 2. College of Arts and Sciences. 3. College of Law. 4. College of Medicine. 5. New York State Veterinary College. 6. College of Agriculture. 7. College of Architecture. 8. College of Civil Engineering. 9. Sibley College of Mechanical Engineering and Mechanic Arts.

The graduate department has charge of the graduate studies of the other departments. Courses leading to the degrees of A.M. and Ph.D. are offered by the department, and 16 graduate scholarships of the value of $200 and free tuition each, 23 fellowships of $400 and free tuition each, and 2 of $300 and free tuition each are annually granted to graduate students, besides one traveling fellowship in Italy, the value of the annual value of $1,000, good for two years. The College of Arts and Sciences allows elective courses in science and the classics and leads to the A.B. degree B. Chem. The College of Law has the usual law courses and grants the degree of LL.B. The College of Civil Engineering provides instruction in all departments of that subject, and particularly in some of the more advanced developments of the science. Special instruction is given in bridge engineering, railroad engineering, sanitary, municipal, hydraulic and geodetic engineering.

The Sibley College includes eight departments: mechanical engineering, experimental engineering, electrical engineering, machine design, mechanical art, shop work, marine engineering, naval architecture and railway mechanical engineering. Courses of study are four years in length, and the degree of mechanical engineer is conferred upon those who successfully complete the respective courses. The laboratories, museums, etc., are parts of the college are very completely furnished and equipped. Hiram Sibley continued making additions to his first donations, and in 1885 the trustees of the university organized the college under the name by which it is now known. Mr. Sibley's gifts amounted to $160,000, and $150,000 additional have been contributed by his son, Hiram W. Sibley. The College of Architecture gives the usual course in this subject, both in theory and practice and confers the degree of B.Arch. The College of Agriculture gives extended and practical courses. An experiment station established by the Federal government is connected with this department. In 1904 the New York State legislature enacted the Sibley College of Architecture at Cornell, and appropriated $250,000 for buildings therefor. The College of Medicine (established in 1898) has a two years' course in Ithaca, and a full four-year course in New York.

The entrance requirements to all courses are...
substantially the same as those of other first-class universities. In 1914 the total number of students in attendance was 5,094, and of this number the College of Arts and Sciences had about 1,875; the Divinity School, 1,168; the School of Music, 679; the School of Dental Surgery, 208; the School of Law, 639; and the School of Mines and Metallurgy, 1,015. The library contains 600,000 volumes, many of which are valuable and rare, and the printing presses, some of which were engaged in university extension work. The summer school has always had a large attendance. See SUMMER SCHOOLS.

The campus is admired for its beauty and extent, and the group of buildings which belong to the university are models of architecture. The library, with its famous Fisk Dante collection and the Andrew D. White French Revolution collection; the laboratories, halls and dormitories; the classrooms, and other features of the university all present special advantages and attractions.

CORNELL, a commercial term used in England and the United States to signify the control of so large a supply of an industrial or commercial product or so much of a stock that the market value of the commodity held is tremendously advanced, and those who have made contracts to deliver the stock or commodity in question must buy at the prices set by the pool. So the actual difference between the manoeuvre of the corner-man and the normal effort to bull prices by controlling supply is that the corner is based upon knowledge of contracts made for future delivery by those who are not in present possession of the stock. In stock exchange parlance a "corner" is procured where somebody succeeds in buying for further delivery more property of a given kind than is possible for the seller to deliver before the day of the maturity of the contract. The term is used in boards of trade, etc., to designate the condition arising when a much greater quantity of any given commodity is sold for future delivery within a given period than can be purchased in the market. The buyers, who are called in the slang of the exchange "longs," then insist on the contract, and by these means succeed in running up prices to a fictitious point, by which deals are run out between the dealers, or by exchanges, or, where the person insists upon it, by actual delivery. A very large margin of price of transactions are no doubt merely speculative, but many of them are actually purchases for manufacturers and exporters. Successful corners depend then not only on a thorough understanding of where the control of the commodity in question lies, but another holder at the critical moment being able to undersell the would-be corner-man, but on the willingness of the buyer to keep his contracts at no matter what cost. In other words, if the corner-man is too greedy and demands too high a price, buyers may smash the corner by refusing to keep their contracts, a procedure with a certain amount of poetic justice in it, at least when the members of the corner have gained control of the supply which they are to re-buy from the contractors. Legally defined, a "corner" is the securing of such control of the immediate supply of any product as to enable those operating the corner to advance arbitrarily the price of the product. It is created ordinarily by the monopoly of exchange or stock exchanges, and by dealings in options and fixtures. A "corner" when accomplished by a confectionary to raise or depress prices and operate on the market is a conspiracy if the means employed are unlawful. Cereals and cotton, because of the large amount of future trading done in them, are favorite fields for the corner-man; but the exact amount of a year's crop and the timber holdings make the manoeuvre particularly dangerous. Typical "corners" of ancient history include: Joseph's buying and storing the corn of Egypt, so that all countries came to Joseph to buy corn (Gen. xiii, 57); and the Athenian corner in grain, outraged against by Lysias (d. 380 B.C.). Many of the worst financial panics in the United States have been the results of attempts, usually unsuccessful, to corner the gold market. The greatest of these was that which culminated in Black Friday, 24 Sept. 1869, through the operations of Jay Gould and James Fisk, Jr. Consult Boutwell, G. L., 'The Mint Bill and the Crime of 1873' and 'Black Friday' (Chaps. 34-35 in Vol. 2, 'Reminiscences of Sixty Years in Public Affair,' the Seat of War 1902); and Lysias, 'Against the Grain Dealers'; also of allied interest 'On the Sacred Olive' (orations 22 and 7 in 'Ten Selected Orations' edited by G. P. Bristol, Boston and Chicago 1892).

CORNET (Fr. 'little horn'), formerly a reed wind instrument of the oboe class; but the name cornet or cornet-a-pistons is now given to a brass musical instrument with a cup-shaped mouthpiece, which has a very agreeable tone, and is much used in orchestras and military bands, and sometimes with organ in church music. The cornet is intermediate in character between the French horn, the trumpet and the bugle. Its characteristic feature is its three pistons, which may be pressed down by the fingers singly or together, so as greatly to increase its compass. The highest note is given by a tone, the second by a semitone, the third by three semitones. Its range is from C' to C". In brass bands it takes the soprano and contralto parts. The name was also applied to the stop or series of pipes in the organ, intended to imitate the tone of an obsolete wind instrument which has been superseded by the oboe.

From its military use the term cornet was transferred to a cavalry troop, because it was accompanied by a cornet player, and then to the color officer of this troop, the cornet of cavalry corresponding to the infantry ensign. This title of the English army was abolished in 1871, the rank of sub-lieutenant taking its place.

CORNETO, kör-nä'tō, or CORNETO TARQUINIANA, Italy, a picturesque, medieval-looking town, situated 12 miles north of Civitá Vecchia, three miles from the Mediterranean, on the Marta River. It is the see of an archbishop, the episcopal see. It rose out of the ruins of the Etruscan city of Tarquinii, whose remains, within a mile and a half of Corneto, are among the most important for the student of Etruscan history. It seems to have been destroyed by the Saracens. The Necropolis of Tarquinii, the most important relic of the ancient city, is on the same hill as the modern city and extends into the neighboring plain. It covers about 16 square miles. The painted tombs, of which some 20 are special objects of trade on the market in the 18th century; but it is mainly since 1842 that they have been examined; valuable new discoveries were made during excavations in 1881-82. Pop. about 7,000. Consult Dennis,
CORNICLE, or BLUEBOTTLE (Centaurea cyanus). A plant of the Composite family, indigenous to Europe. It develops long slender, branched stems, from 12 to 30 inches high, and with a flower about one and one-half inches in diameter. It is a hardy plant and is popular in American flower gardens. There are many varieties and the color ranges from deep blue to white.

CORNHILL, London, one of the principal streets of the city, once a corn market. In medieval times two of its attractions were the Tun, a round house used as a temporary prison, and the Standard, a water conduit and also a point of measurement.

CORNICE (It. "cornice"), LA CORNICE, or CORNICE ROAD, a famous highway between France and Italy, skirting the Mediterranean from Nice to Genoa. The word cornice means literally "shelf," in allusion to the fact that for miles the road is cut in the face of the cliffs. The modern road was begun by the French and finished by the Sardinian government after the fall of Napoleon.

CORNICE, in architecture, the uppermost of the three parts of an entablature, composed of the projected moldings of the roof. The Egyptian form was a high cavetto or fillet above a round bend. Three styles are known in Greek architecture: The Doric cornice consists of a Doric cyma, the corona projecting considerably, and containing the ends of the roofings boards, a second cyma and an erect bell molding. The Ionic cornice shows a fillet either with dentils or quite plain, above which are a wave molding and the corona, terminating in a slab and erect bell molding. The Corinthian cornice differs from the Ionic in having small consoles, composed of volutes and acanthus leaves. In Gothic architecture the cornices are often elaborately adorned with animals or with human figures. In Renaissance buildings, an arched cornice was developed, resting on corbels without arches or moldings. The Renaissance revived the classic type. It is used now as a projection on the top of a wall, which is used to throw off the rain water from the roof.

CORNING, Erastus, American capitalist: b. Norwich, Conn., 14 Dec. 1794; d. Albany, N. Y., 9 April 1872. He became a prominent iron merchant in Albany, N. Y., subsequently engaged in the banking business, and applied much of his time and means to the development of the railroad system of New York State. He effected the consolidation of various roads into the New York Central Railroad, and was its president 12 years; was State senator 1842-45; member of Congress 1857-59 and 1861-63; member of the Peace Congress in 1861, regent of the University of New York in 1833, and vice-chancellor of the board.

CORNING, James Leonard, American physician: b. Stamford, Conn., 26 Aug. 1855. He studied at the universities of Heidelberg and Würzburg in Germany, and was graduated at the latter. He has an international reputation as an expert neurologist, and as the discoverer of spinal anesthesia (1885). He was the first to inject liquid paraffin into the tissues, there to solidify; he also demonstrated that the action of stimulants, sedatives and certain other medicinal substances may be increased if the subject remains in compressed air. As consulting neurologist he served various New York hospitals and, besides his contributions to the medical press, wrote "Caroidea Compression" (1882); "Brain Rest" (1883); "Local Anesthesia" (1886); "Hysteria and Epilepsy" (1888); "Treatment on Headache and Neuralgia" (1888); "Pain in Its Neuro-Pathological and Neuro-Therapeutic Relations" (1894); "Experimenatal Researches Regarding the State of the Mind in Vertigo" (1895). Under the pseudonym of Roland Champion he wrote a romance entitled "Princess Ahmedec" (1900).

CORNING, Iowa, city and county-seat of Adams County, 75 miles east of Council Bluffs, on the Burlington Route. It has manufactories of brick and tile and extensive interests in agriculture and stock-raising. The chief buildings are the public library and the Masonic Temple. The waterworks are the property of the municipality and the government is vested in a mayor and council. The city was incorporated in 1871. Pop. 1,702.

CORNING, N. Y., city and county-seat of Steuben County. It is situated on the Chemung River, the Erie and the Delaware, Lackawanna and Western railroads. Among the more prominent buildings are the city hall, free academy, public library, Corning Hospital, courthouse, city club and Saint Mary's Orphan Asylum. Corning has extensive manufactures of cut and flint glass, railway supplies, pneumatic drills, air compressors, terra-cotta goods, building and paving brick, lumber, sash and blinds, etc. The United States census of manufactures for 1914 recorded 58 industrial establishments of factory grade in the city, employing 2,482 persons; of whom 2,203 were wage earners, receiving annually about $1,473,000 in wages. The capital invested aggregated $4,992,000, and the year's output was valued at about $3,954,000. In 1914 the value of output of this, $2,921,000 was the value added by manufacture. Corning was incorporated as a city in 1890. Under the revised charter of 1905 the mayor holds office for two years and the council is elected. The waterworks are owned by the city. Pop. 15,000.

CORNHILL, Charles Johnson, English naturalist: b. Salcombe House, Devonshire, 28 Sept. 1858; d. 30 Jan. 1906. He was educated at the Charterhouse and Hertford College, Oxford, and for many years was a regular contributor to The Spectator and Country Life on natural history and outdoor life. His published books include "The New Forest" (1894); "The Isle of Wight" (1895); "Life at the Zoo" (1895); "Wild England of To-Day" (1895); "Animals at Work and Play" (1896); "Nights with an Old Gunner" (1897); "Animals of To-Day" (1899); and "The Naturalist on the Thames" (1902).

CORNISH LITERATURE. The ancient language of Cornwall formed with Welsh and Breton the Cymric or southern division of the Celtic Languages (see CELTIC LANGUAGES; CELTIC LITERATURE) and more closely resembled the last. As the discourse of the Welsh, it was generally spoken until the time of Queen Elizabeth.
CORNSTALK—CORNWALL

Its decay dates from the Reformation, and was due to the failure of the Church of England to exploit the Book of Common Prayer and the Bible into the language of the province. After 1678 it ceased to be used in public worship. Dolly Pentreath of Moushele (1676–1771) is reputed to have been the last person to have spoken it wholly; but words and phrases have come down which are still in use. Its vocabulary dates probably from the 13th century; and the sacred dramas that survive are not earlier than the 14th century. Consult Norris, 'Ancient Cornish Drama' (1859); Stokes, 'Mythology of Creation' (1864); 'Glossary of Cornish' (1864); edition of 'Life of Saint Meriasek' (1872); Jago, 'Ancient Language of Cornwall' (1882); 'English-Cornish Dictionary' (1887); Williams, 'Lexicon Cornu-Britannicum' (1863); and supplementary to the last named, Loth's 'Remarques et corrections' (1902); Jenner, 'Handbook of the Cornish Language' (1904).

CORNSTALK, chief of the Shawnee Indians: b. about 1720; d. 1777. He was a man of high abilities and dignity of character. He first appears on the map of the country massacre of July 1763, in Pontiac's war; next in a far higher rôle, as commanding the Indian forces at the bloody and hard-fought battle of Point Pleasant, 10 Oct. 1774, in Dunmore's war. (See COLONIAL WARS.) He had opposed the war, being convinced that it meant ultimately swifter ruin for the Indians; but once embarked, he fought with a skill and resolution that excited the admiration of his enemies. After the defeat he was in favor of carrying on the war to the end, but finding his head men and subchiefs determined on giving up, he went himself to make the best terms he could. His oratory was said by the Virginians to equal Patrick Henry's. Early in 1777 he came with him and two other Indians to the garrison at Point Pleasant, to tell them that, although he wished to keep the peace, his tribe was resolved on war, and if so, he must join them. The party were held as hostages; but one of them started by riding being killed by Indians near by, the rest and their captain rushed to the fort and butchered the four, Cornstalk rising to meet his fate without a word.

CORNUS. See CORNEL; DOGWOOD; TUPelo.

CORNWALL, Duke of, a hereditary title of the eldest son of the sovereign of Great Britain. Cornwall is a royal duchy, the revenues of which belong to the Prince of Wales for the time being. The title of Prince of Wales is conferred by special creation, that of Duke of Cornwall descends by inheritance. The dukedom of Cornwall was created for the Black Prince in 1337.

CORNWALL, Barry. See PROCTOR, BRYAN WALLOR.

CORNWALL, Henry Bedinger, American chemist: b. Southport, Conn., 29 July 1844. He was graduated at Columbia 1864, and from its school of mines 1867, becoming assistant in the latter 1865–73, save for two years' study at the mining school in Freiberg, Germany. In 1873 he was appointed professor of applied chemistry and mineralogy at Princeton University, and in 1910 became emeritus professor. With Caswell, he translated Plattner's 'Manual of Qualitative and Quantitative Analysis with the Blow-pipe' (1858), and has written 'Manual of Blow-pipe Analysis, with a System of Determinative Mineralogy' (1882), and many scientific papers that have appeared in the special journals of his profession.

CORNWALL, Canada, port of entry, and capital of the three united counties of Stormont, Dundas and Glengarry in Ontario, and is situated at the intersection of the main line of the Grand Trunk Railway with the Ottawa and New York Railway. It has admirable shipping facilities, and is 67 miles west of Montreal, 56 miles by northern route and 50 miles by the Adirondacks. It has eight churches, Anglican, Roman Catholic, Presbyterian, Methodist, and one Salvation Army barracks. There are three hotels, eight stores, a commercial college and numerous banks and public buildings. It has large textile industries, paper, pulp, flour and planing mills, machine shops and foundries, and manufactories of pottery and agricultural implements. Building stone is quarried in the neighborhood. The city is in a rich agricultural section and has a large fleet of steamers. The United States is represented by a consular agent. It has weekly newspapers and is lighted by gas and electricity. Pop. 6,598.

CORNWALL (Lat. Cornu Galliae, 'horn of Gaul', that is, the remotest land inhabited by Celts). England, a maritime country, terminating the southwestern extremity of the island. Its form is irregularly triangular. Its area is 1,537 square miles. The northwestern coast-line is broken by a number of shallow bays. The south coast is much more broken, and is marked both by bold promontories and deeper bays. At Land's End, between these two coasts, terminate the hills of the Devonian range. The rivers of Cornwall are numerous but short. Among them are the Fowey, the Camel, the Inny, the Attery, the Lynner, etc. The climate, owing to the elevation and exposure of the surface, is very variable. The soil, consisting of decomposed slate, admits of easy drainage, but requires much manure. In many of the more elevated districts much of the soil is poor. Nearby 70 per cent of the total area is under cultivation, a large amount of grain being grown, and much land being devoted to market-gardening for London consumption. Cattle, sheep and horses are reared. The mines of copper and tin, famous for many centuries, and known to the Phoenicians, still constitute the richest treasures of the county, though the value of both has greatly diminished. The chief mining district is in the southwest part of the county. Several mines exceed 350 fathoms in depth. In the once productive Botallack copper mine, situated a few miles north of Land's End, the workings are on the very verge of the cliff, and, descending beneath the sea, are carried far beyond low-water mark. The Dolcoath mine, near Camborne, is the chief tin mine, and there are other important tin mines in the same locality. The production of copper has greatly decreased in recent times. China-clay is an important mineral product. Owing to depression in the mining industry there has been considerable emigration to the silver mines of Nevada, and to other mining centres. There are few manufactures, but the fisheries, par-
ticularly of pilchard and mackerel, are valuable. The dukedom of Cornwall is always held by the eldest son of the Duke of Cornwall, to which vast estates are attached. At the time of the Roman conquest Cornwall was occupied chiefly by tribes of Cimbri and Damnonii, and became included in the province of Britannia Prima. After the Romans withdrew the natives regained their independence and retained it till the time of Athelstan, when they were subdued by the Saxons. Their Celtic origin is fully established by the abundance of rude monuments spread over the country, and consisting chiefly of unbroken stones placed erect, singly or in circles, with others laid across. It is divided for parliamentary purposes into six divisions, each returning one member. Pop. 328,068. Consult Boase, 'Bibliotheca Cornubiensis' (1874-78).

CORNWALL, or CORNWALL-ON-THE HUDSON, N. Y., village in Orange County on the west shore of the Hudson River, at the foot of Storm King Mountain, 52 miles north of New York by rail. The beauty of the adjacent scenery and the proximity to New York city, which can be reached in less than two hours by the Lackawanna and the West Shore railroads, make it a favorite summer resort. A carpet mill gives employment to a fourth part of the inhabitants. Idlewild Park and Storm King Mountain are among the prominent points of interest. It was settled about 1684, became a precinct in 1764, a township in 1779, and was incorporated in 1885. From the original township have since been taken Highlands, Blooming Grove and Monroe, besides parts of Chester and Hampton. Consult Beach, 'Cornwall,' New York (New York 1874); 'History of Orange County' (Newburgh 1847). Pop. 3,000.

CORNWALL CANAL. See Canadian Canals.

CORNWALLIS, Caroline Frances, English author: b. Kent, 12 July 1766; d. Lidwells, Kent, 8 Jan. 1808. She acquired a thorough knowledge of Latin and Greek, and making herself conversant with nearly every study which occupies thoughtful men, from an early age, carried on a correspondence with many eminent persons. Her refusal to accept the hand of the Italian historian, Sismondi, did not forfeit his friendship, and she lived much in Italy. Her first work, 'Philosophical Theories and Philosophical Experience, by a Pariah' (1842), was a first of a series of 20 'Small Books on Great Subjects,' the said subjects including the 'Connection of Physiology and Intellectual Science'; 'Ragged Schools'; 'Criminal Law'; 'Greek Philosophy', and the 'History and Influence of Christian Opinions.' Twenty-two volumes of this series appeared between 1842-54, all the most important of which were written by herself. She also published in 1847 'Fenicles, a Tale of Athens,' and her 'Letters and Remains' appeared in 1864.

CORNWALLIS, Charles, 1st Marquis and 2nd Earl, English general: b. London, 31 Dec. 1738; d. Ghazipur, Benares, India, 5 Oct. 1805. He was educated at Eton and Cambridge, and entering the army served in 1761 in a campaign of the Seven Years' War as aide-de-camp to the Marquis of Granby. After all the various promotions he obtained the rank of general. He represented the borough of Eye in Parliament from 1760 until the death of his father in 1762, when he succeeded as Earl Cornwallis. In 1770 he was made governor of the Tower. In Parliament he generally supported the ministry, but exercised an independent judgment on several important questions. In particular he was opposed to the policy of waging a war in America, but offered a special leave of absence from the king sailed with his regiment when it was ordered to America in 1776. He served with distinction under Generals Howe and Clinton in the campaigns of 1776-79 in New York and the Southern States, and in 1780 was left in independent command in South Carolina, with 4,000 men. He defeated General Gates at Camden 16 Aug. 1780, and General Greene at Guilford 15 March 1781. He then invaded Virginia, but after moving his forces according to successive and contrary instructions from Sir Henry Clinton, he was besieged in Yorktown, where he had entrenched himself, and compelled to surrender on 19 Oct. 1781. In 1786 Lord Cornwallis was sent to India with the double appointment of commander-in-chief and governor-general; and not long after the government of Bengal declared war against the Sultan of Mysore for an attack upon the Rajah of Travancore, the ally of the British. The first campaign was indecisive, but in March 1791, he invaded Mysore, captured Bangalore; and in the year after besieged the city of Seringapatam, and obliged the sultan, Tippoo Sahib, to sue for peace, and surrender a large portion of his dominions. On the conclusion of the war Lord Cornwallis returned to Great Britain, and in 1792 was created marquis, appointed master-general of the ordnance, and admitted a member of the privy council. In 1798, at the time of the rebellion, he was appointed lord-lieutenant of Ireland, which office he filled until 1801, conducting himself with great firmness and judgment. In the same year he was sent as plenipotentiary to France, where he signed the Peace of Amiens. In 1804 he was again appointed governor-general of India. Consult Marshall, 'Memoirs' (Gateshead 1806); Lord Cornwallis, 'Correspondence' (edited by Ross, London 1859); Seton-Karr, 'The Marquess Cornwallis' (in 'Rulers of India,' Oxford 1890).

CORNWALLIS, Edward, English soldier and colonial administrator: b. 1712. He entered the army, and was present at the battles of Fontenoy and Prestonpans. He was the first governor of Nova Scotia, 1749-52, and the founder of Halifax. He sat in the House of Commons for Ely, 1749, and for Westminster, 1753. He was subsequently governor of Gibraltar.

CORNWALLIS, Kinahan, American lawyer, editor, novelist, poet: b. London, England, 24 Dec. 1834. Educated by private tutors for the ministry of the Church of England, also at Colledge Institution, Liverpool, entered at the School of Medicine, Liverpool, and Trinity College, but was then appointed to a British government post in Australia, and resided two years at Melbourne. He then returned to London and published there 1859. In 1860, one of his travel books was appointed to a post in British Columbia, resigned his British appointment, and soon afterward went
to Washington as correspondent of the New York Herald with the newly arrived first Japanese Embassy to the United States, on an American warship. Then he went to the British and French West Indies, and then on to Brazil. On his arrival, the Herald's correspondent accompanied him everywhere till his departure for England in October. In November 1860 he published in New York and London, with a preface by the Right Hon. Sir R. Bourne, The Woman of the New World, or The Prince of Wales in America. He became Charles Reade's agent in America. Mr. Cornwallis remained on the Herald as financial editor and editorial writer nearly 10 years, and meanwhile bought and edited the old Knickerbocker Magazine. When he left the Herald he also bought and then edited The Albion, a weekly newspaper. In 1880 he established The Wall Street Daily Investigator, which he thereafter owned and edited for 25 years, at the same time practising law, having been naturalized, and admitted to the New York bar in May 1863. He had published the following books in London prior to 1860: 'An Australian Poem—Yarra Yarra'; 'Two Journeys to Japan' (2 vols.); 'A Panorama of the New Madrid' (2 vols.); 'The New Eldorado, or British Columbia'; all the result of travel; also three novels—'Howard Plunkett, or Adrift in Life' (2 vols.); 'Wreck and Ruin, or Modern Society' (3 vols.); and the 'Gutten Family: A Medley.' In 1861 appeared his 'Pilgrims of Fashion'; and 'Adrift with a Vengeance'; and 'A Marvelous Coincidence' followed. Then came two descriptive poems of one volume each embodying the history of America from the time of the Norsemen to the Civil War; viz., 'The Song of America and Columbus'; and 'The Conquest of Mexico and Peru,' to which a third volume was added later—'The War, for the Union, or The Duel Between North and South.' The History of Constructive Contempt of Court while other publications on law and many magazine and newspaper articles and poems were also published by him here and in British periodicals. He is the oldest in membership in the Saint George's Society of New York.

CORO, kór-o', or SANTA ANA DE CORO, Venezuela, town in the state of Falcon, near the Gulf of Coro, an inlet of the Gulf of Maracaibo, two and a fourth miles from the Caribbean Sea, on which is its port, Vela de Coro, about seven miles distant by railway. The trade was once considerable, but has now much fallen off; as is also the town since 1578, when the seat of government was transferred from it to Caracas. Coro contains several churches, interesting for their antiquity, though they either have been rebuilt or lie in ruins. La Vela, its port, has a good harbor and a trade with the Dutch West India and is the residence of United States consular agent. Coro, one of the oldest cities in Venezuela, was settled by Juan de Ampués in 1527 and for a time was the Spanish capital of Venezuela. It was created a bishopric in 1531, but subsequently the see was removed. It was the objective point of Miranda's first descent upon Venezuela in 1805, when he led an abortive expedition against the Spanish in the hope of precipitating the revolution of the Spanish-American colonies. Pop. 9,000.

COROADOS, kō-rō-ā'dōz, Indians of Brazil, the name being derived from their tions, just as the name Botocudo is applied to other aborigines of the same country who wear b togates or tailless loincloths. It is an arbitrary collective title for ethnic fragments whose tribal names have been lost. Tribes thus designated are found at the present day in some of the southern states of Brazil, especially in Paraná, Rio Grande do Sul, São Paulo and Matto Grosso; but only a few thousands remain in scattered groups, evidently representing different stages in development, though in a general way the Indians of the upper Paraná and upper Paraguay region may be classified as true aborigines, the nearest representatives, and probably the direct descendants, of that primitive race whose osseous remains have been found in Lagoa Santa caves and Santa Catarina shell mounds. Consult Keane, 'Man, Past and Present'; Porter, 'Native Races.'

COROLLA, kōr'-ō-lā, the inner whorl of two series of floral envelopes, occurring in the more highly developed plants, the outer being the calyx. In all cases its divisions, which are called petals, alternate with those of the calyx. They are generally colored—that is, they are some other color than green. The corolla is, as a rule, larger than the calyx. When the petals of a corolla are all distinct, they are said to be polypetalous, and this is the normal type. When they cohere continuously by their margins they are called monopetalous, or, better, gamopetalous, meaning that the petals are joined. The petals of a corolla are really only modifications of leaves. The corolla merely assists reproduction by shading the productive organs from injury, and, in some cases, by secreting honey attracts bees and other insects to aid in their fertilization.

COROLLARY (Lat. *crown,* or *garland,* and in a derived sense *gift;* hence something given or granted), in logic, a proposition the truth of which appears so clearly from the proof of another as not to require separate demonstration.

COROMANDEL COAST, the east coast of the Indian Peninsula, between Calimere Point and the mouths of the Kistna. It is open, sandy and has no secure harbors; the surf, continually beating on it, renders landing difficult, often dangerous, and it is commonly accomplished in native boats of a peculiar construction. A violent monsoon accompanied by hurricanes blows from the middle of October well into April.

CORÖN, kō-rō'n, Philippines. See PEÑON DE CORÓN.

CORONA, Cal., city in Riverside County, 50 miles southeast of Los Angeles, on the Santa Fe and the Pacific Electric railroads. It contains a city hall, high school, Carnegie library, the Woman's Improvement Club and a fine circular boulevard. It has extensive interests in citrus fruits, alfalfa milling, clay products and crushed stone. Great quantities of citrus fruits are shipped from Corona. Pop. 3,540.

CORONA. The crown of victory, termed corona, of the ancient Greeks and Romans, was what we, in this day, term a wreath. These corona come under the following classes: Those
CORONA—CORONADO

Dedicated to the victors in peaceful contests and those voted for military achievement.

The crown or garland of the victor in the Olympian and the Pythian games was of laurel, that of the winner in the Nemean contests consisted of oak leaves, that of the Isthmian games was made from the pine tree.

The Roman coronæ were mostly military and termed "triunphal." The most important were: Celestial crown, similar to the Eastern crown (see below), but having each ray surmounted by a small star. Civic crown (corona civica), composed of acorns and oak leaves, given as reward for saving a citizen's life in battle. Eastern crown, often termed antique crown (corona radiata, usually carries, above the gold circle, eight rays), is the Roman crown of apotheosis, but Great Britain has used it to honor successful statesmen in India and her Eastern dependencies, hence the term Eastern. Laurel crown (corona laurea), originally a

martial crown, became a wreath of honor and distinction on civic occasions, and was composed of laurel leaves on their stem. Myrtle crown (corona myrteæ), composed of myrtle leaves (myrtle was dedicated to Venus), was awarded to conquerors and used in wedding ceremonies, also placed upon the heads of the dead. Laurel crown (corona muralis) was a circle of gold surmounted by pinnacles or battlements given for great prowess in scaling a wall and attacking the town within. Naval crown (corona navalis or rostrata) was a circle of gold surmounted by prows (rostral) of boats awarded to victorious sea warriors (the British nation also uses a naval crown composed of a gold rim surmounted by four ships' sterns and four sails alternating). Obsidian crown (corona obsidianalis or graminea), composed of herbs or grass, awarded to a general who delivered a town from a state of siege. Olive crown (corona oleaginea), composed of single laurel leaves closely compact. Vallary crown (corona vallaris or castræalis), composed of a circle surmounted by palisades, was the honor conferred on the first warrior to pass the enemy trench wall (vallum) or fence and enter the foe's camp or fortress (castrum).

Among the ancient religious ceremonial crowns were the corona funebres or sepulchres, funeral chaplets of leaves and flowers; the corona conuivialis, worn at banquets, etc., and the corona natalis, suspended over the door where a birth had taken place (at Athens olive for a boy, wool for a girl). The nuptial crown (corona nuptialis) was composed of flowers (verbena preferred) plucked by the bride herself. See CROWNS AND CORONETS.

CLEMENT WHEELOCK COWPER

CORONA (a crown), in astronomy, a halo or luminous circle round one of the heavenly bodies; specifically the portion of the aureola observed during total eclipses of the sun, which lies outside the chromosphere or region of colored prominences. (See HALO). In botany the corona is an appendage of the corolla in some flowers, coming as it were between the corolla and the stamens, well seen in the cup of the daffodil. In architecture it is the lower member of the projecting part of a cornice.

CORONA AUSTRALIS (the southern crown), one of Ptolemy's southern constellations, containing 49 naked-eye stars, varying from the third to the seventh magnitude.

CORONA BOREALIS (the northern crown), one of Ptolemy's northern constellations, situated near Hercules, and containing about 30 stars visible with the naked eye; a, known as Gemma, is of the second magnitude, the chief of a curved row of seven stars of the third, fourth and fifth magnitudes. In 1866 a new star of the second magnitude appeared in the constellation, but soon after became invisible save with a glass.

CORONACH. See CORANACH.

CORONADO, kō-ro-ná'dō, Francisco Vasquez de, Spanish explorer: b. Salamanca, Spain, about 1500; d. Mexico after 1542. He came to the New World about 1535, and by marrying the daughter of Estrada, the royal
treasurer for New Spain, was appointed governor of the province of New Galicia. On the arrival in Culiacan of Alvar Nuñez, Cabeza de Vaca, from his extraordinary journey from Florida in the year 1538, when the first sight of cultivated fields, of self-cultivated tribes far to the north, living in populous cities, acquainted with the arts, and possessing quantities of gold, silver and precious stones, an expedition was sent out under Marco de Niza, in 1539, to explain the role of Cabeza de Vaca and to strengthen the belief in the existence of great wealth among the nations far to the north, and a second expedition was fitted out under Coronado, which departed from Culiacan, on the Pacific Coast, in April 1540. He passed up the entire length of what is now the Mexican state of Sonora to the river Gila. Crossing this he penetrated the country beyond, to the Little Colorado (called by him Rio del Lino), and paid his visit to the same cities of Cibola mentioned by Cabeza de Vaca and De Niza. In the kingdom were seven cities, but he declares that there was no truth in the reports of his predecessors regarding their wealth. "All was quite the contrary," he adds, "saving only the name of a river called Cibola." From Cibola, Coronado traveled eastward, visiting several towns occupied by a similar people to those he had met, which are recognized in the existing villages of the present Pueblo Indians. He proceeded eastward to what he calls the "big river," which is the Rio Grande, where he heard of the great city of Quivira. In their journey eastward they met with a new kind of oxen, wild and fierce, whereof, the first day, they killed fourscore, which sufficed the army with flesh. They continued to Quivira, almost 300 leagues distant, by their account, traversing "mighty plains and sandy heaths, smooth and wearsome, and bare of wood." Coronado's narrative is of value as it furnishes the first authentic account of the buffalo, the great prairies and the desert plains of New Mexico. It describes, too, with every appearance of truth, the towns of the Pueblo or semi-civilized tribes of Indians, as they existed more than 300 years ago and which are still found in New Mexico. He returned to Mexico with such of his army as had not deserted along the route. The victory received him coldly and allowed him to resign the government of New Galicia. He lived quietly on his estates until his death. The original documents describing his journey are translated by Winship, 'The Coronado Expedition' (in the 'Fourteenth Report of the United States Bureau of Ethnology,' Washington 1896). Consult Winship, 'Journey of Coronado' (New York 1904).

CORONATION, the ceremonial rite of placing a crown on the head of a monarch as a symbol of his assumption of rule. The practice is one of great antiquity and in most countries has been followed in some form or other. Accompanying the crowning has been the anointing with oil, a custom that was followed in the dedication of the Hebrew kings, and is significant of consecration to the will of God. In England before the Norman Conquest the term "crowned" is more frequently "hallowed" than "coronation." Egferth, Prince of Mercia, was "hallowed king" by Offa, his father, in 785; and the essential form of words employed has been altered little in the 12 centuries that have intervened; but various parts of the service employed in later times have been shortened and some omitted altogether. Thus the ceremonial, in the earlier days of the English monarchy performed at Kingston-on-Thames or Winchester, is in essentials the same as that now performed at Westminster. The recognition of the king as rightful lord is followed by a sermon, the anointing, the presentation of the ring as the symbol of kingly dignity and of the sceptre as the symbol of kingly power, the crowning, the presentation of the Bible, the enshrinement, the homage. The service is one in which the religion of the nation is asserted; the covenant is one between God, the king and his people. In addition to anointing, the kings prior to the Reformation were signed on the head with chrism or sacred oil; and touching for the kings evil or scrofula was practised until the accession of the House of Hanover in 1714.

The ancient Scottish coronation stone—the Stone of Destiny in Edinburgh, is the coronation chair at Westminster. It was brought from Scone, where the Scottish kings were crowned, by Edward I in 1296. It is traditionally believed to have been the stone which Jacob used for a pillow, to see a vision; and from Tara, the site of the Irish coronations, to Scone; but the unimaginative Skene says that from its geological composition it must have been quarried from rocks near Scone.

There have been variations in the oath taken from time to time. The declaration which was introduced in 1678 under the excitement produced by the so-called Popish Plot continued almost unabated down to the time of the last coronation, that of George V, 22 June 1911. That oath, aimed at securing a Protestant sovereign and the safeguarding of the Protestant Succession, expressly repudiated two cherished doctrines of the Roman Catholic Church—involution of the Virgin Mary and the saints and transubstantiation. Subscription to this oath was given as the reason by George III and George IV why they would not consent to Catholic emancipation. King Edward VII wished to be relieved from that part of the oath which was offensive to his Catholic subjects; but an attempt at emending the coronation fell through. The subject was again brought up before the crowning of George V, and by the Accession Oath Act of 1910 the objectionable phrases were withdrawn, and the king simply pledges himself as a "fapsed" member of the Protestant Reformed Church of England, to secure the Protestant succession "according to law."

In honor of Charlemagne, the emperors of Germany were always crowned at Aix-la-Chapelle, in the church which he founded. Thirty emperors were crowned there, and until 1793 the regalia and robes were preserved there. The kings of France were crowned at Rheims and their queen consorts at the church of Saint Denis, near Paris; those of Spain, at Toledo or Madrid; of Poland, at Gniezna; of Hungary, at Pressburg; of Scotland, at Scone; and the native kings of Ireland, at Tara. The recent kings of Denmark have been crowned at Fredericksburg; those of Sweden at Upsala, and the emperors of Russia, at the Kremlin, Moscow. Consult Johnston, W. F., 'The Coronation of a King; or, Ceremonies, Pageants and Chronicles of the Coronations of All Ages.'
CORONATION CHAIR—CORONUM

(London 1902); and Perkins, Jocelyn, 'The Coronation Book; or, the Hallowing of the Sovereigns of England' (London 1911).

CORONATION CHAIR, the ancient throne in Westminster Abbey used at the coronation of English kings since Edward I. Beneath the seat is the Lia Fail, or Stone of Destiny, on which Scotland's kings were crowned. The stone is said to have been used by Jacob as a pillar, and to have been in Tara, the residence of the high kings of Ireland, after the 5th century B.C. It was brought to Scotland many centuries later and thence to England by Edward I. Celtic tradition has it that political supremacy goes to the people in whose territory the stone rests.

CORONATION GULF, an inlet on the northern coast of British America into which empty the waters of the Coppermine River. It is north of the Arctic circle and included between long. 107° and 116° W. Bathurst Inlet is an extension toward the southeast. It is connected with other Arctic channels by Dease Strait on the northeast and Dolphin and Union Strait on the northwest. It is studded with islands.

CORONEA, kör-ô-ně'ä, a small town of Boeotia (q.v.), southwest of Lake Copias, where in 447 B.C. the Boeotians defeated the Athenians and became the leading state of Greece; and in 394 Agesilus defeated the allied Greeks. The town is now in ruins.

CORONEL, Chile, a port in the province of Concepción, on the Araucobai River, important on account of its coal mines. The customs receipts average about 700,000 pesos per annum. It is a coaling station. Pop. 5,258.

CORONEL, Battle of. A naval engagement fought 1 Nov. 1914 off the coast of Chile between a British squadron under Rear-Adm. Sir Christopher Cradock (q.v.) and the German Pacific squadron commanded by Adm. von Spee. Cradock's four vessels — two armored cruisers, one light cruiser and an armed liner — were no match in regard to speed and range for the German squadron of five vessels. The Good Hope, Monmouth and Otranto were sunk; only the light cruiser Glasgow escaped. Admiral Cradock went down with 1,650 officers and men. On 8 Dec. 1914 four vessels of von Spee's squadron were destroyed by the British off the Falkland Islands, and the fifth, the Dresden, was sunk off Juan Fernandez on 14 March 1915. See WAR, EUROPEAN—NAVAL OPERATIONS.

CORONER, a functionary whose name connotes, or crowner, implies that he has principally to do with pleas of the Crown or in which at least the Crown is concerned. His office is very ancient, mention being made of it in 925 A.D. His office in England was peculiarly a county institution. In Alfred's time he was appointed by the king, but since Edward I's time the office has been elective. His duties originally had to do with inquiries into fires and cases of wreckage and of sudden death, but now his court is a court of record in which, after sight of the body of one who has died in prison, or so suddenly that suspicions of violence may be excited, a jury summoned for the purpose pronounce a decision as to the cause of death. The proceedings under the auspices of the coroner prepare the way for a criminal prosecution. He also officiates as a sheriff's substitute when the sheriff himself is interested in a suit and cannot therefore act in it himself. In the United States the coroner is an elective county officer. His duties are similar to those of a coroner in England. Generally he has no right to inquire into the cause or origin of a fire except when death has resulted from it, but by statute in some States he has the power and duty to investigate the causes and origins of fires which appear to be of incendiary origin. Consult 'Encyclopedia of the Laws of England' (Vol. III, London 1897); Binmore, 'Instructions for Sheriffs, Coroners and Constables' (2d ed., Chicago 1894); Smith, B. D., 'Powers, etc., of Coroners' (2d ed., Albany 1897); Jarvis, 'Office and Duties of Coroners with Forms and Precedents' (5th ed., London 1888); Boys, 'Treatise on Coroners' (Toronto 1893).

CORONETS. See CROWNS AND CORONETS.

CORONIS, (1) in Greek mythology, the daughter of King Phoroneus, whom Neptune loved, and who was changed into a crow by Athena whom she had begged for protection from Poseidon; (2) the daughter of Phelegyas and the mother of Asclepius.

CORONIUM, a hypothetical chemical element, supposed (by some astronomers) to exist in the sun. The evidence in favor of its existence consists in certain bright lines that are seen in the spectrum of the solar corona at the time of a total eclipse, and which are not known to be due to any recognized terrestrial element. On account of the great height above the sun's surface to which the matter that gives these lines extends, coronium has been assumed to be far lighter than hydrogen, which is the lightest known terrestrial element. Certain French and Italian scientists have reported the discovery of coronium in terrestrial volcanic gases; but their results need confirmation, and the existence of the supposed element, even in the solar atmosphere, has not yet been demonstrated. A line not very remote from the coronium line has been found in the spectrum of the aurora, so that certain scientists suppose that the upper layers of the earth's atmosphere contain a new element, geocoronium, much lighter than hydrogen.
