Seventh Period (1774-1814).—Often termed the "Marcolini" period. Count Camillo Marcolini was made chief director and started retribution to make up for the immense losses caused through severe competition. He forced sales of surplus stock by lowering prices; he reduced salaries. Financial embarrassment, in 1790, forced a subsidy from the state. All without success. His resignation, in face of impossible retrieval, when offered in 1792 was refused. The factory was closed in 1810. This caused so much labor disturbance that the works were opened again and sales prices again reduced, while much was sold without decoration. Such sales account for much of the spurious Dresden ware which is of Dresden body but fake decoration. Marcolini retired in 1814. Napoleon's activities were ruining all European commerce; Wedgwood's ware, from Staffordshire, had become the rage all over the civilized world (see Wrothaway). By 1833, with Kühn as director, the Königliche Sächsische Porzellan Manufaktur gradually began to rally in its finances, now using old forms and decoration which had made Meissen famous. Later, followed Barthel (1871), Bräunemann (1895). Up to the time just before the World War (1914) "Dresden" art ware was made on quite a large scale and found a good all-world demand.

Characteristics.—Wentzel succeeded in producing the noted bleu de roi ground color so long sought, and the factory's rococo style had to change to the more modern Louis Seize style, with its torch and crescent, festoon, creased-ribbon bow motifs, oval medallions encircled with laurels and containing monograms or portraits. Classic forms were revived. Imitations were made of Wedgwood's white reliefs on blue "jasper" backgrounds.

Marks.—The Dresden "cross swords" was used from 1723 to the present time. It was taken from the state coat-of-arms. Chinese marks were used at different times. A.R., for Augustus Rex, was used from 1725 to 1740. K.P.M., for Königliche Porzellan Manufaktur, occurs from 1723 to 1730. Other marks, K.H.C., K.H.K., K.H.K.W., K.C.P., etc., were initials of different branches of the royal household or estates of the king. The cross swords scratched through is the erased mark on pieces that were sold in the white for others to decorate.

established there. In many respects it has pursued a policy parallel to that of the Deutsche Bank, both in domestic finance and overseas business; the latter being initiated in 1892 by the absorption of a branch in Hamburg, followed in 1895 by a branch in Bremen and in 1901 in London. In all, the Dresdner Bank had (beginning of 1909) 27 branches, all, with the exception of the one in London, being located in Germany. In addition it has one Command and 57 deposit offices, 23 being in Berlin. Its foreign business is carried on through subsidiaries in China, Japan, Italy, Switzerland, Turkey, Greece, Egypt, Morocco, Argentina, Mexico and Canada, and in 1905 a close alliance was formed with the banking house of J. P. Morgan & Co., New York, for joint action in international finance and issue operations, particularly the absorption of American securities by German investors. Operations in the Orient and South America have been carried on jointly in co-operation with the A. Schaffhausen'scher Bankverein. Between 1872 and 1909-10, important German banks and banking firms having numerous branches throughout Germany were absorbed by the Dresdner Bank. Important among these was the Deutsche Genossenschaftsbank (Bank for Co-operative Credit Societies), Sörgel, Parrilis & Co., of Berlin and Frankfort-on-the-Main, closely identified with German industrial and agricultural co-operative societies. A special department of the Dresdner Bank is also concerned with the fostering of these interests. In addition, in 1904, jointly with the A. Schaffhausen'scher Bankverein, the banking house of Von Erlanger & Söhne of Frankfort-on-the-Main was absorbed, this latter having 8 branches and 97 agencies, besides community-of-interest connections with 2 banks having 52 agencies. In addition, through board supervision or stock control, 12 other important banks with numerous branches and agencies are included within the Dresdner Bank group. The relations of the Dresdner Bank to the industrial life of Germany are indicated by the fact that at the beginning of 1909 representation was had on the boards of 87 other important industrial and financial organizations. In 1908 the capital was 180,000,000 marks (increased in 1910 to 200,000,000 marks), surplus 51,500,000 marks and dividend 7½ per cent. The total capital power of the Dresdner Bank group in the same year amounted to 56,262,419 marks, of which 227,680,000 constituted the capital and 56,262,419 marks the surplus. Consult Riesser, Dr. J., 'Die Deutsche Grossbanken und ihre Konzentration' (1909); 'Germany's Economic Forces' (1913); 'Report on Cooperation in American Export Trade' (Washington 1916).

DRESS, the clothing or apparel of the human body. Under this title will be considered the principles underlying the wearing of clothes rather than the minute details of their shape and color, which will be found treated under COSTUME. The evolution of dress has always been associated with the growth and decline of nations, with the changes in racial characteristics. In the earliest stage of human history dress must of course have been strictly utilitarian, consisting only of the covering necessary to protect the body against the extreme conditions of climate and temperature. With many uncivilized tribes this conception of the function of clothes still survives.

With the dawn of civilization another utilitarian function is assumed by clothing: becomes a means of indicating distinctions of rank and office in the community. The minimum of clothing is found among slaves and the lowest classes in general, while garments even more massive and extensive than either climatic conditions or considerations of modesty prescribed come to be worn by the higher ranks. Next, a purely decorative motive, which undoubtedly has its source in personal vanity, came to supplement the two more utilitarian ones just mentioned. With some uncivilized or semi-civilized peoples this is by far the strongest and frequently the only motive for the wearing of such scant vestments as neither cover nor protect the body. That personal vanity underlies the use of clothes quite as much as considerations of modesty and temperature even among civilized peoples is a view held by many authoritative writers.

The Assyrians covered themselves entirely with heavy draperies, stiff with embroidery. The Egyptians, of whose dress we have the earliest records, clothed themselves in thin materials which revealed the lines of their bodies and frequently left even the limbs exposed. Their dress was rich in texture and splendid in color, the designs of their textile fabrics being of high artistic excellence and beauty. Class distinctions were very strongly emphasized in the dress of the Egyptians. A peculiar feature of their priestly garb was the leopard-skin worn on solemn sacrificial occasions. The Egyptian women of rank wore beautiful embroidered skirts secured at the waist by a colored sash, or suspended by straps from the shoulders, and over this a long, loose robe. The laboring class used woven fabrics, but their costumes, especially when at work, consisted as a rule simply of a loin-cloth and girdle. Among the Chinese the predominating idea of dress has always been splendor of material and decoration. The intense conservatism of this race is nowhere better shown than in the almost complete sameness of dress from earliest times to the present day. That, as a general rule, progress in civilization—and especially a sudden leap in this direction—makes for radical dress reform, is well illustrated in the case of the modern Japanese. For a long time the figure was merely draped in loose lengths of material, with no attempt at conforming to the lines of the body or limbs—though sleeves and trousers are occasionally observed, as in the Persian sculptures at Persepoleis. The primitive sandal was evidently thought to afford all necessary protection to the foot, until the time of Assur-bani-pal, or Sardanapalus, when soldiers and hunters appear to have worn a sort of net to protect legs and boots or gaiters somewhat like the Greek and Roman cothurnus, laced in front. Save as official costume, hats and caps were little worn in early times. Even in the time of Julius Caesar they were little used except by travelers, most people preferring a fold of the toga or mantle for a head covering. Among the Greeks and Romans the division of classes and professions by dress were very striking. By the Greeks the artistic effect was carried to a height
hitherto unknown, their garments being the perfection of grace and dignified elegance. At no other time has a nation's dress offered such great advantages to the artist. The Greek chiton and himation of about 450-350 B.C. were the highest type of loose clothing, while the higher type of the correct fit of dress was found in France and England in 1350. The costumes of western Europe during the last quarter of the 14th and the first of the 15th century were characterized by a beautiful reasonableness and adaptation at once to use and artistic effect. But there have been other periods in which the exaggeration of good sartorial points led to utter absurdities and demoralization. After the Norman Conquest, which introduced into England, among other unsalutary features, numerous ugly changes in dress, eccentricities in headgear were especially prevalent. In the 17th century shoes grew so small and pointed that they were an encumbrance to the wearer and had to be hooked up by their projecting tips to make walking possible. Small waists were considered quite as essential for men as for women. Even as late as the reign of George III, English tailors advertised corsets for gentlemen. The modern tendency in dress, as in many other things, is decidedly democratic—a tendency toward the complete elimination of differences in dress as marks of social or other distinction. The dress reform movement inaugurated in the 19th century and the greater attention paid to hygienic considerations have resulted in making women more solicitous about the health and comfort of the things than they have been for many centuries previous. Extravagance in dress has always been a mark for social and religious reformers. Both in France and in England, especially during the Puritan period in the latter country, preachers thundered from many a pulpit against the sensuous fashions of their times. Sumptuary legislation has attempted time and time again to regulate it, but usually without success. In England, particularly under the Tudors, considerable drastic legislation was enacted on the subject of dress. Beginning as early as 1463 and taking a most mandatorily form in 1510, when "An Act against wearing of costly Apparel" was passed, such legislation was re-enacted, or re-enforced, again and again, taking a different—usually a more stringent—form from time to time. But, custom proving stronger than legislation, the people constantly overstepped the bounds of dress laws, with the result that all such legislation was finally repealed in England in 1604, a century before such action was taken in other countries. There are two satirical literary treatments of this aspect of dress which are especially famous, that of Swift in the 'Tale of a Tub,' and that of Carlyle in 'Sartor Resartus.'

Bibliography.—Most of the literature on the subject is in the form of magazine articles. The following works treat of dress, specifically or generally: Earle, 'Two Centuries of Costume in America' (2 vols., New York 1904); Evans, 'Chapters on Greek Dress' (London 1893); Farnsworth, 'The Art and Ethics of Dress' (1915); Fox, 'Fashion: the power that influences mankind.' Hill, 'The Influence of the Scientific and Modern Dress and Fashion' (New York 1872); Hill, 'History of English Dress' (London 1900); Lacroix, 'Manners, Customs and Dress of the Middle Ages and the Renaissance' (London 1877); McClellan, 'Historic Dress in America, 1607-1800' (Philadelphia 1904); Walker, 'Dress as it has been, is, and will be' (New York 1885); Winterburn, 'Principles of Costume in Dress 1834.' See Costume; Dress Reform; Fashion.

Dress Reform, a movement of the 19th century, having for its aim the modification of the dress of women along hygienic lines chiefly, but also with regard to comfort and convenience. Many articles of feminine apparel had long been operating against the health of women and the injuries and the discomforts recognized and more or less frankly discussed in private circles before leaders were found with sufficient earnestness and courage to make organized efforts for reform. So far as the United States is concerned dress reform may be said to date from 1851, when American women published some articles in favor of freer dress for women in her paper called The Lily. A few years before the Civil War (in 1857) a National Dress Association was started, but made little headway. It was not until the society was organized in Boston in 1874 that attempts of this nature began to bear any fruit. Several causes seem to have contributed to making the time more propitious for an active propaganda against tight-lacing, high-heeled and cramping foot-wear, trailing garments, etc. The greater attention paid to physiology in schools dispelled to some extent the ignorance which had been a partial excuse for unhygienic methods of dress. The increasing number of women receiving a college education ensured for the new ideas an audience which helped to liberal and judicious minds too sound to be rigidly fettered by conventionality and fashion. A third factor not to be disregarded was the firm attitude of physicians. Prevention of disease and the development of normal conditions was becoming the watchword where formerly curative measures had been emphasized. The cooperation of the medical fraternity by lectures, periodical literature and personal influence should receive due credit for the progress of dress reform. Such co-operation marked feature of the movement inaugurated in Boston. As the century drew to a close conditions became still more favorable. The prominence given to bacteriology associated in innumerable minds the trailing skirt with germ-transportation. The investigation, too, into the relative values of the different fabrics—cotton, linen, silk and wool—as material for underwear (a discussion in which Germany took a notable part) was very timely. It called attention to the lamentable lack of judgment exhibited by many persons, especially women, in protecting themselves by suitable under garments against the changes of the season, and especially the sudden variations of the American climate. The adoption of outer garments suitable for wet weather was undoubtedly hastened by the vogue of the bicycle skirt, which accustomed the eye to a style of garment once attracting unfavorable comment or at least unwelcome observation. Rainy-day clubs, formed in many cities, have done their share toward the introduction of the short skirt. The fact that a great number of women are now daily going to business has also
greatly promoted the movement of rational clothes for women. To athletics, too, woman's dress reform is deeply indebted. The present popular idea that women should dress in a line from the navel down for women and the general interest taken in physical culture have inevitably tended to modify the form of women's garments.

The practice of lacing, with its vicious results of molding the feminine form into abnormal lines and crowding the vital organs into disease-promoting states, still persists among women who place less value on health and bodily comfort than on outward appearance and unnatural "grace." Yet on the whole, the movement toward rational raiment for women is making steady if seemingly slow progress on both sides of the Atlantic. Aesthetic considerations had little effect upon the earliest dress-reformers such as Mrs. Amelia Bloomer and a few women suffragists who first braved public opinion by wearing "bloomers." The Turkish trousers and very short skirt adopted by Mrs. Bloomer did not invite imitation; but later phases of reform, both in England and in America, have aimed at grace and beauty as well as health and comfort in the style of garments advocated. In the United States Mrs. Annie Jenness-Miller has been a prominent exponent of the more artistic aspect of the subject. Very near the time of the establishment in this country of the second National Dress Association an attempt was made by the crown-princess of Saxony to awaken her fellow countrywomen to the importance of dress-reform, the hygienic side of the question being most prominent in that effort. Under the leadership of Lady Harb(er)ton, president of the National Dress Association, the dress reform movement assumed a somewhat different direction than that associated with Mrs. Jenness-Miller. To retain the natural beauty of the human form and succeed in its harmonious appareling were the aims of some of the dress reformers. There was, however, side by side with this movement one having a utilitarian trend. This was allied to the German movement in favor of more hygienic garments; the combining of comfort, lightness and warmth in the material used being a great desideratum. Organized effort along the line of dress reform in England has resulted in the formation of the Rational Dress Association just mentioned and the National Health Dress Association. There is a long for one of its aims a change in the customary mourning apparel. Outside of Germany and England little interest has as yet been taken in Europe in the subject of dress reform, although a certain Russian Minister, or a radition thing in vain to prohibit corsets. Consult Bloomer, "The Life and Writings of Amelia Bloomer" (Boston 1895); Godwin, "Dress and Its Relation to Health and Climate" (London 1884); Harb(e)es, "The Art of Dress" (5th, 1881); Woolton, "Dress Reform" (Boston 1874); see Dress; Costume; Fashion.

DRESS SHIP, nautical term signifying the decoration or ornamentation of a ship with flags. It is done on national holidays or on some special occasion. There are many forms and degrees, according to the importance of the occasion or of the personage to be honored. Hoisting the national colors at the mastheads and at the peak is, perhaps, the simplest form of dressing a ship. Additional flags, usually those of the signal code, are hoisted to full-dress a ship. The ordinary method is to arrange the flags in a line from the stern, one forward stay between the mastheads to the peak and thence over the stern. At the stern and prow weighted lines are dropped to which the flags are attached. When doing honor to a foreign nation the latter's colors are run to the head of the main mast. When more than one country is represented by its colors all must be given posts of honor and none placed in a position of inferiority to another. In naval vessels the flags of the navy signal code and of the international signal code are used jointly. During the Hudson-Fulton celebration in New York in 1909 the American and visiting foreign naval vessels were dressed with electric lights, arranged to outline the hull and superstructure when illuminated.

DRESSER, Henry Ecles, English ornithologist: b. Thirsk, Yorkshire, 9 May 1838. He is best known by his "History of the Birds of Europe" in eight volumes (1871-81).

DRESSER, Horatio Willis, American author: b. Yarmouth, Me., 15 Jan. 1866. He was educated in Denver, Colo., and at Boston; was appointed assistant in philosophy, Harvard University, 1902-11; professor of philosophy, Ursinus College, 1911-12. Since 1893 he has lectured and written extensively on practical philosophy and metaphysics, and he edited and published the Journal of Practical Metaphysics (1896-98); but it must be pointed out that these terms as used by him and his school of thought have meanings entirely different from those in which they have hitherto been used and are generally understood. He edited The Higher Law 1899-1902, and is the author of "The Power of Silence" (1895); "The Perfect Whole" (1896); "In Search of a Soul" (1897); "Voices of Hope" (1898); "Methods and Problems of Spiritual Healing" (1899); "Education and the Philosophical Ideal" (1900); "Voices of Freedom" (1899); "Living by the Spirit" (1900); "The Christ Ideal" (1901); "A Book of Secrets" (1902); "Man and the Divine Order" (1903); "Health and the Inner Life" (1906); "The Greatest Truth" (1907); "A Physician to the Soul" (1908); "The Philosophy of the Spirit" (1908); "A Message to the Well" (1910); "Human Efficiency" (1912); "The Religion of the Spirit in Modern Life" (1914).

DREUX, dré (ancient Durocassæ), France, one of the oldest towns on the Blaise, 20 miles north-northwest of Chartres. It has a number of churches and other buildings of the 11th, 12th and 13th centuries. It has foundries, and manufactures cloth, leather and glass and trades in sheep and cattle. In Roman times it was called Durocassia or Droce and was also important under the Gaules. Here the Due de Guise defeated the Huguenots and captured the Prince of Condé in 1562. The Germans took the town in 1870. Pop. 10,500.

DREVET, drevē, French family of engravers. (1) Pierre: b. Saint Colombe, near Lyons, 1664; d. Paris 1739. He studied at Lyons, and at Paris with Audran and Rigaud. In 1696 he became court engraver and was elected to the Academy in 1707. He left more than 100 plates, of which the recognized master-
piece is ‘Louis XIV’ (1712). He was particularly successful in the engraving of portraits. (2) Pianeta Inserit, his son: b. Paris 1697; d. there 1739. He studied with his father, but surpassed him in art. He, too, was most successful in portrait work, one of his best pieces being a portrait of Bossuet after Rigaud; he also copied the works of Coypel, Restout, Astray and other French painters of the time. He succeeded his father as court engraver and they executed many works together. (3) Claude, the nephew of Pierre Imbert: b. Lyons 1710; d. Paris 1782. He was a pupil of his uncle and copied his style without equaling his art. Consult Firmin-Didot, ‘Les Drevets’ (Paris 1876).

DREW, Daniel, American capitalist: b. Carmel, N. Y., 29 July 1797; d. New York, 19 Sept. 1879. In early life he was a cattle drover and dealer and was subsequently prominent as a steamboat builder, but was most widely known from his connection with railroads and as a leading stock speculator in Wall Street. The failure of Kenyon, Cox & Co. caused the loss of his great fortune, which at one time amounted to about $15,000,000. He was the founder of the Drew Ladies' Seminary at Carmel and the Drew Theological Seminary (N. Y.). He also gave large sums of money to various Methodist colleges and schools. Consult White, Bouck, ‘The Book of Daniel Drew’ (New York 1910).

DREW, John, American actor: b. Philadelphia, N. B., 1653. In 1873, when first appeared at his father's theatre in Philadelphia, then under his mother's management. For the next six years he played with the popular stars of that day, including Edwin Booth and Fanny Davenport. In 1879 he appeared as leading man in the all-star company of Augustine Daly, at Daly's Theatre, New York. His most noteworthy successes there were as Petrucchio in 'The Taming of the Shrew,' and as Charles Surface in Sheridan's 'School for Scandal.' He appeared also in the classic revivals and in original dramas of Mr. Daly. He visited Europe in 1892 with Daly's Company, playing classic roles, and began his starring tours in the autumn of 1892, playing in 'The Masked Ball,' 'The Butterflies,' 'A Marriage of Convenience,' 'One Summer's Day,' 'The Liar,' 'Richard Carvel,' 'His House in Order,' 'Inconstant George,' 'Much Ado about Nothing,' 'The Tyranny of Tears' and 'The Will.' John Drew is the best living interpreter of a certain type of character common in high society in America. In 1901 he appeared in a revival of 'The Second In Command.' Consult Strang, 'Famous Actors of the Day' (Boston 1900); Moses, 'Famous Actor-Families in America' (New York 1906); Winter, 'Walnut of Time' (2 vols., New York 1913).

DREW THEORETICAL SEMINARY, in Madison, N. J., an educational institution founded by the Methodist Episcopal Church for the education and training of its ministers. Daniel Drew donated the ground and buildings. Three years' course suffices to complete the theological courses, which in addition to special training in theology, etc., also cover a wide range of secular subjects in order to provide ministers of broad minds and of good general education. The degree of Doctor of Divinity is conferred on students who already hold an academic degree, and the degree of Doctor of Theology is conferred on students who take the advanced courses prescribed for this degree. Tuition is free, and arrangements have been made whereby the cost of student life is most moderate. There are eight buildings altogether, with which the grounds are valued at about $725,000. The productive endowment funds total over $1,000,000. The seminary is provided with an excellent library of 122,000 volumes and 140,000 pamphlets. The enrolment of students in 1916 was 171, and there were 16 instructors.

DREWRY'S BLUFF, Battle of. When General Grant began his campaign for Richmond in May 1864, General Butler, commanding the Army of the James, was directed to be well up James River toward Richmond by daylight of the 5th and to push ahead with all energy. By the 6th Butler had reached and entrenched at Bermuda Hundred Neck. Kautz's cavalry division, moving from Suffolk, destroyed several bridges on the Norfolk and Petersburg and Weldon railroads and joined Butler on the 10th. On the 9th Butler advanced with the greater part of his force to strike the railroad connecting Richmond and Petersburg, but his advance was barred by Swift Creek, which was found impassable and its bridges heavily guarded, upon which he ordered his troops to withdraw to their entrenchments; but the withdrawal was not effected without an attack by the Confederates on a detachment of the 10th Corps, in which the loss was severe on both sides. Butler's advance was barred by strong works on Drewry's Bluff on the right bank of the river eight miles below Richmond. The works could not be reached by the navy, and on the land side the Bluff was defended by 22,000 infantry and over 2,000 cavalry, field artillery and heavy guns. On the 12th General Butler turned his back on the turnpike and after some fighting the Confederates fell back toward Drewry's Bluff. On the 15th there was heavy all-day skirmishing and some artillery firing, and General Beauregard issued orders for an attack next morning to cut Butler off from Bermuda Hundred and capture or destroy his army. The attack was made very early in the morning under cover of a dense fog; the right of Butler's line was turned and a large number of prisoners taken, compelling it to fall back a short distance. On the left Butler's line held its ground and made some progress, but toward evening Butler ordered his troops to fall back and at night they were in the entrenchments at Bermuda Hundred. Beauregard followed up and entrenched in front of Butler's lines. As General Smith says, 'Both corps re-entered the historic bottle, which was at once carefully corked by a Confederate earthwork.' On the 20th Beauregard assaulted and carried some of Butler's advanced lines and a sharp fight ensued to regain them, which was partially successful, a portion of them being re-taken by Howell's brigade of the 10th Corps.
which lost 702 men; the Confederate loss was nearly 800. On the 29th General Smith with three divisions of the 10th and 18th corps, 16,000 men, and 16 guns, left the James River and joined the Army of the Potomac in time to take part in the battle of Cold Harbor. The Union forces engaged in the battle of Drewry's Bluff, 16 May, numbered about 16,000, the Confederates about 18,000. The Union lost, 14-16 May, was 390 killed, 2,380 wounded, 1,390 missing. The Confederate loss, 16 May, was about 460 killed, 2,060 wounded, 212 missing. From 5-31 May, including all of Butler's engagements and Kautz's cavalry operations, the Union loss was 639 killed, 3,769 wounded, 1,880 missing; the Confederate loss for the same period cannot be definitely ascertained, but it was less than that of the Union forces. See 'Official Records' (Vol. XXXVI); 'Butler's Book'; Grant, 'Personal Memoirs'; Harlows, 'The Virginia Campaign of 1864-65'; Roman, 'Military Operations of General Beauregard' (Vol. II); and 'Battles and Leaders of the Civil War' (Vol. IV).

E. A. CARMAN.

DREWS, Arthur, German philosopher: b. Ulm, Holstein, 1865. He received his education at the universities of Munich, Berlin, Heidelberg and Halle. In 1898 he was appointed privatdocent of philosophy at Karlsruhe and 10 years later was made professor extraordinary. He is the editor of Hegel's 'Religionosophie' (1905) and is the author of works of criticism on Kant, Nietzsche and others in 'Kants Naturphilosophie als Grundlage seines Systems' (1894); 'E. von Hartmann's philosophisches System im Grundrisse' (2d ed., 1905); 'Nietzsches Philosophie' (1904); 'Lebenswerk Eduard von Hartmanns' (1907); 'Plotin und der Untergang der antiken Weltanschauung' (1907). Other important works from his pen are 'Die Lehre von Raum und Zeiten nachkantischer Philosophie' (1889); 'Das ich im Grundproblen der Metaphysik' (1897); 'Die Religion als Selbstbewusstsein Gottes' (1906); 'Der Monismus' (1908); 'Geschichte des Monismus im Altertum' (1913). Drews has become well known in America through his two works attacking the historicity of the narrative of the New Testament. These are 'Die Christusmythe' (1910); English translation by Burns 1911; part II, by McCabe 1912), and 'Die Petruslegende' (1910).

DREXEL, Anthony Joseph, American banker: b. Philadelphia, Pa., 1826; d. Carlisle, Germany, 30 June 1893. He was the head of the well-known firm of Drexel & Company, Philadelphia, having been identified with it from the age of 13. He was zealous in promoting science and art, especially music, and contributed largely to philanthropic and educational interests. The Drexel Institute of Art, Science and Industry, Philadelphia (q.v.) was established by him. He became head of Drexel, Morgan & Co. of New York, and Drexel, Harjes & Co. of Paris. With G. W. Childs, he became owner of the Philadelphia Public Ledger (1864).

DREXEL INSTITUTE OF ART, SCIENCE AND INDUSTRY was founded at Philadelphia in 1891, by Anthony J. Drexel (q.v.). This school was established for the purpose of giving young men and women opportunity to receive training in the practical sciences as applied to the industries. The requirements for admission depend upon the course which the applicant wishes to pursue; no degrees are given. In 1914 the trustees had applied for the right to grant degrees. The buildings and equipment of Mr. Drexel cost over $4,000,000; and the amount of endowment, given also by Mr. Drexel, is $2,000,000. The courses offered are: Fine and applied arts; elective engineering; commerce and finance; mechanical drawing and machine construction; domestic science; mathematics; physics; chemistry; and English. Day and evening classes are provided for all departments. The length of time required to complete the work depends upon the course. The free public lectures provided by the institute are valuable educational factors.

The department of commerce and finance consists of three special departments: First, the course in commerce and finance; second, the office course; third, the evening course. These courses are founded on a liberal basis, resembling generally the commercial schools of Europe, and they are intended to place commercial education in its proper relation to other departments of educational work. The object of the course is to train the young to do business rather than simply to record business. It provides a liberal and practical course of study for a two years' training in the knowledge of the world's industries and markets, the laws of trade and finance and the mechanism and customs of business. The first special department is intended to give a thorough fundamental training for the activities of business which include: (1) The production, sale and transportation of articles of commerce; (2) the management of stock companies and corporations; (3) the buying and selling of securities; (4) the importing and exporting of merchandise; (5) the borrowing and lending of money and credit; (6) the advertising of commercial concerns; (7) the keeping of business records. In addition the three distinct office courses are offered, practice in chiefly, and designed to prepare the student for entering immediately upon the respective lines of employment to which the training leads. In 1895 a beginning was made toward the formation of a permanent commercial museum. The collection now represents quite fully the following industrial products: Flour, wool, petroleum, tea, coffee, sugar, cotton, copper, iron and steel, glass, tobacco, leather, paper, wood, carpets, linen, spices, aluminum, building stone, brick and terra-cotta. The art museum contains collections representing the industrial arts of Egypt, India, China, Japan and Europe. The library contains over 40,000 volumes and is supplied with books, periodicals and pamphlets bearing upon the work and every facility and assistance is afforded for the study of financial, economic and commercial questions. In 1915 the number of students in attendance was 2,900 in all departments. Applicants for admission to any course must pass satisfactory examinations in English, geography and United States history. For admission to the course in commerce and finance or to any of the
DREYER, John Louis Emil, Irish astronomer: b. Copenhagen 1852. He received his education at the University of Copenhagen, and in 1876-78 was assistant astronomer at the Earl of Ross's observatory; in the following four years he served as assistant at the Observatory of Trinity College, Dublin, and in 1882 was made director of the Armagh Observatory. He has published 'The Second Armagh Catalogue of 3300 Stars' (1886); 'New General Catalogue of Nebulae and Clusters of Stars' (1888; supplements, 1895, 1908); 'Tycho Brahe' (1890); 'History of the Planetary Systems from Thales to Kepler' (1906); and an edition of Herschel's 'Scientific Papers' (1912) for the Royal Astronomical Society.

DREYFUS, dräfüs, Abraham, French playwright: b. Paris, 20 June 1847. He had a fine vein of kindly humor and it pervades both his contributions to the public journals and his theatrical compositions, which are mostly in one act. Among these are: 'A Gentleman in Black'; 'The Victim'; 'The Klept'; 'A Break.' His four-act play, 'The Saint Catharine Institution,' a comedy of manners, was brought out at the Odéon (1881); 'A Rupture' (1887, 1894).

DREYFUS, Alfred, French military officer: b. Mulhausen, Alsace, 1859. He was a member of a wealthy Jewish family, became a captain in the 21st regiment of artillery and three years later was appointed to the general staff. On 14 Oct. 1894 he was arrested on a charge of communicating certain important military documents to a foreign government, and at a secret court-martial on 19 December and succeeding days was found guilty and condemned to public degradation and lifelong imprisonment. He was degraded on 5 Jan. 1895, and in accordance with the act passed by the Chambers was sent to the Ile du Diable (Devil's Island) near Cayenne, to undergo the other part of the sentence. On 1 June of the same year Colonel Picquart became chief of the intelligence department of the army, and in the course of his official duties discovered various circumstances which threw doubt on the correctness of the court-martial's decision and pointed to another officer of the name of Esterhazy as the real traitor. In particular he obtained a copy of a telegram card, subsequently known as the petit-bleu, alleged to have been addressed to Esterhazy by a German officer, Colonel von Schwarzkoppen. On 7 Sept. 1896, he wrote to General Gonse urging a reinvestigation of the case, and seven days later a newspaper divulged the fact that certain documents had been communicated to the court-martial unknown to the prisoner's counsel. Not long afterward Dreyfus' accusers took a false step by the publication of the facsimile (memorandum, detailed list of documents), alleged to have been written by Dreyfus; and on 16 November Colonel Picquart was superseded in his office by Colonel Henry. On 15 Nov. 1897 M. Mathieu Dreyfus, brother of the condemned man, charged Esterhazy with having written the Bordereau, but on 11 Jan. 1898 he was acquitted by court-martial which sat closed doors. On the following day Colonel Picquart, who had been sent to Tunis on a dangerous expedition after his dismissal from office, had been afterward required to answer certain charges made by Esterhazy, was arrested and imprisoned. On 13 January M. Zola, the eminent novelist, published in the Aurore a letter headed 'J'accuse' (I accuse), in which he made serious charges against the general staff and the government in regard to the Esterhazy court-martial. After a stormy debate in the chamber it was decided to prosecute him; but the government steadily refused to reopen the Dreyfus case, declaring their determination to stand by the chose jugée. Zola's trial began on 11 February, and on the 23d he was condemned to pay a heavy fine and to undergo a term of imprisonment. On 2 April the Court of Cassation quashed the sentence of Zola on technical grounds, but a fresh prosecution was ordered a few days later. On 27 June M. Cavaignac became head of the war office, and on 7 July he read to the chamber several documents which he regarded as proving the guilt of Dreyfus. Three days later Colonel Picquart wrote to the Premier denouncing these new charges. This interference led to his rearrest, and shortly after Zola was again condemned. On 31 August Colonel Henry was arrested and confessed to having forged the chief document relied on by Cavaignac, but soon after his arrest he committed suicide. The War Minister resigned 4 September and was succeeded by General Zurlinden. The latter resigned because of the government's determination to refer the question of revision to a commission, and on 18 September General Chanoine succeeded him. The commission decided against revision, and on 26 September the government resolved to ascertain the view of the Court of Cassation. On 25 October the Brisson ministry resigned and a few days later the court reported in favor of revision. On 31 October a new ministry under M. Dupuy came into office, and on 9 December the prosecution of Picquart was stopped by the Court of Cassation. The Dreyfus case marked the culmination of the anti-Semitic agitation in France which reached its height in 1897. La Libére Parole in 1882 and became especially menacing after the Panama Scandal in 1892. On 16 Feb. 1899 M. Félix Faure, the President of the republic, died suddenly and three days later was succeeded by M. Emile Loubet. On 3 June of the same year the Court of Cassation, having concluded its hearing of the evidence, ordered a fresh court-martial to be held at Rennes for the purpose of deciding whether Dreyfus communicated to a foreign government any of the documents mentioned in the Bordereau, of which Esterhazy had previously confessed himself to be the author. Picquart was released on 9 June, and on the 12th of the same month the ministry was defeated. On 22 June M. Waldeck-Rousseau succeeded in forming a new ministry. The new court-martial convened 7 August, under the Presidency of Colonel Jousaut, and about this time the press published accounts of the inhuman treatment of Dreyfus in his prison. Dreyfus, who had been brought to Rennes for trial, was defended by M. De Manse and Labouret, the chief witnesses in favor of the prisoner were Colonel Picquart and Captain Freytagtätter, a member of the first court-martial, and against him were Generals Mer-
DREYSCHOCK — DRIFT

of a Projectile

An attempt to assassinate M. Labori on his way to court 14 August was fortunately unsuccessful. On 9 September the judges, by five votes to two, declared the prisoner guilty, with extenuating circumstances. This verdict was flagrantly opposed to the published evidence, yet Dreyfus was sentenced to 10 years' imprisonment in a fortress, but a subsequent full pardon from President Loubet set him at liberty. On 12 July 1906 the Court of Cassation, after a rehearing of his case, began on 19 June, quashed the verdict of the Rennes court-martial. In its survey of the charges the court declared them without foundation; that the borderau was the work of Esterhazy and that the information contained therein could not have emanated from an officer of the general staff, but must have been transmitted by a regimental officer such as Esterhazy. The court further held that three new facts had been established: (1) That the document from General Mercier's secret papers (letters supposed to have been written by Dreyfus, two in 1894 and one in 1896) presented at the Rennes court before which the case was transferred; (2) That the document containing the plans for railway mobilization, supposed to have been given to the Germans by Dreyfus, never reached the War Department and therefore Dreyfus could not have obtained possession of them; (3) That the Rennes court-martial failed to hear testimony which would have established the innocence of Dreyfus. He was therefore restored to the army with the rank of major on 13 July and Picquart was made a brigadier and subsequently Minister of War. In 1908 he was shot at and wounded by a reactionary journalist.

Bibliography.—Consult Dreyfus, "Five Years of My Life" (1901); Barlow, "History of the Dreyfus Case" (1898); Conybear, "The Dreyfus Case" (1898); Eugon, "The Dreyfus Case" (1898); Steevens, "The Tragedy of Dreyfus" (1899); Marin, "Comptes-rendus officielle 1899," Vanex, "Dossier de l'affaire Dreyfus" (1898); Brez, "Le solemucie du bordereau et des lettres de Dreyfus" (1898); Esterhazy, "Les dessous de l'affaire Dreyfus" (1898).

DREYSCHOCK, drīshōk, Alexander, Bohemian pianist; b. Zach, Bohemia, 1818; d. Venice, 1869. He studied under Tomasek at Prague and developed a truly marvelous technique. He began his concert tours in 1828 and continued them until 1848. In 1862 he received the appointment of professor at the Saint Petersburg Conservatory of Music, remaining there until 1868, when his failing health obliged him to travel to Italy. He left no important compositions.

DRIESECH, drēsh, Hans, German biologist: b. Kreuznach, Rhein-Pruessia, 1867. He was educated at the universities of Freiburg, Munich and Heidelberg, in which he obtained his doctor's degree in 1887. He went to Ceylon, India, Java and Burma, and from 1891 to 1900 was employed at the Stazione Zoologica of Naples. In the latter year he removed to Heidelberg and in 1909 became privat docent and in 1911 professor extraordinary of philosophy at the university. Here he is one of the founders of "vitalistic" biology, and has made special studies and experiments in the morphology of animals and made also special investigations in logic and natural philosophy. His published works include "Die mathematisch-mechanische Betrachtung morphologischer Probleme der Biologie" (1891); "Die Biologie als selbständige Grundwissenschaft" (1893; 2d ed., 1911); "Analytische Theorie der organischen Entwicklung" (1894); "Die Lociwalsisms der Lich- tistischen Vorgänge" (1899); "Die organischen Regulationen" (1901); "Die "Scicle" als elementar Naturfaktor" (1903); "Naturbegriffe und Natururteile" (1904); "Vitalismus als Geschichte und als Lehre" (1905); "The Science and Philosophy of the Organism" (1909); "Ord- nungslehre" (1912); "Logik als Aufgabe" (1913); "Die Problem of Individuality" (1914).

DRIFT, or GLACIAL DRIFT, a general name given to the deposits made by the ice sheets of the glacial period, or by the water which came from them. By some geologists the term is restricted to the unsorted deposits left by the ice itself, the deposits worked upon by water being called stratified or modified drift. In this restricted sense drift includes (1) lateral and terminal moraines, and (2) till, boulder clay, or hardpan, the sheet of clay that frequently covers rock surfaces in the glaciated regions. Drift is sometimes very sandy and sometimes contains angular boulders with polished and often striated surfaces, the boulders being scattered through the clay without order. Usually the boulders are derived from rocks nearby, but fragments of tough hard rocks were sometimes transported long distances before being ground up by the action of the ice. Thus boulders from the peridotite at Cumberland Hill, R. I., have been found in the till of Martha's Vineyard, Mass., over 30 miles distant. The exact method by which till was formed is in dispute among geologists, though it is generally regarded as the ground moraine of the ice sheet, in spite of the fact that present glaciers are not forming a similar deposit. The boulders in the till in New Zealand are sometimes as much as 20 feet in diameter and in Ireland the till is so full of boulders as to render the soil formed from it unfit for agriculture. In northwest Ohio the till in many places is over 100 feet deep, and as it includes the detritus from softer rocks such as limestones, in that region boulders are fewer than in New Zealand and the resulting soil is very fertile.Englacial drift is the rock detritus carried along in the body of a glacier. See Glacier; Glacial Period; Soil.

DRIFT OF A PROJECTILE, the deviation of the projectile when fired in still air from the vertical plane. The rifling of the gun makes the bullet rotate about its axis. A body rotating about its axis exhibits what is known as precession; that is, if a force acts to turn its axis in a given direction, the axis will move in a direction perpendicular thereto. A bullet leaving a gun begins to fall at once, and at its front end, which receives most of the air pressure, is consequently raised. This turns it in the direction of the rifling. This drift is often complicated by deflections due to the jump of the gun. The resulting deflection for the Springfield is 0.26 inch to the left at 100 yards, 0 inches at 300 yards, 13 inches to the right at 1,000 yards, 126.5 inches to the right at 2,000 yards and 456 inches to the right at 2,850 yards. The drift is
autonomously corrected for by the sight up to 600 yards, and partly corrected for thereafter.

**DRIFT SAND** is sand thrown up by the waves of the sea and blown when dry some distance inland until arrested by large stones, tree roots, or other obstacles, round which it gradually accumulates until the heaps or dunes attain considerable dimensions. Except in the case of violent storm winds the action is generally a gentle rippling motion, the sand being pushed up by the wind on the seaward side of the ripple and rolling down into the hollow on the other side, thus traveling steadily landward. When these mounds have reached a certain elevation they are urged farther inland.

"The same wind," says Cuvier, "that drives the sand from the sea upon the mound, drives the sand from its summit to its land side." In some parts of the coasts of France, the Landes of Brittany, in particular, these inroads upon the land have been attended with destructive consequences. The quantity of sand annually deposited along that coast is estimated at 5,000,000 cubic feet, and its annual progress inland some 72 feet.

Such has been its destructive effect upon a village of Brittany that nothing is visible of it except a portion of the church steeple. In one or two such instances the sand dunes have moved away, exposing again the buried villages. For the purpose of arresting the inland progress of drift sands on the Biscay gales when unhindered advance upon the land at the rate of 16 to 17 feet per year. They have been checked in their encroachments by the planting of fir-trees in solid belts along the shores. Consult Cornish, V., 'Waves of Sand and Snow' (London 1914).

**DRIFTLESS AREA**, an area without glacial drift, (q.v.) specifically applied to an area of several hundred square miles in extent in Wisconsin and adjacent portions of Minnesota, Iowa and Illinois. Although this region is surrounded on all sides by evidence of glacial action, it has never itself undergone glacial action of any kind, and its topography is in marked contrast with that of surrounding areas. Just why this region should have escaped the glacial action that went on all around it, is by no means clear. Consult Sixth Annual Report, U. S. Geol. Survey, 1885, pp. 199-322.

**DRILL**, an ape of the Gold Coast of West Africa, the Cynocephalus leucopus, closely allied to the mandrill (q.v.), whence its abbreviated name. It is, however, smaller than the mandrill, has a black face and a short, erect tail, not two inches long. It is distinguished by its white beard and profuse white whiskers and has a much less pronounced grooving of the face.

**DRILL, OYSTER DRILL, BORER, or SNAILBORE**, a small muricine gastropod mollusk, the American Urosalpinx cinerea, so named on account of its destructive propensity in boring through the shells of oysters and feeding on them. The drill occupies a spiral, tawny brown shell, about an inch long and found along the Atlantic coast from Maine to Florida. The proboscis contains a radula or flexible band set thickly with transverse rows of teeth. By rotating this the tender shells are readily bored and the soft parts of the oyster sucked out. The only effective means so far devised to combat them, and this is but partially successful, is the digging of a mop of untwisted rope fibre over the oyster beds and close behind it a dredge. The drills stirred up by the mop fall into the dredge and are drawn to the surface and destroyed.

**DRILLING**, sowing in parallel rows as distinguished from sowing broadcast. It was introduced into England by Jethro Tull, who published a work on the subject in 1731. He saw that mere plowing and rough harrowing were not cultivation, but only its rudimentary operations and that the soil required to be stirred and pulverized, not tilled before sowing, but also after the plants had appeared above ground, in order that weeds might be extirpated and fresh particles of soil brought in contact with the roots of the crop. The plan of sowing in drills or ridges and hoeing in the intervals was therefore adopted with the object of saving the seed and of improving the soil. The advantage of sowing in drills has stood the test of experience and drill husbandry, by combining the advantages of continued tillage with those of manure and a judicious rotation of crops, is a marked improvement on the old mode of sowing all seeds broadcast. The crops which are now generally drilled are the grains, beans, peas, carrots, flax, etc. Drilling is of more importance on dry than on moist soils, as in the former weeds are more apt to spring up and injure the crops. See FARM MACHINERY.

**DRILLS AND DRILLING**. Drilling as a mechanical operation is often confused with boring. In machine shop practice, drilling is making a round hole through metal or the like with a rotating pointed tool, this tool may be made by pressure and rotation, taking off spiral chips of the material drilled and bringing them out of the hole through channels cut in the drill for clearance. Boring is enlarging a hole that already exists, as in a cast-iron cylinder, by turning the interior surface with a cutting tool. Cutting a circular hole in wood with a bit and brace, as done by carpenters, is boring, but a similar operation in metal is drilling. The forming of a hole in stone or rock, by repeated blows of a chisel or free-falling tool, as when making a hole for blasting or sinking an oil-well, is drilling. A hollow cylindrical tool for cutting out a core of rock is also called a drill. The forcing of holes in thin metal, as structural steel, by means of opposed dies and sudden pressure, is termed punching.

The machinists' drills are of two sorts: (1) Hand drills, which may resemble the carpenter's bit and brace except that a metal-cutting twist-drill serves for a bit, or which may be made on the ratchet-and-pawl principle, for working in confined spaces, as drilling a hole in the web of a section of laid railway track. (2) Power drills or drilling machines or drill presses—the latter being the more common catalogue name—of which there are a great variety of forms, sizes and styles. They range from the light jeweler's drill, that makes a tiny perforation in a watch-case, to the heavy gang-
DRIMYS — DRIVER 337

drill that cuts a dozen large holes at one opera-
tion in a heavy I-beam. The typical machinist's
drill-press has an upright post with curved top
like a letter f. At the overhanging top is a
driving mechanism with a rotating chuck, made
to grip or swage down the shanks of a series of
drills of varying sizes and to position it perpen-
dicularly for work. In the centre of the machine
is a platform, usually swung lower than the
cross-bar on the f, that is adjustable for height
and arranged to swing in the arc of a circle,
and to move the platform with the work to be drilled in
clamped. When in position the operator lowers
the drill by a lever, or wheel and worm motion,
and throws on a belt to start the drill. When
the hole is cut through he throws up the drill,
and is then ready to repeat the operation.

The miner's drill is known as the rock-drill,
and consists of a tripod frame, having an up-
right steam-cylinder, on the piston of which
is mounted the drill, which is simply a hardened
chisel arranged to rotate as it strikes the rock,
whose edge is turned for evening blow.
Six or seven hundred blows a minute may be
delivered by this drill, which is the standard
machine of the miner as well as the contractor,
for forming holes for blasting rock. (See
MINING AND MILLING MACHINERY.) The oil-
well drill or drilling rig, for sinking petroleum
wells, operates on a similar principle, but a
vastly larger and heavier outfit is required, as
the hole has to go down perhaps hundreds or
even thousands of feet. See PETROLEUM.

The diamond drill is used by prospectors to
take out a core of rock that they may analyze
its content and judge of its value. This tool has
enabled mining companies to test their ore in
the various levels, and thus know far in advance
what they can depend upon for future reserves.
The original diamond drill was a hollow cylinder
with black diamonds on the lower edge for cut-
ters. These being expensive a serrated edge
of hardened steel was next tried. This was fol-
lowed by the shot-bit or shotted drill. This
bit is a soft steel cylinder in connection with
which all steel steel shot are used. The
bit grinds the shot into the rock, thus gradually
wearing it away by repeated minute crushings
or small particles. The hollow drill rods
are rotated and lowered by a machine solidly
placed at the site. The lower drill rod is sur-
rounded by a calyx or cup-like tube and the
are two joined at their lower ends by a plug.
The centre portion of the plug serves as a bear-
ing for a protecting ring and on its lower end
a ring is threaded, while to this the core barrel
is attached on which either the shot bit or the
cutter can be threaded. The shot bit is pro-
vided with a series of triangular notches in its
lower end, one of the walls of the notch being
vertical and the other forming an angle of 30
therewith. The steel shot, which are fed
through the hollow rods from the top, are car-
ried by a current of water under this notch,
and the inclined wall allows them to pass under
the edge of the shot bit. The sizes of shot used
vary with the nature of the rock to be drilled,
single, double, and triple; and water之
coarse or finer. The working edge of the shot bit is
rounded, so that the shot grinds not only
directly beneath the drill, but also to a certain
extent at the inner and outer sides, thus cutting
out proper clearance for the operation of the
drill. Water is pumped into the hollow drill-
rods through a pipe and passes out under the
bit and up the annular space outside the core
barrel, carrying with it the sludge or fine par-
ticles ground up by the shot. The current of
water flows with great strength up as far as
the top of the calyx, where the annular space
widens considerably, so that the current is
reduced and the sludge it carries drops by gravity.
See Boring.

DRIMYS, dri'mis, a genus of plants belong-
ing to the family Magnoliaceae. They are dis-
tinguished by their bitter, tonic and aromatic
qualities. D. winteri, carried to Europe by
Captain Winter from the Straits of Magellan
in 1579, yields Winter's bark, which has been
employed medicinally as an aromatic stimulant.
It somewhat resembles canella bark. The bark
of D. grahamnus is used in Brazil against the
colic. It is tonic, aromatic and stimulant. That
of D. azillisia, a native of New Zealand, has
similar qualities.

DRINK. See DIETETICS.

DRINKHOUSE, Edward J., American
clergyman and author: b. Philadelphia, 1830;
d. 1903. He joined the Maryland Conference
of the Methodist Protestant Church in 1859.
Failing health later obliged him to retire from
the ministry and he went to California to re-
cuperate. He received the degree of M.D. from
Toland Medical College, San Francisco, in 1865.
For 18 years he edited the Methodist Protestant
and was one of the principal leaders in his
church. He is the author of the important
'History of Methodist Reform Synoptical of
General Methodism, 1703 to 1898, with Special
and Comprehensive Reference to its Salient
Exhibition in the History of the Methodist
Protestant Church' (2 vols., 1899).

DRIPSTONE, a corona or projecting tab-
et or molding over the heads of doorways, win-
dows, archways, niches, etc., to prevent rain-
water from trickling down. Called also a label,
weather-molding, water-table and hood-molding.
The term label is usually applied to a straight
moulding. Also a filtering stone, so called by
sailors.

DRISLER, Henry, American classical
scholar: b. Staten Island 27 Dec. 1818; d. New
York 30 Nov. 1897. He was graduated from
Columbia in 1839, was appointed tutor of Greek
and Latin there in 1843, adjunct professor in
1845, professor of Latin in 1857 and of Greek in
1867. He was acting president of Columbia at
the time of President Barnard's absence as one
of the commissioners to the Paris Exposition
in 1857 and again in 1888 and became dean of
the School of Arts in 1894. He assisted Dr.
Anthon in the editing of classical textbooks,
prepared a new edition of Liddell and Scott's
Greek lexicon and co-operated on the seventh

DRIVER, Samuel Rolles, English biblical
1846; d. 26 Feb. 1914. He studied at Win-
chester, and New College, Oxford, was for
some years a Fellow and tutor of his college,
and from 1876 till 1884 a member of the Old
Testament Revision Company. In 1883 he was
appointed to the Regius professorship of He-
brew at Oxford, at the same time becoming

vol. 9 — 22
canon of Christ Church. Among his numerous works may be mentioned 'A Treatise on the Use of the Tenses in Hebrew, etc.' (1874); 'Isaac His Life,' (1893); Notes on the Hebrew Text of the Books of Samuel (1890); 'Introduction to the Literature of the Old Testament' (1897), a work suited for popular reading, which has passed through a number of editions; 'Sermons on Subjects connected with the Old Testament' (1892); and commentaries on Leviticus (1894–98), Deuteronomy (1895), Joel and Amos (1897), Daniel (1900), Genesis and Exodus (1911). He was one of the editors of the 'Variarum Biblic' (1880), and with Neubauer translated a series of Jewish commentaries on the 33rd chapter of Isaiah. He was also joint editor of the 'Hebrew-English Lexicon of the Old Testament.' His presentation of the books of the Old Testament, based as it is on the results of the higher criticism, is at the same time informed with a reverential belief in their inspiration and religious authority.

**DRIVER ANT**, a nomadic predatory ant which makes its forays in column-like masses. The term usually refers to the well-known species (*Dorylus* or *Annoana, arcens*) of western Africa; but the genus embraces several species scattered over Africa, and others in southern Asia and the East Indies. All belong to the formicid sub-family Doryline, which also includes the highly destructive visiting, or foraging, ants of tropical America. The driver ants are reddish brown, and in general (i.e. the workers and soldiers of various castes) small, rarely exceeding one-third of an inch long; but the females and males are huge, ungainly creatures an inch and a half in length. All except the procreative males are totally blind. Most of the species live almost continuously underground; but the celebrated West African driver (*Dorylus arcens*) has a more exposed manner of life. Its colonies in the cassava patch live underground or on the ground where, but move about incessantly, taking shelter during the day in crevices of rocks, under logs, and so forth. Frequently they climb trees, and then hang in clusters, or in long chains that grow until they find an attachment for the lower ends when they serve as ladders up and down which other ants climb.

When they move on one of their expeditions they go at night or in cloudy weather. If detained abroad collecting food until the morning sun is shining, they will construct an arch over their path, as they proceed, of dirt agglomerated by a fluid excreted from the mouth. They march in an army-like column of millions of individuals, which looks like a thick rope, and is flanked by lines of watchful soldiers. Against an excuse of these desperately pugnacious little insects, nothing avails on the part of any beast of the forest but instant flight. "The most fierce and powerful animal," Hamilton asserts, "and the most deadly snake, become, in the face of their attack, mere panic-stricken fugitives, rushing vainly for relief to the nearest water, or desperately rolling on the earth in their endeavors to free themselves from the torture of a million poisonous bites." Animals tied or confined in pens or cages, such as calves, pigs or foxes, will be killed and stripped of flesh to the bones, as has often happened; and a sleeping man wakened by such an onslaught will have hard work to save his life. A sick man, or an infant, will perish. Dr. T. S. Savage, the celebrated American missionary, who has described the gorilla scientifically, had much experience with invasions of his premises by these ants. The first effect of their entrance into a house is the flight or capture of rats, cockroaches and wasps. Insect, indeed, form their principal and ordinary fare. Theyransack the building in regular order, searching for food, preferring fresh meat and fresh fruit-oils, and not touching sugar, milk, pastry and salted meat. We, right here, have the "pillaged" to their satisfaction the whole army leaves it completely and goes on. These habits characterize this West African species in particular. Other species are not so migratory or predaeous. Consult Savage, 'Proceedings of the Academy of Science, Philadelphia,' (1847); Wheeler, 'Ants' (New York 1910); Hamilton, 'Animal Life in Africa' (New York 1912).

**DRIVING.** Since the advent of the automobile, driving has fallen off, and there are fewer and fewer people who know how to drive a horse or a team. A driver should always grasp the reins before mounting to his seat, so that if the horse should start before he is ready, he may have control. Both lines of reins should be held in the left hand, with the elbow at the hip and the hand well in the thumb up. The left line should be grasped between the thumb and forefinger, the right line between the second and third fingers. The whip should be held in the right hand, which may also be used to grasp, when it is necessary to use more strength. The whip should not be used as an instrument of torture, and the spur is a relic of barbarism. A good driver uses the whip to indicate to the horse when more speed is desired, and if he does not mind the hint, gives one sharp cut along the horse's groin, but never descends to beating the animal. A horse should always be started at a very moderate jog, and the speed increased by degrees until the desired pace is attained. Systematic touches of the whip will soon educate a horse to what is desired in this respect. Horses, like people, have all sorts of dispositions, and like people they can be managed easily by firmness, good sense, and fair treatment. Good driving involves good harnessing, and a driver should know when a harness is properly adjusted, and when it is a poor fit. He should know how far from the dash the horse should stand when the traces are taut, and see that the breeching is properly buckled. See Horses, RIDING AND DRIVING.

**DROGHEDA,** drop'è-dá, Ireland, seaport in the southeast of county Louth; on the river Boyne, four miles from its mouth; 32 miles north of Dublin, and 81 miles south of Belfast. It does a brisk trade with the United States, and there are important textile industries. In 1494, the Irish parliament, then in session at Drogheda, passed under compulsion, the "Poyning's laws," sometimes called the "Statutes of Drogheda." In 1649, Cromwell stormed the city and massacred the garrison. William II took possession of the city the day after the "Battle of
DROHOBYCZ — DROOGENBROECK

the Boyne." Pop. 12,501. See POYNTING's

DROHOBYCZ, d'r-hô'biich, Austria, town
in Galicia, 41 miles south-southwest of
Lemberg. Its public buildings include a castle, sur-
rounded by extensive grounds, and a handsome
Gothic parish church of the 14th century. It
has an important trade, chiefly with Hungary, in
corn, leather, linen, earthenware, paraffin,
pepper, and salt, particularly salt, obtained from
salt springs in the vicinity. Near the town are
valuable iron mines and pitch wells. Pop.
34,665.

DROITWICH, droits'ich, England, market
town, six miles northeast of Worcester, on the
banks of the Salwarp, and on a canal connected
with the Severn River. Droitwich is supposed
to have been the Salinae of the Romans, and
some Roman remains have been discovered.
It is still famous for its brine springs, rising near
the centre of the town through strata of red
sandstone and gypsum from a depth of 200 feet,
which contain between 35 and 40 per cent of
pure salt, and yielding annually over 100,000
tons of salt. From these celebrated wyches, or
brine springs, as appears from grants to the
church of Droitwich, salt has been manufac-
tured for more than 1,000 years. Pop.
4,146.

DROME, drô'me, France, a southeastern
department, covered almost throughout by
ranges of the Alps, the average height of which,
however, does not exceed 4,000 feet; area, 2,532
square miles. Drome is bounded on the west
by the Rhone, and the most notable of the
rivers, the general direction of which is west-
ward toward the Rhone, are the Drôme and the
Isère. The surface is most mountainous toward
the east, a spur of the Alps traversing the eastern
limits, and from this spur numerous ranges shoot off westward across the entire area
of the department. The climate is cold, with
piercing winds. The highlands are covered with
forests of pine, oak, beech and chestnut, and
in the mountainous regions are found valuable
deposits of iron, copper, lead, coal and marble.
Oats, wheat and potatoes are the principal
products; sheep and cattle are raised. The staple
productions are chiefly wines, olives, grapes,
chestnuts, and silks. Much attention is given
to the cultivation of chestnut, walnut, mulberry,
and olive trees and vines. The manufactures
comprise hosiery, silk, cotton and woolen
goods, serge, etc. Valence is the capital. Pop.
290,694.

DROMEDARY, a camel either one-
humped or two-humped, of a breed and train-
ing fitting it for use as a speedy saddle-animal.
See CAMEL.

DROMGOLE, William (Miss),
American author and newspaper woman: b.
Murfreesboro, Tenn. Since 1904 she has been
a staff member of the Nashville Banner, hav-
ing served as educational editor and as literary
editor, and furnishing a regular feature known as
Song and Story. She is the author of
‘Heart of Old Hickory’; ‘The Valley Path’;
‘The Farmer's Dog and His Fellow’; ‘Ad-
ventures of a Fellow’; ‘Three Little Cuckoo
Moments from Dixie’; ‘Her Chums’; ‘A
Boy's Battle’; ‘Cinch and Other Stories of
Tennessee’; ‘The Best of Friends’; ‘The
Moonshiner’s Son’; ‘Harum-Scarum Joe’;
‘The Island of Beautiful Things’; ‘Old Thunder’
(1916); and two plays ‘The Tennessean’ and
‘A Nice Little Girl’. They
are twin brothers of close resemblance, who
had been separated early in life, and who meet
as the respective attendants of Antipholus of
Ephesus and Antipholus of Syracuse.

DROMOCYON, a genus of creodonts
(q.v.) typical of the family Mesonychida,
existing in the Middle Eocene era, and found
fossil in complete form in the Bridges forma-
tion of the Rocky Mountain region. They were
long-jawed, wolf-like, fast running creatures,
with heads somewhat hyena-like, blunt grind-
ing teeth, and broad, almost hook-like claws.
It is supposed that they fed mainly on carrion.

DRONE. See BEE.

DRONE-FLY, a dipterous insect (Eristalus
tena) of European origin, but first described
as an American fly in 1870. It prevails from
the Atlantic to the Pacific, and so closely resembles the honey-bee in size and color, that the two are often confounded. Liking
flowers, particularly upon those of agreeable
fragrance, it hovers about dwellings and win-
dows late in the autumn.

DRONGO, or DRONGO-SHRIKE, a
passerine bird of the family Dicruridae, represen-
ted by many species in Africa, Southern
Asia, and Australia. The typical and most
familiar species is the Indian Dicrurus. Of
a glossy black color, it has the stout, hooked
bill and forked tail of the shrike. Its food con-
ists of insects, which it often captures on the
wing. In India it is a common bird, where by
Europeans it is called “king-crow” from its
habit of routing crows and other large birds
defense of its nest.

DRONGO CUCKOO (Surniculus
dicruriformis), an East Indian bird of the order
Picidae. It is especially interesting to biologists
as a conspicuous example among animals
of imitation, according to which one group of
animals gradually assumes some characters
of another and a different group, when such fea-
tures are advantageous. Structurally, the dron-
go cuckoo is true to the pigeon order, but
the yoked toes — two in front and two behind,
—and resembles the cuckoo, of the same order,
in its habits of nesting and of egg-laying. But
in other respects it exactly imitates the drongo-
shrike, having the same description of plumage
and color, with the furred tail, and inhabits
the same locality.

DRONTHEIM, drônt'hım. See TøND-
HJEM.

DROOGENBROECK, droo'gén-brék, Jan
(Van), Flemish poet: b. Saint Amand-on-Scheldt,
18 Jan. 1835. He was long an educator of
eminence, having been for over 22 years a
tutor and professor at a prominent school of
music in Brussels. He issued his first verse col-
lection ‘Ghazels and Makames’ (Arabian terms
for stanzas and songs) in 1866, under the pseudo-
donym of JAN PERRI'C; his subsequent vol-
umes, on Camoens and other important sub-
jects, fully sustaining his reputation. The most
important of his subsequent works are the treat-
ise entitled ‘De Toepassing van het Griekshe
en Latijnsche Metrum op de Nederlandsche Poëzie! (1866), for which he received a prize at Brussels; and Uit zijn Zonnensraken (8th ed. 1884), some popular poems of childhood. He also wrote the libretto for the opera 'Undine' by Lortzing, which was performed for the first time in 1862.

DROP FORGING. See MACHINE FORGING.

DROPPERS, Garrett, American educator: b. Milwaukee, Wis., 12 April 1860. He was graduated at Harvard 1887, and later studied at the University of Berlin 1888-89. From 1889 to 1898 he was professor of political economy and finance in the University of Tokio, Japan. He was secretary of the Asiatic Society of Japan and contributed to its 'Transactions' several important and valuable articles on Japanese currency questions. From 1898 to 1906 he was president of the University of South Dakota at Vermilion, S. D., and since 1907 has been professor of economics at Williams College. In August 1914 he was appointed United States Minister to Greece. He has published a 'Translation of Schopenhauer's Essays' (1881).

DROPSIE COLLEGE, Philadelphia, an institution for the advanced study of Hebrew and cognate subjects founded by Moses Aaron Dropsie in 1895. It has a fine library covering biblical and rabbinical subjects, Semitic languages and Jewish history, the number of volumes and periodicals amounting to about 17,775. The degree of Ph.D. is awarded for special research in one particular branch of these studies. The students in 1917-18 numbered 26; the faculty and officers, 12. Six fellowships are maintained.

DROPSY consists of an accumulation of lymph-like fluid in the subcutaneous tissues and serous cavities of the body. A number of names may be used to designate the fluid accumulation, such as hydrops, when in body cavities; edema, when the fluid is in the lymph spaces; ascites when in the peritoneal cavity. Furthermore, localized forms of dropsy have received special names, such as dropsy in the abdomen — ascites; dropsy of the chest — hydrothorax; dropsy of the testicle — hydrocele; dropsy of the brain — hydrocephalus. The main causes for the symptom called dropsy are (a) insufficient strength of heart-action, allowing the serum of the blood to wander outside the blood vessels, and (b) some obstruction, preventing the return of the blood to the heart. (c) Some acute or chronic inflammation of the organ itself. Thus in many forms of hydrocephalus there is an inflammatory exudate from the choroid plexus of the brain. (d) Some acute toxic process may bring about severe edemas, such are seen in the so-called anaphylactic reaction. The most important cause of dropsy is some disease of the heart and blood vessels whereby there is either increased forward or arterial pressure, or increased backward or venous pressure. The latter is of more importance than the former. Some vital alteration in the walls of the capillaries is important in bringing about the phenomena. The treatment of dropsy is technical to a high degree, inasmuch as the causes are frequently obscure. (See Heart Disease). Consult article on Edema, in 'Reference Handbook of the Medical Sciences.'

DROSERACEÆ, drōs-ə-rē-se-ē, the Sundew family, marsh plants and natives of temperate and warm climates. They are herbaceous rosette plants with glandular hairs on the leaves for the capture of insects. The family has six genera and about 125 species, known throughout the world. Among members of the family are Venus flytrap (Dionaea muscipula) (q.v.), and Parnassia. The family is represented in America by the typical genus of the order Drosera, which has about 110 species, most abundant in Australia, and found also on the heaths and moors of England. Seven species of the sundews are found in various parts of North America.

DROSKY, drōs-kī, DROSHKY, or DROSHCHY, a kind of very small, light, four-wheeled carriage used by the Russians. It is not covered and in the middle there rises a sort of bench placed lengthwise. The driver generally throws one leg on each side of this bench, but the conveyance is also capable of holding two persons. The wheels are covered with wings, which keep off the mud. The term is now applied to several other kinds of vehicles.

DROSEMETR (from the Greek drosos, dew, and metron, a measure), an instrument for ascertaining the quantity of dew which falls. It consists of a balance, one end of which is furnished with a plate fitted to receive the dew, the other containing a weight protected from it.

DROSSINIS, drō-sēnīs, Georg, Greek poet: b. Athens, 21 Dec. 1859. He studied for the law, but later abandoned the practice for literature. He was for sometime editor of the Hestia in Germany. He has published five volumes of lyrics. ‘Spiders’ Webs’ (1880); ‘Stalactites’ (1881); ‘Idyls’ (1885); ‘Straw Flowers’ (1890); ‘Amaranthus’ (1891); also some stories and other minor works in prose. A charming simplicity of language characterizes all his works.

DROUAIAS, droo-ā’, François Hubert, French artist: b. 1727; d. 1775. He was the son of Hubert Drouais (q.v.) and studied under Van Loo, Natoire and Boucher. He was noted for his portraits, which because of their graceful delicacy made him the most popular artist of the time. He became court painter and councillor of the Academy. He numbered among his sitters Madame du Barry, Madame de Pompadour and Mademoiselle Helvetius (at the Metropolitan Museum). His pictures are characterized by the same affection and polished charm which marks his era.

DROUAIAS, Hubert, French miniature painter: b. La Rocque, 1699; d. 1767. He studied under De Troy in Paris, and became court painter in 1744. Most of his works are in private collections. The Louvre possesses two portraits by him.

DROUAIAS, Jean Germain, French painter: b. Paris, 25 Nov. 1763; d. Rome, 13 Feb. 1788. He was a pupil of David, and going from Rome to study was, in 1784, successful in carrying off the great prize, his subject on that occasion being, ‘The Canaanitish Woman at the
Feet of Jesus.' His 'Dying Gladiator,' and particularly his 'Marius at Minturnae,' on being exhibited in Paris, gained for him and David's school a new triumph.

DROUET, Henri, droo-a', French naturalist; b. Troyes 1829; d. —. He became known by his researches in natural science and in 1855 published 'Describtion des mollusques terrestres et fluviales vivants de la France continentale,' due to his travels, examining government and private collections throughout France and his personal observations, which were extended in 1857 by a scientific journey through Portugal. He held a government position in the departmental administration from 1858 to 1870. The chief of his further publications are: 'Les mollusques terrestres et fluviales de la Guyane francaise' (1859); 'Sur terre et sur mer' (1870); and 'Agier et le Sahel' (1887).

DROUET, droo-a', Jean Baptiste, Comte d'Erlon, l'French marshal; b. Rheims, 29 July 1765; d. Paris, 25 Jan. 1844. Entering the army as a private in 1782, he saw active service in 1793-96 and became aide-de-camp to General Lefèvre, and he was appointed brigadier-general in 1799. In the following year he was made general of a division which was active in the campaign of 1805-07, especially at Jena and Friedland, where he was wounded. His services won for him the Grand Cross of the Legion of Honor and elevated him to title of Comte d'Erlon. His conduct in the Peninsular War was highly distinguished. After the fall of Napoleon he was arrested on the charge of conspiring against the royal family. On the return of Napoleon from Elba he contrived to seize the citadel of Lille, in which he had been imprisoned and held it for the Emperor, who made him a peer of France. At the battle of Waterloo he commanded the 1st corps d'armée. After the capitulation of Paris he fled to Bavaria, where he resided till the July Revolution, when he returned to France and received in 1832 the command of the army of Vendée. During 1834-35 he held the office of governor-general of Algeria, and in 1843 was elected to the rank of marshal. Some autobiographical notices appeared in 1844.

DRUYN DE LHIUS, droo-ahn de li-eh, Edouard, French statesman; b. Paris, 19 Nov. 1805; d. there 1 March 1881. He studied law at the Ecole de Droit, and in 1831 became an attaché to the Embassy at Madrid. He represented France at The Hague (1833-36) and was appointed First Secretary of the Embassy at Madrid. In 1840 he was made a member of the chamber of the commercial department under the Minister of Foreign Affairs, and shortly after was elected deputy for Melun; but he afterward was deprived of his office because of his opposition to the government by Guizot. Under Louis Napoleon's presidency he became Minister of Foreign Affairs. After the coup d'état he became one of the vice-presidents of the Imperial Senate, and again Minister of Foreign Affairs. In 1855, he resigned his office; in 1863 he was recalled to his old post, resigning again in 1866. He wrote a work entitled 'Les neutres pendant la guerre d'Orient' (Paris 1868). His 'Mémoires' were published in the collections of the French academy of Moral and Political Sciences.

DROWN, Thomas Messinger, American educator; b. Philadelphia, Pa., 19 March 1842; d. Bethlehem, Pa., 16 Nov. 1904. After graduating in medicine at the University of Pennsylvania in 1862 he pursued the study of chemistry at Yale, Harvard and Heidelberg for seven years, from 1874-81, occupied the chair of analytical chemistry at Lafayette College, and for 10 years a similar chair at the Massachusetts Institute of Mining Engineers. He was one of the founders of the American Institute of Mining Engineers, and served with marked efficiency for 10 years as its first secretary and editor of its 'Transactions,' being later elected to honorary membership and in 1897 to its presidency. Dr. Drown did very important original work in quantitative analysis both in metalurgy and in sanitary chemistry. In 1895 he was called to the presidency of Lehigh University, and by careful and intelligent guidance placed it in its present high position among American schools.

DROWNED COASTS. See SHORE LINES.

DROWNING, a form of asphyxia induced by submersion in water or other fluid. As a rule in drowning the body is submerged, but Peterson and Haynes in their recent 'Legal Text-book' relate the case of an epileptic patient who, while walking on a low, sandy beach, fell in a paroxysm with his face down, causing by his spasmodic movements a small excavation of an inch and a half in depth in the sand beneath his face. This small depression filled with water and he was found dead from asphyxia about an hour or more afler the occurrence. Most cases of drowning result from asphyxia, by which is meant the body becomes poisoned from the lack of oxygenation of the blood, since no oxygen can enter the lungs from the fluid, in a form that can be utilized. Heart failure sometimes occurs in drowning. At one time drowning was a legal method of execution and prevailed in England until the early part of the 17th century; it was much practised in other European countries during the Middle Ages, and is still practised in Mohammedan countries and in the Far East. (See CAPITAL PUNISHMENT.) It is a frequent method of suicide, fully one-third of the cases taking this method. Danger from drowning to swimmers depends very largely upon the ability of the swimmer, although this is not a guarantee of safety, since many excellent swimmers have been known to be unable to sustain the fatigue of being long in the water and sometimes succumb suddenly from muscular cramps or from attacks of syncope. Persons who have respiratory defects, such as asthma or stammering, or who have organic disease of the circulation, are more liable to drown. Drowning occurs more often among men than among women, because of the greater exposure. Extreme coldness of the water seems to be an important factor in augmenting the danger from drowning. Good health, muscular vigor and calmness of mind are of great importance in cases of danger from impending drowning. With reference to temperature there is great variability. Some people who have been submerged suddenly and in water of low temperature are found dead on almost immediate rescue. Here probably the nervous shock and deficient heart action accounts for
DROWSINESS — DROZ

the result. In a great many more cases, how-
ever, there is spasmodic closure of the glottis
from direct irritation of the water as it enters
the nose and mouth, and from nervous reflexes
due to sudden chilling of the surface. Many
of these patients sink to the bottom at once
and remain below the surface, unconscious-
ness occurring in the course of a few seconds.
The respiratory movements are few and con-
vulsively slow and the heart stops. In the great-
ernumber of cases, however, asphyxia results
from the entrance of water into the lungs;
the individual struggles to come to the surface
and as soon as the surface is reached attempts
are made to fill the lungs by long inspirations.
This very frequently draws a small amount of
water into the larynx and then involuntary con-
vulsive efforts result. With each convulsive in-
spiration more water is drawn in and thus pul-
monary congestion becomes more and more
pronounced. The struggle for life becomes vic-
ter and the patient frequently grasps at every-
thing in sight, even tearing handfuls of mud
from the bottom of the body of water. During
the convulsive seizure the face becomes blue,
the eyes bulge, the features become contorted,
the breathing rapid and feeble. The bladder
and rectum are emptied. After a few min-
utes, five or six, inspiration ceases; four to six
minutes more, sometimes longer, the heart con-
tinues to beat, gradually failing in strength and
rapidity.

Treatment of all cases of drowning should
be insistent and prolonged. If there is a great
deal of water in the chest, the chances are les-
sened. Instances have been recorded in which
patients have been submerged 20 or 30 minutes
and have recovered, but if the body has been
beneath the surface for over 4 or 5 minutes the
general chances of resuscitation are slight. If
attempts at resuscitation are made — and they
should always be made unless the body has been
under water several hours — the body should
be placed face downward, the head and shoul-
ders depressed, so as to favor drainage of water
from the lungs and all efforts should be directed
at first toward the restoration of breathing. The
application of harts horn, salting salts or snuff
to the nostrils, tickling the throat with a feather,
dashing cold water and hot water alternately on
the chest and face and vigorous friction of
the upper part of the body to create warmth
are of value, as also wiping and cleansing the
mouth; surrounding the patient with hot bottles;
and hot rectal irrigations of salt solution or
whisky. If these preliminary efforts fail, arti-
ficial respiration should be resorted to and con-
tinued for several hours. The patient should
be still kept face downward, a folded coat or
other article of dress raising and supporting the
chest. The weight of the body on the chest
forces the air out, then turning the body over
but gently on one side, then turning it
on its face again, repeating these movements
about 15 times in a minute, occasionally varying
the side, at each turn and relief of the chest
pressure, as well as the lungs, and exerts breath-
ing. This operation should be assisted between
each turn of the body by brisk and uniform
pressure between and below each shoulder-blade.
At the same time, but without interfering with
these operations, the hands and feet should be
dried, wet clothing removed and the body en-
volved in warm blankets or re clothed with dry
garments. Should these efforts prove unavailing
after from two to five minutes, recourse should
be had to Dr. Silvester's method, which consists
in placing the patient on the back, on a flat
surface inclined slightly upward from the feet,
the head and shoulders being raised and sup-
ported on a small cushion, or folded article of
dress placed under the shoulder-blades. The
tongue should be pushed forward and fastened
by an elastic band, string or tape over the
tongue and under the chin, to keep it projecting
beyond the lips. Then to imitate the move-
ments of breathing and to draw air into the
lungs, stand at the patient's head, grasp the
arms just above the elbows and draw the arms
steadily upward above the head, keeping them
stretched upward for two seconds. To expel
the air from the lungs, turn down the arms and
press them firmly for two seconds against the
sides of the chest. Repeat these movements
deliberately and persistently about 15 times a
minute, until a natural effort to breathe is per-
ceived, when the efforts should be turned
toward inducing circulation and warmth, which
may be best promoted by briskly rubbing the
limbs upward. Sometimes the blood is
forced along the veins to the heart and by the
application of hot flannels, hot water bottles,
heated bricks, etc., to the pit of the stomach,
between the thighs, the armpits and to the soles.

Another method which has the advantage of
simplicity and can be applied by one person
is that of Dr. Benjamin Howard of New York.
The body is placed face downward with a roll
of clothing under the stomach, one arm being
bent upward so that the hand supports the for-
thead. To expel the water from the chest, the
body is pulled feet downward over the roll of
衣物. Then turn the body on the back, with
the roll of clothing under the shoulders, so that
the head falls back, thus stretching the neck.
Kneel over the body, one knee pressed firmly
against either thigh. With both hands spread
over the lower part of the chest, so that the
thumb hooks in under the lowest ribs on each
te side, press forward steadily with the weight
of the body on the arms, thus raising the ribs, en-
larging the chest cavity and thereby forcing
the water out. When the ribs have been pushed
upward to the utmost extent, release them gently
by a receding movement, allowing them to return
to their original position, thus expelling the air.
Repeat this process until respiration is restored.

Then resort to the methods already mentioned
to induce circulation and warmth. No attempts
at resuscitation should be abandoned until all
efforts seem to be absolutely futile. See As-
phyxia; Pulmotor; Respiration, Artificial.

DROWSINESS. See Sleep.

DROYLSDEN, droil's dén, England, town
in Lancashire, five miles east of Manchester,
of which it is an outlying suburb. It con-
tains large cotton manufactories, super-
ners, chemical, and dye works, and print mills.
Pop. 13,259.

DROZ, dró, François Xavier Joseph,
French moralist and historian; b. Besançon,
In 1806 he published 'Essai sur l'art d'être
heureux' (1801) which was very popular; and
in 1833 'Philosophie morale' which procured
his admission into the Academy. His reputation is, however, founded chiefly on his "Histoire du règne de Louis XVI."

DROZ, Gustave, French novelist: b. Paris, 6 June 1832; d. 31 Oct. 1895. He was trained for a painter, but in 1864 gave up the pencil for the pen. The extraordinary success of his first volume, "Monsieur, Madame, Bébé," justified the change. He excelled in little sketches of life and manners, and his lively, playful descriptions of bachelorhood and married life captivated the public. His novel "Au tour d'une source" (1869) is generally considered his best.

DROZ, Pierre-Jacquet, Swiss mechanician: b. La Chaux de Fonds, Switzerland, 28 July 1721; d. Bienne, Switzerland, 28 Nov. 1790. Aspiring to be something more than a mere workman, he succeeded in attaching to common-time pieces, at a small expense, machinery which would be most pleasingly affected as to its time and length of vibration by heat or cold. He afterward made his celebrated writing automaton, which, by means of machinery contained within the figure, was made to move its fingers and hands, and to form handsome letters.

DRUG, a name applied to all substances vegetable, animal, or mineral, used for medicinal purposes, though the term should, perhaps, be strictly confined to what are called simples, balsams, gums, resins, and exotic products used as medicaments in a dry state. The name is also applied to dyeing materials and those used in tanning and other arts. See PHARMACY.

DRUG HABITS. Recent investigations of the United States Department of Agriculture show conclusively a constantly decreasing use of injurious drugs (exclusive of alcohol and tobacco) among the people of this country. Before any means were available for gathering such data, an estimate of the number of the number of drug addicts in the United States ranged as high as 4,000,000. But the report of the Food and Drugs Commissioner of Tennessee on the first year's (1913-14) operation of that State's anti-narcotic law provided definite statistics, which have been accepted by the Government's experts as a fair basis for a close estimate. Applying to the whole country the ratios gained in the Tennessee records, the total number of drug addicts in the United States is now estimated at 110,000. A check upon these figures is supplied in the amount of habit-forming drugs imported into the United States. The Bureau of Chemistry points out that if nine-tenths of all the opium imported into the country were consumed by addicts at the rate of the Tennessee consumption, the number of such users would be 187,000. The same Bureau estimates that all of the importation of cocaine is consumed by addicts at the rate of one ounce per person per year, and that the 150,000 users would consist of 150,000 users. This estimate is corroborated by hospital physicians who declare that many cocaine users and snuffers consume as much as 15 ounces annually. The American Pharmaceutical Association estimates that the total number of drug habitué (exclusive of those addicted to alcohol and tobacco) in the United States in 1914 did not exceed 200,000.

Of the whole number of drug users those addicted to morphine amount to 37.6 per cent; to cocaine, 26.7 per cent; to laudanum, 18.8 per cent; to heroine, 4.4 per cent; to gum opium, 2.2 per cent; and those who have both morphine and cocaine habits, 10.3 per cent. Further official investigations in the other cities show that 54.6 per cent had their beginnings in physicians' prescriptions; 21.6 per cent in the advice or persuasion of drug-using acquaintances; 21.6 per cent as a result of dissipation; 2.4 per cent in the desire to escape suffering in incurable diseases.

The drugs used by victims of drug habits are of two general groups: (1) sedatives, and (2) stimulants. The first group includes the soporifics, such as chloral, sulphonal, veronal, etc., and the analgesics and antispasmodics as opium, cocaine, cannabis Indica (Indian hemp or hasheesh), etc., and the headache-powder constituents, phenacetin, acetanilid, antipyrine and its derivatives, bromopyrine, salicylpyrine, etc., and antifebrin as to the derivatives of phenalgin and ealgin. The second group includes alcohol, tea, coffee, tobacco, etc. In the second class should be included also opium in doses of a certain small quantity relative to the degree of habituation, in which it is highly stimulating. This is true also of the delirium produced by Indian hemp. Coca and cocaine are stimulants in small doses, which, however, speedily require to be made larger. It is for this reason largely that the cocaine habit is regarded as the most insidious and dangerous. The effect of the drug soon passes off, and repeated as well as larger doses are sought by the victim. A debased mental condition follows the brief exhilaration, and a tendency to suicide is developed.

Tea, coffee, cocoa, kola, maté, guarana, etc., depend for their attraction upon their active principles, caffeine, theobromine, or theophyllin. The effect of these drugs is similar to that of cocaine, though in a much less degree. They also develop neurotic tendencies in the user. In most cases the system becomes tolerant of the drug, and, the effects being cumulative, the eventual breakdown is sudden.

The foundation of drug habits is very often laid with soothing syrups given to babies. These have been found to contain opium, morphia, heroin, codeine, chloroform, chloral hydrate, and cannabis. The habits thus begun are nurtured with patent medicines. Asthma remedies contain practically the same series of drugs as the soothing syrups, with the addition sometimes of tobacco. Catarrh cures are largely cocaine, either in powder to be used as a snuff, or in liquid form as a spray. Remedies for coughs and colds contain chloroform, heroin, morphia, codeine, cannabis, and either. Headache remedies consist of acetanilid, acethenetidin, antipyrine, caffeine, etc., in various combinations. Epilepsy cures are chiefly bromides, with morphia or opium. Many tobacco-habit cures contain cocaine. Indeed, almost all of the cures offered for the various drug habits have proved to be preparations of the same drug to which the habitué was addicted.
In the endeavor to check the spread of this pernicious use of dangerous drugs, the Federal Government in 1910 issued the first of a series of pamphlets through the Department of Agriculture warning the people against the use of habit-forming drugs, and calling particular attention to the drunks connecting with many soda fountains. Prior to the appearance of this bulletin, the Federal authorities had forbidden the sale of certain popular beverages for this reason, and the manufacturers were not permitted to supply orders again until they had changed their formulas to the satisfaction of the Bureau of Chemistry.

In view of Secretary Wilson’s charge that druggists, physicians, and patent medicine manufacturers were largely responsible for the development of drug habits, the revision committee of the American Pharmaceutical Association, which met in May 1911, investigated and passed unfavorably upon a number of the so-called “remedies.” Both the Federal authorities and the health officials of the several States began a definite campaign against the sale of pernicious drugs along the following lines:

1. To educate the public through the press as well as by lectures, pamphlets, etc.
2. To secure the enactment of laws forbidding the sale of habit-forming drugs, and preparations containing them, except on the prescription of duly authorized persons.
3. To require a permanent record to be kept of all transactions in such drugs, whether by prescription or otherwise, the same to be subject to Federal and State inspection at all times.
4. The enactment of laws forbidding the handling of such drugs, except by druggists, manufacturers, and others legally qualified.
5. To secure the passage of laws permitting State Boards of Health to revoke the licenses of physicians or druggists convicted of selling such drugs for other than legitimate purposes.
6. To secure the passage of a Federal law prohibiting the interstate shipment of habit-forming drugs, or preparations containing them, except through the regular channels of trade in which records of all transactions must be kept. In 1914 the so-called Harrison bill was passed by the United States Congress, and it went into effect 1 March 1915. It requires that "every person who produces, imports, manufactures, compouds, deals in, dispenses, sells, distributes, or gives away opium, or coca leaves, or any compound, manufacture, salt, derivative, or preparation thereof shall register with the collector of internal revenue of the district, and pay an annual special tax of $1. Every sale is to be recorded with the patient’s or purchaser’s name, age, and address, together with the name of the dealer or physician and the date. It is made unlawful for any dealer or druggist to supply an opiate unless all the requirements have been fulfilled. Exceptions are made in the case of preparations which do not contain more than two grains of opium, one-quarter grain of morphone, one-eighth grain of heroin, one grain of codeine, or any salt or derivative of them in one fluid ounce, or, if solid or semi-solid, in one ounce avoidipois. This exception has been criticized since it has been shown that prescriptions of the strength exempted will readily supply the usual 2-grain dose to an addict if he takes an ounce at a time.

Several of the States have passed similar laws, and the immediate effect has been to curtail illicit sales of these drugs to a very considerable degree. In nearly all of the States these drugs can be procured only on a physician’s prescription, and in some it is unlawful even for a physician to dispense drugs to addicts except in regular professional treatment of disease. In a few of the States these habit-forming drugs are classed as poisons, and may be sold if provided with a poison label. In Louisiana chloroform and hyoscyamus are included among the forbidden drugs. The drug law of Michigan forbids any person except a physician to receive or have in possession any cocaine, alpha eucaine, or beta eucaine, or any of their salts, even as an ingredient of some other preparation. The law of West Virginia makes it a felony to dispense cocaine to addicts.

In China, where the opium habit has held sway since the 13th century the fight against the habit began with the Imperial Edict issued in 1729 against opium smoking. In 1796 an edict was issued forbidding the importation of opium, which then came from India. The Chinese set diligently to work cultivating the poppy, and notwithstanding the death penalty decreed to opium smokers, the trade continued.

India has always been one of the large producers of opium, and England has steadily maintained that, so long as China produced most of the opium used in that country, and even exported it to other countries, there was no justification in the demand that exports of Indian opium to China be forbidden. Even when China had announced the intention of suppressing the trade, many statesmen in England questioned the sincerity of that declaration.

In 1905, however, the influence of the anti-opium societies became so great that the Imperial Senate was compelled to pass drastic laws against the opium traffic. In 1906 China produced 330,000 piculs of opium—a picul being equal to 153° pounds avoirdupois. She also imported 51,000 piculs from India. The government decreed that both the cultivation of the poppy and the use of opium must cease.

In 1910 the area devoted to poppy culture had decreased from 614,000 acres (in 1906) to 350,000 acres, and the production of opium had been reduced by more than 25,000,000 pounds. The reports from the five principal opium-using provinces show that the number of shops in which opium is sold has been reduced from more than 42,000 to about 12,000. The number of users of the drug (13,000,000 in 1906) has also been largely reduced and is steadily declining. To promote this condition, hundreds of public "refuges" for the scientific treatment of victims of the opium habit have been established in China. In 1910, it was reported that nearly 1,200,000 cures had been effected; nearly 1,500,000 patients were then undergoing treatment.

In 1912 the National laws against the cultivation, sale and smoking of opium went into effect with the support of nearly every newspaper in China. Large quantities of opium were burned, as much as $10,000 to $15,000 worth being consumed in a single fire.

One of the most serious obstacles to be surmounted by the anti-opium societies has
been the existence in China of a stock of Indian and Chinese opium valued at $70,000,000, upon which large loans had been advanced by the banks. See CHLORAL; COCAINE; INTOXICATION; OPIUM; TOBACCO.

DRUG TRADE. The American drug trade is largely a modern development, although America's part in the history of drug dates from the days of the first explorers. When the Amerindians travelers returned to the Old World bearing with them specimens of the various products of this new world, the learned men of Europe greeted their arrival with interest and science hastened to affirm that the chief advantage to be derived from the discovery of the new continent would lie in the introduction of new and more potent drugs. From that moment scientists began to devote their attention to the study of American plants and herbs, and all the old chronicles show a considerable space devoted to a recital of the health-giving qualities of these products of the American soil. Nothing that grew in the New World was neglected by the experimenters. Everything was tested, and many things were found to be of great value. For a long time tobacco, Jesuits' bark, and sassafras, were among the most frequently used medicaments, and from time to time, the medicinal properties of other herbs were discovered and utilized.

The drug trade itself has no such ancient record to which one may appeal. A century ago the stock of every wholesale druggist included such articles as glassware, oils, paints, putty, indigo, madder, etc., and sometimes even commodities still more foreign to the trade. Since the early part of the 19th century, however, this has changed, and the drug trade has now assumed a position by restricting his stock to such articles as may be classified as true drugs or medicines. These articles, of course, include many "patent" medicines, and will probably do so as long as the demand for such preparations continues to make them one of the most important items in the drug trade.

From the beginning of the history of medicine and pharmacy the people as a mass have been conspicuous for their faith in the efficacy of the "patent," or more properly, the secret, medicine and the makers of patent medicines have always flooded the market with their nostrums, depending upon this credulity of the people for financial success. Aside from these articles of commerce, however, the staples of the drug trade, the legitimate drugs and medicines of which the secret products are but a small part, have been the great staples of the trade. The drug trade of America is thus closely bound up with the development of the country itself. Since the early days of the country's history, drugs, such as jalap, ipecac, sarsaparilla and balsams, have been imported from Mexico, as well as from Central and South America. As early as 1820, through the investigations of the French scientists, the separate alkaloids in cinchona bark were determined and Pelletier soon began their manufacture. It was at about the same time that John Farr started the first quinine factory in Philadelphia and the popularity of the drug was so immediate that John Currie soon followed by building a similar factory in New York.

In the early days the supplies of cinchona bark were imported through Spain, but the opening of the ports of South America to our commerce enabled us to secure the necessary shipments direct from those countries. In the beginning of the industry in America the Government placed an import duty upon foreign-made quinine, and as long as such duties remained in force, the American manufacturers had a practical monopoly of the home trade. In 1879, however, quinine was placed on the free list, and since that time the foreign makers who are able to produce the drug at a much lower cost than that at which we can make it, have not only shipped their surplus stock to this country, but have secured such a firm foothold that they now control nearly half of the American quinine market.

Stone-oil, or Seneca-oil, the substance which is now known as petroleum, was discovered in West Virginia, where it had long been popularly regarded as a most efficient liming agent. It was found at several places in that State, where it rose to the surface of the ground, a heavy and dark substance, the true character of which was not recognized until many years later. In 1829, a similar supply was found in Hamblen County, Ky., and upon a well being drilled, a phenomenal quantity of oil was obtained. Owing to the fact that no ample provisions had been made to save the oil, the bulk of it was wasted. Some of it was preserved, however, and having been bottled, was sold in Europe under the name of "American Oil." The device on the label, a derrick, first suggested the means by which a sufficient quantity of the crude oil could be obtained to pay the cost of refining it, a process which resulted in the discovery of such valuable filtered paraffine residua as asphaltum, vaseline, etc., preparations which have since become important articles of export.

It is believed that the first historical mention of the manufacture of drugs in this country is that in the instructions given to Sir Francis Wyatt, governor of Virginia, in 1621. In this document he was requested to invite attention to the industrial possibilities to be found in the making of oil of walnuts, and he was authorized to employ such apothecaries as might be necessary to assure its proper production. The colonists were also requested to search for gums, dyes, and new drugs. In 1785, the South Carolina Agricultural Society offered special premiums for the cultivation of such drug plants as sema, cassia, hops, madder, rhubarb and figs. It is useless to attempt to write the various articles known to the drug trade of that day, or to enumerate the uses to which they were put, but in even so brief a review as this, a word or two must be said about the old-time business conditions.
In the wholesale branch of the trade, some 75 years ago, the hours of business were from 7 o'clock in the morning until 9 o'clock at night. There were no railroads then, and means of communication between one part of the country and another were very primitive. After the Erie Canal was opened, the change in conditions brought about a corresponding change in business methods. Instead of dragging along through the year, the wholesale druggist had two busy seasons. There was a rush of trade in the spring, and another rush just prior to the close of navigation in the fall, and clerks, at these times in the year, were often required to remain at work until midnight.

The outbreak of the Civil War had an effect upon the drug trade just as it had upon every branch of business in the North. Many large outstanding accounts were canceled, and many houses, as the result, went out of business, although others were perhaps fewer failures than the wholesale drug line than in other branches of business.

To realize what a great variety of articles were included in the stock of the wholesale druggists of the olden times, it is only necessary to take a tour of some of the old and famous such houses published some 100 years ago, while the extent of the purely drug stock may be pretty accurately approximated by a comparison of one of the early pharmacopoeias with the current edition. The volume for 1830 is, perhaps, the best one to which we can refer to ascertain the condition of affairs which existed during the two or three decades prior to its issue. According to that authority there were 272 articles of materia medica, while 349 processes were given for preparations, making a total of but 621 titles. Sixty years later, the "United States Pharmacopeia" had no less than 1,003 titles, while the "National Formulary," a semi-official work of almost equal practical importance, had 435 more titles, making a total of 1,465 articles of preparations, which the apothecary was able to furnish a customer upon demand.

Of course, the wholesale druggist of those days was compelled to carry many articles which were not strictly entitled to a place upon the shelves of the dispensing chemist; but in fact, the drug feature of the drug trade has so greatly extended that reference to recent price-lists issued by the prominent jobbing houses shows that there are now more than 5,000 articles in the department of drugs, chemicals, oils, etc., and close upon 8,000 articles in the department of "patent," or proprietary medicines. Moreover, if one should go so far as to include the almost incalculable number of articles which come under the head of "druggists' sundries," to say nothing of the "secret proprietary" medicines which, being confined, largely to local trade, do not appear upon any general price-list, there is little doubt that the figures already given would be doubled; a fact which makes it safe to estimate that there are no less than 25,000 different articles handled by the drug trade of to-day.

So far as the retail druggist was concerned, his business at that period was largely a matter of "go as you please." If he could prepare, from the crude material, the prescriptions of the local physicians, he had succeeded in fulfilling the object of his existence. To-day, however, he enjoys most superior facilities, for while he is still required to be acquainted with all processes, he has the convenience of being able to purchase the greater portion of his stock ready for dispensing. To afford such facilities the business of manufacturing pharmacy has been developed, during the past fifty odd years, into a distinct department of the drug trade.

Without laying undue stress upon the wonderful advances in inorganic chemistry, and especially in the remarkable work accomplished in the discovery and improvements of anesthetics, there can be no question that the evolution of organic chemistry is one of the most stupendous scientific triumphs recorded since the middle of the 19th century. Wöhler's discovery, in 1828, that urea could be manufactured artificially from isocyanate of ammonium was really the first step taken toward the synthetic production of organic compounds, for, up to that period, it had been the undisputed theory of the scientists that no organic compound was possible except through the medium of "vital force." Wöhler opened the way to further experiments along the same line, and, since 1828, innumerable compounds of an organic nature have been prepared synthetically, many of which are of such great commercial importance that they are manufactured in extensive quantities. Among such compounds, for example, is salicylic acid, the chief coloring-matter of madder root, of which fully $20,000,000 worth is produced annually from coal tar. Oxalic acid, which formerly came from the juice of the sorrel, is now artificially produced, at one-tenth its former cost, by the use of sawdust and caustic soda; while salicylic acid, which was formerly derived from the oil of wintergreen, is now produced more easily through the action of carbon dioxide upon carbolic acid and caustic soda. Not only has the chemist succeeded in preparing many of the most important organic compounds in his own laboratory, however, but, during the past quarter of a century, he has discovered a vast number of new and interesting synthetic chemicals which have never been found in living plants and animals, among which we may mention the artificial elaborations of aspirin, caffeine, paregoric, phenacetin, etc. Moreover, as the number of these compounds which are of importance therapeutically is constantly increasing, such progress as is represented by these discoveries in allied science has exerted a powerful influence in elevating the drug trade to its present high position.

Of course, it must not be imagined that chemistry is the only agency that has been operative in shaping this development. One of the first in importance among these agencies has unquestionably been the "United States Pharmacopeia." The first pharmacopeia published in the United States was printed in Philadelphia in 1778. It was made up for military purposes. The next publication of the kind was issued by the Massachusetts Medical Society in 1808. But these did not have a considerable circulation, and, as a matter of fact, up to the beginning of the 19th century, and even for some years thereafter, drugs were dispensed according to the pharmacopoeias of foreign countries; and it was not until some time be-
between 1810 and 1820 that any attempt was made to better these conditions. In 1820, the first edition of the "United States Pharmacopoeia" appeared, and this work, which has passed through successive revisions up to this time, is regarded the world over as the standard in all manipulations of drugs and medicinal chemicals, from the identification of the crude material to the final stages in its preparation for the use of invalids. The names of Proctor, Maitland and Roe being inseparable connected with the early issues of this great work.

The governmental inspection of imported drugs, which commenced about 1825, was largely the result of the initiative taken by the newly-established pharmaceutical colleges in New York and Philadelphia. This inspection, still conducted by the national officials, has an important effect in upholding the standard of purity in drug imports.

The first law regulating the retail sale of drugs and poisons that was passed in the United States was enacted by the State legislature of Rhode Island, in 1870, but since that time almost every State in the Union has placed a similar act upon its statutes. While there is a lack of uniformity in these laws, in general they cover the same ground by restricting all dealings in drugs, as well as all compounding of prescriptions to such persons as have been able to pass a satisfactory examination before a board of pharmacy. As such laws were not retroactive their beneficial effect has been only partially determined, as those who were engaged in the drug business prior to the passage of these acts were allowed to continue regardless of their ability to pass an examination.

Another agency that has accomplished important results in the betterment of the drug trade are the various associations that have been founded since the middle of the 19th century. The first association instituted for the conservation and advancement of the material and professional interests of the business was the American Pharmaceutical Association, which was founded by 21 active pharmacists in 1852. This association holds annual meetings for the discussion of scientific and educational questions, and the publication of the "American Pharmaceutical Association Journal." One of the most important influences exerted over the retail trade is represented by the various State pharmaceutical associations, the oldest of which, that of New Jersey, was organized in 1870, while one of the most notable events in the history of the wholesale drug trade during the 19th century was the organization of the wholesale houses of the West under the name of the Western Wholesale Druggists' Association. It was founded in 1876, and has since increased its influence by the peculiar conditions of the times. In 1882, many of the prominent Eastern druggists joined forces with the Western wholesalers, at a meeting held at Cleveland, Ohio, and, at this time, the name of the organization was changed to the National Wholesale Druggists' Association. To secure trade, and, afterward, to hold it, required a competition that finally became so sharp that concerns which had hitherto been regarded as prosperous houses found themselves unable to make profits. As the result a committee was appointed to try to introduce a system that is now known as the "rebate plan." According to the old system such articles as patent medicines had been sold on a very close margin, and the new plan was devised to give the wholesale druggists an opportunity to obtain a fair profit upon such preparations. By the adoption of the "rebate plan," therefore, the wholesale druggists consented to sign a contract by which they agreed to maintain established prices, on condition that they were to receive 10 per cent reduction, or rebate, upon the regular wholesale price, and with the penalty of being placed upon the "cut-off" list, and thus debarred from buying from the proprietors, in case they were guilty of violating their agreement. At this time the only profit to the wholesale trade was this 10 per cent rebate. The plan worked well for a time, but was completely demoralized by the entry of the department stores into the drug business, and their policy of using cut prices on drugs and druggist's sundries to attract custom for other articles. The steps taken to correct this situation brought the trade up against the restrictions of the Sherman anti-trust law, and the government brought suit against the protective combination. The net result has been to reduce the margin in the wholesale drug business to a bare 3 per cent.

The retail drug trade of the present day has become almost altogether a mere distribution of the products of the great pharmaceutical and biological laboratories which are continually adding new remedies to their already extensive lists. The business of the largest manufacturing houses has become sixfold: the gathering of the crude drugs; the extraction of their active principles; the manufacture of synthetic drug preparations; the testing out, standardization, the commercial dispensing of their products; and the discovering of new drugs by specially commissioned explorers in the most remote regions of the earth.

Still another important factor in the growth and development of the drug trade is the press. The American pharmaceutical press. Among the most prominent periodicals are such weekly papers as the "Pharmaceutical Era," the "Shipping and Commercial List," and the Oil, Paint and Drug Reporter, all of New York; semi-monthlies like the American Druggist and Pharmaceutical Record, of New York, and such monthly journals as the American Journal of Pharmacy, of Philadelphia; the Druggists' Circular and Chemical Gazette, of New York; Pharmaceutische Rundschau, of New York; the Western Druggist, of Chicago the National Druggist, of Saint Louis, and the New England Druggist, of Boston. Besides these there are some smaller periodicals of local influence, as well as a considerable number of publications issued by various colleges and societies by prominent drug firms and manufacturing houses.

There is, perhaps, no particular in which the development of the drug trade is indicated more clearly than in the improvements in its methods. Less than a century ago the apothecary was obliged to cut and roll his pills by hand, and
DRUG TRADE

to make his plasters with a "spreading iron." He powdered his drugs in a stone or iron mortar that he put in a wide-mouthed jar with the aid of a stirring stick. To-day such operations are performed by machinery, a process which has so simplified the work that the manufacturing pharmacist is now able, by the use of his power-machine, to turn out more than 1000 pills a day, and plasters almost ad libitum. The power-machines which are used in the making of compressed tablets now made more than 500 tablets a minute.

The making of fluid extracts as a class of pharmaceutical preparations is essentially an American invention. They are made by dilution, or displacement, a process by which the powdered drug, placed in a suitable vessel, is deprived of its soluble constituents, by the descent of a solvent through it, an invention the importance of which cannot be overestimated, as much of the progress in American pharmacy during the last half of the 19th century was largely due to the study and development of the process of percolation, and the introduction of preparations which owed their existence directly to this invention. Percolation received the stamp of official recognition in the "Pharmacopoeia" of 1840, and has occupied a place in all subsequent editions of that work. None of the editions of the "Pharmacopoeia," prior to that of 1850, gave any formulas for the preparation of fluid extracts. In 1850, seven of these formulas were given and by 1890 the number had increased to 88, although this number does not begin to represent the total manufacture of fluid extracts, which have now become as numerous and as popular as the vegetable drugs. The earliest manufacture of these extracts are the names of Henry Thayer of Boston, and Tilden & Co. of New Lebanon, N. Y.

Another innovation is the so-called "elixirs," which were originated some time in the later thirties. For a time this term was used almost exclusively by manufacturers to designate their aromatic, sweetened,spiritious preparations which contained comparatively small quantities of active medicinal substances, but no formula under that name was published for the use of druggists until 1859.

The first sugar-coated pills made in this country were manufactured by Bullock & Crenshaw of Philadelphia, and the Tilden Company, of New Lebanon, N. Y. The use of gelatine capsules as a means of administering nauseous remedies in a readily assimilable condition was also the direct result of American enterprise. This process was originally outlined by Mothes, of Paris, but the success in popularizing it was due to the efforts of H. Planten & Son, the firm which first made them in the United States. A firm which became very prominent in the earliest manufacture of gelatine coated pills was McKesson & Robbins.

It is difficult for us to-day to realize that it was not until after 1825, when the American surgeon, Benjamin Rush, made his carefully conducted observations upon the phenomena of digestion in the living stomach, that the functions of the gastric juice were revealed. His investigations, which lasted until 1833, stimulated and suggested the course for subsequent researches, and, in 1836, when the active prin-

ciple of the gastric juice was discovered by Schwann, he gave it the name of "pepsin." From a commercial point of view, the history of pepsin in America begins with the original notion of Scheffer's pepsin, in 1872. This preparation was made by a simple and practical method known as the "salt" process, and it was a great improvement over all of the older methods of obtaining the ferment from the stomach. A few years later, about 1879, the original form of pepsin in scales, "free from added substances or reagents," was introduced by Fairchild, and the advent of this preparation of phenomenal strength had the effect of causing great activity in the manufacture and improvement of the commercial pepsins. The practical recognition and application of pancreas ferments is due to the efforts of Fairchild, who, in 1880, introduced the extractum pancreatis, containing diastase for the conversion of starch, trypsin for the conversion of albumen, and emulsifying fer-

ment for the digestion of fats, and the milk-curdling ferment, a preparation which proved to be of great utility, especially in the artificial digestion of foods for the sick, and in the preparation of foods for infants. Basing his theo-

eries upon the indulgent idea that was proposed that the farinaceous foods which were commonly used with milk as food for in-

fants should first be digested into soluble form by the use of malt diastase, while, in 1884, Fair-

child proposed a method by which cow's milk might be modified and adjusted to a closer re-

semblance to human milk by the conversion of casein, by the use of trypsin, to the soluble and peptone-like bodies for which the latter milk is peculiar.

The first improvement upon the antiquated method of applying plasters to the human body was the invention of an india-rubber porous plaster by Dr. Shecut, a naval surgeon. He sold his rights in the plaster to Thomas Allcock, and the latter, failing to make its manufacture profitable, sold it to Dr. Bramhall. At this time the only commercial plasters were made of isinglass and resinous mixtures, some of which were spread on cloth and plaster skins. It was about 1867 that Seabury & Porter began the experiments which finally led to the use of rubber in medicinal and surgical plasters.

It was in 1878 that Dr. R. M. Fuller, of New York, introduced another distinctively American form of medication under the name of "tablet triturates." These were made by a method in which the active ingredient was triturated, or ground, with either plain sugar of milk, or with a mixture of sugar of milk and cane-sugar, into a paste which was pressed into tablets in suitable molds. By this process it was possible to administer small quantities of such potent remedies as alkaloids, concentrations, etc., in a convenient, palatable, and readily soluble form. Unique as the idea was, it immediately became so popular with the medical profession that the manufacturers began to produce them upon an enormous scale. The manufacturer alone having no less than 500 different varieties of these tab-

lets on his price-list.

Great as have been the developments along individual lines, however, it is only by reference to statistics that we can gain any idea of the magnitude of the commerce to which the modern drug trade has attained. The United States
government kept no record of the imports and exports in drugs until 1830, and even then the list was confined to a few items. In 1830, the exports from the United States were stated to be $130,238, while in 1835 they were reported as being about $200,000. In 1816 the exports of patent medicines alone amounted to a value of $8,397,977. The value of roots, barks, herbes, gums, resins, etc., amounted to a value of $768,977. These figures by no means show the total value of medicinal preparations sold abroad. The government reports include such commodities with “chemicals” in such a way that they cannot be separated. The imports may be traced somewhat closer, and, omitting the inorganic and mineral substances used both in medicine and the arts, the government figures for the fiscal year ended 30 June 1916, show an importation of crude drugs and drug plants of 3,379,724 pounds, valued at $6,914,688. In addition, antitoxins, serums and vaccines valued at $8,225 were imported. It should be noted in passing that previous to the European War the larger part of the drug supply of the world passed through the ports of London, Hamburg, and Liverpool. The latter ports almost completely demoralized the trade. In the United States prices speedily advanced as stocks diminished, and in some cases reached figures 1,000 per cent above the ante-war prices. Movements to grow drug plants in the United States have been encouraged on the ground that the different climatic conditions would affect unfavorably the effective drug content, and that with the end of the war prices will fall below a remunerative point. Nevertheless the experiment is being made in several states of the country.

Unfortunately there are no data from which we may estimate the number of druggists doing business in the United States at the beginning of the 19th century. The New York directory for 1786 mentions the names of only two. One, druggist, Efingham, Lawrence, was official apothecary to the Medical Society, a committee from which visited his store once every three months to certify that his drugs were genuine and his medicines properly prepared. Among the other drug stores in New York, one, founded more than a century ago, by Jacob Schiefflin, in 1794, is still, under the control of his descendants. The firm of Powers & Weightman, of Philadelphia, began business under the name of Farr & Kunzi, in 1818, while the first drug store in Washington was opened by Frederick Miller in 1796. The oldest drug house in the West is probably that of T. H. Hinchman & Sons, of Detroit, Mich. The earliest wholesale druggists in Chicago were Dr. Clark, Dr. Brinkenhoff—now Peter Van Schaack & Sons—and Dr. John Sears, while among the other wholesale houses doing business in New York three-quarters of a century ago one may mention the firms of Lawrence & Keese, J. A. & W. B. Post, Thomas S. Van Wyck & Sons, John of Bradhurst, R. & S. Murray, Silas Carle, Oscott & McKesson, now represented by two firms, Dodge & Oscott and McKesson & Robbins, and John C. Morrison. Among the manufacturers of medicinal chemicals the following firms are worth mentioning: Jos. S. Son, of Philadelphia; Charles Cooper & Company, of New York; Mallinckrodt Chemical Works, of Saint Louis; Larkin & Scheffer, of Saint Louis; Hirt & Frerichs Chemical Company, of Saint Louis, and the New York Quinine and Chemical Works.

In 1850 Haskell & Merrick put upon the market a select line of drugs, including morpine, chloroform, ether, galenical extracts, opodeldoc, mercurial and some other salts. At that time Philadelphia was the centre of trade for English chemicals, Boston for East India drugs, and New York for Spanish, French, German and Italian drugs and preparations. In the decade following many fluid extracts and some glycerine extracts were added to the list of ready made supplies. One of the pioneers in the manufacture of pharmaceutical preparations was Dr. E. R. Squibb, a past assistant surgeon in the United States Navy, who organized and ran the United States Naval Laboratory from 1854 until 1858. The enormous demand caused by the Civil War was the incentive for the establishment of his remarkable laboratory. Among the other pioneer manufacturers are the Tilden Company, of the New England Paint, Stoving, Color & Chemical Company; the Tilden Company, of the New England Paint, Stoving, Color & Chemical Company; John Wyeth & Brother, and the H. K. Mulford Company, of Philadelphia; Parke, Davis & Company, and Frederick Stearns & Company, of Detroit, Mich.; the William S. Merrill Chemical Company, of Cincinnati; Eli Lilly & Company, of Indianapolis, and Charles S. Baker & Company, and the Searle & Hereth Company, of Chicago. The pioneer manufacturer of druggists' balances, or fine scales, was Henry Troemner, who came to this country from Marburg, Germany, in 1836, and two years later, started business in Philadelphia. Prior to this time the scales which were required by druggists had been made to order by jewelers.

The present volume of the drug trade in the United States can only be approximately estimated, as the data are inexistent. The drug trade is closely allied with those of the chemical industry (q.v.). The most accurate survey to be made is with the aid of the figures recorded by the United States Census of Manufactures for 1914, which gathered separate statistics relating to the manufacture of "druggists' preparations," "patent and proprietary medicines," and "perfumery and cosmetics." Reports were received from 4,082 establishments whose combined products were valued at $172,008,946. Of the total number, 850 were located in New York, 391 in Illinois, 353 in Pennsylvania, 267 in Ohio, 234 in Missouri, 179 in Massachusetts, 155 in Michigan, 142 in California, 134 in New Jersey, 107 in Minnesota, and the remaining 1,109 scattered among 34 other States.

The manufacture of druggists' preparations was reported by 438 establishments with products valued at $48,624,966. Liquid preparations, such as tinctures, fluid extracts, and medicinal syrups, were valued at $13,900,402; and of pills, tablets, powders, etc. at $10,903,056. The manufacture of alkaloids and their derivatives, such as cocaine, codeine, morphine, etc., of which in 1909, 1,729 establishments in New York, with products valued at $11,493,168. The production
of synthetic medicinal preparations, such as aspirin, salicylic acid, salicylate, etc., was reported by 72 establishments, with an output valued at $1,384,996. Medicinal metals and their salts, bromides, citrates, bismuth, etc., were produced at 47 establishments, their output being valued at $732,307. Serums, vaccines, toxins, and other biological products were prepared at 93 establishments, their output valued at $6,223,475.

The manufacture of patent and proprietary medicines and compounds, including household ammonia, insecticides, fire extinguisher compounds, etc., was reported by 3,085 establishments, with products valued at $105,665,611. These figures show an increase in the number of establishments since 1909 of 8.7 per cent, and an increase in the value of products by 26.1 per cent. The larger part of this business was carried on in New York State by 617 establishments—as compared with 300 in Illinois, 275 in Pennsylvania, 209 in Missouri, and 156 in Ohio.

Perfumery and cosmetics, including cologne and toilet waters, face powders, cold cream, etc., were made by 559 establishments, their output being valued at $17,718,369. These figures show a large increase in both the number of establishments engaged and the value of the products, amounting to 30.3 per cent in the first instance and 24.7 per cent in the second. New York claimed the largest share in this industry with 175 establishments, followed by Illinois with 67, Pennsylvania with 45, and Ohio with 34.

The enormous increase in the consumption of medicines in the United States is indicated by the fact that the United States in 1880 had 48,333 prescriptions; in 1910, 81,347 prescriptions. This increase is due to the greater use of medicines by the practitioners of the healing art and the greater public demand for them. The importation of opium and its alkaloids amounted to the equivalent of 1,200,000,000 average doses of morphine. It is worthy of note that in the case of morphine the importations are less than one-third of their normal volume before the war. A much larger effect is shown in the importations of medicinal preparations, which in the year quoted amounted to a value of but $181,643, while in 1913 their value was $1,621,520.

One of the interesting features of the American drug trade has been the introduction of the drug trade carried in stock in the Orient. A few of these are very closely allied to the drugs of the American store, and with practically the same medicinal value. Most of the "remedies," however, are the grotesque collection of triturated deer horns, ginseng roots, curiously sculptured gourd seeds, and magical charms of various kinds and alleged potencies.

**DRUGGET—DRUID**

**DRUGGET**, a coarse and flimsy texture originally half silk and half wool, widely used for covering carpets. It was formerly extensively employed as an article of clothing by the poorer classes, more especially of females; but this and similar fabrics are now almost wholly superseded by cotton goods, which induce greater comfort.

**DRUID**, a member of the Celtic priesthood of ancient Britain and Gaul, which at the period of the Roman invasion existed chiefly in Brittany and along the valley of the Loire, and in the island of Anglesey, in Wales and in Ireland. Scattered throughout these regions, at Carnac in Brittany, at Stonehenge and Avebury in England and numerous other localities, are the stupendous stone structures, known as cromlechs, menhirs, dolmens, kistvans, etc., ascribed by the older archeologists to the druidical cult, and still popularly known as druidical temples and altars, but now assigned by scientists to prehistoric palaeolithic and neolithical predecessors, although it is probable these megalithic monuments were used by the Druids in their mystic rites to impress the populace. The Welsh tradition relates that the Druids, led by a man named Gaul from the Orient with the Celtic Kymric race, and their religious practices have been variously described as of Hindu, Persian and Egyptian origin. Accurate knowledge of the sect is limited owing to the inviolable practice of not allowing their history to be written, all their lore being committed to memory, and all instructions being imparted orally. The best ancient and contemporary account of the Druids is that by Julius Caesar, who thus describes them: "They attend to divine worship, perform public and private sacrifices and expound matters of religion. A great number of youths are gathered round them for the sake of education and they enjoy the highest honor in that nation, for nearly all public and private quarrels come under their jurisdiction, and when any crime has been committed, when a murder has been perpetrated, when a controversy arises about a legacy or about landmarks, they are the judges, too. They fix rewards and punish offenders. The fiscal year ended on the 30th June, 1916, an amount of quinine was imported into the United States sufficient to make 2,000,000,000 average doses—an equivalent of 22 doses for every man, woman and child in the population. The importation of opium and its alkaloids amounted to the equivalent of 1,200,000,000 average doses of morphine. It is worthy of note that in the case of morphine the importations are less than one-third of their normal volume before the war. A much larger effect is shown in the importations of medicinal preparations, which in the year quoted amounted to a value of but $181,643, while in 1913 their value was $1,621,520.

One of the interesting features of the American drug trade has been the introduction of the...
founded in Britannia and thence transplanted into Gaul. Even nowadays, those who wish to become more intimately acquainted with the institution generally go to Britannia for instruction's sake.

"The Druids take no part in warfare; nor do they pay taxes like the rest of the people; they are exempt from military service and from all public burdens. Attracted by such rewards, many come to be instructed by their own choice, while others are sent by their parents. They are reported to learn in the school a great number of verses, so that some remain there 20 years. They think it is an unholy thing to commit their lore to writing, though in the other public and private affairs of life they frequently make use of the Greek alphabet. . . . Beyond all things, they are desirous to inspire a belief that men's souls do not perish but transmigrate after death from one country to another; and they hold that people are thereby most strongly urged to bravery, as the fear of death is thus destroyed."

Besides being priests and teachers of religion the Druids were also diviners, astronomers, astrologers and magicians, and were versed in the mysterious powers of animals and plants; the oak-tree, the mistletoe when growing on the oak, the vervain, the hyssop and marshwort were held in especial reverence among them, and like the Romans, they drew auguries and prophecies from an inspection of the entrails of sacrificed animals and from the flight of birds; their mysterious rites were usually performed in the depths of oak forests. The order was divided into three classes: vates or prophets, bardic or poetasters, and the latter had deprived them of much of their political power. The Druids exerted all their powers to oppose the Roman conquerors and continually incited the people to rebellion, until they were driven out of Britain into Wales, and finally gathered in the remains of Angles who were attacked by Suetonius Paulinus in 61 A.D., and in 78 A.D. were utterly subdued and almost exterminated by Agricola. (See DRUIDS.) Consult Rhys, 'Lectures on the Origin and Growth of Religion as Illustrated by Celtic Heathendom' (London 1888).

**DRUID STONES**, a name given in England and other parts of the country to weather worn, rough pillars of grey sandstone which are scattered over the surface of the chalk-downs in England, in Scotland and its islands, and which exist in great numbers in other countries; generally in the form of circles or in detached pillars; it is not certain, however, that the Druids had any connection with these stones.

**DRUIDS, The United Ancient Order of.** This fraternal and benevolent society takes its name and nomenclature from the history of the Druids of Gaul and Britain. They were the religious guides of the people and the chief guardians and expounders of the law. They taught the immortality of the soul. Their chosen retreats were groves of oaks, and the remains of their temples are circular cromlechs and dolmens of immense stones. They attained their greatest influence in Britain shortly before the Roman invasion, during the last century B.C. They were believed to have incited the patriotic revolt of the Britons against Roman rule; and Agricola, when he cut down their sacred groves and destroyed their temples, when the Druids who escaped fled to the island of Iona. Upon the conversion of the Britons to Christianity, Druidism became only a venerable memory and tradition. Its nomenclature and traditions form the picturesque background of the ceremonies of the modern order of fraternity and benevolence. The modern order was formed in England in 1781 and its centennial was celebrated in America by enthusiastic meetings and addresses in a number of cities. It was introduced into the United States about 1830, but the earliest society died out. A permanent beginning, however, was made in George Washington Lodge, No. 1, instituted in New York in 1839. The order has reached membership in the United States of 30,968; in England, Australia and Germany, 302,247; total membership, 333,215. The order has paid since its introduction in the United States in sick benefit and other relief the sum of $7,141,772.53. The relief granted during the fiscal year 1915 was $103,776.53. In the nomenclature of the order the name Grove is used commonly as the name lodge in other orders. The higher body in a State is called a Grand Grove and different Grand Groves are under the Supreme Grove, which is the head of the Order. The Supreme Grove have the power to make laws for its own government and for the government of its State, Grand and Subordinate Groves. The Order is in union with the Order in England, Australia and Germany. The Order is a moral, social and benevolent society. Its principles and teachings are derived from Ancient Druidism and are founded on reason and sound morality. They do not conflict with any of the established systems of religion and are perfectly compatible with the peace and welfare of the State. No one is administered by the Order binding its members to any creed or faction; in becoming Druids they are still free men. Its so-called secrecy is not a cloak for evil but simply a protection against abuse of its beneficial provisions. Its objects are: to unite men together, irrespective of nation, tongue or creed, for mutual protection and improvement; to assist socially and medically by timely counsel and instructive lessons; by encouragement in business and assistance to obtain employment for those in need; and to foster among its members the spirit of fraternity and good fellowship. Its well-regulated system of dues and benefits provides for the relief of the sick and destitute, the burial of the dead and the protection of the widows and orphans of deceased members. Members of subordinate Groves must be of 18 years of age or upwards, of sound health and character, and are elected on the proposal of members. To promote the prosperity of the Order and cultivate the perfection of its members, Druidic Chapters have been organized. All members in good standing who have attained the third degree, are eligible. In order
to provide women an opportunity to participate in the benevolent work, Circles have been established, to which Druids in good standing and all acceptable women 18 years of age are eligible.

DRUILLETTES, drwëyet, Gabriel, Jesuit missionary: b. France 1610; d. Quebec 1681. He entered the order in 1639 and was sent to Canada in 1643. In 1646 he was sent on a mission to the Abenakis and was the first white man to make the overland journey from Quebec to the seaboard of Maine. In 1650 he was sent by the French authorities on a trade reciprocity and mutual defense mission to the United Colonies of New England and was cordially received at Boston. He returned in the following year with definite proposals for a treaty, which, however, were formally declined. On going back to Canada he resumed his missionary task and in 1671 was put in charge of the mission at Sault Sainte Marie.

DRUM, a musical instrument formed by stretching parchment animal skin over the heads of a cylinder of wood or over a bowl-shaped metallic vessel. There are three kinds of drums. (1) The long drum or bass drum with two heads, held laterally and played on both ends with stuffed-knob drumsticks. This is the ordinary drum used by an infantry or marching band. It is employed mainly to mark the time and also to increase the ferocity. The big drum, or grosse caisse, of the modern orchestra, is a modification of the ordinary drum, with the diameter greatly increased and the length of the cylinder lessened. It is struck on one side only. (2) The side-drum, having two heads, the upper one only being played on by two sticks of wood; the lower head has occasionally strings of catgut stretched across its surface, and then it is called a snare drum. It is the side-drum of the fife and drum bands. It is occasionally employed in the orchestra for special effects. (3) These are either the small kettle-drums of the cavalry band, played on horseback, or the proper orchestral drums, larger in size but similar in construction. They are generally tuned to the tonic and dominant of the composition in which they are used, but this rule is not without exceptions. The tambourine is a species of drum, consisting of a single skin on a frame or vessel open at bottom. The heads are tightened by cords and braces or by rods and screws.

The drum was a martial instrument among the ancient Egyptians, as the sculptures of Thebes testify. Their long drum was like the Indian tom-tom, beaten by the hand. It was about 18 inches long, had a case of wood or metal and heads of prepared skin, resembling parchment. These were braced by cords in a manner somewhat similar to the modern. The instrument was carried by a belt and was slung behind the back on a march. The invention of the drum is ascribed to Bacchus, who, according to Polygenus, gave his signal of battle by cymbal and drum. It was, however, known in very early ages and in some form or other among almost all nations.

DRUM, a Celtic word common in Ireland and Scotland, signifying a knoll, ridge or small hill, frequently found alone as the name of a village, farm, estate, etc., and often also as a prefix, as in Drumalbin, Drumderrg, Drumlanrig, Drummossie, etc. Irish geologists give the name to all elevations.

DRUMCLOG, Scotland, a place in Lanarkshire, on the borders of Ayrshire, 16 miles southeast of Glasgow. In 1675 Drumclog was the scene of a battle in which the Covenanters defeated the Royalists. The battle is described in Scott's 'Old Mortality.' A monument marks the scene of the encounter.

DRUMFISH, or DRUM, certain fishes of the family Scianida (g.v.), so-called from the resonant sound which they produce in the water by forcing gas through the air bladder. In the United States the name is especially applied to the following. The common drumfish (Pogonias chromis) which has a short stout body, numerous barbels on the lower jaw, and large pavement-like teeth on the pharyngeal bones. It is one of the largest of food fishes, though the flesh is not highly valued. The drumfish is common on sandy shores south of Long Island and is caught on lines thrown into the surf. By means of its powerful dentition the shells of the stoutest mollusks and crustaceans are crushed and their contents devoured. At times schools of drumfish create great havoc on oyster beds. The red drum or red-fish (Scianops ocellota) is a small fish, weighing from 10 to 75 pounds, and distinguished by the separate lower pharyngeal bones, the absence of mandibular barbels, and the eye-like spot at the base of the tail. It is one of the most important game and food fishes of the southern United States, especially in Texas. The black drum (Sciana delicosa) is a closely allied dusky bluish species found in the warmer parts of the Pacific coasts of America. The fresh-water drum or sheepshead (Eledone grunniens) is closely related to the common marine drumfish, from which it differs in the absence of barbels. It ranges from the Great Lakes, where its flesh is coarse and rank and of little value for food, to Texas, where it becomes a fine-flavored and important food fish. It sometimes exceeds 50 pounds in weight.

DRUMLIN, a smoothly rounded oval hill of unstratified boulder clay, or till, formed beneath the great ice sheets of the glacial period. Drumlins are most frequently found near what was the front of the ice sheet, and, by their peculiar form, are easily recognized. They are usually over half a mile long and from 100 to 200 feet high and occur with their longer axes parallel to the direction of ice movement. Drumlins are of common occurrence in Massachusetts, particularly about Boston harbor, where some form islands. They are also abundant in western New York and in southern Wisconsin. Their method of formation is uncertain, though they plainly represent material gathered beneath the ice sheet and in some way piled up by it. See Drurr; Glacial Period.

DRUMMOND, Sir George Gordon, English soldier: b. 1772; d. London, 10 Oct. 1854. He entered the British army as ensign in 1789; became lieutenant-colonel of the king's Liverpool regiment in 1794. In 1793-96 he served in the West Indies and in the Egyptian campaign. In 1805 he became major-general and was appointed in command of a division in Jamaica, which post he held for several years. He was on duty in Canada 1808-11, and
promoted lieutenant-general 1811. He was again ordered to Canada as second in command under Sir George Prevost 1813; planned and effected the capture of Fort Niagara; planned the success, in which he was second in command, against Oswego and destroyed the American works and stores, May 1814. He was in command of the British forces at the battle of Lundy's Lane 25 July, and in August invested, but failed to capture, Fort Erie. After being promoted general 1825, he was again transferred to the colony of his old regiment.

DRUMMOND, Henry, Scottish geologist and religious writer: b. near Stirling, 17 Aug. 1851; d. Tunbridge Wells, 11 March 1897. He was educated at the universities of Edinburgh and Tübingen; entered the ministry of the Free Church, and having devoted much attention to science, was in 1877 appointed lecturer on natural science in the Free Church College, Glasgow, being made professor of theology in 1884. One of his most popular books was 'Tropical Africa' (1888), giving his own experiences in that part of the world. His most remarkable work, and the one by which his name became most widely known, is 'Natural Law in the Spiritual World' (1883), which has passed through many editions and been translated into various languages. This work was written with the object of showing that such scientific doctrines and theories as those associated with the name of Darwin and his full work were not inconsistent with revealed religion. He was also author of 'Travel Sketches in Our New Protectorate' (1890); 'Pax Vobiscum' (1890); 'The Programme of Christianity' (1892); 'The Greatest Thing in the World'; 'The Ascent of Man' (1894). The last-named work is a semi-popular review of evolution theories which caused some controversy on its first appearance, mainly on account of its author's insistence on the recognition of altruism, or 'the struggle for the life of others,' as the most important factor in organic and especially in social evolution. His facile and terse style of composition suited the tastes of large numbers of readers. Consult 'Life' by G. A. Smith (1898).

DRUMMOND, James, English Unitarian theologian: b. Dublin, Ireland, 14 May 1835. He was educated at Trinity College, Dublin, entered the Unitarian ministry and became professor of theology at Manchester New College in 1869, succeeding Rev. James Martineau (q.v.) as its principal in 1883. He removed with the college to Oxford in 1889, and retired in 1906. He has published 'Spiritual Religion: Sermons' (1870); 'The Jewish Messiah' (1877); 'Introduction to the Study of Theology' (1884); 'The Character and Authorship of the Fourth Gospel' (1904); 'Studies in Christian Doctrine' (1908); 'Johannine Thoughts' (1909); 'Lectures on the Composition and Delivery of Sermons' (1910); 'Paul: his Life and Teaching' (1911).
As a historian, Drummond is chiefly remarkable for an ornate style, and a strong attachment to the literature and antiquities of the Jacobite party. His 'History of the Reigns of the Five Jameses' was published several years after his death. An ardent Royalist, he was forced to sign the Covenant, and it is said that the news of the execution of Charles I hastened his death. He is now remembered only as a poet, although tinged with the conceits of the Italian school, there is much genuine imagery and truth of feeling in all his poetry, but particularly in his sonnets, which are replete with tenderness and delicacy. He wrote in English, and not in his native Scots. See 'Memoir, by Ward (1894); 'Life,' by Masson (1873).

DRUMMOND, William Henry, Canadian poet: b. County Leitrim, Ireland, 13 April 1854; d. 6 April 1907. In early life he came to Canada; had an education at McGill University, Montreal, and in 1884 was graduated in medicine at Bishop's College, Lennoxville, province of Quebec. Here for some time he taught medical jurisprudence. He established his practice in a mixed community of Indians, French-Canadians, Scotch-Irish and English, which to his unusual powers of observation offered a splendid field for character study. He is especially successful in portraying the French habitant of the forest and lumber camp. His works include 'The Habitants,' and other French-Canadian Poems' (1887); 'A Canoe and Madeleine Vercheres' (1886); 'Johnnie Courteau and Other Poems' (1901); 'The Voyageur and Other Poems' (1905); 'The Great Fight' (1908). In 1912 appeared 'The Poetical Works of William Henry Drummond,' with an introduction by Louis Fréchette and an appreciation by Neil Munro. Consult 'English-Canadian Literature,' on Canada and its Provinces' (Vol VI, Toronto 1914).

DRUMMOND ISLAND, the extreme west of the Manitoulin chain, in Lake Huron, belongs to Chippewa County, Mich. It measures 20 by 10 miles.

DRUMMOND LIGHT. See DRUMMOND, Henry; Calcium Light.

DRUMONT, drū'mon', Édouard Adolphe, French journalist: b. Paris, 3 May 1844. He entered the government service, which he later abandoned to become a contributor to the press. He published several works, many of which were violently anti-Semitic in character. His 'Mon vieux Paris' (1879) was crowned by the academy. In 1892 he founded La Libre Parole as an organ for his views. In 1898-1902 he was for Algiers in the Chamber of Deputies. His works include 'La France juive devant l'opinion' (1886); 'La fin d'un monde' (1888); 'Dernière bataille' (1890); 'Testament d'un antisémite' (1891); 'Secret de fourmis' (1892); 'De l'or de la boue du sang' (1893), dealing with the Panama Canal exposed; 'Les Juifs et l'affaire Dreyfus' (1899); 'Vieux portraits, vieux cadres' (1900). Consult Arnaudin, Stéphane, 'M. Édouard Drumont et les Jésuites' (Paris 1902).

DRUNKENNESS, the mental and physical condition resulting from excessive drinking of intoxicating liquors. In law, it is considered an absolute defense, although in some cases, depending on the nature of the act, and to what extent the person was under the influence of intoxicating liquors, deprives himself of his reason, he cannot offer it as a defense for acts which he commits while intoxicated. If the person is intoxicated to such an extent as to be a disease, such as delirium tremens, or mania a potu, a different question is raised, and, in the first case, it will reduce the offense and in the second case there are some decisions which go so far as to hold that it is a complete defense.

The general rule is that contracts made by a person under the influence of liquor are voidable and not void; so that if a person while intoxicated makes a contract under which some innocent third person, for value, acquires rights, the contract is binding on the person making it, although he was under the influence of liquor at that time. If a person makes a contract when so far under the influence of liquor as to be deprived of his senses, and the contract is so one-sided as to be unreasonable and unfair fraud may enter into the transaction. In cases where a person is tried for murder in the first degree, to prove that crime the evidence must show, according to the statute defining murder in the first degree, malice aforethought. Now it has been held that an excessive intoxication excludes the malice and only passion is shown and the crime is reduced below murder in the first degree. But the person accused must prove intoxication to such an extent that passion and not malice will be shown. Although if a person, while sober, makes all preparation to take a person's life, and then, before committing the crime, becomes intoxicated, doing an act when intoxicated which he was afraid to do when sober, it would be murder in the first degree. In cases of robbery, it is presumed the goods are taken with a felonious intent, but if the accused can prove sufficient intoxication, the felonious taking is not presumed. When a person is tried for an act and the defense is provocation, the amount of provocation to make a good defense would be less when the person who gave the provocation was intoxicated than if he was sober and in his right senses. In itself drunkenness is not a legal offense, though drunken conduct in public may be a nuisance and as such is often made a statutory offense, punishable by fine or imprisonment. Habitual drunkenness may also render a drunkard liable to a judicial inquisition for the appointment of a guardian of him and his property. Such a proceeding is instituted by wife or children or next of kin on the ground of his incompetency to look after his property or manage his business affairs. (See Alcoholism; Disproportion; Intoxication; Temperance; Consult Bishop, 'Commentaries on Non-Contract Law' (Boston 1874); Kent, 'Commentaries on American Law'; Pollock, 'Principles of Contract in Law and in Equity' (2d Amer. ed. by G. H. Wald, Cincinnati 1885); Woodruff, 'Cases on Domestic Relations and the Law of Persons' (New York 1897).

DRUPE, in botany, a simple, succulent stone-fruit composed of a single monosperous carpel, of which the carpellary leaf becomes
fleshy at its external division, and ligneous in its internal division, as in the peach, cherry, plum, olive, etc. The stone which encloses the kernel is the endocarp; the pulpy, or succulent part, the mesocarp. In the horse-chestnut and coconuts, the mesocarp is not so conspicuous, and in the date the endocarp is replaced by a membrane.

DRURY, Alfred, English sculptor: b. London. His art education was obtained at the National Art Training School, South Kensington, and in Paris under Daulou. His principal works are 'The Triumph of Sithem' (1885); 'Circe' (1893); 'St. Agnes' (1894); 'The Age of Innocence' (1897); 'Prophetess of Fate'; 'Little Duchess' (1900); 'Innocence' (1902); 'King Edward VII' (1903).

DRURY, Dru, English silversmith and entomologist: b. 4 Feb. 1725; d. 15 Dec. 1803. He was devoted to the study of entomology and to collecting exotic insects and published 'Illustrations of Natural History' (1770-82), with upwards of 240 figures of exotic insects. His 'Illustrations of Exotic Entomology' was edited in 1837 by Westwood and appeared with nearly 700 figures by Moses Harris.

DRURY COLLEGE, a coeducational institution in Springfield, Mo.; founded in 1873 under the auspices of the Congregational Church. In 1916 the college had 30 professors and instructors and 350 students. The library contained about 32,000 volumes.

DRURY LANE THEATRE, a famous place of amusement in London, located in Russell Street, near Drury Lane. It was first opened in 1663, and was rebuilt by Sir Christo-
pher Wren and reopened in 1674. It was again rebuilt in 1794. The present edifice was opened in 1812, with a prologue by Lord Byron, the advertisement for which gave rise to the famous 'Rejected Addresses.' Garrick opened the theatre in 1747 with Dr. Johnson's prologue and most of the great English actors have trod the boards which are now given over for the most part to pantomimes and spectacular pieces.

DRUSE, a surface covered with projecting crystals. Also a cavity lined with small crystals, in teaching, language. The adjective drusy means covered with small crystals.

DRUSES, a people of Syria, scattered over an extensive tract of country lying to the south-east of Beirut, and south of the country occupied by the Maronites; or, more particularly, they occupy the southern parts of Lebanon and Anti-Lebanon (the slopes of Hermon), while considerable numbers also inhabit the Hauran (south of Damascus), where the mountainous tract occupied by them is now often designated the Druse Mountain. The total Druse population is estimated at from 100,000 to 150,000. In the northern districts occupied by them they are mingled with the Maronites, but many towns and villages are peopled almost exclusively by the Druses. There are some circumstances which tend to show that the Druses are not indigenes to the territory they now possess, although they have long since dropped their own language and adopted the Arabic. They were in Lebanon and Anti-Lebanon as early as the 11th century. The peculiar interest attaching to this people belongs, however, more to their political constitution and their religion than to their origin. Politically the Druses are divided into two parties, that called the Jumblaites, with the family of Jumblat at their head; and the Yezbe-
iches, with that of Abou-Nakid at their head. These two parties live in almost constant strife, except when they have a common foe to contend against, when they forget their internal dissensions and unite their strength for offense and defense. Their religion is a curious mixture of Judaism, Christianity, and Islamism. They believe in one God, who is the only being to whom worship ought to be paid. According to their religious books he cannot be defined by any of the qualities belonging to created beings. The doctrine of the unity of the Deity does not admit, in their view, even of the consideration of any quality or attribute existing in him. They profess to believe in the unity of God with the abstraction of every quality and mode of existence. The Druses also believe that God has at different times appeared to men in a human form, and that his last appearance was in the person of Hakem, of Egypt, who announced himself at Cairo as a divine incarnation about 1030 A.D. They therefore regard Hakem as God, and they believe that he will one day return to earth, cause their resurrection, and punish the unbelieving. They have neither prayers, fasts, nor festivals and with the excep-
tion of a privileged class, the Akals, or initiated, they have no worship. When they go among the Turks they behave as Mussulmans; and in the midst of the Christian community of the Maronites they enter the Christian churches and imitate the Christian believers in the use of the holy water. The uninitiated, called Jahils, are exempt from all religious duties whatever.

The Druses have also a distinctive moral code. They have seven commandments, a number taken from the sacred writings of the Moham-
edans. The following, according to Hamsa, are their seven commandments, or cardinal principles:

1. Truthfulness; 2. mutual defense;
3. renunciation of all other religions; 4. the name of Hakem, of Egypt, who announced himself at Cairo as a divine incarnation about 1030 A.D. They therefore regard Hakem as God, and they believe that he will one day return to earth, cause their resurrection, and punish the unbelieving. They have neither prayers, fasts, nor festivals and with the excep-
tion of a privileged class, the Akals, or initiated, they have no worship. When they go among the Turks they behave as Mussulmans; and in the midst of the Christian community of the Maronites they enter the Christian churches and imitate the Christian believers in the use of the holy water. The uninitiated, called Jahils, are exempt from all religious duties whatever.

The Druses have also a distinctive moral code. They have seven commandments, a number taken from the sacred writings of the Moham-
edans. The following, according to Hamsa, are their seven commandments, or cardinal principles:

**DRUSUS, Nero Claudius, Roman general:** b. 38 B.C.; d. 9 B.C. He was the first Roman general to cross the Rhine and the German Ocean. He became proconsul (11 B.C.), but returned in the next spring to Germany, subdued many tribes as far as the Weser, and commenced the erection of fortresses. On this account he was appointed proconsul; the army saluted him with the title of **imperator**, which was not, however, sanctioned by Augustus. In 9 B.C. he was made consul, but returned soon after to Germany, and penetrated as far as the Elbe. The canal uniting the Rhine with the Yssel (Josts Drau) was his work; and the place called Drusenheim, in Alsace, where he encamped for some time, received its name from him.

**DRUZHININ, droozhë-nin, Alexander Vasilevich,** Russian critic and man of letters: b. 8 Oct. 1824; d. 1864. He received his early education in his father's home where he acquired a solid knowledge of foreign languages. At the age of 16 he joined the Page-Corps where he spent his free moments in writing humorous verses depicting scenes of the school life. After graduation he was sent to the garrison in Finland but military life did not agree with him and, in 1851, he resigned and dedicated himself entirely to literature. His first attempt in the field of fiction 'Polinka Sachs' (1847) was a masterpiece which had a brilliant success. Encouraged by this triumph the young author produced in rapid succession three novels: 'The Story of A. Dimitrievich,' 'Fraulein Wilhelmine' and 'Zhuli.' Soon afterward he began writing criticisms in his famous 'Letters from an Out-of-town Subscriber' which, although written in a humorous style, were eagerly read and earned for him the reputation of the greatest critic of his time. In 1850 his very humoristic work 'A Sentimental Trip of Ivan Chernokozhnikov' produced a scandal in the literary circles of the capital, but nevertheless gained great popularity for its author who often afterward took 'Chernokozhnikov' (the 'Red-Skinned one') as his favorite pseudonym. As editor of the magazine 'Biblotecha Dlya Chitatelia,' he translated magazine dramas of Shakespear and wrote a number of essays on English literature. As a novelist he is profuse, verbose and heavy and shows a powerful, though not beneficent, influence of English master novelists. But as a critic he is a stubborn defender of the purely artistic in literature condemning the didactic element which prevailed in a large measure in the Russian literature of his time. He asserts that the author's creation wing is criminally curtailed by a vain desire to educate his readers. By means of his elegant tone, unimpeachable impartiality, subletness and astuteness, he obtained even from his adversaries the epithet of 'honorable knight.' Consult Starchevski, A. B., 'Nabludatel,' (1885, Nos. 4 and 5); Kiprianovik, A. L., 'Istorich, V yeastik,' (1884, No. 4).

**DRY CARBON PROCESS OF ARMOR PLATE.** See Armor Plate.

**DRY DOCK.** See Dock.

**DRY FARMING.** The phrase "dry farming" is a misnomer, for it implies the growing of crops without the use of water, which is altogether impossible. But in United States territory west of the 97th meridian, in that region once familiarly known as The Great American Desert, the phrase is popularly used to describe all those efforts that are made to produce crops without irrigation.

Dry farming is the careful culture of the soil to the end that as large a percentage as possible of the moisture that falls be made available for the growth of the plant, instead of passing off into the atmosphere by evaporation.

The assumption behind dry farming is that moisture sufficient falls, if it can be conserved in the soil, to produce a great variety of crops where it is commonly supposed that precipitation is inadequate to supply the moisture needed by a growing crop.

It has been demonstrated after many years of experimental work in places widely scattered in what is known as semi-arid America that a very large percentage of the moisture that evaporates from the soil can be conserved by intensive cultivation of the soil. If the soil is tilled intensively 12 inches of precipitation are sufficient in the semi-arid portions of the United States to produce crops adapted to a particular locality. Over a very large portion of the semi-arid area of America the annual precipitation ranges from 12 to 24 inches.

The importance of dry farming in the economic development of the western part of the United States may be appreciated when it is known that more than one-third of the total land area of the nation is contained within the area once known as The Great American Desert and now called semi-arid America. There are upwards of 600,000,000 acres in this region, a goodly portion of which can be made useful for agriculture by now-known methods.

There was formerly a popular idea to the effect that precipitation in what is known as the semi-arid regions of the United States was not sufficient to make agriculture possible and profitable. This idea is erroneous. Over more than half the total semi-arid area—the northern half—the annual precipitation in form of both rain and snow is sufficient, when coupled with intensive soil culture and seed selection, to make general farming as great a success as it now is in the great prairie states of the Middle West.

**Summer Culture.**—The purpose of summer culture is to store up in the soil one season's moisture before a crop is planted, though it does not follow that no crop should ever be planted on newly-broken prairie. In fact a crop of peas does very well on such land and the same fall a crop of wheat may be planted with excellent results, if surface cultivation is carried on the following spring before the wheat is very high.

If the field is summer tilled for the purpose of storing moisture, it should be plowed again about eight or nine inches deep. This time the plow should be followed by an implement with wedge-shaped wheels turning on an axle known as the subsoil packer. It presses the soil down-
ward and sideways at the same time, but it does not pack too hard. It leaves a loose and open and the harrow completes the work of creating the soil mulch again.

This sub-surface packing is regarded as very important. All water moves in the soil as oil moves up a lamp wick, by what is known as the process of capillarity. If the solid soil column is interrupted or broken by large air spaces beneath the surface, the movement of the moisture will be interrupted, and large air spaces in the sub-soil tend to increase the evaporation, for they suck up the moisture from below.

It is not considered absolutely necessary to the success of dry farming to summer till for one whole season in advance of planting a crop as outlined here. But unless the farmer intends to devote himself assiduously to the cultivation of the acreage which he plants after carefully preparing the seed bed, it would be far better to summer till—that is, produce no crop the first season but harrow the ground frequently and store the moisture that falls.

Fundamental Principles.—The principles that have been developed and sub-surface plowing are an evolution. It was at first believed by many that spring plowing was most advantageous, so as to open up the soil for moisture, but it developed that the best results were had by fall plowing, which allowed the snow and water to gather and lie in the furrows through the winter, and to follow with regular cultivation in the spring, especially after rains. It also developed that deep plowing secured better results than shallow plowing, and that the sooner after harvest the plowing was done, the more moisture was conserved.

As soon as the crop is harvested, in fact on the same day, the stubble should be disced so as to again create a mulch and check evaporation from below. When a hot July sun falls upon the open surface of a grain field that has been protected by the grain itself from the sun's direct rays for so long, the rapidity with which moisture leaves the soil and is absorbed by the atmosphere is incredible. As soon as possible after the work of discing has been completed the field should be plowed to a depth of eight or nine inches, the sub-surface packer again brought into use, the surface harrowed, and the crop planted.

Late winter seeding is now strongly urged, and is becoming the established practice. It has been demonstrated that thin seeding is far better than sowing plenty of seed, on the theory that the plants, having scanty moisture to draw upon, should not be crowded.

In western Kansas and Nebraska and eastern Colorado and northern New Mexico fall wheat should be sown from the 1st till the 20th of September. Early the following spring the field should be harrowed several times till the wheat is large enough to shade the ground well. In Colorado, with only a foot of annual rainfall, the 1915 wheat crop was over 12,000,000 bushels, the corn crop was nearly as great, and the oats production attained 12,600,000 bushels, while the hay crop of 2,238,000 tons was worth $17,000,000. Utah, with 16 inches of rainfall, has an annual production of over 5,400,000 bushels of oats and $8,500,000 worth of hay. Montana, with a rainfall of 13 to 19 inches, produced in 1915 26,000,000 bushels of oats and nearly 31,
000,000 bushels of wheat, besides over $15,000,-
000 worth of hay. Such results speak volumes for intelligent methods.

Dr. John A. Wiltsoe, president of the State
Agricultural College of Colorado, and author of the arid-farm law of Utah, advises that
profitable farming by dry methods should be
possible anywhere, with 12 or more inches of rainfall. He is a strong advocate of deep
plowing in the fall, and emphasizes the im-
portance of cultivation of the soil in the early
spring and after every rain, in order that the
moisture may be well distributed and carry the
plant food where it can be reached by the
young rootlets. He mentions wheat, oats, bar-
ley, rye and lucerne as the crops that yield best
returns on dry soils.

A few years ago the government of British
South Africa sent William Macdonald on a tour
through the semi-arid regions of the United
States to study dry farming, and report whether
the methods used here were applicable to South
Africa, where there is much semi-arid land.
Mr. Macdonald was intensely impressed with
the accomplishments here, and wrote an en-
thusiastic report to his home government, com-
mending the holding of annual dry farming
congresses as is done in the States; advising the
establishment of five dry farm experiment sta-
tions in Pretoria, modeled after the American
stations; and urging the scientific study of crops
suitable for South African soils.

**D R Y  G O O D S  T R A D E, A m e r i c a n .** The
beginning of the dry-goods trade in America
dates from the time when the first colonists
landed, but for a long time after the first effort toward the settlement
of this country was made that the demands for
trading facilities resulted in the opening of the
first store. So far as the actual trade in Amer-
ican textiles was concerned it is difficult to say
just when or how it commenced, but as it is
impossible to imagine any time when people who
had been used to the advantages of civilization
would not have felt the need of a place to pur-
chase some kind of dress fabrics, it is pretty
safe to say that the original American shop-
keeper was soon compelled to add such mer-
chandise to his stock in trade, even if it did not
figure in his opening announcement. Of course,
in those days all stores were general stores, and
merchants handled, or tried to handle, every
article for which there was any great demand.

As the result their stock was of a most incon-
gruous character. There were cottons and silks
from India; there were velvets and woolens from various parts of Europe, and, side by side
with the most costly articles known to colonial
commerce, there were groceries, hardware, etc.

In the early days of the colonies, and even
for many years after the settlement of the coun-
try had assumed quite respectable proportions,
but little cloth was manufactured in America.
The textile trade, such as it was, was almost
totally of an import character. In the begin-
ing the retail dealers arranged for consign-
ments of their own, and they were naturally of
small value, but soon the wholesale merchant
became the importer.

So far as actual wearing apparel was con-
cerned, the greater part was made by the people
in their homes. The men of the households
raised the flax or wool, which was carded, spun,
and woven at home, for, at that period in our
history, the distaff, the spinning-wheel, and the
hand-loom occupied an important position at
every well-regulated fireside. Moreover, it was
by no means uncommon for the same hands that
made the cloth to fashion the home-made fabrics
into clothing for the use of the several members of the family. It was only the rich or more
prosperous members of the community who were
able to import their wearing apparel, to say
nothing of their bed and table linens, and some
years had passed before the customs tailor had
assumed a position of any considerable com-
nercial importance. Nowhere in America was the
 cultivation of cotton made a matter of much
attention, and, when its manufacture in anything
like an organized way began, it was, as in the
case of wool, confined to a few establishments
of crude construction and operation. They pro-
duced certain kinds of fabrics, it is true, but the
only importance that they can have for us to-day
lies in the fact that they marked the beginning
of the great industries which have since been
developed.

Really to comprehend the fact that the great
textile industry of our own time is a matter of
comparatively modern development it is only
necessary to remember that the inventions of
Hargreaves, Arkwright, Paul, Crompton, and
Cartwright, had scarcely become known in this
country at the close of the 18th century. At
this time our home products were confined to a
few coarse woolen cloths; a few laces, and some
sundries, in silk, and nothing more than coarse
sheeting and toweling in linen. In fact, during
the 18th century, even our imports of foreign
textiles were of most moderate proportions, be-
ing scarcely more than double the value of the
home products, for it was not until some time
after the close of the Revolutionary War that
American imports of textiles began to show any
marked increase in value. Prior to that time
the value of the dry-goods imported from other
countries ranged from $24,000,000 to $26,000,000
per annum, while the domestic product showed
an annual value of between $12,000,000 and
$13,000,000. Even when the American manu-
factures had grown to the point where this output represented the goods manufactured
in the households of the country, very little of
which ever appeared in the merchants' stock.

Comparatively populous as some sections of
the country were, the village stores outside the
centres of trade, were few and far between.
Having but little demand for anything like
costly grades of goods, the only textile products
which they sold were the coarser textures in
woollens, cottons and linens and these, with the
usual supply of to colonial commerce, there
were groceries, hardware, etc.

People living in the small towns that were located
upon the banks of the inland streams seldom
had greater trading facilities than those that
were offered by the flatboats and small vessels
from time to time with stock which was similar
in character to that of the village stores. Ped-
dlers also went through the country, thus aff-
ording the scattered inhabitants of the interior
an opportunity to make some of their purchases
from their meagre stock of wares.

In the cities, of course, there were both
wholesale and retail dealers in the various com-
mmodities. The wholesale establishments not
only imported such articles as were in most demand, but dealt in those products of home manufacture upon which they might realize the greatest profits. The shops of the retail dealers, however, resembled the country stores in that they sold almost everything that any customer might demand. It was here that the pretentious establishments of the larger cities that there was any apparent tendency toward separate classification, in one or two instances dry-goods and notions being sold to the exclusion of everything else. In one sense of the word these conditions were largely due to the circumstances of the people. The custom of supplying as many of their wants as possible by the use of articles manufactured at home naturally reduced the sale of shop-made products, while the habit of trading by barter, instead of for cash, also had a tendency to retard the development of any large retail establishments.

During the five-year period prior to 1800, the imports of foreign merchandise paying ad valorem duties into the United States aggregated $212,000,000, and in 1800, they represented about two-thirds of this amount. New York then, as now, was the chief importing city of the country, and the kind and character of the importations were cottons, woolens, silks, velvets, linens, laces, edgings, hosiery, gloves and shawls, including damasks, dimities, calico-manoes, durants, tabarets, platillas, listades, mamoodies, guurahs, cossas, bafta, russets, satinetos, duffels, britannias, etc. These goods came chiefly from India and China, and from the cities of Amsterdiam, Hamburg, London and Livorno, and the most important importing houses in New York were those of Bethune & Smith, Murray's Wharf; John Knox, 97 Water street; McCready & Reid, 97 William street; Hector & Scott, 125 Pearl street; John & William Tabele, 260 Pearl street; Benj. & L. Moore, 103 William street; Charles J. Vogel & Company, 92 Maiden Lane; Richard & John Thorne, 141 Pearl street; William Blackstock & Company, 163 Pearl street; A. S. Norwood, 127 William street, and Robert & Co., 84 Pearl street; A. S. Norwood dealt extensively in carpets and rugs, besides handling dry-goods more largely, perhaps, than any other house, while, among the other firms that sold dry-goods in connection with other foreign and domestic commodities, one must mention those of Archibald Gracie, 52 Pine street; James Stuart, 10 William street; Eben Watson & Company, 36 Old Slip; Ferguson & Crichton, 84 Broadway; Rogers & Lambert, 232 Pearl street; H. G. Rutgers & Company, 145 Pearl street; Rutgers, Seamam & Ogden, 93 Front street; Thomas Buckley, 241 Front street; Suydam & Wyckoff, 21 South street; Robert Weir & Company, 16 Gold street; John Knox, 97 Water street; Thomas Warren, 61 Maiden Lane; John Murray, 84 Pearl street; Frederick de Peyster, Governer & Kemble, John Murray & Sons, and others.

The 15 years that elapsed between the beginning of the century and 1815 witnessed some very trying times for the trade and Of these interests of the country. These troubles began with the French complications; they were accentuated by the Embargo and Non-Intervention acts, and they finally culminated with the war with Great Britain. With such restrictions upon our import trade, the wholesale business of the country stagnated, but, as was quite natural under such conditions, the effect had a tendency to foster our home industries. In 1803, our trade interests, both at home and abroad, were seriously influenced by the panic in Great Britain. In 1804 the first consignment of American cotton was made to Elijah Warren, of Philadelphia, Pa., by Amy & Brown, of Providence, R. I., and the former at once became their agent for yarns and thread, and finally, for stripes, plaid, checks, tickings, ginghams, etc. During the next two years, however, the value of domestic cottons, produced by the New England factories and sold in Philadelphia, amounted to only $17,000. When the Embargo went into force, in 1807, the foreign trade, as a matter of course, was almost entirely suspended. At this time, however, there were not more than 4,000 cotton spindles in use in the entire United States, for the progress in this line of industry had been slow. Before the close of the year, however, the number had doubled, and, by 1809, there were no less than 17 mills in operation in Providence, R. I., with 2,256 spindles, producing fully 510,000 pounds of yarn. About 1,000 looms were also in operation weaving cotton cloth.

The census report for 1810 gave some very clear evidence of the more or less rapid advancement that had been made in all the branches of the textile industry, especially in the manufacture of cottons and woolens. According to the report of the Treasury Department, the American product in cottons and woolens, exclusive of clothing and other goods, amounted to scarcely less than $46,000,000, in 1810. Eli Whitney's invention of the cotton gin had effected such a change both in the production and manufacture of cotton that it had suddenly become one of the nation's leading products.

During the period immediately following the war with Great Britain the importation of foreign goods increased so enormously that the cotton market was not only glutted, but both the cotton and the woolen industries were paralyzed. In fact, so great was the fall in prices that many of the leading importers were almost ruined, while there were but few merchants who were not seriously handicapped by the general stagnation in nearly every line of trade. While this condition of affairs was partly due to the result of the war and the sudden reopening of our ports to foreign trade, this was by no means the only or most serious influence which was at work. To tell the truth it is necessary to admit that the business woes of the republic were largely the result of a combined effort on the part of the foreign manufacturers to gain control of our markets. The reopening of American ports had given them the opportunity for which they had long been making preparations. The ad valorem rates of duty which then prevailed were low, and they seized the chance to unload the surplus stocks, which they had been quietly accumulating, upon the markets of the United States, with a view to crippling its textile mills and thus securing the trade of the country. The plot, serious, as its effect was upon American business affairs, was successful,
not only for the time, but for several years succeeding 1815. The census reports for the decades ending with 1820, 1830, 1840 and 1850, give little useful evidence respecting the advancement in the textile industries. We may judge that it was both steady and general by the increased production of the spindles and looms of the country, especially so far as cotton and woolen products were concerned, but it was not until the year 1850 that these manufactures reached the point at which it was possible to plan for a broader national and industrial development. Many important processes and inventions were also perfected during this time. Among these innovations there was the sewing machine, the power-loom, the knitting machine, and several other labor-saving devices which had a marvelous effect upon the future growth of the textile interests.

The history of American industries during the first half of the 18th century is a record of almost countless vicissitudes for which such events as wars, depressions, financial conflagrations, and other adverse conditions were responsible, but, instead of being discouraged by such experiences with unavoidable misfortunes they seem to have had a tendency to spur the manufacturers and merchants to more united efforts. In the latter years of this period, the inauguration of improved methods, not only in the matter of manufacture, but also in the distribution and sale of all products, tended to bring about a finer classification of goods than had hitherto been carried out, and, for the first time in the history of the country, both the wholesale and the retail dealer began to make more or less separate distinctions in the goods which they sold. Importers and wholesale dealers began to handle special or distinct lines, such as silks and dress-goods; cloths, coatings and cashmeres; notions and small wares; hosiery, underwear and gloves; laces and embroideries; white goods and linens; or hats and caps. Gradually, moreover, the same well-defined distinctions came to be recognized by the retail trade in the cities, although the stores in the various towns and villages throughout the country continued to follow their original policy of carrying a miscellaneous stock of merchandise. The inception of the clothing trade, and, later, of the ready-made articles for women's and children's wear, helped to make the classification still more minute, while the inauguration of the commercial traveler system, and the general utilization of the commercial agency which followed, were important factors in helping to bring about the new conditions, the dawn of which was heralded in 1850. In this year the value of our cotton and woolen products amounted to fully $112,000,000, while the total output of our combined textile interests aggregated $129,000,000. At this time our imports of foreign dry-goods approximated $59,000,000.

There were, of course, several factors which played a part in that betterment of conditions that began to be apparent about the middle of the century. The opening of the South and West, the establishment of new towns occasioned by the institution of new industries, and other evidences of prosperity, resulted in a larger and more diversified demand upon the manufacturers. Prior to 1850, practically no domestic commission business had been done in New York. Transactions of this kind had been confined to Boston, Baltimore and Philadelphia. The bulk of the product of the New England mills went to Boston. Philadelphia, which had some 20 mills, gave great attention to the sale of domestic goods, was the chief market for that product which was then designated as "blue goods," and which included denims, checks, stripes, etc. At this time large quantities of dry-goods were also sold at Hartford, Conn., but New York, which had always been the centre for imported goods, was not recognized by the domestic commission houses until the early fifties, when some of the Boston establishments opened branch offices in that city. Immediately, however, these offices sprang into such importance that it was not long before they were doing a greater bulk of business than the parent houses, and it was due to this reason that, one by one, the great Eastern mills began to open regular agencies in New York. In the early years of the decade, as was confirmed as to a number that there were no retail houses above Howard street, and all the wholesale and jobbing business was conducted further down town, largely on lower Broadway, Cedar, Pine, Liberty, and Broad streets.

In the memorable panic of 1857, when all the business interests of the country were paralyzed, the dry-goods business was one of those that suffered the most severely. The trouble started with the failure of the Ohio Loan and Trust Company, on 27 August, and it attained its most serious result in the month of October, when the numerous failures and the hairbreadth escapes from ruin tried men's souls as well as their bank accounts. According to the reports for 1860, the imports of dry-goods into the United States amounted to a little more than $112,000,000, while the total value of our own textile manufactures were about $215,000,000. Compared to the figures for 1795, the former had increased nearly fivefold, while the latter was almost 18 times in the cities, and 30 times in the towns.

Then came the outbreak of the Civil War, and, during that memorable struggle for the preservation of the Union, the dry-goods interests were again affected. Beginning in December 1861 the value of cotton goods continued to increase, until, at the end of two years, the price of such products had risen nearly 300 per cent. The year 1863 showed a still sharper rise, and the increase in price culminated in the fall of 1864, when the average increase in the cost of cotton goods had attained a mark of nearly 1,000 per cent. Even raw cotton, in April 1864 sold at $1.90 per pound. In Europe this period is still remembered as the "days of the cotton famine," for shipments of this staple from the United States had been almost entirely suspended since the beginning of the conflict between the cotton-producing South and the cotton-producing South.

Lee surrendered on 9 April 1865, and by 30 June the price of cotton had fallen to 40 cents per pound. So far as manufactured cotton was concerned, however, no proportionate decrease in price was shown for some time. In October cotton was quoted at 64 cents per pound, but the price of prints, sheetings, etc,
had fallen less than half from the price that had been current for them in 1864. It was during this year that one dry-goods jobbing house distributed goods broadcast throughout the country to the aggregate amount of $72,000,000.

In 1870 the imports of dry-goods amounted to only $36,588,000, an amount very far below the record for 1795, while the aggregate product of the home manufacturers was $520,000,000, or an increase of nearly 2,500 per cent.

There are several reasons that might be cited to explain why the dry-goods industry did not show a corresponding increase during the next decade in the history of the country. In the beginning, it must be remembered that American manufacturers were compelled to face some very serious vicissitudes. The period immediately following the war was a most uncertain one. Moreover, the increased production of the country, to say nothing of the improvement and cheapening of the facilities for manufacture, naturally had a tendency to bring about a decline in all classes and kinds of textile products. Thus, while there was really a noteworthy quantity and variety of America's manufactures, the value of the output indicated but little augmentation. In 1880, therefore, the value of our textile products was but about $533,000,000, an increase of less than $13,061,000 over the record for 1795, while the importations of foreign dry-goods amounted to almost $136,000,000, or an increase of nearly $38,000,000.

It was during the next few years that the dry-goods industry began to attain a more showy and permanent aspect, with better financial conditions and more modern methods, not only in the manufacture, but also in the art of transacting business, the growth of these interests was a steady record of prosperity. That it has since attained to considerable proportions one may easily discover by reference to the later census reports, for the value of the American output, which, in 1890, was $1,261,672,504, had attained the still more enormous figure of $1,637,484,484.

In this review of the history of one of the nation's greatest industries, it is only natural to branch of the subject has thus far been considered, whereas the dry-goods merchants of today handle a multitude of articles that cannot be included in this classification. In fact, the disposition that has been shown by the large retail houses to buy and sell promiscuous merchandise, intermixing dry-goods proper with many different lines of trade, makes it almost impossible to secure anything like exact figures respecting the value of the annual distribution of wares through these sources. The latest census report divides the American manufacturing industries into 363 distinct classes, and of these, fully one-sixth enter into the province of the modern dry-goods business.

The present tendency of the trade is away from the smaller concerns. The United States census no longer makes returns under this title. The old-time dry-goods stores have developed into department stores, and the smaller concerns are notion stores, while men's clothing and women's frocks and suits are sold in stores and by mail order, and now being a part of the dry-goods trade. In the 1903 edition of this encyclopedia it was noted that the number of dry-goods stores then was decreasing, and the decrease continues. Trade grows but it differentiates and much of it is no longer denominated dry-goods. True, there are prosperous dry-goods journals, but the name is becoming a misnomer for them, as they are developing into costumers and manufacturers. Then the advertising by manufacturers of all classes of apparel. The day of buying goods by the yard over the counter for household use, which characterized the dry-goods stores of the seventies, is gone. Nearly all textiles and fabrics are now made up in factories and sold as the completed articles. There are still a few old-fashioned people who go and pick out the goods and have them made up to order, but the multitude like to buy made-up goods, because they can see the finished article and can get it quickly. Because of the tremendous expansion of business and of new methods of manufacture and sale; because of the scientific development of advertising and frequent changes of styles; and because of the vastly increased number of wants of modern civilized humanity, the dry-goods trade is being lost in a multiplicity of subdivisions, and as an entity appears to be doomed, just as wet goods, as a designation of a class of business, has disappeared. See CLOTHING INDUSTRY; COTTON; CARPET AND RUG INDUSTRY; TEXTILES; LACE; LOOM; SILK; WEAVING.

DRY PILE, a very interesting form of galvanic battery, invented by De Luc, so named from the fact of its requiring merely a slight moisture among its leaves. Various kinds of dry piles are considered in this article. The most familiar one, Zamboni's dry pile, is made in the following way: Some sheets of silver paper, covered on one side with zinc foil, are moistened on the back with honey or glycerine and water, and then rubbed over with very finely-powdered black oxide of manganese. These are laid one on the top of the other, the silvered side of one being in contact with the oxide of manganese of the next. They are then cut with a punch into discs of about an inch in diameter and they are put into a glass tube, care being taken that the order just named is preserved. The tube is varnished with shellac inside and out and is fitted at each end with a brass cap through which passed a brass piston which is set down firmly against the paper discs in the tube and furnished with an outer knob. From 1,000 to 2,000 discs may be used. The knob at the oxide of-manganese end will be found positively electrified, the other negatively. A pile containing 2,000 discs will charge a Leyden jar. A pile of 40,000 discs was strong enough to emit a succession of sparks three-fifteenths of an inch in length, to charge a Leyden jar of 50 square inches capacity, and thence to fuse one inch of fine platinum wire. The honey with which the paper is saturated is intended for a hygroscopic substance. If the pile be carefully kept it will preserve its energy for years. A pile of this type with 20,000 discs has kept a pendulum vibrating between two bells so as to keep up a perpetual ringing for several years. If it be artificially dried it loses it, but will frequently regain it when a sufficient amount of moisture has been absorbed from the air. Its action is similar to that of a galvanic battery, but seems to have no chemical
DRAIN POINT-DRYDEN

effect, as saline solutions subjected to its current for several days remain unchanged; and the most delicate vegetable coloring matters are unaffected. An examination of the pile shows that it resembles a conductor, neutral at the centre, one extreme negative and the other positive. The activity of the instrument is increased by artificial heat and is more marked in summer than in winter. The principle of the dry pile is made use of in Bohnenberger's electroscope. Two short dry piles are set side by side an inch or so apart, with opposite poles uppermost, the whole being covered with a bell glass. Through the top of the bell glass passes a rod having a knob at its upper extremity and a strip of gold leaf at its lower end, hanging between the poles of the dry piles. Then any substance even feebly electric is brought close to the knob, the gold leaf instantly announces its electrical nature, whether positive or negative, by flying to the pile which presents the opposite phase of electrification. This test is regarded as more sensitive than any other. See ELECTRIC BATTERY; ELECTRICITY; ELECTRIC STORAGE BATTERY.

DRAIN POINT, a sharp-pointed steel needle or instrument used by engravers to incise fine lines directly upon the copper plate without first coating it with etching-ground. The dry point does not cut into the copper but divides it, forming a sort of furrow with elevated ridges on each side. These are afterward scraped off where the effect is to be gray, but left standing for strong velvety blacks. This tool is much employed in working the more delicate portions of etchings or in making whole pictures on copper, called "dry-point" etchings, and very frequently also as a retouching tool on acid-bitten plates.

DRAIN POINT ETCHINGS. See ENGRAVING.

DRAIN ROT, a popular name for the decay of seasoned timber and for certain forms of decay of the trees while still standing. The latter kind is caused mainly by species of shelf-fungi and toadstools, which also attack the stumps of various trees. Sap rot (Polystictis versicolor) is the most serious of all, destroying 75 per cent of railroad ties in use. Economically, the former kind is the more important, since it attacks timber after it has been put in place in buildings. In such cases the floors or walls may collapse with more or less damage to property, if nothing worse. The fungi producing this kind of dry rot are species of the genera Polyporus and Merulius, which produce similar effects. The most common is M. lacrymans. The spores germinate in the presence of moisture and the branching threads (mycelium) penetrate as far as the wood is moist, later spreading into broad sheets and completely destroying the fibre of the wood. The fungus is at first white but later turns brownish-red, producing what is called "red-striped" timber. Drying only temporarily checks growth, for when moisture again reaches the wood the fungus recommences its work of destruction. The wood exposed to frequent changes of moistening and partial drying is more susceptible. But if it is thoroughly seasoned and then protected by antiseptic treatment or good paint, will be exempt unless the fungus has already gained entrance. In floors and walls only dry and non-alkaline sound-deadening substances should be used, since these do not favor the germination and growth of the spores which may be present. Both Merulius and Polyporus are classed with the poisonous fungi.

DRAIN TORTUGAS, tór-too'gas, Florida, a group of small coral keys or islets, 10 in number, at the western end of the Florida Keys, in the Gulf of Mexico, about 70 miles from Key West, lat. 24° 36' N.; long. 82° 54' W. The principal keys are East Key, Bird Key and Loggerhead, and are a part of Monroe County. During the Civil War the Federal government confined prisoners at Fort Jefferson, on one of the islands, and this practice has been continued. It also serves as a quarantine station. A marine laboratory has been located at Loggerhead Key since 1904 and the entire group has served as a Federal bird station since 1908.

DRAIN, in Greek mythology, a nymph of the woods; a deity supposed to preside over the woods; a wood-nymph. Dryads differ from hamadryads in that the latter were attached to particular trees, with which they were born and died.

DRAINANDER, drú-an'dér, Ernst, German Protestant theologian: b. Halle 1843. He received his education at Halle and Tubingen and was pastor of the Evangelical congregation at Bonn from 1879 to 1882. In the latter year he removed to Berlin as pastor of the Holy Trinity church and there attracted wide attention through his eloquence in the pulpit. He was appointed court preacher in 1898, life member of the Prussian Upper House in 1901 and vice-president of the Evangelical Oberkirchenrat in 1907. He wrote 'Predigten über das christliche Leben' (3d ed., 1890); and 'Der erste Brief Jhannis in Predigten ausgelegt' (1898).

DRAES, (1) a famous Spartan, slain by Diana in the Theban War; (2) a genus of rosaceous plants found in Alpine and Arctic regions; they are small, prostrate shrubs with large white or yellow flowers; (3) a genus of butterflies, of which one species is D. paphia.

DRAINBURGH, the ruin of a Premonstratensian abbey in Berwickshire, five miles from Melrose, on the Tweed. It contains the tombs of Sir Walter Scott and his son-in-law, Lockhart.

DRAFEN, John, English poet, dramatist and critic: b. Aldwincle All Saints, Northamptonshire, 9 Aug. 1631; d. London, 1 May 1700. His family were landed gentry, of Puritan affiliations. He was educated at Westminster School and at Trinity College, Cambridge, where he probably continued in residence until 1657. He then settled in London, which remained his home until his death. His life is exclusively that of a man of letters, and may be divided into two periods, 1667-81 and 1688-1700. In the first of these he is primarily a dramatist, in the second a satirist and controversialist, in the third a translator.

Dryden's first known work, a stilted elegy, 'Upon the Death of the Lord Hastings,' published in 1649, is written in a style rather near by conceits of the school of Cowley, and with its harsh versification gives no promise of future
power. His real career opened with his residence in London, when he began to eke out by literary work the scanty income (about £40) that he inherited from his father. In 1659 he published his " Heroic Stanzas consecrated to the Memory of His Highness Oliver, Late Lord Protector." This work was probably under the influence of his uncle, Sir Gilbert Pickering, who had stood high in Cromwell's favor. In 1660, however, Dryden joined the throng of poets who celebrated the return of King Charles II, and composed his "Astraea Redux" (1660), and his poem, "To His Sacred Majesty, a Panegyric on His Coronation" (1661). Henceforth he was a consistent royalist, and with the possible exception of a short interval in 1680-81 a consistent member of the court party, until the revolution of 1688. His most important non-dramatic work of this period, "Annum Mirabilis" (1667), celebrates the naval victories over the Dutch and the great fire of London in 1666. Here as in his poem on Cromwell Dryden adopts the four-line stanza of Davenant's "Cordelia," and the imitative humor. With some scenes of Davenant's direct and simple style, to which he adds a vigor peculiarly his own. After his change of politics Dryden formed new associations. He became intimate with the family of the Earl of Berkshire, and on 1 Dec. 1667 married his daughter, the Lady Elizabeth Howard, thereby gaining a substantial increase in his income. Scandal, unfounded by any decisive evidence, reports that Dryden's bride had been guilty of misconduct, and that the marriage proved unhappy. Dryden's numerous scores at marriage may be only the reflection of a prevailing fashion; and surviving letters of his wife show her to have been an affectionate mother. The three sons born to her and Dryden died within a few years after their father, leaving no descendants.

At the Restoration Dryden turned to the drama as the surest avenue of success for a young author. His first play, "The Wild Gallant" (1663), a prose comedy, was a failure; his second, "The Rival Ladies" (1663 or 1664), a pastoral comedy in blank verse, with scenes in rhymed couplets, had better fortune. He then collaborated with his brother-in-law, Sir Robert Howard, on "The Indian Queen" (1664), a tragedy, or more strictly a "heroic play," and encouraged by his success, produced independently a similar play, "The Indian Emperor" (1664 or 1665). These "heroic plays," the one type of drama in which Dryden excels all other authors, are always written in the heroic couplet, are half operatic in tone, and with no pretense at realism attempt to reproduce on the stage the effect of an epic poem. "Love and Valor," to use Dryden's phrase, are the subjects of them; and their drawing of character is strongly affected by that of Tasso and other epic poets and by that of the French romancers of Calprenède and Millet de Scarron. These above-listed plays offend our present taste by their artificiality and insincerity; in their own time they pleased a public French enough to enjoy exaggerated gallantry, English enough to endure bombast and to bear the sight of single combats and battles on the stage.

Dryden was now, with the possible exception of the veteran Davenant, who died in 1668, the most prominent English dramatist. About 1668 he became a shareholder of the King's Company, one of the two licensed companies of players in London, on condition of furnishing them three plays a year. This gave him an annual income of £350 or £400 until the burning of the theatre in 1672, when the profits of the company were much reduced. Though he did not fulfill his part of the contract, producing little more than one play a year, he apparently enjoyed the benefits of it until 1678, when he deserted his associates and gave his plays to their rivals, the Duke's Company. The great success of "The Conquest of Granada" (1670), his most famous heroic play, probably helped to reconcile his partners to his small production.

Dryden's eminence was now universally recognized. In 1662 he had been chosen a member of the newly-founded Royal Society, and his early poems show his enthusiasm for natural science. In 1668 he was appointed to the position of poet laureate, to which in 1670 was added that of historiographer royal; the two positions yielded a salary of £200. At a later date he received a pension of £100. But in 1671 his dramas were assailed with keen ridicule in "The Rehearsal," a witty farce by the Duke of Buckingham and some other writers. In 1673 he was humiliated by the success of a poetaster, Ekanah Settle, with a bombastic play called "The Empress of Morocco." When Dryden joined Shadwell and Crowne in writing a pamphlet ridiculing this drama, Settle retorted with equally pungent satire on "The Conquest of Granada." By the contest the laureate lost his dignity and had gained nothing. Dryden's ideas were also affected by French critical works published at this time. Hence in "Aureng-Zeb" (1675), his next heroic play, he adopted a more natural style and then abandoned the type altogether. In "All for Love" (1677) he treated in blank verse the familiar subject of Antony and Cleopatra, and imitated with real success the style and character-drawing of Shakespeare, but the dramatic technique of Corneille and Racine. This play remains the masterpiece of Restoration tragedy, the finest result of the French influence on the English serious drama. Of the plays that followed the most important is "The Spanish Friar" (1680 or 1681), a tragi-comedy which has great merits of style and contains Dryden's best comic writing.

In 1668 Dryden had published his most important prose work, "An Essay of Dramatic Poesy." This is designed to uphold the reputation of English dramatists and to defend its author's principles of composition. Here and in numerous smaller critical writings, which he continued to publish all through his life, Dryden showed himself a perfect master of his "other harmony" of prose. In critical work his style has never been surpassed for ease, grace and unassuming dignity. It is of so modern a type that, with the exception of an occasional phrase, it might seem the creation of a great artist of our own day.

Already a man of 50, Dryden has as yet produced none of the poems on which his permanent fame was to depend. He turned from the drama, of which he was thoroughly weary, to political satire, and brought all his skill to the aid of the Tory government. After the defeat of the Whigs in their effort to ex-
clude the Duke of York from the succession in favor of the Duke of Monmouth, their leader Shaftesbury was accused of high treason and in November 1681 his case was brought before the London grand jury. At this time Dryden issued his Absalom and Achitophel. In this finest of political satires (written, like nearly all his later work, in the heroic couplet, and containing about 1,000 lines), under the transparent veil of a scriptural allegory, he gives portraits of the leading politicians of the time, and of his own old foe, the Duke of Buckingham. Absalom represents Monmouth; Achitophel, "For close designs and crooked counsels fit, Segacious, bold, and turbulent of wit."

Shaftesbury himself. Though the poem had a wide sale and probably affected public sentiment to some degree, it failed of its immediate object, since the grand jury refused to indict Shaftesbury. When the latter's friends had a medal struck to commemorate his liberation, Dryden published a second satire, 'The Medal' (1682), hardly inferior to its predecessor. In regard to Shadwell, once Dryden's friend, assailed him with scurrilous abuse in 'The Medal of John Bayes.' Dryden now turned against Shadwell his tremendous powers of invective and in 'Mac Flecknoe' secured for him an unexampled censure. He closed this series of great satires by some 200 lines contributed to a second part of 'Absalom and Achitophel' (1682), by Nahum Tate, in which he again attacks Shadwell and his other enemy, Settle, under the names of Olig and Doeg. At about the same time he turned to didactic poetry and in 'Religio Laici' he gave a versified defense of the doctrines of the Church of England.

In February 1685, the Catholic James II ascended the throne. During the same year Dryden became a Catholic. For this conversion he has been denounced by judges whose opinion commands our respect as a hypocritical time-server. Perhaps he himself could not tell whether he changed his religion from conviction. Brought up a Puritan, he was by nature a sceptic. His morals were probably little better than those of the dissolute young noblemen whose associate he was proud to proclaim himself. Such a man could have no clinging attachment to the Church of England. On the other hand, with his strongly logical, scholastic temperament, once he had admitted the element of mystery in religion, he could find it possible to accept any of the Catholic dogmas. He would probably not have become a Catholic except for the pressure of external circumstances; on the other hand, in accepting the king's religion he probably was guilty of no moral obliquity. All his work shows a steadily increasing acceptance of the principle of authority, in literature as in religion. He gained no new offices or pensions as the price of his adoption of Catholicism. With the tithe of his change of faith he would have been deprived of those that he already possessed, it would be idle to discuss. After the revolution he was steadfast in his adherence to his new faith.

Church of England, is absurd enough; but the book contains some of Dryden's best poetry. His defense of his own sincerity shows fervor and pathos, almost sublimity; it is his nearest approach to the "grand style."

The revolution of 1688 brought ruin to Dryden's worldly prosperity. Already an old man, he was deprived of his salary and his pension and except for a wholly inadequate income from his landed property, was thrown back on his pen for support. He met the situation with dignity, making no attempt to conciliate the new government, but refraining from any attack on it. He returned to play-writing, on which since 1681 he had done almost nothing. But his latest dramas, though one of them, 'Don Sebastian' (1689), rivals 'All for Love' in poetic merit, had comparatively small popular success. He found a surer support in work as a translator. This he had begun in 1680 with three pieces in a small volume of 'Ovid's Epistles,' and had continued by various contributions to poetical miscellanies. He now undertook, with aid from other poets, a complete version of Juvenal and Persius, which was published in 1692. Dryden himself translated five satires of Juvenal and the whole of Persius, and wrote a long prose preface on 'The Original and Progress of Satire,' compiled from Casaubon and other scholars. He next turned to what is perhaps his greatest single achievement, a complete translation of Virgil, which he began in 1693 and which appeared in a stately folio volume in 1697. This work was hailed with enthusiasm on its appearance, and has never been superseded as the standard English version of the greatest Latin poet. Dryden's 'Virgil' has indeed none of the grace, tenderness and high seriousness of the original; in the 'Bucolics' and 'Georgics' it is markedly inferior. But his 'Enniad' is a masterpiece of animated narrative; the easy, buoyant verse carries the reader forward with no thought of constraint.

In the same year Dryden produced his great ode, 'Alexander's Feast,' the finest lyric poem of the period between Milton and Wordsworth. He adopts the irregular 'Pindaric' structure made fashionable by Cowley, but transforms it by his own genius. The poem is not easily appreciated by modern readers, who in lyric poetry instinctively look for either the expression of moral ideas (Wordsworth), of intense passion (Shelley), or of sensuous beauty (Keats). Dryden gives none of these, but instead a rapid series of flashlights pictures, each expressed in verse that by its music suggests the scene described. No poem has a more youthful vigor than this ode by the weary dramaticatist and satirist of sixty-six.

Dryden next set to work on a volume of translations and adaptations from Chaucer, Boccaccio, Ovid and Homer that was published in 1700 under the title of 'Fables, Ancient and Modern.' This last product of his pen has an enduring charm. Here the old poet is a teller of tales in clear, simple, melodic language, such as was not to reappear during the whole century that followed him, and he has done it in 'The Hind and the Panther' (1687), his longest original poem. The scheme of the work, a polemic dialogue between the Hind, representing the Catholic Church, and her adversary, the Panther, or

Dryden died on 1 May 1700. After an impressive funeral he was laid to rest in Westminster Abbey, in the "Poets' Corner," near the grave of Chaucer.
After the death of Milton in 1674 Dryden was the acknowledged chief of English men of letters. During the 18th century his fame even increased, so that when Scott wrote in 1800 that Dryden 'was next to Shakespeare,' he merely echoed a received opinion. With the rise of romanticism, Dryden's reputation sank, until to-day he is probably the least read of the greater English poets. No memoir or explana- tion, with whom it is most natural to compare him. He indeed lacks the highest poetic qualities. He expresses no great moral or social ideas; he had little sympathetic or intuitive knowledge of human nature,—hence the comparative weakness of his dramas,—and no feeling for the beauty of the external world. His greatness is primarily one of technique. He had a sense of style, a literary temperament, an ardent love for good literature, which increased in him with advancing years. Owing to this he gradually developed a poetic diction of his own, which, with its clearness, strength and genuine, though restricted melody, became the model for Pope, and so, directly and indirectly, for the whole 18th century.

As a critic, Dryden is of the highest rank. Himself familiar with contemporary French critics, he did much to introduce their ideas into England. Hence Dr. Johnson terms him 'the father of English criticism, the writer who first taught us to determine upon principles the merit of composition.' Yet, though the founder of English dogmatic criticism, Dryden was himself no dogmatist; continually shifting his point of view, he can be classed as a disciple of no one school. Unlike his successors, he distinctly recognized that literary ideas are necessarily modified by changing con- ditions of time and country. A lover of all the great English poets, he has left appreciations of Shakespeare and Chaucer that in their way have never been surpassed.

In person Dryden was short and plump; he reddened his rosy cheeks until past middle life. He was a man of kindly nature, whom his companions loved, and whom his enemies hated rather because of literary and political rivalry than for any personal reasons. He is best remembered not as a successful writer of indecent comedies or as a fierce controversialist, but as a genial old man, enthroned in his great chair at Will's Coffee House as 'judge of wit.' See Absalom and Achitophel; Alexander's Feast; Hind and the Panther, The Mac Fleck-Noe; All for Love.

Bibliography. — Editions: The only complete edition of Dryden's works is that of Sir Walter Scott (18 vols., Edinburgh 1808 and 1821), re-edited by Professor Saintsbury (Edin- burgh 1882-93). Saintsbury retains all Scott's material and makes numerous corrections and additions but is not always trustworthy in details. Of the poems aside from the dramas, there are four easily accessible editions. The most complete is the Cambridge edition, edited by G. R. Noyes (1 Vol., Boston 1909); it contains all Dryden's poems and poetical translations, together with about half of his prose es- says. The Aldine edition (5 vols., London) omits the 'Virgil,' and The Globe edition, edited by W. D. Christie (1 vol., London 1870, and often reprinted) omits all the translations from the Greek and Roman poets. These three ed- itions are all in modernized spelling; they contain good notes and biographical introductions; the Cambridge edition includes the essentials of the commentary to 2 Corinthians by J. A. Christie. The Oxford edition, edited by John Sargeant (1 vol., Oxford 1910), reprints in the original spelling the poems and poetical translations, except the 'Virgil,' but contains no memoir or explana- tion. The Cambridge edition (1 vol., London 1903) is included in the World's Classics series (1 vol., London 1904). Saintsbury has edited eight of the best dramas in the Mermaid series (2 vols., London 1904). G. R. Noyes has edited five of the best dramas, with biog- raphy, in 'The Poetical Works of John Dryden' (Chicago 1910). W. P. Ker has edited the most important prose works in 'Essays of John Dryden' (Oxford 1900). The text of most of these is also given in Everyman's Library, No. 463.

GEORGE R. NOYES
Associate Professor of Slavic Languages, University of California.

DRYDEN, John Fairchild, American insurance expert: b. near Farmington, Me., 1839; d. 1911. He was educated at Yale and entered the insurance business. He founded the Widows and Orphans' Friendly Society in 1873, which was succeeded in 1875 by the Prudential Life Insurance Company. Under his manage- ment this company became one of the great- est of its kind in the United States. In 1896 and 1900 Dryden was a presidential elector and in 1902-07 was United States senator. He became interested in several commercial and indus- trial companies and helped to organize the Public Service Corporation of New Jersey. He published some lectures and speeches and the volume 'Addresses and Papers on Life Insur- ance and Other Subjects' (1909).

DRYDEN, N. Y., village in Tompkins County, on the Lehigh Valley Railroad, 36 miles southeast of Auburn; noted principally as a health resort on account of its mineral springs. The Southworth Library is a public institution.
DRIED MACHINERY—DUAL PERSONALITY

The waterworks and acetylene-gas plant are owned by the municipality. The village of Freeville, noted for the George Junior Republic (q.v.), is not far away.

DRIED MACHINERY. Drying machines and processes have become very common in the industries. Time is always a valuable element in every factory, and artificial dryers supply methods of hastening production. One of the simpler methods of drying is by gravity, as practised in the recovery of metals from slimes, by settling tanks and vacuum filters. Absorption by temporary mixture or contact with a dry, absorbent substance, as sawdust, is accomplished on the blotting paper principle in some trades. The chemist often employs a desiccating substance, as quicklime, placing it in the same vessel, below the substance which is to be dried; large clay articles, as toilet fixtures, are dried on this principle. Condensation by refrigeration is another drying process, illustrated in Gayley's air-drying apparatus in the Puchinery. (See BLAST FURNACE). A familiar form of dryer is termed the hydro-extractor or centrifugal machine. A wet substance, as laundry, is rotated in a basket at high speed, and the water thrown out by centrifugal force. Many sorts of drying mechanisms depend on natural evaporation, mechanically assisted. The atmosphere is capable of taking up moisture to the point of saturation. The more dry air can be placed in contact with a thing in a given time, the quicker will it take up the moisture so that it disappears. Therefore blowers and exhaust fans are utilized to dry wet and moist goods in a great number of manufacturing operations, on the same principle that the old-time washerwoman hung her clothes on a line in the wind. Another method is to move the goods through the air, and conveyors dryers are especially economical when the goods have to be transported to another part of a factory for a following operation. Pressure is in many cases a satisfactory means of drying. It is used in garbage utilization works to expel the moisture, as for making a fertilizer from kitchen refuse.

The application of heat is of course the most natural process of drying, and is made use of in countless ways. The steelmaker heats air in great checkered stoves to assist the operations of the blast furnace with a hot blast; boilers, radiators, stoves and heaters of practically endless forms are used in the majority of trades for drying purposes. Kilns and roasting furnaces are made with rotating cylinders through which material is passed until the last vestige of moisture is removed. Hot ovens and long heated tunnels are other devices for the same purpose. In both brickmaking and soap manufacture the hot tunnel is serviceable. The papermaker runs the continuous strip of paper from the fourdriner machine between hot calendar rolls to dry thoroughly his product in a few seconds. The lumber dealer is satisfied with storing his lumber in specially constructed buildings where the drying up of the sap can be hastened in a few weeks or months. Manufacturers of cotton and woolen cloths, bleachers, dryers and practically all handlers of textiles have to resort to dryers to hasten their production. The printer has to put dryer in his inks, and keep his pressroom hot and his paper dry. The brickmaker, cement manufacturer, tilemaker, etc., all depend on kilns of some sort to rid their material of moisture. It would require a complete encyclopedia of manufacturing processes in use to exhaust the details of methods and mechanisms for drying.

DRIEDNESS, in painting, a formal or hard style of drawing and lack of harmony in coloring. It is the antithesis of a free style in drawing. It is also revealed in sculpture which is wanting in roundness of form in general softness of outline. Before the techniques of painting and sculpture were developed such dryness was almost universal, and is thus a characteristic of all early schools, although it is often found in later schools. In these its appearance is largely to be attributed to individual temperament.

DRIYBALANOPS, dri-bál-á-nops, a small genius of trees found in the Malay Archipelago. The principal species is remarkable as the source of the Borneo or Sumatra camphor, which is found filling cracks and crevices in the wood. See CAMPHOR.

DROOPERTIS, a widely distributed genus of ferns, numbering upward of 500 species, of which more than a dozen are found in the United States, including the male fern. Their only economic use is in medicine. The active principles in the male fern and allied species are fufic acid, aspidin and other phloroglucinolike bodies. The action is largely on the tapeworm, for which parasite this drug is given. Poisonous symptoms sometimes are produced. These are pain, muscular weakness, purging, collapse, and even death. Temporary blindness has been produced by male fern.

D'SA, Manoel Francis Xavier, Portuguese-Indian educator; b. Moira, Goa, 25 Nov. 1874. He was educated in the elementary schools of Moira, also at Mapuca, Saint Xavier's College, Bombay, Bombay University, and the Papal Seminary, Kandy, Ceylon. He was ordained to the priesthood in 1904, was attached to Gloria Church and has been principal of the Antonio de Souza School, Mazagon, Bombay, since 1904. He has published "Documents concerning the Concordat of 1866" (1907); "Difficulties Solved concerning Double Incarnation in Bombay" (1907); "The History of the Catholic Church in India" (Vol. 1, 1910). He is a contributor to "The Catholic Encyclopedia," the Catholic Star of Calcutta and the Anglo-Lusitana.

DUAL, in grammar, that number or inflection which is used in some languages when two things are spoken of, whilst another number (the plural) exists to express many. The dual in some languages is a firmly-established grammatical form, as in the classical Greek; in other languages it is used only in certain cases with certain words, or only faint traces of it are to be recognized. The Sanskrit has a dual number. Of modern languages which have a literature, Arabic is the only idiom which has retained it. The Anglo-Saxon had a dual in the declension of the first and second personal pronouns; for example, we, we two; ye, you two; was, of us two; was, of you two.

DUAL PERSONALITY. See PERSONALITY AND ITS DISORDERS.
DUAL PURPOSE CATTLE. See CATTLE.

DUALINE, an explosive compound containing 30 parts of fine sawdust, 20 of saltpetre and 50 of nitroglycerin. Also called dualindynamite. See EXPLOSIVES; NITROGLYCERIN.

DUALISM, the philosophical opinion that the ultimate components of the universe are two in number, and fundamentally distinct classes. In modern times the line of cleavage between the halves of the dualistic world has usually separated the mental from the material. The 17th century view of the universe under the aspect of substance naturally caused dualism to assume the form of a belief in the existence of just two fundamental substances, mind and matter. This was the opinion of Descartes and of Locke. In the rationalistic school of the Continent as well as the empiricist school of Britain, it soon became obvious that the correspondences between the worlds of mind and of matter, as exhibited in experience and conduct, were not subject to an easy explanation on the basis of the existing type of dualism. Accordingly the continental rationalism was either nominalism, or to fall back upon the honesty and the continual intervention of God, or else, as in the philosophies of Spinoza and Leibnitz, to discard dualism altogether. The British school similarly progressed out of dualism, first by Berkeley's denial of the substantial character of matter, and later by Hume's denial of the substantial character of mind. A partial recrudescence of the dualism of substance is to be found in Kant's philosophy of things—in themselves. At present a substantive view of the mind is characteristic of the dualism of William McDougall. However, it may be said in general that since the 18th century the notion of substance has come to play a progressively smaller part in the question of monism and dualism. The modern formulation of the question is: Are there two mutually exclusive orders of being, the one mental, the other material? While the agreement on this point is not by any means complete, there is a strong and growing tendency, not only among those of an absolute idealist trend of thought, but also among relativist such as William James and realists such as Holt and Perry, to regard the elements entering into the combinations of the material world and the components of mental states as not necessarily different. Mind and matter, in a philosophy of this type, are complexes of the same subject matter, but are viewed from different aspects or are ordered in a different manner.

The most interesting form of latter-day dualism is that of Bergson (q.v.). Bergson's philosophy is based on a sharp contrast between the mental, possessing the continuity of memory, which allows the present as it were to contain the past, and the material, the subject-matter of physical science, forming a cinematographic succession of spatial arrangements of particles. In both, the distinctness of these two worlds is emphatically asserted, but more recently he has come to regard matter as an arrested, atrophied manifestation of the same vital impulse that constitutes life and mind. Bergson thus forsakes dualism for monism.

Dualism is not necessarily a cleavage along the mind-matter plane. Accordingly we find that whatsoever manifestations of dualism exist in ancient philosophy depend on an entirely different principle. This principle is the distinction between form and matter. Two crude attempts at cosmology on the part of the Ionian School brought everything back to one fundamental principle—water or air or fire or the unbounded, as the case might be. Anaxagoras made the first step toward dualism by making reason—albeit a rational order but imperfectly distinguished from the objects ordered—the principle of the universe. Plato carried this dualistic trend to its logical consequences, and distinguished between the ideas, representing order and form, and the evil principle of not being ordered and shaped by them. While Aristotle did not directly entity his forms, he made such a sharp distinction between form and matter that he may justly be called a dualist. This dualism was accentuated in the excessive formalism of the scholastics.

Dualism is found in ethics as well as in ontology. Its ethical aspect is the recognition of separate fundamental principles of good and evil. It is especially characteristic of Zoroastrianism, and elsewhere is usually a borrowing from Persian sources. The strife between mumud and Ahriman becomes in Christianity the strife between good and Satan. Manichaeanism, which was peculiarly under Zoroastrian influence had this dualism as its keynote; and Satan was not subordinated to God as in the more formal forms of Christianity. (See MONISM.) Consult McDougall, 'Body and Mind' (New York 1911), and the bibliographies to METAPHYSICS and PHILOSOPHY.

Norbert Wiener, Editorial Staff of The Americana.

DUANE, James, American jurist: b. New York, 6 Feb. 1733; d. Duanesburg, N. Y., 1 Feb. 1797. He established a settlement at Duanesburg in 1765; took up the practice of law, and became prominent in his profession. Having bought a considerable amount of land in the territory known as the New Hampshire grants, now included in the State of Vermont, he was one of the principal advocates of New York's right to that territory; and when New York officials were driven out by Ethan Allen and his followers, Duane was the leader of those who induced the legislature to declare the Vermonters traitors and outlaws. He was elected to the first Continental Congress, and was a member of the Congress throughout its existence. He was a supporter of the conservative party, believing in the English form of government and opposed to republicanism, and he stood against the signing of the Declaration of Independence, striving to delay, and if possible prevent, separation from England. He returned to New York after its evacuation by the British, and was the first mayor under the new charter (1784–89); was a member of the committee to draft the State constitution of New York; sat in the State senate 1782–85 and 1789–90; and was United States district judge 1789–94.

DUANE, James Chatham, American military engineer: b. Schenectady, 30 June 1824; d. New York, 8 Nov. 1897. He was graduated from West Point in 1848, and was instructor there for a time. He was engineer in charge with the Utah expedition 1858, and served in the
Civil War with the Army of the Potomac and the Army of the South. In 1865–68 he had charge of the construction of defenses at the eastern entrance to New York harbor; was lighthouse engineer for the northeast Atlantic coast, and superintendent of fortifications in Maine and New Hampshire; in 1886 he became chief engineer with the rank of brigadier-general, and retired in 1888. From 1888 to 1897 he was one of the Croton aqueduct commissioners. He was the publisher of ‘Manual for Engineer Troops’ (1862).

**DUANE, William,** American politician: b. near Lake Champlain, N. Y., 1763; d. Philadelphia, Pa., 24 Nov. 1835. He was educated in Ireland, learned printing, and in 1784 went to seek his fortune in India. He rapidly amassed property, and became editor of an Indian journal, entitled the World. Having taken sides against the local government in a dispute with some of its troops, he was seized and sent to England, and his large fortune was confiscated. His attempts at redress were unsuccessful, and he remained in England as editor of the General Advertiser, subsequently merged in the London Gazette. In 1795 he returned to America and became editor of the Aurora, published at Philadelphia, which was made by his able management the most influential organ of the Democratic party; so much so, that Jefferson attributed to its vigorous support his own election to the Presidency. The change of the seat of government from Philadelphia to Washington caused the Aurora to decline in political importance. Jefferson appointed Duane lieutenant-colonel in 1805. In the War of 1812 he served as adjutant-general. Duane retired from its editorship in 1822, and then traveled through the republics of South America. On his return he published ‘A Visit to Colombia’ (1826). His other works include ‘Military Dictionary’ (1810); ‘Handbook for Riflemen’ (1813); ‘Handbook for Infantry’ (1813), which were for some time standard authorities.

**DUANE, William John,** American politician: b. Clonmel, Ireland, 9 May 1780; d. Philadelphia, 26 Sept. 1865. He was a son of William Duane (q.v.). Appointed Secretary of the Treasury by President Jackson in 1833 he was removed from office the same year because of his refusal to allow the government deposits in the United States Bank to be removed without the authorization of Congress. He served also as a trustee and director of Girard College.

**DUBAN, dü-bān,** Jacques Félix, French architect: b. Paris, 14 Oct. 1798; d. Bordeaux, 20 Dec. 1870. He studied under Debret, and his first work of importance was the completion of the Palais des Beaux Arts, in the execution of which he is charged with having sacrificed harmony of proportion and strength to a fondness for ornamentation. In 1845 he was employed in the restoration of the ancient chateau of Blois, and in 1848 was appointed architect of the Louvre. The façade on the river side, and the Apollo Gallery, were restored from his plans.

**DU BARRY, dü bā’rē’,** Jeanne Bécu, Comtesse, a French courtesan, mistress of Louis XV, 1745–1774; b. Paris, 2 Dec. 1793. She was the daughter of Anne Bécu Rançon, the wife of a domestic, and because of her beauty succeeded in gaining the patronage of the Abbé Arnaud who sent her to school at Coulanges. Her school was near the abbey of St. Catherine, and she remained there until she was 15 years of age. Her first employment was as lady's maid to Madame de la Garde, and next at a milliner's shop in the rue de Saint Honoré. Here she lived as a courtesan under the name of Mlle. Lange, and soon attracted by her charms the adventurer Jean, Comte du Barry, who made her his mistress. She presided over his gambling house with great brilliancy until the fame of her beauty and wit reached the ears of King Louis XV, who immediately became enamored of her. She was presented at court and installed as his official mistress in 1769. For form's sake the king had her married to the brother of the Comte du Barry and her position was thus secured. Her influence at court became very powerful and for five years she reigned supreme. Important offices and privileges were in her gift and the courtiers abased themselves to win her regard. After the death of Louis, she retired from court to a convent near Meaux, but at the insistence of the queen was restored to the magnificent château of Luciennes. Here a throng of leading men assembled to do her homage; among them Franklin, and the Emperor Joseph II. She received also a pension from Louis XVI and her court was gay and brilliant. On the outbreak of the Revolution she fled to England, but returned to attend to the matter of her stolen jewels. She was immediately arrested by the revolutionary tribunal, condemned to death and executed. The conflicting estimates of the Du Barry are difficult to reconcile. She was gay, witty, of a frank and pleasing manner and seductive, sensitive beauty. It is doubtful whether her political intrigues had any deeper origin than her desire to please her favorites and gratify her own vanity. It is estimated that her luxuries and her liberality to the arts cost France 35,000,000 livres. The ‘Lettres et Anecdotes’ ascribed to her are unauthentic. Consult Goucourt, ‘La Du Barry’ (Paris 1880); Vatel, C., ‘Histoire de Mme du Barry d'apres ses papiers personnels’ (Versailles 1880, containing a bibliography of sources); Douglas, R., ‘Life and Times of Mme Du Barry’ (London 1896).

**DU BARTAS, dü-bár’tás,** Guillaume Saluste, French poet: b. Montfort, in the department of Gers, 1544; d. Ivry, 14 March 1590. He undertook various diplomatic missions to foreign courts for the Huguenot cause; fought in the Huguenot army and was killed in the battle of Ivry. His fame rests upon two epic poems, the second unfinished, entitled ‘La semaine’ (The Week) and ‘La seconde semaine.’ The first, which is far the better of the two, describes the creation of the world; the second the period from the creation to the incarnation of Christ. These poems were very popular in France, and in 1596 Joshua Sylvester translated them into English.

**DU BELLAY, Jean,** zhōn dü bĕl’ē, French cardinal and statesman: b. 1492; d. Rome, 16 Feb. 1560. He enjoyed the favor of Francis I, and was sent as ambassador to Henry VIII of England, 1543–5; Paris, 1548–51. Bishop of Bayonne in 1526, bishop of Paris in 1533 and cardinal in 1535. He was appointed
lieutenant-general of the kingdom during the absence of Francis, who was engaged against the Emperor Charles V in Provence. Falling into disgrace on the death of this king, he retired to Rome. Du Bellay protected and encouraged him at the Royal Hospital, Kilmarnock, a home for army pensioners: Birmingham Tower, and Chapel of Dublin Castle; Dublin University (q.v.); National Gallery; Mater Misericordiae Hospital; College of Surgeons; King's Inns; and Royal University buildings. Monuments.—Nelson Pillar is a column supporting a statue of Nelson, the whole being 134 feet high. A number of statues are from the chisel of Foley, the most important being those of O'Connell, Grattan, Burke, Goldsmith, Lord Carlyle, Stokes, Sir William Congreve, Lord Gough, Lord Iveagh and the Prince Consort. There are statues by Sir Thomas Farrell, the most notable those of Sir John Gray, Sir Alexander M'Donald, Smith O'Brien and Barry Sullivan. A statue to Father Mathew, the temperance reformer, occupies a niche on O'Connell street. There is also the Wellington Testimonial in Phoenix Park, an obelisk 205 feet high. There are some curious statues of no artistic but great historic interest. The one to King William III is an interesting political figure being erected in commemoration of the battle of the Boyne, it has at various times been treated with indignity. It has been blown up with gunpowder, pulled down with ropes, and once even tarred and feathered. At the instance of Mr. Sexton, when lord mayor of Dublin, it was painted and surrounded with an iron railing.

Churches.—The largest and most important architecturally is Saint Patrick's Cathedral, a beautiful Gothic structure commenced between 1220 and 1260 on the foundation of an older church of the same name. The design is a Latin cross of graceful proportions. The church consists of nave, choir and transepts—all of which have aisles—and a Lady chapel. Though frequently restored it retains the main features of the original building. Swift, its famous dean, watched over it with great care. Its present excellent condition is due to the late Sir Benjamin Lee Guinness, who in 1864 had it repaired at a cost of £10,000. It is the chief place of Protestant worship in Dublin. Christ Church Cathedral, a beautiful example of early English Gothic Passing from the Norman, was founded in 1038 by Sitric, Danish king of Dublin. Time played havoc with the original building, of which the present is but a portion. Between 1181 and 1225 the tower was remodelled, and the part of the older structure still in existence belongs to this period. Between injudicious restorations and natural decay it had fallen into a wretched state. The great restoration which took place in 1871–76 is due to the civic-minded citizen, Henry Roe. There are many fine modern churches, but none possesses exceptional architectural merit. The Roman Catholic cathedral in Marlborough street is a large building of the Doric order. The Presbyterian church at Rutland square is handsome and ornamented with a fine steeple. The Augustinian church in Thomas street is remarkable for its tower and steeple 160 feet high. In the tower there is a richly carved, lofty arched recess and doorway which has a striking effect. Saint Auden's
Church, High street, is —after the cathedrals
—of most note historically. Saint Mary's,
Haddington road; Saint Peter's, Phibsboro;
and the small Greek chapel in Dublin Castle
are buildings of merit.

Art and Literary Institutions.—The Picture
Gallery in Merrion square contains a good
collection of pictures and statuary. It is a state
institute and free to visitors. Native art is
fostered by the Royal Hibernian Academy, in
which there is a yearly exhibition of Irish
work. The Museum of Science and Art, a state
institute, possesses antiquities illustrating life
in early Ireland from the Stone to the Bronze
Age. Of special interest are the examples of
gold work, the most notable being the Tara
Brooch, the Cross of Cong and the cover or
shrine of Saint Patrick's Bell. The ornamental
work on these is remarkable for delicacy and
beauty. The Royal Irish Academy, a literary
and scientific society; the Royal Dublin Society;
agricultural and scientific; Royal Society of
Antiquaries; and Dublin Naturalists' Field Club
are important non-academic associations. There
is also a society for advancing the study of
music, called the Royal Irish Academy of Music.
The principal Dublin libraries, with an approximation of the
number of volumes contained in the larger
ones: Dublin University Library, 350,000 vol-
umes, many valuable MSS., including the Book
of Kells, National Library of Ireland, Royal
Irish Academy Library, Marsh's Library and
King's Inns Library. There are also small but
useful municipal libraries.

Parks.—There are two of size, one, Saint
Stephen's Green, being situated in the centre
of the city, about one-quarter square mile in area;
the other the Phoenix Park (from the Irish
Fiann uisg, clear water), on the west side
and adjoining the city. The latter is very large and
of great natural beauty. It is seven miles in
circumference. The valley of the Liffey runs
along the north side, giving setting, with the Dublin
Hills in the background, a series of delightful
views. In it are the residence of the lord
lieutenant of Ireland, the chief secretary to the
lord lieutenant, and the under secretary, the
Omnibus depot, and the national stud. The
Stabley depot, Hibernian School for the Sons
of Soldiers, Zoological gardens and a number of
cricket and football grounds.

Municipal Affairs.—The local government
of the city is carried on by the lord mayor, 20
aldermen and 60 councillors; these represent
20 wards. Though the corporation has spent
a good deal in providing cheap houses for the
poorer citizens, and though private benefactors
—notably Lord Iveagh—have also helped,
there is still a pressing need for suitable ac-
commodation for artisans and laborers. Apart
from the waterworks, the venture which has
been attempted is the electric lighting of the city.
Historical documents in the archives
have been published in 10 volumes, entitled
'The Ancient Records of the City of Dublin.'
The city returns four members to Parliament.
The first charter was received in 1171, and
many since, in all 102.

Education.—Of first importance is Dublin
University, with its one College of the Trinity,
lodged in a large group of buildings in the
heart of the city. Founded in 1591 by Elizabeth,
with funds derived from escheated estates, it
has always been the chief teaching institution
in Ireland and numbers among its students
such famous men as Ussher, Swift, Burke,
Goldsmith, Emmet, Moore, Locke. Prior to
1873 the Provostship, Fellowship and Foundation
scholarships could be held only by the members of the Protestant communion.
The government, subject to Parliament, is in the
hands of the provost and senior fellows, act-
ing in conjunction with the visitors. The sen-
ate consists of the chancellor and the doctors
or masters, who keep their names on the books.
The council consists of the provost, or vice-
provost, and 16 elected surgeons.
The Royal University of Ireland, a state in-
stitution, is not a teaching body, but examines
and confers degrees. Its graduates are mostly
students from the Catholic University, a college
controlled by the Jesuit Fathers, and from the
Queen's colleges of Cork, Belfast and Galway,
besides ladies from various conventual and private
schools. It is governed by a chancellor, vice-chancellor and a senate of 35 members.
Alexandra College, Saint Mary's College and
Loreto Convent, Saint Stephen's Green, provide
higher education and are the principal
Dublin schools. The principal libraries, with an approximation of the
number of volumes contained in the larger
ones: Dublin University Library, 350,000 vol-
umes, many valuable MSS., including the Book
of Kells, National Library of Ireland, Royal
Irish Academy Library, Marsh's Library and
King's Inns Library. There are also small but
useful municipal libraries.

The first charter was received in 1171, and
many since, in all 102.

Education.—Of first importance is Dublin
University, with its one College of the Trinity,
lodged in a large group of buildings in the
heart of the city. Founded in 1591 by Elizabeth,
the close of the 8th century Danish pirates began their raids on the coast, the monasteries, which contained valuable vessels of gold, being their special prey. From the 8th to the 10th centuries they held Dublin, and early records are full of accounts of conflict with the Irish. In 1014 King Brian Boru (*Boru*) defeated the army of Sitric, the Danish king, at Clontarf, a place now a part of the city. This event seems to have been a severe blow to the prestige of the Danes. The arrival of the Normans in 1169 introduced a new element in Irish history. In 1170 the city was captured by Dermot Macmurrough, a native prince on bad terms with subjects and neighbors. In this he was aided by English allies. Dublin was subsequently attacked by Hasculf, the last of her Danish kings, and his defeat and death put an end to their dominion. From this time the city remained the stronghold of the English settlers; the decaying castles studded over the counties Dublin, Kildare and Meath bear silent witness that the old nation was not a secret one. From Plantagenet to Stuart, history tells of innumerable battles and skirmishes between the inhabitants of Dublin and the septa of the Wicklow Mountains, the O'Byrnes, O'Toolees, Kavanughs and others. How strenuous the life of these settlements was, and how frequent it was, the names of some of the prominent men of that period will show. In the native races, adhered to the old faith. This intensified the hatred between the English in Dublin and their Celtic neighbors. The success of the military operations at the end of Queen Elizabeth's reign followed by the extermination of the Cabotins, and the plantation of Scotch and English settlers, which beginning with Elizabeth was continued by James I and Charles I, helped to make the citizens more secure. The failure of the insurrection of 1641 and the work of attempting to persuade the people of the Commonwealth Dublin remained a walled town with little change of appearance, but with the Restoration began its evolution from a medieval to a modern metropolis. After the Williamite wars the native Irish who remained in the country were without property by civil rights and sank into apathy and general wretchedness. This state of things, as it ensured peace, favored the growth of the city, and in the 18th century Dublin, as we now know it, grew. To this period belongs a spell of commercial activity which, however, owing to hostile legislation of the English Parliament at the instance of English manufacturers, did not continue. Before the union with England the Irish capital was a city of first importance, not only in the national but in the national unrest of the time. The history of Dublin in the earlier 19th century seems to be a record of continued decline. Thackeray, who paid it a visit in 1842, says: "A handsome town, with fewer inhabitants, it is impossible to see on a summer day." In 1847 occurred the attempted rising headed by John Mitchell and others, and in 1867 another resort to arms took place.

It is risky to generalize upon the composite population of a capital, but Dublin society may be fairly described as good-humored, unenthusiastic and not very energetic. Political or religious acerbities do not interfere with social harmony. Wages in general among the laboring class are small, and there is much poverty of a depressing kind. Within recent years there has been a marked revival in library matters, and—apart from the Gaelic League—a school of new writers has arisen whose aspirations are of Ireland and for Ireland. The Gaelic League, a powerful organization, whose objects are the revival of the Irish language and the study of Irish history, and many of the members of which were deeply implicated in the rebellion of 1916, has its headquarters in the city. Pop. (1901) 290,638; (1911) 304,802, of whom 83 per cent are Roman Catholics.

The Revolt of 1916.—Coincident with the attempt of Sir Roger Casement (q.v.), with German assistance, to land arms and ammunition in the west of Ireland, a serious revolt broke out in the capital, and in some other parts of the country. It was joined by the Sinn Feiners, the ultra-radical, physical-force nationalistic organization, and was begun on Easter Monday, 24 April 1916. A large body of rebels seized Saint Stephen's Green. The post-office was captured; telegraph and telephone wires were cut; and houses in different parts of the city occupied by the insurgents. An Irish republic was proclaimed, and a provisional government appointed. An attack on Dublin Castle was repulsed. The authorities, while cognizant of collusion between the German government and the Sinn Feiners and apprehensive of armed revolt, were taken unawares by the suddenness of the outbreak; military law was proclaimed, all available troops were hurried from the Curragh Camp, and the work of attempting to recapture the parts of the city taken by the rebels began. On the day following the outbreak a gunboat on the Liffey shelled Liberty Hall, the headquarters of the rebels, and cavalry charged them in Sackville street. Severe fighting, great loss of life among soldiers, rebels and peaceful civilians alike, and many destructive fires ensued; but on May 1 the revolt terminated with the surrender of Provisional President Pearse who at the same time advised the insurgents to lay down arms. In addition to this 1,000 arrests were made. The casualties among the military were 127 killed and 352 wounded, and among the non-military population there were 1,930 casualties, with 200 killed. The end of the revolt was followed by a visit to Dublin of Premier Asquith, and by an abortive attempt to settle by consent the Irish Home Rule controversy. For details of the rebellion, see IRELAND.

of Dublin' (10 vols.); Warburton, Whitelaw & Walsh, 'History of Dublin' (2 vols.); Saint Patrick's Cathedral, and Christ Church Cathedral, in Bell's Cathedral Series; article by Professor Dowdall in 'Century Magazine', Vol. 7, p. 107 (1884); Chart, 'Pictorial Dublin' (1897); Chart, 'Dublin in the Medieval Towns Series' (1907).

JOHN CONDON,
Assistant Librarian National Library of Ireland.

DUBLIN, University of. The first University of Dublin was founded in 1502 in connection with Saint Patrick's Cathedral. Having no endowment, and owing to changes in government and religion throughout the country, the university gradually declined, until it ceased to exist in the reign of Elizabeth. The present university was founded in 1591, when a charter, or letters patent, was granted by Queen Elizabeth for the incorporation of the College of the Holy and Undivided Trinity. This college is stated in the charter to be incorporated as the "mother of an university," whence it appears that it was intended to be only the first of a number of colleges to be afterward established in connection with the same university, the senate of which is incorporated by a charter distinct from that of Trinity College. Up to this time, however, no other such colleges have been established, so that Trinity College alone still enjoys the rights of the university. Although Elizabeth promised much, little was done by the Crown for the support of the institution. The suppressed monastery of All Hallows was given to the new university and a fund was raised among the Irish nobles. Under James I more aid in money and lands was given to the school. In 1637 changes were made in the constitution of the university.

The members of the corporation consist of a provost, 7 senior fellows, 27 junior fellows and 70 foundation scholars. The management of the college is entrusted to the provost and senior fellows in conjunction with the visitors and the council, the last named body consisting of the provost, four senior fellows, four junior fellows, four professors who are not fellows and four other members of the senate. The senate of the university, as incorporated by royal charter, consists of "the chancellor of the university, or, in his absence, of the vice-chancellor, and three or seven matrons or masters of the university as shall have and keep their names on the books of Trinity College." The senate possesses, under prescribed conditions, the right of electing the chancellor of the university. It is also the body which grants degrees, subject to the sanction of the college board and of the caput of the senate. This latter body consists of the chancellor or vice-chancellor, provost (or vice-provost), and the senior master non-regent, and every member of the caput has the right of refusing a degree by a veto. The fellows are appointed for life. The senior fellows are promoted from the number of the junior fellows in order of seniority, and every vacancy among the junior fellows is filled up by the provost and senior master, after a strict examination for 12 days in mathematics, pure and applied, experimental sciences, classics, with Hebrew and cognate languages, and mental and moral science. The scholars are chosen from among the undergraduates, after an examination in pure and applied mathematics and logic or experimental science, or in Greek, Latin and English composition. Non-foundation scholars are not members of the corporation of the college. Scholars receive an annual salary of £20, have their common rooms of expense, and their rooms for half the charge paid by other students. They hold their scholarships until the end of the June quarter of the fifth year following their election, or following the time at which they become or might have become masters of arts, whichever period term for students, before being admitted, must submit to an examination in Greek, Latin, arithmetic, English composition, history and geography. Students may enter as belonging to one of four classes. The first consists of nomen, noblemen's sons and baronets. The second consists of the fellow-commoners (who dine at the fellows' table). The third and most important is the class of pensioners, forming the great body of the students; and the fourth is the sizars, who are partially maintained out of the college funds now admitted by competitive examination. These last are limited to 30 in number. The academic year is divided into three terms—Hilary, Trinity and Michaelmas term. To obtain the B.A. degree the students must keep eight terms in all, covering normally four academic years. Terms are kept during the undergraduate course, either by lectures or by examinations, but terms in divinity, law, medicine and engineering must be kept by attendance on the lectures of the professors. The system of instruction is superintended by the fellows, together with a large staff of professors. Several of the junior fellows act as tutors, and every student must place himself under one of these on entering the college. The tutors during term deliver lectures on the subjects necessary to a degree. These are: In the first year, mathematics, Greek, Latin, English composition; in the second year, mathematics, mathematical physics, logic, Greek, Latin, English composition; in the third year, logic, mathematical physics, languages, experimental and natural science, history, French, German; and in the fourth, astronomy, ethics, English composition, logic, mathematical physics, languages, experimental and natural science, history and political science. During the first academic year a student is called a junior freshman; during the second, a senior freshman; during the third, a junior sophister; and during the fourth, a senior sophister. Students who have successfully passed all the necessary examinations in the course given above have the degree of B.A. conferred on them by grace of the senate in full congregation. Those who wish to obtain honors must pass through a more extended course of study. Honors are attainable in seven departments: 1. mathematics and mathematical physics; 2. classics; 3. logic and ethics; 4. experimental science; 5. natural science; 6. history and political science; 7. modern literature. Those who successfully pass the examinations in any of these departments are classed according to merit as senior or junior moderators and respondents. Noblemen and noblemen's sons are entitled to have the degree of B.A. conferred on them per speciallem gratiam; and fellow-commoners are entitled to receive it with one term-examination.
less than pensioners. The degrees are conferred on commencement days, of which there are four in each year. There are divinity, law, medical and engineering schools in connection with the university, and degrees or licenses in each of these branches are granted by the university senate on the completion of the prescribed courses. The degrees of D.Sc. and Litt.D. are conferred on B.A.'s who have attained scientific or literary distinction. The degrees of bachelor and doctor in music are also conferred.

The college possesses a fine library of about 350,000 printed volumes and 1,700 manuscripts. It has also a well-stocked botanical garden and museum. The observatory, five miles distant at Dunskirk, is the official residence of Ireland of the royal astronomer. In 1613 James I granted to the university the right of returning two members to Parliament. One was taken away at the Union, but was restored by the reform bill of 1832. The parliamentary constituency consists of the provost, fellows and foundation scholars, ex-fellows and ex-foundation scholars, masters of arts, surgery and engineering, and graduates of all higher degrees.

DUBOC, duh-bok, Julius, German author: b. Hamburg, 10 Oct. 1829; d. June 1903. He studied at Giessen, Leipzig and Berlin, and wrote much for the leading liberal periodicals, especially the National Zeitung. He published 'Geschichte der Englischen Presse' (1874); 'Die Psychologie der Liebe' (1874); 'Das Leben ohne Gott' (1875); 'Gegen den Strom' (1877); a collection of his earlier essays, 'Der Optimismus als Weltanschauung' (1881); 'Jenseits von Wirklichen' (1890); and 'Fünfzig Jahre Frauen' (1890), a collection of essays on the woman question.

DU BOIS, duh-bois', Constance Goddard, American author: b. Zanesville, Ohio. She has been an active supporter of efforts to improve the condition of the Mission Indians of southern California. She has published 'Martha Corey: a Tale of the Salem Witchcraft' (1890); 'Columbus and Beatriz' (1892); 'A Modern Pagan' (1895); 'The Shield of the Fleur-de-Lys' (1895); 'A Soul in Bronze' (1900); 'Religion of the Luiseño Indians of Southern California' (1908).

DU BOIS, William Edward Burghardt, American educator: b. Great Barrington, Mass., 23 Feb. 1868, of negro descent. He was graduated at Fisk University 1888 and at Harvard 1890, subsequently studying at the University of Berlin. He has been a Fellow of Harvard, assistant in zoology at the University of Pennsylvania, professor of economics and history at Atlanta University, and since 1910 editor of The Crisis Magazine, New York. He has published 'The Suppression of the African Slave Trade to the United States, 1638-1870' (1896); 'The Philadelphia Negro' (1899); 'Souls of Black Folk' (1903); 'John Brown' (1909); 'Quest of the Silver Fleece' (1911); 'The Negro' (1915), editor of the Atlanta University 'Studies of the Negro Problem' (15 monographs, 1896-1915).

DU BOIS-REYMOND, duh-boh-ree-mahn, Emil, German physiologist: b. Berlin, 7 Nov. 1818; d. there, 25 Dec. 1896. He studied theology, geology and subsequently anatomy and physiology at Berlin under Johann Müller. At the age of 22 he began those researches in animal electricity which occupied him for nearly 40 years. His first experiments were published in 'Untersuchungen über tierische Elektrizität' (2 vols., 1848-49). His instruments were of his own invention, and with them he succeeded in demonstrating the electrical phenomena occurring in muscular activity and in nervous activity, and established the law now known as his name, that it is the variation of a current density and not the absolute value of current density at any given moment that acts as a stimulus to a muscle or motor nerve. He succeeded Müller as professor of physiology in the University of Berlin in 1858. In 1867 he became permanent secretary of the Berlin Academy of Sciences and later was appointed imperial privy councillor. He also performed successful experiments proving that muscular reaction at rest is neutral or slightly alkaline and acid after death, and that acid is produced in the act of contraction. His investigations include important research on the aperiodic state of the magnetic needle induced by high dampening powers. He also invented the method of reading messages over the Atlantic cable by watching the beam of light reflected from a mirror attached to the needle of a galvanometer. His reputation as a scientist is world-wide, and his researches form the basis of all further information on animal electricity. His other publications include 'Über die Grenzen des Naturbewusstseins' (6th ed., 1884); 'Gesammelte Abhandlungen zur allgemeinen Muskel-und Nervenphysik' (2 vols., 1875-77); 'Reden' (2 vols., 1886-87); and 'Vorlesungen über die Physik des organischen Stoffwechsels' (1899). Consult Engelmann, 'Gedächtnissrede auf Emil Du Bois-Reymond' (Berlin 1898).

DUBOIS, duh-bois', Augustus Jay, American engineer: b. Newton Falls, Ohio, 25 April 1849; d. 19 Oct. 1915. He was graduated at Shefield Scientific School in 1869; in 1874 was appointed professor of civil engineering at Lehigh University, and in 1876 professor of mechanical engineering at Shefield Scientific School. After 1884 he was professor of civil engineering at the last institution. He has published 'Elements of Graphical Statics' (1876); 'The New Method of Graphical Statics' (1876); 'Strains in Framed Structures' (1883; 11th ed., 1900); 'Elements of Mechanics' (1893-95).

DUBOIS, duh-boh, Clément François Théodore, French musical composer: b. Rosnay (Marne) 1847. He studied at the Paris Conservatory and won the Prix de Rome in 1861. He was organist at the church of the Madeleine, professor of harmony, then professor of composition at the Conservatory and finally became director of that institution. The Legion of Honor and many other foreign orders were conferred on him. His compositions for the organ were very well received, his popularity as an organist greatly enhancing their favor. In 1894 he became a member of the Academy of Fine Arts. His compositions include the cantata, 'Atala'; the operas, 'Aben Hamet'; 'Xaviere' and 'Circe'; the oratorios, 'The Seven Words of Christ,' and 'Paradise Lost'; 'The Baptism of Clovis,' and a number of organ pieces, masses, etc.
DU BOIS, Edmond Paulin, French hydrographer: b. Brest, 12 July 1822; d. there, 11 Nov. 1891. He made voyages in the Indian Ocean and along the west coast of Africa, and in 1851 was made professor of the Ecole Navale in Brest. He invented a compass with a double needle to determine the variation due to the ship's ironwork, and wrote 'Cours d'astronomie' (1855). 'Entretiens sur le mouvement des planètes' (1851); 'Les passages de Vénus sur le disque solaire' (1883); 'Cercle nautique' (1885), and edited the 'Éphémérides astronomiques.'

DU BOIS, Guillaume, French cardinal and statesman: b. Brives-le-Gaillard, Corrèze, France, 6 Sept. 1550; d. Versailles, 10 Aug. 1723. He became tutor of the Duke of Chartres, afterward Duke of Orleans, and when in 1715 the duke was declared regent Dubois was appointed by the duke councillor of state. He succeeded in overcoming the dislike of George I of England to the person of the regent, and in 1717 concluded the triple alliance between England, France and Holland. He was rewarded by the Ministry of Foreign Affairs and began to aspire to the highest dignities of the Church. The archbishopric of Cambrai having become vacant, Dubois ventured to request it of the regent, although he was not even a priest. As the king of England united with Dubois in his request, he obtained it and in one morning was at the orders and a few days after the archbishopric. By his consummate address he obtained a cardinal's hat and in 1721 was appointed Prime Minister. Consult 'Le régent, l'abbé Dubois et les Anglais' (Paris 1891).

DU BOIS, Jean Antoine, French abbé and missionary: b. Saint-Rémy, department of Ardèche, 1765; d. Paris, 7 Feb. 1848. He spent 32 years in the East Indies, and on his return published 'Letters on the State of Christianity in India' (1823), which produced much controversy in England from the fact of his having frankly expressed therein his disbelief in the possibility of the conversion of the Hindus. He wrote in defense of the religion and the traditions of India and many contributions to the Bulletin des sciences and to the journals of the Asiatic societies of London and Paris. His most celebrated work on India was purchased by the East India Company, published at its expense in London in 1816 and afterward published in French under the title of Mœurs, institutions, et cérémonies des peuples de l'Inde (1825).

DU BOIS, John, American Roman Catholic bishop: b. Paris, 24 Aug. 1764; d. 20 Dec. 1842. As student in the College Louis le Grand he had as fellow students Camille Desmoulins and Robespierre. In 1781 he was ordained priest. With several thousand other ecclesiastics he was forced to flee from France in the Revolution and came to the United States in 1791. His first charge in this country was at Norfolk, Va., whence he was transferred to Richmond; there he was for a time a guest in the house of James Monroe and was the friend of prominent citizens, Patrick Henry undertaking his instruction in the English language. From Richmond he was transferred to Frederick, Md., the only priest then stationed between Baltimore and Saint Louis. In 1809 he founded Mount Saint Mary's College near Emmittsburg, Md., and was its first president, occupying at the same time the two or three years prior to the war. In 1813 he assumed the duties of chaplain and directed the house of the Sisters of Charity, then founded by Mrs. Seaton in the neighborhood of Emmittsburg. He was subsequently appointed bishop of New York, the diocese including that of State and New Jersey, with a Catholic population of 150,000 souls, eight church buildings and 18 priests. Owing to old age and increasing infirmities in 1838 he obtained a coadjutor in the person of John Hughes, who became his successor.

DU BOIS, Louis, Belgian painter: b. Brussels 1830; d. there, 28 April 1890. He was one of the most prominent painters of the realistic school and worked equally well as a painter of portraits, marines, still life and landscapes. Among his works are 'The Rice Eater'; 'The Muse'; 'Priests Preparing for Mass,' and 'The Billiard Player.'

DU BOIS, Paul, French sculptor: b. Nogent-sur-Seine, 18 July 1829; d. Paris, 23 May 1905. In 1837 he entered the College Louis le Grand and later took up the study of law, which he followed until his 27th year, when he became a pupil of Toussaint. In 1863 he exhibited 'Narcissus at the Bath,' now in the Luxembourg, and in 1864 a bronze of 'John the Baptist' as a young man. 'The Florentine Minister,' which won the medal in 1865, is also in the Luxembourg. Among his other productions are a successful statue of 'Joseph of Arc' (in Rheims 1889); 'Alscie and Lorraine' (1900) and portrait busts of Pasteur, Baudry, Gounod and others. The most elaborate of his sculptures was a tomb in Nantes Cathedral, decorated with many statues and bas-reliefs. He was also a painter. He was made an officer of the Legion of Honor in 1867 and became grand officer in 1889. He was a director of the Luxembourg and also of the National School of Fine Arts.

DU BOIS, Pa., borough in Clearfield County, situated on the Buffalo, Rochester and Pittsburgh and the Pennsylvania railroads, about 80 miles northeast of Pittsburgh. It is in a coal mining region, and a large amount of mining and agricultural implements are manufactured. There are also glass and clay works, blast furnaces, large railroad repair shops, machine shops, a foundry, a tannery, an ice-cream factory, etc. The United States census of manufactures for 1914 showed within the borough 34 establishments of factory grade, employing 1,281 persons, of whom 1,105 were wage-earners, receiving annually $686,000 in wages. The capital invested aggregated $3,296,000, and the year's output was valued at $2,395,000; of this, $1,150,000 was the value added by manufacture. The borough contains a general hospital and owns its waterworks. Settled in 1874, Dubois was incorporated as a borough in 1881. Pop. 14,007.

DU BOSE, dé bôz', William Porcher, American theologian: b. Winnsboro, S. C., 11 April 1836; d. 1918. He was graduated at the South Carolina Military Academy; then received his A. M. at the University of South Carolina (1859), and his theological education at the Theological Seminary of South Carolina. He
was chaplain of Kershaw's brigade in the Confederate army during the Civil War (1861-65). In 1864 he was ordained deacon and in 1865 priest in the Diocese of Charleston. From 1866-67, he was rector of Saint John's, Winnsboro, and from 1868-71 of Trinity Church, Abbeville, S. C. He became chaplain and professor of ethics and New and Old Testament languages and interpretation at the University of the South in 1894, serving as dean of the theological department from 1894-1908, when he became dean emeritus. He holds the Adoptionist theory of the purpose of Christ's life. He is the author of 'The Soteriology of the New Testament' (1897); also a number of Eccumenical Councils'; 'The Gospel in the Gospels' (1906); 'The Gospel According to St. Paul' (1907); 'High Priesthood and Sacrifice' (1908); 'The Reason of Life' (1910); 'Turning Points in My Life' (1912).

DUBOIS, Auguste, French politician: b. Arbrisseau, Rhône, 1844. He was a contributor for some time of *La Marseillaise*, and became successively secretary-general of the prefecture of police in 1870, prefect of Orne in 1871, councillor of state in 1879, president of the general council in 1883 and Minister of Justice in the Casimir-Perier Cabinet in 1893-94. He became a senator in 1897 and was elected president of that body in 1906. He was energetic in pointing out the effect on the school children of the country of the teaching of the religious orders, who were in the main opposed to the Republic. He is the author of 'Les suspects en 1838' (1867); 'Les conditions du gouvernement en France' (1879); 'Danton et la politique contemporaine' (1880); 'Danton et les manœuvres de septembre' (1885).

DUBOVKA, doo-bö'vkà, Russia, city in the government of Saratov, on the Volga. The commercial importance of Dubovka has declined considerably, owing to the fact that the railway line from Kalach on the Don connects with Tzaritzin on the Volga. It was once an important centre for trade in farm products. Pop. 16,900.

DUFUFE, du' bôf', Edouard, French painter: b. Paris, 30 March 1820; d. Versailles, 10 Aug. 1883. He was a pupil of his father, Claude Marie Dubufe, and of Delaroche. Among his works are portraits of the Empress Eugenie, Rosa Bonheur, Gounod, the younger Dubufe and Emile Augier; a number of religious paintings, including 'The Prodigal Son.' In 1853 he became Chevalier of the Legion of Honor. The Salon of 1844 awarded him a first-class medal.

DUFUFE, Edouard Marie Guillaume, French painter: b. Paris, 16 March 1853. He is a son of Edouard Dubufe (q.v.). Among his paintings are 'St. Cecilia'; 'Music, Sacred and Profane'; 'Autumn'; 'The Flight into Egypt'; and several portraits. He has also decorated the Hôtel de Ville in Paris and the Salle des Fêtes de l'Elysée.

DUBUQUE, doo-bôk', Iowa, city, port of entry, county-seat of Dubuque County, on the Mississippi River, the Burlington, the Chicago Great Western, the Chicago, Milwaukee and Saint Paul and the Illinois Central and other railroads, 167 miles northwest of Chicago. It has steamer communication with the leading ports on the Mississippi and is connected with the opposite shore of the river by three bridges. It has communication by boat with other points on the river. The city is built partly on a terrace, 20 feet above the river, and partly on the bluffs, which rise 200 feet high. The lower or business portion is regularly laid out and compactly built, and in the upper portion the streets rise picturesquely one above another. Among the prominent buildings are the United States government buildings, the Central Market, the Carnegie-Stout library, Saint Raphael's Cathedral (R.C.) and several other important churches. The city is the centre of the lead and zinc region of Iowa, northwestern Illinois and southwestern Wisconsin, and contains large zinc works. In 1914 there were 139 establishments in operation, with a combined capital of $13,329,000, employing 6,109 persons, paying $3,851,000 for salaries and wages, and yielding products aggregating in value $14,714,000, made from raw materials valued at $8,188,000. It is also an important market for the agricultural produce of the district. The principal manufactures were packed meat, lumber, foundry and machine shop products, malt liquors, bread and bakery goods, wagons and wagons, flour, boots and shoes, agricultural implements, leather, furniture, toys, notions, bricks, oils, engines, steel ship hulls, barrels, brooms, buttons, sashes, doors, millinery and clothing. The national banks have a combined capital and surplus of over $1,000,000. There are State, savings and private banks. The city is the winter harbor for boats on the upper Mississippi. In 1893 it was created the see for an archdiocese of the Roman Catholic Church. It is lighted with electricity, has an extensive waterworks system, public library, several hospitals and asylums, electric street railways and an inclined cable road leading from the river level to the bluffs. Gunboats for the United States navy have been built here.

There are over 4,500 pupils enrolled in the public day schools; about 140 teachers; and public school property valued at $500,000. There are over 3,500 pupils enrolled in the private and parochial schools. For higher education there is a public high school, the academies of Saint Joseph, Saint Mary, Saint Vincent and the Visitation, Wartburg Seminary (Lutheran), the German Presbyterian Theological School of the Northwest and the State Institute of Arts and Sciences.

The city was named in honor of Julien Dubuque, a French trader, who with 10 others settled here in 1788 to mine lead. This was the first settlement in what is now the State of Iowa. The settlement was abandoned after Dubuque's death in 1810, and the site was not again occupied till 1833. This last was the first permanent settlement in Iowa. In 1839 it was incorporated as a town, and in 1840 received its charter as a city. Pop. 39,428.

DUC, duk, Joseph Louis, French architect: b. Paris, 25 Oct. 1802; d. Paris, 20 Aug. 1879. Winning the Prix de Rome in his 23d year, in 1840 he was chosen to assist in designing the monument in the Place de la Bastille. His chief work is the Palais de Justice in Paris, which occupied the greater part of 25 years in building, for which the Emperor Napoleon III gave him $20,000 as a special prize. The architect.
devoted the greater part of this sum to establish a prize for excellence in architecture. (For a description of the Palace of Justice see Paris.) In 1866 he became a member of the Institute and in 1871 inspector-general of all civic buildings.

**DU CAMP, dü kán', Maxime, French writer:** b. Paris, 8 Feb. 1822; d. Baden-Baden, 8 Feb. 1894. He wrote the history of the Paris Commune, 'The Convolutions of Paris' (1878-79), and other historical sketches: 'Egyptian, Nubia, Palestine and Syria' (1852); but his greatest work is 'Paris: Its Organs, its Functions, and its Life' (1869-75). He likewise wrote some lyric poems: 'Modern Chants' (1855); 'Convictions' (1858); and several novels, among them 'Memoirs of a Suicide' (1853); 'The Six Adventures' (1857); 'The Man with the Gold Bracelet' (1862).

**DU CANGE, dü-känzh, or DUCANGE, St Eve, Charles du Fresne, or Dufresne, French historian and philologist:** b. Amiens, 18 Dec. 1620; d. Paris, 23 Oct. 1685. His family name was Dufresne, and Sieur Ducange was his title as lord of his paternal estates. He was an alumnus of the college of the Jesuits in his native town and after completing his studies there took up the study of jurisprudence, and in 1656 was admitted to practise as an advocate at the bar of the Parliament of Paris. Meeting with discouragement in his profession, he withdrew to his native place and there devoted himself to the historical, linguistic and philological studies which have made him illustrious as a scholar. He was indefatigable in research, and his linguistic attainments, critical acumen and various knowledge enabled him to digest and sort out the infinite mass of material the facts of history and the points of philology which were necessary for the composition of the many solid memoirs of which he is author. And those works involved titanic labor even if we consider only the work of the pen in making 'copy' for the printer; for every word was penned with his own hand. Of the long list of his printed works the two which are most enduringly important—and frequent reference to these is imperative on whoever studied the history of the Middle Ages at its sources—are his dictionaries of the Greek and Latin languages in the period of their decline. Among other writings may be named 'Histoire de l'Empire de Constantinople sous les empeurs francais'; 'Historia byzantina duplici commento illustrata'; 'Chronicon Paschale a mundo condito ad Heraclii imperatoris annum vigesimum'; 'Consult Sandys'; 'A History of Classical Scholarship' (Vol. II, Cambridge 1908).

**DUCAS, doo-kás, Michael, Byzantine historian of the 15th century.** He was a descendant from an imperial family, and himself held a high position at the court of Constantine Paleologus, the last emperor of Constantinople. After the conquest of that city by Mohammed II he took refuge with the Prince of Lesbos, Dorino Gateluzzi, and his prudence and skill succeeded in saving the independence of Lesbos for a time. It is probable that he wrote in his old age the history of the Byzantine empire. This begins with an outline of universal chronology, and does not become detailed and truly instructive till the reign of John Palaeologus I, and it terminates abruptly in the middle of a sentence, at the capture of Lesbos in 1462. It is the most difficult of all the Byzantine histories, written in a barbarous style, but is judicious and impartial.

**DUCAT, the name of certain gold or silver coins current in several countries, but is no longer the monetary unit in any country. It had its origin in 1140, and was founded on a favorite coin with the Dutch, and owing to the excellence of the pieces struck, they were sought for and imitated by several other countries, and especially Russia. Ducats now everywhere circulate at a valuation, where they circulate at all, or are bought and sold simply as bullion. The following are some of the best known:

1. The gold ducat of Holland, weighing 3.494 grammes, .983 fine, value about $2.33. 2. The gold ducat of Russia, which is of precisely the same weight, fineness and value as the Dutch ducat. 3. The gold ducat of Austria-Hungary, weighing 3.4904 grammes, .986 fine, value $2.34. 4. The gold ducat of Sweden, weighing 3.486 grammes, .9766 fine, value $2.31. 5. The gold ducat of Hamburg, valued at $1.85. 6. The silver ducat of Sicily, weight 22.454 grammes, .833 fine, value 84 cents.

**DUCATO, Cape.** See CAPE DUCATO.

**DUCATON, dük-a-toon', or DUCA- STONE, formerly a Dutch silver coin worth 3 gulden 3 stivers, or $1.30. There were coins of the same name in Italy. In Tuscany its value was about $1.35, and slightly more in Venice about 97 cents.

**DUCCO DI BONINSEGNA, düch'o dé bön-en-sän'yà, Italian painter, founder of the Sienese school:** b. Siena about 1260; d. about 1320. He was doubtless trained at Byzantium or came into contact with a Byzantine teacher, as his skill in decoration indicates. In 1285 he was at Florence where he contracted to paint an altar-piece of the Madonna for the Santa Maria Novella. In 1298 he served as a member of the official board of the council of Siena. In 1301 he began a chapel of the Public Palace there of which no record remains. His great work is the altar-piece of the cathedral in Siena, which when completed was carried in a procession to the cathedral. It shows the Madonna surrounded by saints and angels; on the reverse is the picture of the Passion of Christ. Some of these are now in the galleries of the Berlin Museum, the Benson collection and the National Museum, London. Two other Madonnas at the Siena Academy are also attributed to him; likewise a 'Crucifixion' in the J. P. Morgan collection, New York. It is as an illustrator that Duccio excels. His groupings and arrangement are admirable, his perspective good and his drawing graceful and careful. But, despite his excellent dramatic sense and his imaginative force, he fails to impose his figures with a sense of reality. They lack
DU CHAILLU—DUCHESS OF MALFI

DU CHAILLU, dū-shā-yū, Paul Belloni, American traveler: b. Paris, 31 July 1835; d. Saint Petersburg, Russia, 30 April 1903. He spent his youth in the French settlement on the Gaboon, on the west coast of Africa, where his father was a merchant, and received his education from the Jesuits there. In 1852 he went to the University of which he afterward became a naturalized citizen. In 1855 he began his first journey through western Africa, and spent till 1859 alone among the different tribes, traveling on foot upward of 8,000 miles. He collected gorillas, never before hunted and rarely, if ever, before seen by any European. The result of this journey was his work "Explorations and Adventures in Equatorial Africa" (1861). This book contained much important information on the zoology, geography, and ethnology of parts of the continent then unknown to Europeans, and by many authorities Du Chaillu's statements were received with suspicion; but subsequent expeditions by others fully confirmed his substantial accuracy. A second expedition was made by him in 1863, an account of which, under the title "A Journey to Ashango Land," appeared in 1867. "The Land of the Midnight Sun," an account of a tour in northern Europe (1881), had a considerable success. He has also published a number of books intended for youth, and based on his travels. Some of his later works are "The Viking Age" (1889), a treatise on the ancestors of the English-speaking peoples. In addition to the works named above may be mentioned his "Stories of the Gorilla Country" (1865); "Wild Life Under the Equator" (1869); "Lost in the Jungle" (1869); "The Country of the Dwarfs" (1872); "The Land of the Long Night" (1899); "The World of the Great Forest" (1900); "How Animals, Birds, Reptiles and Insects Talk, Think, Work and Live" (1900).

DUCHATEL, dū-shā-t'el', Charles Marie Tanneguy, Count, French economist and politician: b. Paris, 19 Feb. 1803; d. there, 6 Nov. 1867. Prior to 1830 he took an active part in editing the "Globe," one of the leading organs of the Liberals. He began his parliamentary career in 1832, was named secretary-general of the finances in 1833, and in 1835 was appointed to the Ministry of Commerce. He resigned with his colleagues in February 1836, and now became one of the most energetic leaders of the opposition. At the accession of the cabinet of Soul and Guizot in 1840 he came again into power as Minister of the Interior, and retained this position with but a short interruption till the revolution of 1848, after which he lived in retirement. The measures supported by him both as deputy and minister were generally of a financial character, but he also took a prominent part in the establishment of railroads and telegraphs in France. He wrote several works on economics.

DUCHESENE, dū-shān', André, French historian: b. Touraine, Isle Bouchard, May 1584; d. 30 May 1640. History and geography were his favorite studies from his youth, and under Richelieu's ministry he was appointed royal geographer and historiographer. His most important works are "Histoire d'Angleterre, d'Écosse et d'Irlande" (1614); "Histoire des Papes jusqu'à Paul V" (1616); "Histoire des rois, ducs, et comtes de Bourgogne" (1619-28), and his collections of the early Norman and French histories. His industry was extraordinary; he is said to have left more than 100 folios in manuscript. He is frequently styled "The father of French History."

DUCHESENE, Jacques Charles René Achille, French soldier: b. Sens 1837. He fought in the Franco-Prussian War of 1870-71, in which he gained distinction. He added to his fame in the Tongkin in 1883, was made brigadier-general in 1888 and a general of division in 1893. In 1895 he was commandant of the expedition sent out to Madagascar, of which his official "Rapport" (Paris 1897) is the best account. In 1900 Duchesne was appointed member of the Superior Council of War.

DUCHESENE, Louis Marie Olivier, French Roman Catholic Church historian: b. Saint Servan, France, 13 Sept. 1843. He was educated in Paris and Rome. From 1877 to 1895 he was professor of Church history and since 1895 director of the French School at Rome. His most noteworthy contributions to Church history have largely been produced as the result of his researches into the early history of the Christian Church. The best known in English are "Christian Worship; its Origin and Evolution" (1902; 3d ed., 1910); "Early History of the Christian Church from its Foundation to the End of the Third Century" (translated from the 4th ed., 2 vols., New York 1913); and "Pontificals" with introduction and commentary (2 vols., 1896-98). Some years earlier he published the results of his study of these documents.

DUCHESS, The, the pen-name of MARGARET WOLFE HUNGERFORD (q.v.).

DUCHESS OF DEVONSHIRE, English noblewoman, made famous by two beautiful portraits, one by Reynolds and the other by Gainsborough. The latter, the more famous of the two, shows the lady wearing a broad trimmed hat with plumes that has come to be known as the Gainsborough hat. The picture is in the gallery of the New British Institution, replaced in 1902 after having been concealed since 1876, when it was cut from the frame by a noted American thief since dead.

DUCHESS OF MALFI, The. One of the mysteries of English theatrical history is the oblivion in which Webster's tragedy rested until it was rescued and published in 1885. The most striking tragedy in English literature outside of Shakespeare it possesses the best characteristics of
DUCK

that writer's free and elevated imagination. Distinctly a play of "school," by this meaning that it belonged to the revenge and blood type, it imbued the type with a veritable psychology that raises it above the class. Webster is to-day remembered only for his two tragedies, "The White Devil" and "The Duchess of Malfi." The latter play, written between 1609 and 1614, was taken from a novel by Bandello in the second volume of Paynter's "Palace of Pleasure." The play adds to a full catalogue of the elements of horror — tragedy, dark scenes, dead hands, dancing madmen and dumb-shows — other qualities of a higher order. These are clarity of purpose in the handling of the plot, beauty of verse and an insight into character amounting to revelation.

Basola, the most human and understandable in our gallery of villains, comes to his malef
ence distraught in counsel. The awful and in fact insufficiently motivated revenge of Ferdin
and is followed by a remorse more vital to the
heits of the play than the revenge itself. The
chess is one of the first figures in the ver
ch of the sufferer, the unrelieved sombre
ure, but woman, mother, wife and queen. With Carilo a one says of her:

Whether the spirit of greatness or women
Regiaest in her I know not.

The play as a whole contains many quotable
asses of poetry and much impassioned phi

THOMAS H. DICKINSON.

DUCK. Ducks are swimming birds, with short legs set far back and fully webbed feet. They are arranged in two groups or sub-families of the family Anatidae, which embraces also the mergansers, or shell-ducks, the geese and the swans. These constitute the family Anatidae, coextensive with the order Anseres, whose distinctive feature is that the margins of the bill bear a series of transverse ridges, varying to a semblance to teeth in the mergansers, between which mud and water may be squeezed out by the closing of the bill, while the edible parts of the mouthful are retained. This crushing-and-straining bill is usually broad and flat, often somewhat spoon-shaped, and contains a large, fleshy tongue with a horny tip. It is designed for crushing aquatic plants and other soft materials, for squeezing the nutrient out of mouthfuls of oozes and for picking up small, slippery animals.

Ducks spend most of their time on or about water, where they are powerful swimmers and so expert divers that the name (i.e., the bird that "ducks") refers to this characteristic. Certain species descend to considerable depths in search of food, but are not able to stay long nor move far under water. Many species habitually sleep on the water, one foot dropped down and gently moving so as to keep the bird slowly turning about in nearly the same place. Adapted to this life, the plumage is exceedingly close, and is underlaid by a coat of down that protects the body from becoming wet or losing heat. In most species this plumage is different in the sexes, the male (or "drake") having as a rule richly colored dress — often of gaudy beauty — while the female (or "duck") is more soberly and more attractively dressed. A distinctive feature of the dress is the speculum, a patch of conspicuous color in the middle of the wing which is often brilliant in color but sometimes is pure white. Molting occurs twice annually, once in summer, when most ducks pluck the loosened down from their bodies and lay it on their nests as a cover for the eggs. This is so copious in the large eiders that it has become an article of commerce. The summer or "autumnal" molt is usually succeeded by a coat for winter wear which, in the drake at least, is far less gaily colored than his spring dress, acquired in his southern winter residence; and it renders him safer from his enemies. The quills of the wings and tail are molted in pairs (one from each side) at intervals, so that the power of flight is not lost.

All ducks are strong swimming and swift on the wing, and many of them make semi-annual migrations between the tropics and the shore of the Arctic Ocean, and their flight is known to attain a speed of 100 miles an hour for short distances in the case of certain species; yet a duck's wing is short and round.

Ducks naturally belong to all parts of the world except the Antarctic continent, and many kinds are very widely distributed. About 125 species are catalogued, of which 35 are to be found in North America, numbering the merganser, geese and swans. Three groups are distinguished less by structure than by habits and food. The first of these groups is that of the pond and river ducks (Anatinae), wherein no webbing connects the hind toe with the foot. The second group, in which the hind toe has a lobe or web, is that of the sea-ducks and bay-ducks (Fuligulinae).

The fresh-water or anatine ducks are better known than the others, for they visit or breed along rivers, lakes and ponds all over the country. They are not as expert divers as the sea-ducks, but prefer shallow and marshy waters, where they may pick up food from the bottom without serious diving, or gather it from the grassy margins. This food is chiefly vegetable, consisting of seeds, grasses and roots, but they devour smalls, aquatic insect-larvae and any small, soft animal food met with. "The flavor of any duck's flesh," remarks Grinnell, "depends entirely on its food, and a bird of whatever kind which is killed after living for a month or two in a region where proper veget
able food is to be found will prove delicious eating." Reverse conditions will spoil the taste of species highly reputed. "Thus the fine feather
ers of a canvas-back are not necessarily a guarantee that the bird wearing them possesses the table-qualities that have made the species famous." The river and pond ducks, of which about a dozen species are native to North America, are most familiar; and one of them, the mallard (Anas boschas) is the "wild" duck of popular speech, for it is well known throughout the whole northern hemisphere. Its head and throat are glossy green, varying to bluish black;
or a coat of down that is
from being wet or being
in the water. The legs are
red; the black bill is very
dark. The neck is usually
in a white color but sometimes
in a yellow color. The duck
has a yellow bill and a
black head. The ducks are
very social and usually
fly in flocks. They feed on
grasses and other plants
that are available in the
water. The ducks are
notable for their
wisdom and com-
mand.
a white ring surrounds the neck; the breast is chestnut; the belly grayish; back and tail brown to black; speculum rich purple edged by lines of white and black. The female has a much duller dress. The mallard is migratory, breeding from the northern United States to Alaska and Greenland, and wintering from the central United States southward. At these seasons it is found in all the interfluvial streams. At an earlier time it was extremely numerous; but the civilization of the country, the draining of the marshes and wasteful shooting previous to the enactment of recent protective laws, have caused an alarming decrease of this handsome and valuable fowl. Its nesting is after the manner of its race, which is described as follows by Dr. F. M. Chapman:

   "All our Anas except the wood-duck, nest on the ground, lining a slight hollow with grasses, leaves, moss or rootlets, and with more or less down from the breast of the incubating bird. . . . The nesting-site is usually near water. . . . The generally greenish, cream or buff eggs number from 6 to 14 and hatch within a surprisingly short time of each other. Incubation of the young takes a month. . . . Few birds show more concern for the safety of their offspring than do the wild ducks. When danger threatens, the young, evidently acting under direction, scatter and seek cover in every direction, while the female gives a remarkable and courageous exhibition of partial helplessness."

The mallard is the original stock from which most of the domestic races of ducks have been derived; and wild pairs of these ducks are still used to breed their race in captivity in many parts of the United States and elsewhere. A considerable part of the market supply in eastern American cities comes from this source.

Another widely distributed and familiar species is the black duck or black mallard (Anas rubripes), which is slightly smaller than the mallard, is sooty brown with buffy markings, and has a purple speculum edged at the end with white. It neither goes so far north to nest in the snow, but south with that its dark plumage is present and numerous at most seasons in the United States east of the plains. The gadwall (Chaulelaasmus streperus) is an important species of the interior States, blackish in plumage, marked with buff and white, giving a brownish, scaled appearance; grayish below; wing chestnut, with a conspicuous white patch. The European widgeon frequently visits the American Atlantic coast. The American widgeon (Mareca americana) is better known as "baldpate," and is a handsome duck, ranging in its migrations all over the continent. Its general aspect is mottled brown and black, with the wings strikingly black and white. The crown is white, below which the sides of the head and nape are glossy green — this ornament is lacking in the female. Their loud whistling cry is known among gunners.

The teal are small, reddish, widely distributed and popular ducks of two Eastern species, the green-winged (Nettion carolinense) and the blue-winged (Queequedula discors), noted for their swiftness of flight, experience in dodging and mellow whistling notes. A third species, the cinnamon teal (Q. cyanoptera), is restricted to the Pacific slope, and takes its name from the color of its underparts. The knobiller (Spatula clypeata) is so called from its great ladle-like bill, likened to a double spatula. Its head, in the drake, is green; the breast and upper parts are white, divided by a wedge of brown on the back; the under-surface is chestnut, and the wings and tail are black and green, while the feet are orange red. The drake is nearly plain reddish brown. This fine duck is most common in the Mississippi Valley and obtains its food from the bottom of shallow water. The pintail (Dafila acuta) is another duck known throughout the whole sphere, and easily recognized by the two greatly prolonged central tail-feathers of the male. In general color it is dusky brown, with a reddish head, white throat and breast, green tail and green speculum. Its long neck and tail make it conspicuous among other ducks in flight.

The fresh-water group ends with the most beautiful of all American water-fowl, the wood-duck (Aix sponsa). It is of moderate size and the upper parts are green with purplish reflections, the breast is dull red, the sides buff and the lower breast white. The drake has a wide, banded, drooping crest, which is divided lengthwise by a white line and is edged with white; and curving white lines ornament the neck, shoulders and coverts of the wing, which displays a speculum of steel blue. The female is equally ornamental in more quiet tones. This exquisite little duck was formerly extremely abundant, and is yet somewhat common throughout the whole temperate zone of the continent and returns only into the southern States for the winter. His haunts are waters in the midst of woods, and he has the singular habit of making his nest in some hollow in a decayed tree, often at a great height from the ground and at a long distance from water. When the young are able to scramble up to the entrance of the cavity, they are encouraged to let themselves drop off to the ground, and fall so lightly as to suffer no injury; but sometimes they are carried down by the mother, who then leads them carefully to the nearest water.

The sea and barrier ducks (Clangula) are mostly to be found in or near salt water, but mingle with the anatine species in river-mouths and brackish marshes. Pond of open waters, many in their migrations frequent the large interior bays and lakes and are among the best for the table. Their food," says Chapman, consists chiefly of mollusks, crustaceans, and the seeds and roots of aquatic plants. They obtain it principally by diving, sometimes descending 150 feet or more. . . . With one exception they are northern-breeding birds, seldom nesting south of our northern tier of States. *

Prominent in this group is the canvasback (Marila vallisneria), famous among epicures. It is rather large, has a reddish-brown head and neck, the breast and upper back black, the belly white, and the hinder half of the body covered with fine, wavy crosslines of black and white, whence its name. It is seen in autumn on every large lake east of the plains as well as along the eastern coast; and although far less abundant now than in old times it is still fairly abundant owing to legal protection. It is also one of the aquatic weed vallisneria, erroneously called "wild celery." Very closely related, and equally
good, when equally well fed, is the redhead (*M. americana*), which has a much broader area of velvety black about the neck, and a brownish instead of a gray back; its range extends to the Pacific coast. The scaups, greater (*M. maria*) and lesser (*M. affinis*), are dark-colored, white-bellied birds, very common along the coasts in bays and salt-marshes, deriving their name from their cry. The ring-neck (*M. collaris*) differs chiefly in having a distinct chestnut collar. The golden-eye (*Clangula americana*) migrates and breeds throughout the northern interior, and is singular in nesting in a hole in a tree, like the wood-duck. It has a glossy green head, with a puffed appearance, due to the length of the feathers, and marked by a large round white spot before the eye. Otherwise it is white with a black back, the female being all brown. The whistling noise of its wings in flight make it known to gunners as "the whistler." The bufflehead, harlequin and old squaw are sea ducks with a highly varied and beautiful plumage, while the scoters are dull in plumage and the eider are, at least in black-and-white ducks of the north, of little interest to sportsmen, and not utilized in this country as is the case in Iceland and northern Europe. The pretty little ruddy ducks close the list.

**Domestic Ducks.**—The various races of domesticated ducks are derived from local wild stock. In Europe and North America the mallard has been the chief progenitor, but in the East and in Africa other species have contributed. The variation resulting from selective breeding and from the mingling of breeds has resulted in a great diversity of color, and in white-and-black varieties in which the black are called as well as in the white. The muscovy duck is not of Russian origin, as its name would imply, but is a native of South America, and is noted for its ornamental plumage, which much resembles that of our wood-duck. It is therefore reared and kept mainly as an ornamental bird. The crested white is another purely ornamental bird, while several strains of pretty bantams are bred by fanciers in emulation at shows.

The breeding of wild ducks in captivity is becoming a serious business, as well as an amusement of country gentlemen. The National Association of Audubon Societies has led the way by means of its experiment station in Connecticut, and has shown it to be possible to rear a large variety of ducks not before attempted, including canvassbacks, black ducks, teals, godwneyes, etc.

**Bibliography.**—In addition to general works (see under Birds) may be mentioned Baird, Brewer and Ridgway, "Water Birds" (2 vols. 1887); Dionne, "Oiseaux de la Province de Quebec" (1887); Elliot, "Wild Fowl of North America" (1898); Forbush, "Game Birds, Water Fowl and Shore Birds" (1912); Grinnell, "American Duck Shooting" (1901); Job, "Among the Water Fowl" (1902); Leffingwell, "Shooting in Upland, Marsh and Stream" (1900); Rich, "Feathered Marsh of the Northeast" (1907).

**Ernest Ingersoll.**

**Duck Ant.** See Termites.

**Duckbill, or Platypus,** an aquatic egg-laying mammal. (*Ornithorhynchus paradoxus*), native of the sluggish rivers of Australia, Papua and Tasmania. Its entire length from tip of bill to tip of tail is usually between 18 and 20 inches. Its body is rather long and covered with glossy blackish hair, close to the roots of which is a soft waterproof undercoat of fur similar to that of the beaver. The head is rounded, the eyes are small and bright and there are no external ears, despite which fact the creature's hearing is very keen. The feature which gives its name to the animal is the duck-like bill, which is the substitute for the muzzle of other animals. This bill is formed of the elongated jawbones covered with a highly sensitive, smooth skin; when the teeth are shed, as they are at maturity, horny plates developed on both jaws take their place and do their work. The duckbill is well adapted to its aquatic and burrowing habits. Its legs are short, its feet webbed and furnished with sharp claws. In the fore-feet, a web and webbed skin form a continuous pad; the hind feet are not webbed, but can be folded back out of their way. The tail is broad and flattened, covered with coarse hair and nearly naked on the other side. In habits the duckbill is almost entirely aquatic, spending its life in or near rivers, but carefully avoiding stagnant or brackish waters. In swimming it propels itself mainly by the aid of its fore-feet, and it dives well. It is gregarious and sometimes congregates in considerable numbers, but is so shy that unless one watches quietly at evening he will not see a single member of the company. The least hint of danger sends them all to the bottom. The food is often collected in the large cheek pouches, where it can be stored and conveniently carried home by the animal. Each pair lives in a burrow in the bank—a gallery or passageway widened out at its interior extremity into a chamber, where the occupants sleep by day and whither the female retires to produce her young. She lays few eggs in her bed of dry grass, often only one, and hatches her young in a comparatively short time. When born the mother holds the eggs in her mouth, which are white, about three-fourths of an inch long by one-half inch wide and, unlike birds' eggs, have a soft and somewhat flexible shell—though, in their having a large amount of food-yolk, they resemble birds' eggs. The food consists of aquatic insects, crustaceans and worms, which live in the water or in the mud and which are found not only by the tactile sense in the bill but also by the unusually keen sense of smell. The voice is like the growl of an angry puppy, but the disposition is quiet and gentle.

**Ducking Stool,** also known as "ducking stool" and "castigatory," a chair in which common scolds were formerly securely fastened to receive their punishment of being ducked in water. The culprit was placed in the chair with arms drawn backward; a bar was placed across the back and inside the elbow, another bar held the body upright; in this uncomfortable position the prisoner was securely tied with cords. The persons appointed to carry out the punishment by raising their end of the beam caused the unfortunate culprit to go overhead into the water. By pulling down their end with a chain the victim was once more brought to the surface. The ducking stool was generally
1 Goosander (Mergus merganser)
2 Brahminy Duck (Fadorna casarca)
3 Elder (Somateria mollissima)
4 Wood Duck (Aix sponsa)
5 Shoveler (Anas Clypeata)
6 Bernicle Goose (Branta bernicla)
DUCKWEED — DUCTILITY

used in Great Britain from the 15th to the 18th century, and one case was known as late as 1809.

DUCKWEED, a genus of plants by some botanists made the type of the small order Lemnaceae. The species are small plants which float on the surface of stagnant ponds or slow running streams and are eaten by ducks and geese. The front takes the place both of the stems and leaves, and are usually of a bright green color. The flowers arise from a slit just below the margin of the frond. Vegetable reproduction may take place by budding. The family comprises the very smallest of the flowering plants, consisting of three free genera, all of which are to be found in North America. Of the 26 species in the family the most numerous in the United States are those of the genus Lemna, of which five are found. The other genera are Spirodela and Wolffia.

DUCWITZ, dük'wits, Arnold, German politician: b. Bremen 1802; d. 1881. He made an extensive tour of England and the Netherlands and on his return became the foremost promoter of shipbuilding in Germany. He advocated a large merchant marine and a powerful navy and was one of the main promoters of a German customs union and proposed extensive harbor improvements at Bremen. Through his efforts a steamship line was established between Bremen and New York and a favorable postal treaty concluded with the United States. In 1848 Ducwitz as Imperial Minister of Commerce and Naval Affairs laid ambitious plans for the construction of a great German navy. Returning to Bremen in 1849 he was elected burgomaster in 1857 and was elected for the third time in 1873. He published memoirs under the title 'Denkwürdigkeiten aus meinem öffentlichen Leben 1841-66' (Bremen 1877).

DUCWORTH, Sir John Thomas, English admiral: b. Leatherhead, Surrey, 28 Feb. 1748; d. Devonport, England, 31 Aug. 1817. Between 1776 and 1779 he served in America. He distinguished himself in 1794 in the great naval victory gained by Lord Howe off Ushant, and in 1798 under Earl St. Vincent acquired new fame at the capture of Minorca. Some years later he set out in pursuit of a French fleet which had sailed to the West Indies to succor Santo Domingo. He came up with it and succeeded in capturing an 80- and three 74-gun ships. For this service he received the thanks of both houses of Parliament and was presented by the city of London with its freedom and a sword of the value of 200 guineas, and by the assembly of Jamaica with thanks and a sword of the value of 1,000 guineas. In 1807, having been appointed to watch the Turkish fleet, he forced the passage of the Dardanelles. Between 1810 and 1815 he was governor of Newfoundland.

DUCLER, dük-klärk, Charles Théodore Eugène, French statesman: b. Bagnères-de-Bigorre, France, 9 Nov. 1812; d. Paris, 21 July 1888. He took an active part in the Revolution of 1848, was a speaker in the Constituent Assembly and Minister of Finance for a time. He was elected vice-president of the National Assembly in 1875, chosen a senator for life in the same year and became Premier in 1882.

DUCLOS, dük-lō', Charles Pinot, French historian and novelist: b. Dinant, Brittany, 12 Feb. 1704; d. Paris, 26 March 1772. He was chosen member of the Academy of Inscriptions in 1739 and in 1747 member of the French Academy, of which he was afterward appointed permanent secretary. In 1750 he was appointed to succeed Voltaire as historiographer of France. Among the best of his 'Confessions du comte de Bellispe' (1741). His 'Considérations sur les moeurs de ce siècle' are full of striking sketches of character and deep knowledge of human nature. His 'History of Louis XI' is esteemed, but shows the hand of the novelist. Of more value are his 'Mémoires secrets sur les règnes de Louis XIV et XV.' This work was composed in his character of historiographer. He also distinguished himself in his 'Remarques sur la grammaire générale de Port Royal' as a grammarian.

DUCORNET, dü-kör'nét, Louis César Joseph, French artist: b. Lille, 10 Jan. 1806; d. Paris, 27 April 1856. Born without arms he learned in early childhood to use his feet for hands and when 13 years old showed such skill in drawing with his toes that Watteau received him as a pupil in the Lille Academy of Design. There his ambition to become a painter was rewarded by some encouragement. At the end of three years he took the first prize for a drawing of the human figure from life and received a pension from the city, which the government subsequently increased. He then went to Paris for more advanced study, painted 'The Parting of Hector and Andromache' (1828) and presented it to his native city. He continued painting till within a few weeks of his death. His last work of note, 'Edith Finding the Body of Harold,' was ordered by Napoleon III and exhibited in 1855.

DUCUTILMETER, an instrument invented by M. Regnier for ascertaining the relative ductility of metals. The metal to be tested is subjected to the action of blows from a mass of iron of given weight attached to a lever, and the effect produced is shown upon a graduated arc.

DUCUTILITY, the quality of adaptedness of solid bodies, particularly metals, which render them capable of being bent, kinked, frayed, drawn into wire; as malleability is for being beaten into leaves. The order of metals in these two respects is as follows: Ductility—platinum, silver, iron, copper, gold, zinc, tin, lead and nickel; malleability—gold, silver, copper, tin, platinum, lead, zinc, iron and nickel. By the device of coating a platinum wire one-hundredth of an inch in diameter with silver, and then drawing the two metals together as fine as possible, and then dissolving away the silver coating with nitric acid, a platinum wire three-one-hundred-thousandths of an inch in diameter has been obtained — so fine that one mile of it would weigh only one-twenty-fifth of a grain. This wire has entirely superseded the spider's thread formerly used as the "cross hairs" in telescopes. These glass dustle soft metals, such as magnesium, which cannot be drawn, are converted into the form of wire by the process of pressing or squirting the heated metal from a nozzle. One effect of drawing metals into wire is to increase to a great degree their ultimate tensile strength. Thus a wire of Swedish iron one-thirty-sixth of an inch in diameter has a breaking strain of 90,000 pounds per square inch; while a wire of
one-two-hundred-and-fiftieth of an inch will not break until the strain is 134,000 per square inch. When glass is subjected to a sufficient degree of heat, one of them are made into globules of filaments much finer than hair, which bend and wave, like hair, with every wind. Two workmen are employed in making them. The first holds one end of a piece of glass over a flame and when the heat has softened it the second operator applies a glass hook and draws out a thread of glass, which still adheres to the mass; then fitting his hook on the circumference of a wheel about two and one-half feet in diameter, he turns the wheel as fast as he pleases till it is covered with a skein of glass thread. The parts, as they recede from the flame, by gradually cooling become more cohesive, the parts nearest the fire are least cohesive and consequently must give way to the effort made to draw them toward the wheel. These threads are commonly of a flat, oval shape, being three or four times as broad as thick; some of them seem scarcely bigger than the thread of a silk-worm, and are surprisingly flexible. If the two ends of such threads are knotted together they may be drawn and bent till the aperture or space in the middle of the knot does not exceed one-fourth of a line or one-forty-eighth of an inch in diameter. The flexibility of glass increases in proportion to the fineness of the threads; and, probably, had we the art of drawing threads as fine as those of a spider's web, we might weave stuffs and cloths of them. Familiar instances of ductility in non-metallic substances are the "hairing" of boiling sugar syrup in candy-making; and the similar drawing out of "threads" of glue from the carpenter's glue-pot.

DUDE, a modern word coined as a slang expression (but now, by constant use, dignified into semi-respectability) to designate a brainless yokel, whose whole business and aim in life are that of Carlyle's dandy—to wear clothes. The term is said to have originated in London about 1882, at the time of the so-called "aesthetic" movement in dress and manners among the ultra-society folk.

DU DEFFAND, Madame. See DEFFAND.

DUDEVANT, düd-väń, Madame. See SAN, GEORGE.

DUDELY, Sir Edmund, English politician: b. about 1462; d. London, 18 Aug. 1510. He was educated at Oxford and Gray's Inn, and in 1497 was appointed under-sheriff of London. He was an instrument of Henry VII in the arbitrary acts of extortion by the revival of obsolete statutes and other unjust measures practiced during the latter years of his reign. In 1504 he was speaker of the House of Commons. On the accession of Henry VIII he was arrested for high treason and perished on the scaffold with his associate, Sir Richard Empson. His work in defense of absolute monarchy, entitled 'The Way of Commonwealth,' was published in 1589.

DUDELY, Lord Guildford, English noble: d. London, 12 Feb. 1554. He was a son of John, Duke of Northumberland, and was married in 1533 to Lady Jane Grey (q.v.), whose claim to the throne the duke intended to assert on the death of Edward VI. On the failure of the plot Lord Guildford was condemned to death, but the sentence was not carried into effect till the insurrection of Wyatt induced Mary to order his immediate execution.

DUDELY, John, Duke of Northumberland and Earl of Warwick: b. 1502; d. London, 22 Aug. 1553. He was a son of Sir Edmund Dudley (q.v.). He was with Bedford's expedition in Scotland (1542); led the assault on Boulogne (1544); created Earl of Warwick (1546); distinguished himself at the battle of Pinkie in 1547 and suppressed Ket's rising in Norfolk in the same year; was created earl, marshal and Duke of Northumberland in 1551, and was instrumental in bringing Somerset to the scaffold. He manifested the most insatiable ambition. The illness of Edward VI, over whom he had gained complete ascendancy, aroused his fears, and he endeavored to strengthen his interest by marrying his son, Lord Guildford Dudley, to Lady Jane Grey, descended from the younger sister of Henry VIII, and persuaded Edward to settle the crown on his kinswoman by will, to the exclusion of the Princesses Mary and Elizabeth. The death of the king, the abortive attempts to place Lady Jane Grey on the throne and the ruin of all those concerned in the scheme are among the most familiar events in the annals of England. "A consummate soldier, a keen politician and a skilful administrator," he had nevertheless the vices of avarice and unbounded personal ambition, and despoiled the religious houses for his own enrichment.

DUDELY, Joseph, American colonial governor of the province: b. 23 Sept. 1647; d. Roxbury, 2 April 1720. He was a son of Thomas Dudley (q.v.). He was graduated at Harvard College in 1665, served in the Indian War in 1675, was sent to England as agent for the province in 1682, appointed chief justice of New England in 1686, superseded by Andros a few months later and made chief justice. He suffered imprisonment for malpractices 1689-90; was sent to England for trial, but the proceedings were quashed; was chief justice of New York from 1690 to 1693, then eight years lieutenant-governor of the Isle of Wight; was returned to Parliament in 1710 and finally governor of Massachusetts from 1702 to 1715. His character has been pithily summed up by the historian: "Dudley united rich intellectual attributes with a grovelling soul. To his mean nature personal aggrandizement was the prime necessity." He had as many virtues as can be consistent with so great a thirst for honor and power.

DUDELY, Paul, American colonial chief justice: b. 9 Sept. 1675; d. Roxbury, Mass., 21 Jan. 1751. He was a son of Joseph Dudley (q.v.). He was graduated at Harvard College in 1690, and afterward studied law in London. He returned to Massachusetts in 1702, with the commission of attorney-general; in 1718 was appointed judge and in 1722 acting chief justice. By his will he bequeathed £100
to Harvard College, the interest of which was to be supported to the support of an annual lecture course, named in his honor. He was well learned in natural history and was a Fellow of the Royal Society of London.

**DUDLEY, Phimmon Henry, American metallurgical engineer:** b. Freedom, Ohio, 21 May 1843. He was chief engineer of Akron, Ohio, 1868–72, and subsequently invented the dynagraph (1874), the track indicator (1880), and the stremmatograph for obtaining and registering stresses in rails. In 1883 he designed the first five-inch steel rail used in the United States, and in 1892 introduced the first six-inch 100-pound rails. In 1902 he stated seven fundamental principles which illustrate the American theory and practice of railroads, in reference to the joint action of the locomotives, rolling-stock and permanent way. In 1916 he discovered a test method by which the flaws in steel rails may be found. He is a member of the American Institute of Mining Engineers and of many other societies.

**DUDLEY, Robert, Earl of Leicester, English courtier:** b. 24 June 1532 or 1533; d. Corbidge, 4 Sept. 1588. He was the fifth son of John Dudley, Duke of Northumberland, and though involved in the criminal designs of his father and included in the sentence of attainder passed against him on the accession of Mary, was pardoned and employed by Queen Elizabeth. After Elizabeth ascended the throne Dudley soon acquired the distinction of being her favorite. Offices, honors and wealth were showered on him. He was appointed master of the horse, knight of the Garter and privy councillor; and received grants of the princely domains of Kenilworth, Denbigh and Chirk Castle. In 1564 he was created Baron Denbigh and Earl of Leicester, and was the same year elected chancellor of Oxford University, having previously been chosen to the same office at Cambridge. He commanded the expedition to the Low Countries in 1585–87 in which he showed no military capacity; and in 1588 was appointed captain-general of the queen's forces to resist the Armada. Cordially detested by the old nobility, he was simply a creature who was for long credited with an intention to marry him; but who proposed a marriage (1563) between him and Mary of Scotland. In spite of Queen Elizabeth's favor, he sent presents to the imprisoned Queen Mary and was privy to the Norfolk plot, anticipating at that time the fall of Elizabeth. The tragic death of his first wife, Amy Robsart, who was found dead at the foot of the stairway at Cumnor Place, has been laid to his charge, without, however, conclusive evidence. Consult Scott's "Kenilworth."

**DUDLEY, Thomas, American colonial governor:** b. Northampton, England, 1576; d. Roxbury, Mass., 31 July 1652. After serving as page to Lord William Compton; captain in the English army which fought the French in 1597, he became a clerk to Judge Nicolls, about 1598, and steward to the Earl of Lincoln 1616–28. He married in 1630 with the commission of deputy governor and he was afterward chosen governor in the years 1634, 1640, 1645 and 1650. He participated in the founding of Newton (now Cambridge, Mass.) and of Harvard College. He was twice elected president of the United Colonies of New England. He was a man of integrity and piety, though intolerant, like most of his generation. Consult Jones, "Life and Work of Thomas Dudley" (1899).

**DUDLEY, Thomas Underwood, American Protestant Episcopal bishop:** b. Richmond, Va., 26 Sept. 1837; d. New York, 22 Jan. 1904. He was graduated from the University of Virginia in 1858 and served in the Confederate army during the Civil War, attaining the rank of major. Completing his studies at the Virginia Theological Seminary he was ordained in 1868 and after filling the rectorship of Christ Church, Baltimore, was made assistant bishop of Kentucky in 1875, and became bishop of the diocese in 1884. He has published "A Wise Discrimination of the Church's Need."

**DUDLEY, William Loofland, American scientist:** b. Covington, Ky., 16 April 1859; d. Nashville, Tenn., 8 Sept. 1914. He was graduated at the University of Cincinnati in 1880, and from 1889 to 1898 was professor of civil engineering and toxicology at Miami College. His iridium process for electroplating is very successful. He discovered the most poisonous principle in tobacco smoke to be carbon monoxide, which, when inhaled, deoxidizes the blood. He first discovered physiological effects from the use of the X-ray. He was professor of chemistry at Vanderbilt University, being also dean of the medical department, from 1888 until his death.

**DUDLEY, England, city, parliamentary and county borough in Worcestershire, eight miles northwest of Birmingham. It is situated in the midst of the "black country" at an altitude of 600 feet, with extensive coal fields surrounding it. The principal manufactures are articles made from brass and iron, flint-glass, tanning and brewing, cycles and telegraph insulators. There are here the remains of a castle, said to have been founded in the 8th century by a Saxon prince called Dudo or Dud, who has given the town its name. Pop. of county borough 51,079; of parliamentary borough, 102,506.

**DUDLEY DIAMOND, The, a diamond found in South Africa in 1808, weighing originally 89 carats, but reduced to half that weight in cutting. It receives its name from its owner, the Earl of Dudley, who bought it for $130,000. See DIAMOND.**

**DUDWEILER, dood'vi-ser, Germany, town in Rhenish Prussia, about 45 miles northeast of Metz. The coal fields near by are a source of wealth to the town; and the chief manufactories are iron works, fireproof bricks and potteries. In the vicinity is Brennender Berg (Kenilk, the mountain composed largely of coal which has been burning for over 200 years. Pop. 21,932.**

**DUE BILL, a written acknowledgment of a debt by the debtor. Its familiar form is the I. O. U. with the signature of the debtor, as follows: "I. O. U. twenty-five dollars. Benjamin Levine." Another form is the following: "Due McDonnell to Heyburn twenty-five dollars; value received. Benjamin Levine." Such an acknowledgment of indebtedness is distinguished from a promissory note.
by the absence of an express promise to pay. A due bill is not a negotiable instrument, although it is assignable by the payee.

**Due Process of Law**

Law in its regular course of administration through courts of justice. This term, due process of law, which occurs in the amendments to the Constitution of the United States (Art. V) and in the constitutions of nearly all of the States, is considered by Coke as equivalent to the phrase "due process of the land" (used in Magna Charta, Ch. 29), and is said by him to denote "indictment or presentment of good and lawful men." Coke Inst. 50. Due process of law includes notice, hearing and judgment. The constitutions of the various States and the Federal Constitution contain no description of those processes which it was intended to allow or forbid. As a general rule they do not even declare what principles are to be applied to ascertain whether it be due process. It is manifest that it was not left to the legislative power to enact any process which might be devised by him in the Constitution of the United States, the article is a restraint on the right by its mere will. It has been held that the amendment to the Constitution of the United States does nothing more than declare a great common-law principle applicable to all governments, both State and Federal, which has existed from the days of Magna Charta. It was held by the Supreme Court of the United States in Murray v. Hoboken Co., 18 How. 272, that the words "due process of law" were undoubtedly intended to convey the same meaning as the words "law of the land" in Magna Charta. Due process of law ordinarily implies and includes a complaining, a defendant and a judge, regular allegations, an opportunity to answer and a trial according to some settled course of judicial proceeding. When applied to proceedings in criminal cases, the expression "due process of law" or the "law of the land" means that no person shall be deprived of life, liberty, property or privileges without indictment or presentment by "good and lawful men," selected, organized and qualified in accordance with some pre-existing law, and a trial by a court of justice, according to the regular and established course of judicial proceedings. It is to be regretted, however, that the constitutional meaning or value of the phrase "due process of law" remains to-day without that satisfactory precision of definition which judicial decisions have given to nearly all the guarantees of personal rights found in the constitutions of the several States and of the United States. Consult Cooley, 'Constitutional Limitations' (6th ed., Boston 1890); Hare, 'American Constitutional Law' (Boston 1880); McGeehe, 'Due Process of Law under the Federal Constitution' (Chicago 1906); McLaughlin and Hart, 'Encyclopaedia of American Government' (New York 1914).

**Duel and Dueling**

(from duellum, derived from due) is a combat between two, at a time and place appointed in consequence of a challenge, and so is distinguished from an encounter taking place without any previous arrangement. The custom of dueling was derived from the Germans, Danes and Franks, who carried the practice of the judicial combat so far that none were excused except women, sick people, cripples and such as were over 60 years of age. Even ecclesiastics were obliged to maintain their controversies by a champion in arms; and this singular species of jurisprudence was not confined to criminal accusations, but the titles to estates were decided in the same manner. At length, however, this mode of trial was limited to acquittances of capital offenses in which there was no other testimony and in which common fame pronounced the accused party to be guilty. The party vanquished was punished by hanging, beheading or mutilation of members. A judicial combat was authorized by the decrees of personal quarrels in the same way, and all cases of which there were no adequate redress provided in the ordinary tribunals.

The example of Francis I of France and Charles V of Spain gave a sanction to this mode of arbitrating of laws by its mere will. It has been held that the amendment to the Constitution of the United States does nothing more than declare a great common-law principle applicable to all governments, both State and Federal, which has existed from the days of Magna Charta. It was held by the Supreme Court of the United States in Murray v. Hoboken Co., 18 How. 272, that the words "due process of law" were undoubtedly intended to convey the same meaning as the words "law of the land" in Magna Charta. Due process of law ordinarily implies and includes a complaining, a defendant and a judge, regular allegations, an opportunity to answer and a trial according to some settled course of judicial proceeding. When applied to proceedings in criminal cases, the expression "due process of law" or the "law of the land" means that no person shall be deprived of life, liberty, property or privileges without indictment or presentment by "good and lawful men," selected, organized and qualified in accordance with some pre-existing law, and a trial by a court of justice, according to the regular and established course of judicial proceedings. It is to be regretted, however, that the constitutional meaning or value of the phrase "due process of law" remains to-day without that satisfactory precision of definition which judicial decisions have given to nearly all the guarantees of personal rights found in the constitutions of the several States and of the United States. Consult Cooley, 'Constitutional Limitations' (6th ed., Boston 1890); Hare, 'American Constitutional Law' (Boston 1880); McGeehe, 'Due Process of Law under the Federal Constitution' (Chicago 1906); McLaughlin and Hart, 'Encyclopaedia of American Government' (New York 1914).
on the strict observance of those against duels. Under his ministry, the Count of Bouteville-Montmorency suffered death in 1627 for having violated a decree of the French Parliament against dueling. This had for a time the effect of deterring others from engaging in this practice. During the minority of Louis XIV the law was more freely administered, and more than 4,000 nobles are said to have lost their lives in duels. With the revolution of 1789 commenced the period of legal impunity for duels and a new class of duels became common, those, namely, between men engaged in political blots. Bills with a view to put down the practice, were brought forward in the Chambers in 1829 and 1830 and a similar proposal was made to the Council of State in 1832; but they were not accepted. At last, in 1837, the Court of Cassation determined to follow a new law with regard to duels, and protesting against the practice in the name of morality and law, it decided that in case of death or injury resulting from a duel the principal parties and the seconds should be proceeded against and punished in accordance with the general provisions of the code penal. The French courts, however, reserve to themselves a discretionary power in dealing with cases of dueling, and the practice is by no means yet obsolete in France.

Dueling is said to have been introduced into England by the Normans. In the time of chivalry numerous single combats took place in England, which, in the proper sense of the term, can scarcely be called duels. It may be said that the duel, strictly so called, was introduced into England about the time that it became common in France, such was the contagion of the example of Francis I and Charles V. In the reign of James I of England there were numerous cases of dueling, the most celebrated of which is that in which Lord Bristol and Lord Sackville (afterward Lord Dorset) were the principals and in which the former was killed. Cromwell was an enemy of the duel and during the protectorate there was a cessation of the practice. It came again into vogue, however, after the Restoration, thanks chiefly to the ardent enthusiasm of the court of St. James. Some of the duels of that epoch are in perfect accord with the loose morality then prevalent. An instance of this is the duel in which the Duke of Buckingham killed the Earl of Shrewsbury, while the wife of the latter, the cause of the duel, who had accompanied the duke to the ground, witnessed the encounter in the dress of a page. A striking thing is that as society became more polished in England duels became more frequent. They were never more numerous than in the reign of George III. Among the principals in the fatal duels of this period were Charles James Fox, Sheridan, Pitt, Canning, Castlereagh, the Duke of York, the Duke of Richmond and Lord Camelford. The last-mentioned was the most noted of all. He was shot in the head and killed in a duel in 1804. Of all the duels which took place during the reigns of George IV, William IV and Queen Victoria, the most celebrated is that which was fought between the Duke of Wellington and Lord Winchelsea in 1829. The cause of the affair was an animadversion which Lord Winchelsea had passed on the duke's conduct in connection with the Catholic Emancipation Bill. The duel passed off without any injury being done to either of the parties engaged. The Duke of Wellington missed his aim, whereupon Lord Winchelsea fired into the air and apologized. Since 1844, when stringent regulations against the practice were passed, dueling has become extinct in the British army.

Generally on the Continent, military practice obtains among the great conscriptionist nations. An anti-dueling league has been formed, in which one of the leading spirits is the Infanta Alfonso, a member of the Spanish royal house, and its operations embrace France, Belgium, Germany, Austria and Spain. Dueling is still practised in Germany and is recognized as having a defined position in the army. As an illustration of the military viewpoint the following case may be cited. Dr. Sambeth, an army officer, on May 1912 was challenged by a brother officer, but as he was a Catholic he refused to accept it, the Church having pronounced against it. On the question being submitted to him, the Emperor William decided as follows: "The refusal to fight a duel based on religious convictions is not a sufficient ground for examination by a court of honor, but the medical officer who in this respect holds opinions contrary to those of his fellow officers, cannot be allowed to remain in the service." Accordingly, he was dismissed from the army. A resolution against dueling passed by the Reichstag in 1912 was negatived by the Bundesrat in 1913. There were 13 duels fought by army officers in the latter year. Dueling is still practised at the universities in Germany and to a less extent in Russia, but these are very seldom serious affairs, being rather sparring matches with sharp weapons than duels proper. The combatants are generally padded all over the body except the face and sword-arm. The late Emperor Francis Joseph of Austria exercised his influence against dueling, and under his pressure aggrieved officers sought redress in the law courts. General Kuroatkpin is a notable opponent of dueling in Russia. Victor Emmanuel III of Italy some years ago directed an officer who had provoked a duel to be dismissed from the army and sentenced the principals and seconds to terms of imprisonment.

Dueling has been known in the United States from the very beginning of their settlement, the first duel taking place in 1621, at Plymouth, between two serving men. In 1728 a young man named Woodbridge was killed in a duel on Boston Common by another young man named Phillips. They fought without seconds, in the night time, and with swords. Applied by some of his friends, Phillips got on board a man-of-war and escaped to France, where he died a year afterward. There were few duels in the Revolution, the most noted being those between Gen. C. Lee and Col. John Laurens, in which the former was wounded, and between Generals Cadwallader and Conway, in 1778, in which the latter received a shot in the hand which he could not recover. Button Gwinnett, one of the signers of the Declaration of Independence, from Georgia, was killed in a duel with General McIntosh, in May 1777. In 1785 Captain Gunn challenged General Greene twice, both being citizens of Georgia, and threatened a personal assault when the latter refused to meet him. Greene wrote to Washington, acknowledging...
that if he thought his honor or reputation would suffer from his refusal he would accept the challenge. He was especially concerned as to the effect of his conduct on the minds of military men and admitted his regard for the opinion of the world. Washington approved of his course in decisive terms, not on moral grounds, but because a commanding officer is not amenable to private calls for his discharge of his public duty.

Alexander Hamilton was killed in a duel with Aaron Burr in 1804, the latter being Vice-President and the former the greatest leader of the opposition. This duel is always allowed the first place in the history of American private combats. That which stands next is the duel between Captains Barron and Decatur, the latter being killed and Barron severely wounded. Henry Clay and John Randolph fought in 1826, and Colonel Benton, in closing his account of the fight, says: "Certainly dueling is bad, and has been put down, but not quite so bad as its substitute—revolvers, bowie knives, blackguards, and street assassinations under the pretext of self-defense." General Jackson killed M. Dickinson in a duel, and was engaged in other "affairs." Colonel Benton killed a Mr. Lucas and had other duels. In 1841 Mr. Clay was on the verge of fighting with Colonel King, then a senator from Alabama and elected Vice-President in 1852. Mr. Gillespie of Maine fought with Mr. Graves of Kentucky in 1838, near Washington, and the former was killed. This duel caused nearly as much excitement as that between Hamilton and Burr. Both parties were members of Congress. Duels have been numerous in California, notably the combat between Terry and Broderick. Formerly they were very common in the United States navy and valuable lives were lost. It is related of Richard Somers, who perished in the Intrepid, and who is said to have been a mild man, that he fought three duels in one day. In 1830 President Jackson caused the names of four officers to be struck from the navy roll because they had been engaged in a duel. Since the Civil War stringent laws have been passed in all the States against dueling and the practice has become obsolete in this country.

Dueling in Upper Canada (now Ontario) was illegal and the person guilty of so taking life was liable for murder, but by the "unwritten law" the Crown counsel, if the combat was fairly conducted, did not press for conviction. Perhaps the most celebrated duel fought in the early days of the colony was that between William Weeke and William Dickson, and took place behind a bastion of old Fort Niagara, on the American side of the river, on 10 Oct. 1806. Weeke was killed; but as the duel had been fought in a foreign country, Dickson was never brought to trial. What is regarded as the last duel in Upper Canada took place on the banks of the Crow river on 13 June 1853 between John Wilson (afterward puisne judge of the Common Pleas of Ontario) and one Robert Lyon, in which the latter was mortally wounded; but following the customary practice, the fight having been a fair one, the jury did not convict.

DUER, dū'ër, John, American jurist: b. Albany, N. Y., 7 Oct. 1872; d. Staten Island, 8 Aug. 1858. He commenced the practice of law in Orange County, N. Y., where about 1820 he removed to the city of New York, where he resided until his death. In 1825 he was appointed one of the commissioners to revise the statute law of the State and in 1849 was elected a justice of the Superior Court of New York, a position which he filled until his death. He published 'Lecture on the Law of Representations in Marine Insurance' (1845); 'Law and Practice of Marine Insurance' (2 vols., 1845-46), which has become a standard authority in the United States.

DUER, William Alexander, American jurist: b. Rhinebeck, Dutchess County, N. Y., 8 Sept. 1870; d. New York, 31 May 1858. He was a brother of John Duer (q.v.). He was admitted to the bar in 1802, and between 1814 and 1820 was a member of the state legislature, taking a prominent part in the debates on the establishment of canals and other important questions. In 1822 he was appointed judge of the Supreme Court in the third circuit, an office which he held until the close of 1829, when he was elected president of Columbia College. He retired from this post in 1842. He was the author of a treatise on the 'Constitutional Jurisprudence of the United States'; and also 'Life of William Alexander, Earl of Sterling' (1847); 'Reminiscences of an Old New Yorker' (1867).

DUERO. See DOUR.

DUÉZ, du-a', Ernest, French painter: b. Paris, 8 March 1843; d. there, 5 April 1896. He was a pupil of Pils, and his paintings include 'The Honeymoon'; 'Splendor and Misery'; 'Saint Cuthbert'; 'Evening in Villerville'; 'The Pont-Neuf'; and 'In Summer.' He painted some excellent portraits also. His work is realistic and colorful.

DUFARÈ, du-for, Jules Armand Stanislas, French orator and statesman: b. Saujon, France, 4 Dec. 1798; d. Paris, 28 June 1881. He practised law at Bordeaux; entered the Chamber of Deputies in 1834 and became an influential leader of the Liberal party. Under the Republic he was Minister of the Interior, but was driven from the public service by the coup d'état of 1851, and for the next 20 years devoted himself closely to his bar practice and pamphlet writing. Under the government of Thiers he acted as Minister of Justice; and in 1876, and again from 1877 to 1879, he was head of the Cabinet.

DUFF, Alexander, Scottish missionary: b. Perthshire, 26 April 1806; d. Edinburgh, 12 Feb. 1878. He set out in 1829 for India as the first Church of Scotland Missionary to that country. He opened a school in Calcutta in which he sought to teach not only the doctrines of Christianity, but also the English language and the science and learning of Europe. He subsequently assisted in founding the University of Calcutta. His chief writings were 'Vindication of Scotland's India Mission' (1835); 'Vindication of the Church of Scotland's India Mission' (1837); 'India and India Missions' (1840);

DUFF, Archibald, English biblical scholar: b. Fraserburgh, Aberdeen, 1845. He was educated at McGill University and Andover Theological Seminary, also at Haile and Göttingen, Germany. In 1864-69 he was a high-school teacher in Canada and in 1875-78 was theological tutor and mathematical tutor in Montreal; in the latter year he was appointed professor of Hebrew and Old Testament theology in the United College, Bradford. He was chairman of the Yorkshire Congregational Union in 1893, was one of the founders of the Atheneum Club and coeditor of Bibliothea Sacra from 1874 to 1894. His publications include 'The Use of the Old Testament in the Study of Origin of Doctrine' (1879); 'The History of Atonement Among the Hebrews' (1880); 'Old Testament Theology' (Vol. I, 8th century B.C., 1891; Vol. II, Deuteronomic Reformation, 1906); 'Hebrew Grammar' (1901); 'Theology and Ethics of the Hebrews' (1902); 'First and Second Esdras' (in 'Temple Apocrypha,' 1903); 'Abraham and the Patriarchal Age' (1903); 'Modern Old Testament Theology' (1906); 'History of Old Testament Literature' (1910); a translation of Duhm's 'Ever-coming Kingdom of God' (1911); and of 'Book of the Twelve Prophets' (1912); 'Isaiah' and Frensen's 'Story of Jesus' (in 'Brother Richard's Bookshelf,' 1913); and commentaries on Esther and Lamentations.

DUFF, Edward Gordon, English librarian: b. 16 Feb. 1863. He was educated at Cheltenham College and Oxford and was librarian of the John Rylands Library, Manchester, 1893-1900. He was Sanders reader in bibliography in Cambridge University 1899-1904, 1904-11. He has published 'Early Printed Books' (1893); 'Early English Printing' (1896); 'The Printers, Stationers and Bookbinders of London' (1899); 'William Caxton' (1902); 'A Century of the English Book Trade' (1905).

DUFF, Sir Mountstuart Elphinstone Grant, English writer and politician: b. Edinburgh, Scotland, 1828; d. London, 12 Jan. 1906. He was educated at Balliol College, Oxford, was called to the bar of the Inner Temple in 1854 and in 1857 entered the House of Commons as a Liberal. From 1858 till 1874 he held the office of under-secretary for India under Mr. Gladstone, and in that state among the second ministry he was under-secretary of the colonies from 1880 till his appointment in 1881 as governor of Madras. His tenure of this important office was very successful and ended with his resignation in 1885. From 1889 till 1893 he was president of the Royal Geographical Society. His published works include 'Notes of an Indian Journey' (1876); 'Miscellanies, Political and Literary' (1878); 'Memoir of Sir Henry Maine' (1882); 'First Impressions of India' (1883); 'Notes from a Diary' (1897-1900); 'Out of the Past' (1903); 'Gems from a Victorian Anthology' (1904).

DUFFERIN, dāf'fər-in, AND AVA, āvə, Frederick Temple Hamilton-Temple Blackwood, MARQUIS OF, Irish diplomatist and author: b. Ireland, 21 June 1826; d. Clademboys, Ireland, 12 Feb. 1902. On the death of his father in 1841 he succeeded to the title of Baron of Dufferin and Clademboy in the peerage of Ireland. He first distinguished himself by contributions to literature and published the popular 'Letters from High Latitudes' in 1859. He was successively under-secretary for India 1860-66 and for war 1869-72, in 1871 was created an earl and was governor-general of Canada 1872-78. His brilliant administration was remarkable for the wonderful development of the provinces and the beginning of construction of the Canadian Pacific Railway. From 1879 to 1881 he was Ambassador at Saint Petersburg, whence he was transferred to Constantinople. In 1884 he succeeded Lord Ripon as viceroy of India, resigning in 1888. Lord Dufferin's tenure of office was made memorable by measures for strengthening the Indian frontier, by the various attempts to delimit the Afghan frontier and, above all, by the annexation of Upper Burma in December 1885. He became successively Ambassador at Rome, marquis (1888) and ambassador to France (1891-96). In addition to the volume named he published 'Irish Emigration and the Tenure of Land in Ireland' (1867); 'Speeches and Addresses' (1868); 'Speeches Delivered in India' (1890). The authorship of the letters of Selina Sheridan (1807-67) was the author of 'The Emigrant's Farewell,' 'O Bay of Dublin,' and other touching songs.

DUFFFIELD, George, American Presbyterian clergyman and hymn writer: b. Carlisle, Pa., 12 Sept. 1818; d. Bloomfield, N. J., 6 July 1888. The son of a well-known pastor, he was graduated at Yale in 1837 and entered the theological Seminary, New York, in 1840. He held various Presbyterian pastorates and wrote the popular hymns 'Blest Saviour, Thee I Love' (1851), and 'Stand Up, Stand Up for Jesus' (1839).

DUFFIELD, William Ward, American civil engineer: b. Carlisle, Pa., 19 Nov. 1823; d. 1907. He was graduated at Cornell in 1841 and served as lieutenant on the staff of General Pillow in the Mexican War 1847-48, and during the Civil War commanded the 4th Michigan Infantry. He was brevetted major-general in 1863, elected State senator in 1876, and in 1882 was appointed chief engineer for railways in Michigan, New York, Illinois, Texas; and United States engineer of improvements on Wabash and White rivers in 1892. In 1894-98 he was superintendent of the United States Coast and Geodetic Survey. In the survey (Report) for 1895-96 he published a valuable table of 10-figure logarithms to 100,009, newly calculated. His writings include 'School of the Brigade, and Evolutions of the Line'; 'Treatise on Logarithms.'

DUFFY, Sir Charles Gavan, Australian statesman: b. Monaghan, Ireland, 12 April 1816; d. Nice, France, 9 Feb. 1903. He took to journalism and in 1842 assisted in founding a Dublin newspaper called the Nation. In 1843 he was convicted of sedition with O'Connell, but the House of Lords in the following year quashed the conviction. He played a prominent part in the founding and directing of the Irish Confederation and in 1848 he was brought to trial along with other members of that body on a charge of treason-felony, but the prosecution could not obtain a conviction. In 1852 he was elected to Parliament as representative of New Ross and
succeeded in forming an independent Irish political party. Dissensions arose, and in consequence he resigned his seat and went to Australia in 1856. For some time he practised as a barrister in Melbourne. In 1857 he became Minister of Public Works in the first responsible Victorian government. In 1858 and again in 1862 he was Minister of Lands and became Premier of Victoria in 1871. In 1880 he returned to Europe. Several works from his pen have been published, including 'The Ballad Poetry of Ireland' (1845, about 50 editions); 'Young Ireland: a Fragment of Irish History 1840-50' (1880); 'Four Years of Irish History 1845-49' (1883), a sequel to the preceding work.

**DUPERNET, dū-fren-ît**, a native basic phosphate of iron. It occurs in small crystals of orthorhombic form, but usually it is in radiating-fibrous masses, sometimes with botryoidal or drusy surface. Its hardness is 3.5 to 4 and specific gravity about 3.3. It is nearly opaque, has a silty lustre and blackish-green color. It is found in Westphalia, Bohemia, France and in East Cornwall, England. In the United States it occurs as a fibrous coating in the Green Sand formation at Quabbin, Mass.; also in compact greenish-brown radiating masses underlying layers of lignite in Rockbridge County, Va. It was named in honor of the French mineralogist Dup renoy.

**DUFRESNE, Charles, shārē dū-frān. See Du Cange.**

**DUFRENNY, dū-frá-nē, Charles Rivièere, French poet; b. Paris 1654; d. there, 6 Oct. 1724.** He was appointed manager of the royal gardens on account of the strong love of flowers which he manifested, and in this capacity introduced into France the taste for gardens in the English style. Among his dramatic pieces may be mentioned 'L'esprit de contradiction,' a one-act play in prose; 'Le mariage fait et rempu,' in verse; and a second prose piece in three acts, called 'Le double veuvage.' He also wrote a romance in which he depicts the manners of the time after the fashion of Le Sage, 'Les aventures sentimentales et comiques.'

**DUGAS, Louis Alexander, American physician; b. Washington, Ga., 3 Jan. 1806; d. 1898.** His parents were of French ancestry and emigrated from Santo Domingo. He was educated at home, studied medicine with Dr. John Dent, and in 1827 was graduated at the medical department of the University of Maryland. After attending lectures in Baltimore and Philadelphia, and spending several years in study in Europe, he settled in Augusta, Ga., in 1831. In 1832 he united with five others in founding the Medical College of Georgia, in which he was for many years professor of surgery. In 1869 the degree of LL.D. was conferred upon him by the University of Georgia. For many years he was president of the Medical Society of Augusta and president of the Medical Association of Georgia. During the Civil War he was volunteer and consulting surgeon of military hospitals. From 1851 to 1858 he was editor of the *Southern Medical and Surgical Journal*. His works include 'Rheumatism'; 'Ophthalmology'; 'Colic and Dysentery'; 'Convulsions'; 'Surgical Operations during Mesmeric Insensibility'; 'Use of Quinine in Fevers'; 'Diagnosis of Shoulder Dislocations'; 'Fractures of the Scapula'; 'Transactions of the Medical Association of Georgia'; 'Pathological Peculiarities of NEGROES.'

**DUGDALE, Sir William, English antiquary; b. Shustoke, Warwickshire, 12 Sept. 1605; d. there, 10 Feb. 1686.** He was, in 1640, made *rouge croix pur suvant*, and had apartments in the heralds' office, with ample opportunities for his favorite study. With Dods worth he prepared the *Monasticon Anglicanum* (1655-73). The principal work of which Dugdale had the sole merit is the *Antiquities of Warwickshire* (1656). At the Restoration he was appointed Norroy king-at-arms, and in 1677 Garter king-at-arms, with the honor of knighthood. Besides the works already mentioned, he published the *Baronage or Peerage of England* (1675-76); *Origines Judiciales*, or Historical Memoirs of the English Law Courts of Justice, 3.5 to 4 and specific gravity about 3.3. It is nearly opaque, has a silty lustre and blackish-green color. It is found in Westphalia, Bohemia, France and in East Cornwall, England. In the United States it occurs as a fibrous coating in the Green Sand formation at Quabbin, Mass.; also in compact greenish-brown radiating masses underlying layers of lignite in Rockbridge County, Va. It was named in honor of the French mineralogist Dufrenoy.

**DUGMORE, Arthur Radclyffe, American artist and author; b. England, 25 Dec. 1870.** He studied painting at the Belle Arti, Naples; came to the United States in 1889, and has devoted himself to the study of ornithology, drawing, painting and illustrating by photography. He exhibited his paintings in London 1913, and lectured in the United States and England 1911-14. In 1914 he went to Belgium to investigate conditions of German warfare against the Belgians. He was taken prisoner by the Germans, but was afterward released. He was made lieutenant of the British army, March 1915, and was wounded at the battle of Aisne. He has published 'Bird Homes'; 'Habits of the Land Birds Breeding in the Eastern United States' (1900); 'Nature and the Camera' (1902); 'Camera Adventures in the African Wilds' (1910), which contains his experiences (many of them extremely hazardous) in photographing African big game; 'Wild Life and the Camera' (1912); 'Romance of the Newfoundland Caribou' (1913), in which he gathered the results of nine seasons of patient and successful camera hunting of the rare animal; 'Romance of the Beaver' (1914).

**DUGONG, dū-gōng, or DUYONG, the Malay name for the genus *Halicore* of the order *Sirenia* or "sea cows." It is from five to seven feet long, occasional specimens attaining a length of nine feet. It is a marine animal, never ascending rivers, and feeds chiefly on sea-weed; in which particular it differs from the related genus *Manatus*. It is found along the shores of Australia, of the Indian Ocean and around the Red Sea. Unlike the manatee it has a crescent-shaped tail, its nostrils are on the upper part of the muzzle and its flippers are quite without trace of nails. The skull of the dugong is characterized by the thickness of the beak and the lower jaw, both of which are bent sharply downward, almost at right angles to the axis of the skull. In the males the incisors are developed into large, sharp, teeth directed downward. In color the animal is grayish-blue, sometimes whitish below. The female is proverbial among the Malas for her maternal solicitude for her offspring, of which
DUGOUT — DUKER-BOK

but one is produced at a birth. And this is sup-
posed to be one of the sources of the mermaid
legend.

The flesh of the dugong is said to be ex-
tremely palatable; but its chief value, from a
commercial standpoint, is the oil yielded by
the Australian species (Halocore australis).
This has been in such demand for medicinal and
other purposes as to have caused a wholesale
slaughter amounting almost to the extermina-
tion of the species. See SIRENIA for structure.

DUGOUT, a cave dug in the side of a hill
or mountain, used as a dwelling, partly built of
logs as seen in some sections of Montana, or as
a place of refuge from cyclones and tornadoes.
These are frequently to be seen in some of the
Western States. Also the name of a canoe or
boat made from a log of wood, hollowed and
shaped for use.

In military usage, a dugout is an artificial
cave used for the purpose of cover from shells.
It is either hollowed out and propped up from
within, or is dug from the surface of the earth,
and then covered with layers of earth and
bricks or stone supported on a framework of steel
ralls. See Fortifications.

DUQUAY-TOUIN, dû-gâ-tro’n-în. René.
French seaman: b. Saint Malo, 10 June 1673;
d. Paris, 27 Sept. 1736. His various successful
privatereeping expeditions attracted the attention
of the government before he was 21, and Louis
XIV sent him a sword. He captured great
numbers of English and Dutch ships on the
coast of Spain and Ireland; in 1696 he took a
great part of the outward-bound Dutch fleet
under Wassenaer; in 1697 he entered the
royal marine as a captain. He signalized him-
self so much in the Spanish war that the king
granted him letters of nobility, in which it
was stated that he had captured more than 300
merchant ships and 20 ships of war. By the
capture of Rio de Janeiro (1711) he brought
the Crown more than 25,000,000 francs. Louis
XIV made him lieutenant-general and placed
him in command at the Seine. Under Louis XV
he rendered important services in the Levant and
the Mediterranean.

DU GUESCLIN, dû gâ-klaⁿ. Bertrand,
constable of France: b. Motte-Broon castle,
near Rennes, 1320; d. 13 July 1380. He served
first in the army of Charles of Blois (1342).
He was knighted in 1354. Mainly to him must
be attributed the expulsion of the English from
Normandy, Guienne and Poitou. He was
captured by Chandom at the battle of Auray in
1364, and ransomed for 100,000 francs. While
serving in Spain against Peter the Cruel he
was made prisoner by the English Black Prince,
but was soon liberated. For his services in
Spain he was made constable of Castile, Count
of Trastamare and Duke of Molinas; and in
1370 he was made constable of France. In
1373 he occupied most of the fortresses of
Brittany and died at the siege of Châteauneuf
de Randon. Consult Luchaire, Historie de Ber-
trand du Guesclin et de son époque (1876);
Stoddard, ‘Bertrand Du Guesclin’ (1897).

DUHM, Bernhard Laward, German Pro-
estant biblical scholar: b. Bingum, Hanover,
1847. He received his education at Göttingen,
where he taught from 1877-89. In the last-
named year he went to Basel in the capacity
of professor of Old Testament theology. He
is especially noted for his brilliant biblical
criticisms. His works include ‘Theologie der
Propheten’ (1875); ‘Über Ziel und Methode
der Theologie’ (1889); ‘Die Kosmologie und Re-
ligion’ (1892); ‘Das Geheimnis in der Re-
ligion’ (1896); ‘Die Entstehung des Alten Testa-
mants’ (1897—1906); ‘Das kommende Reich
Gottes’ (1909, translated into English by Duff,
1911); translations in the original metre of Job
(1897); the ‘Psalms’ (1899); ‘Jeremiah’
(1903); ‘Habakkuk’ (1906); and commentaries
on these books and on the 12 minor prophets.

DÜHRING, dü’ring. Eugen Karl, German
philosophical writer; b. Berlin, 12 Jan. 1833.
He studied at the University of Berlin, and
practised law for a time; he then became professor
of philosophy and political economy at Berlin
in 1864, but gave up the position on account of
quarrels with the faculty. He has written
‘Der Wert des Lebens’ (1865), which did
much to introduce the positivism of Comte into
Germany; ‘Kritische Geschichte der Philos-
opie’ (1869); ‘Logik und Wissenschafts-
theorie’ (1878); ‘Die Judenfrage als Rassen-
Sitten- und Kulturfrage’ (1892); also a num-
er of works in political economy, including
‘Kapital und Arbeit’ (1865) ‘Die Verkleinerer
Careys’ (1867); and ‘Kritische Geschichte
der Nationalökonomie und des Sozialismus
(1879). Consult Döll, ‘Eugen Dürhring’
(1883).

DUKER-BOK, dik’er- or doik’er-bók, a
genius of small antelopes (Cephalophus),
native to southern Africa. They are character-
ized by small, straight horns, generally present
in both sexes; and by an upright tuft of hair
between the horns. The typical species
(C. grimmii) is found in bush-covered districts
from the Cape of Good Hope to the Zambesi
River, and ranges even farther north along the
west coast of Africa. It stands about 26 inches
high; its ears are long and narrow; its color
is yellowish-brown, with a tendency to gray;
but the color is decidedly variable. The horn,
in this species present only in the male, are
from three to five inches long, and rise at a
sharp angle to the face. Of the allied species
the following are the most important: The red-
buck of Natal (C. natalensis), which differs
from C. grimmii in that its horns incline back-
ward, and are present in both sexes; and that
its color is more reddish. The bluebuck of the
jungle (C. monticola) is a tiny creature, only
13 inches high at the shoulder, that swarms in
the Natal region. It is smaller and lighter in
build than a hare; is bluish mouse-color, and
has tiny straight horns. It feeds on berries
and young shrubs. The zebra-antelope of West
Africa (C. dorcas) is distinguished by its coat
of rich golden-brown, banded with eight or
nine transverse lines across the back loin.
The wood antelopes, also West African, are
nearly three feet tall, and are classed in two
species, C. syvicoctor and C. senitinki.

The name ‘duiker’ signifies ‘ducker’ or
‘diver’ in allusion to the animal’s rapidity of
motion when in the thickets. Consult Schwein-
furth, Heart of Africa (Leipzig 1878); and
other books by African explorers and natural-
ists.
DUILUS, Gaits, Roman general: b. about 300 B.C. He was trained to arms by his father, Marcus and rose to the highest rank as a naval and military officer. He became consul in 260 B.C., defeating the Carthaginians near Mykle in that year. In honor of this victory, Rome's first success on the sea, a magnificent column (columna rostrata) was erected.

DUISBURG, doo'is-boorg, Germany, city, an inland port of Prussia, in the Rhine province, about 13 miles north of Düsseldorf. The town has civic, educational and other institutions in keeping with its importance. Its finest of the churches is the 14th century Saint Salvator, with fine wall-paintings. Duisburg has blast-furnaces, foundries and other works depending on the iron trade. Its chemical works, cotton-mills and commerce are extensive. It is an ancient place, early rose to be a free town, and became a member of the Hanseatic league. It possessed a university from 1655 to 1818. The tomb of Mercator, the famous geographer, is here. Pop. about 93,600.

DUJARDIN, dü-zhär-däh, Félix, French naturalist: b. Tours, 5 April. 1801; d. Rennes, 15 April, 1880. From 1827 to 1834 he delivered public lectures in Tours upon geometry and chemistry as applied to the arts. During the same period he published several geological works, in one of which he first made known the curious fact that artesian wells bring to the surface seeds and remains of insects which have been taken from long distances and transported through subterranean passages. In 1833 and 1834 he published descriptions of the flora of the region of the Loire, and of the geology and fossils of Touraine. He then devoted himself to zoo logical researches, and published observations upon the rhizopoda, for which he proposed a new classification. In 1839 he added extended annotations to the third volume of De Lapparent's "History of Invertebrate Animals," and among his later publications were his researches upon the brain of insects, and upon the instinct of bees. He was a professor at Rennes from 1839.

DUJARDIN, Karel, Dutch artist: b. Amsterdam 1640; d. Venice, 20 Nov. 1678. He went to Italy when young, and was a member of the Society of Painters at Rome, among whom he was called Barba di Becco. His works met with general approbation. His landscapes have spirit and harmony, his figures expression and his color the brilliancy which distinguishes his school. His paintings are rare and command a high price. He also published 52 landscapes etched with much spirit and ease. The Louvre possesses his masterpiece 'The Charltons.' Amsterdam, Brussels, Berlin and the National Gallery, London, have specimens of his work.

DUK-DUK, in New Britain (formerly New Pommern) — the largest island of the Bisмарк archipelago in the Pacific Ocean — is a secret male society for the preservation of ancient observances among the Melanesian natives. The inculcation of respect and order among the youthful members of the community, the subjection of women and the enforcement of obedience to the chiefs are among its main objects; its mystic ceremonies, masked dances, etc., are picturesque. The society is analogous to the West African negrital Mumbo Jumbo organizations, and is interesting sociologically as an uncivilized form of the Vehngerich lodges, bachelors' clubs, etc., of Europe and America. Consult Fowell, 'Three Years Among the Cannibals of New Britain' (1897).

DUKE, Basil Wilson, American lawyer and famous cavalry leader in the Confederate army: b. Scott County, Mo., 28 May 1838; d. New York, 16 Sept. 1916. He was educated at Georgetown (Ky.) College and Danville College and the Lexington Law School. Before he had reached majority General Duke was active in the group of men who fought to carry Missouri into the Confederacy. He was born in Scott County, Ky., in 1838, but saw his first military service in Missouri. Returning to Kentucky, he joined his brother-in-law, Gen. John H. Morgan, in raising troops for the Southern Army. From a lieutenant in the famous cavalry organization known as Morgan's Rangers, he rose rapidly to the rank of colonel and led one of the hardest fighting cavalry regiments in the service. He was badly wounded at the battle of Shiloh, but recovered in time to participate in the operations of Morgan's troops in Tennessee and Kentucky, being present at the famous Ohio raid. With his chief and most of the command he was captured and imprisoned in the Ohio penitentiary, from which General Morgan dug his way to freedom with most of his men. He frequently distinguished himself for gallantry and the unusual success of the military operations he directed, and gained a reputation for daring second only to that of his masterful leader with whom he was associated for the full period of the rebellion.

For more than 20 years Brigadier-General Duke was connected with the law department of the Louisville and Nashville Railroad, with headquarters at Louisville. He was the author of many books on finance and the Civil War, among the latter being the 'History of Morgan's Cavalry' (1867) and 'Reminiscences of Gen. Basil W. Duke' (1911). He also wrote the "History of the Bank of Kentucky."}

DUKE, James Buchanan, American tobacco manufacturer: b. on farm near Durham, N. C., 1857. He was educated in the country schools; entered the tobacco business with his father and brothers at Durham under the firm name of Duke Brothers and Company. In 1884 he went to New York and in 1889 organized the American Tobacco Company of which he was president until 1912. He is president of the Continental Tobacco Company and the Consolidated Tobacco Company and since 1912 chairman of the board of directors of the British-American Tobacco Company. He is a director of the Imperial Tobacco Company and of many other corporations.

DUKE (in French duc, in Spanish duque, in Italian duca, in Venetian doge, all derived from the Latin dux, leader, commander), a title belonging originally to a military leader. It seems to have come into use when Constantine separated the military and civil commands of the provinces; the title duc was then applied to the military governor of a province, and the ducal rank was made inferior to that of the comes (count). The Goths, Franks and other
northern tribes who invaded the vast Roman territories, adopted, if they had not before borrowed, the titles of duke and count. Among those warlike peoples, however, the dukes as military chiefs soon acquired a marked preeminence. In the year 616 the Danubian dukedoms were part of a civil and judicial nature. Under Charlemagne, who was jealous of the increasing power of the higher nobility, the dignity was suffered to cease, but under his weaker successors the ducal governors of the provinces attained an almost absolute independence. The concession of hereditary power and independent jurisdiction, first to the central province known as the Isle de France, and then to Aquitaine, extended itself under the Carlvingtins to Burgundy, Normandy, and Gascony, and on the accession of Hugo Capet to all the other subaltern tenures. It was not long until the dukes, feeling secure in the unlimited governing power of their provinces, proclaimed their title to be as good as that of the king. They coined money, assumed the crown and sceptre, gave law to their subjects, made war even against the king and reduced the royal jurisdiction to a few towns such as Rheims and Laon. -From the time of Philip II (Philippe Auguste) to that of Louis XI, however, the dukedoms gradually reunited to the crown, and those subsequently accorded to the members of the royal family enjoyed none of the privileges of independent sovereignty. Prior to the Revolution dukedoms were created by letters patent of the crown, and were of the same character as dukedoms and peers held the first rank and had a seat in Parliament. The dignity of the second class descended to their male children, but that of the dukedoms by brevet ceased with themselves. The rank of duke in the royal family of France was superior to that of prince, and sometimes inferior to that of count. The ducal along with all other titles of nobility was abolished at the Revolution, but was restored by Napoleon in 1806. In Great Britain the title of duke ranks as a title of honor or nobility next below that of a prince or princess of the royal blood and that of archbishop of the Church of England. The first hereditary duke in England was the Black Prince, created by his father, Edward III in 1337. The earldom of Cornwall was bestowed upon him, and was thenceforward attached to the eldest son of the king, who is considered a duke by birth. The duchy of Lancaster was soon after conferred on his third son, John of Gaunt, and hence arose the special privileges which these two dukedoms still in part retain. Richard II was the first sovereign to make creations apart from princes of the royal house. Henry VIII and Edward VI made creations; but through attainders and failure of issue by the reign of Elizabeth and the early Stuart period became extinct, and was not revived till the creation of Villiers, Duke of Buckingham, and Ludovic Stuart, Duke of Richmond, by James I. Charles II bestowed dukedoms on six of his illegitimate children—those of Monmouth, Grafton, Northumberland, Southampton, Richmond and Saint Albans. By William, Anne and George I lower dignities were advanced to the rank of duke—of the 26 dukedoms of the British peerage exclusive of those of royal blood, only two, those of Norfolk and Somerset, were created prior to the Civil War. The coronet of a British duke consists of eight strawberry leaves of a conventional type on a rim of gold. In the Bible the word dukes is used, Gen. xxxvi, 15, for the duces, of the Vulgate.

DUKE OF EXETER'S DAUGHTER, a rank in the Tower of London, so-called after its inventor, a minister of Henry VI. According to Blackstone it was never put in use.

DUKE'S LAWS, so named from the Duke of York, afterward James II, were a code promulgated by Col. Richard Nicolla, the English commander who took New Amsterdam from the Dutch in 1664 and became governor of the colonies under the Duke's patent. They applied first to the Dutch; confirmed the patroons in their estates, which they forthwith were to be called manors; introduced jury trial; amended the criminal code, and provided for freedom of religion and equal taxation and militia service. There was no popular election of magistrates at first, but the code was afterward modified into the instrument of government of New York and New Jersey.

DUKES, Leopold, Hungarian scholar: b. Pressburg, 27 Jan. 1810; d. Vienna, 3 Aug. 1891. He spent the greater part of his life in research work in Jewish literature, fully 20 years being passed in the Bodleian Library and the British Museum. His books, largely of an historical character, threw new light on mediæval Hebrew literature, Hebrew grammarians and lexicography. He was also a frequent contributor to English, German and Hebrew publications. Among his works the most entertaining was his 'Rabbinische Blumenküste,' a collection of rabbinical proverbs and their illustrations from the popular sayings of other races. He was at his best in his sketches of the Hebrew poets of the Middle Ages, Moses ben Esra and Ibn Gabril in particular. He translated into German (1839) the famous Pentateuch commentary of Rashi.

DUKHOBORS, doo-k6'h6r. DUKHO- BORTSY. See DUKHOBORS.

DUKINFIELD, England, a borough in county of Chester, a few miles from Manchester. Extensive collieries, cotton factories, engineering, brick and tile works give employment to the greater part of the population. Pop.: about 19,500.

DULAG, doo'làg, Philippines, a town on the eastern coast of the island of Leyte, at the mouth of the Catbassac River. There are large
DULANGAN, Doo-lan'gåan, or GULANGAN, a heathen tribe of the Philippines, living in the southern part of the province of Davao, island of Mindanao. It is uncertain whether they are of pure Malay race or have an infusion of Negrito blood.

DULANY, Daniel, American colonial lawyer: b. Annapolis, Md., 1721; d. 1797. He was educated in England, at Eton, Cambridge and the Temple, and was admitted to the bar of Maryland in 1747. He was deputy commissary-general from 1754 to 1761 and a member of the provincial council from 1757 to 1775. He also served as deputy secretary and secretary of Maryland from 1761 to 1773. In 1765 he wrote a powerful pamphlet against the Stamp Act, and his arguments against arbitrary taxation furnished material for Pitt's famous speech on behalf of the American colonies in 1766. He was, however, a staunch Royalist, refused to take part in the Revolution and lost nearly all his landed property by confiscation. Consult Tyler, Literary History of the American Revolution

DULCAMARA. See Bitter-sweet.

DULCAMARIN (picroglycin or dulcarin, Ca\textsubscript{3}H\textsubscript{4}O\textsubscript{6}) a glucoside which is separated from the aqueous extract of Solanum Dulcamara — bitter-sweet, and consists of a yellow, transparent, resinous, easily powdered mass, readily soluble in alcohol, sparingly in ether, and very slightly in water. It has a slight alkaline reaction and yields to platinum salt. The narcotic alkaloid solanine is also obtained from bitter-sweet.

DULCE, dool'sè. (1) A lake of Guatemala, on the east coast, 100 miles northeast of Guatemalan City, communicating with the Gulf of Honduras by the lakelet el Golfe. It is about 30 miles long by 12 broad and from 20 to 60 feet deep. Also called Lake Izabal, it is the chief waterway of the state to the Caribbean Sea and the Atlantic Ocean. (2) A river in Argentina, rising in the province of Tucuman, and called in its lower course the Saladiello River. It flows northeast past Santiago and ends in the salt marshes of Lake Porongos. (3) A gulf on the coasts of Costa Rica and Panama, in Central America.

DULCE DOMUM, a famous song sung at Winchester College, England, on the eve of the break-up day for the summer holidays. The origin of both words and music is very uncertain — it is usual to ascribe the former to one Turner, probably him who became bishop of Ely, and was one of the seven bishops under James II; the latter, to Johannes Reading, organist of the college from 1681 to 1689.

DULCIGNO, dool-chén'yo, Montenegro, a small seaport town on the Adriatic. The inhabitants, formerly notorious under the name of Dalmatians, as the most dangerous pirates of the Adriatic, are now engaged in commerce or in the fisheries of the river Bojana. Pop. 5,102.

DULCIMER, an ancient musical instrument used by various nations, and, in shape and construction, having probably undergone fewer changes than any other instrument. In its earliest and simplest form it consisted of a flat piece of wood, on which were fastened two converging strips of wood, across which strings were stretched tuned to the natural scale. The only improvements since made on this type are the addition of a series of pegs, or pins, to regulate the tension of the strings, and the use of two flat pieces of wood formed into a resonance-box, for the body. The German name, Hackbrett (chopping-board), points to the manner in which it was played, the wires being struck by two hammers, one held in each hand of the performer. The fact which makes the dulcimer of the greatest interest to musicians is that it is the undoubted forefather of our pianoforte. A modern grand pianoforte is, in reality, nothing more than a huge dulcimer, the wires of which are set in vibration by keys. It probably came from the East, brought by the Crusaders.

DULCISINA DEL TOBOZO. The idealized peasant girl whom Don Quixote gives the romantic name (meaning sweetheart or lady-love), but who is commonly known as "Dona Aldoriza Lorenzo. The hero of Cervantes' novel adores this humble girl of Toboso madly and becomes her champion.

DULLER, Eduard (1809-53), a German historian, theologian and poet, born and educated in Vienna, who had both literary and ecclesiastical ambitions. Before he was 19, he wrote a religious drama, 'Meister Pilgrim,' which was successfully performed. He took a prominent part in the German Catholic movement, strenuously espousing the cause of religious liberty. Besides several distinctly literary productions and contributing the libretto to Mangold's opera of 'Tannhäuser,' Duller published these standard historical works: 'Vaterländische Geschichte,' 'Geschichte des Deutschen Volkes' and 'Geschichte der Jesuiten.'

DULONG, Pierre Louis (1785-1838), French scientist whose name is associated with the law in physics known as the law of Dulong and Petit. Dulong was educated at the Ecole Polytechnique. Afterward (1820) he was made professor of physics at the same institution. In 1819, in conjunction with a young physicist, Dulong discovered the law that the specific heat of an element, multiplied by its atomic weight, is the same for all solid elements. Although this law has been verified again and again, it has yet to receive a theoretical explanation. In recognition of his scientific achievements, Dulong (in 1823) was admitted into the Academy of Sciences. He lost an eye while experimenting in his laboratory.

DULSE, an edible seaweed growing on rocky seacoasts. In the British Isles dulse is a cheap article of food; elsewhere it is rather expensive and even a luxury. The name is also applied to another seaweed found in the southwest of England, which is also sometimes employed as a food. Still a third brand of dulse is found in Alaska.

DULUTH, Minnesota, city and lake port, seat of Saint Louis County and third largest city of the State, is favorably situated at the extreme western end of Lake Superior. The stycth-like projection called Minnesota Point, with a similar peninsula from the Wisconsin shore, forms a harbor for the city and its twin
port, Superior (Wis.). 19 miles square with a shore line of 49 miles. This fine harbor is entered by two channels, one, natural, near the Wisconsin shore, the other, a canal, 250 feet wide, piercing Minnesota Point. The broad mouth of the St. Louis River is nearly enclosed by other points of land, forming an excellent inner harbor. Federal improvements to the value of $7,500,000 have deepened the harbor from 9 to 22 feet and made 17 miles of channels 22 feet deep and 200 to 600 feet wide. Overlooking the river, harbor and lake from steep and picturesque slopes, the city of Duluth stretches from the old Astor trading-post at Fond du Lac northeastward for more than 20 miles.

Improvements and Buildings.—The city owns its own waterworks and gas distributing system which it values at $4,756,218. It has 85 miles of paving and 186 miles of sewers. The city has profited by the beauty of its surroundings in its parking and boulevard, having laid out the grounds alongside the banks of the several mountain streams that enter the lake at this point, and made roadways that command views of the lake and countryside. Altogether it possesses 21 miles of these drives, the most notable of which is Rogers Boulevard that follows most interesting routes. The city has 442 acres of parks including Lester, the largest, Congdon and Chester; and in addition there are eight playgrounds. The Duluth Superior Street Railway reaches all parts of the city and Superior, Wisconsin, using the Interstate Bridge. It has 60 miles of track. Among the buildings that are noteworthy are the Central High School, Carnegie Library, Court House, Pilgrim (Congregational) Church, Darling's Observatory, the National Guard and Naval Militia Armory, Kitchi Gammi Club, Aldworth Building and Soo Line Station.

Recreation Facilities.—Duluth is a favorite resort for tourists because of the variety of outings it suggests. Excursion steamers make regular trips to Fond du Lac and to Isle Royale, and sightseeing trips on the Lake. The Duluth Boat Club, with 2,000 members, has a high reputation for sportsmanship. There is abundant fishing both for Lake Superior and inland varieties. The curling rink has a capacity of 6,000 curlers and skaters; and the ski hills attract thousands annually. Other attractions for the visitor are the incline railway up the bluff 800 feet high that overlooks the centre of the city and the aerial bridge over the steamer channel through Minnesota Point.

Education.—Duluth has 41 school buildings, including two high schools and three junior high schools. These buildings are valued at $3,533,218. In the system are enrolled 17,000 pupils. A state normal school located here enrols 400 students annually. The Roman Catholic Church represents a capital of $22,000,000 and is also a training school for nurses in Saint Mary's Hospital, and the Episcopalian maintain a school for nurses in Saint Luke's Hospital. In the city there are 90 churches. The Duluth Carnegie Library and two branches circulated in 1916 236,166 volumes. The Duluth Bar Association has an extensive library.

Commerce.—The great advantage of possessing a fine harbor has made Duluth the second port in point of tonnage in the United States. In 1916 its outgoing tonnage of ore and grain equaled that of any two ports in the world. This tonnage has greatly increased during the past few years. In 1900 the total number of tons shipped and received was 14,387,058, and the total number of arriving and departing was 11,334; in 1917 the tonnage was 52,177,333 and the number of vessels 12,445. Four hundred and ninety-nine vessels make Duluth their home port. Less than three hours' run from the Mesabi Range, the city receives iron ore in constantly increasing volume for shipment to mills at Chicago, Gary and Pennsylvania points. In 1916 this business amounted to 38,374,953 tons. Ore trains run directly to the docks from which they are dumped into pockets which in turn discharge into ore steamers. One of these docks is 2,300 feet long and 50 feet wide and contains 384 pockets. Usually it takes three hours to dump 10,000 tons. From the Red River Valley and the fields of Canada 65,072,940 bushels of grain were received at the Duluth elevators which have a capacity of 33,125,000 bushels; and from the forest counties of northern Minnesota 146,892,000 feet of lumber. The district supplying these products depends on Duluth for its coal as also do the manufacturing plants of Minneapolis and Saint Paul, and other points of consumption. In 1916, 9,585,337 tons of hard and soft coal were received at Duluth. The coal docks are equipped with electrically operated machinery so that 1,000 tons can be unloaded in an hour. The docks have a storage capacity of 15,000,000 tons. For the transportation of coal and other commodities the city has ample railroad facilities. With the Minneapolis and Saint Paul it is connected by the Great Northern, Northern Pacific, Soo and the Chicago, Saint Paul, Minneapolis and Omaha; with North Dakota, Manitoba and Montana by the first three and the Canadian Northern; with the Mesabi Range by all of these, excepting the last, and by the Duluth, Mesabi and Northern. The Duluth and Iron Range connects the city with its subport, Two Harbors and with the Vermillion Range. The Duluth, South Shore and Atlantic and the Soo Line maintain service with eastern points; and both the Soo and the Chicago, Saint Paul, Minneapolis and Omaha make direct connection between Duluth and Chicago. The Chicago, Milwaukee and Saint Paul maintains a trolley service between Duluth and the Twin Cities by arrangement with the Northern Pacific Company.

Manufacturing.—With its great commercial advantages the city has been enabled during the past 25 and especially during the past 10 years, to increase its manufacturing capacity very greatly. The largest plant is that of the Minnesota Steel Company (United Steel Corporation) in the western part of the city. It represents a capital of $22,000,000 and employs 4,000 men, for whom it has built a model city within the limits of Duluth. The Zenith Furnace Company produces coke tar and ammonia, as well as gas for lighting and heating the city. Duluth also has many establishments working in iron, a cement factory, flour mills, sash factories, clothing establishments and steamboat works. In all it has 243 establishments employing 12,000 people and producing annually a value of $20,000,000, exclusive of the
value of the steel, of which $8,000,000 is added by manufacture. For this manufacturing there is available 120,000 horsepower of electric current from the Saint Louis River, of which 60,000 is already being used. The city is lighted by this power, the current being distributed by the Duluth Edison Electric Company at a maximum rate of 6 cents per kilowatt hour.

Finance.—Duluth has 10 banks — 4 national and 6 commercial — with a capital and surplus of $7,000,000, and deposit of $30,000,000. Its clearings in 1916 were $283,812,916. Postal receipts were $440,977. Its assessed valuation is $88,596,674. The rate of taxation is 37 mills.

Government.—The government of Duluth has been a model for other cities. Five commissioners, each responsible for a single department of municipal activity, form a council under the presidency of the mayor, the commissioner of public safety. This department includes police, fire, health and harbor divisions. The commissioner for public affairs has charge of the library and welfare divisions; the commissioner of finance controls accounting and licensing; the commissioner of public works supervises the engineering, street improvement and construction of water and gas mains; the commissioner of public utility is responsible for the water and gas systems. The commissioners acting as a council appoint the city clerk, assessor, attorney and auditor; but they themselves have appointive power within their own departments for all necessary employees. Through ownership of the gas distributing system the city has reduced the price from $1.90 to 75 cents a thousand cubic feet. The city is without saloons.

History.—Duluth has had an interesting history. Radisson and Grosilliers, French traders, passed the site of the city in 1659. In 1679 Daniel Greysolon Sieur Du Lhut visited the head of Lake Superior and became very friendly with the Dakota Indians, whose lands then extended into what was later the Chippewa Territory. It was not until 50 years later that the first of the Fur traders arrived. La Vérendrye, father of the famous explorer, sent his son, Henry, to establish a trading post. In 1804 the post was sold to John Collet, who was succeeded by the North West Company. In 1818 the post was bought by James Bayley, who sold it to John Collier. In 1837 the charter of the city was granted and in 1855 it was granted a city charter.

In 1865 the town was incorporated. The first town preacher was Rev. J. G. T. Meigs, who preached in a tent. The church was built in 1870. The first school was built in 1871. The first public library was opened in 1872. The first hospital was opened in 1873. The first newspaper was the Duluth Era, which was founded in 1871. The first. bridge was built in 1876. The first electric light plant was opened in 1880. The first telephone service was established in 1881. The first electric trolley line was opened in 1886. The first public library was opened in 1892.

In 1870, and the Northern Pacific built through from Duluth to North Dakota in 1874. Later the establishment of better connection with the Minneapolis and Saint Paul and the discovery of iron in the Vermilion Range brought prosperity to the village. The first shipment from the Vermilion Range was made in 1884 from Two Harbors; the first shipment from the Mesabi was made in 1892. Since that date, with the exception of a brief period of depression following the panic of 1893, the progress of the city has been continuous.

Population.—In 1860 the total population of Saint Louis County, including Duluth, was 406. In 1870 this had increased to 3,131. In 1880 the population of the city was 3,483; in 1890, 33,115; in 1900, 52,969; in 1910, 78,400. In 1917 the estimated population was 97,000. The foreign born population is 39 per cent of the whole, the leading nationalities being Scandinavian, 14 per cent; Canadian, 6 per cent; Irish, 3 per cent; and a scattering of English, Germans, French and Scotch.

Author of "The Story of Minnesota."

DULWICH (dul'ich) GALLERY, a collection of paintings in Dulwich College, the first 371 of which were presented by Sir Peter Francis Bourgeois, the English painter, with a donation of £12,000 for the maintenance of the collection and the repair of a wing of the college. This original collection contained 22 paintings by Bourgeois. See Bourgeois, Sir Peter Francis.

DUMA, a Russian word signifying a council or assembly, from dumo, thought; dumat, to meditate, reflect. A town council or city hall is called gorodskaya duma, from gorod, town; the national Parliament is termed gosudarstvennaya duma, from gosudarstvo, state, empire. In Western literature Duma means the national Parliament of Russia, the first of which was opened 10 May 1906. On 19 Aug. 1905 the Tsar Nicholas II issued a manifesto announcing that he had granted a constitution to Russia and that an imperial Duma would be created. This was the second attempt made by a Russian sovereign to produce a semblance of popular government. Already in the 16th and 17th centuries the tsars of Old Muscovy convoked occasional Zemski Sobors, with almost nuyatory powers; and Ivan the Terrible once summoned an assembly to deliberate upon the question as to whether a war with Poland should be continued. All that we know of this gathering is that its 399 members readily voted for the continuation of the war and at the same time begged the tyrant's pardon for having dared to express any opinion at all.

Again,
in 1613, when a new dynasty had to be chosen in the place of the extinct Rurik dynasty, the boyars (aristocrats) convoked a kind of States-General which elected the House of Romanoff. After 300 years that house was swept away by the revolution of 1917. But it was the vain-gloriously ambitious Catherine II who first made a show of being imbued with the constitutional and humanitarian maxims of Montesquieu and Beccaria. By a rescript dated 14 Dec. 1766 she announced a great legislative assembly which, though not destined to deal with the form of government, was otherwise left free to discuss the grievances of the people and to suggest remedies. On 30 July 1767 the assembly of 364 members met in Moscow. In December 1768 the majority were called into the army or sent home. A small remnant continued their innocuous sessions till 1774, when Catherine abolished them also. For the next 132 years Russia waited for representative government.

The Duma of 1906 was formally inaugurated by a speech, promised that he would “unswervingly uphold the institutions he had granted.” But the often-disillusioned constitutional democrats who formed the majority received his words with coldness and misgivings. They soon discovered that the wish nears their hearts—an amnesty for political offenders—would not be realized. The first session was brief and stormy. The deputies, overwhelmed with the gifts of oratory and possessing little or no experience of affairs, made magnificent speeches and magnificent demands. The Duma was thwarted at every turn by the government and was finally dissolved after an existence of 10 weeks (22 July). A cruel disappointment has befallen our expectations,” read the Imperial ukase, “the representatives of the nation, instead of applying themselves to the work of productive legislation, have strayed into spheres beyond their competence, and have been making inquiries into the acts of local authorities established by ourselves, and have been making comments on the imperfections of the fundamental laws, which can only be modified by our Imperial will.” The “inquiries” referred to concerned the massacres at Bialystok, whether the Duma had sent a commission; its report created a profound and melancholy impression. It was also the drastic agrarian program of the majority of the Duma that helped to bring about the crisis. Indeed, unless the Tsar had consented to abolish the whole of the bureaucracy and appoint a responsible ministry, it is difficult to see how he could have allowed the Duma to continue. The cleavage was too deep between his officials and those whom he called “the representatives of the nation.” The second Duma was convened on 5 March 1907, and only lived till 16 June 1907. The third one, in November 1907 and sat till 1912. The fourth Duma opened in November 1912. See Russia—Government; History; Revolution.

HENRI F. KLEIN,
Editorial Staff of The Americas.

DUMANJUG, doo-män-joog, Philippines, a town of the province of Cebu, situated on Cebu island, the west coast at the mouth of the Dumanjug River, 37 miles southwest of Cebu. Pop. about 20,000.

DUMAS, dü-mä, Alexandre, The Elder, French dramatist and novelist: b. Villers-Cotterets, 24 July 1803; d. Puits, near Dieppe, 5 Dec. 1870. He was the son of a Republican general who bore the same name, and grandson of Marquis de la Pailletiere and a negress, Tiennette Dumas. He went to Paris at the age of 20 to push his fortune and was employed by the Duke of Orleans as a clerk at 1,200 francs a year. He now devoted his leisure hours to completing his education, and his ambition prompted him to shine in the field of literature. Some of his lighter dramatic works were rejected by the theatrical directors, some were accepted and had more or less success, bringing but little fame or profit to their author. At last, in 1829, his drama of ‘Henri III’ appeared on the stage of the Comédie Française. It was produced when the battle between the Romanticists and the Classicists was at its height and hailed as a triumph by the former school. The piece became popular and brought the lucky dramatist the sum of 30,000 francs and the post of assistant librarian to the Duke of Orleans. In the following year appeared his ‘Christine’ and in quick succession ‘Antony’, ‘Richard d’Arlington’, ‘Térèsa’, ‘Le Tour de Mon cœur’, ‘Mme. de la T Fare’, ‘Mme. de Bel-Ise’, etc. Dumas had now become a noted Parisian character. The critics fought over the merits of his pieces and the scandalmongers over his probity and ‘galanteries’. To escape his attachment to romance and desirous of becoming the Walter Scott of his country he produced a series of historical romances, among which are ‘Les deux Dianes’, ‘La Reine Margot’, ‘Les trois mousquetaires’ which, with its continuations, occupies eight volumes. ‘Le Comte de Monte-Cristo’ and ‘Memoires d’un medecin’ are also well known, through translations, to English and American readers. Several historical works also bear his name: ‘Les Dix et Louis XIV’; ‘Le Regent et Louis XV’; ‘Le drome de ’93’; ‘Florence et les Medecins’, etc. In 1840 he married Ida Ferrier, an actress, but the marriage appears to have severed the friendly relations that had long subsisted between them. In 1846 he accompanied the Duke of Montpensier to Spain as the historiographer of his marriage; and on his return to Paris he opened there for the purpose of producing only his own pieces and built a fantastic and costly country-seat, which was known as the Chateau de Monte-Cristo and on which he expended 430,000 francs.

It is difficult to come to a satisfactory conclusion as to the merits of this author. Some of his productions are little else than mere translations from English and German sources. His first drama, ‘Henri III’, is but a skillful piece of patchwork, Walter Scott and Schiller furnishing him with the bulk of the material. Equally fatal to his reputation is our knowledge of the fact, gained from a lawsuit he had with the Presse and the Constitutionnel newspapers and from a work by Mirecourt entitled ‘Fabrique de Romans, Minutes de Dumas Cie.’ (Dumas & Company’s Romance Factory), that he had arranged to supply those journals during the year with more novels than the most expert scribe could copy in the time, and that he had in his pay numerous hacks who did the serious part of the work and not faster than his hand or any human hand could obey its orders: the mine of his inventive faculty needed a commercial company and an army of diggers for its exploitation;
DUMAS—DU MAURIER

and he constituted himself, "the managing director of the company." The productivity of himself and his hacks extended to 1,200 volumes. Inaccurate in his history and superficial as his character drawing is, of the genius of Dumas there can be no reasonable doubt; he had great fertility of invention, much humor and gaiety and genuine dramatic power, as the works that were undoubtedly from his pen sufficiently testify; and it is masterly till he had saddled a front rank literary by his own exertions that he descended to the unworthy plan of employing assistants to manufacture novels to order. (See COUNT OF MONTE CRISTO, THE; THREE MUSKETEERS, THE; Consult Blaze de Bury, "Alexandre Dumas sa vie, son temps, son œuvre" (1885); Davidson, "Alexandre Dumas père: his Life and Works, with Bibliography" (New York 1902); Maurel, "Les Trois Dumas" (Paris 1896); Farigot, "Le Drame d'Alexandre Dumas" (Paris 1897); and "Alexandre Dumas père" (Paris 1902); Spure, "Life and Writings of Alexandre Dumas" (1902); Wells, "A Century of French Fiction" (London 1898).

DUMAS, Alexandre, the Younger, French dramatist and novelist: b. Paris, 28 July 1824; d. Paris, 24 Oct. 1895. He was the natural son of Dumas the Elder (q.v.), and while a young man shared his father's life in Paris and accompanied him on his travels. In 1847 there appeared a collection of his poems under the title "Péchés de Jeunesse"; his first novel "Aventures de quatre femmes et d'un perroquet," was published in the same year; others of his novels are "Césarine" (1848); "La Dame aux Camélias" (1848); "Le Docteur Servan's" (1849); and "L'affaire Clémentin" (1867). "La Dame aux Camélias" was dramatized in 1852, and marked an important event in the history of the drama—the introduction of realism in the treating of social and moral problems on the stage. His other dramas include: "Diane de Lys" (1853); "Le Demoni" (1855); "La Quiche" (1857); "Le Fils Naturel" (1858); "Le Père Prodigue" (1859); "L'Ami des Femmes" (1864); "La Femme de Claude" (1873); "La Princesse de Bagdad" (1881); "Denise" (1885); and "Francillon" (1887). He has also written a few essays, discussing social problems; these are: "Lettre sur les choses du jour" (1871); "L'Homme-Femme" (1872); "Question du Divorce" (1880); "Recherche de la paternité" (1883). Dumas was made a member of the French Academy in 1874. Dumas brought the drama back from the exalted realms of poetry and romance to prose and sober realities and he was the chief creator of the modern "comedy of manners." Beginning as a realist, he ended as moralist and sermonizer and in a series of what would now be called "problem play" his wit, originality, brilliance but acidulated, his dialogue clear and incisive; his view of woman is somewhat ignoble; the husband, the wife and the lover form a trinity of types that are repeated in his works with a disagreeable and persistent iteration. See LADY OF THE CAMILLAS, LA; DEMI-MONDE, LE.

DUMAS, Jean Baptiste André, French chemist: b. Alais, Gard, 14 July 1800; d. Cannes, France, 11 April 1884. He studied at Geneva and going to Paris in 1821, was first a lecturer in the Ecole Polytechnique, then professor of chemistry at the Athénée, the Ecole Centrale des Arts et Manufactures (founded by himself), and finally, the Sorbonne. He now wholly devoted himself to chemical studies and his views on chemical equivalents and especially his method of reducing the atomic theory, soon attracted attention over all Europe. His views on the laws of substitutions involved him in a long discussion with the great Berzelius. His researches in organic chemistry, especially his determination of the composition of the indigo and the alkaloids, placed him in the first rank of chemists. In 1849-51 he was Minister of Agriculture and Commerce and also held offices under the Second Empire. In 1875 he was called to fill Guizot's chair in the Academy. His chief works are "Traité de Chimie antique aux arts," and "Lecons sur la philosophie chimique," Consult Maundron, "L'Œuvre de J. B. Dumas" (1886).

DUMAS, Matthieu, French soldier and military writer: b. Montpellier, France, 23 Nov. 1753; d. Paris, 16 Oct. 1837. He early entered the French cavalry, took part in the American Revolution and was employed in the Levant and in Holland. At the commencement of the French Revolution he assisted Lafayette in organizing the National Guard. On the triumph of the extreme party in 1792 he was proscribed, but made his escape to Holstein, where he wrote the first part of his "Précis des Événements militaires," a valuable source for the history of the period of which it treats (1798-1807). He d'Autichamp; a part in the Austerlitz and Moscow campaigns and was taken prisoner. On the return of the Emperor from Elba he was employed in organizing the National Guard. After the Restoration, Louis XVIII appointed him Councillor of State. In 1830 he aided in bringing on the new auction of July and after the fall of Charles X was given a peerage.

DU MAURIER, dū mō-rē a George Louis Palmella Busson, English artist, caricaturist and novelist: b. Paris, 6 March 1834; d. London, 8 Oct. 1896. He belonged to the old French family which had been driven to England by the Revolution. He spent some years in France and Belgium and afterward went to school in London. He soon adopted art as a profession, working as a student in the galleries of the British Museum. Then returning to Paris, he entered the studio of Gleyre and next went to Antwerp to continue his artistic training, where he lost the sight of an eye. Returning to London, he began to draw on wood for Once a Week, the Cornelian Magazine, etc., and also exhibited at the Royal Academy. He joined the Punch staff in 1864 and became famous through his weekly drawings of the fashionable and artistic world for that publication. He also illustrated a large number of books, including Thackeray's 'Esmond' and 'The Virginie', the collection of his Punch woodcuts was published in 1880 under the title 'English Society at Home.' In 1891 appeared his first novel, 'Peter Ibbetson,' and it was succeeded in 1894 by 'Triiby,' which was first published in the Woman's Magazine and was overwhelmingly successful. The novel was dramatized and successfully produced in America by Paul M. Potter and in London by Sir Herbert Tree. An incomplete novel, 'The Martian,' was published posthumously,
also in *Harper's Magazine*. His novels can hardly be looked upon as very serious contributions to literature, but his *Punch* drawings and "Trioby" will have permanent value as portraying many of the peculiarities of contemporary society. See Peter Ibbetson; Trioby.

**DUMB AGUE**, an irregular intermittent fever, so named from the absence of shivering chill. See Malaria.

**DUMB-BELL**, see Gymnastics.

**DUMB-CANE**, a popular name for a West Indian plant (Dieffenbachia seguine) of the arum family. The acidity which is characteristic of most of the members of the arum family in this species causes a swelling of the tongue with excruciating pain if the plant is chewed and for a time destroys the power of speech, whence its name. Some species and varieties of Dieffenbachia are in cultivation as foliage plants.

**DUMBA, Dr. Constantine Theodor, Austrian diplomat**: b. Vienna, Austria, 17 June 1856. Descended from a prominent and wealthy family, he was educated at the University of Vienna and the École des Sciences Politiques et Morales, Paris. He entered the Austrian Foreign Office in 1879, was created a privy councillor in 1908 and served for some years as Minister to Sweden. In March 1913 he was appointed Austro-Hungarian Ambassador to the United States and assumed the office on 24 April. During the early stages of the European War Dr. Dumba, in conjunction with Count Bernstorff (q.v.), the German Ambassador in Washington, engaged in a widespread conspiracy to foment labor troubles among the employees of the Bethlehem Steel Works and other plants making munitions for the Allies. The plot was revealed through the detention by the British authorities on 30 Aug. 1915 of an American journalist, J. F. J. Archibald, a passenger on the steamship *Rotterdam*, which put in at Falmouth. A number of documents found in Archibald’s possession were seized. Among them was a long letter written by Dr. Dumba to Baron Burian, the Austrian Foreign Minister, stating that “we could, if not entirely prevent the production of war material in Bethlehem and in the Middle West, at any rate strongly disorganize it and hold it up for months, which, according to the statement of the German Military Attaché (Captain von Papen), is of great importance,” amply outweighing the “relatively small sacrifice of money.” Archibald was also the bearer of a dispatch from von Papen to the German War Office. The publication of these documents by the British government caused a sensation in the United States and evoked general condemnation of the undiplomatic activities of Dr. Dumba in a country at that time both “neutral and friendly” to the nation which he represented. On 5 Sept. 1915 Dr. Dumba denied his “neutral” position to be a very open and perfectly proper method to be taken to bring before men of our races (Hungarians, Croats, etc.) . . . the fact that they were engaged in enterprises unfriendly to their fatherland. Four days later the Secretary of State Lansing announced that the American Ambassador in Vienna had been instructed to demand the recall of Dr. Dumba on account of his impropriety. The Austrian government issued a formal recall on 28 September; the British government granted a safe conduct and Dr. Dumba sailed from New York on 5 Oct. 1915. Von Papen and Captain Boy-Ed, the German attaches in Washington, were dismissed from the United States a few weeks later. It subsequently transpired that Archibald had received $5,000 from the German Embassy in Washington on 24 April 1915. The full story of the Austro-German conspiracies in America is told in *The World’s Work*, Feb., March, April, May, et seq. 1918. See War, European.

**DUMBARTON** (ancient Lennox or Levenix). (1) A maritime county of Scotland. Pop. 113,870. (2) A seaport, and the chief town in the county, on the Leven; 13 miles northwest of Glasgow. Ship-building is the chief business, the six principal yards employing about 4,000 men. The rock and castle of Dumbarton, a short distance from the town, are noted in history. The fortress was erected over a thousand years ago. It is one of the four fortresses stipulated to be kept in repair by the articles of the Union. It was the capital of the British district of Strathclyde. Under the Romans, a naval depot was established called Theodosia. It was made a royal burgh by Alexander II in 1221. Sir William Wallace was imprisoned here, and Mary, Queen of Scots spent her childhood at the castle. Pop. about 20,000.

**DUMBNESS.** See Deaf, The.

**DUMDUM, India**, town in the province of Bengal, seven miles northeast of Calcutta. It includes the municipalities of North and South Dumdum (pop. 10,000 and 11,000 respectively), North Dumdum including the cantonment. The town is famous as being the scene of the first open manifestation of the Sepoys against the greased cartridges which led to the outbreak of the mutiny of 1857, and is the site of the ammunition factory of the Indian ordnance department.

**DUMDUM BULLET**, a bullet so named after Dumdum Arsenal, the place near Calcutta where it was first made. The British found in their frontier wars with the Afghans and the hill tribes, that the ordinary bullet, Lee-Metford, in spite of its immense penetrative power, had not sufficient stopping power, persons hit being known to fight on. The dumdum is a soft-nosed or expanding bullet — one which instead of having its greatest strength at the point is weakest there, so that in striking a bone it will flatten out and shatter it and not, like the modern steel-coated, sharp-pointed bullet, make a small hole and pass through without any other effect. At Santiago the Spaniards were charged with cutting off the brass tips of their bullets so that they had the same effect in inflicting jagged wounds as the regular dumdum bullets. Dumdum bullets are now used to some extent by big game hunters. Their use was prohibited in warfare by The Hague Conference. In the war against the Boers in South Africa (1899-1902) the British were charged with using a modification of this bullet. In the Great European War the French — who use a solid copper-zinc alloy with no jacket and no lead and therefore incapable of expanding —
have been accused of using soft-nosed bullets. See Bullet.

DUMÉRIL, dū-mā-rēl, André Marie Constant, French physician and naturalist: b. Amiens, 1 Jan. 1774; d. Paris, 2 Aug. 1860. From 1801 to 1818 he was professor of anatomy and of physiology of the medical faculty of Paris. His works on natural history and analytical zoology are distinguished both for accuracy of details and for philosophical treatment. In his most celebrated production, 'L'erpétologie générale (1835-51), which contains the first attempt at a systematic description of all known reptiles, he had Bibron as collaborator.

DUMERASAN, dū-mā-rā-sān, Théophile Marion, French playwright: b. Issoudun, 4 Jan. 1780; d. Paris, 13 April 1849. He was employed in the Paris mint. He wrote many plays, all marked by keen wit, the Misanthrope and comic spirit. His 'Angélique et le Diable,' a five-act drama, had a run of over 100 presentations; still more successful was his 'Mountebanks,' his masterpiece and a classic in its kind. Other very successful plays written by him are 'The Wigmaker's Head in Titus'; 'Ridiculous Englishwomen.' Worthy of mention is his volume of 'National and Popular Songs of France.'

DUMFRIES, dūm-frēz', or DUMFRIES-SHIRE, a maritime county, Scotland, bounded on the southeast by Cumberland and Solway Firth. Long ranges of mountains enclose it on the north. The country is divided into Nithdale, Annandale and Eskdale, named according to the three principal rivers, the Nith, the Annan and the Esk. There are a number of small locks; area 1,103 square miles. The surface is irregular; about one-half is good farming and grazing land, and valuable minerals are found in the hill sections. There are also important salmon fisheries. The county is represented by a member in the House of Commons. Pop. about 75,000.

DUMFRIES, Scotland, a river port, railroad and commercial center, capital of the county of same name, on the Nith, six miles from its junction with the Solway Firth. It is connected with the suburb Maxwelton (in Kincardine) by three bridges, one dating from the 13th century. It is built of red sandstone and contains several fine public buildings. The town is especially associated with memories of Robert Burns. The house in which he lived is still preserved. His mausoleum stands in Saint Michael's churchyard. In the neighborhood are the ruins of Caerlaverock Castle, famous in connection with the Maxwells and Lincluden Abbey. Dumfries became a royal burgh in the 12th century. The Border Wars wrought much havoc to the town. The Young Pretender made this place his headquarters in 1745. The principal manufactures are tweeds and hosiery. There is a brisk local trade in farm products. The modern buildings include the County House, the post-office, Crichton Royal Institution (a lunatic asylum), Dumfries Academy. In High street there is a fire tower erected by Inigo Jones. Pop. about 19,000.

DUMMER, Jeremiah, American scholar: b. Boston, about 1680; d. in Plaistow, England, 19 May 1739. He was graduated at Harvard College in 1699, where he was noted for the vigor and brilliancy of his genius. With the purpose of preparing for the clerical profession, he went abroad, and studied in the University of Utrecht. On his return to America he abandoned his chosen vocation, and soon after went to England, where, as agent of Massachusetts, he rendered important services to his countrymen. He was an admirer of Lord Bolingbroke, in whose daring and reckless genius he found much that was congenial to his own character, and in intimacy with whom he adopted something of his moral and religious license. He published theological and philosophical disquisitions in Latin while at Utrecht, and his 'Defence of the New England Charters,' written in England (1728), is admirable both in style and matter. The traditions and records concerning him alike testify to his remarkable powers, and his easy command of them in speaking, writing and in intercourse with men.

DUMMER'S WAR, 1724-25, an episode in the long struggle of the French governors of Canada to check English settlement by inciting the Indians to raids and massacre of the border settlers. It was named after William Dummer, acting-governor of Massachusetts, who organized the resistance against the Indian expeditions sent by Vaudreuil, governor of Canada, against the villages of Massachusetts and Maine, and of Vermont where Fort Dummer had been built on the site of Brattleboro in 1724. One of its chief incidents was the aggressive retaliation of Dummer and the victorious assault by the English on Norridgewock, Me., when Sebastien Rale, the Jesuit missionary and Indian leader, was killed with 26 Abenaki Indians, 12 August 1724. The further crushing decimation in Lovewell's fight (q.v.) at Fryeburg, Me., 8 May 1725, led to four Indian chiefs signing a treaty for the Penobscots and other Abenakis at Boston in November 1725, which was ratified by the latter the following year. Consult Philemon, 'A Century of Conflict' (Boston 1892).

DU MOND, Frank Vincent, American artist: b. Rochester, N. Y., 1865. He was a pupil of Boulanger, Lefebvre and Benjamin Constant. His works include a wide range of subjects, from popular magazine paintings to religious and ideal. Among them are 'Octuber,' 'The Baptism,' 'Portia' and 'Grassy Hill.' He was elected to membership in the National Academy of Design in 1906, and became a prominent teacher at the Art Students' League.

DUMONT, dū-mōn, Albert, French archaeologist: b. Scey-sur-Saône, 1842; d. 1884. He was educated in Paris, and devoting himself to the study of prehistoric, Byzantine, and Christian archaeology, published 'De Plumbis apud Graecos Tessarum (1868); 'Inscriptions grecques de Grèce' (1871); and 'Vases peints de la Grèce propre' (1873). In 1874, in Rome, and the following year in Athens, he lectured on archaeology and the history of art. In 1878 he was elected rector of the academy of Grenoble, in 1879 rector of the academy of Rome, and until his early death was a superintendent of higher education. The most important of his later works is 'Les céramiques de la Grèce
propre, vases peints et terres cuits\(^1\) (1882-90), prepared in collaboration with Chaplain.

**DUHOMONT, dü-mōn**, Augustin Alexandre, French sculptor. b. Paris, 14 Aug. 1801; d. there, 25 Jan. 1884. He was a most prolific worker, and his statues are found on or in many of the public buildings and churches of his native city. His most noted productions are, the colossal statues of the Genie of Liberty\(^2\) on the Column of July, made in 1840, and the statue of Napoleon III on the Column Vendome.

**DUHOMONT, Gabriel**: b. Manitoba, 1838; d. Batoche, 1906. He acted as Riel’s adjutant-general in the North West Rebellion of 1885, and was the organizing brain of the movement, showing great military skill in his conduct of the campaign. After the rising had been crushed at Batoche, he fled to the United States, but returned at a later date to Saskatchewan.

**DUHOMONT, Pierre Étienne Louis**, Swiss scholar: b. Geneva, 18 July 1759; d. Milan, Italy, 30 Sept. 1829. In 1785 he became tutor in London to the sons of Lord Shelburne. His superior was struck with his accomplishments and recommended him to the illustrious Whigs of that period; with Romilly, in particular, he formed a close friendship. During the early years of the French Revolution, DuHommont was at Paris, where he became greatly attached to Mirabeau, regarding whom he has given the world much valuable information in his posthumous Souvenirs sur Mirabeau\(^3\) (1832). In this work he claims to have composed for him many of Mirabeau’s most eloquent speeches. In 1791 DuHommont returned to England, and formed an intimacy with Bentham (q.v.), of whom he became an ardent disciple and the greatest expositor of his philosophy. Deeply convinced of the value of Bentham’s views on legislation, he requested him to allow him to arrange and edit his unpublished writings on this subject. Bentham gave him his manuscripts, which DuHommont laboured earnestly to abridge, elucidate, correct, and simplify. The results appeared in his Traité de législation civile et penale (1802), Théorie des peuples et des empires (1817), Pratique des Assemblées Législatives (1816); Préuves judiciaires (1823); and the Organisation judiciaire et codification (1828). DuHommont returned to Geneva in 1814, and became a member of the representative council.

**DUHOMONT D’URVILLE, Jules Sébastien César**, French navigator: b. Condé-sur-Noireau, Normandy, 23 May 1790; d. near Paris, 8 May 1842. He entered the navy, in which he ultimately rose to be vice-admiral. He was twice wrecked and on both occasions owed his escape chiefly to self-possession and skilful seamanship. He rendered important service by his three years’ search for the remains of the ill-fated expedition of La Pérouse, the survey of long tracts of coast in New Zealand and New Guinea, the discovery of numerous islands and of an antarctic continent, and the exploration of very dangerous and still imperfectly known tracts of navigation, as Torres Straits, in Australia, and Cook’s Straits, between the two large islands of New Zealand. To his contributions to geography and discovery is due the appointment to the office of president of the Paris Geographical Society. One fruit of his voyages was the

\(^{1}\text{Enumeratio plantarum quas in insulis Archipelagi aut Littoribus Ponti Euxini}^{1}\) (1822).
\(^{2}\text{Voyage de l’Astrolabe}^{1}\) (1830–35), and \text{Voyage pittoresque autour du monde}^{1}\) (1834).
\(^{3}\text{He was killed in a railway accident.}^{1}\)

**DUMORTIERITE**, a native basic silicate of aluminum, of somewhat uncertain composition. In some specimens from Arizona, from 2/5 to 5 per cent of the alumina has been displaced by boron. The average constitution is silica 30.5 per cent, alumina 69.5 per cent. It crystallizes in fibrous or columnar forms belonging to the orthorhombic system, and has a hardness of 7 and a specific gravity of about 3.3. It is transparent or translucent, with a vitreous lustre and a blue or greenish blue color, and is strongly pleochroic. Dumortierite occurs near Lyons, France, and also in certain parts of Norway and Silesia. In the United States it is found in upper Manhattan, New York City, and in Yuma County, Arizona. The mineral is named for Eugene Dumortier, a French palæontologist.

**DUMOULIN, dü-moo-lín**, John Philip, Canadian Anglican bishop. b. Dunbehagh, Ireland, 1836; d. 28 Mar. 1911. He was educated at Trinity College, Dublin, and emigrating to Canada was ordained priest in 1863. He was appointed rector and canon of St. James’s Cathedral, Toronto, in 1882, and in 1896 was elected third bishop of Algoma. He died in the exercise of his duties.

**DUMOURIEZ, dü-moo-ré-á**, Charles François, French general: b. Cambrai, 25 Jan. 1739; d. near Henley-upon-Thames, 14 March 1823. He entered the army early in life and at 24 years of age had received 22 wounds, and was made a knight of Saint Louis. In 1772 Louis XV sent him with communications to Sweden, but he was arrested, and for a long time confined in the Bastile. In 1789 we find him a principal director of the Jacobin club, composed of all who aspired to be accounted the friends of liberty. He afterward became a minister of the king in 1793, and was dismissed. He continued to devote himself to the service of the army, he proceeded to Valenciennes, where he soon gained fame by his valor and his firmness, displayed at the head of the French soldiers, having succeeded Lafayette in the command of the Army of the North. He rendered very important service to his country by the stand he so skilfully made against the Prussian invaders in the forest of Argonne, in September 1792, the famous Cannonade of the Varennes. On 20th of the same month. He won the Battle of La Peiroue; but he was defeated at Nierwinden in January 1793. Notwithstanding his successes, the Directory, not without cause, entertained suspicions regarding his designs. Dumouriez, who had no sympathy with the Revolutionary government, had entered into secret negotiations with the enemy, and learning that an accusation of treason was to be brought against him, he fled to the Austrian headquarters. He refused, not to return, to serve against his country; wandering for some time through Europe and lastly settled in England.
DUN—DUNCAN

his 'Memoirs' (Hamburg, 1794) and the enlarged edition published at Paris; the 'Life' by Monchanin (1884); Griffiths, 'French Revolutionary Generals' (London 1891); Rose and Broadley, 'The Defence of England against Napoleon' (London 1908).

DUN Celtic dun, Irish dún, Gael dún, a hill, castle), a word used as a prefix or suffix in the names of cities as in, in Augustodunum (Autun), and in many names in Scotland and Ireland, as in Dunblane, Dundee, Dundalk, Dunboyne, etc.

DUNA, or SOUTHERN DVINA, so named to distinguish it from the northern Dvina, a west Russian river, which flows from a small lake near the source of the Volga, in the southwest of the government of Tver, and after a circuitous route of about 650 miles with a generally northwestern trend, empties into the Gulf of Riga, 10 miles below Riga. For some distance it forms the boundary between the governments of Vitebsk and Livonia on the north bank and Vilna and Courland on the south bank. Although obstructed by rocks and rapids, it is navigable for ocean vessels to Riga, for vessels of lighter draft to Dünaburg and for flat-bottomed barges almost from its source; it commands a large river traffic; on an average it is icebound 115 days in the year. Canals connect it with the Volga, the Beresina, the Niemen and Lake Ilmen.

DUNABURG, dūnā-boorg. See Dvirsk.

DUNANT, dū-nā, Jean Henri, Swiss philanthropist and founder of the Red Cross Society; b. Geneva, May 1828; d. 30 Oct. 1910. He early advocated the cause of suffering humanity and wrote a work on the slave systems of Mohammedan countries and the United States. While traveling near the battlefield of Solferino in 1859 he took part in the relief of those wounded in that battle and realized the inadequacy of the provisions for the work. As the result of his experiences there he wrote 'Un souvenir de Solferino,' advocating more efficient care of the wounded on the field of battle. This work and his agitation directed public attention to the subject and ultimately brought about the Geneva Convention in 1863, followed by the Geneva Convention of the Great Powers in 1864 and the founding of the Red Cross Society (q.v.). Jointly with Frederick Passy in 1901 he received the Nobel prize.

DUNBAR, Paul Laurence, American author: b. Dayton, Ohio, 27 June 1872; d. 10 Feb. 1906. He was of African descent, was educated in the public schools of Dayton, and was graduated from the Dayton High School in 1891, and from that time devoted himself to literature and journalism. After 1898 he was on the staff of the librarian of Congress. He appeared in public as a reader of his poems. He published 'Oak and Ivy' (poems) (1893); 'Majors and Minors' (1895); 'Lyrics of Lowly Life' (1896); 'Folks from Dixie' (1898); 'The Uncalled,' a novel (1898); 'Lyrics of the Hearthside' (1899); poems of 'Cabin and Field' (1899); 'The Strength of Girls' (1900); 'The Love of Laura' (1902); 'The Spirit of the Gods,' a novel (1901); 'The Fanatics,' a novel (1901); 'Lyrics of Love and Laughter' (1903); 'Li'l Gal' (1904); 'Lyrics of Sunshine and Shadow' (1905). Consult 'Complete Poetical Works,' with Introduction to 'Lyrics of Lowly Life,' by W. D. Howells (New York 1913), and Wiggins, L. K., 'Life and Works of Paul Laurence Dunbar' (1907).

DUNBAR, William, Scottish poet: b. Salton, East Lothian, about 1465; d. about 1525. He was a Franciscan friar, but was often employed by James IV in affairs of state. Among his works are the panegyric poem 'The Thistle and the Rose,' written (1503) on the marriage of James with Margaret of England, and 'The Golden Targe' (1508), consisting of allegories in the fashion of the time and of Chaucer, among them a poem on 'The Dance of the Seven Deadly Sins Through Hell.' He is at his best in burlesque poetry, as witness the autobiographical 'Visititation of St. Francis,' He is as 'rich in fancy as Spenser; as homely and shrewd as Chaucer in the 'Miller's Tale;' as pious as Cowper in his hymns, and as wittily grotesque as Burns in 'Death and Dr. Hornbook.' His works, edited by Laing, were published in London (2 vols.) 1834, and by Small and Mackay for the Scottish Text Society (Edinburgh 1884–93).

DUNBAR, Scotland, royal and municipal borough and seaport in Haddingtonshire, at the mouth of the Firth of Forth, 29 miles east of Edinburgh by rail. It is a place of great antiquity, having originated in a castle, once of great strength and importance, which underwent several memorable sieges; on one occasion being successfully defended against the English for 19 weeks by Black Agnes, Countess of Dunbar (1338). Queen Mary and Bothwell (1567) took shelter in this castle. Cromwell, at the "Race of Dunbar," totally defeated the Scottish army under David Leslie. The harbor, opened in 1844, is not very commodious, but the town is an important fishing station. Pop. 3,346.

DUNBIRD, a British sportsman's name for the female of the Pochard duck.

DUNCAN, Isadora, American dancer: b. San Francisco 1888. She was a teacher of dancing in New York and made an earnest attempt to revive the simple ancient Greek dances. Her efforts meeting with little success she went abroad and soon became very popular in Munich, Berlin, and Paris. She established a dancing school at Grünwald, near Berlin, for girls from 4 to 14 years of age, who receive free board and schooling. Miss Duncan popularized the barefoot dance in simple draperies. In 1913 her two children were carried by a runaway motor over the Seine embankment and drowned, after which she went into temporary retirement.

DUNCAN, James, American labor leader: b. Kincardine County, Scotland, 5 May 1857. He was educated at Aberdeen, Scotland, and removed to the United States. From 1873 he was a granite cutter, also granite statue cutter. He was secretary of the New York branch in 1881, of the Baltimore branch in 1884 and international president in 1895 of the Granite Cutters' International Association. He organized and led a successful educational campaign in the union and ultimately the great strike in the granite-cutting industry for an eight-hour workday in 1900. After 1895 he was editor of the Granite Cutters' Journal, was vice-president...
of the American Federation of Labor in 1894; represented the American labor movement to the British Trades Congress at Bristol, England, in 1898. He also represented the American Federation of Labor at the International Secretariat Conference of Labor, Budapest, Hungary, in 1911. He is a member of the American Academy of Political and Social Science.

DUNCAN, John, Scottish theologian and Hebraist: b. Aberdeen, 1796; d. 1870. He received his education at Marischal College, was ordained in 1836, preached for some time in Milton Church, Glasgow, and in 1840 was sent to Pesth as a missionary to convert the Jews. His most celebrated converts were Dr. Edersheim and the Rev. Adolph Saphir. Retiring from Pesth in 1843, Duncan was appointed to the chair of Oriental languages in New College, Edinburgh, a position which he held until his death. Consult Brown, David, 'Life of John Duncan, M. D.' (1872); Knight, 'Colloquia peripatetica' (1870; 5th ed., 1879) and Stuart, 'Recollections of Duncan.'

DUNCAN, Louis, American electrical engineer: b. Washington, D. C., 25 March 1862; d. Pelham Manor, N. Y., 13 Feb. 1916. He was graduated from the United States Naval Academy in 1880, and served in the navy until 1887. During this time he pursued advanced studies at Johns Hopkins University, becoming a Ph.D. in 1885. He was major of the first volunteer engineers during the war with Spain. Later he began his connection with Johns Hopkins, being associate in, and subsequently associate professor of applied electricity (1887-98). From 1902-04 he was head professor of electrical engineering at the Massachusetts Institute of Technology. He was elected president of the American Institute of Electrical Engineers in 1893. He wrote many articles on engineering topics in scientific journals and was a member of several scientific bodies. He specialized in electrical traction and as consulting engineer for the rapid transit commission of New York supervised the work of electrifying New York's first subway system. Under his direction, from 1897 to 1901, the Third Avenue Street Railway system of New York was electrified. He also was prominently identified with the underground trolley system in Washington.

DUNCAN, Norman, American journalist: b. Brantford, Ontario, Canada, 2 July 1874; d. Fredonia, N. Y. 18 Oct. 1916. He was educated at the University of Toronto 1891-95, entered journalism and from 1897 to 1901 was on the staff of the New York Evening Post. In 1908-10 he was adjunct professor of English literature at the University of Kansas. In 1907-08 he was correspondent for Harper's Magazine in Asia Minor and Egypt, and in 1912-13 in the East Indies, Australia, New Guinea, etc. He has written short stories and sketches for the Atlantic Monthly, McClure's Magazine and others, and has published 'The Soul of the Street; Stories of the New York Syrian Quarter' (1900); 'The Way of the Sea' (1903); 'Doctor Luke of Labrador' (1904); 'The Mother' (1905); 'The Adventures of Billy Tossail' (1906); 'The Cruise of the Shining Light' (1907); 'Mrs. Tinsel' (1908); 'Going Down from Jerusalem' (1909); 'The Suitable Child' (1909); 'Higgins' (1909); 'Billy Tossail and Company' (1910); 'The Measure of a Man' (1911); 'The Best of a Bad Job' (1912); 'A God in Israel' (1913); 'The Bird-Store Man' (1914); 'Australian Byways' (1915).

DUNCAN, Robert Kennedy, American chemist: b. Brantford, Canada, 1868; d. 1914. He was graduated at the University of Toronto in 1892 and studied also at Clark and Columbia universities. For several years he taught chemistry and physics in secondary schools and in 1901-06 was professor of chemistry at Washington and Jefferson College. In 1906 he became professor of industrial chemistry at the University of Kansas and four years later was appointed director of industrial research and assumed similar duties at the University of Pittsburgh. In 1911 he was visiting lecturer at Clark University. He was editor of the 'New Science Series' and published 'The New Knowledge' (1905); 'The Chemistry of Commerce' (1907); 'Some Chemical Problems of Today' (1911).

DUNCAN, Sara Jeanette. See COTES, SARA JEANETTE.

DUNCAN, Thomas, Scottish painter: b. Kinclaven, Perthshire, 24 May 1807; d. Edinburgh, 25 May 1845. He began to exhibit at the Scottish Academy in 1828, and became an academician in 1830. He became master of the Trustees' Academy, Edinburgh, in 1840 and an associate of the Royal Academy in 1843. The first picture which extended his fame beyond the Tweed, and helped to procure his admission as an associate of the Royal Academy (1843), was 'Prince Charles Edward and the Highlanders entering Edinburgh after the Battle of Prestonpans' (1840). Another famous picture of his is 'Charles Edward asleep after Cullo- den, protected by Flora Macdonald.' His last exhibited work was the ' Martyrdom of John Brown of Priesthill,' now in the Corporation Gallery of Glasgow. He also executed many portraits.

DUNCAN, William Wallace, American clergyman: b. Ashland, Va., 20 Dec. 1839; d. 1908. He was graduated at Randolph-Macon College in 1858, joined the Virginia conference the next year and held several important charges. During the Civil War he was a chaplain in the Confederate army. In 1875 he was transferred to the South Carolina conference, and elected professor of mental and moral philosophy in Wofford College. He was a member of the general conferences of 1878, 1882 and 1886, and a delegate to the Ecumenical Council of 1881 in London. In 1886 he was elected bishop of the Methodist Episcopal Church South.

DUNCANSBY HEAD, a picturesque promontory, forming the northeastern extremity of Scotland, in the county of Caithness. It consists of a circular rocky eminence of about two miles in circumference, and is intersected by large ravines and remarkable fissures. About a mile and a half west stood the celebrated John O'Groats' house, of which no trace now remains.

DUNCE, a word introduced by the Thomists or disciples of Thomas Aquinas, in ridicule of the Scotists, or disciples of John Duns Scotus, schoolman, who died 1305 A.D., to denote...
a subtle sophist given to caviling where he cannot refute. When the reaction against the schoolmen took place at the Reformation the merits of those acute metaphysicians were temporarily decried, and the celebrated John Duns Scotus came in for a more than ordinary share of vitriol. This, and his reputation as a subtle intellect, was held by the more ignorant or prejudiced of the reforming party to be a man of invincible stupidity. He was, therefore, made to stand as the prototype of all modern dunces. Succeeding generations have the unfavorable verdict thus passed on the cultivators of scholastic philosophy.

DUNCIAD. The. This literary Satire, by Pope, is in the form of a mock-epic of 1,700 lines in heroic couplets, and was published in 1729. It is the monumental example of its kind in English. Though professedly a chastisement of the 4dunces, the "Grub Street fry," with whom Pope quarreled almost all his life, it really attacks all the writers who intentionally or otherwise, with or without cause, had wounded the poet's vanity. Pope always remembered every line written, every word uttered, every jest against himself, and repaid it with interest. Hence, though the professed purpose of his "epic of the dunces" is "to crush these common enemies of mankind," his personal animosity is evident in every line. His protagonist, king of the dunces and the realm of Dullness, was at first Theobald, who had attacked Pope's bad edition of Shakespeare, and had produced a better one, but he was afterward dethroned in favor of Colley Cibber, who in the meantime had ridiculed Pope's unsuccessful play. The Dunciad borrows its general scheme from 'MacFlecknoe' (q.v.), but enlarges the action, notably by the beastly games that celebrate the coronation. Even with this, the action is slight and unimportant. With the third book the Dunciad, or reign of Dullness, the poem properly ends. In 1742 Pope added a fourth book, made up of fragments composed for another purpose, which realizes the reign of Dullness, and in which Bentley, the Greek scholar, is most unjustifiably made the protagonist. The Dunciad is dedicated to Swift, whom Pope addresses as a successor to Rabelais. Swift's influence, though certainly not Rabelaisian, is apparent throughout the poem; but whether or not Swift ever really "laughed and shook in Rabelais' easy chair," Pope certainly fails in his own attempt to use the jovial method of the great French satirist. He ends by mangling his enemies, covering them with showers of vile abuse, and then rolling them in mud of peculiar filth and malodour. Though most of his victims were, even as he asserted, of small importance, he has "preserved his flies in amber." Copious explanatory notes, which were needed even with the first edition, now alone render much of the satire intelligible to the modern reader. Yet it is uncritical to regard it as a little more than an monument of malice. Only one English poet could have written it. Its verse is polished; its expression is concise and incisive to the last degree; its wit is often brilliant; some of its lines, such as "The right divine of kings to govern wrong," have passed into common stock. The concluding passage of the poem, depicting the universal empire of Dullness, attains the very sublime in mockery and is as sure of immortality as almost any other in English poetry. Among the innumerable imitations of "The Dunciad," Byron's "English Bards and Scotch Reviewers" is by far the ablest and most celebrated. Consult Walton, 'Essay on the Genius and Writings of Pope' (Vol. II., pp. 439-454); Paston, George, 'Mr. Pope' (Vol. I., pp. 351-364); for notes, illustrations, list of imitations, etc., consult Walton's edition of Pope's "Works" (Vol. V., 1797); Aldine edition; Thorns, W. J., "Notes on Editions of the Dunciad" (n.d.).

MARION TUCKER.

DUNCKER, doonk'er, Dora, German story-writer and humorist: b. 28 March 1855. The conceits "Incurable" (1893); 'The Sphinx," and other tales and comedies, have succeeded; while in 'Modern Masters' (1893) she has evolved excellent character studies.

DUNCKER, Maximilian Wolfgang, German historian: b. Berlin, 15 Oct. 1811; d. Anspach, 21 July 1886. Politics interested him in early years, but his later energies were given to elaborate historical investigations, of which the best fruits are "The Foundation and Reformation" (1845); "Feudalism and Aristocracy" (1858); and the masterpiece "Ancient History" (1852-57).

DUNCOMBE, Thomas Slingsby, English politician: b. 1796; d. 13 Nov. 1861. He was elected member of Parliament for Hertford in 1826-32, and for Finsbury after 1834, assisted in carrying the Reform Bill, was prominent among the advanced Liberals, and, after visiting Canada, warmly defended Lord Durham's administration of that colony. In 1842 he presented the Chartist petition, signed by 3,000,000 of the lower classes, in favor of universal suffrage, vote by ballot, short Parliaments, etc. In 1844 the then Home Secretary having sanctioned the opening of the letters of Mazzini, Duncombe, in the House of Commons, denounced, with scathing invective, the adoption of the post-office spy system on English soil. Consult his "Life and Correspondence" (London 1868).

DUNDALK, dün-dål'k', Ireland, maritime town, capital of the county of Louth, on Castle-town River, 54 miles north of Dublin. It is an ancient place, has a splendid Roman Catholic cathedral, and in the battle of Paughart (1318) fought in its vicinity, Edward Bruce, the brother of King Robert Bruce of Scotland, was slain. Its manufactures are soap and leather, has shipbuilding and iron founding, and the trade, chiefly in cattle and agricultural produce, is extensive. Pop. 13,128.

DUNDAS, Henry, Viscount Melville, Scottish statesman: b. Edinburgh, 28 April 1742; d. 28 May 1811. He studied at the University of Edinburgh and in 1766 was appointed solicitor-general for Scotland, M. P. for Middlesex in 1774 and lord advocate in 1775. In 1782 he was appointed to the navy and made a member of the privy council; but he continued only a short time in office. His resolution condemning the conduct of Warren Hastings in India led to the impeachment in 1786. In 1791 he was made Home Secretary, and in 1794 became Secretary of War. In 1797 he was created Viscount Melville. In 1804 he was appointed First Lord of the Admiralty.
under Pitt. Next year he was impeached, before the House of Lords, of high crimes and misdemeanors in his former office of treasurer of the navy. As the evidence adduced against him did not directly implicate him in the malversation proved against his deputy, he was acquitted. He was long practically the manager of Scottish affairs in which he showed himself a reactionary, and gained notoriety by his rigorous persecutions of the Scottish radicals in 1795.

**DUNDAS, Sir James Whitley Deans**, English admiral: b. 1785; d. 1862. In 1799 he entered the navy and reached the rank of commander in 1806. He was flag captain to Sir Thomas Parker and afterward to Sir Philip Dunham. He was made rear-admiral in 1841, was commander in the Mediterranean in 1852 and in the same year became vice-admiral. During the Crimean War he was chief naval commander and had charge of transporting the army to the theatre of war. He was severely criticized for his operations against Sebastopol and was superseded by Sir Edward Lyon in 1855. In 1857 he was made admiral.

**DUNDAS, Robert, Lord Arniston**, Scottish judge: b. 9 Dec. 1685; d. 1753. He was admitted to the Scottish bar in 1709, and soon became known as a successful lawyer with forcible and ingenious methods of pleading. In 1717 he received the appointment of solicitor-general, which was followed by advancing positions until in 1737 he became a judge, and in 1747 rose to the dignity, which he continued until his death, of lord president of the Court of Session of Scotland. His eldest son, Robert: b. 18 July 1713; d. Edinburgh, 13 Dec. 1787; was educated at Edinburgh University, studied law at Utrecht and Paris; in 1738 was admitted to the Scottish bar, and, like his father, rose through successive Crown positions to that of lord president of the Court of Session of Scotland, which he attained in 1760 and occupied until his death. Owing to his having given his casting vote as lord president against the claimant, Archibald Stewart, in the famous Douglas Cause, in 1768, he was intensely unpopular in Edinburgh.

**DUNDAS, Canada**, a town in Wentworth County, in the province of Ontario, situated on a bay at the western extremity of Lake Ontario. It is a manufacturing and shipping centre. Pop. 4,299.

**Dundas Island**, British Columbia, an island 40 miles northeast of Queen Charlotte's Islands, separated from Cape Fox, the southernmost point of the Alaskan panhandle, by Chatham Sound.

**Dundas, or Juba Islands**, British East Africa, a group of about 500 coral islets off the east coast of Africa in lat. 1° S. The group has one safe anchorage near the mouth of the Durnford River.

**Dundas Strait**, Australia, a passage about 18 miles wide, separating Melville Island from Cape York Peninsula in northwestern Australia.

**Dundee, Viscount of.** See Graham, John.

**Dundee**, Scotland, parliamentary and county burgh and city in County Forfar, on the estuary of the Tay, 8 miles from the sea, and 5945 miles northeast of Edinburgh by rail. It is the third city of Scotland and rises steeply from the water. Its linen trade is the largest in Scotland, and its jute manufactures are the largest in Great Britain. Shipbuilding is an important industry, and it is celebrated for its marmalade and confectionery. It is the centre of the seal and whale fisheries; there are large wet docks and graving docks; and an extensive shipping trade. The number of vessels entering the port in 1916 was 1,906, with a registered tonnage of 540,826. The revenue from tonnage dues amounted to $99,597. The esplanade is nearly three miles in length. There is a fine old parish church, so large that three separate congregations worship under its roof. It has excellent educational facilities and University College is affiliated with the University of Saint Andrews. The public utilities are municipally owned. There are some fine public parks, notably Baxter Park in the east end, presented by Sir David Baxter, and Balgay Hill in the west end. The Tay Bridge (railway) at the west end of the town, giving trunk rail connection with the south, was completed in 1887 to replace an older structure blown down in a hurricane, in 1879, and is two miles in length. Dundee was erected into a royal burgh by William the Lion about 1200; took a prominent part in the War of Independence; was captured by John of Gaunt in 1385; Robert Wishart, the first of the martyred Reformers, preached from its gateway (still standing); it was sacked by Montrose in 1645, and later by General Monk, who put nearly 1,000 of its inhabitants to the sword; and from the burgh Viscount Dundee took his title, his estate of Claverhouse being north of the city, now on its outskirts. The city returns two members to Parliament. The boundaries were enlarged in 1913 to include the outlying suburb of Broughty Ferry. Pop. 176,062.

**Dundonald, Thomas Cochrane, 10th Earl of.** See Cochrane, Thomas.

**Dundonald Incident.** Douglas Ballie Hamilton-Cochrane, 12th Earl of Dundonald, a distinguished army officer, was appointed in 1902 major-general commanding the militia in Canada. For a considerable time there was harmony between Sir Frederick Borden, the Minister of Militia, and the major-general; but in June 1904, at a private banquet given by the local officers at Montreal to Lord Dundonald, he made a speech complaining of the interpolation of political considerations into militia problems, and in particular of the striking out of the name of one of his nominees for a commission. The speech found its way into the press, and Lord Dundonald was dismissed on the ground that he had attacked the government under which he served. Lord Dundonald thereafter conducted a vigorous campaign in his own defense, and the question was one of the minor issues in the Dominion elections of 1904.

**Dundreary, Lord.** A prominent character in Tom Taylor's well-known comedy of "Our American Cousin." The act is normally contained but 47 lines, but it was enlarged by the actor, E. A. Sothern, who became famous in this rôle.

**Dune, dún, a low sand-hill; an accumulation of sand; a hill-fort, or a regular building**
commonly called a Danish fort. Sand dunes are made by the blowing of sand, this material having been produced by the grinding down of rocks under the influence of breakers on the seashore or coast, or any similar agency. Such sand dunes in many places skirt the shores of Holland, Great Britain, Spain and other countries, in some places encroaching on and covering what once was cultivated land. In Michigan, dunes have encroached on forests, completely burying and killing the trees, and have then passed on, again unheeding the forest. In England and Germany, buildings have even been buried and unearthed. Originally the "downs" of England were similar to the dunes. The dunes along the Atlantic coast of the United States have changed materially the form of the coast line; some of these dunes are high hills, and still higher hills are on the coast of some of the islands of the Bahamas. See GEOLOGY and EOLIAN DEPOSITS.

DUNE PLANTS, plants characteristic of dunes, those somewhat unstable sandy areas formed under the influence of wind. The species existing in this condition are few in number and are marked by well-developed underground parts, including extensive root and numerous root-hairs, and storage organs, especially rhizomes. They are capable also of being partially buried, without apparent injury. Since some dunes are migratory, or tend to extend over wider and wider areas, thus destroying the natural vegetation, crops and even orchards and forests, these plants are of special interest. Some of them, especially marram or beach grass, also known as sand reed (Amphiphila arenaria), are widely planted upon beaches and dunes, to hold the sand and prevent its being blown by the wind. The United States Department of Agriculture, through its division of agrostology, has done immense service to landowners along the shores of both the Great Lakes and the ocean coasts, in the planting of soil-binding grasses, as the plants are called. In time the planted areas support other vegetation and the dune may be considered conquered. In general the vegetation characteristic of dunes consists of xerophytes (q.v.), but the xerophytic character is due to the shifting of the sand and not to the conditions of growth. See PLANT GEOGRAPHY.

DUNEDA, dün'ë-da, New Zealand, town, capital of the province of Otago, on Otago harbor. It is about nine miles from its port, Port Chalmers, with which it is connected by railroad. It was founded by an association of Scottish Free Churchmen in 1848. It is reputed to be one of the finest residential towns in New Zealand. There is a university opened in 1871, with four faculties. Gold discovered nearby in 1861 has caused the recent rapid growth of the town. Wool and gold are the staple exports. Pop. 64,237.

DUNFERMLINE, Scotland, a royal burgh in Fife, 16 miles northwest of Edinburgh by rail. It is situated in a rich coal district, has brass and iron-works, and important lines of manufacture. Andrew Carnegie, the Pittsburgh iron master, a native of the burgh, has furnished it with a public library and baths, presented it with the adjoining Pittencriff Park and Glen, and otherwise liberally endowed it. Dunfermline is a place of great antiquity; its palace was a favorite residence of the Scottish kings; and in its abbey eight kings and seven queens were buried. The royal palace, now in ruins, is said to have been built by King Robert Bruce. The abbey was founded by Malcolm Canmore, son of the first Scottish king, in 1072, rebuilt by David I in the early Norman style, burned by Edward I of England in 1303, and its ruin completed by the iconoclastic zeal of the Reformers on 28 March 1560. The body of King Robert Bruce was laid in front of the high altar, a location now occupied by the pulpit of the Abbey church. The church was built in 1660-70 by Sir Christopher Wren; burned in 1690; repaired in 1740; and was restored in 1860. The churchyard is a famous burial place and contains the tombs of all the Scottish monarchs from Malcolm I to the last Stewarts. The church is of important antiquity and of historic interest, and is one of the most important churches in Scotland. The town of the city for 1916–17 was $825,000, as compared with $755,000 for 1915–16. Pop. 28,103.

DUNG-BEETLE, a name borne by several lamellicorn beetles, of the genera Aphodiis, Bolbocerus, Cophis, Geotrupes, Phaneus and others. These beetles nest and lay their eggs in the droppings of cattle, and are found throughout America, Europe, Asia and Africa. An African species is the sacred scarabaeus of Egypt (Ateuchius sacer).

DUNGAN, Ireland, municipal borough and sea port in the county of Waterford, 28 miles southwest of Waterford. It is a resort for sea-bathing. Its ancient castle, situated in the center of the town, is now used as a barracks. The harbor is shallow and there is little trade. Fishing is the chief occupation. Pop. 4,977.

DUNGENESS, dün'ë-nës, a headland on the south coast of Kent, 11 miles southeast of Rye. It has a fort and government lighthouse.

DUNGLISON, dün'gil-sôn, Richard James, American physician: b. Baltimore, Md., 13 Nov. 1834; d. Philadelphia, 4 March 1901. He was a son of Robley Dunglison (q.v.). He was graduated at the University of Pennsylvania, 1852, and from Jefferson Medical College 1856. During the Civil War he served as surgeon in the Philadelphia military hospitals. He soon gave up the practice of medicine in order to devote himself to literary work and it is by his contributions to medical literature that he is best known, having edited the College and Clinical Record (1880-99) and written constantly for the leading medical journals. He was also one of the original editors of the Philadelphia Medical Times. He revised and edited the following works of his father: History of Medicine (1872), and Medical Lexicon (1874); translated Guersant's Surgical Diseases of Children (1873); and was author of The Practitioner's Reference Book (1878); Elementary Physiology (1879); 'The Present Treatment of Disease' (1886).

DUNGLISON, Robley, American physician: b. Keswick, England, 4 Jan. 1798; d. Philadelphia, 1 April 1869. He was educated in medicine at London and Erlangen, and appointed professor of medicine in the University
of Virginia in 1824. In 1833 he was elected to the chair of therapeutics in the University of Maryland, and in 1836, professor of the institutes of medicine in the Jefferson Medical College of Philadelphia. He published about 20 volumes treating of subjects connected with medical science. They were widely circulated and are said to have sold at a cost of $10 each, a Dictionary of Medical Science and Literature,' being republished as late as 1874.

DUNITE, a heavy, dark, very basic igneous rock of the peridotite group. It contains no felspar and consists essentially of olivine and chromite. It is believed that most workable deposits of chrome ore were formed by local segregations of chromite in a cooling dunite magma, at least the chromite deposits of North Carolina probably had such an origin. Dunites in common with other rocks of the peridotite group change readily to serpentinite, and most deposits of chromite occur in serpentinite. See PERIDOTITE.

DUNKARDS. See GERMAN BAPTIST BRETHREN.

DUNKIRK, dün'kərk (Fr. Dunkerque or Dunkuerque), France, a strongly fortified town in the department of Nord, on the coast of the North Sea, 28 miles northeast of Calais, at the junction of several canals. Of the public squares, that of Charles-V and that adorned by a statue of Jean Bart (1845) are the most noteworthy. There are several interesting churches, among the chief being the church of Saint Eloi, built about 1560, with a fine tower about 300 feet high, now used as a belfry; the chapel of Notre-Dame des Dunes, founded in 1405 and restored in 1815; and the convent and church of Saint-Jean-Baptiste. Dunkirk is well protected by several forts, both on the land side and on that of the sea. Its manufactures are extensive, comprising fishing-nets, ropes, sailcloth, straw hats, starch, soap, leather, earthenware, oil and chemicals, besides distilling, sugar-refining, shipbuilding and other industries. Dunkirk is the third seaport of France, has four dry docks and five miles of quay, chief port of departure of the Ice-fishing fleets. The trade is extensive and important. Dunkirk is the seat of a United States consular agent. Dunkirk was a town under its present name, which means "the church of the dunes," in the 9th century. It has played a prominent part in many wars, has been besieged on many occasions and successively held by Burgundy, Austria, Spain and France. Turennes victory of the dunes in 1658 brought it into the possession of France, by whom it was captured in 1662. In 1662 it was bought back from Charles II. Under the Treaty of Utrecht (1713) its fortifications were to be demolished; but these were subsequently rebuilt. It was unsuccessfully besieged by the Duke of York in 1793. The present commercial importance of Dunkirk dates from the period of the Second Empire. One of the most famous natives of the town is Jean Bart (1651-1702), the celebrated seaman. Pop. of commune 38,891.

DUNKIRK, N. Y., city and port of entry in Chautauqua County, 41 miles southwest of Buffalo, on Lake Erie, and on the Lake Shore and Michigan Southern, the Pennsylvania, the Erie and other railroads. Its lake trade is extensive, facilitated by its fine harbor and breakwater. The important industries are the manufacture of locomotives, steel, engines, lumber, cotton goods, etc. The United States census of manufactures for 1914 showed within the city limits, 62 industrial establishments of factory grade, employing 3,471 persons; of whom 2,969 were wage earners, receiving annually $2,108,000 in wages. The capital invested aggregated $9,354,000, and the year's output was valued at $8,367,000; of this, $4,303,000 was the value added by manufacture. The chief buildings are the school, the public library and the Brooks Memorial Hospital. Gratiot Park and Washington Park are also attractive features. There are two national banks. The property of the town is assessed at approximately $10,000,000. The first settlement at Dunkirk was made in 1809. With the rapid increase in population, it was incorporated as a village in 1837, and in 1850 was chartered as a city. The government is conducted by a mayor, elected biennially, under whom appointments are made to the civil service commission and to the board of health; and by a common council consisting of five members. The city owns and operates its own waterworks, electric plant and power plant. Pop. 17,870.

DUNLAP, William, American dramatist and painter: b. Perth Amboy, N. J., 19 Feb. 1766; d. New York, 28 Sept. 1839. He painted George Washington's portrait and for five years (1784-89) worked under West in London. Returning to America he wrote several successful plays, including 'The Father' (1799), a comedy; 'Leicester' (1794), a tragedy; 'André' (1798), a tragedy. He also wrote 'Life of George Frederick Cooke' (1813); 'Life of Charles Brockden Brown' (1815); 'History of the American Theatre' (1832); 'History of the Rise and Progress of the Art of Design in the United States' (1834); and similar works. He was one of the founders of the National Academy of Design.

DUNLIN (Tringa alpina), a bird of the genus to which the least and pectoral sandpipers, knot and stint belong. It is smaller than the common snipe; is in winter ash-gray above, white below, with dark streaks on the breast; in the breeding season it is mottled with rufous above and the breast is crossed with black. The straight bill is adapted for boring in soft soil and its cavity reaches to the extremity, not, as in the snipe, stopping short of the tip. The dunlin is one of the most common shore birds in northern Europe and Asia, and sometimes wanders into North America, where it is replaced by the closely allied redbacked sandpiper. In Scotland there are several local varieties, those of the east being a half larger than those of the Hebrides. It breeds on moors and marshes along with the snipe and plover, returning after the breeding season to the sandy and muddy reaches of the coast. See SANDPIPERS.

DUNMORE, John Murray, Earl of, English colonial governor: b. 1732; d. Ramsigate, England, May 1809. He was governor of New York in 1770, and in addition governor of Virginia in 1771. He dissolved the Virginia assembly in 1772, and again in 1774 when it had resolved to keep the day of the closing of the port of Boston as a day of fasting and prayer. In 1775 he removed part of a
powder magazine to one of the English warships, and the people, incensed at this, began a mutiny and forced the captain, under Patrick Henry. Dunmore was forced shortly after to take refuge on his fleet, whereupon the burgesses decided that he had abdicated his functions and refused to consult with him. He then kept up a predatory warfare against the Indians, but, being mortally wounded in 1776. He was driven from his position on Gwynn's Island and finally sent the fleet to the West Indies, and returned to England. He was elected a Scottish representative peer in 1776 and was governor of the Bahamas from 1787–96. See Colonial Wars in America.

DUNMORE, Pa., borough in Lackawanna County, on the Erie and Lackawanna railroads, and two miles northeast of Scranton. It is the centre of a coal mining district, and has manufactures of silk, iron and brick. Several public institutions are located here, the principal one being the State Orphan School for the Deaf and Dumb. Under a charter of 1862 the government is vested in a burgess elected every four years, a borough council and administrative officials, the majority of which is chosen by popular vote. Dunmore was settled in 1835 and incorporated in 1862. Pop. 19,757.

DUNMOW, Great and Little, two parishes of England, in the county of Essex. The former (pop. about 3,000) contains the market-town of Great Dunmow, on a height above the Colne, 33 miles northeast of London. At Little Dunmow (pop. 320) are remains of a stately Augustinian priory, founded in 1104. The Dunmow flitch of bacon was a prize instituted in 1244, by Robert Fitzwalter, on the condition that whatever married couple will go to the priory, and kneeling down on two sharp-pointed stones, will swear that they have not quarreled nor repented of their marriage within a year and a day after its celebration, shall receive a flitch of bacon. The prize was first claimed in 1445, 200 years after it had been insti tuted. After 1751, up to which date only five presentations had taken place, the flitch was not again claimed till 1855; between 1860 and 1877 there were four awards; and within recent years there have been recurrent awards. Consult Andrews, 'History of the Dunmow Fitch' (London 1877).

DUNN, Andrew Hunter, Canadian bishop: b. Saffron Walden, Essex, England, 1839; d. 1915. He was graduated at Corpus Christi College, Cambridge, was ordained to the priesthood in 1865 and elected Anglican bishop of Quebec in 1892. He was the author of 'Helps by the Way'; 'Thoughts for Quiet Moments.'

DUNN, Gano, American electrical engineer: b. New York, 18 Oct. 1870. In 1889 he was graduated at the College of the City of New York and two years later from the engineering department of Columbia University. He was for some years in the employ of the Western Union Telegraph Company and subsequently (1891) was with the Crocker-Wheeler Company, of which he was vice-president and chief engineer from 1898 to 1911. In 1911-13 he was vice-president in charge of engineering and construction of J. G. White and Company, New York, and since 1913 has served as president of the J. G. White Engineering Corporation. He was president of the New York Electric Society in 1900-02; of the American Institute of Electrical Engineers in 1911-12 and of the Western Engineering Society 1913-16. He was American delegate and vice-president of the International Electrical Congress at Turin 1911. He has published various papers on electrical subjects.

DUNN, Jacob Platt, American journalist and author: b. Lawrenceburg, Ind., 12 April 1855. He was educated at College, Indiana, and Michigan University, and was State librarian of Indiana 1889-93, when he became an editorial writer on the Indianapolis Sentinel; city comptroller of Indianapolis, 1901, 1904-05, 1914-15; member Public Library Commission of Indiana 1899-1916; member Commission on Taxation of Indiana 1916. Since 1886 he has been secretary of the Indiana Historical Society. He has published 'Massacres of the Mountains, a History of the Indian Wars of the Far West' (1888), 'History of Indiana' (1888), in the 'American Commonwealth Series'; 'The Tax Law of Indiana and the Science of Taxation' (1891); 'The Libraries of Indiana' (1892); 'The World's Silver Problem' (1894); 'Young Men's Indian Stories' (1908); 'History of Indianapolis' (1910); 'The Unknown God' (1914).

DUNN, Samuel Orace, American editor: b. Bloomfield, Iowa, 8 March 1877. He was graduated at the Pratt (Kan.) High School in 1894. He learned the printer's trade in 1890-95; was editor of the Quitman (Mo.) Record 1895-96; associate editor of the Maryville (Mo.) Tribune 1896-1900; reporter of the Kansas City Journal 1900-02, and editorial writer on the latter journal in 1902-04. In 1904-07 he was railroad editor and editorial writer on the staff of the Chicago Tribune; in 1907-08 he was managing editor of the Railway Age, and since 1908 editor of the Railway Age Gazette. He has published 'The American Transportation Question' (1912); 'Government Ownership of Railways, Interstate Commerce', and contributions on transportation subjects.

DUNNAGOE, a nautical term applied to loose wood or other miscellaneous substances used in the hold of a ship to lift the cargo above bilge-water. Also, such articles as old mats or sails stowed among casks and other cargo to prevent their motion and breakage. See Crock.

DUNNE, Edward Fitzsimons, American political leader: b. Waterville, Conn., 12 Oct. 1853. He took a three-year course at Trinity College, Dublin, was admitted to the bar in 1877 and became circuit judge of Cook County, Ill., in 1892. He remained in this relation until 1905 when he resigned to become mayor of Chicago. He was engaged in law practice from 1907 to 1913, and in 1913 was elected governor of Illinois for a four-year term. He is vice-president of the National Civic Federation and was president of the League of American Municipalities in 1906-07.

DUNNE, Finley Peter, American journalist and humorist: b. Chicago, 10 July 1867. He was educated in the Chicago public schools and entered journalism in 1885. He was city editor of the Chicago Times 1891-92; was on the editorial staff of the Chicago Evening Post and Times-Herald 1892-97, and editor of the Chi-
the castle was selected as the strongest place in the kingdom for the preservation of the Scottish regalia. Lauchborn, sir of the monologues by Mr. Dooley, a saloon-keeper of Archery Road, on various topics of the day. His comments were witty, keen and penetrating, mellowed by a kindly, tolerant, philosophic interest in the weaknesses of his fellow creatures. Homey smiles and characteristic Irish-American brogue and humor enliven the essays. During the Spanish-American War, "Mr. Dooley's" words attacked its political and social phases, and were widely read both in England and America.

"Mr. Dooley in Peace and War" contains the best of these more satirical essays, whose popularity rank Dunne among the leading American humorists. He also published "Mr. Dooley in the Hearts of His Countrymen" (1898); "Mr. Dooley's Philosophy" (1900); "Mr. Dooley's Opinions" (1901); "Observations of Mr. Dooley" (1902); "Dissertations of Mr. Dooley" (1906); and "Mr. Dooley Says" (1910).

DUNNET HEAD, a promontory of Scotland, in Caithness, at the western entrance of and projecting into the Pentland Firth; the most northerly point of the mainland of Great Britain. It rises to the height of 400 feet above sea-level. On the northwestern extremity is a lighthouse 346 feet high.

DUNNING, Albert Elijah, American editor: b. Brookfield, Conn., Jan. 5, 1844. He was graduated at Yale University in 1867 and at Augusta, northern point of the mainland of Great Britain. It rises to the height of 400 feet above sea-level. On the northwestern extremity is a lighthouse 346 feet high.

DUNNING, William Archibald, American educator: b. Plainfield, N. J., about 1859. He was graduated at Columbia 1881 and became successively Fellow 1886-88; prize lecturer in political science 1887-89; instructor in history 1889-91, and professor of history and lecturer on political theory since 1891. In 1894 he became managing editor of the Political Science Quarterly, to which he has contributed over 60 important articles and reviews. In 1913 he was president of the American Historical Association. He has published "Essays on the Civil War and Reconstruction, and Related Topics" (1898); "History of Political Theories, Ancient and Medieval" (1902); "History of Political Theories from Luther to Montesquieu" (1905); "Reconstruction, Political and Economic" (1906); "Carl Schurz's Political Life" 1809-1906" (1908); "Paying for Alaska" (1912).

DUNNOTTAR, dün-nöt'är, a parish of Kincardineshire, Scotland, famous for its ancient ruined castle perched on a great rock 160 feet sheer above the sea, one and one-half miles below Stonehaven. The older part of the ruin was built for King James II in 1291, and the castle was rebuilt by Sir William Keith, marischal of Scotland. During the Commonwealth...
DUNQUERQUE—DUNSTAN

Allier he was transferred in 1832 to the prefection of the Somme; this he quitte in 1838 to enter the council of state. This last post was better suited to his disposition, which, though calm, was full of energy and ill-adapted to the compromising attitude necessary to a practical politician. In 1838, he reprinted his volume of 1825 with many additions, under the title of "Nouveaux traite d'économie sociale" (2 vols.), but before the second volume was issued from the press a fire consumed nearly the whole edition. Extending the scope of the work Dunoyer reissued the work in 1848 under the title "De la liberté du travail ou simple exposure des conditions dans lesquelles les forces humaines s'exerceront avec le plus de puissance" (3 vols.). He also contributed to the Revue Encyclopédique, the Revue Française, Journal des Débats and the Journal des Economistes. The revolution of 1848 was a heavy blow to him; he remained, however, on the council of state, and only relinquished his seat there after the coup d'état of 1851. Bitterly hostile to the second Empire, as he had been to the first, he wrote a work directed against the new order of affairs. This book, which was published after his death, and then only at Brussels, is entitled "Le second empire et une nouvelle restauration" (2 vols., 1865). In 1852, he was elected member of the Institut and in 1845 president of the Society of Political Economy. His miscellaneous works—"Notices d'économie sociale" and the second edition of "De la liberté du travail" appeared in 1886 (3 vols.). Dunoyer was one of the great economists of the 19th century. He was a supporter of Malthus on population, but he was no believer in the theory of rent, considering that there was but one factor in production, i.e. labor.

DUNQUERQUE. See DUNKIRK, FRANCE.

DUNRAVEN, Windham Thomas Wyndham-Quin, 4th Earl of: b. Adare Abbey, Ireland, 12 Feb. 1841. He was educated at Christ Church, Oxford; was war correspondent for the "Daily News" during the Franco-Prussian war, and succeeded to the title in 1871. He was undersecretary for the Colonies, 1885-86, 1886-87. He is a traveler and yachtsman and has published: "The Great Divide: the Upper Wyoming" (1874); "The Irish Question" (1880); "Self Instruction in the Theory and Practice of Navigation" (1900); "The Legacy of Past Years" (1911); "Canadian Nights" (1914).

DUNS SCOTUS, Johannes, one of the greatest of the mediaeval schoolmen, b. either in 1274 or 1266, probably in Ireland; d. Cologne 1308. Early in life he entered the Franciscan order and studied at Oxford under William Ware. He was also influenced by Roger Bacon. About 1294 he taught at Oxford and defended the dogma of the Immaculate Conception. In 1304 he went to Paris, and in 1308, by the order of his superiors, to Cologne. The extreme dialect and intricacy of his dialectic won him the title of the Subtle Doctor. He was less a systematist than a critic and attacked most of his contemporaries and immediate predecessors, especially Saint Thomas. He starts from the same initial stock of notions as Saint Thomas, but his reasoning is a different application of these notions. One of the most important principles of Scotism is that theology, unlike philosophy, is not a speculative but a practical science—the science of conduct, and that philosophy is definitely subordinate to theology. Scotism adds to the two forms of matter of the Thomists—that possessing only primary qualities and that also endowed with secondary qualities—a third, unquanted, incorruptible matter, the same in both spiritual and corporeal substances. There are a hierarchy of forms of increasing degrees of specification. The substantial character of whatever is individual has its origin in nature, while that of the universal is derived from reason. The faculty of will is pre-eminent over that of intelligence, and that it is always possible to will the evil. This priority of the will applies to God himself, and the good consists solely of the decrees of the Divine will. The soul is the form of the body, but not the same form that endows it with its organic structure.

Scotus became the founder of the traditional philosophy of the Franciscans. Francis of Mayron (d. 1325) carried to a ridiculous extreme the excessive subtlety of his master. During the Revival of Learning the Scotists were strangely reactionary and opposed to the new studies, so that the word "Duns" or "Dunce" came to mean first "pedant" then "fool".

Scotus' most important work is the collection of his commentaries known as the "Opus Oxoniense." The first complete edition of his works by one Luke Wadding appeared at Lyons in 1639 in 13 volumes (reprinted in 26 vols. Paris, 1597-98). Consul De Wolfe, M., "Histoire de la philosophie medievale" (Paris 1905; tr. London 1909); Hagenbach, C. R., "History of Doctrines" (tr. 1880); Kahl, W., "Die Lehre vom Primat des Willens der Augustinianus Duns Scotus, und Descartes" (1886); Przinskis, "Essai sur la philosophie de Duns Scotus" (Paris 1887); Royce, "Conception of God" (New York 1898); Stockel, "Geschichte der philosophie des Mittelalters" (Mainz 1865); Werner, "Duns Scotus" (Vienna 1891).

DUNSINANE, one of the Sidlaw Hills in Perthshire, 1,012 feet high, seven miles northeast of Perth. On its top are remains of an ancient fort locally known as "Macbeth's Castle." Here Siward defeated Macbeth in 1054. Shakespeare made use of this battle in his "Macbeth."

DUNSMUIR, James, Canadian statesman: b. Fort Vancouver, Wash, 8 July 1851. He was educated at Nanaimo, and Dunedas, Ont., and has built up the mining interests in British Columbia which he inherited from his father. He was a member of the provincial legislature from 1898 to 1900, premier of British Columbia, 1900-02; and lieutenant-governor, 1906-09.

DUNSTAN, Saint, English prelate and statesman: b. Glastonbury about 924; d. Canterbury, 19 May 988. His family was a notable one and related to the royal line of the Anglian kings. He was educated in whatever of science and liberal arts existed in that time, by certain Irish scholars settled at Glastonbury, and he was proficient in music (including music composition), in painting and the mechanic arts. At an early age he entered the service of King Athelstan and continued in that of King Edgar. The spirit of Edmund, but his superior endowments provoked the enmity of his rivals at court, by
 payment of which he was set upon with outrageous violence and driven out. He then went to his uncle, Archibald, 1st Earl of Stewarstoun, and when consecrated as a priest by his uncle, he took the name of Alexander and was ordained a priest. He was appointed bishop of Dunstan in 1057 and held the see of London from 1299 to 1311. He was noted for his asceticism and was a hermit in the desert.

At the age of 22 he was made abbot of Glastonbury by King Edmund, who also appointed him as the first abbot of Glastonbury. Under his successor, Edred (945–57), who was of feebler constitution, Dunstan was in all but name ruler of the kingdom and a wise and vigorous administrator. Under Edwy, who succeeded Edred, he courageously sought out the king while he was in the company of his destined bride, Eilgiva, and to his face denounced the intended union as incestuous. For this action he was outlawed and spent two years in Flanders; but when Edwy's brother Edgar, a youth, became king of Mercia and Northumberland, he chose Dunstan for his chief minister and at the same time (957) was appointed bishop of Winchester; also held the see of London from 959; and in 961 he was promoted to the primacy of Canterbury. He dispossessed all married and concubinary priests, supplanting them with monks where he could, made the canons of his own cathedral chapter a monastic college and raised the standard of monastic life. It was part of his policy to make the Danish influence in England a part of the nation; he introduced civil order and preserved external peace. Edgar's successor, Edmund, owed chiefly to Dunstan his elevation to the throne, and the archbishop continued still to be principal minister of state; but when Edmund was murdered, 979, the archbishop's influence, under his successor, Ethelred, the unready, was small, and disasters befell the kingdom thick and fast: the Danes ravaging the coasts and pillaging and slaughtering the people inland. The archbishop passed the closing years of his life in retirement, going back to the favorite studies and pursuits of his youth—music, painting, calligraphy, the making of musical instruments, and bell-founding. He was a man of discerning, and his name will always be associated with John Milton and Jeremy Taylor. He died in 1305.

DUCK, John, English bookseller and author: b. Graffham, Huntingdonshire, 4 May 1659; d. 1733. He was apprenticed to Thomas Parkhurst, bookseller, in London, but ran away. On his return he began to be very interested in his work, and his bookshop flourished. In 1686 he visited New England, where he sold books and was doubtless the first book agent in the country. After he returned to England, he reopened his business and published the weekly Athenian Mercury (1690–96) and in 1710 planned to launch another weekly with Defoe. His accumulated debts and troubles unbalanced his mind slightly. He was the author of numerous political pamphlets in support of the Whigs. His greatest claim to remembrance is his book 'Life and Errors of Dunton' (1705), a hurried jumble of nonsense and valuable sketches of the literary and political life of the period. His 'Letters from New England' (ed. by Whitmore, New York 1867) are of historical value also.

DUNWOODY, Henry Harrison Chase, American meteorologist: b. Highland County, Ohio, 23 Oct. 1842. He was graduated at the United States Military Academy in 1866 and from the Columbia Law School in 1876 and having been detailed in 1872 for duty on the signal corps was appointed in 1891 to the weather bureau, then first constituted. His especial work has been the great system of official forecasts of the weather, and he originated the system of cold wave warnings; in this connection he recommended the organization of State weather services. He is the author of many papers on meteorological subjects published by the Signal Service. He was made colonel in 1898, and was retired as brigadier general in 1904.

DUODECIMAL SCALE. See ARITHMETIC.

DUPLANLOU, dū-pāⁿ-lò, Félix Antoine Philibert, fā-le-kō fē-le-ber, French prelate and theologian: b. Saint Felix, Savoy, 3 Jan. 1802; d. Lacombe, Isère, 11 Oct. 1879. He was for a time tutor to the princes of the house of Orleans. In 1837 he became one of the vicars-generals of the archdiocese of Paris, and head of the Petit Séminaire de Saint Nicolas de Chardonnet. Duplanloup took a lifelong interest in charitable projects and in measures extending to the masses the benefits of education. He combatted the endeavors of that party in the Church which sought to displace in institutions of higher education the ancient Greek and Latin classics as pagan, and he was instrumental in the removal of the Fathers of the Church. He was made bishop of Orleans 1849; was elected to the French Academy 1854; but withdrew in 1871 when against his earnest protest Lithtré, the leader of the Positivists, was chosen to be a member; he became leader of the clericals in the National Assembly. In the Vatican Council he opposed the decree of infallibility, but was one of the first to make an act of submission. Nominated 1871 to be archbishop of Paris, he declined that office. He was a great pulpit orator, worthy of a place between the great orators of France. His writings are voluminous, dealing almost wholly with questions of education and church interests. Two of his works which are in every good pedagogical library are 'The Child' and 'The Ministry of the Catechist.' Consult Pelleter, 'Monseigneur Duplanloup.'

DUPATY, dü-pā-té, Charles Marguerite Jean Baptiste Mercier, French jurist: b. La Rochelle, France, 9 May 1746; d. Paris, 17 Sept. 1788. In 1767 he became advocate-general to the parliament of Bordeaux and was elected on its name against the Duke of Aiguillon when this nobleman became minister (1770), he was
sent to Pierre-en-Cise (a fortress at Lyons, once a state prison), and afterward banished until the accession of Louis XVI. The memorial by which he preserved the lives of three innocent citizens of Chaumont who were condemned to the wheel deserves particular mention. His other works are 'Rellexions historiques sur les arts', a valuable work; various 'Discours académiques'; and 'Lettres sur l'Italie en 1785,' which appeared in 1788.

DUPATY, Louis Marie Charles Mercier, French sculptor and painter: b. Bordeaux, 29 Sept. 1771; d. Paris, 12 Nov. 1825. He was a son of the preceding. He was a member of the Institute, and professor in the École des Beaux Arts; was at first an advocate, served during the Revolution as a dragoon, then as cartographer, and finally went to Rome, where he studied sculpture and made himself known by numerous works. His principal productions are 'Ajax Pursued by Neptune,' his equestrian statue of Louis XIII (1816), and 'Orestes Pursued by the Furies.'

DUPERRON, dū-pē-рон, Jacques Davy, French ecclesiastic: b. Saint Lô, Normandy, 15 Nov. 1556; d. Paris, 6 Sept. 1618. His father, a physician, having embraced the Reformed religion, had to flee from France and settled at Bern in Switzerland, where he became a Protestant minister. The son, having received at Bern a superior education, came to Paris at the age of 20, and having been there received into the Roman Catholic Church was appointed reader to the king. Henry III, and afterward adopted the clerical profession. He pronounced the eulogy of Mary Queen of Scots after her execution. He is said to have supported the Cardinal de Bourbon's plot to succeed to the throne after the death of Henry III, and to have betrayed its secrets to Henry of Navarre (Henry IV). He was appointed bishop of Erreuse, and was the agent in bringing about Henry's conversion to the Roman Catholic faith. He successfully checked the advance of Calvinism in his own diocese, and brought several back to the Church. He was in Rome in 1604 when Clement VIII died, and was largely instrumental in securing the election first of Leo XI and then of Paul V, who in less than a month succeeded Leo. He was now made bishop of Sens and cardinal. Contra the principles of Gallicanism, he was a zealous advocate of the doctrine of papal infallibility and of the papal supremacy over a general council of the Church. Consult Féret, 'Le Cardinal Duperron' (Paris 1877).

DUPETIT-THOUARS, dū-pē-tô so-är, Abel Aubert, French naval captain: b. Boumois, Saumur, 31 Aug. 1719; d. Aboukir, 1 Aug. 1798. When a mere boy he was so smitten with the love of a sea life by reading 'Robinson Crusoe' that he ran away from the military school of Laffleche and attempted to enter himself as a cabin-boy in a vessel at Nantes, but was discovered and sent back. At length, in 1778, he had an opportunity of entering the navy, and distinguished himself in the West Indies. On the expedition to Egypt in 1798 he commanded an 80-gun ship. He foresaw the only result which could be anticipated if it was resolved to wait for Nelson's attack in the road of Aboukir, and advised immediately to set sail. But though his advice was disregarded he fought with undaunted valor against the enemy and fell in the struggle. His MSS. and correspondence were published under the title of 'Lettres, Mémoires et Opuscules d'Aristide Dupetit-Thouars.'

DUPIN, dū-pān, Louis Ellis, French church historian: b. Paris, 17 June 1657; d. there, 6 June 1719. In 1680 he received the degree B.D. at the Sorbonne, and in 1684 the degree D.D., and then or previously commenced those researches into the history of the Church which resulted in his celebrated 'Universal Library of all the Ecclesiastical Writers' (Vol. I, 1668). The freedom with which in this volume he discussed the teachings of the Fathers of the Church is traced upon the work its condemnation by the archbishop of Paris and it was suppressed; but the author having made a retraction and changed "universal" in the title to "new," he was permitted to continue the series, though later he was banished as a Jansenist and permitted to return only after a fresh retraction. He sought to effect a union between the Anglican and Gallican churches and had a correspondence to that end in 1718 with the Anglican primate, Archbishop Wake. He was now charged with endeavoring to subvert the dogmas of the Roman Catholic Church, and his papers were seized in 1719, in the expectation that they would give proof of the charge; but nothing was found that seriously compromised him. He seems to also have conferred with Peter the Great with a view to union of the Gallican and Russian churches. The 'Library of Ecclesiastical Authors' is a voluminous work of immense erudition, rich in biographical sketches and in bibliographical details of theological literature in the Roman Church till the close of the 17th century; it was soon translated into English.

DUPLEX, dū-plâks, Joseph François, French colonial governor: b. Landrecies, France, 1 Jan. 1697; d. Paris, 10 Nov. 1764. In 1720 he was appointed to a seat in the council at Pondicherry. Ten years later he became superintendent at Chandernagore in Bengal. The remarkable success of his administration there led to his being appointed, in 1741, governor-general of all the French Indies, with the title of Nawab. He now successfully pursued that policy of patient, skilful diplomacy among the native princes which at one time made the Carnatic almost a French province. When war broke out in Europe between France and England (1740), several brilliant engagements planned by Duplex took place between the French garrison and the troops of the Nawab of the Carnatic, who endeavored to take possession of Madras, but was promptly forced to raise the siege. An attack on the English at Fort Saint David failed, but Duplex's science and courage were displayed in the defense of Pondicherry, which Admiral Boscauen in vain attacked for five weeks, with an apparently overwhelming force, but was forced to retire discomfited, though the defense was conducted by a civilian, unsupported by a single general of repute. The ambitious mind of Duplex had long formed the project of founding a French empire in India on the ruins of the Mogul monarchy, but his military designs, able as they were, were frustrated by the energy and military
genius of Clive and Lawrence. The struggle continued till 1750, in which year Dupleix was recalled by Louis XV.

**DUPONCEAU—DU PONT**

**dú-pohn'-sō Fr. dú-pohn'-sō**

Peter Stephen, American lawyer and scholar: b. Saint Martin, Isle de Ré, France, 3 June 1760; d. Philadelphia, 1 April 1844. For a time he was secretary to Count de Gébelin, and afterward to Baron Steuben, with whom he came to the United States in 1777. Receiving a captain's commission he served with Steuben through the American Revolution and after its close settled in Philadelphia and became noted as a lawyer. For several years he was much interested in an effort to introduce into the United States the production and manufacture of silk. His writings are of a miscellaneous character, among which may be mentioned original treatises on points of law; translations from the Latin, German and French on similar subjects; various treatises on philosophy; numerous contributions to American history, including a translation of "A Description of New Sweden," by Thomas Campanius Holm. He was a member of more than 40 literary and scientific institutions of Europe and America, including the American Philosophical Society, the Historical Society of Pennsylvania, and the Philadelphia Athenaeum, of which three institutions he was the presiding officer at the time of his death.

**DU PONT, dú-pohn'-**, Henry, American manufacturer: b. Eleutherian Mills, near Wilmington, Del., 8 Aug. 1812; d. 8 Aug. 1899. He was the second son of Eleuthère Irénée Du Pont de Nemours (q.v.). He secured his early education at Constant's Mount Airy Seminary, Germantown, Pa.; in 1827 he entered the military academy at West Point, from which he graduated in 1833. In the following year, however, in deference to his father's wishes that he should return to Delaware to master every detail of the powder business and so be well assured as to how the mills were managed, he resigned his commission and thereafter gave his attention to the powder industry. In 1850 he became head of E. I. Du Pont de Nemours and Company, and by his executive ability soon extended the operations of the works until the industry had a monopoly of the powder market. The first export of powder from Mexico called for large quantities of powder from the mills and when peace came general enterprises began to demand still larger quantities in industrial operations. The company also supplied the English army during the Crimean War, and during the Civil War in the United States sold enormous quantities to the National government. Politically he was associated with the Whigs, but when the Civil War broke out he heartily supported Lincoln in all his measures to preserve the Union. He became one of the leaders of the Delaware Republicans and was a presidential elector in the campaigns of 1868, 1876, 1880, 1884 and 1888. He was appointed major-general of the Delaware forces in 1861 by Governor Burton, and immediately upon assuming office ordered every man in the military service of the State to take an oath of allegiance to the United States or surrender his arms. There were many people in the State who were undecided as to which cause to espouse and Du Pont's order was calculated to compel the people to declare themselves, but influences adverse to the military occupation of the State were strong and Governor Burton was unable to suspend the order. Du Pont thereupon applied to Gen. John A. Dix, commanding the Federal troops at Baltimore, and the latter sent a body of troops to Delaware to maintain the supremacy of the general government in that State. Like his ancestor, he had a great attachment for rural life and agricultural pursuits, and was probably the largest individual landowner in the State. He was widely known for his many benefactions, took a lively interest in local affairs and was ever to be found in favor of public improvement.

**DU PONT, Henry Algernon, American soldier and legislator: b. Eleutherian Mills, Newcastle County, Del., 30 July 1838. He is the son of Henry Du Pont and grandson of Eleuthère Irénée Du Pont (qq.v.). He entered the University of Pennsylvania in 1855, but spent only a year there and in 1856 entered the United States Military Academy from which he was graduated in 1861, at the head of his class. Immediately after his graduation he was sent south, served in the defenses of Washington, May–July 1861 and in the 5th United States Artillery 1861–62, &c. At the start of the war in July 1861. In 1862–63 he was acting assistant adjutant-general of troops at Fort Hamilton, N. Y. In 1863 he was sent into active service in command of Light Battery B in the fields of Pennsylvania, Maryland, Virginia and West Virginia. He was promoted captain of the 5th Artillery in 1864, and took part in the battle of New Market. He was soon afterward appointed chief of artillery of the department of West Virginia and during Hunter's campaign against Lynchburg he commanded the artillery at the battle of Piedmont, 5 June 1864, at the engagement at Lexington 11 June, the affair near Lynchburg 17 June, the battle of Lynchburg 18 June and the affairs at Liberty 19 June and Mason's Creek 21 June. He served next in Sheridan's campaign in the valley of Virginia commanding the artillery brigade of Crook's corps and participating in the affairs at Cedar Creek 12 August and Halltown 23, 25 and 27 August, the action at Berryville 3 September, the battle of Winchester (Opequon) 19 September, Fisher's Hill 22 September. For his disinguished services at the battle of Cedar Creek he was brevetted lieutenant-colonel and was also awarded a medal of honor by Congress for "most distinguished gallantry and voluntary exposure to the enemy's fire at a critical moment during the battle of Cedar Creek. After the war Du Pont continued in the army for a number of years, holding commands at Fort Monroe, Va.; Camp Williams, near Richmond; Washington, D. C. and Fort Adams, Newport, R. I. He was a member of the board of officers which assimilated the tactics of the three branches of the service. On 1 March 1875 Colonel Du Pont resigned from the army and after a year's absence in Europe went back to live in Delaware. In 1877 he became a director and in 1878 the president and general manager of the Wilmington and Northern Railroad Company, then in very bad physical and financial condition. After 21 years of incessant labor he was at last successful in putting the road into satisfactory shape. He also became associated with the celebrated powder mills established.
near Wilmington, Del., by his grandfather, Eleuthère Irénée Du Pont, and which had proven an important factor in the Civil War. He retired from active business cares in 1902 and has since devoted his spare moments to agricultural pursuits. In 1895 he came into national prominence because of the famous struggle with John Edward Addicks in Delaware for a seat in the United States Senate, a struggle which lasted nearly 20 years and resulted in several deadlocks. The contest finally ended with the election of Du Pont in 1906 for the unexpired term beginning 4 March 1905, and he took his seat in the Senate 3 Dec. 1906. In 1911 he was re-elected for the term ending 3 March 1917. Mr. Du Pont has published several contributions to the science of military tactics, among which are two volumes issued separately in 1875, entitled 'Cavalry Tactics U. S. A., Assimilated to the Tactics of Infantry and Artillery,' and 'Artillery Tactics, U. S. A., Assimilated to the Tactics of Infantry and Cavalry.' He was a member of numerous organizations including the Historical Societies of New York, Pennsylvania and Delaware, the American Philosophical Society, the American Geographical Society, the Society of Colonial Wars, the Huguenot Society and the Military Service Institute.

DU PONT, Samuel Francis, American naval officer: b. Bergen Point, N. J., 27 Sept. 1803; d. Philadelphia, 23 June 1865. He was the third son of Victor Marie Du Pont de Nemours. His parents removed to Louviers, Del., soon after his birth. In 1815 President Madison appointed him a midshipman in the navy. His first service was a voyage to the Mediterranean on the Franklin. In 1821-22 he served aboard the Constitution in the Mediterranean, and was next attached to the Congress for a cruise in the West Indies and off the coast of Brazil. He passed through the various grades reaching that of commander in 1842, when he was sent to China in the Perry, but ill health forced him to leave his ship at Rio Janeiro and return home. In 1843 he assisted in perfecting the land administration of the newly-founded Naval Academy at Annapolis. In the same year he was transferred to the Congress on the Pacific station under Commodore Stockton. On the outbreak of the Mexican War Du Pont was given command of the Cyane, and took a prominent part in all the operations on the California coast, clearing the Gulf of California of hostile vessels, and taking San Diego, La Paz and Mazatlan. He was ordered home in 1848, became a member of the Light-House Board, and in 1855 was made captain and member of the naval retiring board. In 1857 he visited China, Japan, India and Arabia, and in 1860 was placed in command of the Philadelphia navy yard. In September 1861 he was appointed flag officer and ordered to the command of the South Atlantic blockadeing squadron. In conjunction with Sherman's land forces he took Port Royal in November and established 14 blockadeing stations along the coast. He was next ordered to attack Charleston, S. C., which he did on 7 April 1863, but was repulsed with considerable loss. This was the last important action of his life. Du Pont had command of the fleet, as he was relieved from command 5 July 1863. Admiral Du Pont was also favorably known as the author of various papers on professional subjects, among which were those on corporal punishment in the navy and on the use of floating batteries for coast defense. In 1832 Congress provided that "the circle at the intersection of Massachusetts and Connecticut Avenue in the city of Washington should be called Du Pont Circle, and subsequently $20,500 was appropriated for the erection there of a bronze statue of the admiral which was modeled by Launt Thompson and dedicated 20 Dec. 1894.

DU PONT DE NEMOURS, Eleuthère Irénée, American manufacturer: b. Paris, 24 June 1771; d. Philadelphia, 31 Oct. 1834; son of the French political economist, Pierre Samuel Du Pont de Nemours. He was a pupil of Lavoisier and entered the royal powder mills at Essonne to familiarize himself with the manufacture of gunpowder with a view to succeed Lavoisier as superintendent of the government powder mills, but subsequently abandoned this in 1791 to take charge of the printing and publishing house established by his father in Paris. Being a supporter of King Louis XVI, he was in the utmost peril after 10 Aug. 1792, and after being three times imprisoned and having his printing house sacked and destroyed, he emigrated with his father's family to the United States in 1799, arriving at New London, Conn., 1 Jan. 1800. Not long after his arrival attention was called to the poor quality of gunpowder then made in this country and he determined to enter into powder manufacture here. With this in view he returned to France, January 1801, to procure at Essonne plans and models of improved machinery, returning to the United States in August with some of the machine tools. Thomas Jefferson, who was deeply interested in this development, urged that the works be built in Virginia, but owing to his views regarding slavery and its effect on the white race Du Pont was unwilling to make his venture either in Virginia or Maryland. In June 1802 he bought a tract of land with a fine water-power on the Brandywine River, near Wilmington, Del. On 19 July he arrived there with his family and began operations which were so successful that, at the time of his sudden death by cholera, his works were the largest of their kind in the country. Since his death they have been carried on by his sons and grandsons and are still among the largest gunpowder works in this country, while they are the centre of the industrial combination in this industry. He found time also to join every movement tending to promote agricultural and industrial enterprises, and earnestly supported every measure looking toward local improvement. For some time he served as a director of the Bank of the United States; he took a prominent part in the work of the American Colonization Society, and also found time for other philanthropic labors and innumerable private benevolences.

DU PONT SMOKELESS POWDER, a hard-grained porous powder, composed of nitrocellulose of medium nitration which has been formed into grains by suspending the nitrocellulose in an aqueous solution of barium and potassium. The soln. is poured into the mold and after hardening is added, stirring the gelatinized material in the fluid until the grains are formed and hardening
them by steam until the amyl acetate is expelled. A certain amount of vaseline is incorporated during the drying process in the dense powders and these powders are practically proof against atmospheric moisture. The grains may be separated by sifting into the various desired sizes and colored to meet any taste by the addition of a very small amount of an organic coloring matter. The Du Pont smokeless powders are offered in many kinds under four general classifications: (1) for high power rifles; (2) for black-power rifles which have been adapted for smokeless powder; (3) for revolvers and automatic pistols at midrange and (4) for the same weapons at short range. See EXPLOSIVES; POWDER.

DUPONT, dû-pô'nu, Jacques Charles, surname De l'Eure, French statesman: b. Neubourg, Eure, Normandy, 27 Feb. 1767; d. Rouge-Pierre, Normandy, 3 March 1855. In 1789 he was an advocate at the parliament of Normandy. During the republic and the empire he filled successively judicial offices at Louviers, Rouen and Evreux. He had adopted the principles of the Revolution and in 1793 he was a member of the Five Hundred, which was dispersed by Murat on the 18th Brumaire. In 1811 he was nominated president of the Court of Justice at Rouen and in 1813 vice-president of the Corps Législatif. During the Hundred Days he was vice-president of the Chamber of Deputies and when the allied armies entered Paris he drew up the declaration in which the chamber asserted the necessity of maintaining the principles of government that had been established at the Revolution. He was one of the commissioners chosen to negotiate with the allied sovereigns. On the restoration of the Bourbons, Dupont signalized himself as a leader of the opposition. In 1830, after the revolution of July, he was made Minister of Justice, and after the fall of Louis Philippe became a member of the provisional government. In 1849 he failed to secure his re-election to the chamber and retired into private life and on the accession of Napoleon III, in 1852, he ceased to take part in public affairs. His consistent firmness in the era of constitutional liberalism during all the many changes of his times gained him the esteem of his countrymen, by whom he was styled the Aristides of French liberalism.

DUPONT, Piere, French song-writer: b. Lyons, 23 April 1821; d. Lyons, 24 July 1870. His parents both died before he was five years old and he was cared for in the country by his godfather, a village priest. He was educated at the seminary of L'Argentière and was afterward apprenticed to a notary at Lyons. He went to Paris in 1839 and published some poems in the Oeuvres. In 1841 he was saved from the conscription and through the help of Lebrun and a kinsman published his first volume, 'Les Deux Anges.' He was awarded a prize from the academy in 1842 and for a time was employed on the official dictionary and a Government of a peasant song, determined Dupont in his vocation as a song-writer. He possessed no musical knowledge and had to engage Ernest Reyer to write down his airs. He sang his own songs at the workmen's concerts in the Salle du Fraternité du Faubourg Saint-Denis. The public performance of his famous 'Le Pain' was forbidden; 'Le chant des ouvriers' was even more popular and in 1852 his becoming the poet laureate of socialism proved obnoxious to the new government and he was condemned to be banished for seven years; but the intercession of friends soon procured his release and he withdrew for a time from participation in political life. He returned later years in Lyons. His songs have appeared in various forms of 'Chants et chansons' (3 vols., with music, 1852–54); 'Chants et poésies' (7th ed., 1862). The best known are 'Le Braconnier,' 'Le Tisserand,' 'La Vache,' 'La Chanson du blé,' Consult Baudelaire, Ch., 'Notice sur P. Dupont' (1849); Déchant, 'Biographie de Pierre Dupont' (1871); Lenient, Ch., 'Poésie patriotique en France' (1889); Sainte-Beuve 'Causeries du Lundi.'

DUPONT, Pierre Antoine, Count, surname De l'Étang, French soldier: b. Chabanas, 14 July 1765; d. Paris, 7 March 1840. He first served with Maillebois' legion in Holland and in 1794 was on the staff of the Army of the North under Dillon. By his skillful arrangement as a staff officer, he prevented Dupont from falling into the hands of the British at Dourville; and was promoted to the rank of brigadier-general. In 1797 he became general of division. After the proceedings of the 18th Brumaire, in which he took an active part, he was appointed head of the general état-major of the army of reserve assembled at the foot of the Alps and distinguished himself in Italy at the battle of Marengo. In the campaign of 1805 on the Danube, he earned further distinction by preventing the escape of the Austrians from Ulm, thus contributing largely to the capture of Mack and his army. He also freed Marshal Mortier from Russian troops. He was active in the campaign of 1806 against the Prussians and in 1807 contributed to the victory of Friedland. He entered Spain in 1808 at the head of a corps. After the occupation of Madrid, Dupont was created count by Napoleon and dispatched to subdue Andalusia. He was pursuing and cut off by Castaños, his corps was defeated and on 22 July 1808 he felt himself trained to capitulate with 18,000 soldiers at Bayley. After his return to France, Dupont was sent before a court-martial, deprived of his rank and title and imprisoned from 1812 to 1814. On the fall of Napoleon he was released and was given a military command by Louis XVIII, which he lost on the return of Napoleon. He was restored once more to the army after the final downfall of Napoleon and became a member of the Privy Council of Louis XVIII. From 1815 to 1830 he was member of the Chamber of Deputies from Charente. He went into retirement in 1832. He wrote some poems (1838) and verse translations from Horace (1836) and the military works 'Opinion sur le nouveau mode de recrutment' (1818); 'Lettres sur l'Espagne en 1808' (1823); 'Lettre sur la campagne d'Autriche' (1828). Consult Titeux 'Le Général Dupont; une erreur historique' (Paris 1903).

DUPONT DE NEMOURS, Pierre Samuel, French economist: b. Paris, 14 Dec. 1739; d. Eleutherian Mills, near Wilmington, Del., 7 Aug. 1817. He was educated under his mother's tutelage and at an early age gained distinction in his studies, which included engineering and military science, etc. He lived almost unknown in Paris as a private man of
failed within a few years because of the refusal of the French government to reimburse the firm for funds advanced. In 1802 Dupont returned to France, but did not at that time take any political office, notwithstanding the offers made him by Napoleon. He was, however, instrumental in promoting the treaty of 1803 by which the United States purchased Louisiana and he was appointed one of the commissioners to arrange the formal transfer. Later he became secretary of the Paris Chamber of Commerce, and in 1807 was appointed sub-librarian at the Arsenal. After Napoleon's first downfall in 1814 he became secretary of the provisional government that prepared the return of Louis XVIII, and after the restoration of the Bourbons he was again named councillor of state. After Napoleon's return from Elba, Dupont was again forced to flee, settling in the United States where his two sons had already become citizens. Besides his political treatises he is likewise the author of a French translation of the first three cantos of the 'Orlando Furioso.'

DUPONT DE NEMOURS, Victor Marie, American manufacturer: b. Paris, France, 1 Oct. 1766; d. Philadelphia, 1795. He was a son of Pierre Samuel Dupont De Nemours (q.v.), and entered the diplomatic service as attaché to the French legation in the United States in 1787; became secretary of legation in 1795 and was appointed French consul in Charleston, S. C., in the same year. In 1798 he was appointed consul-general of France in New York. He returned to France, was aide-de-camp to Lafayette, then commanding the national guard, later withdrew from the government service and came to the United States in January 1800. He entered business in New York; removed to Wilmington, Del., in 1809, where he joined his brother and established a cloth manufactory. During the War of 1812 he was captain of a company of Delaware volunteers. He was for a time a member of the Delaware legislature, and a director of the Bank of the United States.

DÜPPEL, dü’pĕl, Germany, fortified village in the province of Schleswig-Holstein, Prussia, on the peninsula of Sundewitt, 16 miles northeast of Flensburg, on the coast of the Little Belt. The place has been the scene of some severe struggles between the Danes, to whom it formerly belonged, and the Germans. In 1848 the latter were defeated here by the Danes, then the place was retaken by the Prussians, and in 1866 was again in possession of Denmark. After a long siege it was captured by the Prussians in 1864. Consult Neumann, R., 'Über den Angriff der düppeler Schanzen in der Zeit von 15 Mars bis 18 April 1864' (Berlin 1865).

DUPRAT, dü'prat', Antoine, French statesman, archbishop and cardinal: b. Issore, 17 Jan. 1463; d. Rambouillet, 9 July 1535. He took high rank in the legal profession but the death of his brother, Robert, in 1507 entered him into the Church. Under Louis XII he was president of the Parliament of Paris, and in 1515, on the accession of Francis I, became Chancellor and Prime Minister. The chief event of his ministry was the conclusion of the treaty between the French and the Papal States, which brought an end to clerical and academic opposition, by which the Church and nobility became subject to the
Crown, and by which he nullified the desire of Pope Leo X to abrogate the Pragmatic Sanction, which in 1438 had limited the spiritual power of the Pope in France and laid the foundation of the Gallican Church. In thus consolidating the power of the state he was the pious and able minister of theLeague and Mazarin. He was appointed archbishop of Sens in 1525 and cardinal in 1527. Consult his biography by the Marquis du Prat (Paris 1857).

DUPRÉ, dū-prě', Giovanni, Italian sculptor: b. Siena, Italy, 1 March 1817; d. Florence, 10 Jan. 1882. Among his works are 'Abel'; 'Cain'; 'Sappho'; 'Giottina'; and 'Pieta', the last representing the dead Christ, supported by his mother. He received the gold medal at the Paris Exhibition of 1867. His monument to Cavour 1866-73 was the least splendid of his works, chiefly because he proved his inability to execute large pieces. His work is virile but not forceful. Consult his autobiography (1879, translated by Peruzzi 1884); and Frieze, 'Giovanni Dupré' (London 1886).

DUPRÉ, Jules, French landscape painter: b. Nantes, 5 April 1812; d. L'Isle Adam, 6 Oct. 1889. He began his career as a painter of porcelain in his father's factory, but when 18 years old went to Paris where his talent speedily became recognized. He sent his first picture to the Salon in 1831; was made a Chevalier of the Legion of Honor in 1849, and officer in 1870. He received a second-class medal at the Exposition of 1867 and the same at the Exposition of 1883, and a medal of honor at the Exposition of 1889. In 1834 he visited England where he was greatly influenced by Constable. His studio for some years was in the Forest of Fontainebleau, and later in L'Isle Adam. A number of his pictures are owned in the United States. Dupré was one of the chief members of the Barbizon school. His favorite themes represent nature in its dramatic phases. Consult Claréée, 'Peintres et sculpteurs contemporains' (Paris 1899).

DUPRÉ, Julien, French painter: b. Paris 1851; d. 1910. His masters were Pils and Henri Lehmann. He has been very successful in portraying simple scenes from country life, farm animals and landscapes. His 'Mowers of Lucerne' and 'White Cow' are in the Luxembourg. In 1904, at Saint Louis he exhibited one of his greatest works, 'The Return of the Herd,' and also 'Evening' and 'Near a Pool.'

DUPUIS, dū-pwē', Charles François, French scholar: b. Trie-Château, near Gisors, 16 Oct. 1742; d. Is-sur-Tille, France, 29 Sept. 1805. In his 24th year he was made professor of rhetoric at Liieux. His 'Mémoire sur l'Origine des Constellations et sur l'Explication de la Fable par l'Astronomie' (1781) is erudite, but rather sophistical. Later works of his are 'Origine de tous les Cultes, ou la Rigion universelle' (1794), which gave rise to an embittered controversy; two works on the Pelasgi, which attracted great attention; treaties on the zodiac of Denderah, and on the Phoenix; 'Mémoire explicatif du Zodiaque chronologique et mythologique' (1806).

DUPUIS, Nathan Fellowes, Canadian scientist: b. Port Hope, Ont., 13 Apr. 1835. He graduated at Queen's University, Kingston, in 1866; was professor of chemistry in his alma mater, 1867-80, and of mathematics, 1890-1911. His published works include 'Elements of Geometrical Optics' (1868); 'Geometry of the Point, Line and Circle in the Plane' (1889); 'Elements of Synthetic Solid Geometry' (1893).

DUPUY, dū-pwē', Charles Alexandre, French statesman: b. Le Puy, Haute-Loire, 1851. He received his education at the Lycée of Le Puy and the Lycée Charlemagne, Paris. He was successively a professor of philosophy at the colleges of Nantes and Aurillac, and a teacher in lycées, school inspector for the academies of Lozère and Calvados and vice-rector of the college at Ajaccio, Corsica. In 1885 he entered the political arena, becoming deputy for Haute-Loire in 1885, and securing re-election in 1889. In 1892 he became Minister of Public Instruction and in the following year was chosen president of the Chamber of Deputies. He was twice Premier and Minister of the Interior, in 1893-95 and 1898-99. In 1900 he was chosen senator for Haute-Loire. He is the author of 'Livret de morale' (1891).

DUPUY, Jean, French journalist and politician: b. Saint-Palais, Gironde, 1844. In 1866 he became proprietor of the Petite France. He two years later of the Petit Parisien, and afterward was head of the Paris press syndicate. In 1891 he took his seat in the senate as a Radical Republican and was prominent in the debates on agriculture and finance. In 1899-1902 he served as Minister of Agriculture in the Cabinet of Waldeck-Rousseau, and as Minister of Commerce in that of Briand, 1909-11. From January to March 1913 he served as Minister of Public Works.

DUPUYTREN, dū-pwē-trān, Guillaume, Baron, French surgeon and anatomist: b. Pierre-Buffière, Haute-Vienne, 6 Oct. 1777; d. Paris, 8 Feb. 1835. In 1801 he obtained the situation of overseer of anatomical labs at Paris; and became in 1815 first surgeon to the Hôtel Dieu. In 1823 he was appointed first physician to the king, Louis XVIII, and retained the same situation under Charles X. He possessed extraordinary acuteness in respect of diagnosis, united with remarkable skill and dexterity in the most dangerous operations, in performing which he had a firmness of nerve which was never shaken. He invented several surgical instruments and modes of operation, and also made some discoveries in pathological anatomy. Some of his pupils united in publishing his 'Oral Lectures on Clinical Surgery' (1830-34); and his 'Theory and Practice as to the Treatment by Warlike Weapons,' was published in 1834.

DUCESNE, dū-kwēn, Abraham, French admiral: b. Dieppe 1610; d. Paris, 2 Feb. 1688. In his 17th year he was in the sea-fight off Rochelle, and distinguished himself during and after the year 1637 in the war against Spain. In 1647 he commanded the expedition against Naples. Bordeaux, which had rebelled, he reduced, notwithstanding the assistance afforded it by Spain. In the Sicilian War he thrice defeated the combined fleets of Holland and Spain, under the renowned De Ruyter, who was mortally wounded in one of the actions. After he had reduced Algiers and Genoa to the necessity of supplicating the mercy of Louis
DUQUESNOY, dū-kān-wā, Fransōz, or François FLAMAND, Flemish sculptor: b. Brussels 1594; d. Leghorn, Italy, 12 July 1648. He was taught by his father and became celebrated at an early age. His best works are child figures. Under the patronage of Urban VIII he carved the groups of children which adorn the altar at Saint Peter's, Rome; likewise the statue of Saint Andrew in the same church, Saint Susanna for the Santa Maria di Loreto, at Rome, and numerous others. At the invitation of Richelieu, he set out to the court of Louis XIII of France, but died en route. The South Kensington Museum, London, contains several fine ivory reliefs by him.

DURA MATER, dū'ra mā'ter, the outer envelope or covering of the brain (q.v.).

DURAM, doo-rán', or DURÃO, José de Santa Rita, Brazilian poet: b. near Mariana, province of Minas Geraes, 1737; d. Lisbon, Portugal, 1783. He qualified himself for the service of the Church by his studies at Rio Janeiro and at Coimbra in Portugal, was graduated doctor of divinity at the university of the latter city and joined the religious order of Saint Augustine. In the course of his travels in Spain and Italy he became acquainted with Abbé Daubree and other eminent men of letters, and subsequently during his residence at Coimbra composed a poem founded upon the story of the Galician adventurer, Diego Alvarez Correa, surnamed Caramuru, the legendary hero of Bahía. This poem was published at Lisbon in 1781, under the title of 'Caramurú, poema epico do descobrimento da Bahia,' and a French version appeared at Paris in 1829. On its first appearance the poem was not highly estimated, but since then has risen to the rank of a national epic in Brazil.

DURAMEN, dū-rā'men (a Latin word for hardness), the heart-wood or central wood in the trunk of exogenous trees as found in dicotyledons and conifers. (See CONIFERA.) It is hard and dense, and often dark-colored, with its tubes dry and thick. Thus in the ebony the duramen is black and is the part used for furniture and fine cabinet-making. The albumen (q.v.), or outer wood, is pale. In the beech the heartwood is light brown; in the oak deep brown; in the Judas-tree yellow and in guaiacum greenish. The relative proportion of duramen to albumen, differs in different trees. By ship-carpenters the duramen is known as the "spine."
for the previous 10 years been a regular contributor of portraits, small figure pieces or landscapes in oil to the exhibitions of the National Academy of Design, finally abandoned engraving as a profession. He devoted himself thereafter mainly to landscape painting, in which department of art he became eminent. His subjects included General Jackson, Henry Clay and heads of all the presidents, from nature or copied. With Thomas Cole he founded the American landscape school. His landscapes are large sketches painted directly from nature. His composition was imperfect but his work is interesting in detail. The Corcoran Art Gallery at Washington contains his 'Mountain Forest' (1869), and the Metropolitan Museum, New York, contains four of his works, including 'In the Woods', one of his best landscapes. The New York Public Library has another fine example. He was one of the original members and president of the National Academy of Design. Consult the biography by John Durand (New York 1894) and Isham 'History of American Painting' (ib. 1907).

DURAND, Edward Dana, American statistician: b. Rome, Mich., 18 Oct. 1871. He was educated at Oberlin College and at Cornell University. He was legislative librarian of the New York State Library in 1895-97, assistant professor of administration and finance, Leland Stanford, Jr., University, in 1898-99; secretary of the United States Industrial Commission in 1900-02, and instructor in economics at Harvard in 1902. He served as special expert agent of the United States Census Office on street-railways and electric-lighting plants in 1902 and special examiner of the Bureau of Corporations 1903-07. In 1907-09 he was a deputy commissioner of corporations and was director of the United States census in 1909-13, since when he has been professor of statistics and agricultural economics at the University of Minnesota. He is author of 'Finances of New York City' (1898); 'The Trust Problem' (1915), and contributions on economics and political subjects to various journals, and reports of the United States Census Bureau, the Census Bureau, etc.

DURAND, William Frederick, American engineer: b. Bethany, Conn., 5 March 1839. He was graduated at Annapolis 1880; served in the United States Naval Engineering Corps (1880-87); was professor of mechanical engineering in the Michigan Agricultural and Mechanical College (1887-91), when he became associate professor of marine engineering at Cornell, and full professor in 1895. He continued his work at Cornell University until 1904 when he became professor of mechanical engineering at Stanford University, which position he now holds. In 1915 he was appointed by President Wilson member of the National Advisory Committee on Aeronautics. He also served as chairman of the committee of management for the International Engineering Congress held in San Francisco in 1915. He has published 'Fundamental Principles of Mechanics' (1889); 'Resistance and Propulsion of Ships' (1898); 'Practical Marine Engineering' (1902); 'Motor Boats' (1907), and many special articles in engineering journals.

DURAND, Wiss, city, county-seat of Pepin County; on the Chippewa River, about 20 miles from its junction with the Mississippi, and on the Chicago, Milwaukee and St. Paul Railroad. It is the centre of an agricultural region, and its trade and industries are those that pertain to agriculture and stock-raising. Pop. 1,503.

DURANDUS, dū-rán'dús, Guelielmus, French prelate and jurist: b. Puimisson, Languedoc, 1237; d. Rome, 1 Nov. 1296. He became professor of the canon law in the University of Modena, and there acquired so high a reputation for his learning that Pope Clement IV made him auditor of the Sacred Palace, and took him as his secretary to the General Council of Lyons (1274). In 1277 he was appointed lieutenant-governor of the patrimony of Saint Peter, under Nicholas III; the following year he successfully asserted the sovereignty of the Pope over the provinces of Bologna and Romagna. These two provinces he then governed from 1283 to 1286, in the meantime carrying on a war against the people of Romagna, who were in revolt. He was appointed bishop of Montereale in Languedoc in the latter year, and retired from the governorship. In 1295 he was again in public station, governor of Romagna and the March of Ancona; but his strength was unequal to the task of resisting the attacks of the Ghibelline faction, and he resigned his office. His greatest work, 'Speculum Juris' (mirror of the law), called by himself 'Speculum Judiciale,' was for a long time a work of highest authority in Roman and ecclesiastical law; between the years 1474 and 1678 it passed through 38 editions. He wrote an informal history (commentarius) of the General Council of Lyons, the decrees of which were drawn up by him. His 'Rationale Divinorum Officiorum' published at Mainz in 1459, is a standard work on the liturgy of the Roman Church.

DURANGO, dū-rán'gō, Colo., town, county-seat of La Plata County; on the Las Animas River, the Denver and Rio Grande, and the Rio Grande Southern railroads; about 20 miles north of the boundary line between Colorado and New Mexico. There is a Carnegie library. The town is the centre of the surrounding region in Colorado and New Mexico which produces gold, lead and silver and carries on extensive stock raising and agriculture. The principal industries are the smelting and manufacture of the mineral products, flour manufacture, packing, coal and coke mining. Durango has been governed under the commission plan since April 1913. Pop. 5,000.

DURANGO, dū-rán'gō, Mexico, an inland state of the North, bounded by Chihuahua on the north, Coahuila on the northeast, Zacatecas and Tepic on the southeast and south, and Sinaloa on the west. Its area is 38,000 square miles. It is one of the largest and richest states in the republic. The Sierra Madre range (altitude 8,125 feet to 11,375 feet) traverses the western and southern portions. Less important ranges are the Copoliquina, Topia, Cavelas, Amacutí, Tomimil, Muinora, Guanaccuto and de los Camarones; these, as well as the isolated peaks, Cerro del Mercado, Pánuco de Ávino, etc., are ore-bearing. The Cerro del Fraile is an extinct volcano. Among the rivers, the Nazas, in the northern part of the state, with its afflu-
DURANGO — DURATION

ents, the Santiago and San Juan; the Tunal, which rises west of the city of Durango, and its affluent, the Suchil; the Rio Chico, or Alapona, and the Aguanaval. There are small lakes, mineral springs, etc. Gold, copper and silver are the chief mineral products, and the best mining districts are those of San Dimas, Guarisamay, Buenavista, Gavilanes, Guanacevi, Mapimi, El Oro and Indé. In the San Dimas district is the celebrated Candelaria mine, where the ore assays between $70 and $140 a ton. This mine is said to have yielded over $100,000,000 before the close of the 19th century. The Cerro del Mercado, near Durango city, contains an immense deposit of high grade iron ore and is estimated to contain 300,000,000 tons of that metal. Near it are iron and steel works. The mines are controlled chiefly by American capital. Sulphur, copper, iron, cinnabar, tin, coal and rubies are also found. With the exception of silver, the mineral resources of the state have been but slightly developed owing to inadequate and costly transportation facilities. The Mexican Central Railroad crosses the eastern part of the state from north to south, and the Mexican International crosses it from northeast to southwest, running through the capital and connecting it with the port of Mazatlan on the Pacific coast. The climate varies with the altitude of the different localities, being cool or cold in the mountainous western regions, and temperate, or warm, in the valleys extending from the base of the mountains and in the Nazas basin. There is very little rainfall in the eastern part of the state. The climate is generally dry and healthful, but hot on the western slopes of the Sierra. The plateau is generally of good quality and with irrigation could be made very productive. Cotton is produced to a small extent. Wheat, maize, tobacco, sugar-cane and grapes are also grown in certain districts, and stock-raising is successfully practiced in the higher valleys of the Sierras. Since the beginning of the 20th century manufacturing has been making considerable progress. There are several cotton mills in operation, consuming annually about 500,000 kilos, and with an annual value of approximately 600,000 pesos. Soap and candle factories, tanneries, pottery works, etc., are also in operation. Durango originally formed part of the province of Nueva Viscaya. The capital is Durango (pop. 32,263), and among the principal towns are Quanacevi (pop. 6,859), El Oro, Nombre de Dios, San Juan de Guadalupe, San Dimas and Villa Terdo. Pop. 510,000. The inhabitants are largely of Indian blood, are almost entirely Roman Catholics, and about 84 per cent are illiterate.

DURANGO, Mexico. Capital of the State of Durango. It is situated 6321 feet above sea level, has an average temperature the year round of 70° F. in the shade. Pop. 32,263. Founded in 1563 and decreed a city by Philip IV in 1621. It was long the capital of the province of Nueva Viscaya and has been an important trade centre since a very early day. Of a territory including the Mexican state of Chihuahua and the southern portion of Texas and New Mexico. It is 540 miles from Eagle Pass, on the Texas border, by the International Railway, and 480 miles from Mexico City. It is a city of considerable wealth, the region round about being very rich, both in minerals and agriculture. Many Americans are located here and are actively engaged in enterprises of various kinds, adding materially to the prosperity of the community. Almost within the city's limits rises a wonderful hill of very nearly pure iron, the famous Cerro del Mercado, 640 feet high, 4,800 feet long and 1,100 feet wide, which has been estimated by mining engineers to contain 320,000,000 tons of that metal. Among the local industries are extensive ironworks, cotton and woolen mills, foundries, sugar-cane mills, tobacco factory and flour mills. The stores and shops are particularly well stocked and creditable. A local bank — the Bank of Durango — with a capital of $2,000,000, and a branch of the National Bank and an agency of the Bank of London and Mexico provide for financial needs. The notable buildings are the Cathedral, which was begun in 1695 and completed in 1844; the new City Hospital; the college formerly controlled by the Jesuits, founded in 1594; the Episcopal Seminary; the Methodist Episcopal Church; the Catholic churches of San Francisco, San Juan de Dios and San Agustin; the government palace, the market house and a magnificently built penitentiary and bull ring are located here also. It formerly had a mint, in which was coined annually about $1,000,000 in gold and silver. An Alameda and several plazas tempt the lover of nature. Not far distant is an everflowing stream which is said to exceed the famous one in the grounds of Chapultepec park, at the national capital, and from which the city receives its drinking water. Two electric light companies supply light and there are street railways and telephone service. Durango is called the "Jewel of Mexico."

DURANT, Henry Fowle, American philanthropist: b. Hanover, N. H., 20 Feb. 1822; d. Wellesley, Mass., 3 Oct. 1881. He was graduated from Harvard in 1842 and became a lawyer, changing his name from Henry Welles Smith to H. T. Durant. He practiced with great success at the bar, but on the death of his only son abandoned his profession and devoted his energies to philanthropy. From 1864-75 he was a lay preacher in Massachusetts and New Hampshire. He founded Wellesley College (q.v.), opened in 1875.

DURANT, Okla., city and county-seat of Bryan County, situated on the Missouri, Oklahoma and Gulf, the Missouri, Kansas and Texas and the Saint Louis and San Francisco railroads, 20 miles northeast of Denison, Texas. The Southeastern State Normal School and a Presbyterian College are located here. Agriculture is the chief industry and cotton, corn and berries are raised. There are also flour and oil mills. The city owns its electric lighting plant and waterworks. The government is vested in a mayor and a unicameral council of six members, under a charter received in 1904. Pop. 5,330.

DURATION, in plants, the period for which any given part of the plant remains alive. The duration of the plant as a whole is conditioned primarily by that of the roots; an annual lives for only one vegetative period, a biennial for two and a perennial for a number of such periods. The same plant, such as wheat, may
be an annual if planted early and a biennial if planted late. Similarly, plants such as the castor oil bean, which are perennials in an equable climate, are often annuals where there is a winter and vice versa. In ground left to itself the period of growth of biennials and herbaceous perennials, the part of the plant which survives the winter or dry season is generally underground and the leaves and stalks die away each year and are produced anew.

In shrubs or trees the duration of the stalks may be measured in centuries, or even in millennia. However, the original live wood becomes dead wood after a few years. Leaves are of much shorter duration, ranging from days in the case of cotyledons or some xerophytic leaves to perhaps ten years in the conifers. In deciduous trees the fall of the leaf is due to the formation of a special zone of fracture at the base of the leaf stalk, which gives a scar covered by cork before or after the stalk breaks. In such trees as the oak or beech this zone of fracture is imperfectly formed, so that the dead leaves remain on the trees throughout the winter. The duration of flowers is usually relatively brief and may be limited to a few hours, as is the case with the night-blooming cereus, but there are certain orchids such as odontoglossum which may remain open for almost three months if they are not pollinated. It will be noted that tissues which have a perennial duration are generally woody or other wise mechanical in structure, and protected, whereas delicate, leafy or herbaceous structures are unable to survive periods of climatic adversity.

DURATION or PERSISTENCE IN TIME, one of the attributes of a sensory experience or an emotional state. It is only with difficulty subject to further analysis, if at all. The flash or snap of a spark seems to carry with its place in the scale, longer or shorter, as directly as in the quality scale of redder or yellower, higher or lower in pitch, or in the intensity scale of brighter or duller, louder or more subdued. One of the cardinal problems of the sensory psychology, then, is the study of the properties of this intrinsic temporal relation between experiences.

In the first place, by a historical development with which we are not here concerned, we have come into the possession of instruments which, through the mediation of what we know as periodic processes, enable us to assign a certain number as a temporal measure to the phenomena which we observe. This number stands in a very close relationship to our experience of duration: in general that datum which we experience as more lasting will have a greater temporal measure. The first task of the investigator of duration is to determine to what extent this rule holds good, and what the exceptions to it are. It is found that the situation here is most respects parallel to that in other series. There is in each sense an initial limen (see LIMINA) below which a decrease in the temporal measure produces no decrease in the sensory duration. In the case of light, at any rate, although apparently not of sound, unlike the situation in the intensity series this lower limen of duration does not approximately coincide with the total evanescence of all sensation: thus an electrical spark of just noticeable intensity lasting 1/10,000 of a second, though still visible, cannot be distinguished from a spark likewise of just noticeable intensity lasting 1/100,000 of a second. In addition to the initial limen, duration in each sense has a difference limen, or just noticeable difference in duration and there is a terminal stimulus beyond which increases in the temporal measure although they may be correlated with experiences which enable us to place them in our temporal system (see TIME), are no longer registered by increases in the duration of a single sense-datum. The initial stimulus for a tone of 64 vibrations is 1/40 second; of 187 vibrations, 1/125 second; of 3,168 vibrations or over, 0.0063 second. Observations on the initial limen, difference-limen and terminal stimulus for the duration of sense-data are relatively scanty, but these same sorts of quantity exist for temporal intervals and here the literature is much more rich. If the intervals are measured between sharp sounds, the initial limen, which is with the lower limit of observable intervals, is about 1/400 of a second. The difference limen is about 1/100 of the temporal measure of the stimulus when the latter is in the neighborhood of 0.3 second. For sound, Weber's Law (q.v.) is approximately obeyed. The terminal stimulus is about 0.5 or 0.6 second. The initial limen of visual intervals is about 0.005 second, of tactile (pressure) intervals about 0.0002 second. For intervals between sensations of two kinds, the initial limen, which is between 0.1 and 0.02 second, varies with the order of the stimuli. While it is natural to suppose that the initial limen for sensation differences of a given sort is about the same as for sensations of the sort, it should be noted that this is not an a priori law. Another quantity which is also of much the same size is the length of the liminal experience qua experience. This is the measure by the chronometer of the interval from the instant at which the subject is aware of the presence of the stimulus to the instant at which he is aware it is no longer present. For light Külée has estimated that this period is about 1/20 second.

All the numerical values given are based on measurements which it is difficult, if not impossible, to make with any high degree of accuracy. A rapid succession of like sensations as the speed is increased, does not at once fuse into a single sensation, but goes through the very complicated phases of "flicker" or "rattle" or "vibration," where there seems to be superimposed upon a sequence of experiences a new single experience. Just when the sequence completely disappears is not easy to ascertain. For this reason, estimates as to least noticeable intervals are likely to have a probable error bigger than the measurement itself. (See Brace, HENRI; TIME.) London 1901); Meumann, in Philosophische studien (VIII Leipzig 1893); Stern, 'Psychologie der Veränderungsauflösung' (Breslau 1898); 'Die Differentialpsychologie' (Berlin 1893); Weyser, in Philosophische Studien (IX, Leipzig 1894); Wundt, 'Grundzüge der Physiologischen Psychologie' (Leipzig 1908-11).

DURAZNO, doo-ras'-no, Uruguay, a department bounded on the north by Tacuarembó,
east and southeast by Cerro Largo and Treinta y Tres, on the south by Florida and Flores, and on the west by Flores and Rio Negro. It is the most central of the departments, and in size the third. Area, 5,527 square miles. A range of highlands divides it into three sections or basins, of which one extends northward to the Rio Negro, and the other southward to the Yi River, the department lying between these two rivers. Numerous streams, rising in the central chain of hills, flow toward the south or north; the entire province is well watered, and furnishes grazing for a large number of cattle, sheep, horses and mules. Pop. about 50,000.

DURAZNO or SAN PEDRO DEL DURAZNO, Uruguay, capital of the department of Durazno. It is situated near the Yi River and is one of the principal stations on the Central Uruguay Railroad. As an active center for the trading of the neighborhood, it has substantial buildings, a church, hotels and shops. Pop. about 11,000.

DURAZZO, doo-râtsô (ancient DYRRHACHION or EPIDAMNUS), Turkey, a seaport in the principality of Albania, on the Adriatic, 50 miles south by west of Scutari. A Catholic archbishopric has been located here since the time of Justinian. The chief exports are raw silk, wool, oil and grain. It was originally founded by a colony of Greeks from Corea, in the 7th century B.C., and was long under the name of Epidamnus, the most important maritime town of Illyria. In the early part of the 3d century it fell into the hands of the Romans who changed the name of the city to Dyrachium. Caesar besieged the armies of Pompey here. The Byzantines gained possession of it at the end of the 4th century, and made it the capital of New Epirus. The Ostrogoths, Bulgarians, Normans, the house of Anjou and Venice owned it successively. It was finally taken by the Turks in 1501, who made it a part of the Vilayet of Scutari. In the Balkan War (1912-13) it was an important strategic point because the Servians desired it as an outlet for their commerce on the Adriatic. The final treaty left it in the hands of the new principality of Albania under the government of William of Wied. At the outbreak of the European War, toward the end of July 1914, the prince and the international commission left the province and a state of anarchy followed. Essad Pasha Topkani, the recently expelled Turkish ruler, attempted to establish a military government at Durazzo, but the effort ended in failure (5 Oct. 1914). The Austrians finally overran the country capturing Durazzo on 28 Feb. 1916. A few columns and marble are now almost the only remains of the ancient city. The modern town is a poor place of about 5,000.

DURBAN, dâr-bân, or PORT NATAL, town, the only seaport of Natal; situated on the northern shore of the land-locked inlet known as Bay of Natal, the south end of which is marked by the fortified bluff and its lighthouse. It is the only city of Natal, and the fourth seaport in importance in British South Africa. Durban has become known as a watering place, and has electric street railways and all modern sanitary conveniences, including public baths. The centre of the town is occupied by fine public gardens; there are also botanical gardens, a museum, an art gallery, a public library, a theatre, two parks and a racecourse. In 1910 a new group of municipal buildings was completed at a cost of more than $1,500,000. Water is brought from a river 13 miles distant. The climate, although exceedingly hot during one or two months of the year, is the most healthful of any South African towns. The harbor, greatly improved by extensive wharves and dredging, is well protected and is sufficiently deep for vessels of 30-foot draft. The exports of the port in 1915 totaled $567,525 and the imports amounted to $23,811,955. Besides having a gold harbor, Durban derives much importance from its position as the terminus of two railway lines leading into the Orange Free State and Transvaal provinces. The population of the borough on 7 May 1911 was 69,187, consisting of 31,783 European, 17,784 natives and 19,620 Indians and Asians. The city was founded by the Dutch in 1828, and received its name Durban from Sir James D'Urban, then governor of Cape Colony.

DUBAR, dâr-bâr (Hind. and Pers., darbar, door of admittance), in India, Afghanistan and Persia, a state audience at which important public hearings are given, decrees or decisions announced, distinguished foreign visitors received, and treaties, etc., made. These functions are often of great splendor and under British rule there have been several famous durbars in India. The first after the downfall of the Mogul empire and the Mutiny was held 1 Nov. 1858 at Allahabad. Lord Canning then announced the sovereignty of Queen Victoria, and offered amnesty to all alienated Indians of the English. Each viceroy since has held them to impress the Hindus. One of the most magnificent was held by Lord Lytton in 1877, when Queen Victoria took the title of empress of India. The grandeur of the ceremonies and the pageantry at the Durbar of 1901, when Emperor Edward VII was visiting India, and been received with enthusiastic demonstrations, and the viceroy summoned the feudatory rulers and their representatives to a great durbar at Delhi, where the proclamation of the new title was made, and festivities, including a grand ball, games, parades, fireworks, convocation of the Indian orders, etc., were held. Another of great splendor was given at the same city on 1 Jan. 1903, to proclaim the accession of Edward VII. The growing native unrest led King George V and his consort to visit India for their Imperial coronation. The most brilliant durbar in modern times was held at Delhi on 12 Dec. 1911 in connection with the coronation ceremonies. Unexpected changes were announced for the administration of India, involving the transference of the capital from Calcutta to Delhi. The name "durbar" is used also for the audience chamber, as we speak of a church (building).

DÜREN (ancient MARCODURUM), Germany, town, in Rhineland Prussia, on the Roer and the railroad from Aix-la-Chapelle to Cologne, 18 miles east by north of Aix-la-Chapelle. It is of Roman origin, and is mentioned under its ancient name by Tacitus. In 1543 it was destroyed by the Emperor Charles V, at the head of 50,000 men, and inhabited by Parlemagne (775 and 779). The chief points of interest are the Gothic church of Saint Anna, containing numerous relics of the saint, which
are visited yearly by numerous pilgrims; the museum containing antiquarian and historical exhibits, and a fine public library. The principal manufactures are paper, sugar, linen, cotton goods, machinery and beer. Pop. 32,511. Consult Schoop, "Geschichte der Stadt Düren bis 1543, a Bürgerschaftschronik und Beschreibung des Begieviers Dürens" (Bonn 1902).

**Dürer, Albrecht**, German painter and engraver. b. Nuremberg, Bavaria, 25 May 1471; d. there, 6 April 1528. His father, Albrecht Dürr, came to Nuremberg in 1455 at the age of 28. He was a goldsmith by trade, and it was not long before he found employment with a well-known burgher of the city and master goldsmith, named Hieronymous Holper. In his 40th year, Dürr, who had won the esteem of his master both because of his fine character and diligent devotion to his duties, married Holper's daughter Barbara, then 15 years of age. He became a citizen of Nuremberg, a master goldsmith in 1468, and moved to a back apartment in the house of Johanna Pirkheimer, a patron of arts and letters, who was an enthusiastic lover of classical learning. Here the artist Albrecht Dürr was born, the second son and second child of the Dürr family. After the death of Holper, the elder Dürr acquired the property on the street called Unter der Veste, since renamed Burgrstrasse. Thither the family moved in 1473 and here a great part of the painter's life was spent. Eighteen children were born to the elder Albrecht, of whom two survived the painter. The others died before reaching any grown-up age. It was difficult work to support his numerous progeny. The younger Dürr speaks with the greatest affection and affection of his parents who were marked by their piety, simplicity and earnestness of purpose which earned them the well-deserved esteem of their fellow-citizens. After attending school where he learned to read and write and understand a little of Latin, Albrecht, who was his father's favorite, worked with him in the goldsmith shop and learned that trade. But he soon manifested, at a very early age, a natural predilection for drawing and painting. A likeness of himself drawn with the use of a mirror at the age of 13 is remarkable for its charming clarity of outline and its expressiveness. A year later, he made another drawing, of the 'Virgin and the Child,' which, in spite of defects of drawing, shows fine emotional promise in its tenderness and gracefulness. Accordingly, in 1486, the clever boy was apprenticed to the painter Michael Wolgemuth for three years.

Painting and drawing in Germany at this period, especially at Nuremberg, were very popular and distinguished arts. Under the patronage of the burgher and peasant classes, the wood-cut and copper engraving began to turn toward the life and customs of the people for its inspiration. Pictures were used in books as a means of instructing the illiterate. Religious paintings donated to the Church by the wealthy citizens made room on their canvases for the less than religious and contemplative attitudes. Portrait and genre painting found its sources here. The artist was esteemed as a very clever artisan who wielded his tools for the benefit and glory of the people about him, rather than as a soul aloof, superior and apart from the life of the time, painting or drawing under the patronage of lords and high church. Each master artist had his apprentices and journeymen, as did other artisans; and they assisted him in cutting his drawings, securing orders and selling prints. It was in this wholesome environment that Dürer worked. In 1490, his apprenticeship being over, he began his Wanderjahre. He went through Germany, stopping at the various studios, plying his trade and filling his sketch-book with studies of people, pictures and landscapes. At Colmar, he probably came into contact with Schongauer; and he studied also, it is said, at Basel and Strassburg. Late in 1493 or early in 1494, Dürer arrived at Venice, at a time when the reawakening of the classical spirit was combining with modern theories of exact proportion to developing original forms of art in the work of Mantegna, the two Belinies and Jacopo de Barbari. In 1494, his journeys ended and he returned home. He then married Agnes Frey, the daughter of a wealthy burgher, Hans Frey, a very brilliant man. The pictures of Dürer's wife represent her as a modest, comely housewife. In spite of Pirkheimer's irascible testimony as to the sharpness of her tongue, and the shrewishness of her disposition, there is every reason to believe that the marriage was happy after the fashion of the quiet uneventful domestic life of the city. Dürer moved with his wife to the home of his aged parents and settled there as a master artist, busy with the pressing task of supporting himself and his parents.

The products of this period (from the establishment of his studio to 1505) are numerous, although there is some confusion as to the authenticity of a large number of engravings and lesser paintings attributed to him. The doubtful ones cannot be mentioned here.

The example of Wolgemuth is clearly seen in his earlier works, together with some distinct traces of the influence of Mantegna and a conscious striving for the better grasp of perspective and human proportions gained from Jacopo de Barbari, an Italian painter practising at Nuremberg after 1500. The large works of this period (prior to his second visit to Venice in 1505) are mainly altar-pieces. A comparison of some of the rough drafts with the final canvas shows distinctly that the design and the main figures are probably the only parts which can be rightfully assigned to Dürr. The mass of detail was doubtless executed by the various members of his studio. The Dresden altar-piece, depicting the Virgin in the centre, with Saint Sebastian and Saint Antony on either side, shows extreme care in execution and is homely and naive in its simple representation of the life of the holy family. The Saint Viet altar-piece is inferior in perspective and weaker in color effects. It is a crowded representation of the faithful and the cross, too naturalistic in its suffering and inharmonious. The Holzschuler 'Descent from the Cross' in the Moritskappelle in Nuremberg gains in dignity and simplicity. The best of this group of studio paintings is the Paffgärter altar-piece from the church of St. Catherine in Nuremberg (now at the Pinakothek in Munich) depicting the nativity of Christ. In the wings are the figures of
knights in full armor, who are evidently the donors, representing Saints George and Eustachius. This period of his art belongs also 'The Adoration of the Magi' (Uffizi Gallery). It shows decided improvement in perspective, composition and dignity. The colors are fresh and harmonious; the outlines delicate and clear. But it is in the portraits of this period that Dürer hints at the realistic direction which his later works were to take. Most striking are the two of himself. One, painted in 1498 (now at Madrid), shows a young man attired in the gay garb of the lavish fashion of the time. Long fair hair frames a gentle, refined and sensitive face. The other, dated 1500 (Munich), depicts a more mature face with luxuriant beard and hair and direct, fixed eyes. Dignity and great sensitiveness are combined in the calm expression. Two portraits of his father, one in the Uffizi (1490) and the other at the National Gallery, London (1497), show but a passing resemblance to the artist. The sense of increased age is carried in the second by a Venetian setting, with the now listless hands—which in the first portrait are strong and vigorous. Other portraits are those of Frederick the Wise of Saxony (Berlin); of the 'Fürlegerin,' a lovely young girl with masses of rich golden hair (Royal Gallery at Augsburg); and two copies of disputed authenticity exist at Munich and Frankfort; Oswald Krell (1499, Pinakothek at Munich); and the Imperial Councillor, Sextus Oelhafen (1503), copies of which are in the library of the university, Würzburg. Another unique painting of the year 1500 is 'Hercules Battling with the Stryphalian Birds' in the Germanic Museum at Nuremberg. It is highly important as an indication of the struggle awakening in the artist as he began to be conscious of the wealth of material in theme and convention which was being rediscovered with the renaissance of classical study.

Dürer's first experiments in wood-cuts were copied from Wohlgemuth. After a few preliminary pieces, there appeared his 16 illustrations for the 'Apocalypse' (1498), a German and Latin edition. The series is full of action, vivid in imagination and composition; intensely realistic, even where incorrect in drawing. The whole is permeated by the awakening religious fervor of Germany—the intense desire to invigorate Christianity once more; and is brimming with joyous youthful faith in the possibility of accomplishing that result. In the clarity of the prints, the artistic handling of light and shade and the subtle rendering of texture, Dürer sets a new standard for the engravers' art. Others of his cuts, though of a little later date, are seven of the series of the 'Great Passion'; part of 'The Holy Family' and part of the 'Life of the Virgin.' In his copper engravings, Dürer likewise shows the effect of various influences at work in his desire for self-expression by means of the conventions he had acquired both at Nuremberg and in Italy. The careful study of human proportions is the key to the copper plates of this period. Of special note is the 'Saint Sebastian,' 'The Old Man's Dream,' 'Saint Eustace,' 'Nemesis,' 'Adam and Eve,' 'The Great Horse' and 'The Little Horse.' There are also a few mythological themes—wood-cuts for classical books and for the private possession of the group of humanists who began to carry Italy's past treasures into Germany. From men, such as the old Dr. Hartmann, Schedel, Konrad Celtis and Willibald Pirckheimer, Dürer must have received constant stimulation and encouragement. With the last-named classicist, the artist formed a deep and lasting friendship, the influence of which cannot be overvalued.

Dürer made his second journey to Venice in 1505, to remain for nearly two years. There has been much dispute as to the cause of this journey, but sufficient proof has been brought forward to invalidate Vasari's assumption that the motive was the protection of an abused copyright on his wood-cuts. The most probable reasons were his desire to escape a plague at Nuremberg, to find a market for his works and to execute an altar-piece for the church of Saint Bartholomew at the order of a German use of shade and art. One of the most accomplished of this, Dürer painted his 'Feast of the Rose Garlands' (Prague). The Pope and the emperor are represented kneeling before the Virgin and Child, a crowd of saints kneel in the background, where the artist and donor are also depicted, while cherubs bearing garlands of roses float above. In Venice, Dürer met the elder Bellini for whom he had the warmest praise. Other large religious pieces painted during his Venetian visit are 'The Virgin and Child with the Donor,' (Berlin); and 'Christ Disputing with the Doctors,' an unsatisfactory and hasty work. The best products of those eventful months are several smaller portraits of Italian types. From the letters to Pirckheimer, we receive an accurate account of the busy and, on the whole, happy time Dürer spent in Italy. His health profited by the milder climate; and the admiring courtesy of the Italians afforded him great satisfaction. He had intended to visit Mantegna at Mantua, but the old master died before his pupil accomplished his pilgrimage, and Dürer returned in 1507 to Nuremberg.

The years from 1507-20 in his native town were filled with high honors and praise. His fame became widespread all over Europe and all the great men of the world sought his acquaintance. His paintings showed increased breadth of treatment, more delicate shading and coloring. 'Adam and Eve' is a triumph in the study of the nude. The original dip-tych is now in the Pitti Gallery at Florence. The copies at Madrid and Mayence also lay claim to authenticity. In 1508 he painted 'The Massacre of the Ten Thousand Saints' (in the reign of Sapor II of Persia) which hangs now in the Imperial Gallery at Vienna. It was painted at the order of the Elector Frederick of Saxony. The ghastly subject is depicted with great truthfulness in anatomy against a lovely landscape background. The 'Virgin with the Iris' is evidently a school picture, since the work is not uniform. It is on the whole inferior to the 'Assumption of the Virgin,' a triptych painted for Jacob Heller of Frankfort. This Saint Ursula, the 'Old Man's Dream,' 'Saint Eustace,' 'Nemesis,' 'Adam and Eve,' 'The Great Horse'
all possible refinement and skill. It was hung in the church of the Dominicans at Frankfurt, but was eventually bought by Maximilian of Bavaria in 1515 and destroyed by fire in 1574. The Dominicans had replaced it by a copy which was faithfully and carefully rendered; and from this, together with numerous studies left by the artist, we are able to form an estimate of the great value of this work. There is no doubt that the best effort of his varied training combined here to produce an effect at once realistic, delicate and spiritual. In the foreground the Apostles are gathered about the tomb of the Virgin. A low fence, long and low, carries the eye into the distance, while above, the Virgin appears between Christ and God who lift the crown above her bent head. Gay little cherubs with variously colored wings surround them. Of great originality and precision is the religious painting of 1511, 'Adoration of the Trinity' now in the Imperial Gallery at Vienna.

In wood-cuts, Dürer now completed his series of the 'Great Passion' and 'The Life of the Virgin,' the first of which is remarkable in design and in breadth of handling. The 'Mass of Saint Gregory,' the 'Saint Christopher,' the 'Holy Family' are single cuts of this period. The 'Little Passion' in 37 wood-cuts appeared in 1511 and was executed likewise in copper in the succeeding year. Infiniate variety of conception and splendid imagination mark these works.

In copper engraving, his three greatest masterpieces were achieved: 'The Knight' (1513); 'Melancolia' and 'Saint Jerome in His Study'. In the former, he is vigorous in handling of the bodies and the depth of emotional expression and the carefully studied light effects. About this time also, Dürer began his experiments in dry-point and acid etching and produced several notable studies. During Maximilian's lifetime, and almost up to his death, Dürer executed in wood 'The Triumphant Procession,' 'The Triumphant Arch,' in which work he doubtless employed many helpers. The pen sketches in the emperor's prayer-book are preserved at Munich and Besançon. A portion of the Maximilian 'drawings' were preserved by Maximilian he executed in wood 'The Triumphant Procession,' 'The Triumphant Arch,' in which work he doubtless employed many helpers. The pen sketches in the emperor's prayer-book are preserved at Munich and Besançon. Several smaller copper engravings conclude the work of the artist until the death of his greatest patron and friend in 1519.

In 1520, Dürer journeyed with his wife to the Netherlands, in order to gain further patronage. A journal of his travels supplies us with information concerning the various events. He visited Erasmus at Antwerp and throughout his travels was received with honor and acclaim. After attending the coronation of Charles V at Aachen, his journey led him to Nijmegen, Brussels, Ghent, and Zeeland. Dürer filled his sketch-book with studies of the things he had seen and notes of ideas for new works. In 1521 we find him back in Nuremberg much enfeebled in health. Religious themes, the passion of the last period, occupied him mainly in this last period. Numerous studies and sketches are preserved, showing his plans for new groups. These include drawings of the Virgin, a 'Crucifixion,' the 'Apostles' (1523), Pintanochek, Munich), all admirable studies in expression and temperament, which he presented to the Council of Nuremberg in 1526 and was later sent to Maximilian of Bavaria (1527). 'The Adoration of the Magi' is also a fine pen-drawing, wonderfully simple, realistic and expressive. Copper-engraved portraits of Hieronymous Holzschuler, Pirckheimer, Melanthenon, Erasmus, Frederick the Wise and the Cardinal of Mainz are the best of his line engravings of his last art period. Some woodcuts also survive—coats-of-arms, book illustrations, etc., for his friends. Dürer was sympathetic with the Reformation and a warm admirer of its leaders, especially of Melanthenon, but he remained aloof from the stirring controversies of the time. He had this profound devotion to the Wittenberg confession of faith until his death.

Dürer busied himself also in this period with theoretical works on art, two of which were published during his lifetime, one on geometry and perspective (1525) and the other a fortification (1527). A work on human proportions appeared posthumously. For a long time the artist had been suffering from an intermittent fever, which began to sap his strength as early as 1520. He died, without suffering, in a drawing indicating the source of his disease with his hand. The features are considerably wasted and wan and show the effect of great suffering. Dürer died suddenly. Pirckheimer writes with great bitterness of the fact that his dear friend passed away without a final farewell. He was buried at Nuremberg in the vault of his wife's family in Saint John's cemetery.

The development of Dürer's style is interesting to trace. Throughout his work there is apparent the constant struggle of the artist to free himself from the stiff formal conventions of the old school; to enrich his art by conscious striving for perfection of perspective and proportion. Continuous study of old and new forms, conscientious self-criticism and friendly intercourse found alsoalert minds developed that power for intellectual and artistic realism which characterizes those works on which his claim to renown is justly based.

The drawings of Dürer may be studied best at the Albertina Museum, Vienna. Good collections are to be found also in the British Museum and the British Museum. The rest are scattered throughout the museums of Germany; some are in the collections at Basel, Dresden, Florence, Milan and Oxford; numbers are in private collections.

Bibliography.—Dürer's letters and diaries were partly published by Von Murr in 'Journal zur Kunstgeschichte' (Nuremberg 1785—87); by Campe (ib. 1827); Thaussing (1872); and fully in Lange and Puhse's 'Dürer's schriftliche Nachlass' (Halle 1891). There is a great fund of separate works on the artist, of which there is a careful bibliography by Singer, H. W., 'Versuch einer Dürer—Bibliographie' (Strassburg 1903). The best are by Bartsch, 'Le Peintre-Graveur' (Vol. VII, Vienna 1808); Thaussing (2 vols., Leipzig); the European translation by Eaton (4 vols., London); scholarly is by Scharff; Köflin, 'Die Kunst Albrecht Dürers' (Berlin 1907). His prints have been published in 'The Publications of the Dürer Society' (1898—1908); his drawings in the Albertina by Schönbrunner and Hader (Vienna 1895 et seq.); Colvin, in 'Ninety-Three Drawings of
Albrecht Dürer (London 1898). His engravings have been published by Galichon (Paris 1846-61); Duplessis (ib. 1877); Copper-engravings by Lübke (Nuremberg 1876) and Leitschub (ib. 1900).

Rosa Boochner,
Editorial Staff of The Americana.

DURESS, dū'res or dū-rēs' (Lat. durres, Lat. duritia, deriv. of durus, hard), restraint of liberty, fear of personal injury, or restraint of the person or goods. In its widest sense duress is now said to include all instances where a condition of mind of a person caused by fear of personal injury or loss of limb or injury to such person's wife, child or husband is produced by the wrongful conduct of another, rendering such person incompetent to contract with the exercise of his free-will power. (1) Duress of persons. This is exercised either by incarceration by unlawful threats or menaces, duress per se by fear; in either case the overt act must consist in compelling an unwilling person to do some act, as to execute a deed or commit an offense; in such cases the act is invalid and excusable. In a broader sense, duress occurs whenever by the law a person in extreme poverty or distress is induced to seek alleviation by assuming an obligation. Yet the deed signed or the contract made under duress is not void, though voidable at the will of the party compelled to execute or assume it. (2) Duress of goods refers to the case of one who is compelled to pay money for the release of goods unlawfully detained. Duress may be charged to the collector of a port who charges unauthorized duties.

DURET, du-rē', Francisque, French sculptor: b. Paris, 19 Oct. 1804; d. there, 25 May 1865. He studied sculpture in Paris; in 1823 he won the Roman prize, and gained a gold medal in 1831 by his 'Mercury, Inventor of the Lyre,' which recalled somewhat the refined modernity of Canova. Indeed, Canova seems to have been rather the source of inspiration to him than the models of the antique. In 1833 he produced 'The Neapolitan Fisher Dancing the Tarantula,' a work of life-like realism, of perfect elegance and the most refined modeling, which is his masterpiece and stands in the Louvre. In the same gallery is his 'Improvisatore Singing a Love-Song' (1836), a replica of which is in the city museum of Leipzig. For the museum at Versailles he executed statues of Molière, Dunois and Richelieu; for the Madeleine figures of Christ and Saint Gabriel. The gallery of seven chimney-pieces in the Louvre is adorned by his 'Victory,' and for the foyer of the Théâtre Francais he executed statues of 'Tragedy' and 'Comedy' and a figure of Rachel, the actress. In 1890 he completed the monumental fountain on the Place de Saint Michel in Paris. It is surmounted by a figure of 'St. Michael the Dragon-Slayer.' As professor in the Ecoles des Beaux Arts, his energies were concentrated on the task of teaching and he produced few original works; those which he has left are good examples of modern French sculpture with its ease, its demonstrative fluidity and dramatic point, which take the place of the severe and sonorous but flawless grace of the Greek masters. He was elected a member of the Institute in 1845.

DORE, dör'e, Thomas, American jurist: b. Tiverton, R. I., 6 Feb. 1826; d. Providence, R. I., 6 June 1901. He was graduated at Brown University 1846; was admitted to the bar 1848; reporter of the Rhode Island Supreme Court 1849-53; presiding judge of the Court of Magistrates 1855-60; speaker of the Rhode Island house of representatives 1863-65; associate justice of the Rhode Island Supreme Court 1865-75; and chief justice 1875-91, when he retired. He was elected a trustee of Brown University 1875, and its chancellor 1886, and was editor of 'Reports of Cases in the Supreme Court of Rhode Island' (1851-53); 'Treatise on the Law of Highways' (1857), begun by J. K. Angell; 'The Village Picnic and Other Poems' (1872); 'Gleanings from the Judicial History of Rhode Island' (1883); 'Some Thoughts on the Constitution of Rhode Island' (1884), and several orations on public occasions.

D'URFEY, dör'fi, Thomas, commonly known as 'Tom D'Urfey,' English dramatist and poet: b. Exeter, 1653; d. London, 26 Feb. 1723. He was a good-natured, simple-hearted, thoroughly vulgar and unliturgical writer. His dramas, comedies, operas, tragedies and songs are like what Sancho Panza would have written if he had taken to letters. Many, like 'The Siege of Memphis' (1676), a tragedy, and 'The Plotting Sisters' (1691), a comedy, are verbose; others, like the 'Songs Complete' (1699), are of virginal simplicity, but not of virgilian modesty.

DURGA, door'gā, or PARVATI (Sanskrit, 'The Inaccessible One'), a Hindu divinity, one of the names given to the consort of Siva when she appears to inspire fear. She is generally represented with 10 arms. In one hand she holds a spear, with which she is piercing Mahisha, the chief of the demons, the killing of whom was her most famous exploit; in another a sword; in a third the hair of the demon chief; and in others the trident, discus, axe, club and shield. A great festival in her honor, the Durgapuja, is celebrated annually in Bengal with wild orgies about the beginning of October and lasts for about 10 days in all. See Siva, DEVI.

DURGAH, The, a famous tomb built for the Sheikh Selim-Chishti, at Futehpore, near Agra, in Hindustan. It was erected at a cost of 37 lacs of rupees, or $1,750,000. The tomb, as well as a canopy six feet high which covers it, is made of mother-of-pearl. The floor is of jasper and the walls of white marble inlaid with cornelian. The screens of marble surrounding the building are the most beautiful in India. They are single, thin slabs about eight feet square and wrought into such intricate open patterns that they appear as having been woven in a loom.

DURHAM, John George Lambton, 1st Earl of, British statesman: b. London, 12 April 1792; d. Cowes, Isle of Wight, 28 July 1846. He was educated at Eton, and was returned to the House of Commons as Liberal member for Durham in 1813. An ardent reformer, he was known as "Radical Jack," favored in 1819 shorter Parliaments, was a supporter of Queen Caroline, and refused to accept a qualified Catholic emancipation. In 1828 he was created Baron Durham and in 1833 Viscount Lambton and Earl of Durham. He held the office of Lord Privy Seal in the Cabinet of Lord Grey.
(1830), his father-in-law, and took a leading part in framing the Reform Bill of 1832 and urged the creation of peers as a coercive measure in the event of the House of Lords proving recalcitrant. In 1832 he was Ambassador Extraordinary to the courts of Vienna, Berlin and Saint Petersburg and Ambassador Extraordinary and Plenipotentiary at Saint Petersburg, 1835–37.

Durham was appointed on 30 March 1838 governor-in-chief of all the Canadian provinces and governor commandant of Upper Canada, and this post he held till 1 November in that year. The situation he had to meet on his arrival on 27 May was grave and menacing. The rebellions had been crushed, but in both provinces there was intense irritation against the authorities, and there was threatened trouble on the international border, which was abetted by the state governments. Durham succeeded in securing the co-operation of the Washington government in maintaining peace. He passed an ordinance disbanding the banishing Bermudas, certain of the prisoners taken in the Lower Canada Rebellion of 1837; but this measure was assailed in the British Parliament as beyond the powers of Durham's commission; the Prime Minister, Lord Melbourne, offered only a half-hearted defense, and in the end the ordinance was disallowed. Durham felt he had been betrayed by the ministers who had appointed him, and at once resigned, issuing at the same time a proclamation vindicating his conduct. On his return he busied himself with the preparation of his "Report on the Affairs of British North America," perhaps the most important state paper ever issued on the principles of colonial government. For the evils that existed in the Canadas he proposed the introduction of responsible government by the creation of an executive dependent on the majority in the elective assembly, the union of the Canadas, municipal government, state-aided immigration, the repeal of the laws on the clergy reserves and formation of an inter-colonial railway. Durham's policy in the extension of colonial self-government came to fruition under the administration of his son-in-law, Lord Elgin, and has since been applied to all the British overseas dominions.

In 1855 Durham became chairman of the New Zealand Colonization Company and thus had a part in the early settlement of that British colony. Consult the "Life and Letters of Lord Durham," edited by Reid.

DURHAM, one of the three English counties called counties palatine. Area, 649,244 acres. The soil is productive and good crops of wheat, oats, potatoes and turnips are raised. There is more coal mined in Durham than in any other county of England, and lead and iron mines are worked. Some of its manufactories are ironworks, potteries, linen and woolen-mills, glass and chemical works. Shipbuilding is an important industry. For parliamentary purposes the county is divided into eight divisions. Pop. 1,309,860.

DURHAM (ancient DUNHOLME), England, city and parliamentary borough, capital of the county of the same name, on the River Wear, 14 miles south of Newcastle. It is celebrated for its noble cathedral, which stands in a fine situation on wooded banks of the river, the site of which was chosen as the resting-place of the body of Saint Cuthbert by the monks of Lindisfarne, driven from Holy Island by Danish marauders, and who built a chapel here to receive the body. The present building dates from 1093, with additions in all the styles down to the middle of the 19th century. It is 490 feet long, the greatest height within the building is 84 feet and the central tower is 218 feet high. The venerable Bede is buried within its precincts. The castle was built by William the Conqueror in 1072. The University of Durham was founded by Oliver Cromwell in 1646, suppressed at the Restoration and reconstituted in 1833. The battle of Neville's Cross was fought close by, in 1346, resulting in the defeat of the invading Scots. Four miles west is the Roman Catholic College of Saint Cuthbert, Ushaw, founded after the religious orders were driven from Douay during the French Revolution. The city is the seat of an Anglican bishopric and returns a member to Parliament. Pop. 17,550. Consult Leighton, "Memorials of Old Durham" (1910); Kitchin, "Story of the Deanery" (1912).

DURHAM, N. C., city in Durham County, on the Southern Air Line and the Southern railroads; 26 miles northwest of Raleigh. It is a tobacco and cotton-growing centre, and the seat of Trinity College (Methodist Episcopal South). The city has also a school of fine art and a conservatory of music, a public library and Watts Hospital. The government is administered under a charter of 1899, which provides for a mayor, chosen every two years, and a city council, elected on a general ticket. Settled about 1855, Durham was incorporated in 1869 with a population of 200. The manufacture of a famous brand of smoking tobacco is the staple industry of the place. There are also cotton mills, sash and blind factories, foundries, a fertilizer factory and other industries. The United States census of manufacturers for 1914 showed within the city limits 62 industrial establishments of factory grade, employing 5,453 persons; 4,764 being wage-earners, receiving annually a total of $1,301,000 in wages. The capital invested aggregated $17,752,000, and the year's output was valued at $27,597,000; of this, $15,094,000 was the value added by manufacture.

It was the scene of the treaty between Generals Sherman and Johnston at the close of the Civil War. It has a national bank, newspapers and good schools. Pop. 22,863.

DURHAM, University of, located at Durham and which was originated in 1831 under Bishop Van Mildert by the appropriation of part of the property belonging to the cathedral chapter. In 1832 an act of Parliament was obtained sanctioning the erection of the proposed university; in 1833 the university was opened and in 1837 it was incorporated by royal charter. In 1841 the office of warden was permanently annexed to the deanship of Durham, a canonry in the cathedral was annexed to each of the proctors of divinity and Greek, a professor of mathematics and astronomy appointed and fellowships founded. As at Oxford and Cambridge the students reside mostly within the university buildings, accommodation being provided for them in University College and in Bishop Hatfield's Hall. The university awards the degrees of Bachelor and Master of Arts, Bachelor and Doctor of Literature, of Science
and of Divinity, the usual medical degrees, de-
grees in music and the degree of Doctor of
Civil Law. The academical year is divided into
three terms—Michaelmas, Epiphany and
Easter. No degree is conferred on any
member of the university unless he is a student in
the faculty of theology. Science was taught
from the first, but not to a satisfactory extent
till 1871, when the Durham College of Science
was instituted in connection with the university at
Newcastle-upon-Tyne, the name of which was
changed in 1904 to Armstrong College. The
medical department of the university is consti-
tuted by the Durham University College of
Medicine, founded in 1851 at Newcastle, an in-
stitution which has greatly increased in effec-
tiveness in recent years by the establishment of
additional chairs. Since 1895 all degrees except
those in divinity may be granted to women.
There are over 37,000 volumes in the library.

DURHAM BOOK. The, or SAINT
CUTHBERT’S BOOK, a manuscript of the Latin
text of the gospels, with an interleaved
glossary. The book is in the library of the
DURHRAN, dərē-ən (Durio zibethinus), a
fruit tree of the family Bombacaceae, generally
diffused over the southeast of Asia, especially in
the Malay Peninsula and neighboring islands.
It is esteemed for the flavor of its fruit, which,
however, is an acquired taste, the fruit having
a strong, offensive odor and a somewhat tere-
bithine flavor. The tree, which on an average
yields 200 fruits annually, is about the size and
the form of a pear tree, but with cherry-
shaped leaves, except that they are entire and
smooth at the edges. The flowers are large
and rather yellowish-white. The fruit of globu-
lar or oval form, from 8 to 10 inches long,
high in some species as a man’s head, is not
unlike the bread-fruit externally. It has a hard
prickly rind, covered with warts and tubercles.
When ripe it becomes of a brownish-yellow and
opens at the top; it must be eaten almost fresh
from the tree, as it putrefies in less than 24
hours. The fruit contains five large longitudinal
cells, each containing one to four seeds about
the size of pigeon’s eggs embedded in a custard-
like pulp, which is the delicious part of the fruit.
The seeds are roasted and eaten like chestnuts,
ground into flour and also used as vegetable
ivory. The pharmaceutical qualities of the fruit
are aphrodisiacal.

DURIRON, a trade name for an iron-silicon
alloy, containing about 14 percent of silicon.
The alloy is extremely hard and close-grained,
of a gray color and white fracture, and is highly
resistant to erosion and corrosion. It has a
specific gravity of 7.00 and weighs 437 pounds
per cubic foot. Its tensile strength is 10,000 to
12,000 pounds per square inch and its com-
pressive strength 70,000 pounds per square inch.
Its electrical conductivity is one-fourth of that
of copper. It melts at about 2,500° F. and is
very fluid in the molten state, permitting casting
in very thin sections. The metal is so hard
that it cannot be machined, but is finished by
grinding. Duriron is not affected or but very
slightly by 25 percent sulphuric acid or 25 per
cent nitric acid, sulphate of aluminum, hypo-
chlorites of lime and soda, tannic and gallic
acids, pyrogallous acid, caustic soda, copper
sulphate, hydrofluoric acid, tartaric acid and
ammonium chloride. It is used for kettles,
pumps, pipes, valves and fittings for use in acid
and alkaline manufacture.

DURKHEIM, dərkām, Émile, French
writer on sociology: b. Épinal (in the Vosges),
15 April 1858. He was professor of philology
at the Sens Lycée, the Saint Quentin Lycée and
the Troyes Lycée (1882-87), professor of soci-
ology at Bordeaux (1887-1902), since which time
he has been in the University of Paris, where he
is at present professor of the Faculty of Letters.
He is a knight of the Legion of Honor and a
member of the committee on historical works.
Among his numerous published works are ‘La
Division du travail social’ (1893); ‘Les Règles
de la méthode sociologique’ (1897); ‘L’Année
sociologique’ (1896); ‘Le Suicide, étude de
sociologie’ (1897).

DURKHEIM, dərkām, or DURKHEIM
AN DER HARDT, Bavaria, town in the Palat-
inate, 14 miles southwest of Mannheim. Its
annual sausage market, founded in 1494, is at-
tended by large numbers of people. Durkheim
has saline springs, in the water of which Bunsen
and Kirchhoff by spectros examination first de-
tected the metals rubidium and caesium in 1860.
Durkheim was walled and fortified, so was an
object of keen contest during the Thirty Years’
War. Pop. 6,055.

DURLACH, dərəlākh, Germany, town in
the Grand Duchy of Baden, four miles southeast
of Carlsruhe, at the foot of the Turmberg. It is
of Roman origin. It has manufactures of iron,
machinery, organs, sewing-machines, gloves and
beer, and is celebrated for its fruit. Pop. about
14,000.

DURNING-LAWRENCE, Sir Edwin,
English politician and Baconian: b. London, 2
Feb. 1837; d. 21 April 1914. He was a graduate
of University College, London, and was called
to the bar of the Middle Temple 1867. He rep-
resented as a Unionist the Truro division of
Cornwall in the House of Commons, 1895-1905.
He published in 1910 an essay ‘Shakespeare is
Bacon’, in which he attempted to prove that the plays of Shakespeare were
written by Francis Bacon, of which an abridged
version, ‘The Shakespeare Myth’, was pub-
lised in 1912. He was created a baronet in
1898.

DUSOC, duh-zhok, Michel Gérard
Christophe, Duke of Friuli, French soldier: b. Pont-
à-Mousson, 25 Oct. 1772; d. Bautzen, 22 May
1813. He served as aide-de-camp to Napoleon
in the Italian and Egyptian campaigns. In 1802
he was made grand marshal of the palace and
was frequently employed in diplomatic missions,
but though he still took his full share in the wars of
France till the time of his death. He was a
great favorite of Napoleon and was killed by
his side at the battle of Bautzen.

DURRA, duh-rorah. See SORGHUM.

DURRETT, Reuben Thomas, American
1900. After studying at Georgetown College,
Kentucky, he was graduated at Brown in 1849 and at the law department of the University of Louisville in 1850, and practised his profession in Louisville until 1880. From 1857 to 1859 he was editor and half owner of the Louisville Courier. He was the founder of the Public Library, and a member of the Abstainers and Loan Association and of the Filson Club of Louisville. He collected one of the most valuable private libraries in the Southwest. He published 'The Life and Writings of John Filson, the First Historian of Kentucky' (1884), and contributions in various periodicals.

DURUY, dôr-ya', Victor, French historian and statesman: b. Paris, 11 Sept. 1811; d. there, 25 Nov. 1894. He was professor of history in the Collège (afterward Lycée) Henri IV prior to 1861. In 1862 he was appointed inspector-general of public instruction and professor at the École Polytechnique, and in the following year Napoleon III made him Minister of Public Instruction. During his six years' tenure of this office he carried out many important reforms in spite of the determined opposition of the clerical party. After resigning his office in 1869 he was nominated a member of the Senate. He was elected a member of the Academy of Inscriptions in 1873, and in 1884 a member of the French Academy. Besides many excellent school manuals, he wrote: 'Histoire des Romains depuis les Temps les plus Reculés jusqu'à l'Invasion des Barbares' (1870-79), his most important work; 'Histoire des Grecs' (1882); crowned by the Academy; 'Histoire de France' (1832) and other works. He was general editor of Hachette's great 'Histoire Universelle.'

DURWARD, Quentin. See QUENTIN DURWARD.

DURVÉE, dôr-va', Abram, American soldier: b. New York 1815; d. there 1890. He was educated in the common schools, and going into business made his fortune in mahogany furniture. He entered the State militia in 1833, was made colonel of the 27th Regiment in 1849 and was conspicuous as a maintainer of order during the riots that prevailed up to 1861. During the Civil War he raised the regiment known as "Durée's Zouaves," and was promoted to be brigadier-general of volunteers in August 1861, but resigned in January 1863 owing to a disagreement over a question of rank. His gallant services at the battles of Cedar Mountains, Rappahannock Station, Thoroughfare Gap, Grove- ton, Chantilly, South Mountain, and Antietam gained for him the brevet rank of major-general in 1865. In 1874, as police commissioner of New York, he attacked and dispersed a body of communists seditiously gathered together in Tompkins Square.

DUSE, dûs-ä, Elenaora, Italian actress: b. Vigevano, Italy, 3 Oct. 1859. Her childhood and early youth were filled with sorrow, arising from poverty, hardships, the loss of friends and many hard blows. Her father was a lineage of actors, and her early environment destined her for the stage. Her grandfather founded the Garibaldi Theatre in Padua. She was dragged about the minor theatres of Italy in her father's companies, playing Cosette in 'Les Misérables' at 7, and star of the little troop at 13 in 'Francesca da Rimini.' When she was 14 she played Juliet at Verona, in an open-air theatre, her performance compelling recognition as most extraordinarily brilliant. Still she had to wait for general recognition until 1879, when she played Zola's 'Thérèse Raquin' in Naples in 1887. She appeared in Venice in 1892, and later in London. She has been in American cities, making her début at the Fifth Avenue Theatre in New York as Camille in Dumas' play of that name, January 1893. Among the rôles which she has triumphantly essayed are Marguerite, Magda, Paula, La Femme de Claude, La Locandiera. She was married to the Italian actor-journalist, Signor Chechi, before she was 20, but they soon separated. Duse has remarkable emotional power and the ability to represent suffering and to make the most of tragic situations, at the same time possessing such versatility that she can play parts of opposite character the same evening. She pays little attention to the meretricious accessories of the stage makeup. Great simplicity and naturalness, coupled with striking intensity, characterize her acting. She has great excellence in diction and in facial expression, the latter being continuous and minute. Her repertory is enormous, her art including the plays of Dumas, Scribe, Verga, Prega, Ilsen, Sudermann, d'Annunzio, and Shakespeare. Her association with D'Annunzio lasted for many years, and it was for her that a number of his plays were written. Her splendid interpretation made them great successes on the stage, and added to the fame of the author. After 1899, a disagreement arose between them, and although she often starred in his dramas, she was never to be friends. Her tours in the United States, 1893, 1896, 1902-03, were very successful from the artistic and managerial point of view. After this she acted at intervals in Italy, but her health was such that she was compelled for the most part to live in retirement.

DUSKY DUCK, or BLACK DUCK, a North American duck (Anas obscura), closely related to the mallard, but of a prevailing sooty hue in its plumage. It is peculiar in being confined to the eastern half of North America, breeding abundantly in Labrador and in the United States in winter, when it becomes one of the principal market ducks. Its nest, eggs and general habits are like those of the mallard.

DUSSEK, doo-shëk, Jan Ladislav, Bohemian composer and pianist: b. Czaslau, 9 Feb. 1761; d. Saint Germain-en-Laye, 20 March 1812. He was trained at Ignau, Kuttenberg and Prague, and afterward was organist at Mechin and Bergenop-Zoom. At Amsterdam he met with much success, both as a teacher and performer, and here he produced his earliest works for the pianoforte: he afterward resided at The Hague, and in Hamburg, Lithuania, Paris, Milan and London (1788-1800), where he was very popular. In 1803-06 he lived as instructor and boon companion with Prince Louis Ferdinand of Prussia, whose death called forth his beautiful and pathetic 'Élégie Harmonique' (op. 61); in 1807 he entered the service of Prince Talleyrand, and thenceforward devoted most of his time to composition. His works include 12 concertos, 53 piano sonatas, 80 sonatas for the violin, and many smaller compositions.
DÜSSELDORF, Germany, city, the capital of the government of the same name, in the Rhenish province; on the Rhine, here crossed by a bridge of boats, and on the railroad from Elberfeld, 24 miles north by west of Cologne by rail. It consists of the old town in the north, Karlstadt, the new town, and Friedrichstadt in the south, with the suburbs of Derendorf, Flingern, Oberbilk, Unterbilk and other small places. The chief public squares are the Corneliusplatz, with a fountain and a statue of Cornelius; Schadowplatz, where the emeunt of Schadow; the market-place, with an equestrian statue of the Elector Johann Wilhelm; and the Burgplatz, with the tower of the castle which was founded in 1710 and burned down in 1872. In 1890 a bronze equestrian statue of the Emperor William I was unveiled. The principal churches are Saint Lambert's, a 14th century Gothic building, near the Rhine, adorned with marble monuments of Wilhelm IV and and in 1911, 1,200,000; and in 1894 were 8 of shops by the Elector Theodore, remodelled in 1821 and afterward directed by Cornelius and Schadow. This city has the honor of having founded a school of painting, which takes the name of Düsseldorf. While without the traditions of cities like Cologne, Frankfort and Aix-la-Chapelle, not so distant, this metropolis of the lower Rhine, situated on both of its banks, has a fame of its own in history, commerce, art, industry and education. Its name is derived from the brook Düssel which flows into the Rhine. More than 1,000 years old, it was for centuries the residence of the counts, later the dukes of Berg, then the electors of the Piaza, and finally the grand duchy of Berg, created by Napoleon, until taken by Prussia on 3 May 1815. It owes to its electors its early fondness for art and later its Academy of Arts, which has richly developed within recent decades, containing, in 1910, 14,000 original paintings, 24,000 engravings, 248 water colors, and 1,000 Italian originals. The expansions of German industry under the empire has had a marked influence on its commerce and trade. In 1850 the population was 40,000; in 1900, 210,000; 1914, 400,000. Its area is about half as large again as Paris. Within a circle of 50 kilometres are three and one-half millions of people. In 1883 the Düsseldorf State Railway stations sold 600,000 tickets; in 1911, 5,900,000. In 1883 the goods traffic reached 500,000 tons; in 1911, 8,000,000. In 1882 there were 26,000 employees; in 1914 20,000 shops with 130,000 employees. Of the city's industries in iron and steel manufactures 1,000 works are busy, employing a third of the population. In the machine industry 150,000 are engaged in all its ramifications. Its gun foundry has 5,000 workers. The city delivers half the gas pipes and one-third of the boiler tubes of Germany. In 1907 in the older part of Düsseldorf were 21 rolling mills and forges, 4,000 iron works and 3 glass plate works. Here too scientific and musical instruments are made, gold and silver articles, wire and safes. Here too are textiles manufacured—spinning, weaving, dyeing. There are 10 paper and pasteboard factories; the booktrade is powerfully represented with bookbinding and artistic painting. The chemical industry has 50 works, with glass, porcelain, fire-clay and cement. Artistic carriages and carriages for the many lines of work. The exhibitions of art and industry, which date from 1811, have greatly promoted the city's prosperity, with its vast wholesale business in ironware, chemical products, technical requisites, groceries, oils, grain and wood. The city maintains relations with the Mediterranean, with Russia and the Atlantic ports. No less rapidly has developed the banking and credit business. The Düsseldorf Exchange was founded in 1884. The State Railways have 6 passenger and 11 freight stations. The spacious city harbor on the right bank has five basins and an extended water front,—in the service of its commerce are 50 electric traveling cranes with a 20-ton capacity and 5 grain elevators. There are regular direct steamship connections with the upper Rhine and the chief foreign ports. Leaving its commerce and trade, of what else can Düsseldorf boast? Here Heine was born in 1797. The old house where he was born on the Böllerstrasse has been torn down and replaced by a worthy new structure, but the site still attracts visitors who throng in greater numbers to the Academy of Arts and the Art Gallery with their superb treasures and memories of Cornelius, Schadow and Bendemann, as well as the Museum of Art and Trade and the School of Industrial Arts. Then come the theatres with their varied attractions. Düsseldorf is famous also for its musical gatherings, to which the best soloists of the world find their way. The Conservatoire and College for Music Teachers are among the most famous in Europe.

The city does not neglect the intellectual side of life. It has the Country and City Library with 50,000 volumes, including 1,100 incunabula and 500 manuscripts. There are five town public libraries, reading rooms of some private societies and a Heine Library in one room, reminiscent of the poet. Special collections are found in the Historical Museum, the Natural History Museum, the Hetjens Museum, the Observatory, and a number of technical works in the library of the Society of German Ironfounders. The schools of Düsseldorf are its special pride. There are 90 board schools, with 1,000 classes and 60,000 pupils. Those beginning a trade or in business are compelled to attend either a trade or a commercial continuation school. As voluntary schools are a trade school, a business school and for girls a commercial school. The School of Industrial Art is a higher professional one, and over all is the Royal Academy of Arts (1767). Other high schools are the town academy for medicine (1907) and the academy for municipal administration. There is a police school for police employees. Then as a bridge between board schools and the higher institutes is the Intermediate School for boys. The state supports a gymnasium and a reform gymnasium, the city supports two gymnasia; the town and the state support two Oberrealschulen and Realschulen. There are three primary schools, three intermediate, a school for modern science and a seminary for women teachers. There are high class private institutes for busi-
ness, handwork, cooking, housekeeping, etc. Düsseldorf, too, has frequent public concerts as well as lectures — duly announced on the city's monthly program calendar. Academical courses for general culture are of much significance in developing the educational status of the citizens of all types. It is needless to add that the city, with its 50 or 60 papers, is supplied with every municipal need,—its mayor or manager has been in charge for years, so admirably does he fill his office. It owns its gas, elecricity, tramways, Klompflasch yesterday and slaughter-house. It owns the tramways. With the better residences of the villa type, the fine public buildings and splendid churches, the many pleasure parks and gardens, the numerous well-equipped baths, the woods on the outskirts, Düsseldorf comes as near to being ideal as is possible nowadays. Among the celebrities associated with the city are J. G. and F. H. Jacobi, Varnhagen von Ense, Peter V. Cornelius, Wm. Camphausen, H. Von Sybel. "Studien u. Verwalt. der Stadt D." (Düsseldorf 1902); Albrecht, D., "Streifzüge durch das Düssel. Schulwesen" (Düsseldorf 1912); Dr. Most, 'Düsseldorf, the City of Commerce, etc.' (1912).

DUST, the fine particles of matter which float on currents of air or settle on surrounding objects. These particles consist of sand, soot, cotton fibre, pollen, fine hair, pulverized excreta of animals, parts of seeds, bacteria, molds, etc. This is the ordinary condition of things. Frequently, as was the case after the Krakatoa eruption in 1883, the atmosphere becomes widely and densely charged with volcanic particles of varied minuteness, the smallest and lightest particles of which must months, even years, in settling. The dust from this eruption circled round the entire globe several times, and for two years it gave rise to extraordinary sunset glows and other remarkable optical phenomena. The finest particles are believed to have been raised to an altitude of 50 miles and to have remained buoyed up by air currents for several years. The presence of an abundance of pollen in the atmosphere gives rise sometimes to the "sulphur showers" or "golden rain." The "dry fog" of 1783, which covered Europe for three months, is regarded as having been due to an eruption in Iceland.

On 8, 9 and 10 March 1901 heavy dust storms arose in the desert region of southern Algeria, were carried north by a great cyclonic storm, leaving deposits as far north as Denmark, Russia and Finland, the last traces of the storm settling in those countries on the 12th of that month. The extreme distance carried was 2,500 miles; the total amount falling on the Continent being estimated at 1,800,000 tons, two-thirds of which fell south of the Alps, and as much more is supposed to have fallen in the Mediterranean. One of the west coast of Africa between the Canaries and Cape Verde Islands and dust due to storms from the Sahara Desert is frequently encountered by vessels. The dust storms in certain parts of India are occasioned by accumulations of whirlwind columns moving en masse or in hodograph over the land. Dust due to storms from the Sahara Desert is frequently encountered by vessels. The dust storms in certain parts of India are occasioned by accumulations of whirlwind columns moving en masse or in hodograph over the land. Dust due to storms from the Sahara Desert is frequently encountered by vessels. The dust storms in certain parts of India are occasioned by accumulations of whirlwind columns moving en masse or in hodograph over the land.

Conflagrations are responsible for the spreading of dust over very extensive areas. Forest fires along Lake Champlain and down to the neighborhood of Ticonderoga caused a night-like darkness to fall on New England on 19 May 1780, the unusual phenomenon suggesting to the inhabitants the coming of the end of the world. Cinders from the great fire in Chicago spread over a very extended area, and reached the Azores 45 days after the outbreak of the conflagration. The burning of peatbogs in the barrens of Labrador is supposed to have been the cause of the "yellow day" in New England (6 Sept. 1881), when the atmosphere had an intensely brassy appearance. The dust of such meteorites as undergo complete combustion on contact with atmospheric air has been traced on the earth's surface; fine ferruginous particles are often found on the snowy summits of high mountains and on the icefields of Greenland and other northern regions. This is called by scientists cosmic dust.

The dust with which the atmosphere is impregnated, especially in cities, is not only injurious to health, but causes loss in business, in addition to which certain kinds are explosive. Damage from dust and soot in departmental stores is a definite loss item, causing depreciation in stock and high charges for dusting and cleaning. The drastic remedy lies in the washing of the air, warmed in winter and cooled in summer, with the humidity adjusted for comfort and health. In such buildings the windows will remain unopened—the open window being regarded as a source of contamination. Air was cleaned at first by passing it through a cheese cloth screen, but a common practice now is to subject it to water sprays, which remove as high as 98 per cent of dust and other impurities, after which it is circulated throughout the building. In the running of pneumatic hammers, drillers, riveters, dynamos and other machines, the elimination of dust where practicable is a great economy which materially lengthens the life of the machinery. In mines, flour mills and other places where dust is generated, there is constant danger from dust explosion. The amount of dust that must be present to cause an explosion naturally varies to some extent. Among dusts which propagate flame readily and ignite so easily that an explosion would certainly be produced by lighting a match in the dust-laden space are sugar, starch, rice refuse, fine wood dust, malt, oat husks and grain in flour mills. Dusts from leather, shoddy and shellac compositions and sawdust, while they are readily ignited, are not so dangerous, as they ordinarily require a source of heat of larger size and higher temperature or a source that acts for a considerable time.

Aitken, a Scottish savant, has shown that by condensation of moisture, as in rain, mist, fog (see FOG) could occur without nuclei such as dust particles. If the atmosphere were not impregnated with dust there would be no cloud effects, no radiant sunsets, no soft afterglow; the sun would go down instantaneously, the harmonious color in the world would be lost, the quiet of events would never have been.

Aitken has also devised an apparatus for gauging the number of dust particles in a given
sample of air or gas. He and others have made
innumerable tests in all parts of the world.
The number of particles varies from a few
thousands per cubic inch in mountain regions
to 50,000,000 and upward in dusty towns. A room
near a ceiling has been found to contain 88,000,000
to a cubic inch. Aitken regards that a cigarette
smoker sends 4,000,000 particles into the air with every
puff. A great amount of solid matter is sent into
the air as the result of the imperfect combustion
of fuel. The dust fall in English cities is esti-

mated at from 200 to 2,000 tons per square
mile; in the centre of Leeds 242 tons and Leeds Forge
539; Glasgow and Coatbridge 1,330 and 1,599 respec-
tively. Experiments made in 1914 by the Board of
Health of the Department of the Seine on the
Paris Underground Railway showed that in the
metropolitan section of the road the average
constitution of the dust embraced 46 per cent
metallic iron, 14 per cent iron oxide, 12 limes
and plaster, 1,12 grease, 12,6 water and organic
matter.

But one of the most important and serious
questions concerning dust-laden air is the
greater danger brought to human life as dissemi-
ating the bacteria of disease. Nearly one-fourth of
all deaths are due to consumption. Now the
expectoration of contagious disease may contain
millions of bacteria. Falling on the sidewalk or
causeway of a city, it is soon tracked over a
large area and gradually mixed with the dust;
extraneous on asphalt pavements, where each
wheel acts as a millstone, grinding everything
into the finest powder, to be raised by passing
vehicles into the air and sent into thousands of
healthy lungs. The number of disease bacteria
in the air has been calculated by many analyses.
Taking 10 litres of air for a basis: in the Boston
City Hospital the number of living bacteria
was found to be nearly 450, and of molds
225. In a model New York hospital, where
everything was supposed to be clean, 12 living
forms settled on the disc, and, after sweeping
226. In a New York tenement-house carpeted
living room, 75 living bacteria settled on the
disc in an exposure of five minutes; after
sweping, 2,700, and mold settled on a plate or
disc three and three-quarters inches in diameter.
Precautions are now taken in the majority of
cities against the peril of dust-spreading disease
by constantly flushing the streets and sweeping
away all superficial dust into the sewers.

DUST-BRAND, or SMUT, a disease of
certain plants, as oats, barley, corn and other
cereals. It is caused by a parasite fungus called
Ustilago, which causes a swelling that at length
becomes a powdery sooty mass. The common
forms are Ustilago segetum and U. carbo; that
which attacks Indian corn is Ustilago maydis.
See FUNGUS.

DUSTIN, Hannah. American heroine; she
was the wife of Thomas Dustin and was cap-
tured by the Indians during their attack on
Haverhill, 16 March 1697. Her youngest child,
an infant one week old, was killed, but her
husband, with their other seven children, was
successful in escaping. The mother, with her
nurse, Mary Neff, was carried off and put in
charge of an Indian family consisting of two
men, three women and seven children. The
captives on their way to a large Indian village
battled at a distance of miles above the present
Concord, N. H. Here Mrs. Dustin and her
nurse, assisted by an English youth, Samuel
Leonardson, killed and scalped all the Indians
in their sleep, excepting one squaw and a small
boy, and after a difficult journey in which they
endured many hardships reached home in safety.

DUSTY-FOOT COURT. See PEPPER
COURT.

DUSTY-MILLER, a common name of
some of the plants of the genus Primula of
the primrose family, from the white flower-like
appearance of the leaves. The name is also
applied to Seneca maritimus, a native of the
Mediterranean region and much grown in
gardens.

DUTCH, the anglicized form of the word
Dietzsch, Duitsch or Deutsch, which in the
Middle Ages was applied to the Teutonic people
who spoke a language other than the Latin or the
Romance languages. Dietzsch means, "belong-
ing to the common people; vernacular." While
the term Dutch was once a synonym for Ger-
man, and in the United States is still popularly
applied, to German-speaking peoples and things
German, its use is properly restricted to the
language and people of the Netherlands. The
people of Holland call themselves Niederlansch
and use their forms Duitsch, Niederdeutsch, as
the Germans do Deutsch, Niederdeutsch. For
Dutch language and literature, see NETHER-
LANDS.

DUTCH IN AMERICA, The. Set like a
wedge at the meeting point of the Celtic and
Teutonic races and at the mouths of the rivers
flowing out from the continent, the evolution of
civilization in the Low Countries proceeded
notably on the lines of industry and democracy.
By the sixteenth, the century of exploration, the
7 provinces, with their 216 walled cities, had
taken the richest part of Europe. After the
struggles of the Renaissance and the Reforma-
tion, the Netherlands were left in twain, form-
ing two countries, the one becoming an appan-
age to the Spanish monarchy and the other an
independent federal republic. By 1815 most of the
provinces returned to their old allegiances,
celesiastical and political, and all adherents of
the Reformed faith were expelled. The ref-
guees, mostly skilled artisans and educated
people, added notably to the wealth and power
of other countries, especially to the Dutch Re-
public, which quickly doubled in population and
became a world power. It was from this
country that the Dutch who settled New Nether-
land came. By this time the nation that was
to give organic life to our four Middle States
had developed men, women and institutions that
were the wonder of the world. Representative
government in Church and State— the judiciary
being supreme — was a cardinal feature and free
public education for both sexes was nearly uni-
versal. These republicans led the nation in free-
edom of conscience, of speech and of the press,
as well as in public charities, prison reform,
land distribution and registry, legal codes and
municipal administration; as well as in several
minor matters, such as education, the
uniformity of road gauge, with the law of turn-
DUTCH IN AMERICA

ing to the right, in making wedlock a civil ordinance with public registry, equal distribution of property to children, the protection of the rights of authorship and invention, and the extension of the law of nations to the soil, in 1619, was held the first ecumenical council of the Reformed Churches of Europe. On the roll of her eminent sons were the names of Agricola, Gansvoort, Thomas à Kempis, Erasmus, Wil- liam Brewster, John de Barneveldt, Groote, Maurice, barons of the first water, scholars, jurists, divines and musicians without superiors in Europe—a list to be mightily increased during the next two centuries following the beginnings of New Netherlands.

After the triumph of the forces of union and nationality over those tending to disruption, colonization began, the Dutch sons and daughters, in their youth, vigor and alertness, carrying their ideas, faith, customs and institutions with them. They did not go from home as political or religious exiles, for they had nothing to lose. They were not in protest against their government in Church or State, for their freedom of conscience and civil rights had already been won at a great price. In New Netherlands they felt they were laying the foundations of a trading corporation and later under a system of manors and free towns; but the semi-feudalism thus introduced had been outgrown in Holland and in the New World cut across the grain of the Netherland spirit. The story of the Dutch in America, apart from economics and agriculture, is that of two streams of movement and influence. The one was of a democratic bias, nurtured in the Church, and the other that of officialism and corporational life; the one ineradicable because enrenched in the traditions of free government guaranteed by charter. The other was of survivals of feudalism in the stronghold of aristocratic bureaucracy. One was to abide, the other was to pass away. On the first stream of tendency floated such figureheads as Van Twiller, Kieft and the able governor Stuyvesant, who detested popular freedom. On the other and permanent current arose such noble characters as Peter Minuit, Sebastian Krol, Domine Michaelius, Melyn and Kuyter, who all fell in the service of the commonwealth; Donck, who sought Stuyvesant's usurpations; Arendt Van Curler, founder of a free town; and Jacob Leisler, the people's champion against monopoly and aristocracy. When the chronic contention between these two forces was hottest came the English conquest. The question was never settled by the Crown lawyers as to whether the new province was proprietary or royal, but the people constantly resisted the invasions of royal prerogative and state-churchism. The Dutch, being in overwhelming majority, clamored for a franchise equal to that in force in Pennsylvania, where Penn had borrowed much directly from the Dutch Republic. In the first session of the Assembly in 1683, the people of New York, through their delegates, formed a Charter of Liberties, in which first of all, in an American document, the words "the people," as holders of authority, was used. James as proprietor signed this enactment in 1684, but on becoming king he annulled the charter. The sequel was seen in Andros, and in Leisler, whose boastfully assumed usurpation was the holding of New York for Dutch ideas; that is, freedom of religion, the destruction of the flour monopoly and the restoration of rights to which the Dutch Republicans had been accustomed. The Reformed churches secured charters from King William III, and aided by other "dis- senters," kept up the fight for freedom of conscience and the press, until the constitution of New York, in 1778, was formed. This led all others in eliminating the question of personal religious beliefs from the fundamental law—an example later followed by all the States. In the Revolution the chief battleground was in the middle region where Dutch were numerous, and no people, as a body, were more loyal to the Continental Congress or suffered more, the leading families throwing their weight of influence and example with the patriots, while the ministers and churches were especially marked for British vengeance. The Dutch guns at Saint Eustatius, where half of the war supplies were obtained, boomed out the first salute to the American flag. New York, besides filling promptly her quotas of money and supplies, sent 43,645 men to the army, a number, in proportion to population, excelled by none of the other colonies. The New York regiment, under Van Alstyne, furnished 73 soldiers. To Philip Schuyler belongs the real credit of Burgoyne's defeat and surrender. The constitutional fathers showed close familiarity with Dutch precedents and profited by them. In the century following, the names of an Buren, Roosevelt, DeForest, Vanderbilt, Pennypacker and of hundreds of other eminent individuals and families prove the virility of the stock. After 1840 Dutch emigration, of a quality perhaps excelled by none, recommenced and in a few years 100,000 Netherlanders settled in the West, chiefly in Michigan, Wisconsin and Iowa. They cleared the forests, tilled the soil, initiated new enterprises and built schools and colleges. During the four eras, under which the inhabitants of the middle region have dwelt under as many national flags or civic emblems, each one of the latter has been a symbol of union. The totems of the Iroquois stood for a forest republic, federated first of five, then of six nations. Following these was the provincial republic of the Dutch Republic—the historic basis of our own national ensign, in which each stripe represents one of the original covenanting States. The oft-changed flag of crosses, from 1664 to 1775, was significant of the four nations of the British Isles. Finally the world saw the 13-striped flag of 1775-77, and then "Old Glory," of which the first actual use, known to documents and contemporaneous written testimony, was at Fort Schuyler (Rome, N. Y.), 3 Aug. 1777. No wonder then that the middle region, first settled by the Netherlanders, has always been for union! With the passing of time and fashions the descendants of the Dutch have changed their language and some old customs, but not the principles learned under the republic and the idea of the holding of New York for Dutch ideas, institutions, economic advantages, great inventions, notable books and those contributions to
DUTCH IN AMERICA

civilization, which are recognized as distinctively American, originated or were developed. The legend of unmixed English culture in the making of the world, so much the received historical view of the time, so distorted American historiography is not held by scholars familiar with the Dutch language and history and with the testimony of American witnesses. On the contrary it may be said that in matters linguistic, literary and human, the American patriot as much the teacher of the British nation as they are the pupil of the Netherlands.

The Dutch in the United States.—The first book in English on America was a translation from the Dutch in 1520, and published in London by Laurent Andrew, a Dutchman. Besides printing, England was for nearly two centuries indebted to the Netherlands (100,000) refugees in 1657— for many of the economic features of modern civilization, as records, proverbs, obvious facts show. The animating motive of the first Hudson, in a Dutch ship, was to obtain the reward of 25,000 gilders offered by the States-General for the finding of a new route to China. New York was cosmopolitan from the beginning—a true type of the American commonwealth—which made up of all nations, yet with high ideals, that were nourished as well on the Continent, as on the islands of Europe. Its sea front was first discovered by an Italian on a French ship, and later by an Englishman on a Dutch vessel. There is no such region as New Netherlands, nor ever was, but when the land between the Delaware and Connecticut rivers had been explored and figuratively* mapped by Captain Nye, it was called New Netherland, that is, a new province, not of the Belgic but of the seven northern provinces of the Netherlands, or the Dutch Republic, whose truce with Spain made in 1609 prohibited military occupation or settlement until after 1621. Ignoring fishermen, fur traders and temporary squatters who came for a season, the first home-makers in the region of the Middle States were refugees. Netherlanders from the southern or Belgic part of the old 17 provinces, who spoke French and were of the Gaulish race, or Walloons, g and w being interchangeable in the languages. They came in 1624 on a voyage of the Dutch West India Company named after the new province New Netherland. After these people followed the Dutch in large numbers, every one of the seven provinces being represented, who settled within the limits of what are now the four Middle States, New York, New Jersey, Pennsylvania and Delaware, though a few found homes in western parts of Massachusetts and Connecticut. The total number of emigrants from *Patria,* as they called the Republic, from 1624 to 1664, was not over 15,000, with a probable increase by natural generation, which balanced the loss of the 5,000 or so of those who, not willing to live under the English rulers of the Stuart dynasty, returned to the state without a throne.* One great advantage enjoyed by the Dutch in North America during the eighteenth and nine political life, was that they were all under one social and governmental system, typical of the future American national commonwealth, with a single language and the overwhelming majority of one religion. Whatever limitations these people were under, or whatever their admirers or detractors allege, they brought to the new continent the traits of character, habits, customs and institutions, to which they had been used for centuries, or which were nascent in the time of reformation, and of which the Republic led the world. Certainly no emigrant ship to America excelled in cleanliness of the ships, or the character of their human cargo, or in what they left in vitality behind them or imported on this continent. The Half Moon of 1609 and the New Netherland of 1624 had no superiors in personnel or principles represented, for the Dutch Republic was in the van of ideas now generally accepted by the modern civilized world. Some of these familiar facts were, toleration of religion, freedom of printing, public schools (established since the 12th century by the Church and later sustained by taxation), the principle of treating aborigines as men—the purchase of land from the Indians being obligatory and set down in the charter, the rule of the road—turning to the right—the standard gauge for roads, marriages recorded by the magistrate as well as by the church, universal registration of deeds and mortgages, the equal division of property among the family, not the rule of the strongest, other things not then known, or at least not in operation in England. That the Pilgrims gained much enlightenment and learned to do many things according to the laudable custom of Holland* (as Bradford, before Longfellow, tells us) is patent to all critical students of historical perspective, i.e., of what existed, or did not exist, in the two countries of England or Holland before 1664. In the discussion as to how far the development of the American commonwealth has been influenced by the Dutch Republic, the important point for the truth-seeker is to be familiar with what was known in the Netherlands and contemporaneously unknown in England, and vice-versa, during the days of exile of the Pilgrims, from 1609 to 1621, and during the time of the Tudors and Stuarts, also, when many if not most of the Puritan leaders of New England found refuge within the Republic. It was in the Dutch armies, that every one of the military leaders in the American colonies was trained. England, and her three islands: Great Britain, Ireland, and the Isle of Man had thousands of volunteers or regulars in the republican armies during the 80 years from 1588 to 1648, of the Dutch war for freedom. A large number of these veterans afterward came to America. The colonial fathers, revolutionary leaders and constitution makers of the American commonwealth, were far more generous in acknowledging their debt to the Dutch Republic, than the historiographers of later times, under whom the legend of unmixed English culture grooved out the channels of American public notions and opinions. Washington Irving's caricature of the 'History of New Netherland'-although he had never, before its writing, seen but a small fragment of one or two Dutch southern provinces—has actually been taken for serious history. Its pictures have certainly colored the views of American writers to an extent almost equaling that of a German savant, who annotated, with comments in Latin, one of Irving's broad jokes, taken by the Teuton in all seriousness. Irving himself thought that the originals of the two republics are so much alike, that the history of one seems but
a transcript from that of the other. When the first envoy of the sister republic, that sheltered Pilgrims and Puritans, came before our Congress, Benjamin Franklin, in his letter of commendation, wrote, "in love of liberty and bravery in defence of it, Holland has been our great example." Jefferson and Madison repeatedly pointed to the Netherlands as a good example for American imitation.

As a matter of fact, the English language overcame in the American colonies not only Gaelic, Erse, Welsh and dialectic Anglicisms and Briticisms (later supposed by the insular to be of American origin, in French, German, Swedish). Hence the actual knowledge of what the Dutch contributed, as visible leaven or obvious reality to American life, sunk into oblivion. No historian or widely popular first-class writer of American history, except Bradford and possibly John Fiske, is known to have been a critical scholar in Dutch history or the language, or to be topographically or socially familiar with the Netherlands in America. It is certain that the treatment of neither Molloy nor Fiske of the main points herein mentioned satisfies Dutch critical scholars. Nevertheless, in the revival of pride in Dutch ancestry and of the commercial reciprocation of advantage, through the Holland Societies and Netherlands Chambers of Commerce, and the relatively greater increase of population and prosperity of the Middle as compared with the Eastern States, there have come, since 1876, when our national origins were more inquired into, a new trend of opinion and of spirit, not to be expected in our ancestral and ethnic debts. With the coming, since 1846; of over 100,000 Dutch immigrants of high character and abilities to the United States, chiefly in the Middle West, and the establishment of the Holland-America line of steamers, stimulating visits to the old home and travel therein, with the endowment of professorships of the Dutch language and literature — so long disgracefully absent from our universities — there has developed a more pronounced pride in Dutch ancestry. The history of human nature and the world shows that when men receive new light or knowledge on themes long neglected, they are apt to run to extremes of thought and expression. The chronic trouble, in this particular line of truth-seeking, whether with the flamboyant or with the cautious who hold st stalwartly to the legend of unmixed English culture in the making of America, is a lack of accurate or abundant knowledge of the Dutch language and the real history of the Dutch people. The last sources for these are to be found in the Benighted English histories, over which Dutch scholars have their fun. Besides, a judicial mind is needed, above all things, to keep in view the fundamental fact of modern Dutch history — that the state without a throne (1572-1813) was created by the Church, and that independence and national evolution were the work of a people stirred to revolution and driven to creative energy by religion, even more than by economic or political pressure. Motley declared that in all Dutch history "the real hero is the people," but neither his brilliant narratives nor the ordinary writer in English took right thought about the average man in mass, the actual people. Throughout the whole Netherlandish story, whether of the democratic Belgian communities or the Dutch people, local freedom was large, prolonged and persistent even till to-day. In every political organism, it seems vital to real progress that there should be rivalry between two elements and an opposition of parties. Obvious in a republic, this is visible to a degree even under more or less of apparently real autocratic form of government. In the Dutch Republic, the city magistrates and the office-holding class, generally, were on one side — the obvious one and the element almost exclusively represented in the documents and books. But if these historians take their ideas of reality. The other and numerically much larger class and, in the long run, most potent, even after institutions had changed or passed away, were the people. William the Silent knew this, for he appealed to them, first to lords, then to nobles, and both failed him. He appealed then to the people and they responded and he was not Maurice as against Barneveldt, that secured the national Synod of 1618, vindicating nationality, which in the near generation flowered in art and literature under the triumphant republic. When and for long afterward New Netherland became New York, there were the Dutch colonist and the English, but at the top only. The Netherlanders, who came to America from 1624 to 1664, were those of the Dutch heroic age, many of them veterans of the armies of freedom. Certainly they were the very antipodes that Irving, who, from selected specimens in peaceful times and in back country districts over a century afterward, formed his lay figures and men of straw. As a matter of fact, after the English conquest, the people remained. Their rights being guaranteed by treaty, they elected their own church officers, kept out the Anglican state church officials from their pulpits and pews, and resisted every effort of the king's favorites, their royal governors, to establish a form of religion more or less influenced by political rulers. For 114 years, from 1664 to 1777, when full freedom of conscience for all was guaranteed in the state constitution — which led all others in this respect — they kept up the good fight. It was on the soil of New York that the battle of religious freedom which resulted in victory for the nation was fought and won. It is only by knowing the spirit of the people and the interior history of the Reformed Church, in either one or both of the Netherlands, that a clear perspective can be gained. It was in the Middle States, where the Dutch leaven and elements were so strong, that the
centrifugal tendencies of both the Eastern and the Southern States, as shown in secession or threats of it, was with the help of the West ultimately overcome and the “more perfect union” of which the Dutch Republic, which had gone through all the experiences of National Supremacy vs. State Sovereignty, of secession and reunion, of the ultimate triumph of national over all lesser elements, was a prototype and was forever established, even the kingdom of 1813 being a disguised republic, fulfills the hopes of the old federation.

WILLIAM ELLIOTT GRIFFIS, Author of ‘Brave Little Holland and What She Taught Us; ‘The American in Holland’, ‘The Story of New Netherland.’

DUTCH CHURCH, the church to which the majority of the people of Holland adhere. In the 16th century the Dutch wavered for a time between the Lutheran Church, whose leader was the great reformer, and the Reformed Church, whose leaders were Calvin and Zwingli. In 1571 they publicly professed their allegiance to the latter by embodying its doctrines in the Belgic Confession of Faith, published in that year. As long as they were under the sway of the Spaniards they, however, abstained from the use of the word Reformed, which had been introduced by the French, and styled themselves “Associates of the Augsburg Confession,” the Spaniards considering Lutherans more easy to govern than Calvinists. One of the most notable events in the history of the Dutch Church, after the yoke of Spain was broken, was the Synod of Dort, in 1618. James Arminius, professor of theology at Leyden, having rejected the Calvinistic tenets and adopted those which were destined to be called after himself, Arminian, a synod was convened at Dort to examine and, if need be, condemn his views. This was done, but with little effect, the views of Arminius prevailing to a greater extent after than they had done before their condemnation. The government of the present Dutch Church is Presbyterian. See Reformed Church in America; Luther, Netherlands; Reformation; Zwingli.

DUTCH CLOVER, a common name for the white clover (Trifolium repens), a valuable pasture plant, very common throughout the United States, natualized from Europe. It is also a native of Siberia and is found in all temperate regions. It has a creeping stem, the leaflets are broad, with a horseshoe mark in the centre, and the white or pinkish-white flowers form a roundish head. The plant is so well known that it has a variety of familiar names, all the best-known being sheep’s-gowan, honey-stalks, lamb-suckings and occasionally shamrock. See Clover.

DUTCH CONCERT, the term applied to a social entertainment in which every man sings his own song at the same time that his neighbor is also singing his. Another form is that in which each person present sings in turn one verse of any song he pleases, some well-known chorus being used as a burden after each verse.

DUTCH COURAGE, false or fictitious courage, usually applied to the bravado excited by means of partial intoxication. The phrase probably originated in the 17th century, when England’s wars with the Dutch, and especially the naval reverses England suffered at their hands in the reign of Charles II, rendered, in England the name “Dutch” an offensive epithet.

DUTCH EAST INDIA COMPANY. See EAST INDIA COMPANIES.

DUTCH EAST INDIES, the islands in the Malay Archipelago owned by the Dutch; situated between 6° N. and 11° S. lat., and between 95° and 141° E. long. The names, area and population of the divisions are as follows:

The areas given are accurate; but, except for Java and Madura, the population is estimated. The figures, however, are approximately correct, as the official records give the census every five years. The population of some unexplored sections is not included. The last official returns give the total population, approximately 48,000,000, or about seven times as large as that of Netherlands. The number of Europeans in Dutch East Indies in 1912 was 80,910; of Chinese, 563,000; of Arabs, 29,000; of people from parts of Asia other than China and Arabia, 23,000, and about 37,200,000 natives. The chief occupation of the people is agriculture. The greater part of the land of the island of Java is government property, but in the western part there are a number of private estates. Formerly the government or the private owners of estates were entitled by law to one day’s gratuitous work each week from each laborer on the estate, or, instead, to the payment of one guilder per head annually. In 1882 the granting of these enforceable services was abolished, and the remainder in 1914 in return for an increased poll-tax. Since the passage of the “agrarian"
In 1602 the Dutch created their East India Company. This company conquered successively the Dutch East Indies and ruled them during nearly two centuries. After the dissolution of the company in 1798 the Dutch possessions were governed by the mother-country. The superior administration and executive authority of Dutch India rests in the hands of a governor-general. He is assisted by a council of five members, partly of a legislative, partly of an advisory, character. The members of the council, however, have no share in the executive. The governor-general and members of the council are nominated by the queen. The governor-general represents not only the executive power of government, but he has a right of passing laws and regulations for the administration of the colony, so far as this power is not reserved to the legislature of the mother-country. However, he is bound to adhere to the constitutional principles on which the Dutch Indies are governed, and which are laid down in the Regulations for the Government of Netherlands India, passed by the king and States-General of the mother-country in 1854, and altered many times since. For administration is divided into residenies, divisions, regencies, districts and dessas (villages), each governed by a resident governor of contrôleur, etc.

For defense there is a colonial army entirely separate from the home army. It consists of about one-quarter Europeans to three-quarters natives. Its strength in 1915 was 1,285 officers and 37,041 men, of whom 8,557 were Europeans. There is also a small colonial reserve of both Europeans and natives. There is a navy, maintained by the government, consisting of 27 vessels, with a complement of 237 officers and 2,059 European and 1,329 native non-commissioned officers and sailors. There is besides the colonial navy consisting of 22 small ships, with 167 Europeans and 766 natives, employed for civil service duties. The expenditure for defense in 1915 amounted to $27,367,500.

DUTCH AND FLEMISH FURNITURE.

Under the rule of the dukes of Burgundy Flanders was brought to the zenith of perfection in some branches of the industrial arts, especially tapestry weaving. But not until the 15th century do we find any pieces of movable furniture conforming to our idea of that word. Great coffers (huches or bokhuts) acted as chairs, beds and closets for holding the tapestries, clothing, bedding, etc. They showed rough carving in Gothic motifs, but more often were covered with floriated iron-bracing and widespread branchy lock escuchoens. The churches and monasteries alone had artistically designed pieces consisting of pulpits, reading desks, choir-stalls, etc. We have a few extant closet doors, the recesses of which closets were built into the wall; these doors were panelless boards held together with strap-hinges that straggled across the entire surface in Gothic scroll work and held them together. The tables were boards set on trestles. But the rise of the bourgeoisie with their powerful companies and the corporations and guilds brought not only peaceful conditions but a height of luxury and wealth that made Flanders the envy of her greater neighboring kingdoms. And, late in the 15th century, to the luxurious wealth of cush-

In the administration of justice the principle observed is that Europeans and those assimilated with them are subject to laws nearly similar to those in vogue in the Netherlands, and the natives are subject to their own customs and institutions. The administration of justice for Europeans is in charge of European judges, while that for the natives is almost wholly in charge of native chiefs. Schools are provided for all Europeans and natives. In 1913 there were 10 public intermediate schools and 5 private intermediate schools. In 1914 there were for Europeans 191 mixed public elementary schools and 22 for girls only (24 for Chinese only), with 34 private schools: these schools had 834 government schools and 494 private schools.

Entire liberty of worship is granted to the members of all religious denominations. Christianity is increasing among the natives. In Java and the outposts, in 1914, there were 600,000 Christians.
DUTCH AND FLEMISH FURNITURE

ions, carpets, tapestries and stamped and gilded leather work are added pieces of furniture that have less of an impact on the overall design. They are chosen to complement the existing pieces and contribute to the overall aesthetic.

Renaissance.—By 1530 the Netherlands had developed their Italian influence, but they retained their "linen fold" motif in carving into the 17th century. The earliest Renaissance furniture was of course copied from imported pieces, but the native woodworkers were soon greatly aided by the designs of Cornelis Bos, Frans Floris and Albert Claas, Lucas van Leyden, Jean Vredeman de Vries, Theodor de Bry; Hugues Sambin and Pierre Cour. Large armchairs are often on high legs. The boxed seat and stiff perpendicular back gave way to open work chairs, the four legs are now clearly defined, the back loses its stiff uprightness and leans to the rear; it is a light, movable piece. But, as always the case with style changes, we find many transition pieces, modifications of the Gothic decor, but not entirely representing the Classic. Another change is the partial displacement of the former universal oak by the use of walnut as a medium. In this 16th century product we often meet the carved or the turned, the relief caryatids, grotesque figures, herms, acting as supports, often combined with columns draped with swags, etc., instead of the former prevailing motifs taken entirely from the vegetable kingdom. Ants, birds and natural forms are common. The dressoirs become a buffet, carved feet, take on scenes of native human life instead of panel work. The court cupboards and buffets in this style are magnificent in their rich ornamentation and are the admiration of connoisseurs. Large armchairs are often on high legs. The table, which had evolved the trestles at each end into heavy, carved supports in the form of eagles, chimeras, lions, mermaids and satyrs, now took on revolutionary forms. And we get legged side-tables, folding tables ("drawing"), tables, even dumbwaiters. Besides carved work inlays were becoming a decorative method, and before the 17th century the Flemish cabinetmakers were equaling if not excelling the Italian, German and other nations in this art. Noted Flemish Renaissance talent is found in the work of Le Cauff, Lucas de Badens and Albert Bruhl. The wonderful chimneypiece at Bruges from the designs of Lancelot Blondeau and Guyot de Beauregrant, with its armorial bearings, armorini and floral detail, was carried out by the carvers, Herman Gosencamp, André Raash and Roger de Smet. With the rapid advance of the artisan in inlay work by the 17th century came also the closer commercial relations of the Dutch with the Indies and the consequent importation of exotic woods. The veneered marquetry, which the Flanders woodworker had evolved from the thick inlaid Italian intarsia created a mighty influence. Flat surfaces gained an artistic treatment never before dreamed of. Large heavy wardrobes now came into being, often with columns at each side; in the cheaper, rich square panels in the doors, their centres carved and framed in fine moldings. Philip and Theodore Galle belong to the second half of the Renaissance. The form and decoration are becoming more severe. The salient parts are held in restraint; columns begin to lose their
high reliefs of figures and appear fluted or grooved. Beds are so high steps are needed, and the bedstead comes out into the room, the canopy now resting on the carved or channeled posts. The posts are often of a style termed "distaff" (queromelle) like the French; or "lance" form. The small tables, card tables, chair tables, bench tables (tables à banc), round, square and oval tables, tables standing on one leg, on two and on three legs. They are made of walnut, oak, maple, cedar, cypress, marble and some even of silver. Their decoration consists of beautiful carving, mosaic work, marquetry and some are embellished with gold. The richly carved chairs often have spiral turned legs as well as the old baluster form with bulbous feet; seats and backs are padded with stamped leather, velvet, silk or woolen fabrics, tassels border the seat coverings and large-headed nails add to the decorative appearance. Connecting rails (stretchers) are placed near the ground. It was the age of Rubens, and he well defines in his paintings the furniture pieces in vogue. A peculiar style of ornament was the curved embossing exactly representing the human ear; it was termed genre auriculaire. The chair with caned back and front is said to have had its birth in Flanders. But the grandest and most prized piece of furniture in the Netherlands was the cabinet. Numismatics was the rage and the coins and medals found repose in this unique chef-d'œuvre; it is the Kunstschranks of the Germans. The usual form consisted of two parts, the upper being of smaller dimensions than the lower; being also set some what. Its construction was on architectural lines, and was surmounted by a pediment, usually the "broken" style with a carved figure standing in the open space. Originally the cabinet for curios was placed on a support (often of eigh legs) or table; the lower section was now closed in and had two panels as had the upper half. Lovely classical figures were carved on these panels; the subjects were frequently Neptune (for corals were one of the curio collectors' hobbies), also the Muses, Apollo, etc. The elaboration in decoration was truly lavish and of several varieties. Some had the Italian pietra dura or mosaic of encrusted stones, also amber, enamel work, even Venetian glass. The marquetry work is heightened with small pieces of ivory and mother-of-pearl. Ebony was used to enrich the finest pieces of this period, in fact some pieces were constructed entirely of ebony. Beautiful work was done by Hugues Goltz (Goltius). So renowned were the productions of the Flemish artisans that the French court sent cabinetmakers to learn this ebony and marquetry technique. On their return they were called ébénistes, and the term has lasted to this day for the French cabinetmaker. Artus Quellin did fine decoration, and some of his pieces are still extant; Crispin van den Passe designed many dining tables. The cabinets brought with it poorer work in the marquetry, lacking finish and delicacy of coloring; the veneers ranging from crude to gaudy. Early in the 19th century the School of Woodcarving still kept up the art to an excellence not equalled in other European centres, and Antwerp, Brus sels, Liége and other Flemish centres maintained their precedence in woodcarving.

CLEMENT W. COUMBE.

DUCTGold. See Copper.

Dutch Guiana. See Guiana.

Dutch Harbor, Alaska, a port in the northeastern part of the island of Unalaska, situated on Bering Sea. It is a port of call for steamers passing through the Unimak Pass. See Alaska.

Dutch Language and Literature. See Netherlands.

Dutch Liquid, an oily liquid, insoluble in water, known to the chemist as ethylene dichloride (CH₂Cl₂). It may be obtained by the action of chlorine gas upon ethylene, and also as a by-product in the manufacture of chloral. It is most commonly prepared by passing ethylene into a warm mixture composed of 2 parts manganese dioxide, 3 parts sodium chloride, 4 parts water and 5 parts sulphuric acid. When the mass has become yellow in color it is distilled. It has anesthetic properties, and is reputed to be quite safe, but it is irritating to the throat and is therefore not used. The name relates to its early preparation by the Dutch chemists.

Dutch Metal. See Copper.

Dutch Oven, a spider, skillet or camp oven used by those who cook by hot coals on the hearth, a mode yet common in the Western States of the Union, and unsurpassed in its results with skillful housewives. The pot stands in hot embers, and more of the same are piled on the dish-shaped lid. The phrase is also applied to a cooking-chamber suspended in front of the fire so as to cook by conduction.

Dutch Pink, a yellow lake, prepared from bark of the quercitron (the dyer's oak), used in distemper, for staining paper-hangings and for other ordinary purposes.

Dutch Reformed Church. See Reformed Church in America.

Dutch Rush, a common name for the scouring rush or shave grass (Equisetum hyemale), a plant of the horsetail family, used for scrubbing floors in country places, and imported from Holland as an article of commerce, to be used in polishing hard woods and alabaster. The stems are filled with silica deposited in a regular manner, forming an integral part of the plant. It is native throughout Europe and Asia and nearly the western part of North America, where it is found in wet places and along the banks of streams. See Equisetum.

Dutch School. See Painting.

Dutch School of Fortifications. See Fortifications.

Dutch West India Company. The, an association of merchants of Amsterdam,
Zeland, the Meuse, North Holland and Friesland, incorporated 1621, with a capital of 6,000,000 florins (about $2,500,000). Unlike the East India Company, which was primarily a trading association and in its conquests and colonies had no other purpose than to protect its commerce, the West India Company never had an extensive trade, but strove to injure the Spaniards, to conquer their establishments, to capture their ships and to break the intercourse between Spain and its American gold and silver mines. The design was conceived in the interest of the Dutch, when Spanish persecutions had driven more than 100,000 Protestant families from Belgium to the north. It was thought that the Spaniards would be compelled to evacuate Belgium when their resources had been thus destroyed. Large fleets were sent out, the company possessing sometimes as many as 70 armed vessels. The prizes captured were of such value that during several years shareholders received 25 to 75 per cent interest. Twelve millions were added to the original capital of 1,000,000 florins. By 1628 the great galleon was being united at this time (the union lasting from 1580 to 1640), the company not only captured the Spanish silver fleet in 1628, securing a booty of more than 14,000,000 florins, but took Baja California (1630) and the Portuguese colony of Brazil. The history of Dutch Brazil had a brilliant period (1636-42) under the administration of Count John Maurice of Nassau. Curaçao was taken about this time and the company's North American colony of New Netherlands grew more and more prosperous. But the fatal defect of the company's plan now became apparent. Not being supported by extensive trade, the military and naval triumphs cost much more money than they produced. The financial condition of the company showed, after 1630, a terribly constant downward tendency; the government of Holland, moreover, was very slack in fulfilling its pledges of assistance. The beginning of the end was reached in 1641 when Portugal, having shaken off the Spanish yoke, devised means to regain Brazil. In 1654 the Dutch troops withdrew from that part of South America. The death-blow was struck when New Netherlands, the last valuable possession of the practically bankrupt company, was conquered by the English (1664). Consult Asher's 'Bibliography of New Netherlands and the Dutch West India Company' (Amsterdam 1856-67).

DUTCH WEST INDIES. The possessions of Holland in the West Indies are Surinam or Dutch Guiana and the colony of Curaçao. Surinam is situated on the north coast of South America between 2° and 6° north latitude and 53° 50' and 58° 20' west longitude, and is bounded on the north by the Atlantic Ocean, on the east by the river Merowijne (which separates it from French Guiana), on the west by the river Corantyn (which separates it from British Guiana) and on the south by inaccessible forests and savannas to the Tumac-Humac Mountains. In 1667 Surinam was assured to the Netherlands in the exchange for the colony of New Netherlands in North America. Since then it has been twice in the power of England (1799-1802 and 1804-16). Its area is 46,060 square miles and the population (1915) 85,536, exclusive of negroes living in the forests. The superior administration is in the hands of a governor, assisted by a council of four members, all nominated by the queen. The Colonial States form the representative body of the colony; the members are chosen for six years by electors in proportion of one in every 500 electors. There is a bishopric for the Negroes. At the end of 1915 there were Reformed Lutherans, 10,157; Moravian Brethren, 26,136; Roman Catholic, 18,761; Jews, 882; Mohammedans, 11,359; Hindus, 17,633, etc. There were in 1915, 28 public schools with 3,679 pupils, and 488 private schools for the Negroes. There is a government normal school. In 1915 sugar was produced to the amount of 14,747,100 kilograms, cacao 1,464,200 kilograms, coffee 609,700 kilograms, rice 5,280,200 kilograms, maize 1,857,900 kilograms. Rum and molasses were produced to the extent of 1,693,500 and 112,000 litres, respectively.

In 1915 the export of gold, mostly alluvial, was 1,157,031 grams. In this same year there entered 246 vessels of 209,418 tons and cleared 130 vessels of 224,917 tons. Rail and port facilities were increased and the country was divided into 13 districts. Communication between these several districts is carried on by vessels and small steamers. Capital, Paramaribo (35,530).

The colony of Curacao consists of the following islands: Curaçao (area 47 square miles, pop. 33,675); Bonaire (area 95 square miles, pop. 6,592); Aruba (area 69 square miles, pop. 9,204); Saint Martin (southern part only, area 17 square miles, pop. 3,202); Saint Eustache (area 7 square miles, pop. 1,431); Saba (area 5 square miles, pop. 2,488); a total area of 403 square miles with a population on 31 Dec. 1915 of 56,754. The capital of Curaçao is Willemstad (pop. 11,000), which has one of the best harbors in the West Indies. There is a governor, assisted by a council of four members, nominated by the queen. The different islands, except Curaçao, are under officials called 'gezaghebbers,' nominated by the queen. The chief products are maize, beans, pulse, cattie, salt, phosphate of lime. The most important source of income is the shipping industry, which gives employment to numerous laborers in the work of transshipping goods and as sailors on the vessels that touch regularly at Willemstad. No statistics are available as to the amount of money thus placed in circulation. The making of straw hats continues to be the industry second in importance. The exports of straw hats to the United States in 1916 was valued at $129,034. An oil refinery was established in 1916 for the refining of crude petroleum from the Venezuelan oil fields. In 1916 the exports were valued at $967,336 and the imports at $2,401,528. The revenue is derived from import, export and excise duties, taxes on land and some indirect taxes.

In 1916 the Dutch government sent a specialist to Curaçao to investigate the sanitary conditions on the island. As a result a department of public health was established under the direction of a Dutch pathologist, and this has rendered important service in cleaning streets, wiping out mosquitoes and in the prevention of yellow fever by building a hospital at Bonaire. Measures have been taken for the opening of a bacteriological laboratory and for the passage of quarantine laws suited to the climate. A modern sanatorium was completed in 1917.

DUTCHMAN, The Flying, a phantom ship which sailors believed could often be seen
about the Cape of Good Hope. The story is that a Dutch captain, Vanderdecken by name, being tossed about by adverse winds while trying to double the Cape, swore with many oaths that he would accomplish his purpose if he beat to, and from till the judgment of the world and punishment of his ship never touched land. Another version of the legend is that the Flying Dutchman is condemned to wander the seas forever because a murder was committed on board his ship.

**DUTCHMAN'S PIPE**—DUTTON

College, Calcutta, and University College, London, at which latter institution he became lecturer on Indian history. He joined the Indian civil service in 1871, becoming a divisional commissioner in 1894, the first native of India to attain that position. In 1892 he was decorated for ability as an administrator and his literary researches. Beside a series of novels in Bengali and translations of the 'Rig Veda,' etc., into Bengali, he has published in English 'Civilization in Ancient India,' 'Lays of Ancient India,' 'Mahabharata,' condensed into English verse; 'Ramayana,' condensed into English verse; 'England and India, 1875-83'; 'Famines in India' (London 1900); 'Economic History of British India'; 'Lake of Palms,' a translation from his early Indian novel and an interesting story of Indian domestic life (London 1902).

**DUTCHEAH, doot-'tché-à, DATTIYA or DATIA, India, city, capital of a state of the same name, in the Bundelkhand Agency, central India, on the route from Agra to Sawai, 110 miles southeast of Agra. It stands on a rocky height surrounded by a stone wall and is well built, with an unusual number of stone houses. The chief of the Datia State dwells here. West of the town rises a palace of immense size and remarkable beauty, one of the best pieces of Hindu architecture in India. It is situated within a pleasure ground of about 10 acres, enclosed by a jottey wall, with embattled towers at each of its four corners. Four miles distant there are interesting Jain temples. Pop. 17,329.

**DUTTON, Clarence Edward, American soldier and geologist:** b. Wallingford, Conn., 15 May 1841; d. 1912. He was graduated at Yale in 1860, and two years afterward became captain of the 21st Connecticut Volunteers. He received a commission as second lieutenant in the United States army in 1863, was promoted to the rank of major in 1890. In 1875 he joined Maj. J. W. Powell in the United States survey of the Rocky Mountain region; in 1879-80 was secretary of the United States land system committee, and from 1880 to 1901 was a member of the United States Geological Survey. He was elected a member of the National Academy of Sciences in 1884, for which he made a thorough study of the Charleston earthquake of 1886. His report interpreting the results of his study were significant and stimulated a widespread scientific interest in the earthquake phenomena. His research also led him to important discoveries concerning the nature and speed of earthquake motion, and of the means of measuring the depths of the foci. (See EPIZOA.) His writings embrace the subjects of metallurgy, gunnery and geology, to which last he has devoted his main literary attention. His most
important geologic works are 'Geology of the High Plateaus of Utah' (1880); 'Tertiary History of the Grand Cañon District' (1882); 'Hawaiian Volcanoes' (1884); 'Mount Taylor and the Zuni Plateau' (1886); 'Earthquakes in the Light of the New Seismology' (1904).

DUTTON, Edward Payson, American publisher: b. Keene, N. H., 4 Jan. 1831. He was educated at the Boston Latin School, was a member of Ide and Dutton, booksellers of Boston, 1852-58, bought out Ide's interest and continued as E. P. Dutton and Company. He bought the retail business of Ticknor and Field in 1864, and also that of the General Protestant Episcopal Sunday School Union and Church Book Society of New York, and in 1869 moved the business to New York. One of the firm's notable enterprises has been the 'Everyman's Library,' an important series of inexpensive reprinted classics in all departments of literature.

DUTTON, Henry, American jurist: b. Plymouth, Conn., 12 Feb. 1796; d. New Haven, Conn., 12 April 1869. He was graduated at Yale in 1818, and became professor of law in the same university in 1847, occupying this position for eight years, and in 1854 was elected governor of Connecticut. He was judge of the Superior Court, and Court of Errors 1861-63, and prepared many digests and compilations of State statutes, which are of permanent value to his profession.

DUTTON, Samuel Train, American educator: b. Hillsboro, N. H., 16 Oct. 1849. He was graduated at Yale in 1873 (A.M. 1900). He was in charge of schools of South Norwalk, Conn., 1873-78; principal of Eaton School, New Haven, 1878-82; superintendent of schools of New Haven, Conn., 1882-90; Brookline, Mass., 1890-1900; professor of education and administration and superintendent Teachers' College Schools, 1900-15; professor emeritus of Teachers' College since 1915; lecturer in pedagogy, Harvard, 1895, 1896, 1897; exchange lecturer in Sweden, Norway and Denmark, 1910; chairman of the executive committee of First National Arbitration and Peace Congress, New York 1907; honorary secretary of the New York Peace Society; honorary secretary Japan Society; director of the Congregational Board of Home Missions; member (1913) of the International Commission to Investigate the Balkan Wars; member of the Council Bernouli Bureau of International Peace; member of the Authors and Yale clubs, New York, Sociological Association, Institute of Social Sciences, etc. He has written 'Social Phases of Education'; 'School Management'; edited 'Historical Series'; 'World at Work Readers' (1906), and is associate editor of 'Christian Work.'

DUTY. A course of conduct is a duty if abstention from it is evil. This definition would seem to make duty logically dependent on good and evil, but it is possible to define the good as that which it is one's duty to secure, so that the question of the relative notion of duty and of that of good and evil is not clear. The question as to which of the two definitions represents the real order of priority between duty and good or evil has played a considerable part in ethical discussions. The question may be formulated as follows: are ethical values inherent in things and courses of conduct, without reference to any moral agent—in which case good and evil are prior to duty—or do they consist essentially in the obligations of some individual? Greek philosophy, always realistic in the scholastic sense, displayed its hypostatic tendency in ethics as well as in metaphysics, and made good and evil more or less of the nature of independent entities. Thus for Plato, the basis of morality—the Idea of the Good—is not merely a real entity but the most real of all entities. An objective good of this sort must be free from all dependence on an individual. The Greek ethics, therefore, was an ethics of duty rather than ethics of good. The ethics of the Stoics first brought into any prominence at all the notion of duty: the Stoic good, though not dependent on its relation to an agent, was a course of conduct to be pursued by an agent, so that it was at the same time a duty.

The Greek systems of ethics, as has been said, laid the greatest emphasis on the actual results intended and attained by conduct in making their evaluations. Christianity, on the other hand, made the motive of a deed the most significant factor in the determination of its worth. The good deed, according to Christianity, is that which is done in obedience to God. This obedience constitutes duty, which is thus prior to the good. The original priority of duty has exhibited a continual tendency to lapse and disappear, and moralists of the type of Paley have attempted to point out various objective goods, the attainment of which furnishes an excuse for duty. However, with the philosophy of Kant, duty came into its own again. Kant based his entire ethics on the categorical imperative. The categorical imperative is the injunction to act only on the maxim whereby thou canst at the same time will that it should become a universal law. This is a principle of duty, and good and evil are merely adjectives applied to conduct that conforms or does not conform to the maxim.

The problem whether duty is prior to good and evil, or vice-versa, is in many respects parallel to the dispute between realism and idealism in epistemology. Just as realism claims the existence of reals apart from their relation to a perceiving, the ethics of good and evil claim the existence of goods apart from their relation to an agent. Idealism and the ethics of duty correspond in a similar manner. It is a familiar fact that the difficulty of realism lies in the demonstration of unperceived reals, without involving the absurdity of a being that perceives them. In the same way, as it is difficult to pass moral judgments without putting oneself in the position of at least a hypothetical agent, the issue between the two types of ethics is not easy of decision. However, owing to this fact that we can scarcely pass a moral judgment without feeling ourselves as one of the actors in the situation concerned, we shall miss very little of importance by adopting for purposes of argument the view that duty is prior to the good, and we shall be able to give full consideration to any possible way in which the agent is actually involved in the fundamental questions of ethics. Duty thus gains at least a pragmatic priority.
In accordance with the evolutionistic trend of modern ethics, Herbert Spencer traced duty to fear of revenge, etc. There is no doubt that the experiences of one who acts from duty have a certain measure of resemblance to those of one who acts from fear. However, the two experiences, notwithstanding their qualitative similarity, occupy different places in the life of the individual. Kant expresses this difference by contrasting the universality of the claims of duty with the majority and partiality of the inclinations, which manifestly include such aversions as fear. Whether we go as far as Kant does, and regard duty as that motive to conduct which impels us to act in accordance with laws which we consider and will as universal, we shall undoubtedly be right if we insist that the obedience of duty leads us into, not a chaotic assemblage of different deeds, but a more or less unified course of behavior.

The manifoldness of the experiences of those who act from duty is familiar to all. One man does his duty gladly, another reluctantly. On the battle-field, one may act as a soldier though in utter fear of his tasks, while his comrade is inspired by religious emotions, and still a third is enraged at the misdeeds of the enemy. In short, it is hard to find any common factor in the consciousness of duty at different times, except in the mere fact that these consciousnesses lead to a definite course of conduct. All that can be said so far of duty, then, is that it consists of a group of experiences impelling to action, and in general having fruition in acting—for even the worst scoundrel neglects a thousand opportunities to do an evil deed for every one he uses—which tend toward a unified scheme of conduct. This alone, however, is enough to show that the consciousness of duty is a harmonization and, as it were, a codification, of our various impelling, approving experiences into a workable form. Whether it is anything more, and whether duty itself is prior to the consciousness of it, are issues too wide to be discussed here, but it may be said that this psychological definition of duty and of the consciousness of it is alone sufficient to furnish duty with most of the properties usually regarded as inherent in it. See Spencer, and consult the bibliography of that article.

Norbert Wiener, Editorial Staff of The Americans.

DUTY (customary taxes; in the constitutional struggles of medieval England, so claimed by the sovereigns as of ancient usage and allowance), a tax or impost levied on the exports and imports of a state or district. Apparently, they were at first port fees for the use of the government quays, warehouses, weights and measures, etc.; but in very ancient times they became a general source of revenue, and had many other purposes. The constitutional prohibition of export duties leaves it applicable in the United States to imports alone. Few countries now levy a tax on exports and such a source of revenue no longer holds a place of importance in the fiscal systems of many governments. In the United States levy some duties on exports, such as that on shipments of nitrate from Chile and that on exports of coffee from Brazil; and in 1901 Great Britain imposed a tax of one shilling per ton on all coal exported. But, generally speaking, the term customs duties means duties on imports. In countries of developed commerce these have always been the favorite means of taxation with governments and subjects alike, by a rare and significant harmony. The latter prefer them to direct taxes, as distributing the burden in small unperceived amounts on their daily income, in place of a few severe annual exactions. The former prefer them as making it possible not only to raise a far greater revenue with far less criticism, but actually to win popularity by increasing the burden, in most countries—a unique feature in administrative policy. Direct taxes have been the fertile parent of rebellions; customs duties have generally been popular in proportion to their magnitude. The latter fact is due to two other traits inherent in import taxes; that they furnish an apparent means of transferring the tax burden largely to the foreign producers, and of giving the native producer the monopoly of the home market. It is obvious that the two are more or less self-contradictory—that the foreigner can share the payment of the tax in proportion to his share of the market, and that if imports were annihilated all taxes would be direct; but the discussion of this subject belongs to the question of protective tariffs (see Protection; also Free Trade; Great Britain—The Free Trade Movement and The Tariff Reform Movement). Here it need only be said that it is not necessary for dutiable articles to be such as are produced within a country, for a tax to be "protective" in action: they may be high-grade articles needed in manufacturing, the charge upon which forces a resort to inferior native materials, or increase the price of the better goods. This increase is always much greater than the duty, as it includes interest on the extra capital needed to carry on business with the costlier articles, and a further charge for the restricted market due to heightened price.

Customs duties must belong to one of two classes: those charged on given units of weight or measure, as the pound, ton, yard, gallon, etc., called specific duties; and those charged by a percentage on the estimated value, called ad valorem duties. On many kinds of goods the two are combined in what are called compound duties; and a variant of the ad valorem system is what is called the minimum duty, under which all goods costing less than a certain sum are assumed to have cost that amount and are taxed upon it. In the old English disputes between king and Parliament specific duties were called "tonnage" (so much per ton); and ad valorem duties "poundage" (such a per cent on the estimated value in pounds sterling), though levied so as not to be purely ad valorem.

The merits of the two systems are not unanimously agreed upon; indeed, each has its special merits and disadvantages, which are grave from the standpoint of national welfare. It is fair to say, however, that most of the difficulty of the specific duty lies in the attempt to measure for protective purposes, and that of the ad valorem duty in its enormous volume; that a specific duty for revenue only loses most of its objectionable features if levied on the proper articles, and that a low ad valorem duty would
be free from most of the objections of a high one. This will be evident from a glance at each. *Specific duties* are simple to calculate, easy to collect, do not require a high grade of official skill and leave few loopholes for fraud. The great drawback is that they produce immense inequality in duty from the variation in cost and quality, and that inequality in exactly the wrong direction. That is, a certain number of cents on a pound or yard of cheap material may be very high or even prohibitory, while on expensive material the same may be trivial. Specific duties have an advantage over ad valorem duties in that they can be more suitably applied to raw materials and manufactures of a simple character, where there is uniformity of quality and where few opportunities are presented for fraudulent entries of goods. Hence they are applied to customs taxes on cattle, iron and steel products, minerals, flax, hemp, wool, lumber, grain, sugar, spirits, wines and tobacco. Whenever the tariff is revised attempts are made to extend the list of specific duties, and at times even to include such duties as a check to undervaluation—as in 1857, when President Buchanan expressed dissatisfaction with the exclusive use of the ad valorem rates of the Walker tariff of 1846, since they permitted a large amount of fraud by undervaluation. In order to adjust specific duties to value some tariffs have incorporated a scale of rates, based upon value, which practically amounts to an ad valorem rate. Section 131 of the Payne-Aldrich tariff of 1909 provided a scale of duties on certain kinds of steel products as follows:

<table>
<thead>
<tr>
<th>Value at</th>
<th>Tax Rate</th>

*Ad valorem duties*, theoretically the fairest of all, are full of practical difficulties as a revenue producer and highly unsatisfactory as a protective system, because such duties are levied according to the value of the imported commodities, instead of the weight, bulk or other unit of measurement of the commodity. In the former line the difficulties of fixing the value, the opportunities for fraud and undervaluation, the temptation to officials to connive and the expensive skilled officials needed to work it, all stand in the way of its usefulness to the government. The value is usually fixed at the point of export; but that involves minute knowledge by the official of a vast number of trades and manufactures and the fluctuation of trade conditions; and moreover, the market may have changed materially from the time the duty is assessed to the time the importer pays it, which shifts the burden from the government to the merchant. Furthermore, the power to control is vested in the government to throw all the burden of duty on the importer, to seize his goods on suspicion and confiscate them on proof satisfactory to itself, but not to him, though partially remediable by the courts, and very likely necessary to secure the government, place the importer in a situation by no means free from peril. And the tedious, costly and vexatious red tape of invoicing and appraising and satisfaction of legal forms are bad enough, but still more objectionable is the zeal of officials anxious to win laurels by harassing importers, and desirous of throwing difficulties in the way of even legitimate trade, make it impossible for small capitalists to bear the risks. Thus the small merchant is driven out of the business and the trade concentrates in a few great houses. Under ad valorem rates protection is not assured to home producers since when a decline of prices occurs a corresponding drop of duties takes place, and when he most needs it the producer cannot obtain protection. The Constitution provides that "no preference shall be given by any regulation of commerce or revenue to the ports of one State over those of another" and hence some argue that ad valorem duties do not conform to this and the Democrats have favored such duties as a check to undervaluation—as in 1857, when President Buchanan expressed dissatisfaction with the exclusive use of the ad valorem rates of the Walker tariff of 1846, since they permitted a large amount of fraud by undervaluation. In order to adjust specific duties to value some tariffs have incorporated a scale of rates, based upon value, which practically amounts to an ad valorem rate. *Compound duties* is the term applied to the combination of specific and ad valorem duties imposed upon the same article when imported. The object of a compound duty may be twofold—to shut out cheap grades of goods by adding a specific duty to the ad valorem duty, thereby increasing the amount of taxation, or to afford protection by additional protection where a duty is imposed upon the raw materials used in the manufacture of the article. The tariff of 1824 was the first to levy a compound or mixed duty (on certain kinds of glassware) and the tariff of 1828 imposed a duty of four cents per pound on wool manufactured at 40 per cent ad valorem. In this way the tariff makers hoped to restrict the importation of the coarser grades of wool and, by handicapping the manufacturer who depended on foreign coarse grades, to place the market under the control of the government to throw all the burden of duty on the finer grades. The tariff makers placed the compensatory duty at 12 cents per pound plus an ad valorem rate designed to protect the
manufacturing industry, basing their calculations on the assumption that a pound of finished cloth required four pounds of imported wool, wherefore the duty should be four times the wool duty of three cents levied by the same act. Some later schedules therefrom be exported retained this same rate of four to one. During the Civil War period the list of commodities on which compound duties were imposed was greatly extended, so as to compensate for taxes levied on internal manufactures of the same name, such as iron and steel products, marble, cottons, carpets, cigars, mineral waters, soaps, perfumes, wines and liquors.

Drawbacks of duties are refunds of duties paid on goods that are re-exported; they have been provided for ever since the first tariff act of 1789. If imported raw materials are used in a finished product exported a drawback of 99 per cent of the duties paid when the raw materials were imported is allowed if the exporter of the finished product can satisfactorily identify the raw materials according to Treasury Department regulations. Drawbacks are allowed of the internal revenue duties paid on alcohol that has been used in medical or toilet preparations subsequently exported. Duties on wheat, imported from Canada, may be refunded if the flour made therefrom be exported. Drawbacks differ with the various tariff acts but the provisions are becoming more and more strict, so that the privilege is now limited to operations that can be thoroughly safeguarded.

Maximum and minimum duties is a term employed to a scale of tariff duties levied on goods imported from countries that discriminate unduly against American products. The Payne-Aldrich tariff of 23 Aug. 1909 provided that after 31 March 1910 the duties specified in the act, which constituted the minimum rates, should be increased by 25 per cent of the value of the goods imported if this merchandise came from countries unduly taxing our products in their ports. European tariffs contain such provisions which are designed to place nations on an equal commercial footing. The McKinley tariff of 1890 contained a similar provision but its application was more limited, since the President, by proclamation, could only levy certain duties on goods imported from certain countries which imposed unreasonable duties on certain articles of American production. Under the act of 1909 undue discrimination might have been either by tariff rates, export duty or export bounty or prohibition upon exports, and the President was given power to decide as to the existence of such unreasonable tariffs and the measure of the discrimination. There was considerable fear that the enforcement of the plan of maximum duties might incite a tariff war and that complications would creep into the schedule not previously established in the act without certain definite ends. Though no such trouble arose, or at least became serious, the plan of maximum and minimum duties contained in the act of 1909 was abolished by the Underwood tariff of 1913. See also Internal Revenue System; Stamp Tax; Taxation; United States—History of the Tariff.

DUUMVIRIS, dū-ŭm'vĕrs, among the ancient Romans, two magistrates, or officers, appointed for a particular purpose. They were therefore of various sorts and were specially named from the nature of their functions. The duumviri iure dicundo were the highest magistrates of colonies and towns, where they had the rank of consuls at Rome. The duumviri navales had charge of the construction and equipping and sometimes of the command, of fleets. The duumviri quaestori et scribendi were the censors of municipal towns; the duumviri sacrorum had charge of the Sibyline books, etc.

DUVAL, dū-väl, Alexandre, French dramatist: b. Rennes, 6 April 1767; d. Paris, 1 Sept. 1842. He served in the French fleet during the American Revolutionary War, and on his return to France was an engineer and architect; but finally devoted himself to writing plays, of which he composed more than 60, which won great favor from their skilful construction, interesting situations and fine dialogue. He wrote the text of the very successful opera, 'Joseph in Egypt' (1807).

DUVAL, Claude, English highwayman: b. Domfront, Normandy, 1643; d. London, 21 Jan. 1670. He went to England at the Restoration, in the train of the Duke of Richmond. Taking soon to the road, he robbed many gentlemen of their purses and ladies of their hearts, till, having been captured while drunk, he was hanged at Tyburn and was buried in the central aisle of Covent Garden Church.

DUVENECK, dū'ven-ĕk, Frank, American painter and sculptor: b. Covington, Ky., 1848. He began his artistic education as pupil in the studio of Dietz, at Munich, making a specialty of portraits and genre. He formed a school there, composed mostly of Americans, whom he conducted on painting trips to Venice, Florence and other art centers. Many of his pictures are in this country, although he has lived much abroad and since 1881 has taught and painted at Florence, Italy. He was awarded a medal at the Columbian Exposition of 1893 and a special gold medal of honor at the Panama-Pacific Exposition of 1915. He was for a time director of the McMicken Art School in Cincinnati. He was one of the first to introduce the Munich style into America. His most remarkable paintings are 'A Circassian' (1875); 'Portrait of Charles Dudley Warner' (1876); 'The Professor' (1878); 'Turkish Page and Recumbent Figure' (Pennsylvania Academy); several paintings in the Cincinnati Museum; 'The Yacht Harbor' and portrait of his mother (1903). Of his sculptures the most notable is the monument to Susan Dwight Bliss in the English cemetery of Florence, Italy. He became a member of the National Academy in 1906. Consult Heer mann, 'Frank Duveneck' (1918).

University of Louvain, where he studied theology, one of his fellow students, and his most intimate friend, was Cornelius Jansen (q.v.), after whom a certain system of theological views is named—"Jansenism." The two friends, after both had left the university, continued their intimate relations, first at Paris, then at Bayonne, where Duvergier had been appointed to a prebend. When Jansen left Bayonne Duvergier accompanied him in his prebend and went back to Paris. All this time the two men had diligently been studying the ancient fathers of the Church, and in particular Saint Augustine, from whom Jansen claimed to have drawn his doctrine of Divine Grace. In Paris Duvergier's winning personality and his reputation for austere views of religious and moral obligations commended him to the favor of the bishop of Poitiers, who gave up to him the monastery, or abbey, of Saint Cyran, and there Duvergier brought together a number of devout men, formed them into a convent of monks, under the ancient, unamended rule of Saint Benedict. But his zeal for reform of the monastic life was suspected of being inspired by a secret hostility to the Church and the Pope, and Duvergier was compelled to retire from Saint Cyran, whence he returned to Paris. There he was received with great favor by the highest society, especially the feminine element, and in particular he became the trusted councillor of Angélique Arnauld, abbess of Port Royal, and all the members of the remarkable Arnauld family, those staunch defenders of Jansenism (see Arnauld). A sect was formed and Cardinal Richelieu had strong suspicions that the abbé of Saint Cyran was leader in a conspiracy against Church and State; so he was arrested by order of the cardinal and committed to the castle of Vincennes 14 March 1638, where he was held in close confinement as long as Richelieu lived, or till December 1642; and he survived his liberator only a few months. His biography has been written by Lancelot (Cologne 1738).

DUVERGIER DE HAURANNE, Prosper, French publicist: b. Rouen, 3 Aug. 1798; d. Paris, 22 May 1881. He went to London and became in 1824 a constant contributor to the *Globe*. He was elected deputy from Sancerre, and in the National Assembly he supported Casimir-Perier and Thiéry, while opposing Guizot, who had been his friend and associate on the *Globe*. After the coup d'état of Napoleon III he was imprisoned for a while and eventually sentenced to banishment, but was subsequently allowed to return to Paris. He became a member of the Academy in 1870 and among the works which won him reputation is to be mentioned *Histoire du gouvernement parlementaire en France* (10 vols., 1857-70).

DU VERNET, dü vär-nä', Frederick Herbert, Canadian bishop: b. Hemmingford, Quebec, 20 Jan. 1860. He was educated at King's College, Windsor, Toronto University and Wycliffe College. He was ordained in 1883; consecrated Anglican bishop of Caledonia, British Columbia, 30 Nov. 1904; and became archbishop and metropolitan of British Columbia, 1915.

DUVERNOY, dü-ser-nwā, Georges Louis, French naturalist: b. Montbéliard, 6 Aug. 1777; d. Paris, 1 March 1855. In 1802 he was invited by Cuvier, to whom he was related, to assist in editing his treatise on comparative anatomy. With the aid of the notes and councils of his master, he prepared the last three volumes of this work, embracing the organs of digestion, respiration, circulation, generation and the senses. In 1827 he succeeded Cuvier as professor of the faculty of sciences at Strasbourg, where, during 10 years, he published a variety of papers on anatomical subjects; and after the death of Cuvier was engaged in arranging his papers for publication. In 1837 he was elected professor of natural history in the College of France. He published numerous works, which have furnished important materials to anatomists and zoologists.

DUZINE (derived from the Dutch *dozijn*), or The Twelve Men, the 12 patentes in 1677 of the Huguenot settlement on the Wullik, now in Ulster County, Long Island, N.Y., and known as New Paltz (New Palatinate) from their German refugee after escaping from France. The *duzine* and their successors were the executive and legislative body of the settlement during a century.

DVINSK, or DÜNABURG, dü'nä-boorg, Russia, a fortified town of Russia, government of Vitebsk, on the Duna, 112 miles southeast from Riga. It was formerly the capital of Polish Livonia. It is of great military importance, being a fortress of the first class, carries on a considerable trade and is the junction of three important railway lines. Pop. (including suburbs) 110,912, of which about 30,000 are Jews.

DVÓRAK, Antonin, än't ön-in dvór'zhák, Bohemian composer: b. Mühlhausen, Bohemia, 8 Sept. 1841; d. Prague, Bohemia, 1 May 1904. At first intended for his father's trade of butcher, he showed such musical ability that he was sent to Zlonic to study. Here he found a friend in the village organist, A. Lichmann, who taught him elementary theory, organ and pianoforte playing. He next went to Kamnice, where he studied under Hancke. In 1875 he entered the Gesellschaft der Kirchenmusik at Prague, where he worked for three years. The small financial aid he received from his father soon ceased and Dvořák found himself thrown upon his own resources. For a time he played the tenor violin in a theatre orchestra in Prague, and was also organist for several churches. In 1873 he first made himself known as a composer by a patriotic hymn for chorus and orchestra and not long afterward an opera of his, *The King and the Country*, was successfully produced. His first great success was his setting of the *Stabat Mater,* first performed in England in 1883, which at once raised him to the rank of a popular and widely-known composer. Among his subsequent works are songs, operas, dances, symphonies, cantatas, *The Spectre's Bride,* first performed at Birmingham in 1885, the composer himself acting as conductor, and an oratorio, *Saint Ludmilla,* first performed at Leeds in 1886 under his own direction. Dvořák is characterized by a brilliant imagination, great originality and a
DWARF — DWARFED TREES

rare inventive power. His ‘Stabat Mater,’ which betrays less of the Bohemian nationality than many of his other works, is regarded as one of the greatest works of its kind in modern music. In 1892 he was called to New York as director of the National Conservatory of Music, where he remained three years. He became interested in the music of the Indians and negroes and many of the negro races appear in his symphony ‘From the New World,’ and the overture ‘In Nature.’ He settled in Prague in 1895, where in 1899 he produced the opera, ‘Der Teufel und die wilde Katze.’ The universities of Prague and Cambridge conferred on him the degree of doctor of music, and he was elevated to the Austrian House of Peers. He wrote five symphonies, many sacred compositions and a number of operas, which are very popular in Bohemia. He also composed several works for the pianoforte. To him we are indebted for calling our attention to the wealth of folk-songs among the Slavs. Consult Hadow, W. H., ‘Studies in Modern Music’ (Vol. II, New York 1904); Massai, D. G., ‘From Greece to Brahms’ (New York 1902); Zubrzycki, ‘Dvořák’ (Prague 1886).

DWARF, a human being much below the ordinary size of man. Dwarfs are described by several ancient classical writers. Herodotus gives an account of a race of dwarfs living in Libya and the Syrtis, to which Aristotle and Pliny also refer. Henry M. Stanley, in his journey across Africa in 1888, came on a dwarf race which he thought might be descended from that mentioned by Herodotus. Philetas of Cos, distinguished about 330 B.C. as a poet and grammian, was particularly said to have carried weights to prevent his being blown away. He was preceptor to Ptolemy Philadelpus. Julia, niece of Augustus, had a dwarf named Coropas, two feet and a hand’s breadth high; and Andromeda, a freedmaid of Julia’s, was of the same height. The Negritos, occupying a belt six degrees wide in equatorial Africa the smallest known race, are supposed to have a common ancestry with the Negritos of Asia and Melanesia. The Akkas, a diminutive race, inhabit the country west of Lake Nyassa. In 1895 a dwarf tribe was discovered on the Upper Nile. This race is regarded as the most primitive race on earth, having neither laws nor rules of conduct and destitute not only of clothing but of weapons of offense and defense. In Luzon, in the Philippines, the Ataas, a pigmy race, has been discovered. Dwarfs, in races of normal size, is always a sign of stunted development and may be produced by malnutrition or malnutrition, by disease of the thyroid glands, rickets or spinal tuberculosis. Many dwarfs, however, are well formed and have a perfectly normal. They are as a general rule apt in intellect, but sensitive, quick-tempered and revengeful. Among dwarfs celebrated in history mention may be made of Jeffery Hudson, page to the first Duke of Buckingham. At 16 he was one of the guards of the Duke and was 18 inches high. When Charles I and his queen were the guests of Buckingham, Hudson was brought to table in a pie, out of which he stepped and he was adopted by Queen Henrietta Marie. He became a captain of horse in the Civil War, and figured in two duels, one with a turkey cock and the other with one Crofts, whom, firing from horseback that he might be on a level with his antagonist, he shot dead. The best known of modern dwarfs was Charles S. Stratton, or, as he was popularly called, ‘Tom Thumb,’ who was 31 inches high at the age of 25. He was born in Bridgeport, Conn., and traveled extensively abroad and at home under the management of P. T. Barnum. He went to Europe, and he attracted great attention even from such personages as Queen Victoria and Napoleon III. Another modern dwarf was Francis Flynn, ‘Gen. Mite,’ who was 21 inches in height at 10 years.

In Scandinavian mythology dwarfs (Dvergar) are inhabitants of the interior of the earth and especially of large isolated rocks. They were imagined to be dark in aspect like the caverns in which they dwelt and were often styled ‘dark elves.’ A dwarf was set by the gods at the corner of each of the four quarters of the earth to bear up the sky; and they were named East, West, North and South. All the dwarfs were esteemed great artists in working metals and weapons of marvelous properties were said to be produced in their darkie workshops. Like the Jotuns, they could not endure the sunlight and if its rays touched them they were turned into stone. If a man met a dwarf away from his rock and could throw steel between him and it, it was believed that thereby his habitation was closed up and that any thing in his power could be extorted from him. In the old Norse, echo is called the ‘dwarf language,’ probably because it was thought to be produced by the dwarfs within mountains imitating the sounds which they heard without.

DWARF SNAKE, a common name for small snakes of many genera, given in the United States to species of the genus Carphiophiops, which are found in the South in old logs. They are brown above and yellow or salmon below. The name is also applied to a pretty little snake of the genus Erythmobates with coloring similar to the dwarf snakes of the first genus, but with a dark brown band across the head. It destroys insects and is harmless.

DWARFED TREES, a favorite ornament for dwellings among the Japanese and Chinese, who adopt a peculiar method of dwarfing. They choose some fruit- or flower-bearing branch of any tree of which they wish to produce a dwarf specimen, and cutting off a ring of the bark, surround the stripped part with clay, which they keep moist by means of a covering of moss, which is watered when it becomes dry. After a period, varying in different trees from about three months to two years, roots are sent out by the branch into the clay. The branch is then cut off below these artificial roots and planted in a poor soil, where it is kept scantily supplied with water. In this state the tree will remain for years, with vitality enough to produce leaves and even flowers annually, but never producing any but abortive shoots. Another method is to plant trees in flower pots with a shallow covering of soil, supply them, as in the former case, very sparingly with water and pinching off all the strongest shoots. Still another method, which is said to give good results when tried by amateurs, is to encircle a seed in a small
pellet of earth which is placed in the centre of a ball of absorbent moss, then is crowded into the interior of an orange from which the pulp has been removed. The moss is liberally supplied with water until the roots appear on the outside of the orange, when they are cut off and the orange-skin covered with varnish, and placed in a flower-pot. Thereafter only enough moisture is applied to support the life of the plant.

DWARKA, dwär'kā, India, maritime town of the district of Guzerat, on the Arabian Sea, on the west side of the peninsula of Kathiawar, in the dominion of Baroda, 235 miles southwest of Amedebad. On an eminence overlooking the seashore stands a great temple of Krishna, visited annually by 10,000 pilgrims. Dwarka is claimed as the birthplace of Krishna. Pop. 6,548.

DWELSHAUVERS-DERY, dvël'zhō'vär'-dèr, Victor, Belgian engineer: b. Dinant 1836. He secured his education at the universities of Brussels and Liège and in 1869 was appointed professor of engineering at the latter seat of learning. He wrote extensively on the adjustment and regulation of machinery and on the theory of steam engines. In particular he reduced to exact figures the modern theory of steam power. He represented his government at several international expositions. His more important publications are 'Le monde ou nous vivons' (trans. by Austey 1871); 'Principes de la résistance des matériaux' (1876); 'Exposé succinct de la théorie des moteurs-à-vapeur' (1880–82); 'Étude expérimentale thermique de la machine-à-vapeur' (1892); 'Étude expérimentale calorimétrique de la machine-à-vapeur' (1894).

DIGHT, Harrison Gray Otis, American Congregational missionary: b. Conway, Mass., 22 Nov. 1803; d. Shaftesbury, Vt., 25 Jan. 1862. He was graduated at Hamilton College, Clinton, N. Y., 1825, and became a missionary of the American Board of Commissioners for Foreign Missions in 1830, to the Armenians, making Constantinople the centre of his field of operations. He was abundant in his labors and met with great success in his work. He wrote 'Researches of Smith and Dwight in Armenia'; 'Christianity Revived in the East' (1850); and compiled 'An Armenian Literature in the Middle Ages' for the Journal of the American Oriental Society.

DIGHT, Henry Otis, American missionary: b. Constantinople, Turkey, 3 June 1843; d. 19 June 1917. He entered Ohio Wesleyan University, but left it in 1861 to serve with the Union forces in the Civil War. In 1866–67 he was treasurer of the Northampton Street Railway Company, and in the following five years was business agent at Constantinople of the American Board of Commissioners of Foreign Missions. In 1872–79 he edited missionary publications in the Turkish language, and served also as Constantinople correspondent of the New York Tribune from 1875 to 1892. In 1880 he was ordained to the ministry. In 1901 he resigned his commission as missionary and soon after became connected with various missionary societies. He was also editor of the support of the Ecumenical Conference on Foreign Missions' (1900), and the 'Encyclopedia of Missions' (1904). He is the author of 'Turkish Life in War Time' (1881); 'Treasury of Christian Missionary Literature' (1893); 'Constantinople and its Problems' (1901); 'Blue Book of Missions' (1905; 2d ed., 1907); 'A Moslem Sir Galahad' (2d ed., 1914).

DIGHT, Jonathan, American physician and ornithologist: b. New York, 8 Dec. 1858. He was graduated at Harvard University in 1880 and at the College of Physicians and Surgeons of Columbia University in 1893. From 1894 to 1904 he was assistant surgeon of the department of laryngology at the Vanderbilt Clinic. After 1888 he was a Fellow of the American Ornithologists' Union and treasurer after 1905. He is a member of the American Museum of Natural History and also served as president of the Linnean Society.

DIGHT, Joseph, American soldier: b. Hatfield, Mass., 16 Oct. 1703; d. Great Barrington, 19 June 1765. He was graduated at Harvard University in 1722, became judge of the Court of Common Pleas of Hampshire County, Mass, and afterward of Berkshire County, and judge of probate. He was eminent both as a judge and a soldier. He commanded the Massachusetts artillery at the reduction of Louisburg in 1745 with distinction, and led a brigade at Lake Champlain in the second French War in 1756. He was also for 11 years a member of the general council of Massachusetts.

DIGHT, Nathaniel, American educator: b. Northampton, Mass., 3 Jan. 1770; d. 11 June 1831. He was a brother of Timothy Dwight the elder (q.v.). He prepared and published the first school geography ever issued in the United States, and was also the author of 'The Great Question Answered,' and 'A Compendious History of the Signers of the Declaration of Independence.'

DIGHT, Sereno Edwards, American Congregational clergyman: b. Greenfield Hill, Conn., 18 May 1780; d. Philadelphia, Pa., 30 Nov. 1850. He was a son of Timothy Dwight (1752–1817). He was graduated at Yale 1803 and practised law at New Haven until 1816, when he entered upon a clerical career. He preached in Park Street Church, Boston, 1817–20, and was president of Hamilton College, Clinton, N. Y., 1833–35. Among other works he published 'The Complete Writings of Jonathan Edwards with a Memoir' (10 vols., 1830).

DIGHT, Theodore, American journalist: b. Northampton, Mass., 15 Dec. 1764; d. New York, 12 June 1846. He was a brother of Timothy Dwight, the elder. He was a well-known Federalist, a member of Congress and wrote 'History of the Hartford Convention' (of 1814), and 'Character of Thomas Jefferson.' He was editor also of the Hartford Mirror, the Albany Daily Advertiser and the New York Daily Advertiser.

DIGHT, Theodore William, American educator, jurist and editor: b. Catskill, N. Y., 18 July 1822; d. Clinton, N. Y., 28 June 1892. He was educated at Hamilton College, and was professor of law there and subsequently in Columbia College, in each of which he founded a law school. He was elected (non-resident) professor of constitutional law in Cornell University in 1868, and lecturer at Amherst College in
1869. He was interested in philanthropic work, and served as president of the New York Penjon Association, vice-president of the New York Board of State Commissioners of Public Charities and as a member of the "Committee of Seventy," of New York. In collaboration with E. C. Wines he published 'Prisons and Reformatories in the United States' (1862); he was associate editor of the American Law Register, and editor of Maine's 'Ancient Law' (New York 1864).

DWIGHT, Timothy, American Congregational clergyman: b. Northampton, Mass., 14 May 1752; d. New Haven, Conn., 11 Jan. 1817. In 1769 he was graduated at Yale College and in 1771 became a tutor there. In 1783 he was ordained a minister at Fairfield, Conn., where he opened an academy. In 1795 he was elected president of Yale College, and he also held the professorship of theology. His chief works are 'The Conquest of Canaan,' an epic poem (1785); 'Theology Explained and Defended, in a Series of Sermons' (1818); 'Travels in New England and New York' (1821). Consult Sprague, 'Life of Timothy Dwight,' in (Sparks' 'American Biography').

DWIGHT, Timothy, American clergyman and scholar: b. Norwich, Conn., 16 Nov. 1828; d. New Haven, Conn., 26 May 1916. He was graduated at Yale in 1849. He stayed at Yale as tutor, studied in the theological school and was graduated there in 1853. In 1855 he was licensed to preach as a Congregationalist, but was not ordained until 1861. After studying at Berlin and Bonn he returned to Yale in 1888 as assistant professor of sacred literature and New Testament Greek in the theological seminary. Three years later, at the age of 35, he became a full professor, a position he held until his election to the presidency. Although a famous scholar his early tastes were not entirely academic. A Yale cartoon of the days when he was teaching theology pictures him studying a shelf of books and saying "Oh, come back to the days of my youth." He succeeded Noah Porter as president of Yale University in 1886 and was succeeded by Arthur T. Hadley in 1889. He resigned in keeping with his belief that a president should not serve after the age of 70 years. After he resigned he lived in retirement, spending his winters in New Haven and his summers in Litchfield. He assumed direction of Yale University at a time when its needs were manifold, especially as regards finance. His great task was the securing of money for buildings and for additions to the faculty. In a particularly perplexing period he turned his own salary back into the treasury, supplied the college with his own personal savings as well as president. In response to his efforts Yale entered an epoch of unparalleled expansion. In the 13 years of his administration the permanent funds were increased from $2,111,169 to $4,554,827 — a greater increase than in all the 183 years since Yale College was founded. President Dwight's personal contributions amounted to about $100,000. At his request the Connecticut legislature in 1887 legalized the title "Yale University." Dr. Dwight then welded the colleges and the professional schools into a coherent whole. His greatest work outside the campus was done when he was a member of the American committee for the revision of the Bible, from 1878 to 1885. From 1885 to 1874 he was associate editor of the New Englander. In 1870-71 he published a series of articles on 'The True Ideal of an American University.' He edited several volumes of the American edition of Meyer's 'Commentary on the New Testament,' translated and annotated 'The Gospel of Saint John'; published 'Thoughts Of and For the Inner Life' (1889); and 'Memories of Yale Life and Yale Men' (1903). He received the degree of doctor of divinity from Yale and the University of Chicago and the L.L.D. degree from Harvard and Princeton.

DWIGHT, William Buck, American geologist: b. Constantinople, Turkey, 22 May 1833; d. Cottage City, Mass., 29 Aug. 1906. He was graduated at Yale in 1854, at the Union Theological Seminary, New York, in 1857, and at the Yale Scientific School in 1859. He filled several educational posts in a scientific capacity, served as principal of the officers' school at West Point (1867-70), and from 1878 till his death was professor of natural history and an assistant curator of the museum at Vassar College. In 1891 he invented and patented a rock-slicing machine for the scientific section of minerals, for which he was awarded a bronze medal at the Paris Exposition of 1900. His investigations of the Cambrian and Ordovician strata and his studies of Dutchess County, N. Y., and the Wappinger Valley are extremely valuable.

DWINA, dwé'na. DVINA, sometimes called NORTHERN DWINA, river of northeastern Russia, formed by the union of the Sukhona and Witchegda, in the government of Vologda. It flows in a northeastern course to the junction of the Witchegda, when it pursues a northwest course, entering Dwina Bay, an arm of the White Sea, about 25 miles below Archangel. The whole course, from the source of the Witchegda, is over 1,000 miles. Carry on connect the Dwina with the Volga and the Neva. From the junction of the Witchegda to the sea is about 400 miles, all of which distance is navigable. The导航, a kind of cod peculiar to this river, abounds in its waters.

DYAKS, di'aks, or DAYAKS, the name given by the Malay invaders to the natives of Borneo. They are divided into innumerable tribes differing pretty widely in language, customs and degrees of savageness. Their traditional home was in the mountains of the interior. Physically they closely resemble the Malays, to whom they are doubtless akin, but are somewhat taller; they are intelligent, hospitable and unsuspicious, and greatly excel the Malays in truthfulness and honesty. Many of the dialects spoken by them are little known. The coast tribes have adopted many Malay words and some have completely adopted the Malay speech. Even the most uncivilized tribes have many ingenious arts and industries, weave cloth, make excellent steel weapons and erect most serviceable suspension bridges with huge pole and withes. Their chief weapon is the blow-pipe, not the bow. The barbarous custom of systematic head-hunting is dying out, though the heads of enemies are still cherished trophies of the warrior.

DYCE, Alexander, English Shakespearian scholar: b. Edinburgh, 30 June 1798; d. London,
15 May 1869. He was educated at Exeter College, Oxford; and, taking orders, held several curacies prior to 1828, when he settled in London, where the most of his life was passed. He was first brought to notice by his ‘Specimens of British Poetesses’ (1825), which was followed by editions of Collins (1827), George Fife (1828), Webster (1830), Robert Greene (1831), Middlebeam and Fletcher (1843–46), Marlowe (1850), Shirley (1833), Skelton (1843), Wotton and Drayton, all of which were accompanied by notes and biographies of the authors. In 1840 he founded, in conjunction with Collier, Halliwell and Wright, the Percy Society, for the publication of ancient comedies and ballads. His chief labors, however, were devoted to Shakespeare, an edition of whose works he published in 1857; second edition, greatly improved, nine volumes (1864–67). In his ‘Remarks on Collier’s and Knight’s Editions of Shakespeare’ (1844) he pointed out several errors into which the modern commentators on Shakespeare had fallen; and in another work, entitled ‘A Few Notes on Shakespeare’ (1853), he pronounced very strongly against the emendations of the text of Shakespeare published by Collier, and maintained by him to belong to the first half of the 17th century. His ‘Glossary of Shakespeare,’ which extended to 500 pages, is a standard work. His work is at once learned and scholarly, accurate, sane and luminous.

DYCE, William, Scottish painter; b. Aberdeen, 19 Sept. 1806; d. Streatham, 14 Feb. 1864. In 1830 he settled at Edinburgh, where he soon became known as a portrait-painter and as a distinguished contributor to the exhibition of the Royal Scottish Academy. In 1827 he had exhibited at the Royal Academy his ‘Bacchus Nursed by the Nymphs.’ About 1837 he settled in London. In 1836 he exhibited ‘The Descent of Venus,’ the subject of which was taken from Ben Jonson’s ‘Triumph of Love;’ and in 1839, ‘Saint Dunstan Separating Edwy and Elgiva.’ When the decoration of the interior of the new houses of Parliament was made a subject of competition Dyce exhibited his talents in a new light, namely, as a painter in fresco. His first fresco, ‘The Consecration of Archbishop Parker,’ was executed in Lambeth Palace, and was followed by ‘The Baptism of Ethelbert,’ in the House of Lords (1846). He was elected to the Royal Academy in 1848 and was also a member of the Academy of Fine Arts of Philadelphia. In 1848 he was commissioned to paint a series of seven frescoes in the House of Lords, but he only lived to complete five. Among his other pictures are ‘Joash Shooting the Arrow of Deliverance’ (1844); ‘Virgin and Child’ (1846); ‘Omnia Vanitas’ (1849); ‘Meeting of Jacob and Rachel’ (1850); ‘King Lear and the Fool in the Storm’ (1851); and ‘John Leading Home the Virgin’ (1860). His artistic sense finds best expression in his religious pictures, and he was in full sympathy with the Pre-Raphaelite movement. Notable also is his decorative work, both as a painter and as a designer of stained glass.

DYEA, d vá, Alaska, a former village on Chilkoot Inlet, the east fork of Lynn Canal, which was important during the gold-rush, as being the starting-point of the Chilkoot Trail, a much traveled pathway to the valley of the Yukon, when he settled in London, where the most of his life was passed. He was first brought to notice by his ‘Specimens of British Poetesses’ (1825), which was followed by editions of Collins (1827), George Fife (1828), Webster (1830), Robert Greene (1831), Middlebeam and Fletcher (1843–46), Marlowe (1850), Shirley (1833), Skelton (1843), Wotton and Drayton, all of which were accompanied by notes and biographies of the authors. In 1840 he founded, in conjunction with Collier, Halliwell and Wright, the Percy Society, for the publication of ancient comedies and ballads. His chief labors, however, were devoted to Shakespeare, an edition of whose works he published in 1857; second edition, greatly improved, nine volumes (1864–67). In his ‘Remarks on Collier’s and Knight’s Editions of Shakespeare’ (1844) he pointed out several errors into which the modern commentators on Shakespeare had fallen; and in another work, entitled ‘A Few Notes on Shakespeare’ (1853), he pronounced very strongly against the emendations of the text of Shakespeare published by Collier, and maintained by him to belong to the first half of the 17th century. His ‘Glossary of Shakespeare,’ which extended to 500 pages, is a standard work. His work is at once learned and scholarly, accurate, sane and luminous.

DYCE—DYING

DYING. Dyeing is the art of staining or coloring yarn or cloth in such a manner that the color is to a measurable degree permanent. The art was practised among the Eastern nations from time immemorial, and in the Scriptures we read of the vestments of the priests being dyed purple and of linen cloths being dyed blue, purple and scarlet. The famous Tyrian purple is believed to have been discovered by the inhabitants of Tyre 1500 B.C., and immediately afterward Tyrian purple became the badge of royalty and cloth dyed with it commanded a very high price. The Egyptians, Grecians and Romans practised the art of dyeing and it gradually became more widespread as civilization advanced. In earlier times dyeing was much more extensively followed as a domestic art than at present. The process was accomplished in two stages: (1) absorption; and (2) fixation. The first is a simple diffusion of the dye throughout the fibre; the second is the result of a chemical action in which the dye becomes insoluble in the water after it has been taken up. Where mordants are used it is the mordant which is applied to the fibre in the absorption stage. The textile fibres upon which the dyer exercises his art are of two groups: (1) vegetable fibres, as cotton, linen, jute, ramie and the artificial ‘silks.’ Wool fibre is the most complex, being composed of three forms of cells. Silk has no cellular formation, being practically a long double cylinder. In cotton each fibre is a single hollow cylindrical cell, flattened and twisted. In linen and jute similar hollow cells are grouped in clusters to form the individual fibres. In chemical composition and reaction there are still wider and more significant differences. If the various coloring matters used in dyeing had an affinity for the fibre in its natural state the process would be very simple. It would be necessary only to make a solution of the dye drug and immerse the goods to ensure their being dyed. But so far from this being the case, if we except indigo and safflower, there is scarcely a dyestuff that imparts its color directly to goods. The greater part of the dye drugs have so weak an affinity, for cotton goods especially, that they impart no color sufficiently permanent to deserve the name of a dye. The reason for this is simple. For example, in a decoction of logwood the color matter is held in solution by the water. Upon putting a quantity of cotton into this solution the fibre becomes filled with the colored solution, and if the cotton has no power to render the coloring matter insoluble within its fibres it is plain that by taking out the cotton and putting it into water the coloring matter within it will be diffused in the water. In other words, the dye has no affinity for the fibre, but is carried away. This lack of primary affinity makes dyeing intricate and renders it more dependent upon science. Indeed, it is only by the careful arrangement of processes in accordance with certain chemical laws that the dyer is enabled to turn to advantage the various coloring matters of which
he is in possession. When the dyer finds there is a coloration between the goods and a coloring substance he wishes to use he endeavors to find a third substance which has a mutual attraction for the fibre and coloring matter, so that by combining this substance with the fibre and then passing the cloth through the dyeing solution a new substance is formed, not only differing in properties but differing in color from any of the originals. Consequently, a very little alteration in the strength or quality of a mordant causes a decided variation in the shade of color. As, for example, logwood alone gives no color to cotton worthy the name of a dye, yet by judicious application of a few different kinds of mordants all the shades, from a French white to a violet, from a lavender to a purple, from a blue to a lilac and from a slate to a black, are obtained from this substance. Before any chemical union takes place between bodies they must not only be in contact, but they must be reduced to their ultimate molecules. Mordants that are insoluble of themselves must be dissolved in some appropriate menstrua before the coloring matter can enter the fibre of the goods or combine with the coloring matter. In doing this the dyer must respect the degree of affinity between the solvent and the mordant to determine what force it will exert against the combining of the mordant with the fibres of the cloth. Otherwise, a powerful mordant may be weakened by the attraction of the solvent. For example, common alum even though much concentrated is but a weak mordant for cotton goods, owing to the great attraction between the alumina and the sulphuric acid of the dye bath. But if acetic acid, which has comparatively a weak affinity for the alumina, be substituted for sulphuric acid it becomes a very powerful mordant.

It is with the vegetable coloring matters, however, that the greatest attention must be paid to the many conditions and properties of mordants. Bi-chromate of potash is largely used as a mordant for logwood and fustic for blues, blacks, browns and a variety of shades of color. Bi-chromate of potash, alum and oxalic acid as mordant on wool produce with logwood a very fine navy blue, but one that is not very fast to light. Sulphate of copper is the mordant most largely used with logwood for making black on cotton. These mordants are used almost exclusively for the wool dyes. In dyeing wool, either raw, woven or as yarn, care has to be taken that the wool is thoroughly free from grease before being mordanted. This is done by passing it through either soap, sal soda or soda ash and then the subsequent solution is all from the alkali solution. If this is not done unevenness in the dyeing is caused, as well as a rubbing off of the color. When the dyer is given a shade to match he has to take into consideration the degree of fastness required, as where goods have to be heavily fulled, unless the colors are sufficiently fast, they will full out and be spoiled. In this case only such dyes can be used as will stand this process. The quantity of dye to be used depends on the class of wool to be dyed, as the finer the quality of the wool the more dyestuff it takes to produce the same shade. The dyer also has to study to produce the result at the lowest possible cost, both for labor and dyestuff. Machines are now manufactured which economize in the labor and a large quantity of goods are dyed at one time. It would be generally supposed that where the dyer carefully proportioned out his dyestuff to the weight of the material to be dyed and observed every care in reference to the mordant and heat that the shades would come out alike. However, this is not the case, and with the greatest amount of care the shades will vary and it is necessary to use extra skill after the shades get off the pattern to bring them again to the shade required. The dyer, knowing full well that owing to difference in the water and the stock in the goods, besides conditions that are not always understood, that the shade is apt to vary, begins his operation with a minimum quantity of the dyestuff and if he finds that he is not up to the shade required, he adds dyestuff as is necessary, to give the desired result. In fact, making the shade right when it is once off the pattern requires the highest skill on the part of the dyer. The dyeing of wool is the result of a chemical combination. On the other hand, the dyeing of cotton is a physical combination of the dye and the cotton. Cotton is dyed in the raw state, pieces and yarns, and the amount of dye used to produce a given shade also varies somewhat according to the quality of the staple. In using colors requiring a mordant sumac and antimony are used, and the amount employed is governed by the depth of the shade required.

Dyeing of Mixed Fabrics.—The coloration of textile fabrics composed of more than one kind of material generally requires two or more processes, as the plan pursued in dyeing wool is seldom capable of fixing the color upon cotton. The customary plan followed is to immerse the fabric in the requisite baths to dye the wool and then to treat the partially dried material in the manner found suitable for cotton. Occasionally the cotton fabric is the cloth is dyed of one color and thereafter the cotton is treated so as to acquire a different shade or color. With some of the coal-tar colors mixed fabrics can be dyed in one bath, thus saving much time. The dyer is now able to produce by combination of different dyes a great variety of rich shades on mixed fabrics, and even to dye two shades in the same fabric by first
dyeing the wool in the hot bath with an acid dye, then cooling down his bath and adding his cotton dye and dyeing the cotton another shade from what was produced on the wool. In dyeing silk care has to be taken to free the silk from all gums, and this is done by boiling off in a soap bath. Most of the dyeing is done direct and under the boil.

In imparting deep indigo blue to woollen cloth and yarn a vat six or seven feet in diameter and eight to nine feet in depth is nearly filled with water, along with from 18 to 22 pounds of indigo finely ground in water, 10 to 20 pounds of madder, 7 to 9 pounds of bran and 9 pounds woad. After boiling and the addition of seven or eight pounds of lime to form the alkaline liquid necessary to hold the indigo solution, the whole is well closed over with tightly-fitting wooden covers. Within 24 hours the putrid fermentation of the wood and the bran abstracts the oxygen from the blue indigo until it assumes a yellowish color, and the solution then contains indigo white. If washing cloth or yarn in this liquid it comes out of a yellow tint from the attachment of the white indigo. But when exposed to the air the oxygen immediately begins to act on the white indigo, combining with it to form oxidized or blue indigo, and as the process of oxidation continues the yarn or cloth becomes first of a greenish and then of a blue color. If the cloth be again soaked in the yellowish solution and subsequently exposed to the air the depth of the blue color may be increased, step by step, till it arrives at that deep shade of blue so well known.

In the dyeing of cotton with indigo the vat is prepared differently. The indigo is first ground into a thin paste with water and afterward placed in a vat with protosulphate of iron and milk of lime. The lime (CaO) takes the sulphuric acid (SO₃) from the sulphate of iron (Fe₂O₃), forming sulphate of lime (CaSO₄), and liberating the protoxide of iron (FeO), which rapidly abstracts the oxygen from the blue indigo, reducing it to white indigo, and the latter dissolves in the excess of lime present in the vat, yielding a colorless solution. When cotton cloth or yarn is dipped in this it comes out of the vat almost colorless, but on exposure to the air the indigo becomes reoxidized and the cloth passes to a green and ultimately to a deep blue shade. The cloth or yarn is then washed in water and afterward soaked in a very dilute sulphuric acid to remove any oxide of iron remaining attached and rewarshed in water, when the blue color becomes more bright and clear. Fast fulling colors dyed either in the woolen yarns or pieces are usually dyed with the alizarine colors on account of their being fast to fulling and light. These are usually mordanted with bi-chromate of potash and cream of tartar for one and a half hours at the boiling point. Then they are thoroughly rinsed in cold water and finished in another bath with the alizarine colors. Owing to the great affinity existing between the alizarine colors and the mordanted wool, great care has to be taken to enter the bath at a low temperature and gradually bring to the boil to ensure the goods being dyed even. Extra care must also be taken that no more alizarine is added than is necessary to produce the shade.

Cotton is now largely dyed direct. Formerly dyers were obliged to give a number of baths and even then were not able, in a great many cases, to secure the brilliant shades that are now dyed in one operation. The color simply being fixed in the pores of the cotton, it is more difficult to secure a fast color on this fibre than on wool. As in the case of wool, dyeing machines are now manufactured by which the cotton is dyed both in the raw state, yarns and pieces, which economize in the labor and enable the dyer to produce better results both as to shade and fastness. During the last few years, there has been a large addition to the coal tar dyes, thus giving cotton dyers a much better opportunity to produce brighter and faster colors.

The yarns for carpets are dyed almost exclusively with the coal tar dyes. This is done direct by entering them in the dye bath, which has previously had added the color, with the proper proportion of sulphuric acid and glauber-salt and gradually brought to the boil, being turned by hand. The bath is generally exhausted in about 10 hours. The dyeing and drying are furnished to the dyer are frequently of a mixed material which is dark in color, and in this case he must choose the most brilliant of dyes to give the required brightness of shade. For the finer grades of carpets, the color must thoroughly penetrate and in matching shades the dyer usually cuts his yarn and matches from the centre.

F. H. Prescott,
Expert in Dyes and Dyeing, Philadelphia.

DYER, d’yer, Alexander Brydie, American soldier: b. Richmond, Va., 1817; d. 1874. He was graduated at West Point and joined the Third United States Artillery. He served in the War of 1837–38 and in the war with Mexico in 1846–48, being brevetted captain for gallant conduct. During the Civil War he was appointed chief of ordnance at Washington with the rank of brigadier-general and in this office did much to increase the efficiency of the ordnance department. From 1861 to 1864 he was in charge of the Springfield (Mass.) armory and in 1865 he was brevetted major-general in the regular army.

DYER, Eliphazet, American jurist: b. Windham, Conn., 28 Sept. 1721; d. there, 13 May 1807. He was graduated at Yale College in 1740 and began law practice in 1745. During the French War of 1755 he commanded a Connecticut regiment; was elected a member of council in 1762; chosen delegate to the Stamp Act Congress in 1765 and served as a member of Congress during the War of Independence. He was judge of the Supreme Court, 1776–93, and chief justice for the four last years of his service there.

DYER, George, English antiquary and scholar: b. London, 15 March 1755; d. there, 2
March 1841. He was educated at Cambridge through the kindness of his friends and from 1792 till his death lived by literary work in London. He edited 'Valpy's Classics' and among other writings published a 'History of the University and Colleges of Cambridge' (1814). His great labors consisted in his total blindness. Lamb's essay 'Amicus Redivivus' gives a fine picture of the eccentric, industrious, friendly old antiquary.

DYER, Henry, Scottish educator: b. 1848. He was educated at Anderson's College and at Glasgow University. He received the appointment of first principal of the Imperial College of Engineering, Tokio, Japan, and served also as professor of civil and mechanical engineering. In addition he became director of large engineering works; remained in Japan 10 years and was appointed honorary principal of the College of Engineering on retirement and honorary member of the Institutions of Civil Engineers, Mechanical Engineers and Naval Architects, Japan. After his return to Britain he took an active part in engineering, educational and social work. He is a life governor of Glasgow and West of Scotland Technical College; a governor of the West of Scotland Agricultural College, of the Glasgow School of Art and other institutions. His publications include 'Dai Nippon: The Britain of the East'; 'Japan in World Politics'; 'The Evolution of Industry'; 'Science Teaching in Schools'; 'Education and National Life'; 'Education and Industrial Training'; 'Education and Citizenship' and numerous papers and articles on engineering, educational, literary and social subjects.

DYER, Isaac, American physician: b. Galveston, Tex., 2 Nov. 1865. He was graduated at the Sheffield Scientific School of Yale University in 1887, studied also at the University of Virginia 1887-88 and received the degree of M.D. at Tulane University in 1889. In 1890-91 he served an internship at the New York Skin and Cancer Hospital; was lecturer at the New York Post-Graduate Medical School in 1891-92. In 1892 he began his long connection with the medical department of Tulane University, becoming associate professor of diseases of the skin in 1908 and professor in 1910. He is a life member of the Louisiana Society, of which he has been consulting leprologist since 1902. He is author of various articles in leading medical text and reference books.

DYER, John, English poet: b. Aberglasney, Carmarthenshire, Wales, 1700; d. 24 July 1758. He was originally a painter and his sense of beauty is shown in his 'Grongar Hill,' a poem published in 1727. He took holy orders in 1740 and received the living of Cal-thorpe, Leicestershire, in 1741, but eventually settled in Lincolnshire. He published 'Ruins of Albermarle' (1740) and 'The Fleece' (1757), by which latter poem he is best known.

DYER, Louis, American writer and lecturer: b. Chicago, 30 Sept. 1851; d. 20 July 1908. He was educated in early years in Chicago, Switzerland and France, was graduated at Harvard in 1874 and afterward studied at Balliol College, Oxford. He was assistant professor of Greek at Harvard (1881-87), and settled at Oxford in 1890, where he was lecturer at Balliol College (1893-96). He lectured before the principal colleges of this country and published among other works 'Studies of the Gods in Greece at Certain Sanctuaries Recently Excavated' (1891); a translation of Cossa's 'Introduction to the Study of Political Economy' (1893); 'The Greek Question and Answer' (1884); 'Oxford as it is' (1902); 'Machiavelli and the Modern State' (1904).

DYER, or DYAR, Mary, American martyr: d. Boston, 1 June 1660. She was a victim to the persecution which befell the Quakers in the early history of Massachusetts. She and her husband, William Dyer, came to Boston from London in 1635, but were forced to retire to Rhode Island in 1638. She was again in England from 1652 to 1657 where she became a convert to Quakerism. She came to New Haven in 1657, but was expelled therefrom in the following year. The government of Massachusetts by a statute excluded Quakers from the bounds of that colony, and in 1660, Dyer was sentenced to death any one of that sect who should be guilty of a second visit there. The statute was little regarded, or rather was construed as an invitation instead of a menace by the enthusiastic and devoted believers against whom it was directed. Mary Dyer had already departed from the jurisdiction of the magistrates upon the enactment of the law, but soon after returned on purpose to test its legality. She was arrested, went willingly to prison, and there wrote a remonstrance in which she denounced the injustice of the proceedings. She received sentence of death, and with a rope around her neck witnessed the execution of her friends Robinson and Stephenson, and then was banished from the colony. Seven months later she returned, and for excusing *rebellious sedition* was publicly hanged on Boston Common. Consult Jones, 'The Quakers in the American Colonies' (New York 1911); and Rogers, 'Mary Dyer, the Quaker Martyr' (Providence 1896).

DYER, Nehemiah Mayo, American naval officer: b. Providence, R.I., 27 Jan. 1910. He enlisted in the navy in 1916 and was promoted for gallantry in the Civil War, having attained the rank of volunteer lieutenant by 1865. He rose steadily through the grades to that of captain in 1897 and as commander of the protected cruiser 'Baltimore' took part in the battle of Manila Bay, 1 May 1898; was promoted rear-admiral in 1901 and retired the same year. He was chairman of the commissioners of the Massachusetts Naval Training School in 1903-04.

DYER, Thomas Henry, English historian: b. London, 4 May 1804; d. Bath, 30 Jan. 1888. He traveled and studied for years to prepare a 'History of Modern Europe' (1861-64); 'History of the City of Rome' (1865); 'Pompeii' (1867); and 'Ancient Athens' (1873), all monuments of learning and critical insight.

DYER, Sir William Turner Thistleton, English botanist: b. Westmorland, London, 28 July 1843. He was educated at Oxford, and beside holding other professional posts was director of the Royal Botanic Gardens at Kew from 1885-1905. He has edited 'Flora Capen-
DYER'S BROOM — DYRES

sis'; and 'The Flora of Tropical Africa'; and
is joint author of 'The Flora of Middlesex'
(1869). He was created K.C.M.G. in 1899.

DYER'S BROOM; GREENWEED
WOADWAXEN. See Dyewed.

DYER'S MOSS, a lichen, called also archil or orchil. See Archil.

DYER'S ROCKET, DYER'S WOOL, or
WELD, a plant (Reseda luteola), of the mignonette family (Resedaceae). It is an erect herb, sparingly branched, with long, narrow spikes of greenish-yellow flowers. The plant is extensively cultivated in Europe for the beautiful yellow dye it yields, and was originally grown in American gardens for the same purpose. It now grows wild in waste places, on Long Island, and in various spots near the eastern seaboard. It is known also as woad.

DYER'S WOOL. See Dyer's Rocket.

DYERSBURG, Tenn., city, county-seat of Dyer County, on the north fork of the Deer River, navigable as far as Dyersburg; on the Illinois Central and other railroads, and about 80 miles northeast of Memphis. The neighboring country is very fertile, yielding large crops of corn and wheat. The manufacture of cotton, wagons, flour, brick, tile, staves and headings and the sawing and planing of lumber supply the chief occupations of the town. Tobacco, iron goods, machines and wooden bowls are also made here. The city owns its own electric lights and waterworks plants. Pop. 3,000.

DYES, substances employed to impart colors of a measurable degree of permanence to fabrics. They are classified according to their origin as (1) natural organic dyes—in two groups, vegetable and animal; (2) mineral dyes and (3) artificial organic dyes. The first class includes such vegetable coloring agents as indigo and logwood, and such animal dyes as cochineal. The second class includes such mineral coloring agents as chrome yellow and Prussian blue. The third class is by far the largest and most important, as it embraces the thousand and more coal-tar colors, synthetic indigo, etc. With the exception of indigo and logwood, few of the natural organic dyes are in extensive use, having been in large part superseded by coal-tar dyes of simpler application and more brilliant color. Those still in considerable use are as follows:

Anatto or annatto, prepared from the fermented seed of Bixa orellana, a tree growing in Central America, the Antilles and the East Indies. The color principle is known as bixin. It is insoluble in water but dissolves readily in alkalies. It is used on cotton direct or with a tin mordant, and gives a hue of bright orange. At present it is used chiefly in tinting butter and cheese.

Archil or orchil is developed by fermentation with ammonia principally from the lichens Roccella and Lecanora; the first growing in the Canary and Cape Verde islands, the East Indies, Madagascar, Central and South America; the second on the coasts of Norway and Sweden, Scotland, Ireland and Wales. The active principle is orcein, an alkaline salt of orcin. This dye is used in large quantities for bottoming indigo, and in conjunction with other dyes, on silk and wool, especially for carpet yarns. The color is of great body, and includes shades of red, magenta and violet. The dye appears in the market as a thick liquid called archil, a paste called persis, and a brownish or purplish powder called cudbear.

Berberine is found in the root of the barberry and several other plants. Its active principle bears the same name, and it is the only natural basic dye. It imparts a golden yellow to silk and leather, and also to cotton if mordanted. Brazilwood appears in the market as chips, rapsings and extract, of various species of Caesalpinia, natives of the West Indies, Central America, and of tropical South America, Africa and Asia. The wood yields two active dye principles, brazileum and brazilein, producing shades of pink, purple and crimson, which, however, are not fast in the laundry.

Camwood, and its allies barrwood and sandalwood, yield the coloring principle santalinum, used chiefly in conjunction with logwood and rustic dye for producing compound purple and brown shades on cotton, on wool. The colors obtained range from dull red to claret-brown. It is also used to give bottom to woolen fabrics to be dyed with indigo later.

Cochinial, as marketed, consists of the dried bodies of the females of the coccus cacti, an insect found in Mexico and Central America and other tropical countries living on the opuntia cactus. The black cochineal of commerce is produced when the insects are scalded before drying, the silver cochineal when they are dried in stoves without scalding. The coloring principle is carminic acid. Carmine is obtained by precipitation from the cochineal extract with acid salts. This dye is still much used for bright scarlet and crimson on wool with tin and alum mordants respectively. With chromium and iron mordants cochineal gives purple and with a copper mordant, claret shades.

Cudbear, see Archil.

Cutch, also known as catechu and gambier, is the dried sap of the green wood and pods of the acacia and mimosa trees, and also of the Areca palm. The gambier cutch is obtained from the leaves of the Uncaria gambier, and is called cubical cutch because it is marketed in small cubes. The coloring principles in cutch are catechin and catechu-tannic acid. Both are used in the production of olives and browns on cotton and infrequently on wool. Catechu-tannic acid dyes silk plush a rich seal brown, and with an iron mordant yields a fine black. It is also used as a bottom for some of the basic coal-tar colors.

Fustic, also known as Cuba wood and yellow wood, is obtained from the Morus tinctoria, a tree growing in the West Indies, Central America and tropical South America. The best quality comes from Cuba and Mexico. The wood is marketed in chips or ground, and an extract also is prepared which is sometimes reduced to a soft paste or solid form — often adulterated with glucose and querciton. Fustic yields to tannin color principles, mormor and maclurin, and gives bright yellow with an alum mordant, olive yellow with chrome and bright orange-yellow with tin. It is used more on wool than on cotton. At its best it is not fast.
to light. Its largest use is with logwood to produce a dead black and with cutch to produce catechu shades.

Indigo is obtained by fermentative steeping of the stems and foliage of several species of the <i>Indigofera</i> family, and to a less extent of some others. Its characteristic blue color principle is indigo, but indigo contains also another dye principle, indirubin or indigo red. It is used very extensively in dyeing both wool and cotton, and is employed also as a “bottom” for compound shades—olives, browns and blacks. Indigo extracts are produced by the action of sulphuric acid on indigo. They are, chemically, indigotin sulpho-acids, and are freely soluble in water, and dye wool with rapidity, and a brighter color than ordinary indigo; but the color fades on exposure to light.

Logwood or Campeachy wood is the product of the large and rapidly growing tree, <i>Hamatoroxylon Campechianum</i>, a native of tropical and subtropical America, Cuba, Haiti and the Greater Antilles, as well as of Jamaica and Honduras, the Campeche (Mexico) supply being practically exhausted. Logwood is white in color when first cut, the brown-red hue being developed by exposure to the air. It is marketed in the form of a concentrated extract made from the chips or rasplings after ageing and fermenting. The coloring principle is hamatein. It is used in the dyeing of silk, as it renders the fibre opaque, a quality lacking in coal-tar dyes. It is employed also in the production of cheap blacks on wool and cotton. Indigo extracts are produced with a chrome mordant, producing a bluish-black, and with a tin mordant, producing a violet tone. In conjunction with other dyes it produces blues, greens, olives and browns.

Madder, as marketed, is the ground cortex of the root of the madder plant, <i>Rubia tinc- torum</i>, a native of Asia Minor. It has been cultivated many years in Italy, France and Holland. It yields the dye principles, alizarin, purpurin, pseudo-purpurin, xanthin and chlorogenin. Madder is used in the weaving of wool and carpet yarns, but for few other purposes. With aluminium it gives bluish-red to crimson; with iron, reddish-brown to maroon; with aluminum, scarlet to pink; with copper, yellow-brown; with tin, reddish-orange.

Persian Berries are the dried fruits of several species of <i>Rhamnus</i> (buckthorn) growing wild in Asia Minor. They are also cultivated in southern Europe and the East. They yield two color principles, rhamnetin and rhamnazin. They are used chiefly in printing cotton fabrics, with aluminium mordant for bright yellow, tin mordant for orange and chromium mordant for brown. With cochineal, they produce orange and scarlet, giving redder and deeper shades than fustic or quercitron—although at increased cost.

Quercitron is the inner bark of the <i>Quercus tinctoria</i>, an oak native to America, and growing in large numbers in Pennsylvania and the South Atlantic States. It appears in commerce as the ground bark, and its extract. It contains two color principles, quercetin and quercitrin. A purified or concentrated dry extract in powdered form has the trade name of “flavine.” Quercitron imparts a bright yellow to wool and mordanted cotton and silk. With cochineal it produces bright orange shades, and with logwood gives blacks. With aluminium it produces greenish yellow; with chromium, dull yellow; with tin, bright orange; and with iron, olive to greenish black.

Robinia, a new natural dyestuff, was discovered in 1915, in the Yellow Locust, <i>Robinia pseudacacia</i>. The extract is similar to that of querciton. It is still in the experimental stage.

Saflower, the dried flower head of <i>Carthamus tinctoria</i>, cultivated in India and Egypt. Its active principle is carthamin, which produces shades of pink on bleached cotton. The color is not fast either to light or the laundry.

Saunders-wood or Sandalwood, see <i>Can-wood</i>.

Turmeric or Indian Saffron, is the ground root of the <i>Curcuma tinctoria</i>, a plant growing abundantly in China and the East Indies. The coloring principle is known as curcumin, and dissolves out of the turmeric freely with alcohol, and less freely with hot water. It imparts yellow to cotton, wool and silk, but is used principally in combination, as its color is not fast. Although mordants are not necessary, their use produces modified shades of yellow, orange and olive.

Weld is the dried tops and seeds of <i>Reseda luteola</i>, cultivated generally throughout Europe. The coloring principle is called luteolin. It is regarded as the best and fastest of the natural yellow dyes for silk, and is used chiefly on aluminium and tin mordants, yielding greenish yellow and bright yellow. With other mordants are secured shades of olive-yellow.

Young Fustic, the ground wood or extract of the Venetian Sumac (<i>Rhus cotinus</i>), a tree growing in southern and eastern Europe, the Levant, Jamaica, etc. The coloring principle is fisetin. Young fustic, which is not “fustic” at all, imparts shades of yellow which are so fugitive to light and the milling processes as to be seldom used.

Mineral dyes, though formerly in extensive use, have been largely displaced by the coal-tar dyes. However, they are generally very fast to light and the laundry, and being cheap are still employed to a considerable degree. Their dyeing qualities are due to the deposit of insoluble pigments in the fibres of the fabric dyed.

The few mineral colors now in use are the following:

Bistre, see Manganese Brown.

Chrome Yellow, chemically chromate of lead, is used on cotton only. The fabric is first impregnated with nitrate or acetate of lead, which is then changed to the oxide by ammonia, or to the sulphate by sodium sulphide. It is then passed through a weak solution of potassium bi-chromate. All the chrome colors are poisons, and they are continued in use chiefly because they weight the fabric heavily.

Chrome Orange is produced by first dyeing the fabric with chrome yellow, and then passing it through boiling dilute limewater.

Chrome Green is usually produced by first dyeing the goods with a light shade of indigo blue, and then with chrome yellow.

Khaki is produced on cotton by passing the cloth, after scouring, through a mixture of ferrous and chromic acetates and drying; then aging and passing through a boiling mixture.
of caustic soda one part and carbonate of soda three parts.  

Manganese Brown, or Bistre, is produced on cotton by impregnating the fabric with a solution of manganese chloride, and then passing it through a hot solution of caustic soda—which precipitates the manganese hydroxide in the fibre. On exposure to the air this oxidizes to a brownish hue, and the color is improved and finished by immersion in a weak solution of chloride of lime.  

Iron-buff, or Nankin Yellow, is produced by precipitating a ferric salt with an alkali, or alkaline carbonate. It is used principally on cotton.  

Prussian Blue is produced on cotton by first mordanting the fibre with ferric oxide, and then immersing it in yellow prussiate of potassium. It is also used in weighing silks which are afterward to be dyed black.  

The coal-tar colors which constitute the class of artificial organic dyes are practically innumerable. Several thousand of these dyes have been prepared and hundreds of them have been named. New ones are continually being discovered in new combinations, and many which formerly were highly esteemed have been superseded by better ones.  

From the dyer's point of view, these multitudinous dyes have been thus classified:  

I. Direct Cotton Colors, or Salt Colors— which, in a neutral or weakly alkaline bath containing common salt or Glauber's salt, dye cotton in full shades without mordants.  

II. Soluble Colors, or Sulphur Colors— which, dissolved in the aid of sodium sulphide, dye cotton in full shades from a sulphide bath without mordants.  

III. Basic Colors— those having the qualities of bases, dyeing animal fibres without mordant, and vegetable fibres with tannin mordants.  

IV. Eosins and Rhodamines— of exceptional brilliancy; the first for silks, the second for silks, wools and tannin-mordanted cotton and cotton-mixed goods.  

V. Acid Colors— salts of color acids, dyeing animal fibres without mordants.  

VI. Mordant Colors— which require metallic mordants to fix their colors.  

VII. Acid Chrome Colors— requiring an acid bath; they dye on wool with chrome mordants.  

VIII. Miscellaneous Colors— including aniline black; indigo and other vat dyes; and the insoluble azo-colors, known as "icc-colors."  

Space does not permit specification of even the coal-tar colors in common use. For a condensed review of upwards of 900 of the more prominent of these dyes the student is referred to Arthur C. Green's "Organic Colouring Matters." See also COAL-TAR COLORS.  

Production.—The United States census of manufactures for 1914 reported 112 establishments engaged in manufacturing dyestuffs and extracts in the United States in that year. They employed 3,551 persons, of whom 2,839 were wage earners, receiving annually a total of $1,613,000 in wages. The capital invested aggregated $21,283,994, and the year's output was valued at $51,996,336; of this, $7,982,341 was the value added by manufacture to the $13,237,995 worth of materials used. In addition, there were 22 establishments which reported dyestuffs and extracts as subsidiary products. Their value for the year specified was $764,353. Consult Cain, J. C., and Thorpe, J. F., 'The Synthetic Dyestuffs' (London 1913); Fay, I. W., 'Chemistry of the Coal-Tar Dyes' (New York 1911); Knecht, E., Rawson, C., and Lowenthal, R., 'A Manual of Dyeing' (London 1910).  

DYEWEE, DYER'S BROOM GREEN-WEED, or WOADWAXEN, a plant, Genista tinctoria, of the family Fabaceae. The genus comprises about 80 species, natives of Europe, northern Asia and Africa. The dyeweed is a low-braniching shrubby plant, with a few yellow nearly sessile flowers. It was originally cultivated in New England gardens because of the green dye it produced and escaping is found from Maine to eastern New York. Its medicinal value is small, although it is used in popular practice in Russia as a specific for hydrophobia.  

DYING DECLARATION, a deposition made by one who is near to death. Such declarations are admitted as evidence both in England and Scotland.  

DYING GAUL, a famous work of ancient sculpture, representing a dying Galatian and supposed to be one of a series of figures illustrating the incursion of the Gauls into Greece. The work is now preserved in the museum at Rome. It is not known whether the statue is an original or a copy, the work of Cresilas, a Grecian sculptor and contemporary of Phidias. The right arm of the statue has been restored and it is not positively known by whom this restoration was made. The work has been credited to Michelangelo.  

DYKE, or DIKE, a word variously used to represent a ditch or trench and also an embankment, rampart or wall. It is specially applied to an embankment raised to oppose the incursions of the sea or of a river, the dykes of Holland being probably the most notable examples of works of this kind in the world. Owing to the possibility of great loss of property and of life, the punishment of all neglect or for malicious mischief to dykes is extremely severe, one "placat" of Foch 1726 regulars the inundation in the province of Staten, proclaiming that "anyone cutting jams, dykes, quays, etc., will be punished with death and confiscation of all his property." The dykes which protect the Netherlands and the German coasts of the North Sea go back to the old Roman times. Apparently even before the Romans appeared the Batavians at the mouth of the Rhine protected themselves by dykes. Drusus after the conquest of Holland, 10 B.C., built an elaborate system of artificial canals and dykes. Pliny the Elder gives interesting descriptions of the artificial hills which were erected as places of refuge during the floods. Among the provinces in North and South Holland which have been protected by dykes may be mentioned the province of Hanover, 618 miles, protecting 770,000 acres of marsh land. On the left bank of the Oder River there is a dyke which protects more than 170,000 acres of land. The dyke at the delta of the Vistula protects 134,000 acres of land. On the lower Rhine, between the Weser and Holland are 115,000 acres protected by dykes. Along the Loire River are 280 miles protecting
DYKES — DYNAMICS OF MACHINERY

230,000 acres. Along the Po there are 310 miles protecting 850,000 acres. In England there are 1,750,000 acres protected by dykes. Many of the dykes of Holland are raised 40 feet above the high-water mark and are wide enough at the top for a general roadway or canal, sometimes for both.

In the United States the term dyke is almost wholly restricted to the structures of more or less permanence built in various ways in the best stream to which it is mounted. At the low water cross-section, concentrate the current, increase its local scouring effect and thereby deepen the river channel. The earthen embankments designed to restrain the flood waters are called levees. The most notable examples are found along the Mississippi River. These levees are placed some little distance back from the river and according to the local conditions vary in height from 2 to 3 feet to over 20 feet. Levee building began many years ago along the lower part of the river and it has been carried on practically continuously ever since. See Mississippi Levee System, and Reservoir.

DYKES, James Oswald, Scottish clergyman: b. Port Glasgow, 14 May 1835; d. 1 Jan. 1912. He entered the Presbyterian ministry in 1859, and in 1869 became minister of the Highgate Square Church in London. From 1888 to 1907 he was principal in the theological college of the Presbyterian Church of England. He was the author of 'Beauties of the Kingdom' (1872); 'Law of the Kingdom' (1873); 'Relations to the Kingdom' (1874); 'Daily Prayers for the Household' (1881); 'Plain Words on Great Themes' (1892); 'The Christian Minister and His Duties' (1908); 'The Divine Worker in Creation and Providence' (1909), etc.

DYKES, John Bacchus, English composer and theologian; b. Hull, 10 March 1823; d. 22 Jan. 1876. He was graduated at Cambridge, where he won distinction as a musician. He was ordained in 1847 and was appointed minister of the Church of England in 1849. In 1862, being appointed vicar of Saint Oswald's in Durham, he resigned the precentorship, retaining the minor canonry. Becoming involved in 1874 in a dispute with his bishop on questions of church ritual, he was brought to an ecclesiastical trial, after which his health broke completely and his death soon followed. He was buried in the churchyard of Saint Oswald. As a testimonial of affection for him, a fund was raised for the care of his family and within a few weeks reached the notable sum of $50,000. He was a joint-editor of 'Hymns Ancient and Modern', and composed, besides many services and anthems, a large number of hymn tunes remarkable for harmonic beauty and of striking individuality; most of which are to be found in all English collections. Among these are Bonar, Dominus Regit Me, Gerontius, Hodnet, Hollingside, Horbury, Lux Benigna, Melita, Nicea, Saint Ascribed, Saint Anatolius, Saint Bees, Saint Cuthbert, Saint Godric, Saint Sylvester — to mention only a few of those which have become famous. See Lightwood, J. T., 'Hymn-Tunes and Their Story' (London 1908). Besides his musical works he left many literary remains in the line of sermons and contributions to religious periodicals.

DYNAGRAPh, an apparatus used in modern railroad for recording the oscillations of the car, variations in the level of the rails, condition of the rail joints, the alignment of the track and the elevation of the outer rail on curves. These conditions are recorded on a paper ribbon in such a way that any one of them may be accurately located on the ground afterward. The action of the instrument is through gearing to the wheels of the car in which it is mounted. By electric connections a record may also be made of the amount of coal and water consumed by the locomotive hauling the train, the varying pressures of steam in the boiler, the tension on the drawbar and the distance traveled in any particular group of seconds, minutes or hours during which the train is running. The dynagraph is in constant use on all the principal railroads.

DYNAmeter, an instrument in the nature of a micrometer tube attached to the eyepiece of a telescope for measuring its magnifying power. This power is the ratio of the focal distance of the object glass to the focal distance of the eye-piece considered as a single lens. This being the same as the ratio of the diameter of the aperture of the telescope to the diameter of its image formed beyond the eye-piece, the object of the instrument is to measure the exact diameter of this image.

DYNAMIC METAMORPHISM. See Metamorphism.

DYNAMIC UNITS. See Units of Measurement.

DYNAMICS OF MACHINERY. When an engine has been proportioned to sufficient capacity and strong enough in all its parts to transmit or develop a given amount of power, there still remains the problem of dynamic design which deals with the engine in operation. The requirements in dynamic design are freedom from vibration, constant speed for a given load, and automatic adjustment of the energy developed to the work to be done. Vibrations are produced by the forces which arise from the accelerations of moving masses. An engine or motor in which these forces are counteracted is said to be balanced. The speed for a given load is controlled by means of a flywheel, a governor adjusts the supplied energy to the load.

Rotating Balance.—A particle of weight $W$ revolving with an angular velocity $\omega$ radians per second in a circular path of radius $r$ exerts a force called the kinetic reaction, $mg$, where $mg = W$, on the constraint which deflects it from a rectilinear path. If the kinetic reactions on a rotating shaft are not in equilibrium, which is usually the case for very high speeds, the shaft will bend and therefore whirl and wear its bearings out of shape. An account of whirling, which lack of space forbids here, is given in Stodola's 'Steam Turbine.' The problem has been investigated experimentally by Dunkerly, 'On the Whirling and Vibrations of Shafts' (Phil. Trans. Vol. CLXXXV) in which earlier references are cited; for a rigorous theoretical discussion consult Chree, 'The Whirling and Transverse Vibrations of Rotating Shafts' (Proceedings of Physical Society, London, Vol. XIX). Torisonal vibrations are discussed by Chree and
DYNAMICS OF MACHINERY

When a number of masses all move in one plane perpendicular to the axis of rotation as in Fig. 1 the criterion for a balanced system of kinetic reactions is found as follows: Assume the centroid C of all the masses to lie at a distance from the axis. Any infinitesimal element of mass \( m \), situated at \( (r, \alpha) \), exerts a force \( \omega r m \) along \( \omega \). The reaction normal to \( OC \) in the plane of rotation is

\[
\omega \sum m \cos \theta = \omega \sum r m.
\]

whence the resultant kinetic reaction of a system of masses rotating in one plane normal to the axis is the same as if the total mass were concentrated at the centroid. Therefore if the resultant is to vanish, i.e., if the system is to be in running balance, the centroid must lie on the axis of rotation; from a viewpoint more convenient for the solution of problems, the system is balanced when the kinetic reactions are in equilibrium. \( \omega \) may be taken as unity. But when the centroid is on the axis the system will remain in any position into which it is turned. This is called standing balance. Thus rotating parts such as armatures, turbine runners and flywheels that are constructed to be in standing balance will also be in running balance at any speed provided the centroids of all these parts are coplanar. This condition is usually not fulfilled; furthermore although perfect balance is independent of \( \omega \), unbalanced forces increase as \( \omega \) so that deviations from equilibrium so small as to be unnoticed when the system is at rest may yet have an appreciable effect at great speeds. For example, if a system of 1 lb. weight is mounted eccentrically 0.0001 inch, the turning moment due to gravity is only 0.00009 ft-lb, while at a speed of 1,500 r.p.m. the unbalanced radial force is almost 0.7 lb., at 2,500 r.p.m. about 1.9 lb.

Fig. 2 shows the general case of rotating balance where the masses are not coplanar; \( i \) is the projection on a plane through the shaft and one arm \( r \), and \( ii \) is an end view of \( i \). If the kinetic reactions on the shaft are denoted by \( C, C_1, C_2, \ldots \), along \( r, r_1, r_2, \ldots \) in \( i \), the conditions for equilibrium are found by resolving along and perpendicular to \( r \) in \( ii \) and by taking moments about a perpendicular to both \( r \) and the shaft, and also about \( r \) itself.

There results

\[
C = C_1 \cos \theta - C_2 \cos \theta = \ldots = 0 \quad (1)
\]

\[
C_1 \sin \theta + C_2 \sin \theta = \ldots = 0 \quad (2)
\]

\[
C_3 \cos \theta + C_4 \cos \theta = \ldots = 0 \quad (3)
\]

\[
C_3 \sin \theta + C_4 \sin \theta = \ldots = 0 \quad (4)
\]

Four unknowns can be determined from these four equations; but not more than two of them can be lengths \( l \) because only two equations contain \( l \). The most convenient unknowns for practical work are two pairs of reaction components, one pair at each of two arbitrarily selected points. The reactions themselves may then be found and the proper masses and radii selected accordingly. In short, any system of revolving masses can be balanced by two masses properly placed; the positions of their radii along the shaft are arbitrary but their directions are not. The foregoing solution may be carried out graphically. Suppose that in Fig. 2 the magnitudes and positions of \( M_1, M_2, M_3 \) are known and it is required to find \( C = m \omega^2 \) and \( C = m \omega^2 \) in magnitude and direction. Equations (3) and (4) show that if the moment of each force

\[
\omega \Sigma m \cos \theta = \omega \Sigma m,
\]

about an axis perpendicular, at any point, to the plane through the shaft and the force be regarded as a vector having the direction of the force, the vector sum of all the moments will be zero. Two like forces on opposite sides of the axis have opposite moments which must have opposite senses. By taking the origin first at one unknown force and then at the other and drawing the vector polygon of the moments, the moments of the required kinetic reactions can be found. These determine the forces themselves since the lever arms \( l \) are known. The work may be checked by constructing the force polygon corresponding to Fig. 2, ii. The method of procedure will now be illustrated.

Example. Two cranks at right angles are of 10 inch radii, the distance between them being 1.5 ft. The mass at each crank weighs 320 lbs. Find the balance masses at 1 ft. outside of each crank.

Take \( \omega = 1 \), then \( m \omega^2 = 8.33 \). Fig. 3 shows a perspective view of shaft as a free body; \( H, V \) and \( H', V' \) are the horizontal and
vertical components of the required forces. \( H \) and \( H' \) will evidently point away from the reader. For equilibrium

\[
V + V' = 8.33, \quad H + H' = 8.33
\]

\[
3.5 H' = 8.33 \times 2.5, \quad 3.5 V' = 8.33 \times 1
\]

\[H' = 5.96, \quad H = 2.37, \quad V' = 2.38, \quad V = 5.95.\]

The results were obtained on a slide rule; evidently \( V = H' \), \( V' = H \).

The resultant \( C \) of \( H \) and \( V \) is inclined at arctan \( 5.95/2.37 = 68^\circ 10' \) below \( H \).

To solve the problem graphically select an origin at the point of application of each unknown force and take the moment of each force about an axis normal to the plane through that force and the shaft. The moment polygons are shown in Fig. 4.

![Fig. 4](image)

Now find \( C \) and \( C' \) and from them calculate what masses at the given radii will balance the two cranks.

Unfortunately the subject of revolving balance is not disposed of so easily. A locomotive wheel-pair or a crank shaft may be symmetrical in form and may even be in standing balance without however being in running balance. A disc carefully turned on a lathe is not necessarily in balance because the metal might not be homogeneous. Even if its centroid is on the axis it is quite possible that the material on one side of a plane through the body and perpendicular to the axis may not be dynamically symmetrical with the material on the other side, or the plane of the wheel might not be exactly perpendicular to the axis. The above mathematical methods are indispensable in arranging the positions of cranks and balance weights but the final adjustments must be made experimentally. For this purpose the part to be balanced is mounted and run on a movable platform which can respond to the unbalanced reactions produced by rotation. The platform is sometimes supported by a spring at each corner and vibrates unless running balance exists. In the Norton Balance Indicating Machine, made by the Norton Grindining Company of Worcester, Mass., the axle holding the piece to be examined is mounted on two pendulums which oscillate in response to the motion of unbalanced masses. For details of the method consult a pamphlet on Dynamic Balance issued by the Norton Company. For the Akimoff machine consult Akimoff, 'Recent Developments in Balancing Apparatus' (in Journal of the American Society of Mechanical Engineering, December 1917), also 'Transactions American Society of Mechanical Engineering' (Vol. XXXVIII, p. 367). The Lavaczech machine is described in Jour. A. S. M. E. (March 1916) and in Zeitschrift Ver. deut. Ing. (Vol. LX, Nos. 1, 2, 1916).

Reciprocating Balance.—Fig. 5 represents the connecting rod mechanism, \( P \) being the crankpin and \( C \) the crosshead.

![Fig. 5](image)

If the angular velocity \( \omega = \theta \) of the crank is assumed constant the acceleration of \( C \) is the second time-derivative of \( x \) and is negative because \( x \) decreases as \( \theta \) increases. Now

\[
x = r \cos \theta + l \cos \phi
\]

but since \( \sin \phi = r/l \cos \theta = \sin \theta \)

\[
\cos \phi = \left( 1 - \frac{\sin^2 \theta}{n^2} \right) ^{1/2} = 1 - \frac{\sin^2 \theta}{2n^2}, \quad \text{approx.}
\]

\[
x = r \cos \theta + l - \frac{\sin^2 \theta}{2n}, \quad \text{approx.}
\]

\[
v = -x = r \omega \left( \sin \theta + \frac{\sin^2 \theta}{2n} \right), \quad \text{approx.}
\]

\[
a = -x = r \omega \left( \cos \theta + \frac{\cos^2 \theta}{n} \right), \quad \text{approx.}
\]

If the mass of all reciprocating parts is \( m \) then \( ma \) is the kinetic reaction in the line of stroke transmitted by the connecting rod to the crankpin. But the connecting rod also has mass; if we neglect rotation and consider only translation its mass may be divided into two parts, one reciprocating with \( C \) and one rotating at \( P \). Their centroid must coincide with that of the rod. If \( m \) thus includes the piston and crosshead system and the proper part of the rod, a variable force

\[
Mr \phi \cos \theta + \frac{\omega^2 l}{4}, \quad \text{approx.}
\]

acts at \( P \) in the line and direction of the stroke. This force is transmitted to the shaft and produces to and fro vibrations. There are other terms containing \( \cos \phi \), \( \cos \theta \), etc. but they do not contribute more than about \( 1/4 \) per cent to the expression. The first or primary term equals the component, in the line of stroke, of a mass \( m \) rotating at the crankpin with velocity \( \omega \); it may be equilibrated by attaching an equal mass diametrically opposite \( P \) at radius \( r \). But the vertical component \( Mr \phi \sin \theta \) of the kinetic reaction exerted by the attached mass will be unbalanced. It produces the so-called hammer-blow on the rails of a locomotive. Perfect primary balance of a single cylinder engine is therefore impossible; any attempt results in compromise. It is customary to balance only two-thirds of the reciprocating masses. That is, all the parts actually rotating, two-thirds of the parts actually reciprocating, and the proper part of the connecting rod are regarded as concentrated at the pin and then balanced for rotation.

The secondary term equals the stroke component of a mass \( M \) rotating at radius \( r/4 \) with velocity \( 2\omega \); this secondary crank makes twice the angle with the line of stroke that the actual crank does. It is impossible to balance the secondary force in a single cylinder unless some auxiliary mechanism is introduced to rotate the secondary imaginary crank. The secondary
effects are always large enough to produce decided vibrations such as occur in the usual type of four-cylinder automobile engine in which the primary disturbances are counteracted.

Since the above process reduces reciprocating to rotating balance the necessary conditions to be fulfilled for a multicilinder engine are

\[ \text{Primary } \Sigma m_{i}r_{i} = 0, \Sigma m_{i}r_{i}x = 0 \]
\[ \text{Secondary } \frac{\Sigma m_{i}r_{i}^2}{4l} = 0, \frac{\Sigma m_{i}r_{i}^2}{4l} \times x = 0 \]

where \( x \) is the distance of any crank from any assumed origin. This is Schlick's method of balancing a multicilinder engine. Consult Schlick in Zeit. d. Verein Dest. Ing. (1904). For a general discussion consult Schubert, Mitt. math. Gesell. (Hamburg Bd 2, Heft 8, 1898); Schlick in Trans. Inst. Naval Arch. (Vol. XLII, 1900). The subject is thoroughly treated in Lorenz, 'Dynamik der Kurbelgetriebe' (1901); Dalby, 'Balancing of Engines' (2d ed.); Sharp, 'Balancing of Engines' (1907). In a two-crank engine with equal reciprocating weights and cranks at 180 degrees the primary forces are balanced but there is an unbalanced primary moment about a vertical axis; secondary effects cannot be balanced. For three cranks at 120 degrees the forces of both orders vanish but not the moments. Primary and secondary balance will obtain in a four-crank engine when two of the cranks are coplanar; this arrangement is not practicable; in the usual arrangement all except the secondary moments vanish. Five- and six-cylinder engines will be in complete balance when the cranks are 120 degrees apart, no two being coplanar; in the former the first and fourth cranks must be parallel and also the second and fifth; in the latter the first and sixth, second and fifth and third and fourth. The rotational motion of the connecting rod is only partially allowed for above. To find its exact effect imagine the rod replaced by two particles \( m_{1} \) and \( m_{2} \), being at the crosshead and \( m_{3} \) at some distance \( d_{3} \) beyond the centroid \( G \) as in Fig. 6. If the new system is to have the same mass \( m \), the same centroid, and the same moment of inertia \( m d_{2}^2 \) as the rod, \( d_{1} \) being the distance from \( m_{1} \) to \( G \), and \( d_{2} \) from \( G \) to \( m_{2} \),

\[ m_{1} + m_{2} = m, \quad m_{1} d_{1} = m_{1} d_{1}, \quad m_{2} d_{1} + m_{2} d_{2} = m d_{2} \]

so that \( d_{1} + d_{2} \) is the length of the equivalent simple pendulum which can be found experimentally. The position of \( G \) is got by weighing the ends of the rod. Let \( \alpha_{1} \) and \( \alpha_{2} \) be the accelerations of \( m_{1} \) and \( m_{2} \); then the forces \( F_{1} \) and \( F_{2} \), producing \( \alpha_{1} \) and \( \alpha_{2} \), will have a resultant \( F \) causing the actual motion of the rod. Hence \( F \) must be parallel to \( \sigma \) and concurrent with \( F_{1} \) and \( F_{2} \). In kinematics (q.v.) it is shown how to find the accelerations graphically. To find the effect of the kinetic reaction exerted by the rod resolve \( F \), reversed, into components \( P \) and \( Q \), \( P \) being perpendicular to the crosshead guides and \( Q \) passing through the crankpin. \( P \) tends to lift and rock the engine and \( Q \) exerts a perturbing moment around the shaft.

The Flywheel.—The driving moment exerted by a piston engine varies throughout the stroke on account of the obliquity of the connecting rod, the varying steam or gas pressure and the kinetic reactions of the accelerating masses. If \( P \) is the resultant steam force on the piston at any instant and \( m \) the mass of the reciprocating parts, the effective piston force at the crosshead is \( F = P - ma \). \( P \) is obtained from indicator diagrams and is the difference between the forward and the back gas forces; the acceleration diagram of the crosshead (see Kinematics) gives \( ma \). These, together with \( F \), are shown in Fig. 7 for half a revolution or one stroke. To find the driving moment produced by \( F \) consider Fig. 8. The thrust along the rod is \( T = F \cos \phi \) and its lever arm is \( d = h \cos \phi \)

\[ Td = Fh \]

where \( h \) is to be found graphically from the intersection of the connecting rod with a vertical through the shaft as in Fig. 8. To allow for the inertia of the rod the moment of \( Q \) about the shaft, see Fig. 6, must be subtracted from \( Fh \); the resultant \( D \) is the effective driving moment and is shown roughly in Fig. 9, where, however, \( Q \) is neglected. It is usually considered accurate enough to neglect the rotational effect of the rod and to assume, as in balancing, that part of it reciprocates with the crosshead. The work done by the driving mo-
ment in a single revolution equals the work done by the resistance, for otherwise the engine would speed up or slow down progressively. If the resisting moment, say $R$, is constant, as it nearly is in dynamics, and from spinning machines, etc., it may be represented by the ordinates of the rectangle in Fig. 9 whose area equals that under the curve. Even if the resistance is variable, $R$ is the average moment per cycle; no work is gained or lost on account of changes in kinetic energy because the motion repeats itself after each revolution. The kinetic energy changes only the distribution of the work put in $R$ is obtained from the brake horse power. Friction losses have not been considered but they are comparatively small in a well-designed engine and are best found experimentally.

The area of the $D$ curve above the rectangle equals the area below and is the change in kinetic energy. From (1) to (2) $R > D$ and the engine slows down; from (2) to (3) $R < D$ and the motion is accelerated. The energy acquired from (2) to (3) is used up from (3) to (5) and then acceleration begins again. The velocity is greatest at (3) and (6) and least at (2) and (5); suppose it to be larger at (3) than (6) and less at (2) than (5). Now if $E$ is the kinetic energy of the moving parts at any instant, $\Delta E = E_s - E_i$ is the energy stored in them and equals the work done by $D - R$ from (2) to (3), i.e., the shaded area. $\Delta E$ is called the fluctuation of energy. If the moment of inertia of all rotating parts is $I$, and if for a first approximation the reciprocating masses are neglected

$$\Delta E = \frac{1}{2} (\omega^2 - \omega_s^2) = I (\omega - \omega_i) (\omega_i + \omega) \frac{\omega_s}{2}$$

where $\omega$ is the crank velocity. Usually the change in speed is not large so that approximately $\omega = \omega_s = 2\omega$, where $\omega$ is the mean speed. If the mean energy is $E = I \omega^2/2$

$$\frac{\omega_s}{\omega} = \frac{dE}{2E}$$

which is the coefficient of fluctuation of speed and is half the coefficient of fluctuation of energy. In piston pumps and shearing and stamping machines it may be as high as 0.05; in dynamos for lighting purposes it may be 0.01 and even less. By means of this formula a flywheel can be designed to keep the extreme speeds within specified limits; $\Delta E$ is to be got from Fig. 9. In multicylinder engines the moment curves for the separate cylinders are superposed; the resultant has smaller fluctuations from the mean than the components.

**Governors.**—The function of a governor is so to regulate the supply of power according to the varying work an engine has to do that the mean per revolution speed changes as little as possible. The flywheel on the contrary equalizes the driving moment during one revolution. If the load is constant no governor is required although of course a flywheel is necessary. The governor controls the energy supplied to a steam engine, for example, by changing the point of cut-off to alter the quantity of steam or by operating the throttle valve to alter the pressure. It should act only when the change in speed is greater than the cyclic fluctuation. A governor which operates during the small cyclic variation which it is the function of the flywheel to smooth out is too sensitive; it will oscillate or hunt and by actuating the valve or cut-off mechanism it will change the power so as to reinforce the oscillations and thus produce irregularities in speed which it was designed to correct. The speed of an engine cannot be kept absolutely constant because a governor acts only through a change in speed; moreover since the action is not instantaneous the supply of power always lags behind. The most that can be expected is to keep the variation of speed within sufficiently narrow limits.

Centrifugal governors, which are commonly used, operate by means of the kinetic reactions of revolving masses. The first governor was invented by Watt and was merely a double conical pendulum; as the balls rose or fell they actuated a suitable mechanism for controlling the supply of power. The general principles will be explained in connection with the loaded governor, a modification of the Watt form due to Porter. The vertical spindle is geared to the shaft, the sleeve at the bottom being linked to the power controlling mechanism. This may be taken as the type of all centrifugal governors in some, e.g., the Proell and the Hartnell, the load is replaced by a spring; in others such as the Harting the revolving weights are directly connected by a spring without the aid of oblique arms. When the governor is in equilibrium at speed $\omega$, each ball is acted on by the forces shown; for brevity we shall suppose the arms to be of negligibly small mass. Then

$$T \cos \theta = T' \cos \theta + w$$

$$(T + T') \sin \theta = w = \frac{r \omega^2}{g}$$

$$2T' = \frac{w}{g} \frac{r \omega^2}{\sin \theta} = \frac{w}{\cos \theta}$$
If the sleeve weight is \( W \) then \( 2T \cos \theta = W \)
whence \( \frac{w}{g} = \left( w + W \right) \tan \theta \). When the speed increases or decreases the sleeve tends to move up or down and a friction force \( F \) acts at the sleeve to oppose the motion. Friction \( F \) will consequently permit a certain change in speed \( \Delta \omega \) without a change in configuration.

Hence \( \frac{w}{g} \left( \omega + \Delta \omega \right) = \left( w + W \right) \tan \theta \)

which by the previous equation becomes

\[
\frac{w}{g} \left( 2 \omega \Delta \omega + \Delta \omega^2 \right) = F \tan \theta
\]

where \( \Delta \omega \) is the change on each side of mean speed which the governor will allow without acting. If \( 2 \Delta \omega \) is less than the fluctuation within a cycle the governor is too sensitive to be useful. Suppose now that the speed changes by more than \( \Delta \omega \), increases, say, from \( \omega \) to \( \omega + \Delta \omega \), then the wall will fly outward and the sleeve will rise. Unless the sleeve load is sufficiently increased, as in the spring-loaded form, the sleeve will overshoot the position corresponding to \( \omega \) and oscillations will be set up. We are dealing only with the case considered by the kinetic theory consult Lecompte, 'Dynamique appliquée' (1908); Kroener, 'Die Geschwindigkeitsregler der Kraftmaschinen' (1912), and for an exhaustive treatment, Tolle, 'Die Regelung der Kraftmaschinen' (1910). But the rise of the sleeve is accompanied by the work of operating the valve; this produces an average force \( P \) on the sleeve, \( P \) being called the effort. The work done by \( P \) is usually called the power of the governor, but powerfullness is a better name, because power is used in a different sense in mechanics. Sensitivity is measured by the rise or fall of the sleeve for a given percentage change in speed. A governor is stable when each configuration corresponds to a definite speed and vice-versa. When equilibrium exists for only one speed the governor is isochronous and is then infinitely sensitive. Isochronism will obtain when the balls are so linked that they rise and fall in parabolic paths; it is not desirable, since it causes hunting.

The functioning of a governor is exhibited most clearly by means of diagrams. The kinetic reaction exerted by the balls of any centrifugal governor is called the controlling force and is denoted by \( C \) where \( C = \frac{mr^2 \omega}{\theta} \), \( m \) being the mass of the two balls. Now plot \( C \) as ordinate and \( r \) as abscissa; the curve, Fig. 11, so obtained is the characteristic and was suggested by Hartnell (Proc. Inst. Mech. Eng. 1882) and developed by Tolle (Zeit. d. Verein deutsch. Ing. 1889). For the Porter governor \( C \) is twice the value of \( w \), \( \tau \), \( g \) given below Fig. 10. Friction is omitted. The power or powerfullness is by definition, see above, the area under the \( C \) curve. The properties of the characteristic are usually stated without sufficient proof; the necessary details are as follows. From \( C = \frac{mr^2 \omega}{\theta} \)

\[
\frac{dC}{dr} = \frac{C}{r} + 2mr \omega \frac{d\omega}{dr}
\]

If \( \omega \) is constant for all values of \( r \) the governor is isochronous. In this case \( \frac{dC}{dr} = \frac{C}{r} \) and the locus is a straight line through the origin. If \( r \) increases with increase of \( \omega \) the sleeve is lifted and reduces the power input. Then since \( \frac{d\omega}{dr} \) is positive, \( \frac{dC}{dr} > C/r \) whence the condition for stability is that the slope of the characteristic curve at any point must be larger than the slope of the line through that point and the origin. If \( r \) decreases for an increase in \( \omega \) then \( \frac{d\omega}{dr} \) is negative and \( \frac{dC}{dr} < C/r \), which implies instability. The coefficient of fluctuation of speed can be found from Fig. 11. Let \( C \) correspond to the normal configuration at mean speed, and \( C_1 \) and \( C_2 \) to the extreme speeds. Draw a vertical at any point and radii through \( C_1, C_2, C_2 \) to cut it at \( c_1, c_2, c_3 \). If \( b \) is the abscissa to the vertical, \( c = \frac{bm}{m} \) and as \( \omega = \frac{\omega_1 + \omega_2}{2} \), approximately, the coefficient of fluctuation is \( \frac{c_3 - c_1}{c_2 - c_1} = \frac{\omega_2 - \omega_1}{2 \omega} \).

We have excluded friction; its effect is to shift the characteristic up or down as the balls fly out or in. The controlling force at the balls produces an effort \( P \) at the sleeve where there is also a static force \( S \) due to the load or spring and the power regulating mechanism. L. Rith (Les Regulateurs à force centrifugale, Mémoirs de la Soc. des Ing. Civ. September 1905, No. 9) plots the \( P, \omega \) and \( S, \omega \) curves for several positions of the balls. These loci are all straight lines and are useful in studying the behavior of a governor. Consult Dalby, 'Steam Power' (§ 110, 1915) for the details.

RICHARD F. DEIMEL,
Assistant Professor of Mechanics, Stevens Institute of Technology.

DYNAMITE (from Greek dynamis, power), an explosive invented by Nobel in 1866 and originally consisting of infusorial silica or diatomaceous silica, called 'kieselguhr,' and nitroglycerin. The kieselguhr, being composed of the siliceous skeletons of micro-organisms, is a very fine, dry powder with a great capacity for absorbing and holding liquids, and it will absorb and retain three times its own weight of nitroglycerin, so that the product contains 75 per cent by weight of the nitroglycerin, and is known as dynamite No. 1. Other grades are made by adding less nitroglycerin to the absorbent or dope. The name has now been extended to cover a great variety of pulverulent or plas-
tie solid mixtures of which nitroglycerin is a component.

Dynamite is fired by means of a detonator or blasting cap. As the percentage of nitroglycerin in dynamites with inert bases is reduced, they become more difficult to detonate until when the nitroglycerin is below 10 per cent they cannot, according to Howe, be detonated at all. This does not hold true for dynamites with active bases. Dynamite is usually put up in cylindrical brown paper wrappers, closed at each end and coated with paraffin. These cartridges or "sticks," as they are called, are usually from one to two inches in diameter and eight inches long, and they are packed for transportation in sawdust in wooden cases, there being 50 pounds in each case. The sticks are paraffined to prevent water reaching the dynamite, as this drives the nitroglycerin out of the kieselguhr dynamites and dissolves the nitrate of soda in the nitro-lignan dynamites, thereby diminishing their efficiency. Good dynamite is of about the consistency of cigarette paper, according to the absorbent used, magnesia powder being snow white, kieselguhr dynamite No. 1 pearl gray to red, carbo-dynamite black, the lignin dynamites about the color of coarse brown sugar. There is usually a little sodium, calcium, or magnesium carbonate, mixed with the dope. Dynamite keeps as well as the nitroglycerin, from which it is made. It is safer than the latter, because it avoids the liquid state, while from its softness it will bear blows better. Its sensitiveness to blows increases very rapidly with the temperature, so that, according to Eisler, "at 350° F., the fall upon it of a dime will explode it." At ordinary temperatures it may be exploded by firing musket balls into the mass. The firing point of dynamite is about 180° C. (356° F.), and at this temperature it either burns or explodes. If free from all pressure, jar, vibration, or force of any kind, it burns; otherwise, it explodes. If a thin layer be placed on a plate of tin and heated over a burner the nitroglycerin volatilizes or takes fire. If the layer is of any considerable depth, say over a quarter of an inch, it explodes. This is a dangerous experiment. When heated to any temperature less than this, it is exploded by a detonator, or, better, jar, or vibration with an ease dependent on the temperature and time of exposure. When ignited in comparatively small quantities dynamite simply burns away fiercely, but with moderate and larger amounts ignition causes explosion. To safely destroy dynamite it should be treated with a solution or emulsion of an alkaline sulphide such as the spent lime from gasworks. High temperatures, much below the ignition or explosion temperature, cause the nitroglycerin to exude, or in technical terms, "they will make the powder leak," hence a dynamite should be made to resist exudation at the highest temperature to which it may be exposed.

Dynamite freezes at about 40° F., and remains frozen at temperatures considerably exceeding this. Solidly frozen it cannot be detonated except with great difficulty and uncertainty, but if loose and pulverulent it may be detonated, though the efficiency is much diminished, hence when frozen it is practically useless as a dynamite, except as "tempered" for use. This operation requires great care and the instructions issued with each case should be closely followed. Many persons suppose that since cartridges of unfrozen dynamite may sometimes be set on fire and burned without exploding, it is safe to warm it upon a stove, or in an oven, or to boil it over a stove, or in various other ways which usually lead to a verdict of "accidental death." It cannot be too strongly impressed upon the minds of those handling it that if dynamite or other nitroglycerin preparations are gradually warmed up to a temperature approaching their explosion temperatures they become extremely sensitive to the least shock or blow, and once that point is reached they do not simply ignite, but they explode with great violence, and further that, owing to the poor conductivity of the mass, a portion of it may become raised to this temperature and explode the whole.

Dynamite has a specific gravity of 1.5 to 1.6. In his earlier experiments with absorbents Nobel in 1863 placed gunpowder in a zinc case and filled the interstitial spaces with nitroglycerin. This might be called a dynamite with an active base, but that the nitroglycerin was greatly in excess of that existing in dynamites. See Explosives; Nitroglycerin; Powder.

DYNAMO ELECTRIC MACHINERY. See Electric Machines; Generators, Electric.

DYNAMOMETERS AND THE MEASUREMENT OF POWER. In designing a modern industrial plant or manufactory and in estimating the amount and cost of power for its operation, an accurate knowledge of the amount of power absorbed by the different machines is not only desirable, but essential to economy and efficiency. If the power required is not known the engine or motor provided may prove incapable of doing the work; or, on the other hand, the motive power may be largely in excess of that required: in either case there is an unnecessary expense—in the first case, in remedies the deficiency; and, in the second, in the daily expenditure for excess of power to overcome friction and other losses. If a more accurate knowledge of the power required to drive machine-tools were known, there would be a greater economy in running them. Moreover, the increasing use of electric motors and internal combustion engines for various purposes has created a demand for accurate determinations of the power developed so that exact methods must be employed in measuring the power.

The attempt to determine the amount of horse power given up by a motor, or required to operate a machine, by considering the velocity and width of belt used in a similar machine is futile and very misleading results are obtained; for while this method will give a close approximation to the amount of power a belt of a given width ought to transmit at a given velocity, there is nothing definitely known about the actual stress in the belt, therefore there cannot be anything definitely known about the power transmitted by it.

The only satisfactory method of ascertaining the amount of power is by the use of some form of dynamometer—by which is meant an instrument or machine for measuring the power
DYNAMOMETERS AND THE MEASUREMENT OF POWER

exerted by a prime mover, or the amount of power consumed by a machine or group of machines. Among the many machines and devices for measuring power one of the simplest

![Prony Brake Diagram](image)

is the Prony friction brake. Primarily this consists of a lever $L$, Fig. 1, connected to a revolving shaft or pulley in such a manner that the friction induced between the surfaces in contact will tend to rotate the arm in the direction in which the shaft revolves. This rotation is balanced by weights $P$, hung in the scale-pan at the end of the lever. A counterpoise attached to the brake-arm is often used in order to balance it before adding weights in the scale-pan. If not balanced, the weight of the lever-arm must be ascertained and its moment added to the total moment of the weight to obtain an accurate measure of the friction. In order to measure the power for a given number of revolutions of pulley, weights are added to the scale-pan and the bolts $bb$ tightened, until the friction induced balances the weights and the lever is maintained in its horizontal position, while the revolutions of shaft per minute remain constant. That this measure of the friction is equivalent to a measure of the work of the shaft will be seen when one considers that the entire driving power of the shaft is expended in producing this friction at the required number of revolutions per minute—and this driving power is equal to the mechanical effect of the shaft when running at the same speed in the performance of useful work.

A regulator or dash-pot attached to the end of the lever-arm or scale-beam may be used with the Prony brake—and other various forms of dynamometer in which the pressure is weighed, in order to maintain a more even balance and to prevent vibrations and sudden shocks due to momentary slip of the belt or inefficient lubrication of the brake. Instead of hanging weights in a scale-pan, as in Fig. 1, the friction may be weighed on a platform-scale; in this case the direction of rotation being the same, the lever-arm will be on the opposite side of the shaft as shown in Fig. 2.

![Water-cooled Brake Diagram](image)

This brake consists of a flexible metal strap to which are fitted blocks of wood forming the rubbing surface; the ends of the strap are connected by an adjustable bolt clamp, by means of which any desired tension may be obtained. A small stream of water constantly discharges into the pulley rim which is provided with internal flanges; a waste pipe $p$, with its end flattened, is so placed in the trough that it acts as a scoop, and removes all surplus water.

![Alden Brake Diagram](image)
The horse power or work of the shaft is determined from the following: Let \( W \) = work of shaft in foot-pounds per minute, equals work absorbed per minute; \( P \) = unbalanced pressure or weight in pounds, acting on lever-arm at distance \( L \); \( L \) = length of lever-arm in feet from centre of shaft; \( V \) = velocity of point in feet per minute at distance \( L \), if arm were allowed to rotate; \( N \) = number of revolutions per minute; \( H \). \( P \) = horse power. Then will \( W = PV = 2LNP \); therefore since 
\[
H. P. = \frac{PV}{33,000} \quad H. P. \text{ will equal } \frac{2LNP}{33,000}
\]
If \( L = 33 \) then \( H. P. \) will equal \( \frac{NP}{1,000} \).

It will be evident that leather belts and ropes may be used as friction brakes to absorb the power of a shaft or motor. In such cases it becomes necessary to ascertain the back tension in the rope or belt and subtract this from the total weight or pull on the other side.

A disc absorption-dynamometer, by which any desired constant load can be maintained on the engine, or motor, is the invention of Mr. George Alden, of Worcester, Mass. This dynamometer is essentially a friction brake in which the pressure causing the friction is distributed over a comparatively large area, thus giving a low intensity of pressure between the rubbing surfaces.

This friction is produced by the pressure of water acting upon two copper plates in contact with a smooth cast-iron disc, keyed to the shaft which revolves in a bath of oil between the plates. These latter are secured by a water-tight joint to a casing which does not revolve, and to which is bolted a lever-arm carrying weights as in an ordinary Prony brake. The shell or casing is so constructed that it permits an equal pressure upon both sides of the disc—a sufficient quantity of the water being allowed to pass through the machine to carry off the heat due to the energy absorbed.

An interesting application of the Alden brake has been made in the Experimental Laboratory of Purdue University by which the power of a locomotive is absorbed. In this arrangement, Fig. 5, the locomotive is mounted with its drivers upon heavy supporting wheels free to revolve in either direction by contact with the drivers: the prolonged axles of the supporting wheels are each provided with a large flat cast-iron disc keyed to the shaft and allowed to rotate in a closed case between plates of copper, which can be forced against the rotating disc by hydraulic pressure as in the Alden dynamometer. The locomotive is free to move forward or backward only through a very small distance (about a quarter of an inch), its tendency to motion in either direction being measured by a system of levers and weights connected to the draw-bar by which the traction of the engine can readily be weighed. Any desired load and speed can be maintained by means of the friction brakes which are bolted securely to stone foundations—in this respect differing from the Alden dynamometer, which is free to rotate through a small arc. A modification of this mounting has been constructed for use in the railway laboratory of the University of Illinois. In this case there are eight supporting wheels arranged on four shafts each provided with a brake at both ends of the shaft. These brakes contain three cast-iron discs which run between copper plates arranged as in the Alden brake. Each of the eight brakes is capable of absorbing 450 horsepower.

Another form of absorption dynamometer is that of Froude originally designed to measure the power of large marine engines. The resistance in this dynamometer is obtained by the reaction of a series of fluid jets maintained at a high velocity by a modified form of turbine which revolves in a casing filled with water, both turbine and casing being mounted on the end of the screw shaft in place of the propeller—the turbine revolving while the casing is dynamometrically held stationary. In a dynamometer of this type the reactions which tend to stop rotation of the turbine and give motion to the casing vary as the square of the speed of rotation of the shaft to which they are attached; and, further, by comparing two similar but differently-dimensioned turbines, the respective moments or reaction for the same speed of rotation will be found to vary as the fifth power of their respective diameters.

An earlier form of hydraulic brake was an ordinary centrifugal pump, the resistance to rotation being regulated by a valve placed in the outlet pipe. This apparatus was rather cumbersome, particularly at low speeds, and the range...
DYNAMOMETERS AND THE MEASUREMENT OF POWER

supply. The rotor is fixed on the shaft, which projects on either side of the casing, so that the engine or motor to be tested may be readily coupled to it. Motors running in either direction can thus be tested by coupling to either end of the brake shaft. Each face of the rotor is formed with a semi-elliptical annular channel divided into a number of compartments by means of oblique vanes. The corresponding faces of the casing are also formed with similar channels and divided in the same way. When in action the water in each annular channel is rotated continuously by the centrifugal force imparted to it by the rotor, and passes consecutively from one compartment into the next. An extremely high speed of rotation of the water may thus be obtained and the power put into the dynamometer is by this means converted into heat which passes away in the water leaving the machine. Incidentally it is interesting to note that Osborne Reynolds used one of these dynamometers to check the mechanical equivalent of steam condensation. He found that the value given by the dynamometer—778 ft. lbs. per min.—was the value in use at the time. The motion of the water causes the rotor to react on the casing, which tends to turn on the friction rollers. This is prevented by means of an external driving mechanism, working between steps, at the end of which are the balance weights.

The Alden friction brake and the Froude hydraulic brake suggest another form of dynamometer, especially useful for absorbing the power developed by high speed machinery such as steam turbines. This machine, which was designed by Prof. J. B. Webb, consists of a series of steel discs, such as old circular saws, connected to a rotating shaft having separating washers between the discs. The shaft and discs rotate within a fixed casing to which a series of annular discs is secured in the rim; these are so spaced that they alternate with the rotating discs on the shaft but are not in contact with them. The casing is filled with water which acts as a drag and tends to rotate the stationary discs and hence the casing. The tendency to rotation can readily be determined by placing weights upon an arm attached to the casing from which the power of the turbine or other motor may be found by the usual method. The temperature of the water may be regulated as desired by controlling the flow through the dynamometer.

All of the preceding dynamometers absorb the power delivered to them; in order to transmit the power from a prime mover or other source, to a machine or group of machines, some form of transmission dynamometer must be used.

Morin, one of the early users of dynamometric apparatus, gave as the requirements of a dynamometer the following:

1. The sensibility of the instrument should be proportioned to the intensity of efforts to be measured, and should not be liable to alterations by use. Second. The indications of flexures should be obtained by methods independent of the attendance, fancies or errors of the observer, and should consequently be furnished by the instrument itself, by means of tracings, or material results, remaining after the experiments. Third. We should be able to ascertain the effort exerted at each point of the path described by the point of application of the effort, or, in certain cases, at each instant in the period of observations. Fourth. If the experiment from its nature must be continued a long time, the apparatus should be such as can easily determine the total quantity of work expended by the motor.

To meet these conditions Morin made the spring-dynamometer, in order to obtain the magnitude of a force, as for instance, the traction of a horse on a loaded wagon or canal-boat. In this dynamometer a force was measured by the flexure produced by it on two springs connected at their ends and loaded in the middle. The force is applied at the centre of spring, and its magnitude is determined by the increase of the distance between the two springs when one of them is attached to its load at the centre. In order to meet the second, third and fourth requirements Morin designed a self-registering recording dynamometer, by which the work performed was traced upon a continuous roll of paper set in motion by suitable wheel-work. Such a dynamometer is practical now, but there still remains room for the present time to determine the tractive efforts of animals or gas tractors in the field or with loaded wagons on roads of different character.

When required to determine the force of rotation on the driving or driven shaft or pulley, the dynamometer requires modification; the essential features, however, remain the same. In this case a pulley, free to rotate on a shaft, is connected to it by means of two parabolic springs which are fastened to the shaft and also to the rim of pulley. These springs turning with the shaft deflect more or less, according to the resistance encountered, and when the resistance to bending overcomes the resistance of the machine, motion is transmitted through the springs to the pulley and thence to the machine under load.

Using the same notation previously given, and substituting R — radius in path in feet — for, L the work done is \( W = 2 \pi RNP \); where \( P \) is the resistance overcome in the machine driven by the dynamometer, \( N \) is the number of revolutions, \( \pi \) is a constant to be ascertained when deflection of spring is known.

Another form of transmission dynamometer, sometimes called the differential dynamometer, has long been in use. In this machine it is assumed that it requires as much power to hold a weighted radius arm horizontally as it does to lift the same weight through the distance which would be traversed by it in any given number of revolutions if rotated in the circle and in the time required for such number of revolutions. This it will be seen is similar in principle to the method used in determining power by means of any friction brake, or absorption dynamometer; but while the latter absorbs the power, the differential dynamometer measures or weighs the power transmitted through it.

Still another form of transmission dynamometer by which the tendency to rotation is weighed is that designed by Prof. S. W. Robinson. This machine consists essentially of a supporting frame, or pedestal, a T-shaped arm carrying the driving pulley, a graduated scale or weighing apparatus. In use, the lower pulley of the dynamometer is belted to the machine to be tested, while a second belt connects the upper pulley with the one on the power shaft. The two pulleys of the dynamometer are mounted upon a strong iron bar so that they both overhang and can be
swung around to any position. These pulleys have each a gear on the end of the hub, both of which mesh into a smaller gear between, the latter being supported on a pin made fast as a crank-pin in an arm attached to a shaft which passes through the center of the hub of the cross-tree. To the opposite end of this shaft the poise-bar is made fast by a set screw in a boss to which the poise-bar is secured. As work is transmitted from one pulley to the other through the intermediate gear on the crank-pin, the latter will be thrust to one side with a force proportional to the effort transmitted; this tends to tip the poise-bar which is prevented by adding weights. The equilibrating weights on the poise-bar, together with the speed, furnish data for calculation of the work being transmitted.

The Briggs and Tat- ham dynamometers are well-known forms of belt dynamometers but these are now seldom used since in most forms of belt dynamometers there is a tendency of the belt to produce excessive vibration at high speeds which causes very irregular readings. Notwithstanding this disadvantage, the belt dynamometer may be very satisfactorily used in certain cases.

It is quite feasible to measure the power transmitted to a machine or given out by a motor by supporting the machine upon trunnions and directly weighing its turning effect. This method of supporting a machine on its trunnions and determining its torque has been utilized by the Sprague Electric Works in the design of an electric dynamometer, for testing automobile and other motors, which consists of an electric generator supported on its bearings and connected by a flexible coupling to the motor to be tested. The pull is weighed directly on a scale-beam which can be calibrated with great accuracy. By weakening the field of the dynamometer the speed of the engine under test and the dynamometer can be varied and in this way values obtained for plotting the power curve of the engine. With this form of dynamometer it is possible to return the generated energy into the shop line instead of wasting the power as is usual with dynamometer work. It is to be noted that in this machine the electrical readings have nothing to do with the measurement of power. In this respect it differs from an ordinary electric motor which may be used as a dynamometer with a very high degree of accuracy, where suitable current is available, provided the motor be properly calibrated and the efficiency factor thus obtained.

used in determining the power transmitted to the machine to be tested.

In the Brackett cradle dynamometer the torque is determined by suitably mounting the machine to be tested upon a swinging platform suspended from knife-edges and supplied with a scale-beam and sliding weight; the tendency of the driving belt to rotate the machine may be weighed on the scale-beam, and this will give a measure of the power when the speed is known. This dynamometer consists essentially of a strong stiff platform, furnished with two rigid uprights carrying steel knife-edges from which the platform is suspended. These knife-edges rest upon firm supports bolted to the floor and so constructed that a slight swinging motion is allowed to the platform upon which the machine to be tested is mounted. To one of

Fig. 6 — Brackett Cradle Dynamometer.
known Fairbanks platform-scales. This dynamometer is largely used in cotton-mills to determine the power consumed by the individual machines, and when used with care forms an excellent instrument for the purpose, being self-contained and readily applied. In this machine the pulley which receives the power is loose on the shaft, and is connected with the latter by means of a spider which is keyed to the shaft, the hub of the spider forming one of the guides to the position of the pulley. Around this spider is a loose rim from which studs project and serve to connect it to the pulley. In transmitting power from the shaft to the loose pulley the tendency of the rim to rotate on the spider is resisted by a system of levers which communicate with a pendulum balance-weight.

Another form of shaft-dynamometer is the power meter devised by Franklin Van Winkle. This is a rotary transmitting dynamometer shown in Fig. 7, in which helical pull-springs are employed for weighing the amount of force transmitted from the driving to the driven portion of the dynamometer. This instrument is especially adapted for adjustment to any shaft or pulley for measuring power transmitted by a shaft to a pulley, or vice versa, in this respect resembling the Emerson power-scale.

A portable dynamometer capable of giving a continuous autographic record, designed by the writer with especial reference to the measurement of power required to drive machine tools, is illustrated in Fig. 8.

In its latest form, this machine consists essentially of three pulleys carried by a hollow shaft which runs upon roller bearings mounted on a stiff frame as shown. The pulley on the right is fixed to the shaft and may be used for the belt which connects the dynamometer to the machine to be tested, or it may be used for a brake-band; the middle pulley is an idler and runs loose on the shaft; while the one to the left receives the driving belt and is free to turn only within given limits. This latter pulley is connected to the shaft through the hydraulic cylinders and cylinder carrier. The cylinders and shaft are filled with oil, so that any resistance to turning produces a pressure in the cylinders. This pressure is transmitted by the oil through the hollow shaft, and is recorded by the movement of an indicator-piston which is fitted into the end of the shaft; the pressure is also shown by the gauge at the opposite end. In addition to the force curve traced by the indicator pencil, the zero or datum line is traced by another pencil which is adjustable in position and may be located at pleasure on a line parallel with the axis of the shaft. Thus one is enabled to measure the total power required to run a given machine or any subdivided part of it. Springs of various intensities are used to transmit the pressure from the shaft to the indicator pencil, depending upon the pressure to be recorded. These springs are changed as in any ordinary steam engine indicator. One of the interesting features about this machine is its adaptability to either transmit or absorb power. In either case an autographic record is traced upon a roll of paper which can be stopped or started at pleasure.

An examination of a diagram from this dynamometer shows that the power required to drive the machine empty can readily be determined if desired, for all that is necessary is to run the machine at the same speed without
to operate the feed mechanism of the machine, or the dynamometer itself. The actual value of the power is obtained by methods which will be obvious.

For many years the attention of engineers and power users has been directed to the practicability of using the twist or torsion in a shaft as a means of determining the horse power transmitted by it. When power is applied to one end of a shaft the amount of twist varies directly as its length, directly as the moment of the applied load, inversely as the rigidity of the material, and inversely as the fourth power of its diameter all of which is expressed in the formula: \[ \theta = \frac{32 \, M \, L}{G \, D^4} \]
or, for hollow shafts \[ \theta = \frac{32 \, M \, L}{G \, (D^4 - d^4)} \]
in which \( \theta \) = the angular displacement in radians, \( M \) = twisting moment in inch-pounds, \( L \) = length of shaft in feet, \( G \) = the modulus of rigidity, or modulus of transverse elasticity, \( D \) = outside diameter of shaft and \( d \) = inside diameter if hollow, both taken in inches. Various methods have been developed for determining the magnitude of the twist in the shaft by means of torsion metres or torsion indicators, most of which have been designed with especial reference to marine service. The rapidly increasing use of steam turbines in ships and the necessity of determining the power of the turbines— for which the steam engine indicator is not adapted — has created a demand for an accurate, easily operated torsion dynamometer, since the use of some form of torsion meter is the only known method of obtaining the desired information. The principle of operation in general consists in the observation of the twist between two given points on the shaft and this has been frequently accomplished by means of beams of light in combination with rotating discs; in other cases electrical observations are used to determine the distortion: in any case the horse power is obtained from: 

\[ H.P. = \frac{D^4 \, N}{C \, L} \]
in which \( \theta \) is the angle of twist in degrees, \( D \) = diameter of shaft in inches, \( N \) = revolutions per minute, \( L \) = length of shaft in feet, \( C \) = a constant depending upon the modulus of transverse elasticity, and other numerical factors.

It should be noted that tensile tests and percentages of elongation of the metal are of little use in obtaining the transverse modulus of elasticity. This modulus may vary in apparently identical shafts all the way from 11,500,000 to 12,500,000 so that in order to obtain accurate results the modulus for each shaft must be separately determined.

The Bevis-Gibson flashlight torsion meter will serve to illustrate the general method of determining the power exerted by a propeller shaft. Two blank discs are mounted on the shaft at a convenient distance apart. Each disc is pierced near its periphery by a small radial slot, and these two slots are in the same radial plane when no power is being transmitted and there is no twist on the shaft. Behind one disc is fixed a bright electric lamp masked, but having a slot cut in the mask directly opposite the slot in the disc. At every revolution of the shaft therefore a flash of light is projected along the shaft toward the other disc. Behind this disc is fitted the “torque finder,” an instrument fitted with an eyepiece and capable of slight circumferential adjustment. The end of the eyepiece next its disc is masked except for a slot similar and opposite to the slot in the disc. When the four slots are set in line, a flash of light is seen at the eyepiece every revolution, and if the shaft revolves quickly enough the light will appear to be continuous. This effect is apparent at anything over 100 revolutions per minute. At lower speeds the flash is seen to be intermittent, but this in nowise affects the accuracy and reliability of the result. At each end of the shaft section, therefore, there exists what is virtually an instantaneous shutter fixed directly to the shaft, and the only connecting link between the discs is the beam of light which flashes once in each revolution clear through the two shutters. Suppose the shaft to be transmitting power. One disc lags behind the other by a definite amount, and although three of the slots are still in line the one in the lagging disc is not in line and therefore effectually breaks the flash and no light is seen at the eyepiece. To pick up the light again the eyepiece of the torque finder must be moved by an amount equal to the circumferential displacement of the lagging disc. This is accomplished by manipulating the micrometer of the torque finder on which is a scale and vernier graduated in degrees. While the scale is fixed its vernier moves with the eyepiece, and the graduations are so marked that by the aid of a simple microscope conveniently hinged, differences of 1/100 of a degree can be readily discerned. For shafts of ordinary size the scale is set at 14.325 inches radius from the centre of the shaft, so that the degrees are 3/4-inch apart. Since an ordinary shaft twists 1 degree in 10 feet at full power it is quite possible to get the shaft horse power to within 1 per cent of full power; but as it is frequently possible to fit the discs 40 or 50 feet apart even this accuracy may be improved upon, and the power determined to within 3/4 of 1 per cent of full power.

One type of the torsion dynamometer described by Amsler is illustrated in Fig. 9. In
this form it is intended to be coupled directly by its flanges between the driving and driven shafts. It is also made, however, to receive and transmit its power by belt, in which case the dynamometer is provided with a belt pulley at each end. The two flanges are coupled together by a central shaft G capable of transmitting all the power without being stressed beyond its elastic limit. The flange at the end H carries a disc M, to the outer edge of which an engraved celluloid scale U is attached. From the flange at the end F a tube A extends toward the other end and is carried by a ballbearing within the flange at H. This tube carries two discs N and O, in each of which slits T and P are cut. A lamp is hung behind the scale and a mirror may be arranged, as shown, to facilitate the reading.

It will be understood that when the shaft twists under the influence of the power transmitted the scale U moves relatively to the line through the slits PT. With each revolution of the shaft, therefore, a momentary glimpse of the scale division is seen by the eye at Q as the slits PT cross the line of sight. If the speed be sufficiently great and the torque constant, a continuous impression is received of a given scale division. This reading, in conjunction with the speed, gives data from which the power being transmitted is calculated. This type of dynamometer is usually made for speeds of about 4,500 revolutions per minute; it has, however, been used in cases where the speed was as high as 8,500 revolutions.

In the torsion dynamometers just described the measurement covers the average angular displacement for a given load with fair accuracy but it is obvious that where reciprocating engines are used, and even with steam turbines, the torque undergoes various changes in a complete revolution; this is especially so when the shaft carries a propeller, in which case the complicated fluctuations cause irregular oscillations in the angle through which the shaft is twisted. To determine these variations in twist throughout a revolution various modifications of the torsion meter have been employed, by which instantaneous readings are obtained throughout a revolution. Several types have been arranged to record the twist graphically. Among these the Denny-Edgecombe torsion indicator merits attention. This instrument, Fig. 10, consists of a cast-iron sleeve made in two sections and parted to the shaft. If this were measured directly, however, the result would be subject to serious error, for there always is a longitudinal movement of the shaft itself due to thrust or expansion. This is eliminated by means of a turned base or dummy flange cast upon the sleeve. The traveler flange is made to fit accurately against this base flange for setting in position, and is then drawn along the tube and secured to the wire rope at a convenient distance from the base flange. The variation of distance between these two flanges will thus be an exact measure of the variation of torsion of the shaft.

An indicator is applied to these two flanges to further magnify the movement and make it easily readable. If it be desired to obtain a permanent diagram, a recorder may be attached to the front of the indicator. This recorder has drums which are driven by means of small double-worm gears from the spindle of the wheel which runs on the base flange. Change gears, actuated by a small lever, are provided, so that the drums can be kept revolving in the same direction whether the ship is going "ahead" or "astern." A diagram paper is thus made to move with the drums, upon which pens attached
DYNNACHUIM, dfr-rä"ki-um. See Durazzo.

DYSART, d'zär-t, Scotland, seaport in the county of Fife, on the Firth of Forth; 28 miles northeast of Edinburgh by rail. Dysart possessed great importance in the 15th century, and was famous for collieries and salt-works. Shipbuilding and linen weaving are among the industries. Pop. 3,022.

DYSENTERY, a general term denoting a series of diseased conditions of the large intestine or colon (q.v.). These may be of an infectious, nervous or chronic inflammatory origin. At the present time, it is becoming

recognized that most cases of dysentery are due to different micro-organisms, and within recent years a bacillus has been described by a Japanese observer, Shiga, which is thought to be responsible for a number of the cases of dysentery, both in adults and in children. Certain mild cases of dysentery have been shown to be dependent upon the pernicious activities of certain bacteria belonging to the genus Proteus. And it has now been known for a long time that a certain lowly organized animal form, the Entamoeba, can induce a peculiar type of dysentery known as amebic dysentery. Thus the dysenteries may be divided into (1) Animal parasite dysenteries: (a) Protozoa; (b) Plathelmint, Schistosom, etc.; (c) Nematelminth; (d) Arthropods. (2) Bacterial dysenteries.

The general mode of onset of dysentery of the non-amobic form, that is particularly epidemic dysentery, is rapid, with diarrhea following perhaps a mild constipation or alternating constipation and diarrhea with a mucous or serous discharge. Symptoms of indigestion frequently precede the attack, and it is characteristic that diarrhea is accompanied with much wind. The fecal movements are large, loose, very fetid and usually mixed with blood and mucus. The movements are accompanied by a great pain of a colicky or grippy nature. Tenesmus, or straining, is a very frequent symptom. There is usually much general pain, some rise in temperature, loss of appetite, nausea, restlessness and irritability. In favorable cases formed faces commence to reappear in the stools and there is disappearance of the gripping and straining. In the patients in whom the disease becomes more acute, the passages become looser, watery, slimy and of a dark red color. The odor is mawkish, and in later stages may even become putrid. The fluid that is passed consists largely of an albuminous serum with epithelium blood cells, pus cells, tissue fibres and small sloughs, and if the disease becomes even more pronounced the stools become dark brown in color, with sloughs and blood clots, and a distinctly gangrenous odor. These sloughs from the intestine usually indicate an extremely severe form of the disease and oftentimes the patient dies with completely relaxed anus, with subnormal temperature, shrunken features and in complete collapse.

Amebic dysentery is, as a rule, a more gradual form of disease. It is extremely intermittent in its course and much protracted, running on sometimes months and even years. It very frequently begins with painless diarrhea, alternating with constipation; the stools being loose and yellowish, containing much mucus and a little blood. The patient commences to lose flesh, becomes weak and asthenic, and the complication of abscess of the liver is extremely common. Chronic dysentery is a form of acute colitis and can be found under that head. The treatment of dysentery consists in rigid hygiene and skilled medical attendance, as the different type of parasites must be recognized by the microscope and appropriate remedies for each type administered. See AMOEBA; CHOLEIRA; COLITIS; ENTERITIS; ENTEROCLYSIS; INTESTINE; PARASITISM AND ANIMAL PARASITES.

DYSLYSIN (Gr. "hard to dissolve"), an amorphous, resinous substance, having the formula C₃₅H₃₅O₇, and obtained from cholic acid
DYSMENORRHEA — DYSEPSIA

by heating to about 600° F. or by prolonged boiling with dilute hydrochloric or sulphuric acid. It is soluble in ether, slightly soluble in boiling alcohol and insoluble in water; and it is reconverted into cholic acid by boiling with an alcoholic solution of caustic potash. It is found in small quantities in the contents of the large intestine of herbivorous and carnivorous animals, and also in their faces, being in such case the result of bacterial processes upon the cholic acid of the bile.

DYSMENORRHEA, dis-men-ôr rhe-a, painful menstruation. To constitute dysmenorrhea, the pain accompanying menstruation should be very distinct and persistent. Inasmuch as dysmenorrhea is found accompanying a vast variety of abnormal conditions of the uterus and ovaries, it seems not improbable that this affection has various pathologies, but may be associated with almost any abnormal condition within the generative apparatus of women. A vast variety of forms of dysmenorrhea have been described, the most important of which seems to be that of obstructive dysmenorrhea, or a mechanical form supposed to be due to some interference in the escape of the menstrual fluid. Those who suffer from dysmenorrhea are apt to be anæmic, which anaemia in itself may be a sufficient cause for the disease. They are apt to be extremely nervous and run down. Many cases of dysmenorrhea are psychic in origin, how great a proportion it is impossible to say, but probably 25 per cent. A large group are due to underdeveloped organs. Here endocinous gland disturbances are to be found. Treatment should be directed to the supplying of the deficiency of the iron in the blood to overcome the anæmia, and the use of cod liver oil and other reconstitutives for the anaemic forms and proper psychotherapy for the psychogenic types. The endocinous types need internal glandular or opothrapy. Pronounced ovarian disease, usually found only in older patients, requires surgical therapy. Of the various drugs that have been used for the temporary treatment of dysmenorrhea those that relax muscular fibres and arterial walls seem to give the best results. This is true of a number of the newer synthetic drugs that have been employed very widely of late. As no two cases of dysmenorrhea are due to precisely the same cause, general directions for treatment would be out of place in a work of this character, but rest in bed, free movements of the bowels and hot water in the form of hot-water bags, or hot-water enemata, are very useful household remedies. See Menstruation; Ovary; Womb.

DYSON, Edward, Australian poet: b. Morrison's Diggings, 4 March 1865. He has been in journalistic work since 1883. Among his published works are 'Rhymes from the Mines' (1886); 'The Golden Stanty' (1898); 'Below and on Top' (1898); 'The Gold Stealers' (1901); 'In the Roaring Fifties' (1906), and 'Fact'ry' 'And's' (1907).

DYSEPSIA is that combination of symptoms that results from interference with the proper digestion of food in the stomach. Because of the taking in of unsuitable food, the mucous membrane of the stomach becomes irritated and there is set up an acute or subacute gastric catarrhal condition which prevents the proper digestion of the food. This food is apt to ferment and to decompose, and as a result the familiar picture of acute dyspepsia may arise. In mild cases there may be nothing more than an uncomfortable feeling in the stomach, with a certain amount of depression, heartburn, appetite, and perhaps belching of wind and occasionally vomiting. There may also be accompanying intestinal symptoms, such as diarrhoea and colic, particularly in children. There may be only the familiar heartburn, due to the over-dilatation of the stomach, from fermentation or putrefaction. In the more severe cases, those that last over a day or two, the symptoms enumerated may be much more intense. The distress may be marked, and the general constitutional symptoms more evident. Vomiting, loss of appetite and mental depression are much more pronounced. This is particularly true of acute gastritis, due to the excessive use of alcohol.

Very frequently, from continued errors in diet, the acute or subacute symptoms become chronic, so that there is a continual indigestion. Here the symptoms persist for an indefinite period, the appetite is very apt to be variable, although at times very good. Oppression after eating, which may amount to actual pain, is one of the most constant symptoms. Occasionally the pain may be pronounced when the stomach is empty. Heartburn is frequent, if not constant, the stomach is painful on pressure, the tongue is coated, there is bad taste in the mouth, there are changes in the amount of salivary secretion. Frequent belching of gas is a very common accompaniment of chronic dyspepsia, particularly of the flatulent variety. Here also the intestines suffer from distention. Nausea is more pronounced, particularly in the morning hours, and vomiting is common in the morning. Constipation is usually present, although diarrhoea may alternate with constipation, and mental depression is almost characteristic. The treatment of acute and chronic dyspepsias constitutes one of the most difficult problems in modern medicine. Very few patients are willing to undergo the ordeals of a rigid dietary regimen. Most cases of dyspepsia can be cured if the diet is looked after, although each case needs careful consideration from the standpoint of causation. Proper eating and proper amounts of food are the two most important features in the treatment. Most people eat too fast and eat too much. If the food is taken slowly, observing the old-fashioned rules of counting between mouthfuls and small amounts are taken, many patients suffering from indigestion can treat themselves with success. More than one-half of the dyspepsias are really mental in origin. They are produced by worry and by impatience, and are best treated by proper psychotherapy. One group of recurring dyspepsia is the one on in attacks lasting a few weeks or a few months, with slight depression, are mild forms of a manic-depressive psychosis. These are amenable to psychotherapy also. They get well by themselves, but are apt to recur without proper therapy. As to the details of the dietary and as to the medicinal treatment of the condition, medical advice is absolutely necessary.
DYSPHONIA—DZIGGETAI 471

One of the most pernicious of all practices in the treatment of dyspepsia is the taking of many of the patent medicines which are so blatantly advertised in the religious and lay press. As most of these so-called tonics are hardly more than alcoholic beverages, it is evident that their use is not unattended with a great deal of danger. The treatment of the constipation that is so frequent an accompaniment of chronic dyspepsia by means of the many patent pills, powders, teas and liquids is positively suicidal. See Constipation; Enteritis; Gastritis.

**DYSPHONIA**, roughness of sound; in pathology, a difficulty in speaking. The disorder known as "clergyman's sore throat" is a common example. Rest of the vocal organs, tonics, muscular exercise, change of scene, are generally needed to aid recovery.

**DYSURIA**, dis-t'u-ria, difficult or painful urination, a symptom of temporary disorder, or of deep-seated disease. When dysuria is merely the result of a slight cold it can often be relieved by a dose of sweet spirits of nitre or linseed tea. Sometimes this symptom is the result of a stricture, or it may be caused by gravel, or stone, in which case the services of a physician should be obtained, and that without delay.

**DYVEKE**, dů'vě-kě, mistress of Christian II of Denmark; b. Amsterdam, 1491; d. 1517. She was the daughter of an innkeeper at Bergen and Christian met her for the first time in the inn of her father. She accompanied the king to Denmark in 1507 and was constantly with him for the 10 years following. She is one of the most romantic figures in Danish history and has frequently been celebrated in poetry and fiction as the victim of royal passion and the insane jealousy of the nobility, who resented her exaltation. She was poisoned by her enemies, but Christian allowed her mother to remain at court as his chief counselor for the remainder of his reign.

**DZEREN**, dzěr'ěn, the "goitred" yellow antelope of China (Gazella or Procapra gutturosa), with unusually pale horns and a protruding goitre-like crop in the males, and pronounced its fleetness. The name "dzeren" is Mongolian.

**DZIGGETAI**, dzig'ge-ti, the native name for the Mongolian wild horse or wild ass (Asinus or Equus hemionus), also known as the Kiang (q.v.), and sometimes compounded with the Kulan (Equus or Asinus onager).
E

The fifth letter of the English alphabet, as also of the alphabets of Greek and Latin, and of all the European languages except those which, as the Russian, use the Cyrillic alphabet, where the E has sixth place. The character corresponding to E in Hebrew and other Semitic languages, as Phoenician, Samaritan, Chaldean, holds the same relative place in the alphabets of those languages. The form of the letter e in early Hebrew and early Phoenician was Ε and from that is derived the Greek E (epsilon), which is the Phoenician character reversed, with stem shortened and made perpendicular: this character represented in the Hebrew and other languages of western Asia, not the vowel sound E but the soft breathing. Taken into the Greek alphabet it was at first used to represent the vowel sound e whether short or long; but afterward the character Α was employed in Greek for the long e and was called eta, while the E received the name epsilon. The Latins used the E for both the long and short vowel and adopted the H of the Greek alphabet to denote the aspirate. The name and sound of this letter in all European languages except English is et as in our interjection of inquiry: long e in those languages is invariably equal to a in mate, and short e equal to e in met: the long E of English is in those other languages expressed by the third vowel, I: thus, English he, me, lee, would in those languages be written phonetically hi, mi, li. In the standard alphabet employed in linguistic science the vowels a, e, i, o, u, are taken to represent the sounds ah, eh, ee, oh and oo, and are named accordingly. The letter E occurs in English words far more frequently than any other letter of the alphabet: compared with A, I, O, U, its frequency of occurrence is as 1,000 to 728, 704, 672, 296 respectively; compared with various other letters it is as 1,000 to 770 (i), 670 (n), 392 (d), 280 (c), 236 (f), 120 (b), 22 (z). In frequency of occurrence as an initial letter it ranks only as eleventh and is to T as 340 to 1,194. One reason of the greater frequency of E in general use is that it often takes the place, in modern English words, of the vowels a, o and u of Anglo-Saxon words; another reason is that final e is largely employed to lengthen the vowel of a preceding syllable, as in there, here, cape, pane: it is employed even where it serves no purpose of pronunciation at all, as in gone, live. E as an abbreviation is used for East, editio, emeritus, and ergo; e.g. and e.c. for exempli gratiâ, and exempli causa.

In music E is the third tone in the key of C, and the fifth semitone in the chromatic scale. Consult Soames, 'Introduction to the Study of Phonetics,' and Sweet, 'History of English Sounds.' See Alphabet.

E. C. SPORTING POWDER is a super-ficially hardened, soft-grained, smokeless sporting powder, consisting, according to an analysis by C. E. Munroe, of 53.37 per cent of soluble cellulose nitrate, 1.86 per cent of insoluble cellulose nitrate, 3.12 per cent of unconverted cellulose, 34.26 per cent of barium nitrate, 4.55 per cent of potassium and sodium nitrates, 1.17 per cent of volatile matter, and 0.55 per cent of aurine, the latter being an organic coloring matter, used to impart an orange color to the grains. The manufacture, as carried out by the Explosives Company, after the method invented by Reid and Johnson, consisted in placing the moistened, pulped cellulose nitrates and metallic nitrates in barrels where, by rotation, the ingredients were mixed and then broken up into rounded grains, which were dried and then sprayed with ether-alcohol which at first gelatinized the surfaces of the grains, and then by evaporation left a hard skin about the grains. The coloring matter was added in the solvent. The grains are then dried and passed through a sieve in order to separate any grains which have stuck together during the gelatinizing process. No. 2 E. C. powder contains a little camphor and is treated throughout the grain with ether-alcohol. This results in a harder and denser powder which burns more evenly and yields a higher velocity than No. 1 powder.

E PLURIBUS UNUM, é plou'rif-būs ú'num ("one from many"), the motto of the United States; chosen for its Great Seal 10 Aug. 1776, by Franklin, Adams and Jefferson, as a committee. It has been part of the motto of the Gentleman's Magazine, founded 1731; apparently taken by it from a sentence in Voltaire's (?) "Moretum," "color est e pluribus unum."§

EADMER, or EDNER, a mediæval churchman, historian of his own times and biographer: he flourished in the 11th and 12th centuries; d. Canterbury, about 1124. He was a Benedictine monk and was the companion, counsellor and friend of Saint Anselm, Archbishop of Canterbury, whose life he wrote. He held a like relation to Saint Anselm's successor, Radulphus, or Ralph, till 1120 when, invited to Scotland by King Alexander I, he was nominated bishop of Saint Andrews; but went back to his monastery because of a controversy having arisen over the king's right to nominate and the pretensions of the archbishops of Canterbury to primatial jurisdiction over the bishops of Scotland, which pretensions Eadmer upheld. He was even wont to say that he would refuse the highest see in Scotland if he must divest himself of his character as a monk of Canterbury. He wrote 'Historia Novorum,' that is, history of recent occurrences of his own times. Besides the life of Saint Anselm he wrote the lives of three of
Anselm's predecessors in the primatial see—Saint Ode, Saint Dunstan, and Saint Bregwyn; also the lives of Saint Wilfrid and of Saint Oswald of York; all of which writings have been printed in Wharton, 'Angla Sancta.' Consult Grub, 'Ecclesiastical History of Scotland' (Edinburgh 1861).

EADS, edz. James Buchanan, American engineer: Lawrenceburg, Ind. 23 May 1820; d. Nassau, New Providence, 8 March 1887. He began as a clerk in a dry-goods house in Saint Louis in 1833, and then secured work on a Mississippi steamboat in 1839. He early designed some useful boats for raising steamers, and in 1861, when called to advise the Federal government, constructed within 100 days eight ironclad steamers for use on the Mississippi and its tributaries. He afterward built a number of other ironclads and mortar-boats, which were of considerable service to the North. He built an arch bridge across the Mississippi at Saint Louis 1867–74. His works for improving the South Pass of the Mississippi delta were successfully completed in 1875–79; and his great plan for deepening the harbor as far as the mouth of the Ohio by means of jetties has been demonstrated to be entirely practicable. A later suggestion, for the construction of a ship-railway across the Isthmus of Tehuantepec, attracted much attention. In 1884 he received the Albert Medal of the Society of Arts, being the first American citizen to whom this honor had been awarded. Consult How, 'James B. Eads' (Boston 1900).

EAGAN, Charles Patrick, American military officer: b. Ireland, 16 Jan. 1841. In 1862 he entered the Union army as first lieutenant; in 1874 was promoted captain and commissary of subsistence; in 1892, major; in 1897, lieutenant-colonel; on 11 March 1898, colonel, and on 3 May, following, brigadier-general and commissary-general. In January 1899, he made remarks concerning General Miles, in his testimony before the War Investigation Commission, for which he was tried by court-martial and sentenced to dismissal from the army. His sentence was commuted by the President to suspension from duty and honors for six years. On 6 Dec., 1900, he was restored to duty and immediately afterward retired.

EAGLE, as a popular name, includes several raptorial birds which vary in some respects from the strictly defined group in which science has been wont to place it. The order Accipiter, to which it belongs, is broad enough in definition to include all the vultures, the typical eagles, and the buzzards. Recent osteological demonstrations, however, have led to the separation of American vultures from the Old World vultures, including the North American species of the family Falconidae, to which eagles and vultures belong. This family, which embraces 300 species of diurnal raptors, is characterized by imperfector nostrils, legs of medium length, and, except in the Old World vultures, a feathered, or beaked, the hind toe inserted on a level with the three front ones, and the claws rounded curved and sharp. The sub-family Aquilinae makes prominent the cutting edge of the upper mandible, the body shielded over the eye, the feet hairy and short, either scutellate or feathered. The Lämmergeier (Gypaetus barbatus), lamb-killer, or bearded vulture of the Alps, the Pyrenees, and the Himalayas, finds its nearest affinity here. The Aquilinae are naturally divided into two genera: Aquila, land eagles, and Haliaeetus, sea-fishing eagles. The former is feathered to the toes, the latter half way to the tarsus. The leading specimen of Aquila is the golden eagle (A. chrysaetus) one of the largest and most magnificent of its kind, dark brown with purple gloss; head and neck brownish-yellow; tail rounded and dark brown, ending in light and dark tints. The length is about three feet, the extent of wing seven feet. In North America its range is from Mexico north. It is very scarce in the United States but more abundant in Canada, where it is distinguished as canadensis. It is regarded as a variety of the European species, which seldom occurs in England, though more prevalent in Scotland, where the demand for its eggs has favored its increase. The nest is usually placed on some inaccessible cliff, the eggs are spotted and do not exceed three. Closely related to the eagle are the imperial eagle (A. mogulina) of southwestern Europe and of Asia, and the king eagle (A. heliacus) of the same range. The smallest of the kind is the dwarf eagle. (A. pennata) which measures less than two feet and is native in Southern Europe, North Africa and in India.

First in interest among the sea-eagles stands the bald-headed eagle (Haliaeetus leucocephalus), selected as the national emblem of the United States. Its markings are familiar, though the term "bald" is to be referred not to the absence of feathers, but to the effect produced by the white feathers on the head. In size, it corresponds nearly to the golden eagle, but it differs in its habits, living mainly upon the fish which it seizes along the sea-shore and around lakes and rivers. The nest is built on a high tree top or upon a rocky cliff. A finer specimen than this is the northern sea-eagle (Haliaeetus pelagicus) of northeastern Asia. It is conspicuous by its large size and bill, and by the contrast of its main color, brown, with the white of its shoulders, rump and tail. The African sea-eagle (H. vocifer) is a fish-eater, about half the size of the "bald-head," remarkable for its color, being white on the head, neck and breast, while the under parts and wing coverts are chestnut, and the upper parts are black or brown. Nearly related to the Haliaeetus is the fishing-eagle (Poliopterus capensis) of India and the East Indies, with extremely curved talons, and living entirely on fish. In countries bordering on the Mediterranean and ranging into India and Central Europe, is the serpent-eagle (Circaetus gallicus) with short toes, white, brown-spotted under parts, and dark brown upper parts. It feeds upon reptiles, which it kills and carries away, not eating the game on the spot, as do other eagles. A buzzard-like genus, Helotarsus, is represented in Southern Africa by H. ecaudatus, the short-tailed eagle, ornamented with maroon and black plumage, and bright red, very short legs. The buzzard-eagles include some species which command notice from their great size and powerful action which fairly entitle them to their name. In South America and the forests of the Amazon, is the habitat of the
Guiana eagle (*Morphyus guianensis*) relatively small, but with a tail longer than that of almost any other species. The wings are short and rounded, adapting it to a loafing down on its prey, rather than for lofty or prolonged flight. From southern Mexico through the forests of Brazil, the harpy-eagle (*Thraasetus harpyia*) has its home, and for muscular power is scarcely surpassed by any bird of prey in the world. It is larger than the golden eagle, gray in color, with long crest feathers, a stout, vicious bill, and talons of extraordinary force and sharpness. Though rapacious and apparently destructive, the eagles are useful in killing many other birds which prey on smaller animals and human habitations, in reducing the number of injurious reptiles and small mammals, and in helping to preserve the balance of the animal world. From the most ancient times the eagle has been regarded as a symbol of might and courage. Its great power of vision, the vast height to which it soars in the sky, the wild grandeur of its abode, have likewise commended it to the poets of all nations. It was associated with Jupiter in Roman mythology and was used as a device of several Roman legions, whence it has descended to the national ensigns of Germany, Russia and the United States. See BIR, and consult authorities there given.

**Eagle**, a gold coin of the United States of the value of 10 dollars, or £2 1s. 1d. sterling in British currency, the rate of international exchange. An eagle weighs 258 grains troy, 300 fine. It was first coined in 1795, in accordance with an act of Congress, dated 2 Jan. 1792. There are also half eagles (first coined in 1795), quarter eagles (first coined in 1796), and double eagles (first coined in 1840), of proportionate value.

**Eagle, Black**, a term applied to the golden eagle, *Aquila chrysaetos*, also to the young of the bald-eagle. See EAGLE.

**Eagle, Black, Order of,** a Prussian order, founded by Frederick II in 1701. The number of knights in the order was originally limited to 30, exclusive of the princes of the blood royal; and unquestioned nobility used to be required of all members. The order is now conferred also for distinguished military or civil service. The badge is a Maltese cross of blue enamel having in the centre a circle with the monogram T.E. (for Frederick Rex); the four arms are enameled red with the eagle of Prussia in black enamel between each two arms. It is worn on a broad ribbon of orange hung across the left shoulder, and it is accompanied by a double-headed (Jonatanae) eagle, held in such reverence by the Teutonic race as sometimes to figure "nimbed," that is with the Catholic halo surrounding each head. In Christian iconography a double-headed eagle represents Elisha, the prophet.

In ecclesiastical art the term "eagle" is applied to a piece of church furniture—the lectern (q.v.) (reading desk) of brass or carved wood in the form of an eagle with wings displayed to hold the Bible on its back. It represents, of course, Saint John the Evangelist. See LECTERN.

**Clement W. Coumbe**

**Eagle Hawk, or Hawk Eagle** is the name for a group of some rather small and some large raptorial birds, closely related to *Aquila*, and chiefly represented by the genus *Spizaetus*. They are beautifully crested and range in South Africa, Central and South America. A notable specimen is the crowned eagle (*S. coroanatus*) of South Africa, of medium size, its under parts buff, banded with black, the head furnished with a crest of long, brown feathers. Of the same geographical range is a species of *S. (Lophaetos) crassus*. The Persians and other ancient nations such as the Assyrians and Egyptians all utilized the eagle's form in art. Xenophon tells us that eagles were on the Persian ensigns. The ancient armies of the Romans had the eagle carried as a standard, hence they used the term "eagle" to designate their legions. In the Greek mythology we find Apollo's attendant upon Zeus; it held in its claws the god's lightning bolts (fungens), and it was an eagle that carried off Ganymede on its wings. In ancient times the eagle was often considered as symbol of the soul's flight after death. In early Christian art the eagle was used to personify Saint John the Evangelist, with his wonderful divine vision and spiritual flights. Strange to say, the early Christians often adopted the pagan carved gems containing representations of the heavy-bearded Zeus and his eagle as symbols of God the Father and his Apostle, whether wittingly or not, was matter for conjecture. One favored form in Christian iconography represents the Evangelist in human form but with an eagle's head.

When Rome became an empire the eagle's form was used in picturing an emperor's apotheosis. Probably for this reason Napoleon Bonaparte made proliic use of the majestic bird as a device in his palaces when he became emperor; in 1804 he even adopted it as ensign for his victorious armies. The eagle to this day is almost inevitably present in war and triumphal trophies.

In America, the eagle has long since figured as symbol of the republic, and a ten-dollar gold coin is named after it.

In heraldry, the eagle became an armorial charge quite early (about the period of Charlemagne). For this purpose its appearance had to be considerably transformed. It took on a more attenuated form, the displayed wing feathers becoming few and distinctly separated, so that, depicted on the shield of a knight, its outline would be visible a long distance off. In this heraldic form, Germany, Austria, Prussia, France (as empire) adopted the eagle.

The double-headed eagle device is a bearing in Russian, Austrian and German arms. In the latter two cases the twin heads refer to the assumption of power, both east and west. This double-headed (Jonatanae) eagle is held in such reverence by the Teutonic race as sometimes to figure "nimbed," that is with the Catholic halo surrounding each head. In Christian iconography a double-headed eagle represents Elisha, the prophet. The
1 The Golden Eagle (Aquila chrysaetos)
2 The Black Eagle (Aquila melanaetus)
3 The Pomarine Eagle (Aquila pomarina)
4 The Oriental Eagle (Aquila orientalis)

EAGLE OWL.—EAMES

475

talis, a small bird with a crest four inches long. In Central and South America are crested members of the group, S. (Lophotriorchis) tidiori and S. ornatus.

EAGLE OWL, an owl of the genus Bubo (family Strigidae, horned owls, order Accipitres), predominated nearly all parts of the world except Australia. Of rare occurrence in Great Britain, it is common in the foot-hills of the Ural Mountains, and throughout Siberia as far as China. In the northern Old World B. ignatus is one of the largest owls, of unsurpassed strength and daintiness. The colors are black, brown and white, mottled. A grown specimen weighs about eight pounds and measures 26 inches from bill to end of tail; the wing is 18 inches long, and the plume feathers, constituting the horns, are nearly four inches in length. It is the boldest and most ravenous owl, and is a match for the eagle. To the superstitious people of the north, its weird call-note sounded at night in the depths of the forest announces the presence of evil spirits. The great white owl of America (B. virginianus) bears a general likeness to its European congener, though smaller in length of body and wing. The colors are the same but differently arranged. The lower parts are barred rather than spotted, the breast and throat are marked with a large white patch, and a black ring is stamped on the disc of the face. Like the European species, it preys upon hares, large ground birds, rats, mice, reptiles and fish, and besides on the young of the American turkey.

EAGLE PASS, Tex., town, county-seat of Maverick County, on the Rio Grande River; about 15 miles southwest of San Antonio. The principal occupations are coal-mining, agriculture by irrigation, stock-raising, and the manufacture of lumber and bricks. There is active trade in hides, wool and cattle. Eagle Pass is the port of entry for the Saluria district, and as such engaged in extensive trade with foreign ports during the Civil War. The chief structure is the Federal building for the 14th district, which is under the commission plan. Pop. 3,536.

EAGLE RAY, a fish of the order Rystae, of which the torpedo and the string-ray are familiar members, and associated with the sea-devil in the family Myliobatidae. It is a flat fish with a very broad disc distinguished by pectoral fins which continue to the snout and then reappear at the extreme end of the head. The tail is long and slender like a whip. The teeth are flat for crushing crabs and for grinding shells. Though much smaller than the sea-devil, which is sometimes immense, the eagle ray often attains a considerable size. It breeds forth its young alive and inhabits tropical or subtropical waters.

EAGRE, a Norse word signifying a formidable influx and surging of the tide, the same as bore in a river, as in the Severn and Humber rivers and the Bay of Fundy. See BORE.

BAKINS, ek’inz, Thomas, American artist: b. Philadelphia, 25 July 1844. He was a pupil of Gérôme. He has taught water-colors in several art schools, lecturing there on anatomy and painting. Among his works are many pictures of American domestic scenes, out-of-door sports, portraits and several large canvases, such as Dr. Gross and Dr. Agnew at their clinics. His best work is conceded to be the ‘Clinic of Professor Gross’ (now at Jefferson Medical College), painted with careful attention to detail and good imagination. Other noteworthy works are ‘Chess Players’ (Metropolitan Museum, New York); ‘The Crucifixion’ (Overbrook Seminary); ‘The Cell Player’ (Pennsylvania Academy of Fine Arts); ‘The Mother’; ‘A Bohemian’ (1913). He died in 1920. He has designed for sculptors models, and also designed the horses of the Brooklyn Soldiers and Sailors Monument and the relief designs on the Battle Monument at Trenton.

EALING, é’ling, England, town, and also a parliamentary division of Middlesex, the former a few miles west of London. The town has a free library, science and art schools and a training college for teachers of the deaf. Pop. of town 33,031; of the parliamentary division about 72,000.

EAMES, ê’ms, Charles, American lawyer and journalist: b. New Brunswick, N. J., 20 March 1812; d. Washington, D. C., 16 March 1867. He was graduated at Harvard in 1831, and began the study of law. After accepting a position in the Navy Department at Washington in 1843, he took editorial charge of the Washington Union. He was sent by President Polk as United States Commissioner to the Sandwich Islands and afterward became United States Minister to Venezuela, under President Pierce. Returning in 1858 he gained a great reputation as a lawyer in admiralty cases.

EAMES, Emma, American operatic prima donna: b. Shanghai, China, 13 Aug. 1867. She studied music in Boston and Paris, singing in churches and concerts in the former city and making her début in grand opera, Paris, 13 March 1889, in ‘Juliette,’ appearing in grand opera at the Covent Garden, London, 1891, and in New York the same year, since which time she has been a popular member of grand opera companies in Europe and America. She married the well-known artist, Julian Story, 1891, but was divorced in 1907. She married Emilio de Gorgorza of Paris. She created the rôle of Colombe in Saint-Saëns’ ‘Ascanio’ and the title part in ‘Zaire’ by De la Nux. Her repertoire includes rôles in French, Italian, Spanish, German and English.

EAMES, Wilberforce, American bibliographer: b. Newark, N. J., 12 Oct. 1855. He has long been prominent in bibliographical matters, having been assistant at the Lenox Library, New York, 1885; assistant librarian 1892; librarian 1893-95, when upon the consolidation of the Astor Library and Tilden Trust as the New York Public Library, Astor, Lenox and Tilden Foundations, he became librarian of the Lenox branch. He edited volumes 15-20 of ‘Sabin’s Dictionary of Books relating to America’ (1885-92). Among his works are: ‘Biographies of the Bay Psalm Book’ (1887) of ‘Ptolomy’s Geography’ (1886), and of ‘Sir Walter Raleigh’; bibliographic notes on ‘Eliot’s Indian Bible’ (1890), reprinted from ‘Pilling’s Indian Biographies,’ and a bibliographic account of the early catechisms of New England (1898). He edited ‘John Eliot’s Logick Primer 1672’ (1904); ‘Humble Request of Governor Winthrop and the Company, 1630’
(1905). He contributed a list of catalogues, etc., published for the English book trade from 1595–1902 to Growoll's 'Three Centuries of English Booktrade Bibliography' (1903). He compiled for the New York Public Library a list of maps of the world (1904).

EAMES, William S., American architect: b. Clinton, Mich., 4 Aug. 1857; d. 5 March 1915. He received his education at Washington University and at the Ecole des Beaux-Arts, Paris, and at Rome. He settled at Saint Louis, Mo., and there practised his profession after 1862, where he also served as deputy commissioner of public buildings in 1881–83. In 1904 he represented the United States at the International Congress held at Madrid, Spain. In 1904–05 he was president of the American Institute of Architects.

EAR, Anatomy, Physiology and Disorders of the. In most of the animal creation the vibrations which we term sound have special portions of the body for their recognition, more or less precise; although in the lower forms every part of the simple organism may respond to them in some degree. The earliest separation of a distinct organ of equilibrium rather than of hearing is seen in the Meduse, of which the natural nettle of the salt waters is a well-known example. Here we find certain of the tentacles provided with delicate cells having hair-like projections and enclosing a chalky concretion, the otolith (Fig. 1). This structure of a tiny vesicle with single or multiple otolithic contents (Fig. 2), connected with the more sensitive or distinctly nervous portions of the organism may be regarded as the fundamental form of the ear; but it must be questioned whether the otolith apparatus has a really auditory function or is wholly concerned with the equilibrium or static sense, the stony less defined, passes to the sac (Fig. 3) and connects it with the sensory centres, which in the vertebrates and some of the higher invertibrates may be called brain-centres. This apparatus is in the vertebrates embedded in the cartilage or bone on either side of the head; and in those creatures which do not live in the water, accessory apparatus is present to help transmit the air-vibrations to the fluid ("endolymph") of the labyrinth. As we pass up the scale of animal life the organ of equilibrium is found more distinct from that of hearing; and thus in the lowest fishes we find that the sac assumes a ring-form (Fig. 4) by reason of the formation of a semi-circular canal with a pear-shaped widening or ampulla at either end. In these the nerve terminates in hair-cells without otoliths; while between these a large portion of the sac receives the main nerve-supply at a prominent "macula" supplied with hair-cells and otoliths. A second and a third semi-circular canal, each with its own ampulla and nerve, is found in the higher forms, and the main sac divides into two increasingly separate portions with separate nerve-supply. One of these portions communicates with the semi-circular canals while the other is connected with a tubular outgrowth, which in the highest forms coils into a spiral and is encased in a snail-shell covering, which gives it the name of "cochlea." The nerve passing to this becomes highly developed and the end-organ is greatly elaborated into an apparatus generally called after its discoverer "Cort's organ" (Fig. 7). Around this essential apparatus more and more complex protective envelopes and spaces filled with "perilymph" have been developed; while accessory apparatus, called middle and external ear, have been formed to aid in the conduction of sound-waves to the perceptive contents of the labyrinth.

The development thus roughly traced in the ascending scale of animals can be still more perfectly seen in the development from the ovum of the embryo of the higher forms. Here we see a portion of the external surface dip inward as a pit, become separated as a closed sac beneath the surface, undergo the elaboration described, secure nerve-connection with the brain and at such points of communication develop its hair-cells and otoliths. Originally a spherical sac, its complexly rolled nature of labyrinth and this membranous labyrinth gives form to a surrounding labyrinth of cartilage or bone, which has been longer known and studied (12, Fig. 9).

Taking the human ear as representing that of all the higher vertebrates and as an elaboration of that of lower animals, we find an acoustic nerve emerging from each side of the
pons or lower back of the brain, to pass, in close association with the nerve giving motion to the face, into the stony-hard innermost part of the temporal bone which encloses the ear. The facial nerve passes on through and practically has but accidental relation to the ear, but may be paralyzed by involvement in tympanic disease. The acoustic nerve, containing nerves for the equilibrium-organ, divides and is distributed to the various parts of the labyrinth. At each point of its distribution cells with hair-like projections form end-organs through which impressions are received to be conveyed to the brain. Three of these points are in the three pear-shaped swellings of the semi-circular canals, each of which is at right angles to the others, so that motion of the head in whatever direction can act upon the fluid in one or more of these canals and thus be analyzed and reported to the equilibrium center in the brain. Two are in the two vestibular sacs, and the most elaborate is where the real acoustic nerve enters the base of the snail-shell (Fig. 8), and is distributed to the highly elaborated organ of Corti, here located. This consists of a fairly orderly arrangement of hair-cells without otoliths, supported by curiously modified cells of like origin (Fig. 7), all resting upon a delicate "basilar membrane" narrowest below and broadest above, which winds spirally from the bottom to the top of the shell-like cochlea, and is formed of parallel transversely stretched fibres. Here we have an apparatus comparable to the strings of a harp or piano; and just as each string of a musical instrument can vibrate in accord with those attuned to it in another and can even repeat the tones of an inaudibly distant instrument with which it is connected by a wire; so there is much to support Helmholtz's claim that each fibre of the basilar membrane is a cord tuned to a certain pitch and vibrating responsive to any tone of that exact pitch which reaches it. This serves to excite a special hair-cell resting upon it and send a nerve-impulse along the ultimate nerve-fibril of which this forms the terminus. Certainly the apparatus in form and elaboration meets most of the requirements of such a theory and its partial destruction by disease has caused loss of hearing for certain tones—low tones if the apex, high if the base, be injured.

Outside of the labyrinth or perceptive apparatus we find a conducting apparatus of external and middle ear (Fig. 9). The outer ear is formed by the in-growth of a pit of the skin-surface to constitute an external auditory canal, around the edge of which gristly projections raise the skin-covering into the prominent but unimportant feature to which the name "ear" is commonly applied. The inward growth of the canal brings its bottom into close relation with the middle ear, so that only a thin partition, "the drumhead," intervenes. The middle ear is an outward development of the mouth-cavity, which hollows out the tissues between the external and internal ears—forming the Eustachian tube as its inner portion, the drum-cavity or tympanum just within the drumhead at the bottom of the external canal, and other air-spaces, "mastoid cells," of less constant presence and form and of doubtful value, but notable because of serious disease-conditions to which they are subject. Two "windows" make communication between the middle and internal ear, both closed by membranes shutting in the fluids of the labyrinth—that closing the lower "round window" being called the secondary tympanic-membrane. The upper or "oval window" is occupied by the foot-plate of the stirrup-bone, which with the little hammer and anvil forms (Fig. 11) a compound lever between the drumhead and the labyrinth-fluids. This serves to increase the force while lessening the amplitude of the vibrations of the drumhead and thus aids the transmission of waves of sound, especially of low tones, from the air to the internal fluids. The higher animals move the external ears as an aid in locating sounds, but the muscles effecting this are rudimentary in man and the external ear can be lost with little recognizable impairment of hearing. More important, although of ill-determined working, are the muscles moving the little bones of the drum-cavity; one, the drumhead tensor, drawing in the hammer-handle and thus tightening the drum-membrane to which it is attached, and

second and up through 10 octaves, should be audible to a healthy ear. If a cog-wheel touching a card or other elastic plate be turned with increasing speed the individual strokes or vibrations can be distinguished up to 16 per second; the numbers up to 100 make good tests if rightly selected and should be spoken clearly with the *reserved air* which can be expelled from the lungs after an ordinary "tidal expiration"; and they should be repeated by the person examined in evidence that they have been correctly heard. The watch is a variable, limited and imperfect test, which may be ill-heard by ears otherwise perfect, well-heard by some with little useful hearing and imagined or falsely claimed to be audible when it is not, in a way not always easy of detection. All measurements of hearing for sounds or speech should be made with the eyes screened from seeing the approach of a sound in the body or "reading the lips" as many deaf persons do most successfully, yet at times unconsciously. Medically, the best tests of hearing are by speech and by tuning-forks—the latter serving not only to measure the hearing or loss of it, but to locate the seat of trouble as a prime requisite to successful effort for its recovery. A "continuous tone-series" of tuning-forks or other instruments may be used by the expert to test the entire 10 or more octaves; and the aurist should always have several forks, although much may be learned with a single one. A fork of 200 to 500 double vibrations per second is the most useful and should be seven or more inches in length and weigh as many ounces: the latter is important as the loudness and duration of tone depend upon it. One of 30 to 50 and one of 2,000 double vibrations should also be used, while intermediate tones have value. The lower forks should have thickened ends or clamps or pieces of rubber tubing on the tips to damp the "over-tones," which may be heard by ears fundamental note is inaudible. The fork should be struck by falling of its own weight through its own height upon a rather dead surface such as the top of the knee, and will thus give a tone of fairly constant strength; and testing a number of normal ears will show for each fork at what distance or for how many seconds it should be heard after a standard blow. Thus if a fork which a normal ear hears at 15 inches or for 100 seconds is heard by a deaf ear only 5 inches or for 30 seconds, 5:15 or 30:100 fairly represents the fraction of hearing remaining.*

*Note.—Strictly, the hearing is at the *inverses* of such numbers.

Fig. 5.—Developing labyrinth dividing into two sacs with separate areas of hair-cells.

Fig. 6.—Diagram of the cochlea in section with the channels for its nerves and the perilymph spaces which surround the cochlear canal in its windings.
Ears with impairment of the percipient apparatus of the internal-ear hear high sounds relatively less as a rule; those with the more usual conduction-defect hear low tones worse. A case of "nerve-deafness" may hear no sound from the 2,000 fork—a case of tympanic catarrh none from the 50 fork; although all other tones are fairly or even perfectly heard.

A whistle devised by Galton giving tones from 4,000 up to 32,000 double vibrations is a practical and useful aid in studying the upper limits of hearing, as are the steel rods suspended by threads introduced by Koenig, since tuning-forks of such a pitch are unusual and costly. All of these tests should be made at the side of the head, but not so near that they may be felt instead of heard. The other ear may need to be closed with a down cushion or other adequate cover and we must avoid several "deaf-spots" nearly opposite the opening of the canal where the sound-waves by interference are weakened or lost.

Thus far we have considered tests of the hearing for sounds coming through the air in the usual way; but if the handle of a vibrating tuning-fork or other sounding instrument be rested upon the head it will be heard through the bone, and the sound will generally be much louder if the fingers are stuck into the ears. If only one ear be stopped, it will be heard louder in this ear—so much so that the other generally fails to recognize its vibration, even though the fork is resting close behind or above it. Normally this "bone-conduction" is only half as loud as "air-conduction"—the fork which should be heard for 100 seconds through the air in front of the ear is heard but 45 when resting behind it. It can usually be heard from the bridge of the nose or the teeth after it has become inaudible back of the ear; but when unheard here it should be audible for a further period if held close outside of the canal-opening. Yet disease-conditions can affect the matter like stuffing the fingers in the ears; the obstructions in the conducting apparatus which bar out in greater or less degree the outside air-vibrations shut in and echo back upon the percipient apparatus sounds produced or conducted within the head. The deafener ear may hear the sound by bone-conduction better than its fellow. More than this—it can often hear better than a normal ear, perceiving through the bone for 55 seconds, perhaps, the vibrations which ought to be heard for only 45. With this generally goes a marked loss of hearing through the air, which may be reduced from 100 seconds to 40, 20 or less. Under such conditions bone-conduction will be better than air-conduction and the sound will be louder as well as longer when resting on the head. This constitutes Rinne's or Schwabach's test and is simplified by resting the handle of the lightly vibrating fork back of the ear and then placing it outside the opening with the question "louder back or front, front or back?" The perception through the bone, especially at the bridge of the nose, ought to be nearly the same in duration as the feeling of the vibrations by the examiner's fingers; and Gardner Brown saved time and confusion by noting how many seconds before or after his fingers lost the vibration, it ceased to be heard in the ear. Bone-conduction may greatly preponderate, in evidence of the conductive defect in an ear with marked loss of air-conduction, and yet this test or Schwabach's timing will show that the perceptive apparatus is also defective and loses the sound sooner than normal, instead of having it exaggerated. So we must test the actual, as well as the relative, perception through the bone.

Another delicate and important test may be here mentioned. The drum-cavity communicates with the throat back of the nose by a trumpet-shaped tube called after its describer Eustachius. This serves as a drain for the removal of any mucus from the drum-cavity and as a ventilating passage for maintaining equal air-pressure on each side of the drum-head. It is really a slit habitually closed, but opens in the act of swallowing or yawning, from the action of the muscles lifting the palate. If a sounding tuning-fork, then, is held before the nostrils as the patient swallow there should be a brief opening of these tubes permitting freer passage of the sound to the ear: We thus determine the normal action or its lack in these very essential parts of the apparatus.

This proper ventilation of the drum-cavity is needful for perfect function. It is said that the head of the military drum will split if there is no opening in the side; and certainly a stuffed Eustachian tube makes all concussions painful if not damaging to the drum-membrane. Any
excess of pressure within interferes with the freedom of the windows, while any lack of air makes pressure on the outside preponderant, forcing in the drumhead and through the chain of bones pressing upon the labyrinth. More than this, if the partial vacuum in the drum cavity is increased through absorption of the unrenewed air by the moist lining, the drumhead becomes stretched until it collapses into contact with the inner wall, or the walls congest and swell to fill the space or else fluid is poured out to occupy the cavity. Generally all of these results are present in varying degree and from this comes the large majority of ear-diseases. So, too, interference with the freedom of the breathing through the nose unfavorably affects the ears. If one holds the nose and blows, air will be forced up the tubes into the drum-cavities, and swallowing motions have to be made to relieve the distention. If this swallowing is done while the nose is held closed, strong suction is exercised, making partial vacuum in the drum-cavity, and this occurs when cold-taking stuffs up the nose or tonsillar enlargement narrows the upper throat just behind it. It is not surprising, then, to find that two-thirds of ear-patients have middle-ear trouble, only one-fourth external-ear affections and in hardly one-tenth is the percipient nervous apparatus at fault. This explains why much of the treatment of ear-diseases must be directed to or through the nose and throat in the effort to restore free ventilation and repair the injury due to the lack of it. The unfavorable influences are often slow and insidious in action; deafness may be advanced in one ear without attracting the notice which any defect of the second ear quickly forces upon the attention; and treatment must be long continued if it is to retrace much of the course by which the affection has passed to its later stages. Discouragements are frequent, and the conscientious aurist has to tell his patient that only the recent losses can probably be recovered, and that ill-health or recurrent cold-takings may offset his best efforts. Yet many of these cases tend to grow steadily worse unless judiciously treated and a gain, however slight, is better than a loss. Mere inflation of air up the Eustachian tube by the Politzer bag or the catheter can aid the earlier stages; but in chronic conditions intratympanic medication must be used to stimulate the lining of the drum-cavity and retrace the steps by which it has become thickened and stiffened.

 Accompanying the defect of hearing for outside sounds there may be greatly increased hearing of noises within the head. Every one hears a singing in the ear when a shell or other resonator is held against it; and similar results often follow any thickening and stiffening of the conducting apparatus. Tinnitus, as the subjective sound is called, may be due to many causes, however, and its relief is often difficult. Generally a perception of the sounds of the blood-circulation, it may be caused by changes in the blood itself in anemia, by overaction of the heart, by brain-pressure due occasionally to stuffiness of the upper nasal passages, as well as to more local affections. It is usually worse when lying down and in a silent place, since outside noises and occupation of mind and body make it less noticeable; but it is in some cases unceasing and intrusive, seeming to bar out other hearing, and may be almost maddening. In its milder forms it is annoying and excites apprehension of deafness or of brain-disease, with which it is known to be sometimes associated; but its many causes, often wholly trivial, must be remembered and rational measures employed for its relief. As stuffing of the Eustachian tubes or tension of the drumhead and chain of bones are its common causes, much relief can often be gained by simple hot gargling to free the former, or gentle massage of the drum-structures, as may be well done with the hands.

 A curious characteristic of conduction-defects is the ability to hear better in a noise, often better than normal ears. A person deaf to ordinary speech in a quiet place will hear on a train much that is inaudible to persons nearer the speaker. One with nerve-deafness will be uneasily disturbed by other noises, although perhaps unconscious of defects in a still place.

 Only less important than freedom of the Eustachian tube is a healthy free condition of the external canal. This is lined with skin and supplied with glands like the sweat-glands elsewhere, but furnishing the ear-wax or cerumen, which consists of the dead skin-scales and oily material. The purpose of this seems to be to arrest by its stickiness the entrance of dust, small insects, etc., from outside; but it serves a more useful purpose in cleansing the ear. The growth of new skin is most active at the centre.
of the drumhead and is there rapid enough to spread out over the membrane, moving the older cells before it by a glacier-progress which carries them beyond the margin and out upon the walls of the canal before they become effete enough to be thrown off. Hence the normal drumhead is self-cleansing and needs no officious aid. The looser scales of dead skin pass out along the walls of the canal and about its middle become a pasty mixture with the secretion of the cerumen-glands. This clings to the fine hairs of the canal, but is gradually worked outward by the motions of the jaw-joint, which presses upon the canal, and drying into unnoted scales, it escapes from the exit. Under diseased conditions, including those of the throat and middle-ear, the wax tends to diminish in quantity and grow harder, escaping less readily or collecting in firm plugs. So long as any crack remains for the sound-waves to pass between it and the wall, hearing may be unaffected by an almost total filling of the canal; but jarring may force it down upon the drumhead and moisture may swell it into complete closure. Marked and sudden deafness results, often with dizziness, tinnitus or coughing. The plug may dry or crack away from the wall, quickly relieving the trouble, but only for the time; and it becomes so molded to the irregular curves of the canal as to make it difficult to remove. Most of the sponges and spoons offered in the drug-stores are good only for ramming in the wax more firmly and pressing it down upon the drumhead. They should never be used. The best solvent for ear-wax is hot water, and it should be syringed in with gentle force until the last particle of the plug has been removed. Dropping in of oil or other fluids rarely does much to loosen the collection — they can often increase the distress caused by its presence — they certainly cannot remove it, although some hope that they will do so seems present to many that use them. Any violence in digging out the plug or too vigorously working even with the syringe is to be condemned. Underneath it skinflakes have been forming which are often partly inclosed in its mass, partly still fast to the walls — ready like hang-nails to tear down into the quick and leave open wounds, very easy of infection. One-seventh of the cases of the aural surgeon require removal of this ear-wax, rather especially of those of his private patients who seek to be too clean. It is easy to do it skillfully and promptly, yet it is often not so removed. If spoon-like instruments be used at all they should be sharp — they will thus be more efficient, while a mistaken idea of harshness will make dull instruments doubly dangerous. It is true of many a thing besides a firearm that a man "did not know it was loaded."

Seeds, beads and other foreign bodies are sometimes put into the ears. If they are let alone they may remain for many years without doing the least harm; but forcible removal has often done great or fatal injury. If the ear is directed downward they will often fall out, especially with a little rotary rubbing in front of the ear — the drum and the circumference bring them away promptly and safely. If they have been rammed in and fixed, it is really gentler to remove them by laying forward the soft parts under ether and operating in the bony canal, even chiseling it wider at need.

Two other affections of the external ear make up much of the 25 per cent of diseases involving this part — the diffuse and the circumscribed inflammations of the canal. The first may be broadly called eczema — the latter furuncle or boil. Gout and many general conditions can predispose to the eczematous inflammation, which by its heat and moisture makes the ear a hot-bed for the growth of the molds and bacteria which maintain or increase the trouble; and it may have an intensity verging into erysipelas. The milder, chronic forms are generally responsible for furuncles, for they furnish the itching which leads to scratching and the germs which punish this "What did you scratch it with?" will generally bring con-

![Fig. 11.—Inner surface of drumhead (9), to which is attached the handle (7) of the hammer, the head (5) of which is hinged to the anvil (4), the long arm (6) of which connects with the stirrup (10) the chain pivots on the horizontal arm (3) of the anvil and conveys vibrations to the labyrinth.](image-url)
Bony outgrowths of the walls sometimes narrow or close the external canal and less often cancerous growths involve it and the external ear. The bony growths are frequently found in the ears of ancient Peruvian and Mound-builders' skulls and in modern times in Hawaii and in England. The London surgeons among their private patients see and remove more of these bony outgrowths than are reported from all the hospitals of the world. Their causes are not clear, and bathing has been suggested as influencing their formation. As seen in other than Englishmen, the great majority seem due to long-continued discharge from the ear; and this suppuration must be cured or the growth removed, lest the confinement of pus may lead to serious or fatal complications.

The supplicative inflammations of the middle-ear form the most important phase of our subject, not only because of their malignant effect in producing deafness and deaf-mutism, but from their serious menace to life. Thousands are known to die annually from ear-diseases, and the records of large numbers of post-mortem examinations show that a large proportion usually escape recognition during life. The practice of inoculating ears many years past has hugely increased the frequency of serious outcomes, as well as served to bring them to notice; but even before that the record was long and grim. All the eruptive fevers, especially scarlatina, measles and typhoid, are apt to bring involvement of the ears. These should, therefore, be closely watched and generally guarded in some measure by coverings, especially in children, who may never call attention to their ears and yet if they lose hearing are prone to become deaf-mutes.

It is well known that discharge from the ear is apt to lessen or cease at the onset of serious extension and that bottling up of the flow may give rise to such results; but the somewhat prevalent view that such suppuration should be "let alone and it will be outgrown" is as mistaken as is the idea that it is dangerous to bring it to an end. To "stop it up" is wholly different from stopping it by cure; and the chronic cases of slight discharge, often hardly noticeable, are those from which fatal diseases such as brain-abscess, pyæmia and sinus-clotting are generally recruited. Few good insurance companies will have anything to do with a man having a long-standing running ear—the risk for the individual may not be very frightful, but it is enough in any large aggregate to consume all the profit of insuring lives.

Suppuration of the middle-ear is ushered in by pain, and the severity of this "ear-saché" is at times some measure of the seriousness of the attack. The onset may be insidious or misleading, however, and relief may be sought of the dentist; while in children the fever, delirium or convulsions may draw attention away from the ears. Stains on the pillow or visible moisture in the canal may be the first indications that the ears are involved. But every such case, however stormy or mild its beginning, may go on immediately or remotely to the worst of issues; and it is our duty to take reasonable precautions from the start, lest we have reason later to reproach ourselves. Mere external protection as by ear-tabs or a night-cap may conserve the recuperative powers; gentle hot douching with clean water may relieve the pain by reducing the inflammatory congestion; and spray and gargling may strike at the root of the trouble in nose and throat. If suppuration may be in other respects, it is mistaken kindness to withhold these simple yet often effective measures of treatment. The tendency is to a "gathering in the ear," which may be watery or mucous or may be purulent and infective. If the simple measures named fail, the use of a salt-bag or hot water-bottle fail, there is need for surgical aid. Drainage by the natural Eustachian channel can only sometimes be gained; but after good cleansing of the nose and upper throat, it should be gently attempted by the Pollitzer method or the catheter. Abuse of these means is rightly condemned; so only the expert can maintain his right to use them if ill results follow—in spite rather than because of them. If they fail and the drumhead is seen to be bulging, especially with yellowish fluid, it should be delicately cut along its back margin to furnish a free escape for the collected fluid. If the swelling is marked at its upper portion, the knife should be carried up into this region, coming out in a sweep to the bone along the upper limit of infection. The use of heat is encouraged by warm douching and is more effective from such a cut than from external leeching; yet since much of the blood-exit from the drum-cavity is along the front wall of the canal, leeching in front of the ear may be almost as good, but should remove not less than four to eight ounces. A wick of gauze or absorbent cotton, dry or moistened with carbolic or boric glycerine, should be inserted deep into the canal and the protective covering replaced. "But if you cut the drumhead you destroy the hearing," is a fallacy which is still repeated. The opening of the drum is a delicate operation, often very painful so as to require ether or other anaesthesia and capable of doing injury to the structures beyond it; but it only forestalls the opening which would occur spontaneously, makes a free and well-placed operation, really saves a drumhead from ulcerating through. Far more important is its influence for good in relieving the injurious pressure in the drum-cavity and it may be really life-saving in preventing fatal extension of the suppuration.

It is impossible to foresee how fatal or serious any case is going to prove; and without panicicky fighting of shadows, it is only reasonable to press home all due precautions. The patient is best in bed, especially if feverish, and all exposure and stimulating diet should be avoided. Constipation must be relieved, for straining of every sort is not only painful but increases the congestion.

With the opening, artificial or spontaneous, of the drum-membrane, there is generally relief of the pain; yet this is almost sure to recur, especially at night, but with lessening severity, duration and frequency. The fever, which is commonly marked in children, declines and some of the lost sleep is made up. The tension within the drum-cavity is lessened by the escape of the "gathering" and obtains continued relief by the steady exhalation. Slight bleeding is thin and bloody at first, then thicker and probably stringy. Its amount is often surprising, so that hourly cleansing is needful, and it may excoriate the skin in and about the canal, cali-
ing for protective ointments. The ideal treatment is thoroughly to cleanse before cutting the drumhead and thereafter as frequently as the flow demands to change the sterile wicks of cotton in the canal. If these are prepared by the hundred, each wrapped in a waxed paper and the package of them baked, the patient can readily remove the moist plug and substitute a clean one without contaminating it. Practically, frequent syringing with boiled water at 110° F. or more and a clean soft-rubber bulb, better relieves the pain and cleanses the deeper parts of the canal. The heat can penetrate where the water cannot and is the best astringent and stimulant. After two or three weeks the discharge should cease, and another week or two should bring cure; but the cardinal fact in these cases is the infected character of the inflammation, which endangers serious destruction in the drum-cavity and adjacent more vital regions. Often worse than the destruction is the scarring which results from nature's effort and repair. An opening in the drumhead generally heals and may leave no visible scar; in an important minority of cases the edges are skinned over, preventing its closure and grafting skin upon the mucous surfaces within. Nature is prepared to sweep away fluid waste material in the drum-cavity, but skin-fibres forming there are difficult of removal; they tend to collect and by their presence excite more exaggerated scaling. Onion-like masses may thus form, constituting "cholesteatoma" or pearly tumor, and these can do much damage by their pressure as well as maintain or renew the suppuration. The bony walls and the little ear-bones may be destroyed by pressure or decay, and while an exit may thus be made for the cholesteatoma-mass, it often works inward instead of outward, damming the labyrinth and may carry the infective process into the brain-case. Just under the thin floor of the drum-cavity is the head of the jugular vein, its intracranial part is equally vulnerable just behind, and an even thinner roof alone protects the brain-membranes above. It is not surprising, then, that symptoms of brain-inflammation are not unusual in ear-diseases; and while these may be merely irritative symptoms, they are at times of deadly meaning. Where the bone suppures and decays the mastoid-projection just behind the ear is apt to be involved, forming a "mas-toid abscess," and may need to be chiseled open to give exit to the matter and dead bone. Even without this, the inner wall of bone can decay and an abscess-collection form on the outer surface of the brain-membrane. Yet this is strong and firm and may thicken to better protect all within; so such "extra-dural abscesses" have but a fraction of the danger of a collection upon or in the brain itself. Even this can now be often recognized in time by its subnormal pulse and temperature, and located sufficiently by its symptoms to permit of surgical relief; and nearly 50 per cent of the reported operations have been followed by cure. The infection can penetrate the adjacent great blood-vessels and cause clotting within them, with general blood-poisoning and formation of abscesses in the lungs or other parts of the body. The abscess is often safely removed in many cases even when extending down almost to the heart.

Disease of the nervous apparatus of the internal ear is met in hardly 10 per cent of ear-patients. Some of these are due to injury and fracture at the base of the skull, others to cerebrospinal meningitis or other severe fevers, more still to the extension inward of the catarrhal or the suppurative middle-ear inflammations. Mumps, too, or diphtheria may be followed by sudden total deafness. Inherited syphilis is one of the insidious and slowly acting causes, generally also giving rise to clouding of the cornea of the eye and marked by typical malformation of the second and third. In any of these conditions the main hope of relief is through the absorption by mercury and iodine of the exuded material, which in the meningitis cases may be in the brain itself and not in the labyrinth. Of notable interest are the cases of "boiler-makers' deafness," as we sometimes call a group of occupation-disorders, usually located in the internal ear, and affecting those subject to persistent clanger — a condition which may compel change of work, if freeing the Eustachian tubes and good plugging of the external canals fails to relieve the persistent deafness. Important too are the cases of vertigo, due to ear-disease. Menière called attention to some of these as caused by labyrinthine apoplexy and they are often called by his name; but the recognizable disease may be of different nature and often is located in the drum-cavity, indirectly affecting the organ of equilibrium in the semi-circular canals. Influenza has caused a number of these cases in which the hearing for more or less of the scale has been suddenly lost and the ear made incapable for days or weeks of lifting the head from the pillow. Absorption is here also the best hope; but in some extreme cases advantage has been taken of the damaging effect upon the ear of large doses of quinia, and the irritative condition was thus changed to a destruction with cessation of the vertigo.

The systematic development by Barany and others of tests of the equilibrum-apparatus has given us a most valuable power to stimulate chosen portions of the labyrinth and thus investigate not only the end-organ, but the brain-centres and the paths which convey impressions to them. Revolving the patient in a pivoted chair or using a cold or hot douche in the ear can elicit marked and definite oscillation of the eyes, technically known as "nystagmus"; and this, which may be varied at will in the normal, is modified or prevented by diseased conditions. Vertigo is usually produced by such stimulation and the perverted equilibrium-sense causes the patient to point astray, to fall in a known direction or to be made "sea-sick." Interruption of transmission along this path or that may clearly point to the exact site of disease and furnish information of far-reaching value to the brain-specialist and the surgeon for life-saving intervention.

Finally we may mention the brain-affections in which the hearing-centres, especially that for speech, are involved, when we may have "word-deafness," which prevents recognition of the spoken word, although the hearing is perfect for tones of every pitch; for while the ear itself is uninjured, it is only through ear-examination that one can by exclusion reach a correct diag-
nosis and perhaps point the way for the surgical removal of a brain-tumor.

**EAR COCKLE,** a disease peculiar to wheat caused by the presence in the grain of worms belonging to the family **Vibia.** In some parts of Europe the disease is known as purples.

**EAR OF DIONYSIUS,** a famous quarry near Syracuse, in which the slightest whisper was audible at a great distance. It was connected by a secret passage to the palace of Dionysius, the Elder, who died 362 B.C.; also an acoustic instrument with a large mouthpiece to collect the sound, which a flexible tube conducts to the ear. The cave was afterward used as a prison.

**EARRINGS.** Primarily the ear-ring is a ring for adornment of the ear. More broadly it implies any ear ornament. Usually the ring is attached to the ear by passing through its pierced lobe. A gracefully curved hook is often the attaching part where the ornament is composed of more than one piece (pendant). In modern times the ear-ring is frequently fastened to the ear by screwing firmly to a small plate at the back of the ear, thus avoiding the piercing of the lobe. Ear-rings date back to prehistoric times. In Homer's *Iliad* we read that Juno "put in her ears, skillfully pierced, ear-rings worked and ornamented with a triple precious stone." The ancient East Indians, Medes, Persians, Egyptians, Arabsians and Hebrews wore ear-rings. The Egyptians wore them in ornamental artistic forms. The Etruscans made gold ear-rings, showing a tendency to those of the Egyptians, of delicate filigree work and minute granulation. They took the form of flowers, fruits, vases, shields, rosettes, crescents, cornucopias, tasses, peacocks, swans, cocks, Medusa heads, etc. The Greeks excelled in the art of making gold ear-rings and gave them numerous beautiful forms; the simpler form was a ring and these were termed *elloba* or *enota.* Their *stalagmas* were pendants in the form of drops of water, as the name implies; their *crotales* were composed of little rows of pendant forms (usually pitcher shape) and their name was derived from the fact that they *rattled* as they struck one another on the motion of the wearer. Even the statues of the goddesses (whether of stone, wood, ivory or precious metal) had golden ear-rings; the Athena of Phidias, ancient writers tell us, wore such adornment. Men did not wear ear-rings after adolescence. The Romans adopted the Greek fashion, but their ear-rings were of a heavier, more elaborate form; the Roman ladies' *inaires* were often gems of great value. Seneca (1st century A.D.) wrote scathingly of the fashion in his day: "Thy wife carries in her ears the revenue of a rich family." Elsewhere he says: "I see pearls, not one only for each ear; the ears are now strained to carry heavier weights. The pearls are in a cluster; they are superposing one another in rows. The folly of women never before so subdued the wish of men; it is two, it is three patrimonies that they suspend from their ears." The Republican Romans despised the use of ear-rings by men, and the comic poet Plautus rails at the Carthaginian men that wore one. Later, however, the men took to this adornment so popularly that the Emperor Alexander Severus (3d century A.D.) had to forbid their use by men in an edict. The Byzantines appear to have abstained from ear-rings, in spite of the strong influence of Asia. The ancient Gauls and Germans adorned themselves with bronze ear-rings after East Roman prototypes. At the time of the migration of the nations the wearing of ear-rings had become a universal custom. The oldest ear-ring extant, probably, is of gold pierced like filigree work; it is in the Germanic Museum at Nuremberg, where are also some East Gothic ear-rings reminding one forcibly of present-day pendants. A thin wire loop (to thrust through the ear) has a richly or-
ANCIENT EARRINGS
namented part attached, and a precious stone or pearl hangs from the centre. Superstition was attached to the ear-ring by the Northern races at least, for, as the sagas tell, ear-rings prevent evil sounds and malicious suggestions from entering the ear, hence their ornamentation with mysterious talismanic signs.

Ear-rings and figure of goddess. Cyprostis.

In the Middle Ages ear-rings were generally termed "rings for the ear," clearly indicating their form. Men wore them later on in one (the left) ear. Labordé quotes from 1452 thus: "Gift of Monseigneur the Dauphin for two circles of gold, which were hanging and attached to the ears of Milton, the fool of Monseigneur the Dauphin, 9 livres. Royal Accounts." Later, the custom of wearing the hair over the ears caused ear-rings to fall into disuse, coming again into vogue in the 15th and 16th centuries. A change took place in jewelry by the 17th century, and ear-rings, like the rest, were valued for their precious stones more than the richness of their material and the beauty of their handbook which the Renaissance afforded.

Our great-grandmothers wore extremely long ear-rings with dangling tassel or pitcher forms, but we now restrict the ear-ring to diamonds, single gems or coral, mostly. Ear-rings for men had a short vogue at the court of Henry II of France, and have since never been popular. We see only gypsies, sailors and a few Latin (Italians and Spanish) yet wearing gold circles in their ears. And the medical authorities have renounced their former belief that piercing the ears was an aid to that organ.

CLEMENT W. COUMBE.

EAR-SHELL, a much flattened univalve mollusk of the family Haliotidae, allied to the keyhole limpets. It takes its name from its rough resemblance to the human ear, and is known as ormer and oreille de mer in the Channel Islands, where one species is extensively used in making ornaments. These mol- lusks in various species occur on rocky shores in all warm regions, and in California are called abalone. Their richly nacreous shells are used extensively for the making of buttons and fancy articles; and in China and Malaya the animals are eaten fresh and also preserved as food in large quantities. Consult Cooke, 'Mollusks' (New York 1895).

EAR-TRUMPET, an instrument used to strengthen the sensation of sound in the partially deaf. The first mechanical contrivance for the purpose of improving the hearing was made by Dr. Yardsley of London in 1848. Since that time, numerous curious devices have been invented. The unpopularity of these is due to their awkwardness in size and shape for portability. Before advising the use of such mechanical aids a careful diagnosis of the ear should be made, and the condition of the middle ear should be especially ascertained. In general these aids are apt to induce temporary improvement and result eventually in more serious complications. The object of the ear-trumpet is to collect the sound waves and throw them into the ear in parallel waves. The curve of the collection or resonator—the reflector—must be more or less parabolic so as to give the maximum amount of sound at the entrance of the tube. For hearing at short distances Currier's conico-cylindrical tube is considered the best. It consists of a tube three and one-half feet long, which has a bone or hard rubber tip at one end while at the other is a bell-shaped mouthpiece made of the same material. The tip and mouthpiece are connected by an elastic spiral wire tube covered with rubber and over-spun with silk or mohair. The tube is conical, and the speaker must place his lips close to the mouth of the tube. The London hearing dome is made of metal, of the same variety as that used in musical instruments; the Aikou concentrator intensifies as well as concentrates sound, and is made of bell-metal; the Hearsoll churchphone is of hardened rubber and partly collapsible. It is of great use in long distance hearing, as are also the audiat, of black japanned tin; the folding fan trumpet, a tin horn attached to a folding black fan to conceal its use; and the Largemot hearing horn, of hardened rubber. The otophone has been used to teach articulation to deaf-mutes, because it carries low tones extremely well. The denti- phone conveys sound through the medium of the teeth and is worn at tension in the mouth. The acousticon is a modification of the telephone principle, extremely complex, showing on its surface the battery, carpiece, transmitter and connecting cord. It is the most perfect and most expensive of ear-trumpets. The auris is a modification of the acousticon, simpler and less expensive. Countless other instruments have been developed. In general their use is to be discouraged, and other aids for deafness should be used, such as lip reading, and insistence on being addressed in clearly enunciated tones.

EAR-WORM. See Corn Insect-Pests.
EARL, a degree of the British nobility between marquess and viscount. Until 1357 it was the highest title in England. The name came into use in the reign of Canute as earl, which was translated in English to earl, and was applied to the officials who presided over the counties and who supplanted the old Saxon ealdorman. The title was made hereditary by William the Conqueror, who also assigned its judicial powers to the sheriff or vicecomes, appointed for himself. After that, numerous earls were created and for a time the name was used interchangeably with count, the corresponding title on the Continent. The name of the ealdom was derived from the name of the shire. The title was granted by investiture at first and it was not until the reign of Edward III that earls were created in Parliament and invested without ceremony by charter or letters patent. The last method is the one still employed. There are more than 200 earls in the United Kingdom, although the sovereignty of the title over the county has in some cases disappeared. The wife of an earl is still called a countess. The eldest son is called viscount, the younger sons honorary earls or viscounts. An earl's coronet is composed of eight pearls raised upon points, with small leaves between, above the rim. (See HERALDRY.) Consult Pike, 'Constitutional History of the House of Lords'; Selden, 'Titles of Honor' (London 1614).

EARL MARSHAL, the eighth great officer of state in Great Britain who had, anciently, several courts under his jurisdiction, as the Court of Chivalry and the Court of Honor. He is the head of the College of Arms (Herald's College), grants armorial bearings and determines all matters in connection with them. The office is hereditary in the family of the Howards.

EARLE, Alice Morse, American writer: b. Worcester, Mass., 27 April 1853; d. 1911. She was married to Henry Earle in 1874. She wrote extensively upon the manners and customs of the colonial period in New England and New York, and in her various books presents a mass of quaint and interesting information. Her published works are 'The Sabbath in Puritan New England' (1891); 'Customs and Fashions in Old New England' (1893); 'Life of Margaret Winthrop' (1894); 'Diary of a Boston School Girl' (1894); 'Costumes of Colonial Times' (1895); 'Colonial Dames and Goodwives' (1895); 'Old Narragansett' (1896); 'Curious Punishments of Bygone Days' (1897); 'Colonial Days in Old New York' (1897); 'Home Life in Colonial Days' (1898); 'Child Life in Colonial Days' (1899); 'Stage Coach and Tavern Days' (1900); 'Old Time Gardens; Sundials and Roses of Yesterday' (1903); 'Sun-Dials and Roses of Yesterday' (1903); 'Yesterday and Today; Centuries of Costume in America' (2 vols., 1903).

EARLE, Franklin Sumner, American agriculturist and botanist: b. Dwight, Ill., 4 Sept. 1856. He was educated at the University of Illinois and made special studies, chiefly in botany and biology, at the Alabama Polytechnic Institute. In 1886 he was associated with the University of Illinois, doing special mycological work, the results of which were published, with the title 'The Erysiphaceae of Illinois,' in collaboration with T. J. Burrill. In 1894-95 he investigated Mississippi fungi for the Mississippi Agricultural Experiment Station. In 1895-96 he was assistant pathologist in charge of the mycological herbarium of the United States Department of Agriculture. From 1896 to 1901 he was professor of biology at the Alabama Polytechnic Institute. In 1897 he was appointed assistant curator in charge of the mycological collections of the New York Botanical Gardens; he was sent to Cuba and Jamaica to gather material, and in 1903 to Porto Rico for the same purpose by the United States Department of Agriculture. In 1904 on the recommendation of the department he became director of the Estación Central Agronómica de Cuba. From 1906 to 1911 he was consulting agriculturist to the Cuban-American Sugar Company and after 1911 served as president of the Cuban Fruit Exchange. He is the author of 'Southern Agriculture' (1907).

EARLE, John, English philologist: b. Elston, Devonshire, 29 Jan. 1836; d. 31 Jan. 1903. He took his B.A. at Oxford in 1854; was presented to the rectory of Swanswick 1857 and was professor of Anglo-Saxon in the University of Oxford 1876-1903. His chief publications are 'Gloucester Fragments' (1861); 'Two of the Saxons: Chronicles Parallel' (1865); 'A Book for the Beginner in Anglo-Saxon' (1877); 'English Plant Names from the Tenth to the Fifteenth Century' (1880); 'Anglo-Saxon Literature' (1884); 'English Prose: its Elements, History and Application' (1890); 'The Psalter of 1353: a Landmark in English Literature' (1894); 'A Simple Grammar of English Now in Use' (1897); 'The Alfred Jewel' (1901).

EARLE, Mortimer Lamson, American classical scholar: b. New York, 14 Oct. 1864; d. New York city, 26 Sept. 1905. He was educated at Columbia College; was instructor in Greek at Barnard College for six years beginning 1889, and was then appointed associate professor of Greek and Latin in Bryn Mawr College; 1896 to 1900 was lecturer in Greek at Columbia; and in 1900 was professor of classical philology in Barnard College. Among other literary work he edited Euripides' 'Alcestis' (1895) and Sophocles' 'Edipus Tyrannus' (1900). His lesser works were published in collected form in 'The Classical Papers of Mortimer Lamson Earle, with a Memoir' (New York 1912).

EARLE, Pliny, American inventor: b. Leicester, Mass., 17 Dec. 1762; d. there, 19 Nov. 1832. In 1785 he became engaged in the manufacture by hand of machine and hand cards for carding cotton and wool and invented in 1790 a machine for the manufacture of such cards by which the labor of one man for 15 hours could be performed in as few minutes.

EARLE, Pliny, son of the preceding. American physician: b. Leicester, Mass., 31 Dec. 1800; d. Northampton Mass., 18 May 1892. He was educated at the Friends' School, Providence, R. I., and graduated as M.D. at the University of Pennsylvania in 1837. He was resident physician of the Asylum for the Insane at Frankford, near Philadelphia, 1840-42; physician to Bloomingdale Asylum, New York,
1844-49; elected professor of materia medica and psychology in the Berkshire Medical Institution at Pittsfield, Mass., in 1863, and was superintendent of the Massachusetts State Hospital for the Insane 1864-85. In the years 1837-39, 1849 and 1871, he traveled in Europe visiting the most important insane asylums. He is the author of 'Marathon and other Poems' (1841); 'Institutions for the Insane in Prussia, Germany, and Austria' (1853); 'An Examination of the Practice of Blood-letting in Mental Disorders' (1854).

EARLE, Thomas, American lawyer: b. Leicester, Mass., 1796; d. 1849. Early in life he removed to Philadelphia, where he was a member of the Constitutional Convention of 1837. His advocacy of the extension of suffrage to negroes antagonized many Democrats, and in 1840 Earle was the vice-presidential nominee on the ticket of the Liberty party. Not succeeding in politics he abandoned it for literary work and subsequently published 'Essay on the Penal Law', 'Essay on the Right of States to Annex Their Chariters', 'Treatise on Railroads and Internal Communications' (1830); 'Life of Benjamin Lundy' (1844).

EARLE, William, English soldier: b. Liverpool 1833; d. 10 Feb. 1885. He received his education at Winchester, entered the army in 1851 and distinguished himself in the Crimean War. In 1872-76 he served as military secretary to Lord Northbrook, viceroy of India. He commanded the garrison of Alexandria in the campaign against Arabi Pasha and in 1889 was division commander in the expedition hurried to the relief of Gordon at Khartum. He was killed while leading his troops against Arab entrencheds at Kirbekan.

EARLHAM COLLEGE, a coeducational institution in Richmond, Ind., founded in 1847, under the auspices of the order of Friends. It is located on a tract of 120 acres, adjoining the western limits of the city of Richmond. The campus has an area of 40 acres, is shaded by native forest trees and is tastefully laid out with walks and drives. The college has eight buildings and the degrees of B.A., B.M. and M.A. The endowment amounts to about $750,000 and the value of buildings and grounds to about $375,000. The annual income is about $140,000. The total number of students in 1916 was 430, and the instructors numbered 30. The library contained 15,000 volumes.

EARLINGTON, Ky., city in Hopkins County, on the Louisville and Nashville Railroad, 55 miles south of Evansville, Ind. It is an important coal-mining centre and has extensive coke manufactories. The government is invested in a mayor, elected for four years, and a council of six members. The city has two public libraries. Pop. 3,931.

EARY, John, American clergyman and publisher: b. Bedford County, Va., 1 Jan. 1786; d. Lynchburg, Va., 5 Nov. 1873. In 1807 he entered the ministry of the Methodist Episcopal Church South, and his early ministry were the slaves of President Jefferson. He was agent for Randolph-Macon College, 1833-40. When the Church divided he went with the Southern faction and aided in forming the Methodist Episcopal Church South. In 1846, he was elected the first publishing agent of the Church and began the business in Richmond, Va. In 1854 it was removed to Nashville, Tenn. In the same year he was elected bishop, serving until 1866 when he retired from active service.

EARLY, Jubal Anderson, American soldier: b. Franklin County, Va., 3 Nov. 1816; d. Lynchburg, Va., 2 March 1894. He was graduated from the United States Military Academy in 1837, fought in the Seminole War (1837-38) and having resigned from the service, entered legal practice at Rocky Mount, Frasolin Co., Va., in 1838. A member of the Virginia house of delegates in 1841-42, he was also attorney to the Commonwealth in 1842-47 and 1848-52. During the Mexican War he was major (1847-48) of volunteers; and at the outbreak of the Civil War, although strongly opposed to secession, he received the appointment of colonel in the Confederate forces. Promoted brigadier-general for services as a brigade commander in the Shenandoah, possession of which he contested with Sheridan, then commanding the Federal army in the valley. On 19 September he was defeated at Opequon Creek, with the loss of 3,000 prisoners and five guns, and on 22 September at Fisher's Hill, where he lost heavily and from which point he was driven to the mountains. On 19 October he surprised the Federals in the morning at Cedar Creek, but the tide of victory was turned by Sheridan's arrival from Winchester, and he was completely routed. After his defeat by Custer at Waineborough (March 1865), he was removed from his command. He attained lieutenant-general's rank. Subsequent to the war he practised law in Virginia, and was, with General Beauregard, a director of the Louisiana lottery. He never took the oath of allegiance. He was on the list of Confederate officers, and by some authorities was considered not inferior to "Stonewall Jackson." His chief publication is a 'Memoir of the Last Year of the War for Independence in the Confederate States of America' (1867). Consult Battles and Leaders of the Civil War, 3rd ed. by Johnson and Beuel (1887).

EARLY ENGLISH ARCHITECTURE, the name generally given to the first pointed Gothic used in England. This style of architecture began to be used in England about the end of the 12th century and lasted for about 100 years. It immediately succeeded the Norman and finally merged in the Decorated style. It is characterized by long lance-shaped windows, which are often gathered into clusters and enclosed by a large trefoil niche in which and the tops of the windows is often pierced with circular, trefoil or quatrefoil ornaments. The molding consists of alternate rounds and deeply cut hollows, separated by small fillets. The doorways are often divided.
into two by a single shaft. The stones used were large and massive; the windows small. Later the entire structure was made lighter and thinner. The vaults were low and the flying buttress and arch were for the most part replaced by side-wall roofs. Of this style are the choir of Canterbury (1175-84); Salisbury Cathedral (1220-58); and the choirs of Chester, Gloucester, Worcester and portions of the choirs of Ely and Winchester. Consult Moore, 'Medieval Church Architecture in England' (New York 1912); Prior, 'History of Gothic Architecture in England' (London 1900); Bondy, 'Gothic Architecture in England' (ib. 1907).

EARMARK, a slit or notch on one or both ears of cattle made when the calf was being branded and to serve as a means of identification. It was much used in the Western States of the Union in the halcyon days of the great ranches. Earmarks could be distinguished at a greater distance than the brand as the cattle when approached by a cattleman turned and faced him, thus permitting him to decipher the earmark readily.

EARTH, The. The earth is at once the subject and the object of many sciences. Of these the most elementary are geography and physiography, which deal primarily with the salient surface features of our planet. Next in order of difficulty are geodesy and geology, which deal more minutely with the shape, the size, the constitution, the mechanical properties and the material history of the earth. The science of meteorology is concerned with the phenomena of the atmosphere; and our theories of the tides and terrestrial magnetism must be added to the list of purely physical sciences of the globe. All of these sciences are intimately related, and they are sometimes grouped under the single term geophysics. In a broad sense, also, these sciences may be regarded as branches of astronomy for astronomy is founded, and hence includes, geophysics. This article is written from the point of view of geophysics and deals especially with the physical and mechanical properties of the earth.

THE SHAPE AND THE SIZE OF THE EARTH.

First Approximation.—The form and the dimensions of the earth have presented a problem of the greatest interest and difficulty to men of science for more than 20 centuries and they promise to tax the resources of the ablest physicists for some centuries to come. The first approximation to a solution of this problem, of which we have definite record, was made by Eratosthenes of the Alexandrian school of astronomers. Assuming the surface of the earth to be spherical, he measured the length and the angular amplitude of an arc of a great circle extending from Alexandria to Syene. He observed that at Syene, which is about 500 miles south of Alexandria, the sun shone vertically downwards into deep wells at noon on the day of the summer solstice, proving thus that at that place and time the sun was in the zenith. On the same day at Alexandria he observed, by means of the gnomon, that the sun at noon was south of the zenith by one-fiftieth of a circle, or 7.2 degrees. The principles involved in these measurements and in the calculation of the size of the earth are very simple, but they are so fundamental as to justify a full explanation. They assume, first, that the earth is spherical in shape; secondly, that the plumb-bob at any point of the earth's surface is directed toward the earth's centre; and, thirdly, that the sun is so distant that lines drawn to it from different parts of the earth are sensibly parallel. Thus, in Fig. 1, if A and B indicate the relative positions of Alexandria and Syene and C the centre of the earth, lines from A and C to the sun will be parallel; and hence the angle ZAS, or the meridian zenith distance of the sun at Alexandria, will be equal to the angle ACB. Knowing this angle and the distance AB, the rule of three gives the entire circumference.

Second Approximation.—No substantial advance beyond this first approximation was made until Newton showed that the gravitation and the rotation of the earth ought to make it somewhat flattened at the poles, or that the surface of the earth should have the shape of an oblate spheroid of revolution. The proof of this theoretical conclusion of Newton constitutes the second approximation to the figure and the size of the earth. Such a figure, however, is much more difficult of measurement than a spherical figure. This is seen by a glance at Fig. 2, representing an ellipse, which, if revolved about its shorter axis PP', will generate an oblate spheroidal surface. The principles of mechanics show that when such a surface is due to the attraction and the rotation of a fluid mass, the plumb line at any place will not in general point toward the centre of the mass, but will pass somewhat to one side of it, as shown by the line LIQ in the figure.

Newton's conception, therefore, involved the difficulties of the more complex spheroidal figure and of the hypothesis that the earth was primatively a fluid mass. Two ways of testing Newton's views were proposed. One was to

measure the meridional lengths of a degree of latitude at different places on the earth's surface. If the earth is an oblate spheroid, it is seen from Fig. 3 that the meridional distance along the surface intercepted by two plumb lines which make an angle of one degree (or any constant angle) with each other is greater at the poles than at the equator, or in general, greater in high than in low latitudes. The other method proposed to measure by means of the pendulum the varying acceleration to which a body is subject in different latitudes on the earth's surface. If the Newtonian view is correct, that acceleration, which is the resultant of the effects of attraction and rotation of the earth, and hence the weight of a body, must increase in passing from the equator to the poles.

![Fig. 3](image)

But the Newtonian theory was neither readily accepted nor easily verified. In the early part of the 18th century, in fact, the theory was hotly opposed by the justly distinguished Cassinian school of French astronomers, whose erroneous interpretation of a carefully measured arc of a meridian in France indicated that the earth is an oblong rather than an oblate spheroid. The question was permanently settled by the famous Lapland expedition sent out by the Academy of Sciences of Paris, in 1735, under the auspices of Maupertuis and Clairaut. They proved beyond doubt that the earth's surface is very closely that of an oblate spheroid, thus "flattening the poles and the Cassinis," as Voltaire remarked at the time.

A vast amount of labor has since been devoted to the determination of the dimensions of the spheroid which best fits the earth's surface. This is, indeed, the principal problem of the precise geodesy of to-day. The dimensions of the earth which have been provisionally very generally adopted are those of Gen. A. R. Clarke published in 1866. The theory of a spheroidal surface requires a knowledge of the lengths of the longer and the shorter axes of the generating ellipse, or equivalent data. Generally the half axes, or the equatorial and the polar radii, are given. The values of these are as follows:

- Equatorial semi-axis = a, polar semi-axis = b:
  - a = 20,926,062 feet = 3,963.3 miles = 6,378,259 metres.
  - b = 20,855,121 feet = 3,949.8 miles = 6,356,635 metres.

It should not be inferred from these figures that the semi-axes are known to the nearest foot or metre. The values given above are those derived from computations carried out to the nearest foot. More approximate values will be determined from computations now in progress, and they may possibly show Clarke's values to be in error by a few hundred feet.

The following derived values appertaining to the earth's spheroid are often referred to:

- Equatorial diameter of the earth: 7,926.6 miles
- Polar diameter of the earth: 7,896.0 miles
- Difference of diameters: 30.6 miles
- Circumference of equator of earth: 24,901.8 miles
- Meridian perimeter of earth: 24,859.8 miles

| Area of the surface of the earth | 196,040,000 square miles |
| Area of the earth in square kilometeres | 510,071,000 square kilometers |
| Circumference of earth | 197 x 10^6 square miles (about) |
| Meridian perimeter of earth | 24,859,800,000 cubic miles |
| Volume of earth | 1,083,200,000,000 cubic kilometers |
| Volume of earth in cubic kilometers | 260 x 10^9 cubic miles (about) |
| Volume of earth in cubic kilometers (about) | 108 x 10^9 cubic kilometers |

The following table gives the length of a degree of a meridian in different latitudes; the length of a degree in longitude measured along a parallel of latitude; and the areas of quadrilaterals of the earth's surface for one degree square in latitude and longitude.

<table>

From the second column of this table it is seen that the length of a degree of a meridian is about seven-tenths of a mile greater at the poles of the earth than at the equator.

Third Approximation.—A third approximation to the figure of the earth may be briefly referred to here. Imagine the mean sea-level, or the surface of the sea freed from the undulations due to winds and to tides. This mean sea surface, which may be conceived to extend through the continents, is called the geoid. It does not coincide exactly with the earth's spheroid, but is a slightly wavy surface lying partly above and partly below the spheroidal surface, by small but as yet not definitely known amounts. The determination of the geoid is now one of the most important problems of geophysics. Its solution will be accomplished by means of gravimetric surveys, or by measuring the acceleration of gravity at a great number of points on the earth's surface.

**Physical Properties of the Earth.**

**The Atmosphere.**—Adopting the convenient terminology of geologists, the earth may be divided into four parts, namely: the atmosphere; the hydrosphere, or oceans; the lithosphere, or
crust; and the centrosphere, or nucleus. These are considered in turn without encroaching on the fields of the meteorologist or of the geologist.

The atmosphere is a gaseous envelope covering the earth to an extent not yet fully determined. The pressure it exerts at the surface of the earth is easily measured and is definitely known to be about 14.7 pounds per square inch, or about 1,033 grams per square centimeter.

The pressure, density and temperature of the atmosphere are observed to decrease rapidly with increase of height above the earth's surface, but the exact laws of decrease are not yet known. Hence it is impossible in the present state of science to assign a height to the atmosphere. It appears certain, however, that it is more than 200 miles high, since it is dense enough to set meteorites on fire at that height.

Many investigations of the properties of the atmosphere have been made during the past century. These are all too technical for presentation, even in abstract, here. But their results may be summarized as follows:

(a) If the earth did not rotate and if the atmosphere were of the same density throughout as at the earth's surface, its height would be 26,200 feet, or about five miles.

(b) If the earth did not rotate, and if the adiabatic law (pressure proportional to the 1.4 power of the density) held in the atmosphere, it would be about 17 miles high.

c) But the earth rotates and the atmosphere must be supposed to rotate with the same angular velocity. From this fact, and from the assumption that the atmosphere behaves like a fluid, Laplace concluded that it must be limited by a lenticular-shaped envelope as indicated in Fig. 4. The revolution of this figure about the axis LM, which is supposed to be coincident with the axis of rotation of the earth, E, will generate the envelope and the earth in their true relative dimensions. The polar and equatorial axes LM and AB are, respectively, 4.4 and 6.6 times the diameter of the earth. According to this theory, therefore, the atmosphere may be about 17,000 miles high above the poles of the earth and about 26,000 miles high above the equator. The latter limiting height is that at which the centrifugal force due to rotation is just balanced by the attraction of the earth. The volume of the envelope is 156 times the volume of the earth. Whether the atmosphere actually extends to the limits thus defined has not been determined either by Laplace or by subsequent investigators.

A question of great interest is that of the quantity of the atmosphere, since the oxygen thereof is essential to the existence of all higher forms of life on our planet. By quantity is meant the amount of mass in the atmosphere. If the law of distribution of this mass within the Laplacian envelope were known the total quantity could be computed. But the law is not known, and hence it is only possible to attain an approximation, or to set limits, to the actual amount. A lower limit may be found from the adiabatic distribution of (b), above, for a non-rotating earth. This distribution does not differ widely from the actual distribution near the earth's surface; but since it is limited to a height of 17 miles it will give too small an amount. A computation on this basis makes the mass of the atmosphere 1-1170000th part of the total mass of the earth; or, in round numbers, one millionth part of the mass of the earth. This result is also reached, substantially.

It is assumed that the mass of the atmosphere is the same as the mass of a uniform layer of water, or mercury, which would produce the same pressure at the earth's surface. On the other hand, if the adiabatic distribution is supposed to hold within the Laplacian envelope, of (c), above, an upper limit of about 1-1200th of the mass of the earth is obtained. The actual value of the mass of the atmosphere is undoubtedly much closer to the lower than to the upper limit; how much closer is still a matter for investigation.

The Hydrosphere.—It is well known that about three-fourths of the earth's surface is covered by oceans and seas. Precise measures of the relative areas of land and sea are difficult to obtain, and the present state of knowledge does not justify the use of more than three significant figures in defining these areas. The values given below are derived from H. Wagner's Lehrbuch der Geographie. They do not differ widely from the values given recently by other German authorities, though they make the total ocean area about 1 per cent greater than the earlier estimates of the distinguished British geographer, Sir John Murray. The table below gives the continental areas along with their average heights and the total oceanic area along with its average depth:

<table>

</tr>
</tbody>
</table>

The total area of the continents is, therefore, 26.3 per cent of the total surface of the earth; leaving, with the same degree of precision, for the total area of the sea surface 73.7 per cent of the surface of the earth.

The average depth of the oceans according to Wagner is 3,500 metres or 11,480 feet, or, in round numbers, 2.2 miles.

The data thus given show that the volume of the oceans is 315,000,000 cubic miles, or in
round numbers 1,800th of the entire volume of the earth. Assuming the density of sea water to be 1.03 times that of pure water, and the density of the latter to be 62.3 pounds per cubic foot, the oceans is found to be $1.49 \times 10^8$ tons of 2,000 pounds, or one and one-half million million million tons.

It is interesting to contrast this mass of the oceans with the mass of the continents which lies above the sea-level. The average heights of the continents given in the above table require an average height for the entire land area of about 2,300 feet. This combined with the area of the continents gives for the volume of the continents above sea-level 22,500,000 cubic miles. If to this mass a density of 2.75 times that of water be attributed, the resulting mass of the continents above sea-level is $284 \times 10^6$ tons. This is about one-fifth the mass of the hydrosphere or oceans.

The Lithosphere.—The lithosphere is the special province of the geologist, and is treated in detail under Geology. It is here considered, therefore, only in its broader physical aspects.

No precise value of the thickness of the shell which is called the crust can be assigned. The estimates of geologists make it 5 to 10 miles thick. It is the shell to which are confined the phenomena of crustal transformations with the attendant phenomena of crustal crumbling, folding and faulting. For the present purposes it may be assumed to be 10 miles thick.

In its mechanical aspects the most important fact presented by the crust is that it rests on the core, the mass of the oceans, in substantially the same manner as a fluid crust would. In other words, the crust is essentially, in view of the forces to which it is subject, a viscous mass, which may be likened in its behavior to seal wax. This conclusion is reached when one compares the compression to which the crust would be subjected if it were self-supporting, like a dome, with the crushing strength of rocks. That compression is about 30 times the crushing strength of the finest steel and 500 to 1,000 times that of the hardest stones. We may infer that at a depth of a few miles there can be no such thing as a cavity in the crust. Another conclusion of great importance, also, is that the surface shape of the earth must conform very closely to the shape it would have if it had been originally fluid, as assumed by nearly all geodesists and geologists, many of whom adduce that shape as a proof of primitive fluidity. Given time enough, and the amount of time available is ample, as seen below, the viscous earth will assume the same shape, essentially, as a fluid earth.

Since the lithosphere, the hydrosphere and the atmosphere are the theatre of the principal activities, physical and biological, of our planet, it is of interest to know their volume, mass and chemical constitution. The volume of the crust less 10 miles thick below sea-level is 1,969,400,000 cubic miles. Adding to this the volume of the crust above sea-level, namely, 22,500,000 cubic miles, there results for the volume of crust and hydrosphere down to a depth of 10 miles below sea-level 1,992,900,000 cubic miles. Of this, as stated above, 315,000,000 cubic miles are sea water, leaving for the solid matter of the crust to the depth in question 1,677,000,000 cubic miles. Contributing to this volume a density 2.75 times that of water, the mass of this solid part of the shell is $21 \times 10^6$ tons of 2,000 pounds. This is about 14 times the mass of the oceans.

These two masses and that of the atmosphere, in round numbers, a total of $23 \times 10^6$ tons, the contribution from the atmosphere being taken as $7 \times 10^6$ tons.

Prof. F. W. Clarke, making use of the above data, has worked out the relative abundance of the chemical elements in the combined mass of the atmosphere, the hydrosphere and the lithosphere. His results are given in the following table. (Consult Bulletin of the United States Geological Survey, No. 78.) It is interesting to note that nearly one-half of that part of the mass of the earth visible to us is oxygen, the next most abundant contributions being, in order, silicon, aluminum, iron and calcium.

The Centrosphere.—Since the crust of the earth, as seen above, rests like a viscous fluid on the centrosphere, the latter, whatever its temperature and other properties, must be subject to great internal stress. Indeed, the mechanics of celestial bodies of large mass leads inevitably to the conclusion that pressure is the dominant factor in the earth at no great depth below the surface. Given time enough, therefore, the distribution of pressure will be essentially the same as if the mass of the earth were fluid. This justifies the application of the laws of hydrostatics to the earth as a whole, whether it was originally fluid or not. With this concept, and with the law of gravitation, several facts enable us to determine within narrow limits what must be the constitution of the earth as regards distribution of density, gravity and pressure. The principal of these facts are (1) the surface density, (2) the mean density, and (3) the surface value of the acceleration of gravity. In addition to these facts, there are some others of less importance depending on the attraction of external bodies of the earth. Laplace correlated all these facts by a hypothesis with regard to the compressibility of matter. This asserts that the pressure in the earth increases as the square of the increase in density. Adopting the indications of Laplace the fol-
lowing table showing the variation of density, acceleration of gravity and pressure with depth below the surface of the earth has been computed. The relatively unimportant effect of the rotation of the earth is ignored in the calculation. The assumed values of the surface density and the mean density are 2.75 and 5.5, respectively, times that of water. In the third column of the table \( g \) represents the average surface value of the acceleration.

</tbody>
</table>

It is seen from this table that the acceleration attains a maximum value. This value is 1.05 times the surface value and it is attained at a depth of about 610 miles. At this depth a given mass would have a greater weight than at any other distance from the earth's centre. A more extended table, computed by the author from slightly different data, is given in the article on GEOLOGY.

**Fig. 5.**

The variation of the density, acceleration and pressure are shown graphically in the following diagram, Fig 5, in which these quantities are all measured horizontally from the line AO, representing the earth's radius, to the right. The curves have different horizontal scales and are designated, respectively, D.C. (density curve), A.C. (acceleration curve), and P.C. (pressure curve). The pressure curve intersects the axis OQ at right angles at Q.

Another interesting question in this connection is what total radial compressibility is compatible with this Laplacian distribution of density, acceleration and pressure. The answer may be stated in convenient form thus: If the pressure of the atmosphere were to be doubled the radius of the earth would be shortened everywhere by about 2 metres, or 6.5 feet. This explains how mere inequalities in surface loading of the earth may account for some of the great observed movements of the earth's crust.

**The Rigidity of the Earth.**—It cannot be doubted (as shown below) that the temperature of the nucleus of the earth is very high, probably sufficiently high, under normal conditions, to melt and even render vaporous the materials of which it is composed. But if the figures of the last column of the above table are examined, it will appear reasonable to suppose that the behavior of the central mass under such great pressures may be very different from that ordinarily associated with fluids. The first attempt directly to measure the rigidity of the ball of the earth was made by G. H. and Horace Darwin in 1880. They employed for this purpose a horizontal pendulum, but the results were not conclusive. Their method has since been successfully employed, however, by several observers (Ehler, Hecker, Kortazzi, Schwydar and Orloff), who arrived at definite and consistent results. All of these observations, as well as the classic investigation of G. H. Darwin based upon the phenomena of the tides, concur in showing that the nucleus of the earth is solid throughout and that it is somewhat more rigid than if composed of steel.

A most promising investigation of the rigidity which the earth offers to change of shape was recently begun by A. A. Michelson. (Consult The Astrophysical Journal, Vol. XXXIX). The method is based essentially on a very accurate measurement of the tides produced in the water level in two buried pipes, each 500 feet long, one running in an east and west and the other in a north and south direction. It is the intention to measure the variation with the interferometer, the observations being carried on continuously for a long time. Though this has not yet been done, the measures thus far having been secured with a microscope merely, it is evident that even the preliminary results are of a very high order of accuracy. They indicate that the rigidity of the earth, or its resistance to change of shape, is about one-third greater than the rigidity of steel.

**Acceleration at Surface of Earth.**—What is commonly called the acceleration of gravity at the surface of the earth is the resultant of the accelerations due to the attraction and to the rotation of the earth. This quantity has been measured with considerable precision at many points of the earth's surface by means of the pendulum, and the results have been obtained in the following formula, \( g \) being the acceleration at any point of the sea-level whose altitude is \( \phi \):

\[
\phi = -978.00 + 5.52 \sin^2 \phi \text{ centimeters / (seconds)}^2 = 32.087 + 0.171 \sin^2 \phi \text{ feet / (second)}^2
\]

**Mean Density and Mass of the Earth.**—Since the volume of the earth is known accu-
rately, the mass can be computed if its density can be ascertained. The author has recently shown (The Astronomical Journal, No. 424), that the product of this mean density and the gravitation constant may be derived with a precision comparable to that of the value of the acceleration just given above. The gravitation constant is the quantity essential to convert the proportionality of Newton’s law of gravity into an equality. That is, if \( m \) and \( m' \) are two masses, \( D \) their distance asunder, \( F \) the force of attraction they exert on one another, and \( k \) the gravitation constant, then

\[ F = k \frac{mm'}{D^2} \]

It is thus seen that \( k \) is not a mere number, but a quantity such that the second member of the equation is force as well as the first member. \( k \) is, in fact, the cube of a length divided by the product of a mass and the square of a time.

Denoting the mean density of the earth by \( \rho \), it is found in the paper referred to that

\[ k\rho = \frac{3\pi}{2} \times 36707 \times 10^{-11} / \text{second}^2 \]

this quantity being the reciprocal of the square of a time. In a more interesting, as well as a more intelligible, form this relation may be written

\[ k\rho = \frac{3\pi}{2} \times 6673 \times 10^{10} \text{kg/m}^3 \]

where \( \pi \) is the number 3.1415+ and \( T \) is the time it would take an infinitesimal satellite to pass around the earth under the law of gravitation, just grazing the equatorial, if there were no atmosphere to impede its progress. This time is seen to be 1 hour, 24 minutes, 20.9 seconds.

It is clear then that \( \rho \) will be given by the above equation if \( k \) is known. This quantity has been measured directly by several observers. A mean of the most recent and most trustworthy determination, is in C.G.S. units (see ‘The Century’s Progress in Applied Mathematics,’ Science, N.S., Vol. XI),

\[ k = 6673 \times 10^{10} \]

Thus \( \rho \) is found to be 5.514 times the density of pure water. The uncertainty of this value as shown by the computation is about four units in the last place of decimals. In view of this fact, and of the great difficulties in measuring the quantity \( k \), we shall use the round number 5.5 as hitherto.

From the volume of the earth given above the following results are derived for its mass:

- Mass of earth = 5.952 \times 10^{24} tons (of 2,000 pounds)
- \( k = 3.111 \times 10^{25} \) pounds
- \( k = 3.111 \times 10^{25} \) kilograms

For convenience of reference the masses that have been given above are here collected and expressed in tons of 2,000 pounds.

- Mass of earth = 5.550 \times 10^{24} pounds
- Mass of core = 6.529 \times 10^{24} pounds
- Mass of lithosphere = 21 \times 10^{24} pounds
- Mass of hydrosphere = 1.45 \times 10^{24} pounds
- Mass of atmosphere = 7 \times 10^{24} pounds

The Internal Heat of the Earth.—That the earth has a great store of heat a few miles below the surface is amply proved by a variety of geological phenomena. Wherever deep wells, or bore holes, have been sunk the temperature is observed to increase with depth at a rate of about a degree F. for 60 feet. This shows that heat is being conducted from the interior to the surface of the earth and is thence radiated into surrounding space. The amount of this heat is sufficient to melt a layer of ice 1 meter (or one-fourth inch, say) thick, covering the globe, per annum, or more than 800 cubic miles of ice. It seems most probable (though it is by no means certain) that the temperature of the center of the earth is high enough to melt all known rocks, although the lower crust do not assume the molten or viscous form of lavas except on relief from the great pressure to which they are subject. This was, essentially, the view of Fourier, the earliest physicist to investigate this question, and it is still regarded as the most plausible hypothesis with respect to the actual state of the earth.

Whether this hypothesis is exact or not, however, the theory of heat conduction founded by Fourier enables us to draw with certainty two important conclusions with respect to the earth, namely: (a) that the heat conduction from the interior to the surface escapes as if there were neither atmosphere nor oceans; and (b) that a million years is the smallest unit of time convenient for measuring the historical succession of thermal events.

With less certainty it may be affirmed that the earth is shrinking in bulk as it cools, and that this is one of the principal causes of the grand crust crumplings and volcanic activities to which geologists pay special attention. This cubical contraction goes on exceedingly slowly; however, requiring, so far as one can infer from present indications, nothing short of thousands of millions of years for its completion.

The Earth as a Time Keeper.—The time of rotation of the earth is the most trustworthy unit of time man has discovered. The present value of this unit is 86164.1 mean solar seconds. That the earth must rotate with great steadiness is at once apparent when the immense amount of its energy of rotation is considered. This energy is about 156x10^{26} foot-pounds, or 2x10^{26} ergs. It is more than will be delivered at Niagara (at the present rate of 5,000,000 horse power, say) in a million million years. Nevertheless, the period of rotation of the earth is subject to variation from four obvious causes.

These are (1), secular contraction of the earth's mass; (2), the influx of meteorites, or meteoric dust; (3), tidal friction; and (4), shifting in position of the surface load of the earth, as in the processes of sedimentation, glaciation, etc.

The effects of the first two causes have been investigated. (Astronomical Journal, No. 502). Contraction tends to shorten the day, and may possibly cause a diminution of as much as 6 per cent of the present length. The change goes on very slowly, however, and will not be perceptible in any such interval as that of human history (20 centuries, say). Meteoric dust tends to lengthen the day, but at the present rate of influx (about 20,000,000 meteorites daily) the effect will not amount to so much as a quarter of a second in less than a million million years. During this interval of time the total effect, substantially, from secular contraction will have accrued.

The effects of the other causes named have not been evaluated, though the last one is probably the most important of all of them; since
it may be easily shown that such shiftings of the surface load as are now taking place on the earth may modify the length of the day by an amount which, if cumulative, might in a few centuries seriously disturb astronomical reckonings.

EARTH-HOUSES, a name generally given throughout Scotland to underground buildings, also known as "Picts' houses" or "Picts' dwellings." The earth-house in its simplest form consists of a single irregular-shaped chamber, formed of unhewn stones, the side walls gradually converging toward the top until they can be reached by steps of four or five feet in width, all covered in by a mound of earth rising slightly above the level of the surrounding district. In the more advanced form of these structures two or three chambers are found. Earth-houses are most frequent in the northeast of Scotland, occasionally 30 or 40 being found in the same locality. Very similar structures, known as bee-hive houses, occur in Ireland. In the United States modern earth-houses are to be found in Nebraska, Kansas and other Western States, and are commonly called "digouts." In Arizona and California certain dwellings of adobe may be designated as earth-houses. See Adobe.

EARTHENWARE, vessels or objects of clay, as distinguished from porcelain, is opaque; as distinguished from stoneware the body is dull and earthy. The clay is baked or fired in a kiln, or more rarely sun-dried. The glaze depends on the quality of the ware; generally it is of a readily fusible character and contains lead; but a simple salt glaze is employed for common articles. Occasionally the unglazed body is employed, as for water-bottles, cream-jugs, vases and ornaments; these have generally a reddish brown color, due to iron. The finer kinds of earthenware, such as Majolica, Delft ware, Faience and Palissy ware, are not only glazed, but are besides elaborately colored and enamelled and ornamented with raised figures of various kinds. See Faience; Pottery.

EARTHLY PARADISE, The, the great narrative poem of William Morris, was written in the years 1865 to 1870, the height of his career as craftsman and business man. The scheme that holds together this strange medley of Greek myth, Norse saga, French romance and Arabian tale is amazingly simple. The scene is laid at the end of the 14th century in "a nameless city in a distant sea," inhabited by descendants of the Great Race of Norse wanderers, driven into years of voyaging by those two recurring medieval motives: fear of the dread Black Death and hope of an Earthly Paradise, of endless life. Here the wanderers linger on, finding, not immortality, but rest, and at last, release from fear; and here, month by month, each company tells the other a tale—once classical, once medieval, till the 24th ends the year. This scheme is successful, not only because out of the most diverse material it builds a single, simple structure, but because it justifies an equally simple and simple treatment. Differences of tone there inevitably are. Some stories are from Scandinavian sagas, 'The Lovers of Gudrum,' taken direct from an Icelandic saga, moves with a swift relentless, a tragic intensity; 'The Land East of the Sun and West of the Moon' carries out the dream device in its dreamlike leaping and lingering. But the unity that links such variety as 'Cupid and Psyche' and "The Man Who Never Laughed Again" (from the 'Arabian Nights') goes deeper than any narrative scheme or recurrence of metrical form. It is the spirit of Morris himself—master story-teller—that unites these stories of lovers fair and strong, of great things dared and endured. And for those who weary of this endless revel of love and adventure, of sunshine and color, there is the subtler lyric beauty of the interludes, in which the artist's own imagination is most surely revealed. It is not simply that these brief interludes—one for every month—are among the loveliest of English landscape poetry; but that in them, from the famous Prelude to the moving Envoy to his master Chaucer, the poet utters his deepest feeling about his life and his art. A "dreamer of dreams, born out of my due time," a hater of death, "not knowing what it meant," but a lover of life, "through green leaf and through sere," he has learned with his wanderers and his Norse heroes to face life and death heroically. Consult 'The Collected Works of William Morris' (ed. by May Morris, London 1910); Mackail, J. W., 'The Life of William Morris' (2 vols. 1904).

FRANCES CUTLER

EARTHNUT, a common name for many unrelated plants. The most common are probably the following: Bunium flexuosum and B. bulbocastanum, both members of the natural order Umbelliferae, the latter referred by some botanists to the genus Carum (caraway). Certain species of Carum, Oenanthe and Capparis of the same natural order, also bear this common name. All these species are natives of Europe and all bear tubers which have been used to some extent for human food, but are more valued as food for swine, since the animals can be turned loose to root them out of the ground. They are also known as earth chestnuts, pig-nuts, etc. Certain species of Cyperus of the order Cyperaceae are also called earthnut (see Nut-grass), and so are various species of the natural order Leguminosae, especially Arachis hypogaea (see Peanut), Apoios apius, or tuberosa (see Ground-nut), known also as wild bean.

EARTHQUAKE. Earthquake denotes a shaking of the earth's crust, due to the passage of elastic waves, depending on some internal cause. These waves are principally of two classes: longitudinal, in which the earth vibrates as in sound; and transverse, in which they vibrate as in light, but near the origin of disturbance both classes of vibrations coexist.
and the movement of the earth particle is a combination of the two oscillations. A cubical element of the earth's crust has its volume compressed and its form distorted, with the passage of each successive wave and the rapid recurrence of this movement constitutes the trembling called an earthquake. The velocity of this wave propagation varies according to the elasticity and average density of the rock, the observed values lying between a few hundred feet and about five miles per second, as in the recent San Francisco earthquake, which was propagated across the continent with great speed. Powerful earthquakes are now recorded all over the world by means of very sensitive seismographs and it is found that the greater the distance of propagation the more the waves are separated, the compressional waves outpacing the distortional ones.

The record of a South American earthquake, like that of Valparaiso, 16 Aug. 1906, occupies from two to three hours when registered upon seismographs in the United States and Europe; and moreover the further the disturbance is propagated the slower the earth movement becomes, so that from a violent agitation near the origin it becomes a gentle swaying of very slow character in the distance and may not be felt by men nor animals, though faithfully recorded on delicate long-distance seismographs. As more than 60 world-shaking earthquakes occur each year, one of these disturbances on the average is due each week and by the investigation of the propagation of these waves through the earth seismologists have drawn important conclusions regarding the constitution of the globe. In this way Mr. R. D. Oldham shows (Quarterly Journal of Geological Society, 1906) that the earth is fairly homogeneous throughout until we reach a distance of about 0.4 of the radius from the centre, when a change takes place, the cause of which is not yet understood. Moreover, it is possible for a seismologist to calculate from his record of an earthquake how far off the disturbance was. The empirical formula given by Professor Omori of the Imperial University at Tokyo, for very distant earthquakes is as follows (Publications Asiatic Soc. Pacific, 10 June 1906):\[X_{km} = 6.54Y^{8/3} - 7.20km;\]
where \(X\), in kilometers, denotes the actual distance between the centre of disturbance and the place of observation; and \(Y\), in seconds, the total duration of the first and second preliminary tremors. When the distance is small the formula becomes\[X_{km} = 7.27Y^{8/3} - 3.83km;\]
From the records obtained at the Lick Observatory Professor calculates that the most central part of the San Francisco earthquake was 80 or 90 miles to the west of Mount Hamilton, which places the origin under the margin of the Pacific Ocean.

The motion of the earth particle usually is only a small fraction of an inch and houses resting on solid ground do not suffer greatly; but where the land is made by the filling in of soft earth it remains loose and by the passage of the earthquake waves is thrown into balls so that all buildings and other foundations are frequently destroyed. This was observed to be the effect at Lisbon as long ago as 1755 and illustrated again very clearly at San Francisco and at Valparaiso in 1906. Even the steel frames of brick buildings were destroyed on the made land at Valparaiso, though houses standing on rock foundation suffered but little. Observations by Professor Omori and the writer of this paper showed that on the made land the oscillations did not exceed about three inches. Owing to the rapidity of vibrations of this amplitude, however, few structures are able to withstand them. But on hard ground, where the vibrations were about a quarter of an inch, the worst that would result would be a cracking of the plastering and perhaps of the walls.

There are many modern investigators of earthquake phenomena. The names of Milne, Omori, Dutton, Oldham, Wiechert and many others are familiar; and in Europe and Japan many earthquake observatories are in active operation. Several such observatories have been established in the United States and now that the Seismological Society of America has been founded at San Francisco, usually doubt the study of earthquakes will become an important object of attention. The Seismological Society of Japan has done much for the investigation of earthquakes in the Orient and elsewhere.

The distribution of earthquakes is very similar to that of volcanic action, but there is a quite definite earthquake zone encircling the whole earth, only a part of which is distinguished by volcanic activity. This zone includes the Mediterranean Sea, the Azores, the West Indies, Central America, Japan, China, India, Persia and Asia Minor. This may be regarded as a main earthquake zone from which there are many branches following the coast line of the continents and thus, in general, nearly coinciding with regions of volcanic action. In many cases it is, indeed, evident that volcanic eruptions and earthquakes which accompany them are closely related, both being due to explosions of steam, with a consequent readjustment of pressures and material within the immediate region. A great volcanic eruption is thus usually preceded by earthquakes which are frequently felt for a great distance from the volcanic zone; upon the actual commencement of the eruption, however, the earthquakes diminish greatly in intensity or wholly cease, doubtless because the interior steam pressure has been relieved by a passage through the outlet formed. Yet these disturbances are only very local compared with the effects of really great earthquakes. Nor is it true that a very large proportion of the heavier earthquakes, even in these regions, are closely associated with volcanic activity; the original centre of the disturbance is usually found to lie at a distance, where there are no volcanic rocks.

A second and more widespread cause of earthquakes is a sudden setting, faulting or bending of the earth's crust owing to the strains which are set up within it. The slow secular contraction of the earth's interior must set up such strains in the material resting upon it; though the rocks may withstand this strain for a considerable period, yet ultimately they may suddenly give way, causing a tectonic fracture a few miles in length, the rock on one side sinking down and causing a fault,—or there may be a general jarring subsidence under a territory of.
EARTHQUAKES, INSTRUMENTS FOR RECORDING

Considerable extent. These phenomena are most frequent along the greater mountain ranges where earthquakes are closely associated with regions of present folding and upheaval or subsidence of the earth’s crust. Both they and volcanoes are obviously associated with lines of weakness in the crust of the earth. Similarly, earthquakes may be produced by the deposition of sediment on an ocean bed, which latter being overloaded (and possibly heated and thus weakened by the superimposed material), may suddenly yield.

We have thus far no accurate data for estimating accurately the number and situation of earthquakes along the ocean shores is the violent disturbances of the sea, giving rise to enormous waves which sometimes prove more disastrous than the earthquakes themselves. These seismic sea waves are divided into two classes: First, those in which the water is noticed slowly to withdraw from the shore sometime after the earthquake and later returns as a great wave carrying everything before it; and second, those in which the water rises suddenly and overflows the coast, without any previous recession from the shore. In the first class are to be included the waves which inundated Lisbon after the great earthquake of 1 Nov. 1755; Callao, 28 Oct. 1746; Concepcion, 20 Feb. 1835; Arica, 13 Aug. 1868; and Iquique, 9 May 1877. In all these cases the water retired some little time after the earthquake, say from a quarter to half an hour and sometimes after longer intervals; and moreover the withdrawal is gradual, so that ships at anchor simply settle down upon the sea bottom laid bare by the slow withdrawal of the water. Then after an interval of 20 minutes, or half an hour, the sea returns as a great wave, which is said to have been 80 feet high (or the overflow of Callao in 1746 and from 50 to 60 feet high at the inundations of Arica and Iquique. The wave is naturally made higher with a more vertical front as it approaches the shore, owing to the resistance to propagation in shallow water.

The slow draining away of the water some time after the earthquake shows that the sea bottom has sunk and the water rushes in from all sides to fill up the depression; the currents met at the centre and raise a ridge where there was formerly a depression and the ridge then collapses and sends ashore the first great wave. After this has swept the shore the sea slowly withdraws again to fill up the depression, leaving bare the land as before and after the same interval again returns and sweeps the coast. At Arica in 1868 and at Iquique in 1877 it is said that the sea continued to oscillate for nearly two days before it finally quieted down and meanwhile the waves were propagated around the world.

In seismic sea waves of the second class, where the water rises suddenly without recession from the shore, it is always an upheaval of the ocean bed, which also lifts the water resting upon it. The result is the sudden appearance of a great wave. This class of waves appears to be less frequent than the preceding class and therefore is not so famous as those in which the water first withdraws from the shore. At great distances from the origin, waves of the first class, in being propagated round the world, resemble those of the second class; so that to classify sea waves intelligently a careful investigation must be made of the place of origin of the disturbance.

A quite different theory of earthquakes, which includes also the cause of volcanoes and the mode of mountain formation, has recently been very fully developed by Prof. T. J. J. See. This is in brief, that under the enormous pressures existing at the bottoms of the ocean beds a portion of the water is forced downward to a considerable depth within the earth’s crust; here, becoming diffused among the molten rocks and having its explosive power greatly increased through superheating, it penetrates under the lands along the coast lines where it may elevate mountain ranges parallel to the coast, giving rise in its explosive pressure to faults, volcanic outbursts, and, as a consequence of each of these, to earthquakes. Admitting the possibility of water penetrating the crust in this way, this theory explains the situation of the great mountain ranges of the earth, the general absence of seismic disturbances beneath the interior of continents (since here the storage of water would be less), the observed fact that the density of mountain masses is often small and many other associated phenomena. Consult ‘The Cause of Earthquakes, Mountain Formation and Kindred Phenomena Connected With the Physics of the Earth,’ (Proceedings of the American Philosophical Society, 1906).

EARTHQUAKES, Instruments for Recording. The first record of an earthquake really worthy of being regarded as accurate and complete was obtained by Prof. James Ewing at the University of Tokyo, on 3 Nov. 1880, by the aid of a new seismograph of his own invention. This great epoch-making result was dimly foreshadowed, no doubt, by earlier crude attainments, yet Ewing’s work was far in advance of that of the times, and his records were the first and only ones from which the approximate amplitudes, periods, and accelerations of the motions of the ground could be deduced.

In order that a seismograph may faithfully record the motion of the ground during an earthquake it is in general a necessity that some portion of the instrument must remain relatively at rest throughout the disturbance. It
seems to the writer that to Ewing more than any other is due the credit of having formulated the kinetic basis of all modern seismology. It was he who first showed how to realize and utilize the principle of the steady mass in the measurement of earthquake motion. There is scarcely any type of seismograph now in use that does not find its prototype among the large number of devices and arrangements cited in his papers, or one of them employed by Ewing at the University of Tokyo from 1880 to 1883. We cannot attempt to describe in this brief account any of his early work, or the equally important contributions to seismology by Milne, Gray and others of that period.

Within the past 25 or 30 years seismographs have multiplied very greatly throughout the civilized world, and by their records it is found that any considerable earthquake literally sets the entire crust of the globe vibrating and the tremors are measurable at almost any point on the surface by the aid of the sensitive instruments now employed.

**Nature of Earthquake Motion.**—A short statement explaining the motions of the ground was the first to show how the phenomena and their records. The commonly current conception that earthquake motion is a comparatively simple vibratory displacement of the ground in some particular direction is shown to be decidedly erroneous by the actual records. The motions, in fact, are exceedingly complex; the vibrations in a horizontal plane take place in all conceivable directions and are compounded with motion in the vertical. With this complex sort of vibratory displacements there may also coexist certain twisting and tilting rotations. No single instrument can possibly produce the record of such highly intricate motions. They must be separated or resolved into elementary components for satisfactory registration. It is generally recognized that no less than six distinct and separate components of the ground are to be measured, namely, three displacements in directions at right angles to each other, that is, one north, and south, one east and west and one vertical; also, three components of rotation about the same three axes. The turning on the vertical may be called a twisting component. The turnings on the horizontal axis are tilting effects. Seismologists have not yet succeeded in recording all of these elementary components. Unfortunately most of the instruments thus far employed are influenced by more than one component of motion, and the records cannot therefore be entirely interpreted.

**Seismographs.**—The seismographs chiefly employed up to the present time are those designed to register the horizontal vibratory displacements of the ground. In a limited number of cases efforts have been made to register the vertical component of motion. In still fewer cases the tilting motions of the ground have been the subject of special measurements. The writer is not aware that the twisting component has thus far ever been recorded, although forms of apparatus for the purpose have been proposed.

**Vertical Component.**—Instruments for vertical motion are not so easy to design, and the results obtained by their use have been less satisfactory than with other types either because the vertical motion of the ground is relatively very small, or because it may be absent altogether. In seismographs for vertical motion the so-called steady mass must, in general, be suspended by means of very flexible springs, or their equivalents, in order that it may remain at rest in the vertical sense while the ground may rise and fall beneath it. If the springs are too stiff the steady mass fails to remain at rest but is made to rise and fall with the movement of the ground. On the other hand, if the springs are too weak, very slight variations of strength, due to temperature and prolonged excessive stress, cause the steady mass to wander slight amounts from its normal position of rest. As the motions are generally greatly magnified, these slight progressive displacements often carry the tracing entirely off the sheet designed to receive it, or otherwise prove fatal to the desired result. These characteristics of ordinary springs constitute serious limitations in the construction of seismographs for vertical motion. What is needed is some sort of available material for springs that, under very great extension, does not exhibit with the lapse of time any minute slow, progressive, after-deformations and is unaffected by variations of temperature.

**Horizontal Motion.**—A simple pendulum consisting of a massive bob, weighing several hundred pounds in some cases, suspended by a steel wire from a massive support has been extensively employed especially in Italy and Spain as the "steady mass" for a seismograph. The motions of the ground with respect to such a mass must be magnified from 10 to 100 or more times if we are to produce satisfactory records of small distant earthquakes. The means of doing this will be shown later.

A simple pendulum of this character fails to provide a reliable steady mass for two or three reasons. If the length is short, 10 or 20 feet, the mass very quickly responds to the earthquake movements and presently the pendulum is itself swinging in a more or less violent manner. A longer pendulum (several hundred feet) cannot be supported with sufficient rigidity. The top of a lofty tower, even during the absence of an earthquake, wanders all about a fixed point within it, due to the influence of temperature, wind, etc. on the tower, and the effects of moisture, temperature, rainfall, etc. upon its foundation and the adjacent earth. During an earthquake the motions of the top of such a tower cannot be the same as those of the ground and are doubtless much greater, thereby seriously influencing the steady mass, notwithstanding the great length of its support.

**The Horizontal Pendulum.**—The type of pendulum employed first by Ewing for the measurement of earthquake motion in the horizontal plane is commonly called the horizontal or conical pendulum. A modern design of this form of seismograph is shown in Figs. 1 and 2. The steady mass C (about 40 pounds) is supported upon the massive column A by a horizontal strut and the diagonal wires W. W. so that it is exceedingly free to swing about a
pivot point at D and another at B. The two points D and B are not quite in a vertical line, hence the steady mass is in slightly stable equilibrium and if disturbed oscillates like a very long pendulum. As one firmly adjusted at the Weather Bureau the pendulum illustrated, makes a complete oscillation in about 35 seconds. This is equivalent to a simple pendulum about 4,000 feet long. The record is made upon the clock-driven drum R by means of the lever L, carried in the heavy yoke piece G. For this purpose the surface of the drum is closely covered with a piece of smooth white paper which is uniformly coated with soot from a wide-flame, smoky, kerosene lamp. The drum makes one revolution an hour, and each minute of time is electrically marked on the record sheet by the time-ticker magnet M. The distant end of the drum-shaft is cut with a coarse thread which causes the drum to move endwise about 3-16 of an inch with each revolution, thus separating the lines traced by the stylus.

The manner in which the registration of the earth motion is effected is more clearly seen in the Milne seismograph used in the English work records photographically without the use of mirrors. A small steady mass is suspended on a horizontal strut only an inch or two long, but the strut is prolonged beyond by a very light boom to a length of nearly three feet or more. This long boom at the outer end carries a light aluminum vane pierced with a narrow radial slit. The photographic paper, in the shape of a long ribbon, is placed in a box just under the vane. The box has a slit in its top at right angles to that in the vane. Light from a lamp is thrown upon the aluminum vane and passes into the box at the point where the two slits intersect, thus making the photographic record.

Magnetographs.—It has been found that the delicately suspended magnetic needles employed for the purpose of recording continuously the small diurnal and other changes going on in the earth’s magnetism are nearly always disturbed by even very small earthquakes. These are not seismographs at all, in the ordinary meaning of the word, and the records give very little information except the time at which

![Record of San Francisco Earthquake as made by the Seismograph at the U. S. Weather Bureau, Washington, D. C.](image_url)

Fig. 2. The lever L is pivoted very freely in the stirrup F. The short end of the lever is forked and engages the slender steel staff f, which is pivoted in the most delicate manner in the frame F, rising from the steady mass C. Observing now that the steady mass is free to remain at rest with respect to the lateral motions of its pier and the yoke piece G, it is plain that the stylus at the long end of the lever will trace a magnified record of all the lateral displacements of the pivot d, because the point of the fork which engages the steady mass at f must remain at rest with the mass. The amount of magnification depends upon the ratio of the lever arms. In instruments of this kind illustrated a 10- or 15-fold magnification is usual. Owing to the fractional resistance offered by the yoke and at the pivot points greater magnifications require proportionately greater mass in the pendulum, if the same period is retained.

Very similar devices to those shown are quite generally employed in all instruments with mechanical registration.

Two separate pendulums installed at right angles to each other are required to register both components of horizontal motion.

Photographic Registration.—Much less massive horizontal pendulums can be employed to register photographically by the aid of light reflected from a mirror in the usual manner. the needles were disturbed. The needles act like any other small, light pendulum and simply suffer certain mechanical agitations during the earthquake. In some less frequent cases there appear to be certain distinct magnetic effects that occur with the earthquake, but these are only imperfectly understood at the present time.

Interpretation of Records.—Serious complications are likely to enter into the records of seismographs especially of the horizontal pendulum. This instrument is more and more sensitive to minute tilting motions the greater the period of oscillation. If the ground at the Weather Bureau instrument tilts as little as only one inch in a mile the stylus of the seismograph will be thrown out of the line nearly one-quarter of an inch. Furthermore, the instrument is sensitive to the twisting component of motion and finally we cannot feel entirely sure the steady mass has remained quite at rest. If the earthquake motion synchronizes with the free motion of the pendulum, the latter is quite certain to be set swinging. In the face of these complications it is hardly possible, as yet, to interpret exactly the records obtained. Great improvements in the instruments are constantly being made and it appears as if the horizontal pendulums are likely to be displaced in the future by better types of apparatus.
Records.—The interesting features of the Weather Bureau record of the San Francisco earthquake appear in Fig. 3. The small preliminary tremors began at 8 A.M.—19 m.—20 s., and the strong motion recorded at the University of California. The stronger motion begins at 8:35, on the record at Washington and at 8:32 to 8:35 the pen was deflected off the sheet by the very strong motion, producing a gap in the record, which was filled in by a later motion. This motion subsided a little. The original record sheet is 36 inches long and vibratory motion is perceptible for fully four hours. The complete period of the larger waves was from 20 to 30 seconds. Such vibrations are very slow and appear to be entirely imperceptible to human beings, nor do they affect buildings or other structures injuriously, so far as can be ascertained.

C. F. MARVIN.

Chief of the United States Weather Bureau.

EARTHS, a term applied by chemists to substances which were considered elementary bodies, but since the researches of Lavoisier and Sir Humphry Davy, defined as metallic oxides or compounds of oxygen with metals similar to potassium and sodium. Earths are seldom found in a state of natural purity, but constitute chiefly the component parts of gravel, soil or strata. The more important earths are divided into two classes; alkaline earths, lime, baryta, strontia and magnesia; and proper earths, alumina, zircoma, glucina, yttria and thorina; most of these are treated under separate titles, to which refer. The alkaline earths resemble the alkalies. They are soluble in water; baryta and strontia readily, lime sparingly, and magnesia very slightly. Their solutions affect vegetable colors similarly to the alkalies. They combine with acids, forming neutral salts, some of which are readily soluble in water and others insoluble. The proper earths are insoluble and infusible, and by exposure to heat lose the property of easy solubility in acids.

EARTHWORKS, in military parlance, are permanent or temporary defenses chiefly of earth forming a shield against the enemy's fire. For the various forms of military earthworks see Fortifications.

EARTHWORM, any terrestrial annelid of the order Oligocheta. Although certain families of Oligocheta are strictly aquatic and others exclusively terrestrial, still others contain both aquatic and terrestrial species, and aside from peculiarities which are obviously adaptations to the mode of life no sharp distinctions can be drawn between these two classes. The earthworms generally are larger and more robust, with shorter setae than the waterworms and have dorsal pores. Within recent years the earthworms have attracted much attention from systematic writers and now less than 800 species, of which upward of 90 inhabit North America, are now known. Externally they look much alike, but in their internal anatomy exhibit an astonishing variety. The common earthworms of Europe and America are numerous. Many species may be found in almost any suitable locality, belong chiefly to the genera Lumbricus and Allolobophora which have the setae arranged in four pairs on each somite, a well-developed girdle or citellum occupying a variable number of segments toward the anterior end, the female and male genital pores on the 14th to 15th segments respectively, and various complex internal peculiarities of the reproductive organs. While our species rarely equal a foot in length, several South African and Australian species reach five feet. Earthworms inhabit nearly all parts of the earth except the frozen regions of high land, and all types, dry sandy soils and some portions of the North American prairies. Their habits are everywhere much alike. They burrow in damp earth, which the common kinds penetrate to the depth of about two feet. They swallow the soil and after digesting its nourishing elements reject the rest in the form of castings from the mouths of their burrows. At night they partly leave their burrows and draw to them the petals of leaves, etc., on which they feed and with which they close their burrows in cold weather. In this way they also seek one another's company and copulate, as hermaphrodites mutually fertilizing each other. A cocoon is formed by secretions of the citellum and receives the eggs and spermatophores in a stock of albumen as it slips past the openings of the genital ducts toward the head, from which it passes and remains in the earth. During the winter they burrow to a depth beyond the reach of frost, but some species at least will survive actual freezing. The importance of earthworms as cultivators of the soil can scarcely be overestimated. By their burrowing they render it porous and permeable to the rain and air; they continually turn the earth by bringing up soil from beneath the surface and add to its fertility by burying vegetable matter and by their secretions. Darwin has estimated that earthworms bring to the surface in rich meadow lands not less than one-fifth inch of soil per annum, and recent laboratory experiments demonstrate most emphatically the beneficial influence on plants of the presence of earthworms.

The body wall of earthworms consists of an epidermis, one layer thick except on the citellum; a layer of articulation, an inner layer of longitudinal muscles. The chæte are shaped like a large S. The nervous system consists of a pair of dorsal cerebral ganglia, connected with a ventral ganglionated cord. Special sense-organs are absent, except for tactile cells, but touch, sensitivity to light and color-sense exists. There is a definite body-cavity, split up into separate compartments for each segment. It communicates with the outside through dorsal pores. The vascular system is closed and consists primarily of a dorsal contractile vessel and ventral noncontractile one, communicating by transverse contractile trunks in front and capillaries behind. The excretory system consists of variously modified nephridia opening into the coelum and to the outside. The digestive tube is usually straight and consists of a ventral mouth, a buccal cavity, a muscular pharynx, an esophagus and an intestine opening by a terminal anus. Various glandular appendages exist and the whole system is often complicated in several respects. The reproductive glands lie in the wall of the coelum; their complicated ducts are probably modified nephridia.
Consult Beddard, 'Earthworms and their Allies' (New York 1912); Darwin, 'Formation of Vegetable Mould' (London 1881).

**EARWIG**, an orthopterous insect, forming type of a family, Forficulidae. This insect has generally a habit of concealing itself in cavities, entries, crevices or under their innermost recesses, and in some rare cases may have sought a hiding place in the ear, but its passage into the internal ear would be stopped either by wax or secretions of the tympanic membranes. In any case, there is not much basis for the legend that it is in the habit of creeping into the ears of sleepers. The common earwig (F. auricularia) is found throughout Europe, in North Africa, Asia Minor and North America. It has a length of from two-fifths to two-thirds of an inch; the antennae are thread-like, and the number of joints is 15. The fore wings are short, horny and somewhat rectangular, but the larger hind wings are thin and mainly membranous and fold up somewhat to the underside of the fore wings. The last segment of the abdomen carries a pair of curved, horny, pincher-like appendages, which in the male are toothed at the base. The eggs are laid in spring, about 20 at a time, and are carried in the case by the female. The young earwigs differ little except in size from the mature insects; they are guarded by the mother during the first period of their existence. Earwigs shun light as far as possible and this habit is taken advantage of by gardeners to catch and destroy them. However, their partly predatory habits benefit the gardener by destroying more obnoxious insects. In the daytime they may be found in various situations, such as beneath the bark of trees, under stones, in the soil, or in any suitable hole. They feed on fruits, seeds, leaves and flowers, and at times on animal refuse. Eight other species of this genus are found in Europe. In the genus Cheilidura, represented in Europe by nine species, the wings are altogether wanting. *Labia* is another genus, with only one European species (*L. minor*), which is common in Great Britain about mature heaps and similar habitats. See ORTHOPTERA.

**EAUSEMENT**, a legal term, denoting a privilege comprising a permanent public or personal right as legal owner of one parcel of land, to use, or forbid its use, for some special purpose, with regard to a parcel of land belonging to another owner. This definition includes easements strictly so called, which are always appurtenant to land, public easements and easements in gross or such as are attached to the person. In more general terms it is said that the right of making use of the land of others, whether it be that of the public or individuals, for a precise and definite purpose, not inconsistent with a general right of property in the owner, expector or the servient owner; he is in legal contemplation an easement or franchise, and not a grant of the soil or general property. In the civil law the land against which the privilege exists is called the servient tenement, the right in the owner is called the servient owner, and in whose favor it exists the dominant owner; his land the dominant tenement. And, as these rights are not personal and do not change with the persons who may own the respective estates, it is very common to personify the estates as themselves owning or enjoying the easements. Easements have these essential qualities. There must be two tenements owned by several proprietors; the dominant, to which the privilege is attached; the servient, upon which it is imposed. Considered strictly, easements exist only in favor of, and are imposed only on, corporeal property. They confer no right to any profits arising from the servient tenement. They are incorporeal. At common law they may be temporary; by the civil law the cause must be perpetual. They impose no duty on the servient owner, except not to change his tenement to the prejudice or destruction of the privilege. Easements are of various kinds. They are as various as the exigencies of domestic convenience or the purposes to which buildings or land may be applied. The following attach to land as incidents or appurtenances, to wit: The right of passage or egress and ingress on other land; of fishing in other waters; of taking wood, minerals or other produce of the soil from other land; of receiving air, light, or heat from or over other land; of receiving or discharging water over, or having support to buildings from other land; of draining other lands to clear a mill stream, or repair its banks or draw water from a spring there, or to do some other act involving ownership; of carrying on an offensive trade; of burying in a church or a particular vault, etc. Some of these are affirmative or positive, that is, authorizing the commission of acts on the lands of another actually injurious to it, as a right of way — or negative, being only consequentially injurious, as forbidding the owner from building to the obstruction of light of the dominant tenement. Easements of every kind must originate in a grant or agreement, express or implied, of the owner of the servient tenement. By the common law, the evidence of their existence may be by proof of the agreement itself, or by prescription, requiring actual and uninterrupted enjoyment immemorially, or for upward of 20 years, to the extent of the easement claimed from which a grant is implied. Easements of the negative kind do not and cannot last, and by the civil law they cannot be acquired by prescription and can only be proved by grant. Use is not essential, therefore, to their existence. Easements may be extinguished by release; by merger, when the dominant and servient tenements are united under the same title and to the same person; by necessity, as by a license to the servient owner to do some act incompatible with its existence; by cessation of enjoyment, when acquired by prescription — the non-user being evidence of a release where the abandonment has continued at least as long as the user from which the right arose. A shorter time will answer in some cases. Interference with a right of easement is an action of trespass, or of case, where the offense is one of consequential damages. Redress may be gained through a court of equity for the infringement of easement.

EAST—EAST AFRICA PROTECTORATE

EAST, Sir Alfred, English artist: b. Kettering, Northamptonshire, 15 Dec. 1849; d. 28 Sept. 1913. He studied in Paris at the Ecole des Beaux Arts under Juliaan and Bouquerese. He was knighted in 1910 and was elected a Royal Academician 1913. He has exhibited at the Royal Academy for many years and among his works are 'A Passing Storm,' 'A Haunt of Ancient Peace,' 'The Nene Valley,' 'An Idyl of Spring,' 'London at Night,' 'The Morning Moon'; 'Autumn in the Valley of the Seine.'

EAST AFRICA, British. See EAST AFRICA Protectorate.

EAST AFRICA, German, the German possessions in east Africa, acquired in 1885–90, lying immediately to the south of British East Africa, and having an estimated area of about 384,800 square miles and population (1913) of 7,678,132, of whom 5,236 are Europeans. They are bounded on the north by a line running northwest from the Umba River to the eastern shore of the Victoria Nyanza and continuing west from this lake to the Congo State. Lake Tanganyika forms the western boundary and the line to Lake Nyassa and the river Rovuma form the southwestern and southern boundaries. In September 1894 it was agreed that the German-Portuguese frontier should follow parallel lat. 10° 40' S. from the coast to its intersection with the river Rovuma, leaving Kionga and the mouth of the Rovuma to Germany and Cape Delgado to Portugal. Several stations have been established by the German East Africa Company. Two railway lines—the Usambara (223 miles) completed in 1912, and the central railway (780 miles) from Dar-el-Salaam, the seat of government, to Ujiji on Lake Tanganyika, completed in February 1914—are the main arteries of communication. The revenue for 1914 was £25,100 and expenditure £1,180,000. In 1912, 1,134 vessels of a total of 1,913,743 tons entered the various ports. The products of the country are coffee, tobacco, cotton, ivory, caoutchouc and gum. The highest mountain is Kilimanjaro, reaching 19,600 feet. Among the chief rivers are the Rovuma, Rufiji, Kinongwe, and Ujiji. The last, flowing into the Indian Ocean; the Kagera, Shumiyo and Ruwara flowing into Victoria Nyanza; and the Malagarazi flowing into Tanganyika. In the north there are several small lakes and in the southwest the larger salt lake, Rukwa or Hikwa. On the coast the chief towns are Mikindani, Lindi, Dar-es-Salaam, Bagamoyo, Pangani, Wanga, and the English mission station Saadani. Inland there are Mpwawpa, Kanyenyu, Tabora (Kasela), Urambo and Ujiji. The country is under an imperial governor. After the outbreak of the great European War the colony was attacked by the Entente Powers, the chief forces being the British and South African troops led by General Smuts, who attacked from the north, while Belgian and Portuguese troops attacked from the south and east. Its conquest was completed on 3 Dec. 1917. For details see War, European.

EAST AFRICA, Portuguese, or MOZAMBIQUE. The possessions of Portugal, comprising three distinct entities: the province of Mozambique (293,580 square miles) the Companhia do Moçambique (59,840 square miles); and the Companhia do Nyassa (73,292 square miles). The first-named is divided into five districts, with Lourenco Marques as the capital. Its course extends south from Cape Delgado, the southern extremity of the coast-line of German East Africa to Kosi Bay, just below Delagoa Bay, at a point separating British from Portuguese territory, as fixed by the Anglo-Portuguese agreement of 1891; the northern boundary is the river Rovuma, running west from Cape Delgado to Lake Nyassa. The frontier between German and Portuguese East Africa runs along parallel lat. 10° 40' S. from the coast to its intersection with the river Rovuma, leaving the mouth of the Rovuma and Kionga to Germany and Cape Delgado to Portugal. The eastern boundary is the lake and British Central Africa, or the Nyassa Protectorate down to the junction of the Shiré with the Zambesi; while from that point Rhodesia, including Mashonaland and Matabeleland and the Transvaal form the boundary. Its total area is 426,712 square miles, and the population is estimated to be between three and four millions. The principal exports are sugar, oilnuts and seeds, caoutchouc, ivory and mining products. The Mozambique Company administers Sofala and Manica. The Nyassa Company has jurisdiction in the northern part between Lake Nyassa, the Rovuma and the Lucio, Bulawayo. The railway from Delagoa Bay (57 miles in colony) connects with Pretoria; and that from Beira (204 miles in colony) with Bulawayo; and there are three smaller lines. There were in 1912 2,959 miles of telegraphs. The coast-lands are low-lying and not very healthy, but in the region of the Namuli Mountains there is one of the finest and most beautiful tracts of country in the whole continent. There are several important rivers, including the Zambesi, Limpopo, Rovuma, Sabi, Punwe, Lucio, Mtepe, Lukuga and many others. The most important towns are Lourenco Marques (pop. 9,849; 4,691 Europeans), Mozambique, Ibo, Zumbo, Tetet and Sena. Gold is found in the Manica region on the west and has been worked by British capitalists.

EAST AFRICA PROTECTORATE, a British dependency, extending from the Umba to the Juba River, and as far inland as Uganda. It includes certain lands rented at an annual fee of £17,000 from the Sultan of Zanzibar; namely, the Lamu Archipelago; a strip 10 miles inland reaching from the German frontier to Kipini; and the area for 10 miles around the fort of Kismayu. The rest of the country is divided into seven provinces, and an extraneous unorganized piece of land in the north, as follows: Seyidie, Ukamba, Tanaland, Jubaland, Kenya, Naivasha and Nyanza. The area is estimated at 250,000 square miles; the population at 4,038,000. The various nationalities which go to make up the Protectorate are distributed as follows: Arabs and Swahilis along the coast; Bantu tribes further inland, and still further, non-Bantu tribes. The Asiatics number some 25,000, and the Europeans and Eurasians 5,000. Agriculture is extensively carried on, the products grown being rice, maize, grains, casava, coconuts, sisal hemp, Ceara rubber, cotton, etc,
in the lowlands; and on the highlands, oats, barley, wheat, potatoes and various products of truck farming. Coffee growing is a rapidly increasing industry. In the uplands cattle grazing is becoming most important. Sheep, cattle and ostriches are profitably farmed. There is also some dairying. There are more than 3,000 miles of forest land, a deep tropical forest occupying about 180 square miles of the lowlands. Ebony, copal and rubber trees are found near the coast, while the upland countries yield valuable cedars, yellow woods, camphor, jarrah, cork, iron-wood, pillar-wood and olive. The entire timber resources are not yet completely explored. The mineral resources likewise have not been fully developed. In the Rift Valley, near German East Africa, numerous deposits of natron and diatomite have been found. A little gold has been mined in South Kavirondo; graphite, marble, limestone and manganese have been produced in appreciable quantities, and some fine opals have occasionally been unearthed in the Rift Valley. The chief imports are clothing, provisions, building materials, iron and steel products and livestock. In 1916-17, the imports amounted to £3,024,123; the exports £1,613,853, and the tonnage entered and cleared, to 1,441,877 tons. The State Railway is called the Mombasa—Victoria or Uganda Railway, and is 618 miles. There are competent telegraph, telephone and postal services.

The government of the Protectorate is under a governor and commander-in-chief under the Colonial Office. An executive and legislative council are also provided. The principal cities are Nairobi, where the administrative headquarters are located; Mombasa, the chief port (pop. about 30,000; 230 Europeans); Kilindini, a splendid harbor on the east coast; Jubaland, Kenya, Nawasha and Kisumu. The expenditure of the government for 1917-18 is estimated at £1,484,075; and the revenue for 1916-17 amounted to £1,533,783, derived from licenses, dues, taxes, court fees, railways, customs, etc. A railroad was built by Col. J. H. Patterson for the government in 1869, from Mombasa to Nyeri, afterwards called the British East Africa and Uganda (London 1892); Elliot, 'East Africa Protectorate' (ib. 1905); the 'Oxford Survey of the British Empire' (Vol. III, London 1914); and the publications of the Colonial Office of Great Britain.

EAST ANGLIA, an ancient kingdom of England, its territory corresponding to what is now Norfolk and Suffolk counties. Redwald was its first historical king (593-615).

EAST AURORA, N. Y., village in Erie County, on the Pennsylvania Railroad, 18 miles southeast of Buffalo. The place is noted as the home of the colony of Roycrofters (q.v.), who produce the principal manufactures of the village: hand made furniture, pottery, de luxe edition bindings, etc. Roller mills and agricultural implement works are located here. There are also mineral springs and a covered race track. The village owns its waterworks and sewage plant. It is a residential suburb of Buffalo. Pop. 2,784. See Roycrofters.

EAST BRIDGEWATER, Mass., town in Plymouth County, 23 miles south of Boston, on the New York, New Haven and Hartford Rail-

road. It contains an iron foundry and a cotton gin. Pop. 3,363.

EAST CAPE, the name of the southeastern extremity of New Guinea, in Gosenh Strait, and of the most easterly headland of New Guinea Island; also on the North Island of New Zealand; also in Siberia, on Bering Strait, in long. 169° 44' W., in the eastern extremity of Asia. The latter is a bold, rocky promontory, almost cut off from the mainland by swamps and shallow lakes. On the north side is a village, Udelle, of less than 100 huts, with a population of about 260.

EAST CHICAGO, Ind., city located in Lake County, on the southeasterly shore of Lake Michigan, 19 miles from the central business district of Chicago, but only two miles from the east line of Chicago's city limits. It contains three railway stations, known on the maps as East Chicago proper, or as called locally, "The West Side"; Calumet, one mile east of the old town; and Indiana Harbor, on the lake front.

In 1853 title to the land where the city is now built passed from the United States government to the State of Indiana. The following year State patents were given at the rate of $1.25 per acre. During the year 1888 the city of East Chicago was laid out, the town starting two and one-half miles inland from Lake Michigan, it being the idea that the development toward and at the lake would be rapid when once started, owing to natural advantages. It was incorporated as a town in 1889 and chartered as a city in 1893. The panic of 1893 retarded the progress, so the first 10 years' growth was slow and fraught with difficulties. The population in 1900 was 3,400. In 1901 the development of that part of the city known as Indiana Harbor was commenced. Owing to the unlimited rail and water shipping facilities and other natural advantages this development has been phenomenal and with its growth the older section of the city has kept pace. The city has the following excellent transportation facilities: The Lake Shore and Michigan Southern; Pittsburgh, Fort Wayne and Chicago; Chicago, Indiana and Southern; Baltimore and Ohio; Wabash, Pere Marquette and The Chicago Lake Shore and South Bend trunk lines, all of the above passing through the city; and the Elgin, Joliet and Eastern; Baltimore and Ohio Chicago terminal; and the Indiana Harbor Belt Railway lines encircling Chicago and terminating at this point. In addition to the rail facilities the lake shipping facilities are unsurpassed. A harbor 350 feet wide and 22 feet deep, protected by the most modern breakwaters, forms the entrance to the Indiana Harbor Ship Canal, which has been completed from the lake south to the Calumet River to a width of 200 feet and a depth of 21 feet. In addition thereto, a branch of the canal extends west to Lake George; so there is a total of 10 miles of dockage within the city, limits which can be reached by the largest vessels on the lake.

This canal connects with the Calumet River so when the latter is impounded it will increase the available deep water dockage to 22 miles, and upon completion will give the city one of the best and most extensive commercial harbors in the country. At no other point on Lake Michigan is it possible for three belt railroads
to come into direct connection with navigation. These three belt railroads cross every trunk line entering Chicago, and inasmuch as Chicago freight rates apply to and from this city, it enjoys the best shipping facilities that can be had at any point. In addition to the shipping facilities and trunk line services mentioned, there are three interurban and street car systems in operation in the city and this affords ample accommodation for local transportation. There are 44 industries in full operation, employing 15,000 men, with an annual pay-roll of over $15,000,000. In addition to the plants now in operation, one $5,000,000 plant has been constructed and approximately $12,000,000 more has been spent in additions and improvements. In 1917 it was estimated that there would be employed 5,000 additional men, with a corresponding increase in pay-roll and population. The manufactured articles consist of iron and steel products taken from the raw material and finished to a complete state, embracing everything of iron and steel manufacture from a small bolt to the largest locomotive; also, fire brick, soap, chemicals, liquid air, conduits, hay and cotton presses, auto trucks and cements. The city has seven banks, eight public schools, five parochial schools, four public parks, 20 churches, three public libraries, 50 miles of paved streets, 70 miles of cement streets, 45 miles of sewerage, 35 acres in parks, 350 ornamental light pools, four newspapers, a fine city hall and one of the largest electric power plants in Indiana. There are 105 daily trains to and from Chicago. Over $4,000,000 is invested in bascule bridges across the canal and the city is directly connected with the immense coal fields of Illinois and Indiana and cheap fuel oil supply. The per cent increase in population during the decade ending in 1910 was 559, the largest per cent increase of any city in the United States.

The city is the hub of the great Calumet district in Indiana, and the centre of a population of 120,000 people. Adjoining on the northeast is beautiful Lake Michigan, on the west the city of Whiting, on the west and south the city of Hammond, and east the city of Gary, all of these cities being within a radius of five miles from the centre of East Chicago, which thus forms a natural hub for the entire Calumet district. The government is vested in a mayor and a council of six members. Pop. 30,000.

FRANK L. EVANS,
Secretary East Chicago Chamber of Commerce.

EAST GRAND FORKS, Minn., city of Polk County, at the junction of the Red and the Red Lake railways, opposite Grand Forks, N. D., and on the Northern Pacific and the Great Northern railways. It is surrounded by a fertile farming and wheat-raising district. The chief manufactures are lumber and beer. Pop. 2,533.

EAST GREENWICH, R. I., town, county-seat of Kent County, 14 miles south of Providence, on Greenwich Bay and on the New York, New Haven and Hartford Railroad and on the local summer resort and residential town, and has manufactures of cotton and woolen goods, dry salters works, dextrin, soap and chemicals. Greenwich Academy is situated here, and the town has a public library, public water and electric lights. It was the birthplace of Gen. Nathanael Greene. Pop. 3,420.

EAST HAMPTON, N. Y., town in Suffolk County, in the eastern part of Long Island; on the Long Island Railroad, about 102 miles east of New York. The town is picturesquely situated, and enjoys some reputation as a resort. It contains the Clinton Academy building, erected in 1784, which has been transformed into a town hall and library. After the war with Spain the volunteer troops were mustered out of the Federal service at the camp nearby at Montauk Point. Every two years town meetings are held. The first settlement was made in 1649 and the place was considered as belonging to Connecticut from 1657 to 1664 when it came under the jurisdiction of New York. During the Revolution it was frequently pillaged by the English. It was the home of John Howard Payne (q.v.). Pop. 3,500. Consult Gardner, 'Records of East Hampton' (Sag Harbor 1886-89); Hedges, 'History of the Town of East Hampton' (Sag Harbor 1897).

EAST HARTFORD, Connecticut in Hartford County, on the New York, New Haven and Hartford Railroad, and on the Connecticut River, two miles east of Hartford. The town contains the Raymond library, a town library and a cemetery over 200 years old. It was first settled in 1640 but was not incorporated as a town until 1783. It is the birthplace of William Pitkin, Colonial governor. The form of government is by town meetings. The railroad shops and paper-mills give employment to a number of people. Large quantities of tobacco and garden vegetables are raised on adjacent farms. Pop. 8,875.

EAST HUMBOLDT MOUNTAINS, Nevada, a forested range of mountains principally in Elko County, separating on the east and west, respectively, the Ruby and Huntington valleys, Fremont's Pass is in these mountains.

EAST INDIA COMPANIES, the various European trading companies chartered by their respective governments for the trade in India and the adjacent countries and islands. From an early period, the Italian republics had established a flourishing trade with these Eastern dominions, which was interrupted by the Moslem conquest of Egypt and Constantinople and the establishment of Turkish rule in Africa and Europe. Under these circumstances arose that spirit of maritime exploration in the 15th century for the discovery of a new passage to the Indies which resulted in the discovery of America by Columbus while seeking a westward route, and in Vasco da Gama sailing around the Cape of Good Hope and reaching the Malabar coast in 1498. This latter discovery gave a new impulse and direction to commercial enterprise, and in nearly all the leading nations of Europe steps were taken to participate in the advantages prospectively revealed in the opening up of this new ocean highway. The 16th century was marked by the Portuguese establishing themselves in India; by English efforts to discover Greenland and northern passages to India, while fruitless in the latter direction gave rise to commercial relations with the northern coast of Russia; by the union of Portugal and Spain in 1580, and in the war with England which closed
the Spanish-Portuguese avenues for Indian produce to that country; and by the revolt of the Dutch against Spanish dominion which gave a parallel check to the Dutch Indian trade. These two latter events complicated Holland and England to seek direct communication with India; in 1582, a Captain Stephens was the first Englishman to reach India via the Cape of Good Hope, and in 1586 Thomas Cavendish followed by way of Cape Horn. In the following decade the great historical commercial corporations known as the Dutch and the English East India companies were organized, and later were followed by Danish, French and Swedish enterprises.

The Portuguese East India Company was organized in 1587, when, owing to laxity in the official management of the trade developed since 1498, it was entrusted to a company of Portuguese merchants in consideration of an annual payment. The company had a turbulent existence, chiefly of conquest by the Dutch until its dissolution in 1640, since which time the unimportant Portuguese settlements have been under Crown administration.

The Dutch East India Company was formed at Amsterdam in 1595 as a company for remote parts, in 1602 amalgamated with several minor companies and received a charter conferring the exclusive privilege of trade to the East Indies for 21 years, with the necessary civil and military powers. It had a wonderfully prosperous career and its charter was extended to 1644, when French and English competition had made itself so felt that the Dutch company had difficulty in raising the government subsidy for a 21 years' renewal of the charter.

The Peace of Westphalia in 1648, ensuring the independence of Holland, inaugurated a new era of prosperity; the company colonized the Cape of Good Hope between 1650 and 1670; in 1658 captured Ceylon from the Portuguese; the same year took Formosa, from which they were driven three years later by a Chinese adventurer; in 1663 obtained possession of the chief Portuguese settlements along the Malabar coast, and in 1666 monopolized the spice trade by the capture of Macassar. Their charter was renewed periodically until 1776; in 1781, owing to the expenses of the prolonged struggle against English encroachment, the company had to be assisted with a government loan, and in 1795 the proclamation of the Batavian republic terminated its existence; in 1798 the mother-country assumed the administration of the company's former possessions.

The English East India Company formed in 1599 and chartered by Queen Elizabeth in 1600, under the title of the "Governor and Company of Merchants of London trading with the East Indies" was the most important, commercially and historically, of the East India companies. The trading limits assigned by the charter for 15 years were all the islands, ports, havens, cities, creeks, towns and places of Asia, Africa, and America, or any of them, beyond the Cape of Good Hope to the Straits of Magellan, which by exception of such places as are already in possession of any Christian prince in league or amity with the British Crown who shall refuse his consent to such trade. The company comprised 125 stockholders, including a governor and 24 directors elected annually to supervise the company's business. The early voyages of Lancaster, Beal, Best and others resulted in large profits; in valuable commercial treaties being entered into with native princes, English prestige being considerably enhanced throughout the Orient by naval and political successes over the Portuguese. The establishment of factories in various stations, however, excited the jealousy of the Dutch, who in 1624 massacred the members of the English factory at Ambon, an atrocity for which Cromwell in 1654 compelled the Dutch government to cede an island and to pay a sum of $1,500,000 as compensation to the victims' families. This incident inaugurated the struggle which resulted in the loss to the Dutch of all their possessions on the Indian peninsula. With periodical renewals of its charter, the company, overcoming all rivalry and opposition, maintained its position. From 1745 to 1761 it was engaged in a crucial fight throughout the Carnatic for supremacy with the French company established in 1664, and which under La Bourdonnais and Dupleix had obtained almost paramount power in India; Clive (q.v.) brought it safely through the struggle. It was with reluctance, however, that the company accepted the terms by which their victories over the French and the native states was forcing upon them of territorial magnates and unconsciously of founders of the British empire in India; especially when their growing political importance inspired the British government with a desire to control their company.

In 1766 the right of the company to acquire territorial possessions formed a subject of inquiry in the British Parliament; and a year later resolution of the propriety of paying the dividends to 12½ per cent was vetoed. The question of political rights of the company being thus raised, the British ministry acted on their view of it by sending a Crown plenipotentiary to India, and after a protracted struggle, a regulating act was passed in 1773 delimiting the powers of the company and placing it under the control of Parliament. The constitution of the councils of the presidencies was regulated and their superintendence assigned to a Crown official, Warren Hastings (q.v.) being appointed first governor-general; and introduced by Pitt in 1784 modified the political power of the company by establishing a board of control to superintend, direct and control all acts, operations and concerns relating to the civil and military government or revenues of India. From this time the political power of the company was little more than nominal; the right of nominating its officials still remained with the directors, but the absolute right of recall was vested in the Crown. The company's charter was renewed with a few changes in 1793 and subsequently at intervals of 20 years; in 1813 it lost the monopoly of the Indian trade, which under certain restrictions was thrown open to all British subjects; its right of exclusive trade was restricted to China, but in 1833 this monopoly was also abolished. Its charter was renewed for the last time in 1853; the Indian mutiny, 1857-58, discredited the company's administration, and in November 1858 a proclamation at Calcutta announced that Queen Victoria had assumed the native princes of India. The company continued to receive and distribute the dividends guaranteed by the government.
EAST INDIAN MANUFACTURES

1, 2 Musical Instruments
3 Bangle
4 Pendant of a Necklace
5, 6 Vases of Glazed Pottery
7 Earring
8 Engraved and Gilded Bottle
9 Spearhead
10 Dagger; from Khuttar
11 Saw-edge Sabre
12 Flint Matchlock
13 Wooden Spoon
14 Border of a Mat
15 Symbol of Juggernaut
16 Nose Ornament
17 Printed Cotton
18 Cotton Carpet
19 Emblem of Jain Sect
20 Illuminated Manuscript
until the East India Stock Dividend Redemption Act became operative in 1874 when the company was dissolved.

The Dutch East India Company, founded in 1618, dissolved in 1634, reconstituted in 1670, again dissolved in 1729, was succeeded in 1732 by the Danish Asiatic Company. This company held tremendous power between Great Britain and Denmark in 1801, when its trade declined and ended with the cession of Tranquebar and Serampore to Great Britain in 1845.

The French East India Company, known as "La Compagnie des Indes Orientales," was founded in 1664 by Colbert, Minister to Louis XIV. It had extensive privileges, and in 1675 made a settlement at Surat, and in the following year at Pondicherry. It had a long and prosperous career, notwithstanding the loss of trading privileges at various periods and its connections with the Mississippi Bubble (q.v.). It reached the height of its prosperity under Duplex (q.v.) and La Bourdonnais, extending its operations until the Deccan and the Carnatic were practically under French control, when antagonism with the English under Clive, the recall of Duplex, and practical abandonment by the French government, led to the dissolution of the company by royal decree in 1769.

The Swedish East India Company, founded at Gothenburg in 1741, was reorganized in 1806.

Bibliography.—Charters granted to East India Company from 1601; Macpherson, History and Management of East India Company (1779); Bruce, Annals of the East India Com.

EAST INDIES, or MALAY ARCHIPELAGO, the double chain of islands which extends from the southeastern corner of Asia to the northern extremity of Australia. On the Pacific side there are the islands of Borneo, Celebes, Buto, Sula Island, Buru, Morotai, Jilolo or Halmahera, Amboyna, Ceram, Banda, Waigeo, Misol, Salwati and New Guinea. The Sulu Archipelago and the Philippines are regarded as the northern extension of this chain, the connecting links being Sangir and Talaut groups of islands. Next the Indian Ocean the southern chain includes Sumatra, Singapore Island, Riau-Lingga, Banca, Billiton, Java, Madura, Bali, Lombok, Sumbawa, Sandalwood, Flores, Timor and the Timenber, Kei and Aro groups. All these belong to the Netherlands, except the Philippines and Sulu Islands (property of the United States), the northern part of Borneo (British), the eastern half of Timor (Portuguese), the eastern portions of New Guinea (British), and Singapore Island (British). Several of the islands (e.g., Java, Sumatra) are studded with active volcanoes. The entire archipelago seems to represent the surviving fragments of a great land mass which has connected Asia and Australia, the evidence in support of this view being especially strong in Borneo and Celebes. The inhabitants are mostly of the Malay race; though Chinese, Arabs, indigenous tribes and various Europeans are also present. As the islands lie between the equator and the Tropic of Capricorn, their climate is equably hot; and it is also moist, for they fall within the influence of the monsoons. Consult Angier, A. G., The Far East Revisited, with a preface by Sir Robert Hart (London 1908); Day, C., The Policy and Administration of the Dutch in Java (New York 1904); Gomes, E. H., Seventeen Years Among the Sea Dyaks of Borneo (London 1911); Swettenham, F., British Malaya (London 1907); Taunton, H., Australind: Wanderings in Western Australia and the Malay East (London 1903); Robson, J. H. M., Motor in Malaya (London 1911); Wallace, A. R., On the Physical Geography of the Malay Archipelago (Royal Geographical Soc. Jour., London 1863, v. 33) and The Malay Archipelago (London 1889 and 10th ed., London 1906).

EAST LIVERPOOL, Ohio, city in Columbiana County, on the Ohio River, and on the Pennsylvania Railroad, 45 miles west of Youngstown. It has freight packet connections with all important Ohio River ports, extensive chins, porcelain, earthenware, terra cotta and glass works, foundries and machine shops. East Liverpool is the most important center in the United States for the manufacture of porcelain, including porcelain dinner ware, floor tile and porcelain electrical supplies. The United States census of manufactures for 1914 showed within the city limits 86 industrial establishments of factory grade, employing 5,180 persons, 4,830 being wage earners, receiving annually $2,935,000 in wages. The capital invested aggregated $6,595,000, and the year's output was valued at $7,093,000; of this $4,251,000 was the value added by manufacture. It has the largest pottery works in the United States, natural gas furnishes light and fuel, and the waterworks are owned by the city. It has a Carnegie library and three parks. Two bridges connect the city with Chester and Newell, W. Va. It has good schools, one business college, three national banks and daily and weekly newspapers. Under the Ohio Code of 1902, the government is vested in a mayor and a board of public service, elected for two years, and a council. The board of public safety is appointed by the executive and council. East Liverpool was settled in 1795 and was incorporated in 1834. Pop. 21,877.

EAST LYNNE, a novel by Mrs. Henry Wood, which appeared in 1861. It takes its name from the ancestral home of the heroine, Lady Isabel Vane. Several years after marriage, mistakenly doubting her husband's fidelity, she leaves him for another, but later returns in disguise as nurse to her own children, and on her deathbed receives his forgiveness. Although 'East Lynne' has little literary merit it secured immediate popularity, has been through many editions on two continents, and proved extremely successful as an emotional drama.

EAST MAIN, Canada, region of the Dominion which formerly belonged to the Hudson Bay Territory, but which, with the District, province of Quebec. It is a bleak and desolate country, yielding little to commerce but fish oil and a few furs. The East Main or Slade River crosses its southern section, entering James Bay, the southern extension of Hudson Bay, about 52° N. The river has a length of about 400 miles.
EAST ORANGE—EAST SAINT LOUIS

EAST ORANGE, N. J., city in Essex County, on the main line of the Lackawanna Railroad, and on a branch of the Erie Railroad, about 12 miles west of New York. It is a residential city, its population being made up largely of people who do business in New York and work in Newark. It has many handsome churches and private residences, a public library, municipal playgrounds, an orphan asylum, a women’s club, high and graded schools, a national bank and weekly newspaper. Its industrial plants include electrical works and manufactories of pharmaceutical supplies, brass and iron casting and bread. The United States census of manufactures for 1914 showed within the city limits 51 industrial establishments of factory grade, employing 2,610 persons, 1,949 being wage earners, receiving annually a total of $1,130,000 in wages. The capital invested aggregated $6,618,000; the year’s output was valued at $5,407,000; of this $3,018,000 was the value added by manufacture. The government is administered by a mayor, elected biennially, and a city council. All municipal officials are appointed by the executive with the consent of the council. The waterworks are owned by the city. East Orange was part of Orange until 1863, when it was incorporated as a separate township. In 1899 it was chartered as a city. Pop. 39,852. Consultant Whitemore, ‘The Founders and the Builders of the Oranges’ (Newark 1896).

EAST PROVIDENCE, R. I., town in Providence County, on the Seekonk River, and on the New York, New Haven and Hartford Railroad. It lies directly opposite the city of Providence. East Providence and the town of Seekonk, Mass., were once a part of the old town of Rhoboth. It was set off from Seekonk when the Massachusetts-Rhode Island boundary line was fixed and was incorporated in 1852. The town has extensive chemical works, electrical and wire works, bleachers, linoleum factories and beer breweries. The government is administered by a town council, which elects a majority of the local officials. The council members are elected annually by popular vote. Pop. 17,369.

EAST RIVER, the strait connecting Long Island Sound and upper New York Bay. The East River receives the waters of the Harlem River, which is connected with the Hudson by the Harlem Ship Canal, thus making a complete waterway around Manhattan borough, which the East River separates from Brooklyn and Queens boroughs on the Long Island shore. The designation covers a length of about 16 miles having a width of from 1,000 yards to three miles. Blackwell’s, Randall’s, Ward’s, Rikers, and North Brother islands are on the East River. Between Ward’s Island and Long Island there are rapids known as Hell Gate; long a danger to mariners they have been rendered safer for the large vessels by blasting the sunken reefs. The river is spanned by the Williamsburg, Queensboro, Manhattan, the old Brooklyn, and the new Hell Gate bridges.

EAST SAINT LOUIS, Ill., city of Saint Clair County, located on the left bank of the Mississippi, opposite Saint Louis, Mo., with which it is connected by several bridges.

Communications, etc.—East Saint Louis is served by 27 trunk line railroads, all connected by four terminal belt lines. One hundred and twenty-five passenger trains and 150 freight trains are at the daily service of East Saint Louis. The total mileage of all railroads entering the city is 64,000. The list of steam railroads is as follows: Rock Island; Chicago, Peoria and Saint Louis; Burlington; Chicago and Eastern Illinois; Chicago and Alton; Wabash; Illinois Central; Big Four; Toledo, Saint Louis and Western; Cotton Belt; Saint Louis, Troy and Eastern; Litchfield and Madison; Pennsylvania; Baltimore and Ohio; Saint Louis and O’Fallon; Southern; Louisville and Nashville; Mobile and Ohio; Iron Mountain; Frisco; and Missouri Pacific.

In addition to the steam roads there are also the Illinois Traction Company, known as the McKinley System, the East Saint Louis, Columbia and Waterloo Railway, and the Alton, Granite and Saint Louis and Southern Railway, and Saint Louis and Belleville Electric Railway, and Southern Traction Company, all electric roads. These roads tap the large and prolific agricultural district around East Saint Louis. There are 75 miles of paved streets and 35 miles of electric street railways.

Public Buildings, Educational Facilities, etc.—The noteworthy public buildings are the city hall, high school and public library. The city maintains 38 primary and secondary schools, two business colleges, and there are 40 churches of various denominations and four theatres. There are four amusement parks and eight public parks, including Jones Park, with an area of 47 acres.

Commerce and Industry.—East Saint Louis is an important manufacturing centre, manufacturing everything from nails to locomotives. Its industrial interests are aided by the valuable bituminous coal deposits of Illinois, 10,000,000 tons of which are mined annually in the vicinity of East Saint Louis. The city has many factories of baking powder, oxide of alumina, roofing paper, malleable iron, glass, railroad frogs and switches, white lead, paint, car trucks, bridges, vehicle springs, forgings, pneumatic tools and silica, and there are 40 elevators, flour mills, foundries, a rolling mill and fertilizer plant. It is the largest alfalfa stock feed producing centre in the United States, and there are also stock yards, a horse and mule market, the largest in the world, and pork and dressed beef packing industries. The live stock receipts of the National stock yards of East Saint Louis during 1912 filled over 84,000 cars. The live stock sales during 1915 exceeded $150,000,000. In 1915 the report shows that the National stock yards received 991,700 cattle, 2,591,768 hogs, 642,141 sheep, 270,612 horses and mules. Over 5,000 men are employed in and around the National stock yards. The freight charges paid on live stock received at the yards exceeds by $4,000,000 the market cost of maintaining a railroad of 36 miles, operating 14 first-class locomotives. East Saint Louis has 25,000 industrial workers. The annual payroll of the city manufacturers is $20,000,000. Thirty million tons of freight are handled every year. Its factories consume several thousand tons of coal every year. The mortality rate of East
Saint Louis is 11.58, lower than the mortality rate of the United States, which is 15.00. It has six banks with combined resources of $15,000,000.

**History, Public Improvements, etc.**—The city was incorporated as a town in 1801 and received its city charter four years later. It is a progressive municipality, having expended upwards of $65,000,000 in street and other improvements, principally for flood protection and drainage. The flood protection includes a river front levee along the Mississippi, 31 miles in length and seven feet higher than the flood record of 1903. The Cahokia Creek, which is formerly passed through East Saint Louis, is being converted into a drainage sewer, most of its headwaters having been diverted to the Mississippi River through a channel four and one-half miles long and 18 miles north of the city. A three-mile limestone wharf is being constructed along the Mississippi River in front of the city. Water, gas and electric power are supplied by private corporations. Hydro-electric power from the Keokuk Dam plant is available at lower rates. The quality of well water for manufacturing purposes can be obtained anywhere at a depth of 100 feet.

**Government, Population, etc.**—The government is vested in a mayor, elected for two years, and a city council, of which the mayor is a member ex-officio. The people elect the city treasurer, city attorney, justices of peace, tax assessors, city clerk and City Court judges. The city has adopted the Commission form of government which becomes operative April 1919. The growth of the city has been very rapid. East Saint Louis had a population of 5,664 in 1870; 58,547 in 1910; and 92,983 in 1917.

D. WALTER POTTS, Superintendent of Schools.

**EASTBOURNE,** England, county, borough and bathing place in Sussex, near Beachy Head, and between Brighton and Hastings. It contains a fine park of 13 acres and several other smaller recreation grounds. A fine esplanade skirts the shore for over two miles. In 1886 the town hall was erected. The town was incorporated in 1883 and became a county borough in 1911. The electric-lighting plant, omnibus lines, technical institute and hospital are the property of the borough. Its excellent water supply and sewage system and its healthful situation combine to make it one of the most popular resorts on the famed south coast. Pop. 52,544.

**EASTCHEAP,** London, England, formerly a large market in the east of the city occupying what is now Billingsgate and Leadenhall market. Several streets or roads converged at the great square, then called Eastcheap. Two of those highways were the old Roman roads which extended northeast and northwest out of the city. Some of the old taverns, notably "Boar's Head," mentioned by Shakespeare and other English authors, were at Eastcheap. At the north end of London Bridge there is now a small street called Eastcheap.

**EASTER,** the Christian spring festival celebrated very lowly. The term in Teutonic and Anglo-Saxon languages is derived from Ostara, the divinity of spring of the ancient Norsemen, who was welcomed in a festival of celebration on her annual return, reclothing the earth with greenery and flowers. After each winter and might of death had stripped the world of its faded robes and hidden them away, the sun even in the northernmost inhabited regions disappearing during the coldest winter months. In the Greek and Latin and in the language of the infant church the spring festival is called Pascha, Pasch, Pasqua, Pascua, Pásqua, Pasqua, Pascha, etc., from the Chaldee word *Pascha,* signifying *passing,* the equivalent of the Hebrew *Pesach,* that name recalling the "passing over" of the Hebrew households, when Death smote the firstborn of the Egyptians, as recorded in Exodus xii. To the Norsemen the festival of the divinity of spring which they called Ostara or Easter (whence Easter) was especially the season of new birth. From this festival arose the symbols of the Easter egg and of the Easter rabbit, as prolific reproducers of species; the decoration of springs and wells with flowers in token of the returning flow of water as a life-giving necessity; and the custom of baptismal cleanliness, purification and cleanliness. Every rite has a physical basis. The coloring of the Easter eggs, red, blue, yellow, etc., was borrowed from the rays of the Aurora borealis—the northern lights—and the dawning hues of the Easter sun. At Easter the hearth fire was lighted afresh. Easter bonfires were kindled on the hills, dispersing the germs of evil so far as an Easter fire shed its light. Around these purifying fires young men and maidens who desired marriage during the coming year sang and danced three (or nine) times or gave three leaps over the flame. The foundation of drama is found in these early myths and attendant songs, for example, the desire to express the two great emotions attributed to Nature, her sorrow when the sun is withdrawn and her joy when the fruitful season of growth begins again, is poetically developed with repetition in the Greek dramatic myth of Demeter and Persephone—Latinized as Ceres and Proserpine. While gathering flowers on the plains of Enna in Sicily, Persephone was seduced by "Glaucus, the Diaduma"—Pluto, the god of the dead—and reigned in Hades as his wife, the majestic queen of the underworld. Her mother, Demeter or Ceres, seeking her, hurries over the earth with a torch in her hand and at last gains the concession from the gods of Persephone's return for a third part of every year. In later years, with the development of agriculture, the festival came to be overshadowed by the rejoicing of the harvest season and by the autumn celebration of the cereal mysteries of the earth-goddess. In the beginning she was not separated from the divinity of spring, who, having wandered for nine months, at last returns, bringing new life and warmth and sunshine to the waiting earth. Therefore at "Eleusis," a general term for a "place of coming or assembly," and not originally a name attached to a special locality, the Greeks celebrated their festivals with the mysterious processions of veiled figures with torches moving from side to side in mimic search for the lost Persephone. The modern Maypole dances have the Easter or Eulssian spring celebrations, for the rhythmic interlacing circles of figures holding the brightly colored ribbons recall inevitably the measured
torch-light dance of Eleusis, the search from side to side for lost Persephone. The resemblance between spring festivals throughout the history of the world discloses the universal inclination to worship and reverence, to natural piety. Following the Mosaic injunction of the remembrance of Passover, with its offerings of lamb and unleavened bread, the Christian Easter day is commemorated by a ceremony of the Church, a memorial of the Paschal lamb. The Paschal lamb was a sacrifice to the memory of the Paschal lamb of God, which was the first lamb slaughtered and offered as a sacrifice in the Temple of Jerusalem. The Paschal lamb was a symbol of the sacrificial Lamb of God, who was to come and take away the sins of the world. The Paschal lamb was a symbol of the risen Christ, who was to come and conquer death and sin. The Paschal lamb was a symbol of the love of God, who was to come and show his love to humanity.

Easter Island, with its characteristic stone statues, is a remnant of ancient cultures that flourished on this isolated island. The statues represent various stages of formation, some finished, others nearly completed, and others just commenced. In size they range from three to four feet to nearly 80 feet in length. The largest found in an unfinished state measures 70 feet in length, smallest three feet. What race of men carved these statues and for what purpose is still a matter of speculation. Easter Island is supposed to be the remnant of a greater land which was overwhelmed by the sea after some great earthquake and volcanic eruption, about 1,000 years ago. The largest statues buried to the neck in ashes and scoria. Recent scientific analysis and deduction places the race of sculptor-builders as of a proto-Samoan character, inhabiting the land when the seismic catastrophe overwhelmed them probably less than 1,000 years ago, or at a period approximating with the Norman Conquest of England. Alvaro Mendana, according to Spanish geographers, was the first of modern

EASTERN SUNRISE PILGRIMAGE — EASTERN QUESTION

Navigators to discover the island in 1566; it is marked Davis Island on some maps from Edward Davis, buccaneer and adventurer, who repelled the Spanish from it in 1688. Jacob Roggeveen sighted it in 1722 on Easter Day and in commemoration gave the island its present name. The natives then numbered about 3,000 and according to their traditions came from a group. In 1864 the island was almost depopulated by Peruvians who kidnapped and transported the bulk of the inhabitants to work the guano diggings on the Chincha Islands. Consult Sandberg, H. O., 'Easter Island, the Mystery of the Pacific', Pan-American Union Bulletin, Vol. XXXV, pp. 897-910 (Washington 1912); Churchill, W., 'Easter Island, the Rapanian Speech and the Peopling of Southeast Polynesia' (Washington 1912).

EASTERN SUNRISE PILGRIMAGE. The annual "Easter Sunrise Pilgrimage" to the Father Serra Cross (so called from Father Junipero Serra, the founder of the Californian missions), on Mount Rubidoux, about 70 miles from Los Angeles, Cal., is an unusual ceremonial, inaugurated by the late Joseph Riis on Washington's birthday. May 1907, and an annual service developed until, in the Easter of 1914, over 6,500 people, including many distinguished Americans, attended to hear the reading of a poem by Mr. Henry Van Dyke, "God of the Open Air," and to watch a pageant representing some chapters in the history of the valley.

EASTERN EMPIRE, the ancient empire lasting from 395 A.D. to 1453 A.D., which had its metropolis at Constantinople as distinguished from the Western empire with its capital at Rome. It is known also as the Byzantine empire, the Roman empire of the East and the Greek or Later Roman empire. The separation was created by the death of Theodosius in 395, when the Roman empire was divided between his two sons, Arcadius taking the eastern half with his capital at Byzantium or Constantinople, and Honorius the western half with Rome as the capital. See BYZANTINE EMPIRE.

EASTERN QUESTION, The. The rivalry between the Great Powers for control of the Balkans and the political struggle among the Balkan states themselves constitute the Eastern Question. Prior to the 19th century the rivalry between the Great Powers turned upon religion as an ostensible motive, while politics remained at the same time the underlying cause for interference in Balkan affairs. The young and recalcitrant national states of the Balkan Peninsula have always been striving to gain self-government and religious autonomy. The liberation of Serbia was acknowledged in 1804, that of Greece in 1827. Rumania and Bulgaria secured their independence by Russia in 1878, and Bulgaria.

Before the Congress of Paris political control of the Balkans rested largely in the hands of Turkey; after that date the Balkan Question concerned not only Turkey but all Europe. Russia's interest was identified with the protection of its subject Tatars gaining thereby of a route through Constantinople to the Mediterranean Sea; France pretended to protect Roman Catholics in the Levant, in order to maintain there her trade; and Austria worked for aggrandizement of her empire through economic and political supremacy consistent with her policy Drang nach Osten, which in this case meant "Drang nach Rumänien." Great Britain regarded the safety of the route to her Asiatic possessions as paramount, and Germany planned a commercial outlet through the Balkans to the Persian Gulf.

From the end of the 18th century to the Treaty of Paris (6 March 1856), Russia's policy with Turkey in regard to the Balkans was that of the character of the "closed door." She began by allying with Turkey (Unkiah-Skelessi, 8 July 1833), a move which in 1840 was objected to by France, England and Austria, and which Russia opposed in 1850 only to find that Turkey was on the side of her enemies. In 1853 the Russo-Turkish War showed England and France as Turkish allies, and Austria and Germany were neutral till the war had reached the point where the latter two powers threatened to join the Turkish allies if Russia proved intractable. The Treaty of Paris (1856) consequently left Constantinople in the hands of the Turks. Russia gained Sebastopol but she was humiliated as to the limitation of her armaments in the Black Sea, to withdrawal from the mouth of the Danube by the partial retrocession of Bessarabia, and finally to a renunciation of all special rights to protect Christians in the Ottoman Empire.

Turkey, possessor of the field, carried a Balkan policy of massacre and torture; a massacre of Christians in Syria occurred in 1860, an insurrection in Crete followed, and finally in 1875 an insurrection broke out in Herzegovina. Russia had strongly protested against this policy, that of Catherine II, to expel the Turks from Europe, but England was split by two parties, that of Gladstone which favored the liberation of the Balkan nations, and that of Lord Beaconsfield which sanctioned Turkish policy. In 1876 the clash came. Serbia and Montenegro arose against Turkey on behalf of oppressed Serbians in Bosnia-Herzegovina. The sympathy of Europe was won for the valiant Balkan fighters. Tennyson in England idealized the Montenegrins as a nation of "warriors beating back the swarm of Turkish Islam for 500 years." Gladstone said: "The Balkans for the Balkan peoples." This was answered later on in Turkey by: "Turkey for the Turks." In 1877-78 Russia carried the cause of the Balkan nations further by marching her army to the very walls of Constantinople and dealing a defeat to Turkey. The Russian forces now sat down with the representatives of the Sublime Porte and dictated the Peace of San Stefano (3 March 1878), by which was declared the complete independence of Serbia, Rumania and Montenegro. Bosnia and Herzegovina were left to the European powers for future decision, yet Austria being the contiguous power was recognized to have a predominating voice in the disposal of the latter. Bulgaria was made an "autonomous principality," which extended from the Black Sea to the Albanian Mountains, and from the Danube to the Aegean.

Thus appeared the complexion of Balkan politics on the eve of the Congress of Berlin (13 July 1878). At this Congress Russia and Austria did not enter with free hands, for previously each had made a secret treaty with the other (at Reichstadt, 8 July 1876) whereby
for Austria's lack of participation in Russia's Turkish imbroglio Russia granted Austria the ultimate disposal of Bosnia and Herzegovina. By the Treaty of Berlin Serbia gained four districts, Nish, Vranje, Pirot and Toplita. Montenegro was to receive compensation in lands, accession to the sea and complete independence. Bosnia and Herzegovina fell as spoil to Austria, according to article 25, of the "honest broker's stipulation." Austria justified this stipulation by the need of making peace in that territory. Serbia, not knowing of Austria's secret understanding with Russia, naturally resented the disposal of Bosnia and Herzegovina. A new insurgency broke out in Bosnia (Hadjii-Loja), and Bismarck was known to have exclaimed that all the Balkans were not worth the bones of a single Pomeranian grenadier.

The Treaty of Berlin, the Magna Charta of the Near East, did not by any means succeed in securing the peace of the Balkan states. Almost without exception each signatory power violated some provision of this solemn international agreement. The British of new Cyprus, the third largest island in the Mediterranean, Austria-Hungary annexed Bosnia-Herzegovina, Russia closed and fortified Batum, and Turkey did not introduce promised reforms into Armenia and Macedonia. Even the Balkan states themselves were guilty of violating the treaty, for Bulgaria annexed eastern Roumelia, and Serbia, jealous at seeing the Balkan equilibrium upset, declared war upon Bulgaria, 14 Nov. 1885. Yet the war, lost by Serbia to Bulgaria, brought no issue other than status quo ante-bellum, which gave prominence to the alliances existent at that time, of Austria with Serbia, and Russia with Bulgaria—alliances which within the next generation were to be completely reversed.

In Turkey political events following the Congress of Berlin were coincident with the reign of Sultan Abdul-Hamid II, who centralized his government to a great extent. Pan-Islamism ran apace with Pan-Cermanism and Pan-Slavism. An alliance was cemented between the sultan and Germany, which was anxious to hold and control the Bagdad Railway (1902). In fact even from 1888 this pact had been growing, while Great Britain since 1872 had been approximately disinterested in Turkish interests, no longer needing the latter as a foil to Russian aggrandizement in the Middle East. Disturbed by the German advance in the East, however, she came to a rapprochement with Russia in 1907, opposing bitterly Germany's aspirations toward the Persian Gulf. More perilous to European peace, however, than any of these issues was the perennial unrest in Macedonia, which threatened again to open up the whole Eastern Question. The situation was due to the intertwining struggle of the rival Balkan nationalities: Serbian, Greek and Bulgarian, which aimed at securing the right to reversion of territories not yet derelict. But behind these lesser struggles lay the eternal struggle of the Triple Entente (France, Russia, England) and the Triple Alliance (Germany, Austria and Italy). Beyond the European powers the unknown forces of the Mohammedan world were also ominously stirring. The very vastness of the perils involved in any attempt at a definite settlement compelled the powers to accept a compromise which, it was hoped, would hold the wretched peoples in the wretched countries. But the "Mürzsteg programme," concert between the Austrian and Russian emperors, and imposed upon the Porte by diplomatic pressure did not produce the effect hoped for. In 1908 the powers were still united in bringing pressure to bear on Turkey to make the reforms effective, but the proposal of Great Britain to commit the administration of Macedonia to a Mussulman governor appointed by the Sultan and removable only by consent of the powers, met with little favor either at Constantinople or among the powers whose ulterior aims might have been hampered by this arrangement.

Such was the condition of affairs when in 1908 the revolution in Turkey altered the whole situation. The easy and apparently complete victory of the Young Turks took the whole world by surprise. The question of the Near East seemed in fair way of settlement by the action of the conflicting races themselves, who in the face of their defeat appeared ready to forget their ancient inter民族 feuds and to fraternize on the common ground of constitutional liberty. The European powers received the proclamation of the constitution with unanimous approval. Whatever views, however, may have been openly expressed, or secretly held, as to this revolution so far as it affected the Ottoman Empire itself, there could be no doubt that its effects on the general situation in Europe would be profound. These developments were not slow in revealing themselves: Prince Ferdinand proclaimed himself king (tsar) of Bulgaria 5 Oct. 1908; and two days later Emperor Francis Joseph issued a rescript announcing the annexation of Bosnia-Herzegovina to the Hapsburg monarchy. Whatever cogent reasons there may have been for altering the status of these countries in view of the changed conditions in Turkey, there could be no doubt that the method employed was a cynical violation of the public law of Europe. The other powers, confronted with the fait accompli, protested, but the astute statesman, Baron von Aehrenthal, then Foreign Minister of the Dual Monarchy, gauged his opposition with Napoleon's dictum: "Providence is with the big bat," and was bent on making the best of an impossible situation. He was quick to grasp this truth, and they temporarily reconciled themselves with circumstances. They realized that it was the immense armed power of Germany that had made Austria the arbiter in a question vitally affecting the interests of the Balkan states. Germany alone emerged from the crisis with prestige enormously enhanced; without her intervention Austria could not have resisted the pressure of the powers.

But Germany being on the side of Austria earned the animosity of the Triple Entente, especially Russia, which urged the Balkan states to form a confederation. Such a confederation should expel the Turks from Europe and, in the other three, be a rival to the Triple Alliance drive eastward. The alliance between the Balkan states, Serbia, Bulgaria, Greece and Montenegro, was consummated (1912). Turkey, entangled with Italy in Africa, was not able to meet the demands of the Balkan Allies whose forces marched victoriously on to Constanti-
nople. Austria and Germany, calling a halt, insisted on the London Conference (1913), a conference which gave quasi-autonomy to Albania and put a German vassal selected by the powers upon the Albanian throne. Serbia, viewing herself bereft of Albania and the Adriatic coast, while all of Thrace remained in the hands of the Bulgarians, swallowed her resentment for the moment and continued to place confidence in her Greek alliance to the extent of making a new treaty in May 1913. But Bulgaria, secretly prompted by Austria, suddenly attacked Serbia, which was backed by Russia and the active participation of Rumania. The Peace of Bucharest (10 Aug. 1913), concluding the second Balkan war, tried to solve the intimate jealousies and antagonisms by giving Serbia a part of Macedonia, allowing Salonika to Greece, and satisfying Rumania with added territory in Dobrudja. As a matter of fact the Balkan nationalities are never allowed to work out their own destinies; some superior power is the King of the Dance. The event which precipitated the Great War of 1914 was the Sarajevo assassination and Austria immediately used it as a casus belli against Serbia. The partial refusal of the Serbian ultimatum by Serbia caused the war on 28 July, although it has not been proved that Franz Ferdinand’s death served Serbian or general Southern Slav ambition at that time.

The entrance into Balkan lands, occurring in August 1914, and the second invasion of northern Serbia in November 1914, marked the defeat of Austrian arms, with Belgrade taken and retaken. Only in November 1915 did Austria and Germany, reinforced by Bulgaria’s entry into the war, succeed in bringing about the general retreat of the Serbians through Albania. The arrival of the French and the British in the peninsula which had already begun in August was unable to forestall the fate of their retreating allies, the Serbs and Montenegrins. It was, in fact, the attitude of Greece which paralyzed any forward military moves of the Allies. Venizelos, the Greek Premier, realizing the necessity of allied advance, invited the protection of Greece by the Entente. Allied Powers, but the King insisted that the Great Powers were violating Greek neutrality by their presence in that territory. The Greek treaty with Serbia for mutual protection was now fainly read by Greece to mean “protection against Balkan powers” instead of being construed in its general sense, protection against any power. Nevertheless, a partial recuperation in Serbia saw the beginning of Balkan military activity again in 1916–17. Once more Greece proved obdurate. Resignation of the king appeared the only course to be countenanced, and on 12 June 1917, this event was forced by the Entente Allies.

University of California.

EASTERN RITE. Churches of a name given to various bodies of Eastern Christians who are members of the Roman Catholic Church but who have been permitted to retain many of their ancient customs, which differ from those in general use throughout the world. The Armenians, Coptic, Greek, Maronites and some others belong to the Eastern Rite. They differ from the Latin Church in nothing doctrinal, only in some matters of discipline. Their liturgy is in the language first used by their bishops and priests, and in no case is the mass said in their vernacular of to-day. For instance, the Syrians use now the Arabic language (in some places modified) but the Maronite liturgy is in the old Syriac language, as used at the time of Christ. (See MARONITES). They differ as to the manner of administering communion; some using for consecration only the leavened bread, others only the unleavened, and some giving communion to the laity under the form of both bread and wine, others using only one of the species as in churches of the Latin Rite. The discipline of marriage for the clergy differs from the Latin Church. Candidates for the priesthood may marry before becoming deacons, not after. All points of difference between the Eastern and Latin Rites are of discipline, not of faith.

EASTERN SHORE, a name given to all that part of Maryland lying east of Chesapeake Bay, and also the counties of Accomac and Northampton in Virginia. Delaware is sometimes included in the Eastern Shore. The country is noted for its fruit and for its mild climate. Great quantities of oysters are taken annually from the waters of the Eastern Shore lands.

EASTERN STAR, Order of the, composed of members of Freemasonry, their wives, sisters, daughters, mothers and widows, may justly be termed a monster fraternity. The membership in 1916 was about 800,000, with a trifle over 8,000 chapters, an estimated gain of about 50,000 a year. In addition to the United States, there are chapters in Alaska,
Canal Zone, Cuba, Hawaiian Islands, Philippines, Manitoba, New Brunswick, Quebec, Ontario, New Zealand, Australia, Scotland, and England. The Order is rapidly extending to all parts of the globe. The largest chapter is Peninsular of Grand Rapids, Mich., with 1,073 members. Illinois has the largest membership, viz., 87,000 with nearly 300 chapters. New York has 60,000, with a little over 500 chapters and all other States have a proportionate membership. Miriam Chapter of Chicago, Ill., the oldest chapter known, was organized as Miriam Family No. 116 6; 1866, and emerged into a chapter 4 March 1869. New York city, however, has the honor of the birth of the chapter system, Alpha Chapter No. 1 beginning 28 Dec. 1868. Masonic histories state that the Order was introduced into the colonies in New York city in 1776 by, it is supposed, French officers. In the system of 1774 (France) was an emblem of a five-pointed star, presumably copied from the Masonic emblem called the Blazing Star. From an old ritual, it is evident that certain members on 18 May 1773, Boston, Mass., met and formulated a ritual. This work also states Lafayette was interested in the Order. In 1850 Rob Morris, a prominent Masonic lecturer, arranged the degree, calling the bodies constellations. Later he changed the system to families, and still later (1866) the lecture system was adopted. In 1868 Robert Macoy, a Masonic publisher, arranged the chapter system, at the suggestion of certain female members of a society known as "Alpha Sisters of the Eastern Star," with the first meeting as before stated (Alpha No. 1, 28 Dec. 1868). To show how the Order has gained in the Empire State, in 1880 there were 29 chapters, 1,367 members; in 1900, 41 chapters, 2,448 members, and in 1910, 438 chapters and 38,774 members. In New York State the Order has a home and an infirmary for indigent and sick members, with a hundred thousand dollars as a reserve fund to maintain these institutions.

The Grand Chapters of 23 States are jointly interested in the Masonic bodies in the maintenance of homes, and every State has its auxiliaries of societies engaged in some special line of charity. The object of the Eastern Star is principally social and about on the same lines with the Odd Fellows. It is a secret order; the degrees are imparted with great care; all modern devices are introduced to make the same attractive and effective.

**EASTERN STATES**, in popular parlance, the six New England States—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut; in the Mississippi Valley and in the States to the west of it the inhabitants refer to the Eastern States as that section lying east of the Allegheny Mountains.

**EASTHAMPTON**, Mass., town in Hampshire County, on the New York, New Haven and Hartford and the Boston and Maine railroads, 12 miles northwest of Springfield and in the Valley of the Connecticut. The chief manufactures are cotton goods, yarns, button, shoe, felt, rubber and elastic goods. There is a large dyeing and mercerizing plant and a public library. Williston Seminary, a preparatory school for boys, is located here. Easthampton was settled in 1665, and on 13 May 1704 an Indian attack upon the settlement resulted in 19 killed and much loss of property. It was incorporated 1793 and was organized as a town in 1809. The government is administered by annual town meetings. The waterworks are owned and operated by the municipality. Three villages are included in the town of Easthampton. Pop. 9,768.

**EASTLAKE, SIR CHARLES LOCKE**, English artist; b. Plymouth, 17 Nov. 1793; d. Pisa, Italy, 23 Dec. 1865. He entered the schools of the Royal Academy, where Haydon supervised his education. In 1810 his "Raising of Jairus' Daughter" brought him to the attention of the public. In 1816 he went to Italy, and for 14 years his home was at Rome, his Italian life being broken by visits to England and Greece. Pictures of banditti and other subjects exhibited in England procured him the associateship of the Academy in 1827. "Pilgrims Arriving in Sight of Rome" (1828) became so popular that the artist became tired of repeating it in different versions. In 1830 he made an R.A., his diploma picture being "Hagar and Ishmael," "Escape of Francesco Carrara" (1834); "Gast on de Foix" (1838); "Christ Blessing Little Children" (1839), and "Christ Weeping Over Jerusalem" (1841), were next among noteworthy productions. "Helen" (1849); "Ippolita Torelli" (1851); "Violante" (1853), may also be mentioned. He translated Goethe's "Theory of Colors" (1840) and published in 1847 "Materials for a History of Oil Painting." He became president of the Royal Academy in 1839, being knighted on the occasion; was keeper of the National Gallery in 1843-47, and director of the same institution from 1855 onward. His "Life" was written by Lady Eastlake (London 1879).

**EASTLAKE, CHARLES LOCKE**, English art critic; b. Plymouth, England. He studied in the Royal Academy schools, but subsequently devoted himself to literary work and design, and was keeper and secretary of the National Gallery 1875-93. He has published "History of the Gothic Revival" (1871); "Hints on Household Taste" (4th ed., 1874), a book which exerted much influence in its day; "Lectures on Decorative Art Workmanship" (1876); "The Present Condition of Industrial Art" (1877); "Our Square and Circle" (1893); "Pictures at the National Gallery" (1898).

**EASTLAKE, LADY ELIZABETH (Rigby)**, English author; b. Norwich 1809; d. 1893. For some years she resided in Germany and at Reval, Russia. Her first book appeared in 1841; it was an account of her sojourn at Reval, entitled "A Residence on the Shores of the Baltic." Through a meeting with Lockhart she became a regular contributor to the "Quarterly Review." In 1848 she married Sir Charles Lock Eastlake, and with him traveled extensively in Italy. In 1848, in the columns of the "Quarterly" she attacked Bronte's "Jane Eyre," the episode being one of the least pleasant of her literary career. She was the author of "Text Jewels" (1843); "Livonian Tales" (1844); "Music and the Art of Dress" (1852); "Life of John Gibson, R.A. Sculptor" (1870); "Life of Mrs. Grote" (1880); "Five Great Painters" (2 vols., 1883). She edited her husband's works (1870) and the edition of Kugler's "Handbook of Painting."
Italian Schools) (1874), and translated Brand's 'Samuel Taylor Coleridge and the English Romantic School' (1886), and Waagen's 'Treasures of Art in Great Britain' (4 vols. 1854-55).

EASTMAN, Charles Alexander (Obiyesa), American homeopathic physician and author: b. Redwood Falls, Minn., 1858. His father was a Santee-Sioux Indian, Many Lightnings (Jacob Eastman), and his mother a half-breed Sioux, NAME (Estate). He was graduated at Dartmouth College in 1887 and at Boston University School of Medicine 1890. He married the poetess, Elaine Goodale, 1891. He served as government physician at Pine Ridge Agency 1890-93, where he had charge of the wounded prisoners at the time of the Ghost Dance Outbreak, being Indian secretary of the Y. M. C. A. 1894-97. He acted as attorney for the Santee-Sioux at Washington 1897-1900, later becoming government physician at Crow Creek, S. Dak. (1900-03). In 1903 he received an invitation to become a professor in the Provincetown School; he became widely known as a lecturer on Indian history and life. He has published 'Indian Boyhood' (1901); 'Red Hunters and the Animal People' (1904); 'Old Indian Days' (1907); 'Minigum, Evening's Story' (1909); 'The Soul of the Indian' (1911); 'Indian Scout Talks' (1914); 'The Indian Today' (1915). Founder and director of a camp for girls at Munsonville, N. H., 1915.

EASTMAN, Charles Rochester, American paleontologist: b. Cedar Rapids, Iowa, 5 June 1868; d. 27 Sept. 1918. He was graduated at Harvard 1890; received the degree of Ph.D. from Munich University in 1894; was appointed the same year instructor in geology and paleontology at Harvard and Radcliffe colleges, and became curator of vertebrate paleontology at the Harvard museum. In 1910 he was made professor of paleontology at the University of Pittsburgh, and at the same time curator at the Carnegie museum in that city. In 1914 he accepted a similar position at the American Museum of Natural History, New York, where he is also curator of the vertebrates. He is author, editor, and translator of numerous scientific publications.

EASTMAN, George, American inventor: b. Waterville, Oneida County, N. Y., 12 July 1854. As an amateur photographer in Rochester, N. Y., he turned his attention to the production of dry plates, which achieved an instantaneous success. In 1881 the Eastman Dry Plate Company was organized, which developed later into the Eastman Kodak Company. Eastman companies have also been established in London, Paris, Berlin and elsewhere, and the business has now reached vast proportions. The various companies under his management employ upwards of 11,000 hands and over $40,000,000 of capital.

EASTMAN, John Robie, American astronomer: b. Andover, N. H., 29 July 1836; d. 26 Sept. 1913. He was graduated at Dartmouth College in 1858 and became assistant in the United States Naval Observatory. In 1865 he was appointed professor of mathematics in the navy. Retired in 1898 with the rank of captain, he was in 1906 promoted rear-admiral. He was a member of several astronomical expeditions in the United States and accompanied one to Sicily in 1870. He conducted a party to Cedar Keys, Fla., to observe the transit of Venus and subsequently became president of the Washington Academy of Sciences. His works include, besides many reports, 'Second Washington Catalogue' (covering the results of about 80,000 observations made between 1866 and 1891); 'Transit Circle Observations of the Sun, Moon, Planets and Comets' (1903), and a 'History of the Town of Andover, N. H.' 1914-1920.

EASTMAN, Max, American editor and lecturer: b. Canandaigua, N. Y., 4 Jan. 1883. He was graduated at Williams College in 1905, and then pursued a post-graduate course at Columbia University (1907-10), during which time he was also assistant in philosophy. In 1911 he was associate professor at Columbia, but abandoned teaching for literary and social reform work after that year. Mr. Eastman, as editor of The Masses, has been prominently connected with the Socialist party. He is also active as a lecturer and as a promoter and writer on the progressive democratic movement. The publication of The Masses was suppressed in 1918, the company with Mr. Eastman at its head was reorganized for the publication of The Liberator. He is also the founder of the first Men's League for Women Suffrage in the United States (1910-12). Besides contributions to his own and numerous other magazines, Mr. Eastman is the author of 'Child of the Amazons and Other Poems' (1913); 'Enjoyment of Poetry' (1913); 'Journalism Versus Art' (1916); 'Understanding Germany, and Other Essays' (1916).

EASTMAN, Seth, American soldier: b. Brunswick, Me., 1808; d. 1875. He was graduated at the United States Military Academy in 1829 and became a lieutenant in the First Infantry. He performed frontier duty at forts Crawford (1829) and Snelling (1830), and in 1831-33 was on topographical duty. From 1833 to 1840 he was assistant instructor in drawing at the Military Academy. He served in the Bureau of Indian Affairs in 1850-57 as illustrator of 'The History, Condition and Future Prospects of the Indian Tribes of the United States.' In 1861 he was made a lieutenant-colonel of infantry, was retired two years later and brevetted brigadier-general in 1866. He published 'Treatise on Topographical Drawing' (1837).

EASTON, Morton William, American philologist: b. Hartford, Conn., 18 Aug. 1841. He was graduated at Yale in 1863 and at Columbia in 1866, and afterward studied at the University of Vienna. He was for several years professor of comparative philology in the University of Tennessee and later (1882-1912) in the University of Pennsylvania. He was professor emeritus since 1912. His writings include 'Observations on the Platform of Persepolis' (1892); 'Readings in Gower' (1895), and numerous papers on Phonetics, Sanskrit, Iranian and English to The Journal of the American Oriental Society, The American Journal of Philology and other periodicals.

EASTON, Nicholas, American colonial statesman: b. Wales 1593; d. Newport, R. I., 15 Aug. 1675. Emigrating to America in 1634, he was the first settler in Agawam, now Newbury, Mass., 1635. He built the first English
house in Hampton, N. H., 1638, and the first one on the site of Newport, R. I., 1639, and was elected president of Providence Plantations 1649 and 1654. He was deputy governor of Rhode Island for four years, and governor 1672-75. His son, John Easton, was governor 1690-95, and wrote a 'Narrative of the Causes which led to King Philip's War,' edited by F. B. Hough (Albany 1858).

**EASTON, Mass.** A town in Bristol County, on the New York, New Haven and Hartford Railroad, about 25 miles south of Boston. The town includes several villages and has important manufactures of shovels, thread, foundry and machine-shop products, hardware, automobiles, shoes, shoe heels and wire. It has a public library and some fine public buildings, gifts of the Ames family, showing some of the best work of H. H. Richardson and John Lafarge. Pop. 5,063.

**EASTON, Md., town and the county-seat of Talbot County, on the Philadelphia, Baltimore and Washington and the Baltimore, Chesapeake and Atlantic railways, about 28 miles southeast of Annapolis, 50 miles south-south-east of Baltimore, near a navigable inlet of Chesapeake Bay. It is the seat of a Protestant Episcopal bishop and has a fine county building, high school, churches, etc. It is the market centre for a rich grain and fruit-growing country. The manufactures are chiefly iron machinery, fertilizers, carriages, wagons, handles and spokes, lumber, bricks and tile, flour, canned fruits, furniture and short wool. It is connected with Baltimore by steamship lines. Easton is governed by a mayor and council. The waterworks, electric-light plant and sewage system are owned by the city. Pop. 3,083.

**EASTON, Pa., city, county-seat of Northampton County, situated at the extreme eastern part of the State, on the banks of the Delaware River, at its confluence with the Lehigh River and the Bushkill Creek, 74 miles west of New York and 65 miles north of Philadelphia, scarcely two hours distant by rail from each city.**

**Railroads and Canals.**—Through Easton pass the two great trunk lines, Lehigh Valley and the Central Railroad of New Jersey, and the smaller local roads, Lehigh and New England, Easton and Northern, Easton and Western and the Bangor and Portland railroads. Immediately across the Delaware River from Easton is located the thriving city of Philadephia, population about 18,000. Through this town run the Belvidere and Delaware division of the Pennsylvania Railroad, and the Lehigh and Hudson Railroad, which make direct connections with the Hudson River Valley and the New England States, also the Delaware, Lackawanna and Western Railroad. Seventy-seven passenger trains arrive and depart from Easton daily and 159 freight trains. There are two canals, Morris and Essex from Philadephia, N. J., to New York, traversing the entire State of New Jersey, and Lehigh Canal, offering direct communication from the anthracite coal regions to Philadelphia and its tide water points, connecting at Lambertville with the Delaware and Raritan Canal. The Atlantic Deep Waterway Commission of the United States is dredging the channel of the Delaware River from Tren-

ton to Easton, so that ocean-going barges of 1,000 tons capacity can load and unload at Easton and ultimately at Martin's Creek and Bethlehem.

**Electrical Roads.**—The Easton Transit Company has a splendid suburban system reaching all local points and interurban lines out to Alpha, N. J., where large cement works are located, and to Bethlehem, South Bethlehem and Nazareth. These lines make direct connections with all points in the Lehigh Valley and at Allentown for Philadelphia. Another system, the Philadelphia and Easton, extends from Easton to Philadelphia, via Doylestown and Willow Grove, traversing the right bank of the Delaware River for 15 or 18 miles and affording scenery unsurpassed by any trolley road in the United States. Two other roads, the Northampton Traction Company and the Northampton, Easton and Washington Traction Company (familiarly known as the Hay Lines), extend both in Pennsylvania and New Jersey from Easton. The first named extends from Easton to Nazareth, the centre of the cement belt of the United States, and to Bangor, the centre of the slate producing region of this country, thence to the Delaware Water Gap and Stroudsburg, reaching the very heart of the Pocono Mountains, the famous mountain resort of the Eastern States. The Jersey road, called the Northampton-Easton and Washington, extends from Philadelphia due east through the Musconetcong Valley almost to Hackettstown, through the important points, New Village and Washington. It is intended in the near future to connect this line with Lake Hopatcong. When finished it will be possible for passengers starting anywhere in the Lehigh Valley to proceed by trolley, all the way to New York, Boston and far off Maine, and from Philadelphia to the Pocono Mountains.

**Climate and Surroundings.**—The climate of Easton is particularly good. The great Blue Mountain Range shuts off the harsh winter winds which have so sorely injured other places. The summers are fine. The rivers offer bathing and boating for its young people. The rivers cutting through the mountain chains give it a scenic setting not surpassed by any city in this broad land. The soil immediately surrounding Easton is wonderfully fertile and Northampton, of which Easton is the county seat, is far famed for the wealth of the farms' resources of its soil.

**Manufactures.**—The industries are wonderfully varied and Easton is signallly fortunate in the character of its labor. At least 60 per cent of its men wage earners own their homes. This gives Easton a class of skilled men and fine citizens, foremost in every good work and public cause. The factories make almost everything from pig iron and steel castings and machines down to delicate silk underwear, hosierly, silks and small articles of every day use. Among the industries and their products are IngersollRand Company, machine tools, sewing machines, electric typewriters, drills, etc., Taylor Wharton Iron & Steel Co., steam railroad and electrical supplies, frogs, switches, special work, etc., Treadwell Engineering Company, steel casings, mining machinery, separators, etc., Victor Balata Textile and Belting Company, machinery belts. The silk industry is very large. Over 5,000 operators
work in the silk mills of Easton and Phillipsburg, making broad silks, velvets and ribbons. C. K. Williams Company, ground paints and ground stone; General Crushed Stone Company, crushed stone among the largest in the United States. Many flour mills. Charles Chipman Sons, hosiery; a very large concern; H. Lehr & Company, pianos; Lehman Brothers, silk and cotton underwear for ladies. Kinek Cordage Company, hemp and manila. Smith, pencils and crayons, one of the largest in the world; Easton Finishing Company, carton finishers; American Flag Company, flags and bunting; Fitzgerald, Speer & Company, doors and sash; American Horse Shoe Works, horseshoes; Canister Company, making cans and packages for grown products; General Chemical Company (Baker & Adamson Branch), and J. T. Baker Chemical Company, general chemicals and acids; Tippett & Wood, stand pipes and reservoirs. The repair shops of the Lehigh Valley employing about 750 men. North Ore Company have one pig iron furnace within a mile and a half of Easton. The Kuebler Foundries, malleable, cast iron and general iron works and the Easton Brass and Finishing Works. Within a radius of 10 miles there are about 50,000 people and a very large output. There are numerous other industries of various kinds, all uniting to make Easton a great manufacturing centre.

Business Conditions and Stores.—Easton is a natural trading centre for a large surrounding rural and wholesale. Over 200 commercial travelers leave Easton every Monday morning representing the large wholesale grocers, produce, dry-goods, boot and shoe, hardware, stoves, confectionery and other local houses. There are three large department stores, selling not only to Easton people, but the surrounding country about 40 miles north and south; 30 miles to the east and 12 miles to the west, with an aggregate business of $2,500,000 per annum. The art, jewelry, drug, piano, phonograph stores, clothing, confectionery, books, millinery and other trades are important.

Banks and Trust Companies.—Easton has three national banks and two trust companies, and Phillipsburg, N. J. (across the river), has two trust companies. Phillipsburg, N. J., and Easton, divided by an arbitrary and imaginary State line and the Delaware River, are to all intents and purposes one commercial community. Many doing business in Phillipsburg reside in Easton, and vice-versa. The combined capital of the banks and trust companies is $1,550,000; the combined surplus and undivided profits are $1,786,917; the combined deposits of these banks and trust companies are over $18,000,000. One of these banks, the Easton National, celebrated its 100th anniversary a year ago, still retaining its old name "Easton," it being originally a State bank.

Colleges and Schools.—Easton is the seat of Lafayette College founded and named after the Marquis de Lafayette at the time of his second visit to America. It has a national reputation; over 700 students enrolled, with numerous and well-equipped departments in every branch of science and literature. Easton is the birthplace of Governor Wolfe, long deceased, founder of the public school system in Pennsylvania, and father of the public school system in the United States. A beautiful memorial arch in front of the high school building commemorates this fact. The public schools are unsurpassed and Easton has a number of private, preparatory and parochial schools and is a noted centre of learning, culture and education with a splendid public library and by local taxation, an original Carnegie foundation.

Newspapers and Magazines.—There are two daily, old and largely circulated newspapers; all evening papers published every day except the Sabbath; each of these papers has a semi-weekly and weekly edition; one Sunday paper called the Sunday Call, of large circulation and great importance, with a weekly edition, the Easton Sentinel; a German paper, the Northampton Democrat; a number of trade journals issued semi-monthly and monthly, particularly the Easton Labor Journal, Chemical Journal, Lafayette College Weekly, Lafayette College Monthly and a number of periodicals of special trades.

Churches and Clubs.—Easton and Phillipsburg being one community interchange their church people, and with a combined population of about 50,000 have the following churches: Lutheran 11, Presbyterian 9, Reformed 5, Methodist Episcopal 6, Protestant Episcopal 2, Moravian 1, Baptist 30, Catholic 4, Christian Science 1, Jewish synagogues 2, Mennonite 1, Salvation Army 1 barrack, Italian Missions 2. The services in these churches are held in English, German, Italian, Hebrew and Slovak, indicating the diversity of the nationalities of the worshipers. The religious and charitable element of Easton have a second hospital which they are about to rebuild at a cost of $250,000. Also a Y. M. C. A. and Y. W. C. A., old ladies' hospital and a home for friendless and orphan children and a charity organization society. Fraternal orders and societies are numerous and strong and Easton has a number of social clubs; the Pomfret Club, the Northampton Country Club; the McKinley Club, the Northampton Republican and Jacksonian Democratic Clubs, all owning their own homes; the Triakas Club, and numerous others. The club and social life in Easton is ideal, pleasant and extensive.

History.—Easton is an old "Penn" town. It was an original concession and trading place of the early settlers with the aborigines. In 1739 David Martin built his ferry house at the foot of the present Ferry street to convey passengers across the Delaware River. The entire site of the town was then covered with forests and bushes. The only signs of life were the few settlers, white men, and their neighbors, the Indians. The Delaware and Lehigh rivers were the channels of transportation for the Indians in their canoes. It was the garden spot of the Lenape and Delaware Indians. The landing point for their canoes was a long sandy place at the junctions of the Delaware and Lehigh rivers and still retains its name "The Point." The Delaware and Lehigh rivers were filled with sand in running season. The Indians caught them by the thousands. On the peninsula formed by the Bushkill and Lehigh rivers with the Delaware, William Parsons, the surveyor general of Pennsylvania and the father of the "Pens," located the present city of Easton. In 1752 it was formally laid out, with wide streets, north and south, east and west and
as in all 'Penn' towns, with a small square or public commons, now 'Centre Square,' in the centre of the small level area which the new town afforded, hemmed in then as now by great hills. In 1789 it was chartered as a borough. Easton was always the banking and trading centre of a large section. As far north as New York and Canada its venturesome traders and merchants sold their goods and as far west as the Susquehanna and Ohio rivers. It has not lost any of its commercial and trading institutions; it is still essentially a trading town. In the last few years only Easton has awakened to full conception of its wonderful advantages and possibilities, and has become a great railroad and great manufacturing centre. In 1897 it was chartered as a city. Since 1913 it has been administered under a commission form of government. Electrically lighted streets are well paved with brick, asphalt and amesite, and a salaried fire department and efficient police force afford ample protection. Pop. (1900) 25,238; (1910) 28,523; (1918) est. 35,000.

THOMAS A. H. HAY, Secretary Easton Board of Trade.

EASTPORT, Me., city and port of entry in Washington County, on Moose Island, in Passamaquoddy Bay, and on the Maine Central Railway, 190 miles east-northeast of Portland. A bridge crosses the narrow channel to the mainland. It is the northeastern city of the United States, and has a fine harbor, which on account of its high tide, 25 feet, is clear of ice all the year, and has daily steamship service with Boston, Calais and Portland. Eastport and the island of Campobello, on the opposite side of the harbor, are popular summer resorts. The city has extensive fishing and shipbuilding interests, and is the centre of the American sardine-canning industry, with 20 factories. It also manufactures shoes, box books, etc. It has a custom-house, public library, the Boynton high school, churches, national and savings banks, weekly newspapers, and is lighted by electricity. Eastport was settled about 1782. The islands in Passamaquoddy Bay were long under dispute and claimed by Great Britain. The town was captured by an English force 11 July 1814 and held under strict martial law until 30 June 1818. Its trade was severely crippled by the Embargo Act, and the town was for several years, especially during 1807-18, notorious as a smuggling centre. The government is administered under a charter of 1893, by a mayor, elected annually, and a board of aldermen. Consult Kilby, 'Eastport and Passamaquoddy' (Eastport 1888). Pop. 5,000.

EASTWARD HO! a comedy written by Marston, Chapman and Johnson, and produced in the season of 1604-05. It is best known for its satire on the Scotch, which caused the imprisonment of its authors.

EASTWICK, Edward Backhouse, English Orator. He was born at Macclesfield, Cheshire, 13 March 1814; d. Ventnor, Isle of Wight, 16 July 1883. After studying at Merton College, Oxford, he became professor of Hindustani at the college at Haileybury and assistant political secretary in the India office in 1858-59. He served as secretary of legation in Persia (1860-63); commissioner for the Venezuelan Loan venture, and as private secretary to Lord Cranborne, Secretary of State for India. He was a voluminous writer on Oriental (especially East Indian) subjects, and rendered very important service to English literature by translating Persian and Hindu, for example: Sadi's 'Gulistan' or 'The Rose Garden' (1852); and the version of Pilpay's fables called 'Anvar-i-Suhailli' (1854). He also wrote a 'Journal of a Diplomat's Three Years' Residence in Persia' (1864); and 'Venezuela,' or the Commercial and Trading Institution of the Republic of America' (1868). Between 1878 and 1882 he brought out a sumptuous edition of the 'Kai-sar-nama-i-hind,' or 'Lay of the Empress.' He was a frequent contributor to literary journals.

EATON, Amos, American scientist: b. Chatham, N. Y., 1776; d. 1842. He was graduated at Williams College 1799; settled in Catskill, N. Y.; practised law, and engaged in civil engineering, while prosecuting studies in chemistry, geology and mineralogy. He made a survey of Albany and Rensselaer counties 1820, and later of the Erie Canal region. In 1824 he became senior professor of the Rensselaer School of Science in Troy, subsequently the Rensselaer Polytechnic Institute. Among his works are 'An Index to the Geology of the Northern States' (1818); 'A Manual of Botany of North America' (1833); and 'Geological Note-Book' (1841).

EATON, Arthur Wentworth Hamilton, American clergyman and author: b. Kentville, Nova Scotia, 1839. He was graduated from Harvard in 1860, entered the university of the Protestant Episcopal Church, and served at Chestnut Hill, Mass., 1885-86. He then settled in New York, where he taught literature, wrote and preached. Since 1907 has lived in Boston. He is the author of many books: 'The Heart of the Creeds; Historical Religion in the Light of Modern Thought' (1888); 'Acadian Legends and Lyrics' (1889); 'The Church of England in Nova Scotia and the Tory Clergy of the Revolution' (1891); 'Tales of a Garrison Town' (with C. L. Betts, 1892); 'Acadian Ballads' (1905); 'Poems of the Christian Year' (1905); 'The Lotus of the Nile and Other Poems' (1907); 'The History of King's County, Nova Scotia, Heart of the Acadian Land' (1910); 'The Famous Mather Byles' (1914). Also various books compiled and edited (1890-1901); and many historical and biographical monographs (1885-1917). Degrees: B.A. Harvard 1860; M.A. Dalhousie (Halifax) 1904; D.C.L. King's (Windsor, Nova Scotia) 1905.

EATON, Charles Warren, American artist: b. Albany, N. Y., 22 Feb. 1857. He studied at the National Academy of Design, and the Art Students' League, New York and in London; and is a member of the American Water Color Society, New York. He exhibited at the Paris Exposition 1900; the Pan-American Exposition 1901. He received the Pullman prize 1902, the Blinnness prize 1902 and Shaw prize 1903 at the Salmagundi Exhibition. He received a silver medal at the Saint Louis Exposition in 1904. Among his landscapes are 'The Forest'; 'The October Tints'; and 'Connecticut Pines.' 'Gray Dunes' and 'Forest Lane' (1911); 'The Valley of Sunset' (1912) and 'Gathering Mists' (1913).
EATON, Dorman Bridgman, American lawyer: b. Hardwick, Vt., 27 June 1823; d. New York, 24 Dec. 1891. He was graduated at the University of Vermont in 1843 and at Harvard Law School in 1850; was admitted to the New York bar; and later became widely known by his advocacy of civil service reform. In 1883 he was appointed a commissioner of the United States Civil Service Commission, resigning in July 1885. He was reappointed in November of the same year, but again resigned in April 1886. In the latter year he drafted the laws which created the Metropolitan Board of Health of New York; subsequently those on which the present police courts were organized; and in 1883 the National Civil Service Act. His publications include 'The Independent Movement in New York' (1880); 'Civil Government in Great Britain' (1880); 'The Term and Tenure of Office' (1882); 'The Problem of Police Legislation' (1895); and 'The Government of Municipalities' (1899).

EATON, Edward Dwight, American educator: b. Lancaster, Wis., 12 Jan. 1851. He was graduated at Beloit College in 1872, from Yale Theological School three years later and studied also at the universities of Leipzig and Heidelberg in 1875-76. He was ordained to the Congregational ministry in 1876, was pastor at Newton, Iowa, 1876-79 and of the First Congregational Church at Oakland, Ill., from 1879 to 1886. Since 1886, with the exception of two years (1895-97) spent as pastor at Saint John's, Vt., he has been president of Beloit College. He was member of a delegation sent in 1898 to inspect Congregational missions in China. He was Southworth lecturer at Andover Theological Seminary in 1904 and Pond lecturer at the Bangor Theological Seminary in 1906. Since 1910 he has served as vice-president of the American Board of Commissioners for Foreign Missions, and since 1911 as chairman of the Wisconsin College Association.

EATON, John, American educator: b. Sutton, N. H., 5 Dec. 1829; d. Washington, D. C., 9 Feb. 1906. He was graduated at Dartmouth College in 1854, edited theology; and in 1862 became chaplain of the 27th Ohio Volunteer Infantry. Subsequently he was appointed superintendent of freedmen for Mississippi, northern Louisiana, Arkansas and west Tennessee, and remained on duty till May 1865. He was brevetted brigadier-general of volunteers in 1865. He was editor of the Memphis (Tenn.) Post in 1866-67, and State superintendent of public instruction for Tennessee (1867-69). In 1871-86 he was commissioner of the United States Bureau of Education; from 1886-91 he served as president of an Extension College in 1895 became president of Sheldon Jackson College at Salt Lake City; and in 1898 was appointed a special commissioner to arrange for the establishment of the American system of education in Porto Rico. His publications include 'History of Thetford Academy'; 'Mormons of To-day'; 'The Freedmen in the War' (report); 'Schools of Tennessee' (report); and reports of the United States Bureau of Education.

EATON, John Henry, American statesman: b. Tennessee, 1790; d. 1856. He practised law in Nashville, and was Secretary of War 1829-34, when he became governor of Florida. He was appointed Minister to Spain 1836, and published a 'Life of Andrew Jackson' (1824).

EATON, Margaret O'Neill: b. Washington, 1796; d. 1879. As the wife of Maj. J. H. Eaton, Jackson's Secretary of War, she was the subject of a social war in government circles owing to certain charges connecting her name with that of Major Eaton, while she was still a neighbor of Timberlake, her first husband. It was said that from this social disturbance arose an estrangement between General Jackson and Calhoun, leading to the nomination of Van Buren for the presidency 1816. After the death of her second husband she married a third, an Italian dancing-master, much her junior, from whom she was divorced.

EATON, Seymour, American author: b. Epping, Ont., 1859; d. Lansdowne, Pa., 13 March 1916. After seven years of district school teaching he became a resident of Boston. He started later in Philadelphia the Booklovers Library and the Tabard Inn enterprise. The feature of the Booklovers Library was a delivery system whereby subscribers received the latest literature at their homes. Branches were opened in American cities and in Europe, and the business increased until Mr. Eaton felt it necessary to organize a subsidiary system called the Tabard Inn Library, which permitted purchasers to get books at the regular retail price and to exchange any volume for another on payment of five cents. Mr. Eaton founded next the Booklovers Magazine, which made a specialty of the reproduction of famous paintings. Then drugists' specialties and food separations were taken up, and finally Tabard Inn undertook the manufacture of artistic house furnishings.Tabard Inn became a $12,000,000 corporation and sold a good deal of stock before going into the hands of a receiver in 1905. After the insurance investigation of 1906 he became Secretary of the international policyholders' committee, but resigned after a dispute with the committee's managers. For five years he was director of Drexel Institute in Chicago and for four years a daily contributor to the Chicago Record. He wrote 'The Teddy Bear: His History and How to Use Him,' 'Comedy,' 'Prince Domino and Muffles,' 'The Telepath,' 'Barzillai Brown,' 'Bachelor,' 'The Mysterious Giver,' and a series of pamphlets setting forth short cuts to business success. He was long credited with being the creator of the famous teddy bears. The fact is that the toy bearing that name was originated in Germany by Margaret Steiff, a poor woman, who became prosperous through the success of these toys and now has factories employing 5,000 persons. When first imported here the bears were not called teddy bears. That name became attached to them a year or two later, after illustrated verses by Mr. Eaton, dealing with the adventures of the 'Roosevelt Bears,' for the 'Teddy Bears' were printed in the Sunday newspapers. So apparently Mr. Eaton is to be credited with the name, but not with the figures themselves.

EATON, Theophilus, American colonial governor: b. Stony Stratford, Buckinghamshire, England, about 1591; d. New Haven, Conn., 1658. He came over to Massachusetts with the
Rev. John Davenport, 1637, founding with Davenport the town and colony of New Haven, in 1638, he was chosen governor October 13, 1639, and re-elected annually as long as he lived. He was prominent in the organization of the New England Confederation 1634, and the so-called Connecticut "Blue Laws" were drawn up by him, assisted by Davenport, 1655.

EATON, Timothy, Canadian merchant: b. Clogher, Ireland, October 1835; d. Toronto, Canada, 31 Jan. 1907. While a boy he was apprenticed to a draper at Portglenone, but having served his five-year term and received his wages of about £100, in 1857 he emigrated to Canada. He first opened a store at Kirkton, in Huron County; later went to Saint Mary's; and finally settled in Toronto, where, in 1869, he opened the store which has since expanded into one of the largest department stores in America, with a branch at Winnipeg.

EATON, William, American officer: b. Woodstock, Conn., 23 Feb. 1764; d. Brimfield, Mass., 1 June 1811. He served in the army 1780–83, and then went to Dartmouth College, where he graduated 1791. Becoming captain in the United States army in 1792, he served in campaigns against the Indians till 1798, when he was sent to Tunis as American consul. During the war against Tripoli in 1801 he resolved to re-establish Hamet Caramelli as Bey of Tripoli, but was not supported in his attempt by the American naval officers. He returned to America in 1803 and was subsequently appointed naval agent of the United States for the Barbary powers. Returning to Africa he captured the city of Derne 27 April 1805, but when the United States concluded a treaty of peace with the usurper Yussuf, Eaton returned to America. See DERNE EXPEDITION.

EATON, Wyatt, American painter: b. Phillipsburg, Quebec, 1849; d. 1896. He came of American parentage, removed early in life to New York and studied at the National Academy of Design and under Gérôme at the Ecole des Beaux-Arts, Paris. He also associated with Millet at Barbizon and his work was greatly influenced by this artist. Eaton dissociated himself from the various schools and went to the old masters for his inspiration. His portraits form the most notable part of his work, in which he almost invariably caught much of the personality of the subject. The best known are the series of American poets, engraved by Cole for the Century Magazine. Notable portraits are those of Cole, Mrs. Richard Watson Gilder, W. C. McDonald and Archie Gordon. He was one of the founders and first secretary of the Society of American Artists. Of his subject pictures the most widely known are 'Harvesters at Rest' (1876, Smith College); 'Reverie' and 'Harvest Scene,' in the Montreal Gallery.

EATON, Ohio, village, county-seat of Preble County, on the Pittsburgh, Cincinnati, Chicago and St. Louis Railroad, 58 miles northwest of Cincinnati. Its industrial establishments comprise glove factories, cigar factories, and cement plants. It has also extensive agricultural interests, a library, and a water-supply system. Nearby are many remarkable springs. The town saw here the struggle between the Indians under Little Turtle and the white pioneers led by John Adair. Pop. 3,187.

EATONTON, e-ton-ton, Ga., city, county-seat of Putnam County, on the Central of Georgia Railroad; on the Oconee River, about 68 miles southeast of Atlanta. The city has extensive agricultural, cotton and fruit-growing interests. Its industrial establishments include cotton factories, gins, and compresses, and creameries. The fruit trade is noted. It is situated on the Oconee, the city owns the water supply system and sewage disposal plant. It is the birthplace of Joel Chandler Harris, of Uncle Remus fame. Pop. 2,036.

EAU, ő, a French word signifying water, and used in English with some other word for several spirituous waters, and particularly perfumes: (1) Eau de Cologne, a fragrant water made originally and in most perfection in Cologne. It was invented by Farina. It is manufactured by adding to distilled alcohol a few aromatic oils. Although there are three firms which claim the original invention, the general process of manufacture is known. The important factors are the quality of spirit used and the amount of time allowed for maturity. Distillation produces equally good results. Synthetic oils used by various perfumers are in the typical combination as follows: 30,000 grams spirit; 100 neroli oil; 30 rosemary oil; 100itch lavender oil; 300 lemon oil; 300 bergamot oil; 50 petit-grain oil. (2) Eau Créole, a highly esteemed cordial made in Martinique, West Indies, by distilling the flowers of the mammee apple with spirit of wine. (3) Eau de Javelle, a preparation of chloride of soda, used as an antiseptic, and a bleaching agent. (4) Eau de Luce, invented by a person named Luce, at Lille, in Flanders, is a volatile preparation, made from oil of amber, alcohol, and ammonia. It is a milky fluid, powerfully antispasmodic, and stimulant. Mixed with nitric acid it forms a substitute for musk. (5) Eau de Paris, a substitute for cologne, and which is sometimes taken in sweetened water as a cordial, and stimulant. (6) Eau de Vie, a brandy; specifically the less perfectly purified varieties, the best being called cognac. (7) Eau de vie de Dantzic, a wine, sweet and strong, in which are introduced for ornament small particles of gold-leaf. (8) Eau de vie d'Hendaye, a sweet French cordial, of which there are three varieties—white, green and yellow. Consult Otto, 'Les Parfums'; Mann, 'Die Moderne Parfumerie.'

EAU CLAIRE, ő klär, Wis., city and county-seat of Eau Claire County, at the mouth of the Eau Claire River, and the head of navigation of the Chippewa River, and on the Chicago and Northwestern; Chicago, Milwaukee and Saint Paul, and several other railways: 85 miles east of Saint Paul and 150 miles northwest of Madison. It is the commercial centre for northwestern Wisconsin, and the outlet of the Chippewa lumber district, with extensive water power. It has a great trade in lumber and manufactures over 800,000,000 feet annually. There are extensive manufactures of iron and linen goods, furniture, refrigerators, boxes, harness, sashes and doors, machinery and shoes. The city is noted as a summer resort, and has electric railroads and street lighting, waterworks, public library and high school, Sacred Heart
EAUX-BONNES—EBERHART

Hospital, Norwegian Lutheran Hospital, national and savings banks, daily and weekly newspapers. Eau Claire adopted the commission form of government in April 1910, being the first city in the State to do so. Pop. 18,647.

EAUX-BONNES, ë-bôn, France, a celebrated watering-place, department of Basses-Pyrénées, at the bottom of a narrow gorge, about 25 miles south of Pau. There are seven hot springs, which have a temperature of about 90°, are strongly impregnated with sulphur and considered of special efficacy for throat diseases and tuberculosis. About 6,000 to 10,000 visitors resort hither in the course of the season, which lasts from June to October. A short distance away is Eaux-Chaudes, with sulphur springs.

EAUX-CHAUDES, ë-shôd, France, a watering-place in France, three miles southeast of Eaux-Bonnes. Some of its springs have the same properties as those of the Eaux-Bonnes, and others are more strongly impregnated with sulphur.

EAVES or CLIFF SWALLOW, one of the familiar North American swallows (Petrochelidon lunata) common about buildings where, as explained under BARN-SWALLOW, it has taken up its residence as fast as the country became settled. It is to be recognized by the squareness of the tail (not deeply forked as in its larger associate, the barn-swalow), the chestnut rump, whitish belly and blue spot on the breast. It is most peculiar, however, in its nests, which are always attached to the outside of the building, and not under the protection of the eaves. These nests are made of pellets of mud; are shaped like bulbous flasks with a curved neck forming an entrance; and are attached by their base to the wall. In the primitive wilderness these nests are attached in crowded colonies to the faces of cliffs, where whole masses would frequently scale off by reason of the weight or of the loosening action of rain. Much safer and better foundations are found under the protection of the eaves of buildings; and not only has this swallow everywhere taken advantage of this fact, but striking modifications in their architecture have followed. The eggs closely resemble those of the barn-swallow, and two broods are usually raised. The species abounds in suitable localities all over the continent, migrating to the tropics in winter.

EAVESDROP, an ancient custom, or law, corresponding to the well-known urbanervitude of the Romans called stillicide, while a proprietor was not allowed to build to the extremity of his estate, but must leave a space regulated by the charter by which the property was held, so as not to throw the eavesdrop on the land of his neighbor.

EBAL, ë-bal, a mountain in Palestine, nearly 3,000 feet in height; 35 miles north of Jerusalem, situated north of Mount Gerizim, from which it is separated by a narrow valley containing the town of Nablus, ancient Shechem. Here the Israelites were commanded, on their entrance into the Holy Land, to set up an altar to Jehovah of hewn stones. The fulfilment of this is recorded in Joshua (viii, 30-35). From Mount Ebal an oracle was given in the time of King Saul, and hence this name is given to the district east of the Jordan, where the Israelites were commanded to set up an altar to Jehovah (Deuteronomy i, 34).

EBELANS, ë-bel'ans, German sect, named after Ebel, a Prussian archdeacon, one of the founders. It arose in Königberg, Prussia, about 1836, the Archdeacon Ebel and Dr. Dietzel being its leaders. They believed in spiritual marriage. In 1839 sentence was passed against their leaders, who were charged with unsound doctrine and impure lives, but it was removed in 1842. Their enemies called the sect Mucker, that is, in German, hypocrites.

EBELING, ë-bel'ing, Christoph Daniel, German scholar: b. Garmissen, near Hildesheim, Hanover, 20 Nov. 1741; d. Hamburg, 30 June 1817. He was noted for his extensive knowledge of Oriental languages, of classic and foreign literature, and of history and geography. He published a history and geography of North America (1796-1816), for which he received the thanks of the United States Congress. He paid special attention to the geography of the New World, and collected about 10,000 maps and nearly 4,000 books, all relating to America. This library was purchased in 1818 by Israel Thornsdiik Osgood, of New York, and presented by him to Harvard College.

EBENZER, ë-bë-ne'zer (Heb. "the stone of help"), commonly used as any memorial of divine assistance, originally the name of a field where, at Samuel's request, the Lord discomfited the Philistines with thunder, etc. On this occasion Samuel set up a stone and gave it this designation, to indicate that the Lord had helped them. The site has never been definitely ascertained.

EBENSBURG, Pa., borough and county-seat of Cambria County; on a branch of the Pennsylvania Railroad, about 113 miles east of Pittsburgh and 16 miles west of Altoona. The manufactories include woolen-mills, tanneries, a foundry and saw-mills. It is about 2,300 feet above sea-level and enjoys some reputation as a health resort. It is situated in a rich bituminous coal region. Pop. 1,978.

EBERHARD, ë-bër-hârd, Christian August Gottlob, German poet and descriptive writer: b. Belzig, 12 Jan. 1769; d. Dresden, 13 May 1833. His idyl 'Little Hans and the Chickens' (1822) has been translated into many languages and still enjoys a wide popularity. His long poem in hexameters, 'The First Man and the Earth' (1828) is distinguished by its noble diction.

EBERHARD, Johann August, German philosophical writer: b. Halberstadt, 31 Aug. 1739; d. there, 6 Jan. 1800. He was a preacher first in Berlin and then in Charlottenburg, and was appointed to the chair of philosophy at Halle in 1778. He first attracted attention with a 'New Apology of Socrates' (1772), an attack upon the narrow theology of the day, to which succeeded 'Universal History of Philosophy' (1788); 'Handbook to Esthetic' (1803-05); and other works from a Wollfian standpoint, in harmony with Leibnitz and in opposition to Kant.

EBERHART, Adolph Olson, American public official: b. Sweden, 23 June 1870. He is a son of Andrew Olsene, whose conviction of the court changed his name because of several Adolph Olsons living in same town.
He came to Minnesota in 1881. After graduating from Gustavus Adolphus College in 1895 he studied law and was admitted to the bar two years later. He served as a deputy clerk of the United States circuit and district courts 1897–1906, and as United States commissioner for the district of Minnesota for the same period. In 1903 he was elected State senator and re-elected in 1905. He was elected lieutenant-governor in 1906 and re-elected in 1908. Upon the death of Gov. John A. Johnson in 1909 he succeeded him as governor by virtue of his office. At the expiration of this term he was elected governor in 1910 and re-elected on 5 Nov. 1912. As governor he has been a consistent advocate of the conservation of the State's natural resources, consolidation of the rural schools and of many social and economic reforms.

EBERLE, aˈbɛr-le, Robert, German artist: b. Berlin, 22 July 1815; d. Ebering, near Munich, 19 Sept. 1860. He was a pupil of Bierman and later of Van de Velde. His talent was particularly displayed in painting sheep. One of his works, 'A Shepherdess,' is in the Modern Gallery, Munich.

EBERLEIN, Gustav, German sculptor: b. Spiegel, Hanover, 1847. His chief work is a long frieze ornamenting the façade of the Ministry of Cults, Berlin, with 50 figures attending religion. He did also decorative work for the University of Kiel. Among his works are 'Drawn from Thorn'; 'Great Flute Player'; 'Psyche' and the 'Archer.' From his hand also are five allegorical groups at Stuttgart, and monuments of William I at Elberfeld, Geislingen, Mannheim, Altona and Ruhrodt, of Frederick I and Frederick William III in Berlin, of Bismarck at Krefeld, Wagner in Berlin and Goethe in Rome. He is the author of 'Aus Eines Bildners Seelenleben, Plastik, Materie und Poesie' (1892).

EBERS, aˈbɛrz, Emil, German genre painter: b. Breslau, 14 Dec. 1807; d. Beuthen, 1884. He studied at the Academy of Düsseldorf and early turned his attention to dramatic subjects such as scenes of battle in the Middle Ages, brigandage, sailors, fishermen, etc. In later years, after traveling much and visiting the shores of the North Sea, Holland and Normandy, he devoted himself to marine painting exclusively. Among his works are 'Smugglers About Land' (1830), in the National Gallery, Berlin; 'Fisher- man’s Hut' (1831); 'Smugglers Surprised' (1832); 'Smugglers in Tavern' (1835); 'Repressing Revolt'; 'Dutch Smugglers on the Coast of Normandy' (1842); 'Prussian Hussars Maltreating French Peasants' (1843); 'Life Boat' (1844); 'Pilot Boat' (1845); 'Storm on Inland Sea' (1845); 'Mutiny on brig ' (1848); and some historical paintings, such as 'Saint Goar concerning the Rhine Province.'

EBERS, George Moritz, German Egyptologist and novelist: b. Berlin, 1 March 1837; d. Tutzling, Bavaria, 7 Aug. 1889. About 1859 he began to devote himself almost exclusively to Egyptian studies, and in 1869 was appointed extraordinary professor of language, history and ancient Egypt at Jena. In the following year he traveled in Egypt, Nubia and Arabia, and on his return in 1870 became ordinary professor of Egyptology at Leipzig. Another visit to Egypt in 1872–73 resulted in the discovery of the important medical papyrus known by his name, now in Leipzig, and of which a facsimile was published in 1859. Among his published contributions to Egyptology are 'Disquisitiones de Dynastia viesima, sexta Regum Aegyptorum' (1865); 'Agypten und die Bücher Moses' (1868); 'Durch Gosen zum Sinai' (1872); 'Papyrus Ebers' (1875); 'Eine Galerie der hieroglyphischen Schriftzeichen der Agypter' (1880); and 'Agypten in Bild und Wort' (1878–79), translated into English as 'Egypt, Descriptive, Historical and Picturesque' (1890). Besides these works he published many novels, mostly dealing with Egyptian subjects, among which are 'Eine Aegyptische Koenigstochter' ('An Egyptian Princess' 1864); 'Uarda' (1877); 'Homo Sum' (1878); 'Die Schwester' ('The Sisters' 1880); 'Der Kaiser' (1881); 'Seraip' (1886); 'Josua' (1889); 'Per Aspera' (1892); 'Kleopatra' (1894) and 'Arachne' (1897). He also published a poem called 'Elison' (1888), and an autobiography (1892), entitled 'Die Geschichte meines Lebens.' A collected edition of his works in 25 volumes was published at Stuttgart (1893–97).

EBERSWALDE, aˈbɛrtsˌvaːldə (ancient NEUSTADT-EBERSWALDE), Germany, town on the Finow Canal, about 28 miles northeast of Berlin. It is a busy industrial centre, having a number of machine-shops, sawmills, car and locomotive works, and doing a considerable trade in lumber and coal. The paper for the notes of the Imperial Bank is here manufactured and there is a royal academy of forestry. Eberswalde, set in a finely wooded district, is a favorite summer resort for the people of Berlin. Pop. 20,984.

EBERT, aˈbɛrt, Karl Egon, Austrian poet and dramatist: b. Prague, 5 June 1801; d. there, 4 Oct. 1882. He began with dramas of Bohemian history, many of which were staged but only one printed, 'Wratislaw and Jutta' (1835). As a lyric poet and balladist he was more successful; his 'Poems' (1824) contain fine lyrics, and 'Schwering the Saxon Duke' is still held in popular favor. His longer poems — 'Wlasta, ein böhmisch-nationales Heldengedicht in drei Büchern' and 'Das Kloster' — are fluent in style as well as pure and elegant in language. The 'Denkmal für Karl Egon, Fürsten von Fürstenberg' (1885), consists of a garland of sonnets; 'Fromme Gedanken eines weltlichen Mainm' (1859) is a didactic poem.

EBERTH, aˈbɛrth, Karl Josef, German anatomist and bacteriologist: b. Würzburg, 1835. He was educated at the University of Würzburg; was appointed to the chair of pathological anatomy at Zürich in 1865, and to a similar chair at Halle in 1881. The results of his anatomical researches, including 'Über den Peitschenwurm' (1859) and 'Über Nematocenben' (1863), appeared in Virchow's 'Archiv für pathologische Anatomic.' His bacteriological investigations were chiefly concerned with the bacillus of typhoid. He published 'Die Untersuchung des Answurs, auf Tuberkelbazillen,' 'Die Thrombose,' 'Das Schimanschus' (1888); 'Mikroskopischer Technik' (1900).

EBIONITES, ˈɛbɪ-on-ɪts, a sect composed of Jewish believers in Jesus of Nazareth as being the Christ or Messiah, who nevertheless retained many of the practices and beliefs of their
ancient religion. Their name, Ebionites, seems to be formed from the Hebrew word *ebionism*, poor folk; but some of the ancient writers, unacquainted with the history of the primitive church of Jerusalem and Judea and with the Hebrew language, derive the name from that of a supposititious heresiaebion. If the name was originally *ebion*, the sect will have chosen for itself in effect the same name as the medieval sect of the Poor Men of Lyons. The Ebionites are by many authors confused with the Nazarenes or Nazarites, another body of Christians Jewish by race and in a measure also Jewish in religion. The rise of the Ebionite sect is commonly referred to the time of Trajan, when, the whole Jewish race being excluded from *Ælia Capitolina* (as Jerusalem was named anew), these people, despised alike by Jews, Christians and pagan Romans, migrated to Persia, the country beyond the Jordan, and there freely developed their religious tenets and practices. They were Jewish rigorists, zealots, with some tinge of Christian belief, in that they held Jesus to have been the Messiah; but they held him to be only man and begotten like other men. The Mosaic law they believed to be of everlasting obligation upon all believers in Jesus Christ whether of Jewish or Gentile race. Saint Paul they regarded as a traitor and arch-apostate for his having declared Mosaicism superseded by the law of Christ. Of the Christian sacred books they held the Hebrew gospel of Saint Matthew to be the only one given through Divine inspiration.

**EBLIS, or FATHER OF DEVILS,** in Arabian mythology, the ruler of the evil genii or fallen angels. Before his fall he was called Azazel or Hharis. When Adam was created, God commanded all the angels to worship him; but Eblis replied: *Me thou hast created of smokeless fire, and shall I reverence a creature made of dust?* God was very angry at this insolent answer, and turned the disobedient angel into a Sheytan (devil), and he became the father of devils. He is described as of enormous size, with a red-striped face, a ring-pierced nose, long hair, large flapping ears and a very ugly tail. See Devil.

**EBNER-ESCHENBACH,** Abner of Chézénhâbt, Baroness Marie von, Austrian author: b. (Countess Dubsky) Castle Zislavic, Moravia, 13 Sept. 1830. In 1848 she was married to an officer of the Austrian army. Her whole life was spent between Castle Zislavic and Vienna. Her early products were dramas long since forgotten. She began in 1860 as a playwright with *Mary Stuart in Scotland* (1860), and the tragedy *Marie Roland,* with the one-act dramas *Doctor Ritter,* *Violets,* and *The Disconsolate One,* all of which were moderately successful. Her fiction beginning with *The Princess of Banalia* (1872), a satirical tale, made little impression; but *Two Countesses* (1885), a story of Austrian high society, met with striking favor. Her other writings include *Tales of the Village and Castle,* *The Prisoner of the Parish* (1887); *The Rival,* *Aphorisms* (1880); and *Parables, Stories and Poems* (1892); *Margaret* (1891); *Drei Novellen* (1892); *Glaubenslos* (1893); *Das Schadlichste* and *Der Totenmarkt* (1894); *Rittmeister Brand* (1895); *Bertha Vogelweid* (1896); *Alte Schule* (1897); *Ausz Spathers-

**EBONY.** See Diospyros.

**EBORACUM,** ἐβόρα-κύμ, the Latin name of York. See York.

**EBRO,** a'brow (Lat. *Iberus*), a river in Spain, once the boundary between the territory of Rome and Carthage, has its source in the province of Santander, 10 miles west of north of the town of Reynosa. It flows the river for about 500 miles, it flows into the Mediterranean by two mouths. It is navigable for boats up to Tudela, about 180 miles from its mouth, but is obstructed by shoals and rapids, to avoid which it is about 100 miles long, has been constructed south of and nearly parallel to the river.

**EBULLITION,** ἐβ-ll·θl·th'on, the bubbling up or agitation which results from the action of heat on a liquid. The escape of vapor from water depends not merely upon the temperature, but upon the presence of gases and other bodies, upon the vessel, and a variety of circumstances, so that a strict definition is necessary. The usual statement is that ebullition is the conversion of a liquid into a vapor or gas having the same tension or elastic force as the air. This conversion takes place at different temperatures for different substances, but it is so constant for each substance that the fixity of the boiling-point of a fluid is regarded as a very good test of its purity. In determining what that point is, it is of course necessary to observe the atmospheric pressure, to see that it does not vary during the experiment, and to fix upon some standard pressure for comparison of results. The pressure is estimated by the barometer. It is possible to heat water 20° F. above its boiling point without ebullition. See Heat.

**EÇA DE QUEIROZ,** a's-dá-k'roz, José Maria, Portuguese novelist: b. Póvoa do Varzim, 25 Nov. 1845; d. Neilly, France, Septembre 1900. At first a journalist, he traveled and was in the consular service at Havana, New York, Lisbon and Paris. He introduced the naturalistic school into Portugal. His powers of observation and description are extensive, and in his novels—*The Crime of Father Amaro* (1874, rewritten in 1880); *The First Monk of Saint Basil* (1877); *A Relic* (1886) and *Antigôo* he wrote the master strokes the failures of Portuguese society. His strange, half realistic, half fanciful story, *The Relic,* weaves into a narrative of Oriental travel a dramatic representation of the Passion of Christ in the form of a dream. In collaboration with Rui Cândido Orsilho he wrote the tale of adventure, *The Mystery of Cintura Street.* Several of

**EBONITE.** See Vulcanite.
his works have been translated into English by Edgar Prestage.

ÉCARTÉ, "t'kär-tä', from the French, meaning "card, a game at cards for two persons. The game is played with a piquet pack, that is 32 cards, the small cards, from 2 to 6, being excluded. For convenience of dealing, two packs are generally used. The players cut for the deal; the lowest card (in France the highest) deals. The dealer gives 5 cards to each player, 3 and 2 at a time, and turns up the 11th card as trump (French, atout). If the turn-up is a king the dealer scores 1, and if a king turns up in the hand of either player the holder may score 1, but in each case this must be announced before the first trick by saying, "1 mark king." The king is the highest card, the queen next, then knave, ace, 10, etc. Trump takes all other suits. The non-dealer leads, if satisfied with his hand. If not, he proposes, i.e., he states that he wants to change some of his cards for new ones in the stack. The dealer may or may not accept the proposal. If he does, each one discards as many cards as he chooses and takes fresh ones, the non-dealer receiving them first. This may continue until the non-dealer is satisfied. After the non-dealer has led the other player must follow suit, and take the trick if he can; if he cannot follow suit, he must play trump, if he holds one. The winner of the trick leads again till the 5 tricks are exhausted. Three tricks count 1 point, 5 tricks 2 points. Five points make a game. The player, according to the French game, must announce the suit he plays, and if he plays differently, can be compelled to play as he announces, or if he cannot, as his adversary pleases. If the non-dealer fails to score 3 tricks, the dealer scores 2. The rules varied in different countries. Pool écarté is played by more than two players; the extra player serving in the capacity of adviser and replacing the loser in turn, until one player wins two or three successive games. The loser must always leave the game, unless he has guaranteed to take all bets, which is called playing "la chouette."

ECBATANA, the ancient metropolis of Media, built by Seleucus. It was the summer residence of the Persian and Median kings and existed in great splendor at a very early period in the history of the world. There are no traces now remaining of the site of this once celebrated city. Herodotus (1, 90), and Polybius (X, 20) are the main sources of information attesting its magnificence. In the absence of excavations, these must be regarded as authentic. The city was built on a hill, on top of which the temple of the sun Seven concentric walls circumscribed the city,—the innermost of gold,—the next of silver, the next orange, blue, scarlet, black and white, respectively. The stronghold and the palace were richly ornamented and carved. It fell successively into the hands of Alexander, the Seleucids, and Antiochus the Great. Finally the Parthians gained possession of it, and it gradually diminished in splendor. The present Hamadan is generally conceived by scholars to have been the original site of the city. Consult De Meynard, B. Dictionnaire de l'Archéologie de la Perse (Paris 1861); Crawshay-Williams, 'Across Persia' (New York 1907).

ECCE HOMO, ēk'ē ha'mō ("Behold the Man"), the rendering, in the Latin Vulgate, of the words with which Pilate presented Christ, in scarlet robe and crowned with thorns, to the populace. The figure of Christ in this scene is the subject of a celebrated painting by Correggio which is preserved in the National Gallery of Painting in London. Other great painters have chosen the same subject, among them Guido Reni, whose 'Ecce Homo' is in the picture gallery of Dresden; Titian, in the Scuola di San Rocco, Venice; Suvonia, in the Petti Palace, Florence, and Tintoretta, in the Munich Gallery.

ECCENTRIC, or ECCENTRIC CIRCLE, in ancient astronomy a circle whose centre was supposed to be displaced from the centre of motion. It was a makeshift to try to account for the motions of the planets before Kepler's discovery of their true orbits. The centre of attraction at one of the two foci of the ellipse. Also, in mechanics, a term applied to contrivances for converting circular into rectilinear motion, consisting of variously shaped disks attached to a revolving shaft.

ECCENTRICITY, deviation from a center; the state of a body with respect to the non-coincidence of its center with that of another circle. The eccentricity of an ellipse is the fractional quotient (always less than unity), which is obtained by dividing the distance from the focus of the curve to its center by the half length of its greater axis. The greater the eccentricity is, the longer the curve becomes in proportion to its width: as the eccentricity diminishes the form of the curve approaches that of a circle: the eccentricity of the circle is zero. The eccentricity is one of the most important of the so-called Elements of the orbits of the planets and of the double-star systems.

ECCHYMOSIS, ēk-imō'sis, a subcutaneous hemorrhage due either to bruising or some form of external injury, or occasionally the result of a peculiar blood disease hemophilia. Ecchymoses usually result in varying degrees of discoloration, and are best treated by means of hot water, locally applied.

ECCLEFECHAN, ēk-ī-fĕn'an, Scotland, village of Dumfriesshire, near the main line of the Caledonian Railroad, 20 miles northwest of Carlisle. It is the birth- and burial-place of Thomas Carlyle, and is unmistakably the "Entepfuhr" of his famous spiritual autobiography, 'Sartor Resartus.' The house in which he was born, 4 Dec. 1795, still stands, and in the west corner of the churchyard is the United Presbyterian church, which represents the old Secession church, he was laid, as he wished to be, beside his father and mother. Pop. 670.

ECCLES, Robert Gibson, American chemist; b. Scotland, 1 Jan. 1848. He came to the United States in 1862 and became chemist in the Bureau of Indian Affairs and professor and dean in the Brooklyn College of Pharmacy. He has discovered calycanthic acid and the alkaloids calycanthic, glaucosine, etc., and devised the official method of assaying pepsin and investigated the effects of drugs on hepatic digestion. He also exposed numerous fraudulent medicines, among them the Scotch oats essence.
He has written more than 100 articles on philosophic and scientific subjects, including "Food Preservatives" (1905); "Darwinism and Diabetes" (1908); "Letters from Foreign Lands" (1908); "Darwinism and Malaria" (1909); "Darwinism and Monarchy" (1909); "Touring the Lands where Medical Science Evolved" (1909); "Darwinism and Anaphylaxis" (1911).

**ECCLES.** England, a municipal borough in Lancashire, four miles west of Manchester, of which it is a suburb. There are here numerous cotton-mills. Pop. 41,944.

**ECCLESFIELD.** England, a parish in the West Riding of Yorkshire, six miles north of Sheffield. The chief manufacture is cutlery, then flax, linen, paper and nails; while in the vicinity there are coal and iron mines. Pop. 22,404.

**ECCLESIA ("convocation"),** a popular assembly, especially of that of Athens, where the people exercised full sovereignty and at which every citizen 20 years of age was entitled to vote. In early times, the ecclesia met once in each prytany, a period of 35 days, into which the year was divided. Later they met four times during that period. They were called by the praetor, a magistrate not only the presiding over the assembly, but later they were governed by a committee of nine. The people voted either by show of hands or occasionally by ballot, the latter method being by white and black pebbles. Besides the legislative powers of the assembly, it could make war, peace, treaty, war, or peace, treaties, legislation, etc. This term was also applied to any group acknowledging Christ as their Saviour and Lord. The word thence was adopted by the New Testament writers to designate "church."

**ECCLESIASTES.** One of the books of the Old Testament. The title in the Greek Bible, transliterated in the Latin and some modern versions, is a rendering of the Hebrew Qoheleth. Plato ("Gorgias," 452 E) and Aristotle ("Politics," iii, 1) use the term for "a member of the assembly." The Hebrew word is a feminine participle in the plural form, and the modern Hebrew verb derived from qahal, "assembly." It occurs nowhere else than in this book, and in the present text is clearly a designation of Solomon, probably invented by the author on the basis of 1 Kings viii, 18, where the king assembles the elders of Israel and addresses them (according to 2 Chronicles vi, 13 from a specially constructed brazen scaffold), to describe the wise monarch on whose lips he places his diatribe as the orator "par excellence." Luther's translation "Der Prediger" and the English alternate title "The Preacher" have a somewhat different connotation. Less probable are the views that the word indicates "collector of the legal and practical" (Rashi, Ibn Ezra, Ibn Ghibyat, Tanchum), or "collector of the opinions of the wise" (Grotius), or "gatherer of an assembly of sages" (Jepheth ben Ali, Delitzsch); or that "wisdom" is understood as the speaker (Grecus Venetus, Baruch ibn Baruch, Ewald, Hitzig, Kleinert, Derenburg); or that the title means "popular sayings," or "words intended for public use" (Kamenetzky).

In the Hebrew manuscripts and printed editions Ecclesiastes is one of the five megiloth, or "rolls," and is placed between Lamentations and Esther. This position is probably not much older than the 12th century when it apparently began to be read at the feast of tabernacles. In the Talmud ("Baba batha" 14b, 15a, 15b) the passages are not put together, and in the Greek Bible the book follows Proverbs and precedes Canticles, an order that has been adhered to in the later versions. When it was first read in the synagogue as "Scripture" is not known. That it was quoted as such by Simon ben Shetach in the reign of Alexander Janneus, by Baba ben Buta in the time of Herod, and by Gamaliel I is vouched for only by late and scarcely reliable testimony ("Talmud" "Berakoth" vii, 2; Bab. Talmud "Baba batha" 4a). Questions as to its canonicity arose in connection with the Pharisaic innovation of washing the hands after contact with sacred books. The school of Shammai held that it did not defile the hands, consequently was uncannical, while the school of Hillel maintained that it did. The council of Jamnia, c. 90 A.D., was in doubt, but the majority seems to have admitted its canonicity; yet a century later Jehuda ha-nasi declared: "Qoheleth is disputed" ("Mishna" "Yadain" iii, 1; "Eduyoth" vi, 3).

The critical apparatus by which it is generally possible to restore, at least tentatively, the original text of a biblical book is, in the case of Ecclesiastes, regrettably limited. It has been seriously questioned whether a Greek translation existed before the 2d century A.D. Following a suggestion of Freudenthal, Grätz reached the conclusion that the version in our manuscripts was made by Aquila, and this view was accepted by Renan and König. Dollmann maintained that the original Greek text had only been worked over by the Aquilian version, and this was also the opinion of Klostermann. But McNeile has convincingly shown the improbability of this theory. Since Jerome refers to two editions of Aquila's version, he assumes that the text in our manuscripts is the first of these and that Origen inserted it in the column devoted to the so-called Septuagint, because the Alexandrian version did not contain this book, while the second edition was placed in the _Aquila_ column. The second edition has been adopted by Barton, Swete ("Introduction to the Old Testament in Greek," 1900) and Reider assigns the present text to "the school of Aquila."
Since the Syro-Hexaplaric version represents our Greek text, there can be no doubt that it essentially goes back to Origen, and the problem is how this critic, who must have recognized "the school" as quickly as the master, could have substituted it for the Alexandrian version, if one was known to him, or in any case how he could have been silent about the matter. An earlier version might conceivably have been lost, as has that on which Theodotion's recension is supposed by many scholars to be based. If the author of Wisdom of Solomon, 1:94, whether he lived in the 1st century B.C. or at the time of Caligula, really undertook to correct certain sayings of Ecclesiastes or misinterpretations of their trend, as appears probable, it is likely that he had before him a Greek translation, and it is not inconceivable that Aquila may have used it to some extent in his first edition, before he began to apply his principles more rigorously. Unfortunately, there are no quotations of the book in Philo, Josephus, or the Septuagint, and few in early patristic literature. It is thought that the fragments from the Aquila column represent Akiba's recension of the Hebrew text, while the first edition of Aquila may have preserved readings also after Akiba's text. Among the early versions, the Syriac Peshitta and the Latin Vulgate are derived directly from the Hebrew; the Old Latin, Sahidic, Arabic, Armenian, and Slavonic are translations of the Greek text. In the Sahidic, iv, 4-7, 19 is lacking, probably because this section did not harmonize with the prevailing ascetic sentiment among Coptic Christians. Of the Syriac version, made from the Greek by Paul of Tella, a photolithographic reproduction was published by Ceriani in 1874. The integrity of the book was not questioned by those who in earlier times were struck by its apparent contradictions and conflicting sentiments. Pope Gregory I and many mediaeval writers assumed that thoughts not approved by the author were given expression only to be corrected, so that the work had something of the nature of a dialogue. This interpretation was naturally favored by scholars who understood the title as designating a "collector." When the difficulty of ascribing the book to Solomon began to be realized, speculation increased, and the origin of the sentiments introduced to be corrected. If already Jerome, Gregory I, and Bar Hebraeus had suggested a similarity to Epicurus, Empedocles, Aristeippus, and the Cyrenaic philosophers, Luther thought of actual extracts from writers in the library of Ptolemy III Euergetes in Alexandria; Grotius apparently had Oriental philosophers in mind; Yeard supposed the book to be a dialogue between a sensual worldly and a God-fearing Jew; Grotius supposed it to be a dialogue between a modern Qoheloth such as Hebraeus who had become a Greek sophist and an orthodox teacher represented by Solomon; and others thought of the book as a dialogue between Thucydides and Xenophon. The tendency inevitably led to a denial of the unity of the book. Van Limburg-Bouwer believed that two different works were united by an editor who interpolated the original with long extracts from another different written by a skeptic. In addition to the idea of dislocations, already put forth by Van der Palm in 1784, Bickell and Hauck also accepted the theory of interpolations on a large scale, but supposed the sceptic to be the original author. Bickell's notion of dislocated leaves has been shown to be archaeologically untenable, and although Hauck's view is not original to the same objections and the book of Ecclesiasticus reveals the possibility of such dislocations, it is not easy for even the most ingeniously and tastefully arranged anthology to win recognition as a reliable reconstruction of a lost original. Siegfried supposed that the original book was interpolated by an Epicurean Sadducee, a pious Chassid, a wisdom-teacher, and at least three others. While Dillon and Lauer have adopted this analysis, it has been modified by McNeile who assumes that the book was edited by an admirer employing the guise of Solomon, and interpolated by the annotations and criticisms of two contemporary thinkers, one adding more or less isolated apothegms bearing on life and nature, another a pious Jew following the calm and thoughtful reflection, and few in early patristic literature. It is thought that the fragments from the Aquila column represent Akiba's recension of the Hebrew text, while the first edition of Aquila may have preserved readings also after Akiba's text. Among the early versions, the Syriac Peshitta and the Latin Vulgate are derived directly from the Hebrew; the Old Latin, Sahidic, Arabic, Armenian, and Slavonic are translations of the Greek text. The tendency inevitably led to a denial of the unity of the book. Van Limburg-Bouwer believed that two different works were united by an editor who interpolated the original with long extracts from another different written by a skeptic. In addition to the idea of dislocations, already put forth by Van der Palm in 1784,
sorted to a sprinkling of pious utterances to conceal his heresy. It would be natural for a Hebrew king, if he had a real name, to indulge his taste for quoting wise saws, even if they fitted loosely in the context, and to give to some sayings a subtle turn. Aside from the epilogue and a limited number of glosses in the text, Ecclesiastes is probably the work of one man, who has never, quoted some songs and sayings of others.

According to Jewish and Christian tradition the book was written by Solomon. The Taalmudic statement (‘Baba bathra 15a) that the men of Hezekiah wrote it, probably suggests only some kind of editorial activity. Even the heretics mentioned by Philastrius of Brescia, Theodore of Mopuesia, who was condemned by the Fifth Ecumenical Council for failing to recognize its divine inspiration, and Abul Faraj Bar Hebraeus, who held a similar view, did not doubt the Solomonic authorship. This was apparently first done by Luther (‘Vorrede auf die Bücher Salomonis’ 1524; ‘Tischreden’ IV, 400); Grothus (1644); Le Clerc (1685); Von der Gabelentz (1813); this development has continued (1759; 1769); Gibbon (‘Decline and Fall of the Roman Empire’ c. xli; 1776-88); Eichhorn (1779); Herder (1780); Doederlein (1784); Zirkel (1792); J. Jahn (1793); J. E. C. Schmidt (1794); Nachtigall (1796); Herzog (1799); Bertholdt (1813); Umbrecht (1817); Rosenmüller (1830); Köster (1831); Knobel (1836); Ewald (1837); Herbst (1840); Hitzig (1847), and a host of later interpreters, including conservative Protestant like Hengstenberg, Valhinger, Haerentick, Kel, Stuart, Zoëckler, Gillispie, and Wright; Jewish scholars like Geiger, Luzzato, Grätz, Herzfeld, Seinecke, and Derenbourg, and such Catholic interpreters as Zirkel, Jahn, Herbst, Movers, Cardinal Newman, Veith, Kaulen, Bickell, Grimm, Loisy, Von Hügel, Zenner, Durand, Prat, Zapletal, Gigot, and Peters. The traditional view has been recently defended by Wordsworth, Milman, Glaire, Pusey, Wagemann, Hahn, Bohl, Bullock, Schäfer, Von Essen, Lesètre, Gietmann, and Conbe, but on insufficient grounds.

It has been urged against the traditional view that the pretended Solomon says: ‘I was king over Israel in Jerusalem’ (i, 12), ‘I have gotten me great wisdom above all that were before me over Jerusalem’ (i, 16), and ‘I was great and increased more than all that were before me in Jerusalem’ (ii, 9); that he complains of wickedness in the place of judgment (iii, 16), oppression with no comforter (iv, 1), tyranny and corruption of judges (v, 8; vii, 7), and the dangers of espionage (x, 20); and that there is no sign of repentance or warning against idolatry. In view of Ps. lxxxviii, 4 it is quite possible that we should translate ‘I, Qoheleth, am king over Israel in Jerusalem,’ though Solomon himself would certainly not have used the verb at all more frequently than the form of the pronoun employed. There would be no impropriety in Solomon mentioning his capital. Nor would there be any psychological improbability in a reference by Solomon to his greatest predecessor in his capacity of ruler, whether the Queen of Sheba, or his comparing himself with former kings in Jerusalem of whom we are beginning to learn something, even though Jerome observes that it is not greatly to his glory that he boasts his superiority over his father. It is not clear why a wise king should have hesitated to express his sympathy with the poor and oppressed, or to inveigh against the corruption of judges, or should have failed to recognize the limitations of royal power to alleviate social distress and prevent such insurrections as troubled his reign. There is no evidence that Solomon repented of his sins or regarded his polygamy and worship of other gods as sins. The Chronicler, who made other kings repent, left out of his record the deeds of Solomon of which he disapproved. The most important arguments against the Solomonic authorship have been derived from the language, style, and thought of the book. It is not merely the vocabulary, with its Persian and Aramaic words, and Hebrew terms occurring as a rule only in post-Christian times, but the regular use of the shorter relative, the form of pronouns, prepositions and conjunctions, the abandonment of the characteristic vow vow consecutively, in general the deteriorated syntax and the cumbrous construction of sentences clearly point to the latest stage of biblical Hebrew. Even when the difference of subject matter is duly considered, the style is widely removed from that of the Law and the Prophets, and there is a marked change even from that of such late books as Job and Proverbs.

With some scholars one of the determining factors in assigning a very late date has been the assumed influence of Greek thought in general, or specifically that of some of the philosophical schools. Such an influence seems to have been felt by Luther. Zirkel pointed out what seemed to him translations of Greek phrases, and in the case of some of these he was probably right. Especially Tyler and Plumtree have endeavored to show the presence of ideas peculiar to the Peripatetic, Stoic, and Epicurean schools, and Ed. Pfeiffer that of Heraclitian conceptions. The objection that some notions equally or more characteristic of these schools are absent, or that a somewhat strained interpretation has now and then been resorted to, is not altogether sufficient to offset the impression of their arguments. A certain eclectic ism is to be expected; a grafting of new ideas on a traditional conception of life is unmistakable, and the author can scarcely be regarded as a logical thinker. Havel called attention to some striking similarities between passages in Ecclesiastes and the Festal Dirge ascribed to a king of the 11th dynasty, published by Goodwin (‘Records of the Past,’ 1st series, iv, 115ff) and the Song of the Harper from the 18th dynasty, published by Stern (ibid. vi, 127ff), and Grimm noted the analogy of sentiment and language to a cuneiform document of the Hurrurapi period, published by Meissner (‘Mitteilungen der Vorderasiatischen Gesellschaft,’ 1902), quoted also by Barton to show that Ecclesiastes depended on the Old Testament in Semitic thought. But such expressions of sentiments common not only to Semites and Egyptians but to men of all lands and ages in certain moods do not constitute the most significant points indicated by Tyler and Plumtree. Dillon
finds analogies to Buddhist ideas; but Mar- goliouth rightly queries why there should have been a little of this, if there had been any knowledge at all of the conical hymns of India. The moderate view of Kuenen, Kleinnert, Cornill, and Cheyne, who find a general ac- quaindance with Greek ideas that were in the air in the Hellenistic age rather than an attachment to a particular school, seems to commend itself. The text of the book has been closely scrutinized for possible historical references, that might throw light upon the real author and his time. Luther thought of Sirach as the author, Grotius of Zerbabel, Von der Hardt of Joshua ben Jotha, Leimdirfer of Simon ben Shetach, Winckler of Alcimus and Grimm of Jehoiachin. But this search for his name is an unprofitable "chasing after wind." Hitzig saw in iv, 13ff; x, 16ff allusions to Ptolemy IV and Ptolemy V; Grätz to Herod the Great and his son Alexander; Winckler to Antiochus IV and Demetrius I; Haupt to Antiochus IV and Alexander Balas; Barton to Ptolemy IV, Ptolemy V and Antiochus III. "So already Böttcher, *Neue Aegyptische Untersuchungen* is most probable. The little city saved by a poor wise man (ix, 14ff) was sup- posed by Hitzig to be Dor, though the account in Polybius v, 66, would then have to be in im- portant respects supplemented by that of Ec- clesiastes. Ewald thought of Athens and The- mistocles, Friedländer of Syracuse and Archi- medes, though neither of these places could be spoken of as a little city, and neither of these men was ever forgotten. Haupt supposed Bethsheba was meant (1 Macc., vi, 31ff; 2 Marex, xii, 19f). This is not improbable, though in that case also the remark of Ecclesiastes that "no one remembered that poor man" would be justified by the silence of the historians. While many scholars in the early part of the 19th century assigned the book to the Persian period, the great majority in recent times have reached the conclusion that it must have been written about 200 b.c. Zirkel, Renan, Kleinert, Winck- ler, Leimdörfer, Haupt, Schmidt, and Peters would descend still another century. To this the objection has been made that Jesus son of Sirach was familiar with Ecclesiastes. But none of the passages that led Nöldeke somewhat hesi- tatingly to change his former view on this point is at all conclusive, as Peters has shown, and those adduced by others in addition have little weight. Less probability attaches to the con- jecture of Grätz, adopted by Havet and Cheyne, that the book was written in the time of Herod the Great. The scruples in regard to oath- taking would be as characteristic of the Essenes in the time of Alexander Jannaes as later. Ecclesiastes may have written his work c. 100 b.c. That the book, though substantially written, in prose, contains some scraps of poetry was seen by Desvoeux in 1760, and Lowth inclined to the same view in the second edition of his *Praelectiones*, 1763. Nachtigall attempted to show a strophic structure throughout, and Köster assumed that the entire book was writ- ten in the parallelisms characteristic of Hebrew poetry, but accustomed to the idea that parts only had this literary form. Derenbourg supposed that reminiscences of a rich apoph- thematic literature were occasionally inter- spersed by the author after the fashion of the poetic fragments introduced in their works by Arabic writers; and Renan recognized the metrical character of these insertions and, in rendering them, imitated the style of the ancient prosaic poetry of Marcus Curtius, Marcius Pibrac, and Chatonnet. Grimm (Zeitschrift der Deutschen Morgenländischen Gesellschaft, 1897) assumed that the whole book (except xii, 13, 14) was written in metrical form. Schmidt (in *The Comedion*, 1890) maintained that the "Song of Youth and Age" (xi, 7-xii, 7 except some interpolations) was an elegiac poem in a regular metre quoted by the author. Sievers ("Metrische Studien" 1901) treated i and ii as poetry. Zapletal and, independently, Haupt in 1904 reached the conclusion that practically all parts of the book were written in metrical form. The contention of Genug and many other scholars that the work is throughout written in prose can scarcely be maintained. While a large part seems to present to us a prose strug- gling to free itself from the traditional vehicle of gnomic literature and create an instrument more suitable for philosophical discussion, the marks of poetic diction are unmistakable, not only when it enriches his work with quotations, but also when he feels the demand of a more elevated style.

Concerning the purpose and character of the book there has been much difference of opinion. Jerome who read it to Blesilla and wrote his commentary at her suggestion regarded it as intended to show the worthlessness of mundane existence and to bring home the need of an eternal life. This was typical of early interpre- tation. Some mediæval Jewish exegetes recog- nized in it a serious testing of the foundations of belief and were encouraged by it to phi- losophical speculation. Luther laid stress on the injunctions to a simple enjoyment of the pleasures of life in the fear of God. But the dominant note of sadness in reflecting upon the transitory and apparently profitless course of man's life and the hopelessness of any future reward could not be missed when the allegoriz- ing tendencies were discarded and the literal sense alone was sought. Hence the impression of a pervading pessimism and scepticism that appeared to Voltaire who regarded it as "un monument précieux" and dedicated his render- ing of it in verse to Madame Pompadour and Frederic the Great; to Heinrich Heine who styled it "Das Hohllied der Skepsis"; to Eduard von Hartmann (*Das Lied vom Ewigchen*, 1889) who defined it as "ein Brevier des allermodern- sten Materialismus und der äussersten Blas- sheit"; and to Renan who called it "un des ouvrages des plus charmants que nous ait légues l'antiquité." Theologians like de Wette, Knob- bel, Umbreit, Bruch, and Pumplière emphasized its scepticism. But whatever influence of Greek philosophy or free and fearless speculation may have been felt in the book, the frequent mention of God did not seem to allow the inference that the author had lost completely his childhood's faith. The careful avoidance of the name Yahwe is indeed, as Bergst saw, a sign of a late date, but not of a diminished faith in a living God, as many of the Psalms and Daniel prove. It is important, but certainly not the whole of his references to God. A certain resentment against the power of God, checking with ap- parent jealousy every effort of man, has been discerned by McDonald and others. At bottom more religious," says Renan, "the author of Job
is more audacious in his language; Qoheleth has no longer the strength to be indifferent at God; it is useless.6 Kleinert observes that the thought of an immanence of God in the world and in history, the heroic confidence, the expectation of impending judgment, the imperishable hope, the fervent prayer, the sense of sin and the need of atonement are gone. There are no longer any sacred places, no sacrifices, nor is there any breath of warm life; the conception of an inscrutable and inexorable omnipotence approaches the lifelessness of Fate.

It is true that the attitude of Ecclesiastes toward death does not differ essentially from that of his ancestors. But the question: "Who knows whether the spirit of the sons of man goes upward and whether the spirit of the beast goes downward to the earth?" seems to show that the somewhat strenuous denial of immortality are made in view of contemporary assumptions, probably reflecting foreign speculation, that the spirit does not go down to Sheol, but up into the empyrean. The recognition of a fixed cosmic order does not lead to a discussion or an annihilation of the transcendent. The second is given on the assumption that, within certain limits, man can determine his own conduct. Against the conception that theoretically Ecclesiastes reaches no other conclusion than that of the essential worthlessness of existence and that, in view of this, he adopts an opportunistic hedonism, Gegenstrongly emphasizes his scientific spirit, advancing by the inductive method in the search for truth, his restraint when confronted with theories still lacking a basis of verifiable fact, his discernment of relative values, and his stress upon character and recognition of the intrinsic importance of work and pleasure. There is much justice in these observations, even if at times they leave the impression of a subtlety that discovers aims and ideas which may not have been present in the author's mind. Struck by the circumstance that in the proto-canonical books "from Genesis to Paul" the fall of man is not mentioned except by Ecclesiastes (vii, 29), McDonald has assigned to it a doctrine, which appears to be as casually referred to, if at all, as in Ecclesiasticus xxv, 24, or Wisdom of Solomon ii, 23, 24, a larger place than seems to be warranted by the rest of the book. The value of the poetic insertions has long been recognized. In the Song of, Yoid and Age with which the work fits closely, the deep sense of the desirability of life, the intrinsic worth of human existence, adds to the pathos; it touches every heart because it sings the universal fate of man; it is at once a chant of death's advance even in the midst of life and life's affirmation of its joy even in full view of death.

ECCLESIASTICAL ARCHITECTURE.
See Architecture; Byzantine Architecture; Roman Architecture.

ECCLESIASTICAL ART. The science of ecclesiology consists of two entirely distinct
and separate branches of religious work. One of these concerns itself with the organization and development of the Church body, the polity of the Church community, all from the standpoint of the clergy or prelates. The second branch of ecclesiastical treatises of Christian church edifices, the churches' contents, including all that goes into the furnishing of the interior of the building, such as its decoration, every- thing connected with ceremonial or symbolic use in the religious ceremonies. This article devotes itself entirely to the category of sub-
jects pertaining to the latter branch of ecclesi-
ology. Few writers appear to have attacked this subject as a whole in a monograph. The sculptured mural decorations of the different periods have been expatiated on in works on "Christian Architecture"; the sculptured statu-
ary and bas-reliefs of the world's Christian churches have been written on by laymen and clerics under the title of "Christian Icono-
graphy"; the painted mural, altar and other polychrome decoration of Christendom's churches has been treated by works on "Christian Art." Church furniture has found numerous writers to expound the topic of the consecration and carving of altars, pulps, choir-stalls, altar services, embroi-
dered art work on priestly vestments, decora-
tive lighting apparatus, etc. Many of such works are written in a lucid and popular style, devoid of all clerical Latin terms unint-
telligible to the lay reader. But the works entitled "Christian Art" include in their text and illustrations paintings and sculpture depicting religious subjects created for public buildings other than ecclesiastical, such as courts of justice, city halls, public galleries, etc. As the entire subject of Ecclesiastical Art in its various branches is quite volun-
nously covered in the volumes of the Encyclopedia Americana, this article necessarily avoids long repetitions of such treatments. Articles on the Church edifices, their ground plans, façades, etc., will be found under the different specific titles as cross-referenced in the body of the text, such as Architecture, Roma-
nesque; Basilica; Byzantine Architecture, etc. The same can be said of altars and their furnishing, which are fully discussed under the titles Altar; Chalice; Corona; Chandeliers; Crosses and Crucifixes; Costume, Ecclesi-
astical; Art Enamels, etc.

An exceedingly interesting feature that con-
fronts the student of ecclesiastical art is the fact that practically all art talent of Christen-
dom up to, and perhaps inclusive of, the 14th century was dedicated to the Church. And until the last few years of the Middle Ages all art was either carried on by the Church or under the supervision of the clergy. Much of the early art work was created in the cloisters (manuscript writing and illumination exclu-
sively, of course) by the monastic orders. And under the tutelage and patronage of such prel-
ates as Abbé Suger and Saint Eloï of France, Bishop Bernard of Germany, etc., schools of art were established and the Fine Arts sustained while all the lay world was battling in dynastic and baronial feuds.

**Art of the Catacombs and of the Primitive Christians.**—The more distinguished among the early Christian dwellers in Rome received in-
tement in the Catacombs in specially contrived chapels dug out from the sides of the innum-
erable subterranean passageways of the vast series of vaults and galleries then existing. These mortuary chapels usually took as ground plan a Greek cross (+); the roof was scooped out to form a dome or cupola (generally painted over in blue), the entrance of the recess was surmounted by conch-shells, the sides covered or simply used in the religious ceremonies. (See Symbolism.) In the recesses spaces dug out at the extremity and two sides were placed the sarcophagi of confessors, bishops, martyrs, etc. The sar-
cophagus at the furthest end was used as an altar or communion table. There are a number of these in the Catacombs of Rome. These subterranean specimens of architecture and the art of the earliest Christian believers remained forgotten for many years after Constantine I was converted and the secret assemblage of the persecuted believers became unnecessary. In 1578, by accident, the presence of these underground passages was discovered by laborers and public interest was excited to investigate these very ancient remains. Antonio Bosio spent 35 years exploring and investigating the cata-
rine and making plans of its ramifications and producing copies of sculptures and paint-
ings; the work resulted in the monumental work Roma sotterranea (1632). Aringh(1659) and others continued the work. These acts of devotion preserved to us a view of these interesting works which have since decayed and perished. With the freedom of worship ac-
corded the Christians by Constantine grew up, by the 4th century, three forms of buildings in which to perform religious ceremonies: baptisteries for Christian initiation; churches for the congregations' worship; sepulchral chap-
els for prayers in commemoration of the departed. The architectural plan adopted for a building in which the devout could worship was that of a vertical basilica (see Basilica) with its atrium (front court), nartex or portico, nave, cancellum (choir), ambone (pulpit with entrances on both sides), triumphal arch (entrance to sanctuary), transept, presbytery (sanctuary), altar, obelisks, etc., with its bishop's throne (suggestus) side aisles. A crypt beneath the sanctuary contained the tomb or shrine of the saint or martyr to whom the church was dedicated. It is frequently claimed by authorities that this crypt was added to the pagan plan of basilica as reminder of the cata-
comb location of the first Christian church; in fact, a number of the early churches had preten-
sious subterranean quarters for worship. The steeples were later additions of the Lombard architects about the 8th century, when bells were introduced from Greece. Some scholars recognize a resemblance in the early baptisteries to the ancient Roman baths. Mostly they are octagonal buildings. Some claim that the octa-
gon form is symbolic of regeneration; very ap-
propriate for the rite of regeneration by bap-
tism. By early orientation the baptisteries were placed in front of the central entrance to the cathedral; symbolic of the initiation before en-
trance in the Church (see Baptistry). The font was located in the center of the building, which was surmounted by a dome. The font was reached by descending three steps to the

shallow octagonal basin; the early rite was one of submersion. Even when they built baptisteries in circular form the font persisted in its octagonal shape. Baptisteries continued to be distinct, if not always detached, buildings for eight centuries after Constantine’s time, but later the fonts (still octagonal) were placed in the church near the main entrance to maintain the idea of initiation to the convert.

Funeral chapels were a common purtenance of the church buildings, but have long since become obsolete and the old structures have decayed, so we know little of them. They were termed memoriae and commemorated certain saints or martyrs. Two extant (both at Ravenna) are the mausoleum erected by Galla Placidia for the remains of herself and her two sons, the Emperors Honorius and Valentinian; the other erected to the memory of Theodoric the Goth, raised by his daughter Amalasuntha. Most of the art productions of the catacombs and ancient Christian Rome have been obliterated by time, the extant remnants are in the Museum Christianum (Vatican) and in the descriptive work ‘Roma Sotterranea.’ Art compositions were mostly confined to symbolism. Our Saviour, the Good Shepherd, is found invariably depicted in the central space in the Catacomb domes, the others distributed around the walls. There were the Saviour on the Symbolic Rock, or mountain of Paradise with four rivers (mostly found on fronts of sarcophagi); ‘The Fall,’ Adam and Eve standing to right and left of the Tree of Knowledge, round which the Serpent coils; Noah and the Ark; Abraham’s sacrifice; Passage of the Red Sea; Moses striking the Rock; Jonah swallowed by the Whale; Jonah disgorge; Daniel in the Lions’ Den; the Nativity; Adoration of the Magi; Saviour turning Water into Wine, etc. Some 40 have traditional form. These pictures were continued by the Latin Church in sculpture and painting for many ages, probably under special sanction.

Byzantine Art.—The Byzantine church plan was a modification of the Roman basilica (see BASILICA) and we now have four naves of pillared avenues instead of one; they are of equal length and breadth, at right angles, forming a cross. In the centre, combining the terminations of the naves, arose the dome or cupola. (See BYZANTINE ARCHITECTURE.) The Byzantine church edifice was adorned with mosaics. The floor was paved in the style termed opus Gracanicum (or Graecum), while finer incrustations covered the eiboria (domes) and reading desks. A peculiarity of Byzantine (and contemporary) depiction is the representation of personages of superhuman power being given superhuman stature. Thus we see the devout paying homage in diminutive forms and

Byzantine mosaic of St. Mazimianus and Emperor Theodorus in S. Vitali, Ravenna (6th century).

the courtiers in pictures of emperors are pigmies. Monuments of Byzantine mosaic art are the 6th century work of the Holy Eucharist in the basilica of S. Apollinari di fuori (Ravenna); Transfiguration in the tribune of the same church; another in S. Apollinari di dentro, ‘Approach of the Three Kings,’ in Ravenna and Theodora in the wall of the tribune of S. Vitali, Ravenna. The mosaics in the nave and triumphal arch of S. Maria Maggiore, Rome (5th century). Other noted Byzantine mosaics in Rome are in S. Pudenziana, S. Prassede (9th century). Two centuries of war and barbarism in Italy intervene, while in Greece work was being done by such artists as Georgius, Pantaleo, Nestor, Menas, Symeon, the Blachernae on the illumination of the velum (Menologion for Emperor Basil II (10th century), now in Vatican. Beautiful work had already been done on such manuscripts as the Book of Joshua, in Vatican; Genesis, in Imperial Library, Vienna; Syriac Gospels, in Laurentian Library, Florence. A 9th century fresco in Byzantine work adorn an abside wall in S. Cecilia in Trastevere, Rome. By the 11th century decadence had set in, but fine work was done on such pieces as the ivory tablets inserted in the missals binding presented to Bamberg Cathedral by Saint Henry (emperor), now in Munich Library, and the bronze gates, done at Constantinople in 1070, for the basilica of S. Paolo fuori le mura (Rome). To this period belong the S. Marco pala d’oro and ciborium. Byzantine art revived in the 12th century; examples are the mosaic in San Clemente, Rome (1112); others in San Marco, Venice; in the tribune of the Duomo at Murano and those at Torcello. The Latin conquest (1206) and that of the Turks (1453) stifled and killed Byzantine art. Beautiful work was done in goldsmithing and enamels (see ART ENAMELS; GOLDSMITHING; for church plate, altar-pieces, see ALTAR); the emperors made great gifts of such work to the different churches. Carved ivories show more freedom of expression than, perhaps, other mediums. In viewing the work of the Byzantine
ECCLESIASTICAL ART

artists we find a primitive method of expression which often belies the perfection of execution. Draperies are apt to hang in folds suggestive of a series of ropes; the facial expression is often crude to extinction. They are methods laid down rigorously by the church and rigid conventions are still, more or less, maintained in oriental ecclesiastical art in Russia and the Greek Church.

Romanesque (Lombard or Italo-Byzantine).—This is a cruciform ground-plan for churches; the nave or arm continuing west from the sanctuary is lengthened, transforming into a Latin cross (+) the former Greek cross (+) plan. Three entrance doors are usual on the western front, mostly covered with sculpture. Over the central door a “Saint Catherine wheel” window is usual. Galleries of pillars or trefoils range themselves all around beneath the roof’s eaves. Galleries of such pillars sometimes cover the western front, rising tier on tier reaching even to the pediment and engirdling the cupola. They are mostly for purely decorative purposes. The baptistery and the campanile (bell tower) belonging to Lombard cathedrals are detached adjuncts of the church edifice. The arch is always round in pure Lombard architecture. (See Architecture). Early style is seen in the façade of S. Michele at Pavia; Victory of Saint George over central door; Jonah vomited by whale (right and left doors); diverse dragons, griffins, eagles, sphinxes, snakes, centaurs, etc., all very crude. Better work is found to the left of the doorway of S. Zenone, Verona (two warriors charging) and King Theodoric to the right. Next period improves as shown in monsters introduced in church pillars, often of admirable execution. Two lions on porch of S. Cyriaco, Ancona, perhaps are the finest in this style. Sometimes monsters appear on cathedral roofs, as the bronze hippocroft was, that is now in the Campo Santo, Pisa. All this was Teutonic element. Byzantine influence is shown in the work of Willigelmus at Modena: the King Arthur bas-relief in the doorway near the Campanile; story of S. Gimignano on southern side of cathedral; Passion of Our Lord in the chapel. Contemporary is the Last Judgment bas-relief in the façade of the cathedral at Ferrara; Biduino’s work (flourished about 1150) over baptistery door at Pisa; bronze door to Cathedral of Monreale (Sicily) by Bonanno (flourished 1174–86). Antelami’s (flourished 1178–1206) Deposition in Parma Duomo is greatly admired. Mosaics were considered as painters and held chief positions in art depiction till the Dominicans and Franciscans patronized the actual painters — Guido of Siena, Giunta of Pisa, Cimabue of Florence (master of Giotto), etc. Guido did the Madonna of S. Domenico (1221). Giunta did the decoration of the Upper Church of the Franciscans at Assisi. Margaritone (architect, sculptor and painter) belonged to this period. Cimabue did the Virgin and Child in the gallery of the academy, Florence; worked on the Assisi Upper Church fresco decoration; did the crucifix now in the S. Croce sacristy, Florence, and painted the noted Madonna for the chapel of S. Maria Novella. Other painters were Buffalmanco, Florence (1311–55); Tomas de Stefani, Naples (about 1230–1310); Filipo Teguturo, Naples (about 1290–1320); Bertolino di Piacenza and Nicco di Reggio (flourished about 1260). Noted in this period were Fra. Giacomo da Turrita, the Cosmati, Pietro Cavallini, Andrea Tafi, Gaddo Gaddi, Andrea Orcagna, etc.

Merovingian moldings in S. Maria-Trastevere, Rome.

French.—Nothing remains in France in the way of church buildings dating from the 4th, 5th and 6th centuries. The only extant ecclesiastical mementoes in stone of this Merovingian

Merovingian molding in St. Irene, Lyons.
period are numerous gravestones, capitals, moldings, etc. A predominating motif in such carvings is the complex interlacing lines like wattlework termed "lacertine" ornament. This method of intertwining and curving of numerous parallel lines in rounded bas-relief is contrived in guilloches (opposed waves intertwining to produce a series of circles, etc.), rosettes, even crosses. Crude foliation and floriforms intermingle with conventional bird forms (the symbolic peacock is frequent), contorted interlacing dragon and dog forms. The vaults and walls of the church edifices as well as the paving sometimes consisted of mosaics. Altars, while mostly of stone, were sometimes of wood. (See Altar.) In the Carolingian (spelled also Caroleinian) period (752-987) the powerful genius of Charlemagne becomes felt but, as Viollet-le-Duc says, our ideas of the primitive churches are very vague and it is only after the 10th century that we gain some conception of them. (See Architecture.) The fragments of ecclesiastical stone carving would make it appear that the same motifs as in the former period were in use: the interlaced ornament, the birds and other symbolic animals, but the lozenge (diamond) form is frequent. The treasures of the church were becoming very rich in objects of art. Altar and ceremonial pieces, such as chalices, patens, crosses (see Chalices, Crosses, Goldsmithing, etc.) were liberally donated by kings and nobles. These gold objects were often encrusted with garnets and ruby-colored glass paste in cloisons (bezels). Of such were the gold goblet and plateau recently discovered at Gourdon and the chalice and paten of Saint Goslin, bishop of Toul, green and blue enamel (see Enamel) figuring in the latter. Textile fabrics of this period and the former are very rare, most of those discovered in France being attributed to Byzantine manufacture, but found in a number of French churches. With the 11th century we commence the second French Romanesque period. As the 9th century found but few of the Merovingian edifices still standing, it is likely they were built of very perishable material. But the buildings of the period in consideration were more stable, stone being the main substance used. The prophecy of the end of the world having lost its discouraging effect with the passing of the 10th century, when the disaster was to arrive, the perspective broadened. Their figures, as a rule, differed. One of the finest was the font used by Charlemagne at Aix-la-Chapelle, which, in turn, was a reproduction of S. Vitali of Ravenna and others. (For further information see Architecture.) The ornament is becoming more and more enriched with carvings of birds pecking at fruit, strapwork, geometric repeat forms ("dog-tooth," lozenge, "pearl and button") and acanthus leaf. The tympanum over the door begins to obtain quite elaborately carved subjects as groups of ecclesiastical symbols of the Evangelists, full figures of Christ, etc. In the second half of the 12th century "wheel-windows," with columnar radiations starting from a circle in the centre and reaching to the periphery, appear at the extremities of the transepts above the western portal; these round windows are found on a number of churches of this century. Belfries are rare before the middle of the 12th century. The placing of vanes in the form of a cock, acting as wind indicators, dates very far back, the poet Wolstan (end of the 10th century) mentions the cock on Winchester Cathedral, and the Bayeux tapestry shows one on Westminster Abbey. Many were gilded. They were a symbol of the church to be ever watchful. The iconoclasts had done much to hinder the artistic expression of Christian sculptors and painters and former crude and unnatural depiction was largely due to fear of beauty in statuary or pictures leading to idolatry. But, by the 12th century, the figures coming from ecclesiastical artists were speaking a new language, besides displacing zigzags, lozenges, meanders and other geometric designs on archivols and voussures over doors where human forms are now found. High relief stone carving of large size figures are now seen on the façades and on the decorations at the sides of doorways, representing personages of the Old and New Testament. They are done by the best sculptors available. Most of them are clothed in long tunics surmounted by a kind of mantle opening in front and disclosing richly adorned materials, often edged with gold or silver lace. A peculiar feature of these statues is the extreme length of bust, protruding eyes, arched eye-brows, stiffness of movement, all vestiges of the Byzantine style; the same char-
acteristics prevail in bas-reliefs and paintings. They also retain the same Byzantine treatment of Christ enthroned, the right hand in benediction; symbolic representations of the Evangelists surround Him (eagle, angel, lion and ox). His feet rest on a stool (crabellum); waves like water figures sometimes at the side of the stool. In other cases Christ is accompanied only by two angels, one on either side, holding censers and in the attitude of prayer. An altar dedicated to the archangel Michael is sometimes found in large arches, above the central doorway, or above the porch where the latter does not exist. Where the façade boasted two towers we sometimes find one has an altar dedicated to the archangel Gabriel and the other one dedicated to the archangel Raphael. All such holy personages are found nimbed (see Nimbus), as also is the lamb (usually carrying a cross), when representing Christ crucified, and also the dove, when representing the Holy Spirit. Other subjects of iconography of the period are the Sirena (terminating as a fish), Manicora (human head, globular body, tail of fish), elefants (elephant), and numerous other fantastic creature symbols as shown in the contemporary illustrations of the *Bestiary* books. Mural painting was successful in the Romanesque period. The walls and vaults were covered with fresco polychrome work. Unfortunately few have escaped the renovator, but the remnants afford some idea of the work done. Some columns were painted red, some capitals green; the vaults were, of course, sky blue. Proofs survive that often bas-relief figures were painted in a different color to the background, also that clothing was painted and gilded. Scriptural scenes were usual. We find in the church of Saint Savin, in Poitou, depictions of the Holy History and the Apocalypse, history of Saint Savin and of Saint Cyprian, combat of Saint Michael with the dragon. Other mural paintings are at the churches of Saint Julien at Tours, Notre Dame de Rivières, near Chinon; at Tavan, near Ille-Bouchard, etc. Perspective is absent.

Germany and England.—While France is devoid of Romanesque ecclesiastical buildings, a number still remain in Germany, such as those found in Cologne, Lorsch, Aix-la-Chapelle, Germrode, Worms, Hildesheim (see Architecture). In England, Edward the Confessor determined to rebuild Westminster Abbey after Norman style [he had lived in exile in Normandy] and it was finished in 1065. Part of the monastery still exists. There are also other Norman churches in England.

Illuminated Manuscripts.—The manuscripts of the Romanesque period naturally partake of the very numerous stylys found in the Romanesque plastic art. In the luxuriously illuminated books are found border and initial decorative motifs such as palmettes, acanthus leaves, vines, meanders (Grecian key pattern) and wattle work (*lacerine*), or combinations of foliage and geometric figures. This complex interlaced work decoration of manuscripts is quite universal, spreading from the Lombard, Merovingian, Carolingian, Western Gothic manuscript right into the 16th century. Mingled with this involved interlacing is foliation, figures of humans, dogs, fishes, birds, dragons, etc. Repeat motifs, true copies of moldings taken from church edifices, are also often utilized in the manuscripts. The use of architectural motifs includes pillars, capitals, etc., and even extends to the point of absorbing the arch above the pillars. We find also the Oriental horse-shoe form of arch in these illuminated works of the period. Pointed arches also appear in these works centuries before in actual use in buildings (Hunnman). Finally, we have whole sectional views of church interiors, frequently with active human groups displayed. Among the most beautiful Carolingian MSS. are the Sacramentary (about 750) in the National Library, Paris; Ada Codex (about 775) in Municipal Library, Treves; Psalter of Dagulphus (about 780) in Imperial Library, Vienna. In Saint Gall, a magnificent collection of illuminated MSS. is in the Abbey and the Town Hall Library. Some of the masterpieces are the Sacramentary of Gelasiusus (8th century); Golden Gospels of Saint Gall (9th century); Evangelarium Longinquin (10th century). Evangelary of Abbot Angilbert of Centula (about 793) is in Abbéville; Evangelary of Saint Medard of Soissons (8th century) is in the National Library, Paris; Alcuin Bible (about 800) is in British Museum as also is the Golden Gospels of Athelinus (about 850).

Altar fronts (*antependia*) of the richer churches are frequently of gold or silver and made detachable; magnificent examples are that of Saint Ambrose at Milan; in S. Marco, Venice, Basel Cathedral. (See Altar). The Eucharist was preserved in receptacles shaped like towers or doves either suspended or kept in *armoires* (cupboards); they were very beautifully enameled and embellished with relief-work. Altars of the 11th century were often dedicated to several saints and enclosed a number of relics. The credences consisted of niches built into the wall, and are frequently elaborately carved; they are often on the castle side, sometimes on both sides of the altar. They held the altar vessels, liturgical books, etc. The *piscina* into which the water was poured after washing the chalice, etc., was also sometimes in the wall, at other times it stands on legs free near the altar. Baptismal fonts were mostly of stone, a few being of bronze or of lead. They are more or less tub-shaped; some round, some oval, others quarterfoil. They were frequently carved with bas-reliefs, some with columns. Some fonts are mounted on shafts. A peculiar custom of this period was that of erecting very substantial towers in the centre of the large cemeteries surmounted by a lantern in which light was burned at night, a species of beacon. In the base of these towers was the decorated altar at which mass for the buried was read. Some of the tombs of this period were very large elaborately carved architectural monu-
ments, their sides consisting of arched colon-
ades; examples are seen in that of Troyes
Cathedral erected to Cardinal Ivo (1142), and
that of Henry I, Count of Champagne, fo-
rmerly in the church of Saint Bénigne at Troyes.
In the 12th century commenced the practice of
carving an effigy of the deceased for the tomb.
Of such are those of Richard I (Cœur de Lion),
Henry II and his queen at Fontevrault;
painting brings out clearly the draperies of
their costume. Some tombs are heightened
with enamelled copper or silver, as those of
Henry I, formerly at Saint Étienne at Troyes.
Great chandeliers or "crowns of light" were fre-
frequently suspended in the churches of this
period, such as those still existing at Hildes-
heim and Aix-la-Chapelle. See CHANDELIER;
CORONA.

Gothic Period.—The Gothic style of archi-
tecture is frequently termed pointed or ogival,
on account of its pointed or ogive arches.
(See ARCHITECTURE). In the 12th century this
style is in its transitional stage and, therefore,
we find moldings, capitals and column shafts
in Romanesque decoration. The ground-plans
become more and more complex, with numer-
ows excrescences in the interiors, buttresses,
lying buttresses, etc. A great change in the
treatment of architectural ornament in this
style is noticeable. Oriental plant life, chiefly
acanthus, that prevailed during the Byzantine
and Romanesque periods, now gives place to
motifs taken from the European vegetable
kingdom, and conventionalization of such
forms; we now see ivy-leaves, oak-leaves,
roses, willows, leaves of the water lily, straw-
berry plant, ranunculus leaves, and the rounded
leaves of the trefoil, conventional violets.
Crockets break the continuity of lines on angles
or edges, sometimes these crockets terminate
in human forms or the heads of animals.
"Rose" windows take the place of the former
"wheel" windows, and their open spaces are
enclosed in cusps or in trilobate piercing. The

human form, facial expression and drapery, by
the 13th century, takes on softer and more nat-
ural depiction. Generally carved out of
the architectural stone itself, very salient parts
(such as forearms, etc.) are frequently done
separately and attached and fastened by iron
clamps. Statues are usually placed in re-
cesses (niches) and are supported on consoles
(cul-de-lampe) in architecturally designed
canopy projects over the head; the combina-
tion is termed a "tabernacle." The stone-carry-
ing of this period discards former simplicity
and becomes very rich and complex. A favo-
rite subject for treatment is the "Tree of Jesse"
child in her arms, whereas before she was usually seated, the child resting in her lap. In the 15th century sculptured work becomes more pretentious as to pose and drapery but shows "dryness" in execution. The "Father Eternal" is frequent, clothed in the costume of the Pope and wearing his tiara. He holds a large crucifix before him, a dove appearing between the head of the Father and summit of the cross—evidently symbolic of the Trinity. Baptismal fonts assume, for the most part, four pillars as corners, in the 14th century, and, whereas in the 13th and 14th centuries those of octagonal exterior had round interiors, they are in the 15th century given octagonal interiors conforming to the outside form. The fonts of the 15th and 16th century have the basin composed of two parts, one only to hold water; the custom of infant submersion was no longer practised, so the child, placed in the empty section, was sprinkled with water from the other. Some fonts of this period have a form somewhat resembling a great chalice, the exterior of the basin flares out upward into octagonal cup shape, an octagonal short length of shaft beneath supports the basin on a flaring base. One of these, in Basel Cathedral, is elaborately carved; eight panels disclose biblical subjects in relief, with a border above of foliage, the shaft is pierced with octagons, the base has Gothic mullioned traceries and eight reclining human figures at the corners. Saint Sebal's separating the nave from the choir and supporting the roof-loft or gallery. One of the most magnificent is that at A, composed of white stone; other noted ones are at Folgoat, Brou, Troyes and other French churches. Some are constructed of carved wood. Until the 15th century but few pulpits are met with, such as those of Strassburg and Freiburg; those of Saint Lo and Vitre (St. A.) are outside the church for outdoor exercises. They have very elaborately carved canopies in architectural design. Among the most prominent of the interior fittings of the church are the "stalle." They are generally of intricately carved wood-work, and served as seats for the members of the choir. They are separated by arms, and the seats are constructed so as to be turned up during that part of the ceremonies in which the celebrants are in standing posture. Beneath the seat is a flat-topped projection which, when the seat is upturned, serves as a slight rest during prolonged standing. These console-shaped rests are termed "misericordes," and had, generally, carved work of the most grotesque character. The backs of the stalls are high up, to keep off draughts, and were also used architecturally and had beautiful canopies or hoods. Examples of great beauty exist at Amiens, Saint Martin-des-Bois, Rouen. For some unknown reason, both the monks and lay woodcarvers allowed themselves much license in depicting grotesque figures, both human and animal, in uncouth postures, little appropriate to the solemn ceremonial occasions for which they served. Another important piece of church furniture, usually of carved wood, was the lectern or reading desk. It generally took the form of an eagle whose spread wings acted as support for the book.

"Stained Glass Windows."—Up to the Gothic period the painted mural decoration required a fairly strong light, and that colorless as possible, for its appreciation; therefore stained glass was not in over-frequent use. Now, however, the talents of the artist in glass work come into full use. Stained glass in windows from the 13th century and for a long time thereafter were of medallion form such as quarterfoil, lozenge, circular, elliptic, etc., symmetrically disposed over a ground of mosaic, with borders of strapwork, crockets of foliage. Green, red and blue predominated, yellow, brown, etc., being used sparingly. Grisaille decoration also appears (this is a pattern of gray or black strapwork, on white). The fashion spread rapidly and human figures soon were the usual motifs; bishops, abbots, barons and knights who were the election were commonly depicted, their appended names acting, at the present day, as date authentications. Stained glass windows dating from the later centuries are, of course, the more common; and the date of production is the easier of verification from the fact that much of the detail is given over to architectural decoration, which changes as the Gothic periods advanced from primitive or (Early), Pointed (or pure), to Florid (or Flamboyant). Fine examples are the following: Of the 13th century (Early Gothic), shrines at Chartres Cathedral; those in the cathedrals of Le Mans, Bourges, Poitiers, Rouen, Chalon-sur-Marne, Angers, Laon, Coutances, Beauvais, Rheims, Sens, Tours, Auxerre, Troyes, Amiens, Notre Dame de Semur, Sainte Chapelle and
Notre Dame, in Paris; the Becket windows in Canterbury Cathedral and those of York, Lincoln and Salisbury. Of 14th century (or late Gothic), are those in Gloucester Cathedral, Tewkesbury Abbey, Merton Chapel and Saint Michaels (both in Oxford), in the churches at Willesborough, Selting, Chatham, in York Minster, cathedrals of Bristol, Exeter, Wells, Ely and Lincoln. In France are windows of that century in the cathedrals of Evreux, Sées, Beauvais, Nantes, Narbonne, Toulouse, etc. In Germany are those at the cathedrals of Cologne, Strassburg, Regensburg, Augsburg, Erfurt, etc. In Italy are examples in the cathedral of Saint Francis of Assisi, and Santa Croce and Maria Novella in Florence, etc. Of the 15th century (or Late Gothic) specimens of note are those in the Minster, All Saints, Saint Michael’s, Saint Martin-le-Grand, all in York; in Westminster Cathedral; Saint Stephen’s Chapel, Westminster (London); Saint George’s, Windsor; and in many county churches. In France are those in Rouen Cathedral, Le Mans Cathedral, Lady Chapel of Evreux Cathedral, Bourges Cathedral, church of Saint Severin, Paris. In Germany they are found in the cathedrals of Munich and Ulm and Saint Lorenz at Nuremberg.

Paintings and Sculptures.—Niccolò Pisano, who founded the Pisano school, did the sculpture and "Deposition" at the cathedral of Lucca (1233), then the pulpits of the Baptistery at Pisa and the cathedral at Siena; the shrine (ara) of Saint Domenic at Bologna. Arnolfo, Niccolò’s pupil, did the Gothic ciborium at S. Paolo fuori le Mura, Rome (1253); Giovanni Pisano did the marble shrine of S. Donato in the cathedral of Arezzo, the pulpits of Pistoja Cathedral (1301) and that at Pisa Cathedral. Andrea Pisano did the bronze doors of the Baptistery of Florence (now removed and replaced by Ghiberti’s ‘Gate of Paradise’) and many bas-reliefs on the Campanile. Orcagna started the shrine of the Madonna of Orsanmichele, to be finished by Ugolino. Agostino and Agnolo of Pisano did the tomb of Guido Tarlati, bishop of Arezzo (in the cathedral); Pietro de Stefani did the Gothic altar of Minutoli, Naples. Andrea Ciccone created the Gothic tombs of Ladislas of Hungary (1414) and of Ser Gianni Caraccio, both at S. Giovanni a Carbonara. Giotto did the mosaic in the Navicella di S. Pietro, Rome, painted the wall decorations in the chapel (Bagello) at Florence (‘History of St. Mary Magdalene’), also the frescoes in the chapel of the Arena, Padua, 28 large frescoes in the Assisi Upper Church and five in the Lower Church; ‘Coronation of the Virgin’ in S. Croce, Florence; ‘Agony in the Garden’ in the Uffizi gallery; the crucifix in the chapel of the Ognissanti, etc. (d. 1337). Pietro Cavallini, of Rome (1259-1334), did the ‘Crucifixion’ in the Lower Church of Assisi; Taddeo Gaddi created the frescoes in the chapterhouse of S. Maria Novella (now Capella degli Spagnuoli) and others in the southern sacristy of the S. Croce. Giovanni di Milano did the great altarpiece in Ognissanti, as well as the frescoes (about 1371). Duccio di Buonensegna (1310) painted the cathedral altar at Siena; Simon de Memmo, in 1332, started painting fresco in the chapterhouse of S. Spirito, Florence, in 1333 did the ‘Annunciation’ for Siena Cathedral (now in Uffizi palace) assisted by Lippo di Memmo; in 1317 he did the fresco Madonna in Santa dei Consegni, S. Gimignano. Pietro and Ambrogio of Lorenzo flourished middle of the 14th century; the former did the ‘Fathers of the Desert’ fresco in Campo Santo, Pisa, and Ambrogio did the allegorical frescoes of the Sala delle Balseire (Palazzo Pubblico). Taddeo di Bartolo did the painting in the chapel of the Palazzo Pubblico (1414).

Bells.—Pope John IX, about 900, ordered bells to be used in churches. Early so-called ‘Theophilus’ bells are in Augsburg Cathedral, Halberstadt, etc. That at Erfurt dated 1497 weighs 13 tons 15 cwt. The greatest bell, called ‘Czar Rotol,’ at Moscow, was cast in 1736, but fell to the ground and broke in 1737; it serves as a chapel. The weight is about 193 tons. But most of the very large bells are for municipal or other civil, not ecclesiastical, purposes. An interesting 15th century bell is that to-day in the church of Saint Pierre at Gaillac, but formerly in Candell Abbey (France). Its upper inscription is in beautiful Gothic letters, nearly two inches high, starting with a Paschal lamb in bas-relief and above it a cross pattée in a circle; the second inscription is in smaller letters, also Gothic. In the middle of the body is the monogram of Christ (IHS) encircled by 14 flames.

Manuscripts.—Of illuminated manuscripts of this period the most noted German Gothic are: The Salzburg Missal (about 1530) in Munich Royal Library; Passionale of Abbess Cunigunde (1312) in University Library, Prague; Oplontis (same date) in same library; Bible of Emperor Wenzel in Imperial Library, Vienna; Gospels of John of Oppavia (1368) in same library; Würzburg Bible (about 1400) in British Museum; Missal of Emperor Frederick III (1448) in Imperial Library, Vienna; Gospels (1498) in Public Library, Nuremberg; Choir Book of SS. Ulrich and Afra, Augsburg
ECCLESIASTICAL ART

(1489), in Augsburg Library; Prayer Books of Albert of Brandenburg, William IV of Bavaria; Horne (late 16th century) in British Museum. Anglo-French works are Psalter of Queen Ingeburga (1193-1236) in National Library, Paris; Psalter of Queen Blanche (about 1220) in

Renaissance Period.—The discovery of the manuscripts of Vitruvius, the work of Alberti and of Brunelleschi and other Italian architects together with other influences brought into favor a revival of the Classic antique in art. It really meant the rebirth of Paganism in Christendom, and as such the ecclesiastic world accepted few religious structures to be so built in the 15th century; in fact, even in the 17th century Gothic architecture was employed largely in church construction, though civil buildings were erected in the new style. As to church plans, they will be found treated in the article ARCHITECTURE. Concerning ornament in the places of worship, the most lovely stone carving was done on designs of the greatest delicacy and perfect artistic character. Panels and friezes, pilasters and other architectural members were all covered with a profusion of decoration in animal and vegetable motifs in conventional form scrolled and interlacing in capricious but entrancing beauty. They are the Mohammedan Arab conceptions transferred to Italian art ideals and termed by them arabesques. They have not the slightest tendency to the canons of ecclesiology, nor do they touch upon Biblical lore. The 16th century pulpit in Basel, Switzerland (see illustration), afforded a good conception of the blending of Gothic cusps, flamboyant traceries, quatrefoils, etc., into a Renaissance adaptation for a beautiful piece of church furniture. The arts of painting and sculpture of this period are represented by such transcendent genius as that of Raphael and Michelangelo. But such art subjects are treated in other articles as painting, sculpture, etc.; they scarcely belong to the present topic. For further special church equipment see ALTAR, BASILICA; CHALICE; CROSSES AND CRUCIFIXES; CORONA; CHANDELIERS; CATHEDRALS AND CATHEDRALS; COSTUME, ECCLESIASTICAL; GOLDSMITHING.

ECCLESIASTICAL COMMISSIONERS—ECCLESIASTICUS

CLEMENT W. COURBE.

ECCLESIASTICAL COMMISSIONERS, for England, are a body corporate with a common seal, perpetual succession and power to hold real estate, constituted by acts 6 and 7 Will. IV, chap. lxxviii, 3 and 4 Vict. chap. xcviii and 13 and 14 Vict. chap. xciv. It consists of all the bishops of the Church of England, the deans of Canterbury, Saint Paul's and Westminster; the chief justices, five cabinet ministers and other legal dignitaries and 12 lay members appointed by the Crown and the archbishops of Canterbury. This body has extensive powers in regard to the organization of churches, the distribution of episcopal duties, revenues, etc. The schemes adopted by the commission, on being laid before the king in council, approved of and gazetted, acquire the force of acts of Parliament. The dean's salary and revenue from an endowment furnished by the wealthiest sees. Consult Whitehead, 'Church Law' (London 1892).

ECCLESIASTICAL COSTUMES. See Costume, Ecclesiastical.

ECCLESIASTICAL CROSSES. See Crosses and Crucifixes.

ECCLESIASTICAL TITLES ASSUMPTION ACT, a law of the British Parliament, enacted in 1850 (14 and 15 Vict. chap. 60) to prohibit, under penalty, the assumption of ecclesiastical titles (for example: Archbishop of Westminster, bishop of Clifton, dean of Sheffield) by any persons not duly appointed to such stations according to the laws of the realm touching the Church establishment. There was already in the statute book a law of 10 Geo. IV, chap. 7, which provided that any person who should assume or use the name, style or title of archbishop of any existing ecclesiastical province, or bishop of any existing diocese, or dean of any existing deanery of the Established Church of Great Britain and Ireland, the same not having due legal right to such name, etc., should for each violation of the act forfeit £100. But in the year 1850 Pope Pius IX, by apostolic brief, instituted an ecclesiastical province or archbishopric comprising all England and Wales, with Nicholas Wiseman (afterward cardinal) as archbishop, with the style and title of archbishop of Westminster and with 12 suffragan bishops praebendaries over dioceses named: Beverley, Birmingham, Clifton, Hexham, Liverpool, Newport and Menevia, Northampton, Nottingham, Plymouth, Salford, Shrewsbury and Southwark; none of these towns was then the see of any bishop of the Church of England. They had the jurisdiction of the statue of George IV did not apply. But the announcement of the setting up of these Roman Catholic dioceses provoked a fierce anti-papal agitation and the Prime Minister, Lord John Russell, introduced in the Parliament a bill, which was speedily passed, extending the penalty of the act of George IV to persons who should assume the titles archbishop, bishop or dean in any place within the United Kingdom. The new dignitaries ignored the act, assumed their titles, brazen procedure and not one of them was ever called into court for contumacy. After the act had stood on the statute book as the law of the realm during 20 years it was annulled by an act of 34 and 35 Vict. chap. 53. The penalty was dropped, but the so-called repealing act recited against the legal grounds for the penal enactment and declares that "no ecclesiastical title of honor or dignity derived from any see, province, diocese or deanery recognized by law, or from any city, town, place or territory, within the realm can be validly created"; and that "no pre-eminence or coercive power can be conferred otherwise than under the authority of Her Majesty"; decisions of law that had never been impugned in England since the time of Henry VIII.

ECCLESIASTICUS. One of the deutero-canonical books of the Old Testament. It is found in the Greek Bible and its daughter versions, in the Latin Vulgate, and in Syriac manuscripts, and recognized as a part of the canon of the Orthodox churches, but not included in that of the Palestinian Jews, and therefore counted as apocryphal by Jerome and other Church fathers as well as by the Protestants, and withdrawn from public use in the Greek Orthodox churches of Russia, Serbia and Bulgaria. The title is a transliteration of the Greek ekklesiastikos which is the superscription in Cod. 248. It has been plausibly explained, on the basis of a statement by Rufinus, as derived from the custom of referring to books used in the Church, but not in the synagogue, as *libri ecclesiastici*, or *ecclesiastical reading-books,* this designation attaching itself permanently to the one especially employed in the moral instruction of the catechumens. In the Greek Bible it is called "The Wisdom of Jesus son of Sirach" or "The Wisdom of Sirach"; Clement of Alexandria and others speak of it as "The Pedagogue" or "The Teacher of all the Virtues" (Panaretos). From the prologue to the Greek translation of any extant manuscripts originally written in Hebrew. Jerome states, in his preface to the Solomonic books, that he found a Hebrew copy of Ecclesiasticus, united in one volume with Canticles and Ecclesiastes, entitled "Proverbs." Rabbits of the Talmudic period frequently refer to it under this title, or as "The Wisdom of Ben Sira," or simply as "Ben Sira." About 80 quotations, many of them from the Babylonian Talmud, five from the Palestinian Talmud and a number from other Jewish sources down to the 11th century, have been gathered. Not infrequently it is quoted as "Scripture," showing that, in spite of its exclusion from the Palestinian canon, it still had some sort of recognition, especially in Babylonia, similar to that which it enjoyed in the Church. So many passages of the book, known of copies provided with vowels-points and accents like the biblical books. Too much must not be inferred from this, however, as he alludes to other writings similarly treated and mentions it in defense of having thus pointed out one of his own books. As late as in the 11th century the Hebrew text was known...
to Nissim ben Jacob of Kaifawan who spread in the first third of Sura. The so-called "Alphabet of Ben Sira," translated by Lagus and published with a commentary by Drusius, is only in part composed of genuine quotations from the book. For many centuries neither Jews nor Christians had any further knowledge of the Hebrew original; and only in recent years scholars ventured the opinion that the passages quoted had been translated from the Greek or the Syriac.

The recovery of extensive portions of the lost Hebrew text between 1585 and 1900 was, therefore, as unexpected as it was welcome. Fragments of four manuscripts, covering approximately two-thirds of the work, were discovered. Though the first leaf was brought from Palestine by Mrs. Agnes Lewis Smith, the discovery is rightly connected with the name of Solomon Schechter who surmised whence it came, gained permission to examine the genus, or hiding-place for worn-out copies of the Scripture and books not approved for use in the synagogue. In 1857 a large part of its contents, and identified most of the leaves. The manuscripts seem to come from the 11th and 12th centuries. It is of considerable value that they occasionally overlap, so that in some cases two, for instance, 1:13, 1:14, and 2:28, are available, especially as they have the appearance of exhibiting to some extent two different recensions of the text. On the other hand, it is to be regretted that so many parts are still missing. Among these is the fine poetic description of wisdom in chap. xxvii, the Hebrew text of which was conjecturally restored by Lowth and Fritzsche; of chap. I, Fritzsche's translation can now be compared with the original, and the measure of success and failure is highly instructive.

The contention of Margoliouth that the discovered manuscripts represent a translation from the Greek made by a Persian Jew slightly acquainted with the Syriac version has not commended itself to other scholars. But there are three, no doubt, descendants of the Hebrew original, they are late copies and have manifestly suffered much in transmission. It is not inconceivable that some changes and additions may be due to a version which, as it is preserved, is in a second recension of the Hebrew text before the Syriac translation was made. The Persian glosses in the margin of one manuscript only indicate the home or nativity of the copyist.

For some parts we are still wholly dependent upon the versions; and the earliest Greek translation remains our oldest testimony to the original text of the whole book. It is possible to show that the translator had insufficient knowledge of both Hebrew and Greek, a failing he shared with other translators of biblical books, but there is less reason for charging him with negligence or arbitrariness than for crediting him with quite unusual efforts to master the Greek language and to acquire a distinctive style. As a result, he has been accused of being a forger. It is extraordinary that we are far from having an autograph copy of his work. It can only be approximately restored by a critical use of the Greek manuscripts, such versions as the Old Latin, Coptic, Ethiopic, Armenian, Syro-Hexaplaric and Old Slavonic, and patristic quotations. When this material is closely examined, the peculiarities of the text that demand an explanation. All exist Greek manuscripts (including Cod. 248, as Rssel and Bollig have verified), as well as the Coptic, Ethiopic, Armenian and Syro-Hexaplaric, have suffered from a dislocation of xxxii, 13 bc; xxxiv, 1-xxxvii 1 line; the original race between xxx, 24 and xxx, 25; while the Old Latin and the Old Slavonic (probably influenced by the Latin Vulgate) have preserved the order exhibited in the Hebrew and the Syriac Peshita. A number of Greek manuscripts, headed by Cod. 248, printed in the Complutensian Polyglot, the Old Latin, and quotations in Clement of Alexandria and Chrysostomus present a longer text, while the uncials codices and another group of minuscules are free from these additions. Yet in some other respects the former group comes much nearer to the original than the latter. Noldeke first suggested, and Smend, Hart and Oesterley have developed, a theory that may explain these remarkable facts. It is supposed that a secure text, as it has come down to us, existed in the 2nd century A.D., based on the earlier version, but containing also a considerable number of additions freshly translated from the second, expanded edition of the Hebrew text. This would account for the presence of these additions both in the Old Latin and in the manuscripts and versions having the dislocation. The manuscript in which two layers of 160 stichs were put in a wrong place would be later than the Old Latin, and of such authority as to affect all subsequent copies. It may be surmised that it was Origen's, and that he allowed the additions to stand, though indicating with his usual sign that he did not regard them as belonging to the original Hebrew text. In the uncials and a group of minuscules they were not copied in deference to his direction; in other manuscripts his sign was wholly disregarded. The relative excellence of Cod. 248 in other respects would be due to some good codex from which it was copied.

Concerning the date of the first translation we are unusually well informed. In his preface the translator tells us that he came to Egypt in the 38th year of King Euergetes. Ptolemy III Euergetes reigned only 26 years (247-221 B.C.). Ptolemy IX Euergetes came upon the throne in 170 B.C., and though his reign was twice interrupted, he counted his regnal years from the original accession. There is nothing peculiar about the phrase that is used, as it is found elsewhere in the Greek Bible and in Egyptian papyri of the time, and the objection of Hart that, on account of this king's hostility to foreigners, no Jew would be likely to emigrate to Egypt in his reign is not of sufficient weight to throw doubt upon the national import of the statement. It was consequently in 132 B.C. that the translator arrived in Egypt. His sojourn there had "synchronized" with the remainder of Euergetes' reign, when he "found a book of no little learning or one of the most famous books that had been translated which seemed to him of no small pedagogic value. It appears, therefore, that it was in the time of Ptolemy X Philometor, called Lathyrys (117-106 B.C.), that he undertook to translate this book which he ascribed to his grandfather,
into Greece, fully realizing the difficulties of such a task. His preface is invaluable as a means of determining approximately the date of the original work, and also because it shows that in the time of John Hyrcanus (134-104 B.C.) not only the Law, but also some prophets and other religious books had been rendered into Greek. His description of his grandfather's intention to write a book of the same kind as those he had mentioned, and calculated to serve the same end, and his own manifest purpose to give his translation a place among the other versions by his fellow-countrymen in Egypt, throw an interesting light on the slow development of the idea of a canon. In the Complutenian Polyglot another preface of an unknown author was printed. As substantially the same text has been found in the synopsis of biblical books wrongly ascribed to Athanasius, it has been supposed that it was taken from this source. But the reverse is also possible. It is of uncertain age. The translator's name may have been Jesus, and his grandfather's work may to some extent have been a compendiation of the statements in the place. There is no evidence of this. The Old Latin was not made from the Hebrew, as Sabatier and Bengel attempted to prove. In this version, chaps. xlv-11 were not translated by the same man, or in the same country, as the first part of the book. This section is not found in the Armenian version; and there are other indications that it once circulated separately. That the Syriac was from the Hebrew was already suggested by Cornelius a Lapidea, and seen more clearly by Benzemann in 1789; but Bickell and Smend have recognized that it has frequently been corrected with the aid of the Greek. The order of the text in the Old Slavonic renders it probable that this translation has been corrected with the assistance of the Latin Vulgate. This version itself represents only the Old Latin, since Jerome confesses that he "spared" his pen when he came to Ecclesiastical. The Arabic version was translated from the Syriac Peshita. The translator distinctly states that his grandfather's name was Jesus. He probably also wrote the superscription designating the work as "The Wisdom of Jesus, son of Sirach." Before the Hebrew text was discovered, it has been inferred that Jesus was the son of Eleazar, and that Ben Sira was the family name. The Syriac reading in this passage: "Jesus, son of Simeon Bar Sira" was puzzling, and even more so Saadia's reference to the author as "Simeon, son of Jesus, son of Eleazar Ben Sira." But the latter is precisely what we find three times in the Hebrew text (1, 27; li, 30 a b). Most interpreters explain Simeon, son of as due to the carelessness of a copyist, who, having Simeon on his mind since he wrote 1, 1, abstemiously inserted the words three times in the colophons before the name of the author of the book, and some editors have had such confidence in this explanation that they have simply removed the name of Simeon from the Bar Sira. However, 1903 proposed to accept the statement in the colophons on the assumption that it referred solely to the Praise of Famous Men (xlv-1) which may have circulated separately at an early time in Palestine as it did afterward elsewhere and may have been written by Simon, a generation later than the original work composed by his father, Jesus Ben Sira. He was confirmed in this view by the very close correspondence between the description of Simon the high-priest in 1, 1 ff. and that of Simon, the Hasmonean high-priest, in 1 Mac. xiii-xiv. The achievements of the former are also recorded of the latter, and the language used is strikingly similar. Simon is called in Ecclesiasticus "the greatest of his brothers, the glory of his people" (cp. 1 Mac. xiv, 4, 5, 26, 29); in his days "the Temple was greatly honored" (cp. 1 Mac. xiv, 15) and "the temple was fortified" (cp. 1 Mac. xiii, 52); "the wall was built" (cp. 1 Mac. xiv, 37) and "the battlements of the fortress on the temple hill were constructed" (cp. 1 Mac. xiii, 52); "he cared for his people against the spoiler" (cp. 1 Mac. xiv, 4) and "fortified his city against the enemy" (cp. 1 Mac. xiii, 33; xiv, 37); and he was entitled to wear "robes of honor" and "vestments of beauty" more glorious than those of his predecessors (cp. 1 Mac. xiv, 44). If Simon the Hasmonean added the closing prayer for the preservation of the high-priesthood in his family and the reference to the promise given to Phinehas is significant. The priests and the people had made Simon's pontificate hereditary (1 Mac. xiv, 41). But a high-priest marching sword in hand against the enemy was a new type that had to be justified by the example of Phinehas (Num. xxv, 6). The promise of an everlasting priesthood as a reward for such zeal helped to legitimize the new pontificate of the family, and the emphasis shifted for a while from Aaron and Zadok to Phinehas (1 Mac. ii, 26; Ps. cv, 30). The Hebrew text in xiv, 24 ff. even suggests that the pact with Phinehas included also the covenant with David, consequently such a union of princely and high-priestly dignity as was first accorded to Simon the Hasmonean. Against this interpretation it may be urged that this Simon was the son of Mattathias, son of Johanan, while the Simon described according to the Hebrew text, son of Johanan (Greek Onias). But the Syriac has Nenethiah, and in the Ethiopic the father's name is not given at all. The original may have read only Simon, the high-priest. Scholars generally, however, have identified him either with Simon I, who is supposed to be a contemporary of Ptolemy I, or with Simon II, who lived in the time of Antiochus III. The former has, as a rule, been identified with Simon the Just, and it has been thought that he may have repaired the temple and built some wall destroyed by Ptolemy I. Of this there is no evidence, and a man who came to Egypt in 132 B.C. cannot have had a grandfather who lived in the beginning of the 3rd century B.C. Simon II may indeed have been a contemporary of Jesus Ben Sira. Josephus ('Antiquities,' xii, 138 ff.) quotes a letter from Antiochus III to Ptolemy V, in which he informs him that he is resolved to confer certain gifts on the Jews for sacrifices and repartition, and to exempt them from certain taxes. But he does not even suggest that these promises were ever kept, and makes no mention of Simon in connection with them. Grätz deemed it impossible that this "Law-despising Hellenist" could
have been the object of so much praise; but some scholars hastened to deny the existence of Simon I, and maintained that Simon II earned the deeds recorded in Ecclesiasticus the surname of "the Just." In reality Simon the Just is a very shadowy figure. The Talmudic statements concerning him are so contradictory and mixed with other legends as to be wholly unverifiable. Grothius supposed that chap. li. was written by the grandson of Jesus Ben Sira; and the colophon at the end of chap. I certainly indicates that it is a later addition; but as it exists in the Hebrew, it is more likely to come from some earlier owner of the manuscript. The hymn interpolated after vs. 13 may have been written much later. Galmet and others have been struck by the apparent allusions in ch. xxvii to the persecutions of the Maccabean period; they may have come from the hand of Simeon. The work of Jesus Ben Sira, probably completed about 175 B.C., had received more or less extensive interpolations when it was found by his grandson in Egypt, is now widely recognized as was suggested in the second preface, that the book was a compilation, and this view has been held by many scholars. It is supported by the analogy of Proverbs. Gfrörer maintained that ch. xxiv was copied by the author in Egypt. Ewald thought that only one of the three parts into which he divided the book was written by Jesus Ben Sira. Some sections have the appearance of being anthologies of gnostic sayings. They may have been taken from lips of the people, heard in the conversation of sages, remembered from earlier reading, or copied from manuscripts; but the author undoubtedly wrote much himself, and his work became impressed with his own view of the world. Lowth recognizes its poetic character, and its metrical structure has been recently studied by Bickell, Schloegl, Peters and others. John Billings was a diligent student of the older biblical books. He was well acquainted with Proverbs and Job, but apparently not with Ecclesiastes. His theological views are substantially those of the Sadducees. He has no place for angels. Those mentioned in Job xxxiii, 24; Kings xxviii, 3; and Deuteronomy xxxii, 8, become, in his rationalistic interpretation, respectively a physician, a plague, and a ruler. He recognizes no devil or demons. He thinks that "divinations, soothsayings, and dreams are vain" (xxxiv, 5), he indulges in no speculations as to the future; he has no Messianic hope. He is convinced that "the son of man is not immortal." In his conception of God, his wisdom revealed in all his works, his goodness that leads to repentance, and his fatherhood are emphasized. In xlii an interest is taken of the cult, and an enthusiastic loyalty to the high-priesthood, manifest themselves that are not seen elsewhere in the book. The author of these chapters probably lived to see a most glorious high-priest through whom the promises to David had also been fulfilled. Ecclesiasticus is in many ways a reflection of the cult, and the book as a whole is a protest against the sacrifice of the cult, and an attempt to replace it by a study of the Hebraic antiquity. It teaches a man how to govern his wife, his children and his slaves; how to deal with his friends and his foes, his superiors and his inferiors, his creditors and his debtors, the rich and the poor; how to behave at the banqueting table and in the house of mourning, in the temple and in the market-place; how to control his passions, practise moderation, cultivate nobler tastes, emulate the example and seek the company of the wise. His moral philosophy is utilitarian and individualistic. The motive is the happiness of the soul of mankind, will bring, while the welfare of others is not urged as a consideration. He lays down rules rather than principles, and his work is a noble attempt to commend to the young a righteous and well-ordered life.

Bibliography. — The commentaries of Venerable Bede, Rhabanus Maurus, Lyranus; Jansenius of Gand, Camerarius, Palacios de Salazar, Hoeschel, Drusius, de Pina, a Lapide, Grotius, Calmet, Bretschneider, and especially Fritzsche, O. F., 'Die Weisheit Jesus Sirach's' (1859); Ruska, E., 'L'Ecclesiastique' (1878); Bissell, A., 'The Apocrypha' (1880); Lesèpere, P., 'L'Ecclesiastique' (1880); Edersheim, A., 'Die Apocrypha' (1888); Zöckler, O., 'Die Apokryphen des Alten Testamentes' (1891); Levi, in 'L'Ecclesiastique' (1890); Bissell, V., 'Die Apokryphen des Alten Testamentes' (1900); Knabenbauer, J., 'Commentaries in Ecclesiasticus' (1902); Peters, N., 'Der jüngst wiederentdeckte Hebräische Text des Buches Ecclesiasticus' (1902); Schmidt, N., 'Ecclesiasticus' (1903); Smend, R., 'Die Weisheit des Jesus Sirach' (1906-07); Oesterley, W. O. E., 'Ecclesiasticus' (1912); Box, G. H., and Oesterley, W. O. E., 'Sirach' in Charles, R. H., 'The Apocrypha and Pseudepigrapha of the Old Testament' (1913). T. libris apocryphis' (1789); Gfrörer, A., 'Philos' (1831); Ewald, H., in 'Jahrbücher für die biblische Wissenschaft' (1865); Otzat, H., 'Fränkel's Monatsschrift' (1872); Cowley, P., and Neubauer, A., 'The Original Hebrew of a Portion of Ecclesiasticus' (1897); Schechter, S., and Taylor, C., 'The Wisdom of Ben Sira' (1899); Herkenne, H., 'Beiträge zum Alten Ecclesiasticus' (1899); Nöldke, T., in 'Zeitschrift für alttestamentliche Wissenschaft' (1900); Hart, J. H. A., 'Ecclesiasticus' (1909); Buttenwieser, M., in 'Journal of Biblical Literature' (1917).

NATHANIEL SCHMIDT, Professor of Semitic Languages and Literature, Cornell University.

ECCLESIOLOGY, the science of the Church as an organized society, a branch of knowledge which deals with ecclesiastical antiquities, buildings, rites, vestments, organization, principal features and divisions.

ECCLESTON, Samuel. American Roman Catholic prelate: b. Kent County, Md., 27 June 1801; d. Georgetown, D. C., 21 April 1851. He was educated in Saint Mary's College, Baltimore, and ordained to the priesthood of the Roman Catholic Church in 1825. He subsequently served Saint John's College for many years as president and principal; became archbishop of Baltimore in 1834; and established the College of Saint Charles in 1850. He was president of five provincial councils and inaugurated the movement which resulted in the laws for the transmis-
sion of church property from a bishop to his successor and for the excommunication of any Roman Catholic who, after being divorced by the State, should marry again.

**ECDYYSIS**, the process of casting the skin (see **MOLTING**). The term is used mainly in reference to the exuviation of the pupa of insects and of the outer cuticle of lower invertebrates, as crabs.

**ECHARD**, or **EACHARD**, Laurence, English clergyman and historian: b. Barsham, Suffolk, 1670 (?) ; d. Lincoln, 16 Aug. 1730. His *History of England from the First Entrance of Julius Cesar and the Romans to the End of the Reign of James the First* (1707) contains a wealth of information, including the particulars of Cromwell's interview with the Devil on the morning of the battle of Worcester. Other historical and scholarly works increased his reputation.

**ECHEGARAY, José, hó-sa' á-ché-gá-ra'é.** Spanish dramatist: b. Madrid, March 1833. He is author of several treatises on mechanics and civil engineering, and was for a time Minister of Commerce and of Public Instruction. Since 1838 he has been a poet. Production of *The Avarice's Bride* opened a new and brilliant life for the Spanish stage, he has given himself wholly to the drama; producing in a few years 70 plays rich in imagination, dramatic force, and lyric talent. In 1904 he was presented with the Nobel Prize for literature by the Swedish Academy. Of his greatest pieces may be named *The Great Galeoto*; *Madman or Saint*; *Conflict Between Two Duties*; *A Merry Life and a Sad Death*; *Mariana* (1892); *The Son of Don Juan* (1892), based on, and identical in theme with Ibisen's *Ghosts*; *The Stigma* (1895); *The Madman Divine* (1900); to Americans the best-known work with *El gran Galeoto* (Eng. trans. by Charles F. Nirdlinger). It was produced on the stage by Mr. and Mrs. Walker at the Proctor's Theater in New York, and in 1890, was produced by Mr. and Mrs. James A. Connell in Boston. *The World's Wife* and its sequel, *The World's Wife and His Wife*. (See *Great Galeotto*, The; Son of Don Juan, The.) Consult Vezinet *Les maîtres du roman espagnol* (Paris 1907); L. Antón del Olmet and A. García Caraffa, *Echeagaray* (Madrid 1912); H. de Curzon *Le théâtre d'Echegaray* (Paris 1912); and S. Zacher, *Don José Echeagaray* (Berlin 1892).

**ECHELLENSIS, Abraham, Maronite scholar: b. Ekhel in the Maronite country of Mount Lebanon; d. 1664. He was a graduate of the College of the Maronite nation at Rome, and was called to the chair of Syriac and Arabic in the College of the Propagandists and later at the College of France. From 1636 till 1642 he was engaged in Paris in making Arabic versions of books of Scripture for a Polyglot Bible; afterward, from 1652 till his death, he was employed in similar work under the auspices of the Congregation de Propaganda Fide at Rome. He made Latin translations of numerous works in Arabic.

**ECHERON, ésh' é lôn** (Fr. *a ladder or stepping stone*), used in military language. A battalion, or regiment, marches *en écheron, or par écheron*, if the divisions of which it is composed are placed side by side but run parallel lines. The divisions are not exactly behind each other, but each is to the right or left of the one preceding, so as to give the whole the appearance of a stairway. This order is used if the commander wishes to bring one part of a mass sooner into action and to reserve the other. If the divisions of the *écheron* are battalions, these are generally from 100 to 200 steps from each other. An *écheron* is said to be direct if its head maintains a position perpendicular to the original line, as in direct attack or retreat; it is said to be oblique when it deviates from the line, as in changing the order of formation.

**ECHENIQUE, á-chá-ne-ká, José Rufino.** Spanish-American soldier and statesman: b. Puno, Peru, 1808; d. Arequipa, 18 Oct. 1879. He joined the Patriotic party as a boy, rose to the rank of colonel and induced the revolted troops of Gamarra and Bermudez to return to their allegiance in 1833; at the battle of Yungay 1839, he fought on the side of Vera Cruz; in 1843 he was a member of Castillans council of state, and in 1851 was elected President of Peru. In 1854 he was charged with financial irregularities and Domingo Fisas led a revolt against him which terminated in the battle of Saraju 1854. He was defeated in a second revolt at the bridge of Iscuchacha, 2 Aug. 1854, retired again defeated at the battle of La Palma, 5 Jan. 1855, and driven into exile. He was permitted to return in 1862, was elected deputy and later chosen president of the senate. He was even a Presidential candidate in 1872, but spent the last years of his life in retirement.

**ECHEVERRIA, á-chá-vá-re'é, Esteben, Argentine poet: b. Buenos Aires, Argentina, 1809; d. Montevideo, Uruguay, 1851. He was educated in France, and his early works showed that influence, but he afterward became more national. He was exiled by the Dictator Rosas and went to Montevideo, where he died. Among his works, which are in great repute among his countrymen, are *Consuelos* (1834); *Rimas*; *Cautiva* (1837), containing delightful descriptions of the pampas; *Guitarrá* (1842); and *La Insurreccion del Sur*. Complete works were published at Buenos Aires in 1874, in five volumes, under the direction of Juan Maria Gutierrez, an Argentine man of letters.

**ECHIDNA, or SPINY ANT-EATER**, an Australian monotreme animal of the family *Echidnidae or Tachyglossidae*, closely related to the duckbill, but very different in outward appearance. Echidnas are spiny, porcupine-like creatures, 12 to 18 inches long, with broad bodies, stout legs terminating in large, strong claws well suited for digging, and a small head, ending in a slender snout. The male has spurs like those of the duckbill. The mouth is toothless but the palate bears a number of recurved spines, which answer the purpose of teeth, the tongue is extensible and glutinous. The animal resembles the hedgehog in that it curls up when in danger, presenting its long spines, and protecting by this method its naked belly. It lives in burrows and feeds chiefly on the juicy larvae of ants, into whose hill it digs with its great claws. Like the duckbill, the echidna lays eggs. The period of gestation is about four weeks. The eggs (rarely more than two), when laid, are carried in an abdominal pouch. In another two weeks they hatch, and the young are carried in the pouch for a considerable period thereafter. The creatures are docile and are easily tamed, becoming playful in captivity and exhib-
iting considerable intelligence. They are nocturnal in habits, and spend periods of drought curled up in their burrows. The common echidna (E. aculeata) is found in Tasmania and New South Wales. It is so variable in color and size that it is sometimes held to form two species, differentiated by their general size and habitat. The *nodiak* of Papua (Proechindna brujin) is a kindred animal hunted by the natives for food. See *Monotremata*; *Prototheria*.

**ECHINADES**, *ē-kī-nō-dēz* (modern Kurzolat), a group of islands at the entrance of the Gulf of Patras, and now in part united to the mainland by deposits brought down by the Achelous River. It was near these islands that the battle of Lepanto was fought in 1571. See *Lepanto, Battle of*.

**ECHINOCACTUS*, *ē-kī-nō-bak'tūs*, a genus of plants of the natural order Cactaceae, characterized by globular or nearly cylindrical forms with prominent ribs and strong spines. Over 200 species, mostly Mexican, have been described; about 40 species are natives of the southern portion of the United States, extending as far north as southern Utah, Colorado and Nevada. The flowers, which are highly colored, mainly in shades of yellow and red, are borne just above the areas producing the youngest spines and are succeeded by dry or succulent fruits of no economic use. The plants are raised with comparative ease from seeds, given abundant light, but not direct sunlight, which tends to dry the little seedlings, supplied moderately with water before the soil has a chance to bake and kept in a temperature of about 60 degrees. When about two inches in diameter they may occupy single pots as specimens. About 50 species are cultivated in American greenhouses and are among the favorite plants of their order.

**ECHINOCEREUS*, *ē-kī-nō-kērō-zēz*, a genus of plants of the natural order Cactaceae, with generally low, thickly clustered stems, mostly short funnel-formed, brilliantly colored flowers of various tints and globose or ellipsoidal fruits which are spineless until they reach maturity. By some botanists the genus is united with Cereus, from which it is distinguished mainly by technical characters that are present in some species of each group. About 25 species are general favorites in American greenhouses. They are cultivated in about the same way as Echinocactus and Cereus (q.v.).

**ECHINOCOCUS*, *ē-kī-nō-kōk’ūs*, a small tapeworm (*Tania echinococus*), to which is due the disease called *hydatids* in man and in various animals. See *Tapewurm*.

**ECHINODERMA*, *ē-kī-nō-dēr’mə-tə*, or *ECHINODERMA*, one of the most distinct phyla of the animal kingdom, embracing the crinoids, sea cucumbers, sea urchins and starfishes. On account of a predominating radial symmetry Cuvier united them with the *Calenstra* in his type *Radiata*. Leuckart was the first to clearly perceive that only a superficial resemblance exists between the members of these two great groups and to him is due the elevation of the *Echinodermata* to the importance of a distinct phylum. The skin is always more or less indurated by the deposition of calcium carbonate in the form of variously shaped spicules, spines, discs or plates, either isolated or united to form a reticulum or a continuous test. There is a principal axis around which most of the organs of the body are repeated five times in a radial manner. While this pentamericism is generally predominant, certain organs (madreporeic stone, plate canal, "heart") occur in but one radial axis which, therefore, lies in a median plane to which all other organs are bilaterally related. Of the repeated organs the digestive glands, radial canals, nerves, various vessels, the eye-spots and some others are radial, the genital organs (single in *Holothuroidea*) and polian vesicles interradial in position. The partial suppression of one ray or two rays, and among the starfishes a multiplication of rays, may take place; furthermore, in some *Echinoidae* and *Holothuroidea* certain of the organs or rays may shift so extensively with regard to the principal axis and the median plane that the original pentamerism becomes obscured. There is a well-developed circulatory system which consists of an axial organ or "heart," a circumoesophageal ring, radial vessels and a more or less extensive system of lacunae. In addition to the blood vascular system there is a very characteristic water-vascular system which, when typically developed, consists of a median madreporic or sieve plate and stone canal, a circumoesophageal canal bearing polian vesicles and other diverticula, and giving rise to radial canals which in turn bear rows of ampullae and tube feet. The latter are the chief organs of locomotion, and the most important function of the water-vascular system is to provide for their distension by means of the water which is strained through the madreporic plate and enters the stone canal. In some cases the tube feet assume an exclusively respiratory function. With few exceptions the sexes are separated and, following fertilization in the water external to the body, a free swimming larval form develops, except in a few cases, from the egg. This is always bilaterally symmetrical, has a curved buccal and circi a pair of eolicouches. Older larvae often develop irregular processes and a larval skeleton. The several classes differ considerably in structural details and have been named auricularia, bipinnaria, pleuteus, etc. The Echinodermata are exclusively marine. The following classes may be recognized.

**Crinoidea**, usually fixed to the sea bottom by the aboral surface; the mouth uppermost and the viscera all contained in the central disc or theca. When arms are present they are solid and usually branched.

**Stone or crinoids.** Here belong also the extinct blastoids and crinoids which are often regarded as forming separate classes.

**Stelleriodea**, never fixed to the sea bottom; the mouth or oral surface always in contact with the surface over which they are moving; tube feet confined to the oral surface; form stellate. There are two quite distinct sub-classes, the *Ophiuroidea*, or brittle stars, serpent stars and basket stars, and the *Asteroidae* or true starfish.

**Echinoidae**, never fixed to the sea bottom; ambulacral areas with the tube feet extending
more or less over the aboral surface; form compact, more or less discoid or spheroidal. Sub-classes, Regularia, or regular sea-urchins; and Irregularia, or irregular sea-urchins.

Holothuroidea, never permanently fixed to the substratum; many of them with a circle of oral tentacles; more or less elongated along the principal axis to a cucumber or worm-like form; skeleton in the form of separate plates or sometimes totally wanting. See Cucumaria.

Cystoidea, Pelmatozoans with saclike body enclosed in an irregular box. The arms are poorly developed. The mouth is central. The primitive members of the class are spherical. Some genera tend to the Grinoid type; others resemble the echinoids. They appear in the rocks of the Upper Cambrian Age, being the earliest group of echinoderms. They disappeared at the close of the Paleozoic.

Blastoidea, a small, extinct specialized group derived from the cystoidea, which became extinct at the close of the Paleozoic age.

ECHINOIDEA, é-kí-ño-lé'de-a, or SEA URCHINS, a class of Echinodermata with a more or less spheroidal or discoidal body enclosed in a continuous test or shell composed of polygonal pieces of various shapes accurately fitted together and arranged in radial rows. Alternating ambulacral and interambulacral areas, usually repeated five times, may be recognised. The former exhibit rows of perforations for the tube feet, generally reaching to the aboral pole. The skeletal plates support movable spines which sometimes attain a great size and are used in defense and to a certain degree in locomotion. In addition the original segment bears the remarkable structures known as pedicellaria, which are three-jawed pincers borne on movable stalks, which by continually snapping and bending carry away particles of fecal matter and secure cleanliness. The body of the discoidal form is generally provided with a complicated masticatory apparatus known as Aristotle's lantern, and the canal itself is tubular and looped, usually not pouched. The gonads are interradial with outlets to the exterior near the aboral pole. Development may be direct or through the larval form called pluteus, which is provided in its later stages with long processes supported by movable spicules. The number of known Echinoidea is very small, many of them being fossil. There are two sub-classes: Regularia, form regular, spheroidal; mouth and anus at opposite poles of the central axis, and the latter usually surrounded by small skeletal plates; in only a few cases are the plates terminal. Here belongs the common sea-urchin (q.v.). Irregularia, form markedly bilateral; anus always displaced from the apical pole into the posterior interradius and the mouth frequently in the opposite direction, in which case the form is sometimes heart-shaped. Examples are the sand-dollar and heart urchin (q.v.).

ECHINORHYNCHUS, é-kí-nó-rín'-kúz, a parasite worm. See ROUNDWORMS.

ECHO, from the Greek, meaning "sound," noise; a sound repeated by reflection, or a sound heard again at its source. The waves of sound on meeting the surface are turned back in their course according to the same law that hold for reflection of light. Even clouds are capable of producing echoes, as is observed at sea when a gun is fired off under a dense cloud. Echoes from the clouds also, in all likelihood, play an important part in the long rolling of thunder. In order that the echo may return to the place from which the sound proceeds the reflection must be direct and not at the angle to the line of transmission, otherwise the echo may be heard by others but not by the transmitter of the sound. This may be effected either by a reflecting surface at right angles to the line of transmission or by several reflecting surfaces which end in bringing the sound back to the point of issue. To make a distinct echo the reflected sound must be concentrated rather than diffused. To this result a degree of concavity in the reflecting body is conducive. If the sound is repeated several times, which is the case when it strikes against objects at different distances, many echoes are heard. The reflecting surface must be at a certain distance so that the echo may come to the ear after the sound and be distinctly separated from it. Sound travels about 1,100 feet in a second; consequently, an observer standing at half that distance from the reflecting object would hear the echo a second later than the sound. Such an echo would repeat as many words and syllables as could be heard in a second. This is called a polysyllabic echo. If the distance is less, the echo repeats fewer syllables; if only one is repeated, then the echo is monosyllabic. The most practised ear cannot distinguish in a second more than from 9 to 12 successive sounds, so that a distance of not less than 60 feet is needed to enable a common ear to distinguish between the echo and the original sound. Echoes at least distances, as from the walls of churches and public halls, are liable to mix with and destroy the distinctness of the original sound.

ECHO, in classical mythology, a nymph (one of the Oreads), who, according to Aelian, was changed by Hera (Junö) into a rock, because her loquacity prevented Hera from preventing to the conversation of Zeus with the nymphs. The use of her voice, however, was left her so far as to be able to repeat the last word which
she heard from others. Another account is that Echo fell in love with Narcissus and because her voice was a echo she was turned away until nothing was left but her voice.

**ECHO CAÑON**, Utah, gorge formed by the Weber River, in the northern part of the State, not far from Salt Lake, through which the Union Pacific Railroad passes. The high, almost vertical walls of the cañon have fantastic canyons made by the elements, principally water. The peculiar echo heard within the gorge has given it its name.

**ECHTER, Énutér, Michael**, German painter: b. Munich, 5 March 1812; d. there, 4 Feb. 1879. He studied at the Munich Academy, as a pupil of Hess, Zimmerman and Olivier. He assisted Kaulbach in work on the mural paintings in the Berlin Museum, painted the 'Battle of Lechfeld' for the Maximilianeum; the 'Beethoven of Frederick Barbarossa with Beatrice of Burgundy' and 'The Burial of Walther von der Vogelweide' for the National Museum at Munich, and 32 scenes from the 'Nibelungenlied' for the royal residence. He was appointed professor in the School of Industrial Arts and was a member of the Munich Academy.

**ECHUCA, é-choo’ka**, Australia, town and river port of Victoria, on a peninsula at the junction of the Campaspe with the Murray River, 157 miles north of Melbourne. It is opposite Noama, in New South Wales. A road and railroad bridge, 1,905 feet long, of the Murray River Railway, connects Noama and Echuca. It has a trade, partly by the river, in timber, wool and wine, and the vine is cultivated in the neighborhood. Pop. about 5,000.

**ECIJÁ, é-the-há** (Rom. Astigi; Agusta Firma), Spain, a city in the province of Seville, on the Genil, 42 miles northeast of Seville. It is of very ancient origin and according to tradition was visited by the apostle Paul. At a very early period it became an episcopal see, and its importance under the Romans is attested by many ancient remains. The climate is so hot that EciJA is often called the 'Oven of Spain.' It has hospitals, arsenals, barrack, theatres. Its principal manufactures are shoes, woolens, leather, silk, flour. Pop. about 25,000.

**ECK, Ernst Wilhelm Eberhard**, German jurist: b. Berlin, 1838; d. 1901. He received his education at the universities of Berlin and Heidelberg; was professor at Berlin (1877), Giessen (1872), Halle (1872-77), Breslau (1878-81) and thereafter at Berlin. Of his numerous works the principal are 'Die sogenannten doppelseitigen Klagen des römischen und gemeinen deutschen Rechts' (1870); 'Die Verpflichtung des Verkäufers zur Gewährung des Eigentums nach römischem und gemeinem deutschen Recht' (1874); 'Die Stellung des Erben,' etc., in Bekker and Fischer, 'Beiträge zur Beurteilung des Entwurfs eines bürgerlichen Gesetzbuchs' (1890).

**ECK, Heinrich**, German geologist: b. Göttingen, in 1817; d. 1892. He took his education at the University of Breslau; took part in the geological survey in Thuringia and Silesia in 1852, from 1866 to 1871 he was lecturer at the mining school in Berlin and in the latter year was appointed professor of mineralogy and geology at the Stuttgart Polytechnic Institute. He made numerous investigations dealing mostly with Triassic deposits, the results of which appeared in the publications of the German Geological Society. His principal works are 'Ueber die Formationen des bunten Sandsteins und des Muschelkalks in Oberschlesien und ihre Versteinerungen' (1865); 'Rudersdorf und Umgebung,' in 'Altvorderen und neueren geologischen Spezialkarte von Preussen' (Vol. I, 1872); 'Das Erdbeben in der Gegend zwischen Strassburg, Forbach... am 11 June 1887' (1892); 'Verzeichnis der mineralogischen, geognostischen, vorgeschichtlichen und halangeographischen Literatur von Baden, Württemberg, Hohenzollern'... (1880; with additions in 1901).

**ECK, Johann Maier von**, a Catholic theologian, life-long adversary of Luther: b. Eck, Suabia, 13 Nov. 1486; d. Ingolstadt, 1543. His father, a peasant named Maier, assumed the name Maier von Eck or Maier of Eck, after becoming bishop of Eichstätt. At the age of 11 years, entered the University of Heidelberg whence he passed to the University of Tübingen and there at the age of 14 years took the degree of master of arts. Successively at Tübingen, Cologne, Freiburg, and universities he studied divinity, jurisprudence, and mathematics and at the same time was instructor in philosophy. He was appointed professor of theology in the University of Ingolstadt (1510). While on his travels in Italy (1515) he took part in a public disputation in the University of Bologna and won high distinction; in 1516 on a similar occasion at Vienna he had a like success. In 1518 he published a pamphlet, 'Obelisc,' in defense of the Catholic doctrines attacked in Luther's celebrated 'Theses' of 31 Oct. 1517. Eck was now chancellor of the University of Ingolstadt and Luther put forward Carlstadt as a defender of the 'Theses'; Carlstadt not only replied to Eck in print, but challenged him to a public disputation. Eck accepted the challenge and the disputation was held at Leipzig, with Eck as the champion of Catholicism against both Carlstadt and Luther. The disputation was commenced 27 June 1519 and lasted till 15 July. More than a year previously Luther had written a letter to one of his friends credited with eminent scholarship and great natural gifts, but after the disputation he was for Luther 'a pitiful theologian' and 'a miserable sophist.' The numerous audience and the townspeople with unanimity awarded the crown of victory to Eck, and Luther, in a private letter to his intimate friend Spalatinus, confessed defeat. Eck, stimulated by his success, devoted himself thereafter wholly to working for the overthrow of his adversaries. He procured from the universities of Cologne and Louvain a condemnation of Luther's writings and was honored at Rome with the commission to publish in Germany Pope Leo's bull 'Exsurge Domine' against Luther. But he was received with manifestations of popular enmity almost everywhere; even at his death he was committed to the flames by the students and the populace. On several notable occasions afterward— at the diet of Augsburg (1530), the conferences at Worms (1540) and those at Ratisbon (1541), he was again a principal
champion of Catholicism. Some of his works are a German translation of the Old Testament, and a revision of Luther's translation of the New Testament. His pamphlets and books against the doctrines of Luther are included in 'Opusum Johannis Eccii contra Lutherum.' Consult Wiedemann, 'Dr. Johannes Eck' (Regensburg 1865).

ECKERMANN, Johann Peter, yóh'hn pá'ter ek'ær-má, German poet; b. Winsen, Harpoy, 21 Sept. 1730; d. Weimar, 3 Dec. 1854. He has a permanent place in literature through his record of 'Conversations with Goethe in the Last Years of His Life' (1823-32), which has been translated into nearly all the languages of Europe, even Turkish. He edited the posthumous as well as the 40-volume edition of Goethe's works (1839-40).

ECKERT (Friedrich Eduard), Max, German geographer; b. Chemnitz 1858. He received his education in Lübau and Berlin; taught some time at Lübau and Leipzig and in 1903 became professor at the University of Würzburg. In 1897 he was appointed to the chair of geography in the Royal Technical High School of Aachen (Aix-la-Chapelle). He has published 'Schulatlases' (5th ed., 1912); 'Wesen und Aufgabe der Weltkarte' (1907); books on cartography (1903); 'Grundriss der Handelsgeographie' (1905); 'Leitfaden der Handelsgeographie' (3d ed., 1911); 'Neue Entwürfe für Erdkarten' (1906); 'Die Kartographie als Wissenschaft' (1910); 'Die neuen Arbeitsfelder der Geographie' (1912); 'Wirtschaftsstatistik der deutschen Kolonien' (1912); 'Die wirtschaftliche Bedeutung des Panama-Kanals' (1913); 'Die Metallverbreitung und Metallgewerbe der Welt' (1913).

ECKERT, Thomas Thompson, American telegrapher; b. Saint Clairsville, Ohio, 23 April 1825; d. 20 Oct. 1910. In 1852-53 he was superintendent of the telegraph line between Pittsburgh and Chicago; in 1859-61 superintendent of a gold-mining company in North Carolina; and in the latter year was appointed superintendent of the military telegraph department of the Potomac. Subsequently he was general superintendent of the military telegraph of the army, and was breveted brigadier-general of volunteers for his services. In 1864-66 he was Assistant Secretary of War; in 1866-75 general superintendent of the eastern division of the Western Union Telegraph Company; in 1875-81 president of the American Union Telegraph Company, and in 1892 became president and general manager of the Western Union Telegraph Company. He retired in 1902.

ECKFORD, Henry, American naval architect; b. Irvine, Scotland, 12 March 1775; d. Constantinople, 12 Nov. 1832. He became a shipbuilder in New York, in 1790; designed and constructed a fleet of war vessels for the United States government in 1812-14; built the Robert Fulton, which made the first voyage by steam from New York to New Orleans and Havana; became naval constructor at the Brooklyn navy yard in 1820; and built several war vessels for European and South American governments. At the invitation of the sultan he became chief constructor in the Turkish navy, and established a navy yard at Constantinople.

ECKHART, ék'hart, Johannes ('MEISTER ECKHART'), the first of the German mystics in order of time and among the foremost in rank; the probable place of his birth is Cologne, and the year 1260 or a little earlier; d. 1329. He studied philosophy and theology in the University of Paris and joined the order of the Preaching Friars, or Dominicans, in which order he was promoted to offices of high responsibility, for example, that of vicar-general of the Dominicans for Bohemia, provincial of the order in Saxony. In these places he effected many reforms in the houses of the order and was in high estimation as a preacher notwithstanding the abstruseness of his mystical speculations. Toward the end of his life this dissemination of his mystical views touching the nature of God and the relations between Deity and the human soul brought him under persecution and the sympathy with the Bechhards, the Brethren of the Free Spirit, the Apostolic Brethren and other fanatics, and 1327 he was cited before the Court of Inquisition at Cologne to make answer to charges of heretical teaching, but he escaped on passages in his sermons. There he defended the inculcated propositions as entirely orthodox, but expressed his readiness to repudiate them if in the judgment of the head of the Church they were in conflict with the Church's creeds. In 1329 the decision arrived from Rome: 28 propositions contained in his sermons were condemned as heretical and Eckhart was ordered to recant; but he was now dead.

Whether these 28 propositions were or were not formally heretical, contradictory of the express teachings of the Church, they certainly contain doctrines that never have been put forth in any of the Church's formularies. However extravagant, they may have been tolerated or ignored had they been entertained or discussed merely in the schools of theology and philosophy; but proclaimed from the pulpit and addressed to the common people, some of them ignorant, they were invitations to rebellion against all Church authority in teaching. His doctrine concerning the Godhead is pantheistic. For him there is no real being, but God is the unknown and unknowable. We cannot validly affirm anything of the Godhead; to predicate anything of Deity is to limit infinity. Yet though God is unknown and unknowable, and though we cannot predicate anything of him, still we can know the true God, the personal God, the Father; this personal God, the Godhead itself. The trine God, Father, Son and Spirit, is evolved from the Godhead. And the Father comes to know himself in the Son; the return of the Son into the Father is the Spirit. In begetting the Son — who is coeternal with the Father — the Father brings into existence the universal world of things. His death occurred a little while before the arrival of the Pope's condemnation of his doctrines.

ECKHRL, ék'el, Joseph Hilary, Austrian numismatist; b. Enzersfeld, Austria, 1737; d. 1798. After becoming a member of the Society of Saint Ignatius he was appointed keeper of the imperial cabinet of medals and...
ECKSTEIN—ECLIPSE

professor of archaeology at Vienna. Eckhel may be regarded as the founder of the science of numismatics, the primitive, upon which an elaborately developed in his treatise, 'Doctrina Numorum Veterum' (8 vols., 792-98). He also published catalogues of the ancient coins and gems in the imperial cabinet.

ECKSTEIN, ÉK-stén, Ernst, German humorist, poet, and novelist; b. Giessen, 6 Feb. 1845; d. 1900. From the university he went to Paris, and there completed his comic epos, 'Check to the Queen' (1870), and wrote 'Paris Silhouettes' (1873), the grotesque night-piece 'The Varzin Ghosts' and the 'Mute of Seville.' Later he wrote the stories 'Margherita': 'At the Tomb of Cestius': 'The Mosque at Cordova.' He was editor of a literary and critical journal, Hall of Poets, and of a humorous weekly, The Wag, at Leipzig, for some years, and in 1885 settled in Dresden. He also wrote 'The Claudii': 'Aphrodite, a Story of Ancient Hells': 'Decius the Flute-player: a Merry Story of a Musician in Ancient Rome.' He is distinguished by a polished literary style and careful handling of plots.

ECLAMPSIA. See FETTERAL ECLAMPSIA.

ECLECTIC SCHOOL OF MEDICINE. See MEDICINE, ECLECTIC.

ECLECTICISM (from the Gr. ἐκλεκτικός, out of, and λέγειν, to choose or select) is a term that may be applied to any body of theories or doctrines that are combined without regard for their systematic coherence and real unity. We may thus find eclectic in theology, in philosophy in medicine, politics or in the sphere of any of the theoretical sciences. The eclectic is usually guided by practical motives: he adopts from the various conflicting systems what seems to him the most plausible and useful opinion on this point or that, drawing now from one school, now from another. He is not concerned primarily with the systematic connection, or even the logical consistency, of these various doctrines with one another, but rather with the plausibility and practical applications of the views thus singly.

In philosophy there have been many men, both in ancient and in modern times—some of them writers of great popularity and influence—who, without attaching themselves to any particular system or forming one of their own, undertook to select from various quarters the particular doctrines that appeared to them to be true and to combine them in their teaching. This eclectic tendency was most prominent in the ancient world during the later period of Greek philosophy, when the theoretical interest of earlier times had greatly declined and when skepticism had infected many of the best minds. The differences between the three principal schools (Platonists, Peripatetics and Stoics) began to be less emphasized and elements from one school were adopted by adherents of another. Moreover, a form of eclecticism appeared in Alexandria also, where thinkers like Philo sought to unite Hebrew theology with Platonism and Neo-Pythagorean and Neoplatonic conceptions. Cicero, who did more than anyone else to ac-

ECLIPSE (Gr. ἐκλείπειν from ἐκλέπτω to forsake the accustomed place, to fail to appear), an obscuration of the light of a heavenly body by another, effected either, directly, by its intervention between the body and the observer, or, indirectly, by its interception of the source of light which illuminates the body. The earth, by means of its shadow, may indirectly cause an eclipse of the moon. Similarly, eclipses of the Jovian satellites are caused by the passage in front of Jupiter, and for the system of Saturn a more complicated result arises on account of its rings. When the shadow of a satellite falls upon either of these planets it is called a transit of the shadow. Eclipses are not observable in the other planetary systems, since, in the case of Mars, the satellites disappear in the light of the planet, and with the more distant planets the shadow cone extends too slight a distance beyond the disc. Again, our moon can be by its direct interposition between the sun and the earth produce eclipses of the sun. The moon may interpose itself between the stars or planets and occult them (see OCCULTATION), and the other bodies of the solar system may act similarly. The most important of some important of these phenomena are the eclipses of the sun and moon.

Eclipses of the Moon.—A lunar eclipse is caused by the interposition of the earth between the sun and moon, with the consequent immersion in the shadow of the earth. This can occur only when the moon is in opposition to the sun in the heavens, that is, at the time of full moon, and is only possible when both the sun and moon are near the moon's nodes, i.e., the points where her orbit crosses the plane of the ecliptic. Let the sun, earth and moon be regarded as spherical bodies and their centres ranged in a right line. Then the sun will project beyond the earth a conical shadow called the umbra, in which the moon is centrally immersed. The surface of this cone will be described by a line tangential to the plane of the moon and the moon's nodes.

Unless the moon be near one of her nodes at the time of full moon, she will not strike the
shadow, but pass below or above it. If the sun is less than eight days from a node of the moon's orbit, an eclipse must occur; if more than 15 days from a lunar node, an eclipse is impossible. These are called lunar eclipse limits. Since the moon must be quite near her node to produce a lunar eclipse, it may happen that an entire year may elapse without an eclipse of the moon. The lunar eclipses may be tabulated according as the moon is immersed either partly or entirely in the earth's shadow cone.

The phenomena of a total lunar eclipse are of a simple character. The immersion of the moon in the penumbra can be observed only with difficulty. The edge of the shadow itself presents a hazy outline when seen in a telescope and the times of contact cannot be observed with accuracy. When completely within the earth's shadow, the moon is usually still plainly visible; it is then usually of a dull copper color, although it may be greenish or even of a deep red; usually the moon's disc appears mottled by patches of different colors. The cause of this coloration is the sunlight shining through the earth's atmosphere refracted out of its higher tints and experiencing deflection into the shadow cone through refraction. Lunar eclipses have, however, occurred in which the moon was entirely invisible during the total phase. The obscuration of the earth's atmosphere by clouds accounts for these dark eclipses. The most interesting physical observations effected during its eclipse concern the luminous and heat radiations of the moon. Valuable astronomical observations then possible are the determinations of the times of occultation of faint stars whence precise values of lunar position, diameter and parallax may be derived.

Eclipses of the Sun.—Solar eclipses can occur only at the time of new moon. If the sun be more than 19 days from a node of the moon's orbit an eclipse is impossible, if less than 13 days, a central solar eclipse is inevitable. These are the solar eclipse limits. The sun causes the moon to project toward the earth at new moon, umbra and penumbral shadow. The previous positions are of interest from those which the earth projects toward and beyond the moon at full moon. The shadow cone of the moon may strike the earth's surface, but on the average it does not. Two distinct cases may arise. If the axis of the shadow cone may strike the earth's surface, and upon it the right line joining the centres of the solar and lunar discs traces the curve of centrality. Here three cases result: (1) The apex of the shadow cone reaches the earth's surface and a central total eclipse occurs. (2) The apex of the shadow cone does not reach the earth's surface and there occurs a central annular eclipse. (3) The apex of the shadow cone reaches the earth's surface only at a middle stretch of the curve of centrality and there occurs a central annular-total eclipse. Second, the axis of the shadow cone may not strike the earth's surface but the earth may still enter the shadow cone, or shadow cone produced, and there occur total, annular and partial eclipses, all of which are of a non-central character. The path of a total eclipse on the earth may traverse a length from west to east of several thousand miles. An annular eclipse has also a path of the annulus in which the annular phase is visible. Outside of both of these paths the sun is only partially eclipsed. The least number of eclipses, solar and lunar, which can occur in a year, is two, and these must be central eclipses of the sun, with the maximum number occurring is seven, two of the moon and five of the sun or four of the sun and three of the moon. A simple record of the date and character of eclipses revealed by early astronomers the fact that after a period of about 18 years eclipses again recur in the same order and kind whether solar, lunar, total or partial. This cycle, called the Saros, is one of 223 lunar months, each of a little more than 29.5 days, and is precisely 6,585.32 days in length. Depending on the number of leap years, 5 or 4 intervening, this is equal to 18 years 10.32 days or 11.32 days. At the end of the Saros the relative positions of the sun, moon and node of the moon's orbit are nearly the same as at the beginning, and other factors of the motions of the sun and moon also recur, as Newcomb first pointed out, to nearly original values. The excess of one-third of a day in the cycle causes the eclipse to be thrown out of its position of the previous time on the earth's surface. Hence only after three cycles does the eclipse again recur in approximately the same longitude. If the intervening leap years be regarded, the application of the Saros to various series of solar eclipses of the following table may readily be made.

Ancient eclipses are chiefly of value in historical and chronological investigation (see TIME). The records of the supposed eclipses of the ancient historians are usually very uncertain as to place, time and character of the occurrence, and hence have proved of questionable value to the astronomer. The precise circumstances of an eclipse occurring centuries ago can readily be computed from the modern tables, but the comparison with the vague historical references has apparently contributed but little to science. Ginzel has, in his 'Special Canon of Eclipses,' collected a splendid array of ancient eclipse literature, and this has been used to derive corrections to the lunar tables, but Newcomb seems in this respect to have much the better of the validity of the results. The eclipses observed by the older astronomers and carefully recorded are of great value. And in later times the description of eclipses has been so accurately interwoven with even historical accounts as to furnish unquestionable data for chronology. The terror and apprehensive uncertainty associated with an eclipse in ancient times has given place to a lofty appreciation of the grand occasion and to a careful and inspiring scientific study of the phenomena.

The annexed table is a complete list of all the eclipses of the century having a total phase, however brief. The first column gives the date for the point on the earth where at noon the eclipse is central. The second column gives the Greenwich civil time of the conjunction of the sun and moon in longitude. The next column states the greatest interval in minutes during which the most favored place may experience the total plan-total phase. The last column gives the latitude and longitude of the place where the eclipse is central at noon. The last column indicates the areas traversed by the moon's shadow. Several of the eclipses, occurring in the polar regions, have no noon-point
and hence, for these, the place of the beginning or end of the eclipse, lowest in latitude, is placed in the fourth, and the corresponding time, sunrise or sunset, in the last column. The eight annular-total eclipses of the century are indicated by a *, and in these the duration of total phase may be but a few seconds. Two of the list, namely 1928 and 1967, are non-central in character and the moon’s shadow just grazing the pole of the earth.

The Phenomena Observed in Total Solar Eclipses.—As totality approaches, a pale purple coloring spreads over the landscape. Within a minute of the total phase the phenomena begin to succeed each other so rapidly that no single observer can note them all. By those glancing at the landscape in the direction of the approaching shadow a majestic darkness will be seen to sweep forward with a swiftness truly impressive. Those looking at the earth, and away from the eclipsing sun, will see a succession of flitting bands, alternately dark and bright, known as the shadow bands, which for many decades remained an unexplained puzzle. About 15 seconds before the total phase, the mountain peaks sharp into outline, due to the elevations and depressions in its surface, will have diminished the solar crescent to such an extent that the remnant of it usually begins to be crossed by black lines,—the mountains on the moon’s edge connecting the limbs of moon and sun. Then it rather suddenly presents the appearance of a string of detached brilliant points, irregular in size and spacing. The appearance is due to irradiation which alike exaggrates the length and thinness of the project of solar mountain and the size of the resulting bright points of the disappearing solar crescent. Totality, the appearance of the prominences, whether red or white, along the moon’s edge, and the presence of the radiant, outspreading corona, are simultaneous. The phenomena of the earlier eclipses were recorded in the most general manner. Hasty drawings of the streamers of the corona, accompanied by descriptions reflecting but the dawn of scientific method, are the chief results. It was not until the application of the spectroscope and the photographing camera that the astronomer attained real insight into the stupendous phenomena.

The great eclipse of 8 July 1842 may be said to mark the beginning of serious and accurate attention to the complex physical features of total solar eclipses. Then the path of totality swept from Spain across France, Italy, Austria, Russia and central Asia and thus permitted many expert European astronomers to view and record the marvelous phenomena. It is noteworthy that in reports of this eclipse the red solar prominences were first described with precision, three large ones having been seen on the upper edge of the moon. The corona was also described as of a brilliant white luminosity and extending at least 15 minutes from the moon’s limb. Among the objects observed, the objects of special speculation were the newly discovered red flames or protuberances which Baily considered as “forming a portion of the corona,” and Airy, who observed the eclipse through clouds, attributed to some irregularity in the density of the cloud’s edge.

During the total solar eclipse of 28 July 1851 both the corona and the prominences were observed in greater development than in 1842, and for a considerable duration. Several carefully selected prints of light were noted near those parts of the lunar disc where the rays of the sun had disappeared, or else were about to appear. The observers for the most part became certain that the prominences were true solar appendages, because they were formed by the moon’s edge on the western edge of the sun, and extinguished on the eastern limb. A precious photographic achievement was the single successful daguerreotype taken by Barlow in 1851 with a telescope of 24 inches necessity attached to the Königsberg heliometer, and with an exposure of 84 seconds. It distinctly pictured the corona and several prominences, and thus became the first unchallenged record of these features of an eclipse.

It was, however, at the eclipse of 18 July 1860 which traced its total path across northern Spain, the Mediterranean and northeastern Africa, that photography was first applied with marked scientific success. Mr. Warren de la Rue and Padre Secchi each secured good representations of the outline, details of the traces and the latter good portrayal of the corona. Comparison of these photographs set at rest, once for all, any doubt still existing as to the true solar character of the prominences. The photographic method of attacking the problems arising in total solar eclipses was from this time firmly established. Its progressive development was determined chiefly by three elements: First, increase in the sensitiveness of the plates; second, knowledge of the exposure time required of a given instrument; and third, advancement in practical optics. The gelatin emulsion process introduced by Maddox in 1871, and given the touch of great sensitiveness by Bennett, in 1878, secured the first. Successive failure and success, coupled with scientific method in photographing the corona, brought the second. And, finally, refined theoretical discussion of the principles of optics as applied to celestial photography, coupled with marked improvements in optical manufacture, supplied the third. So that now by separate and regulated exposures, with astronomically designed instruments, and with any a curious relation to the prominences and chromosphere.

The application of the spectroscope to the study of the brilliant red prominences during the total solar eclipse of 18 Aug. 1868 will always be memorable. Tracing its course across the Indian and Malay Peninsula, and affording a total phase of more than five minutes and a half, this eclipse was spectroscopically observed by Janssen, Major Tennant, Lieutenant Herschel, Pogson and Kayet. The light of the prominences was recorded by each of these experts in photometric study, and the data were clearly indicative of the gaseous nature of those remarkable objects. The hydrogen lines C and F were certainly identified, and a yellow line, thence to figure famously in astronomy as D, and as due to helium, was too hastily assigned to sodium. Another notable result of this eclipse was the discovery by Janssen of

* Annular total eclipses.
method by which the bright lines of the prominences could be observed apart from any eclipse whenever the sky was sufficiently clear. On the day of the eclipse he was able successfully to apply the new method; to demonstrate beyond controversy that the bright lines of hydrogen prevailed in the prominences; and to make a third discovery always to be associated with this great Indian eclipse, namely, that he discovered and rapidly changed form occurring in the prominences. Lockyer in England had for some time been at work on the same method for observing the bright prominence lines, and his final success was reported to the French Academy at the same meeting at which Janssen’s achievements were announced. The coincidence was evidently rather determined by the progressive advancement of spectroscopic science than by accident. The spectrum of the corona of this eclipse was generally observed as a faint continuous one without lines dark or bright. Rayet, indeed, noticed a certain bright line near E as extending above the prominences. The polariscope observations of Lieutenant Campbell and Captain Branfil proved that the coronal light was polarized, in planes passing through the sun’s center. The inference thus seemed doubly plain that some solar light was reflected by the corona, although the absence of the dark Fraunhofer lines required explanation.

During the total eclipse of 7 Aug. 1869 spectroscopic observations established the existence of a bright green line crossing the continuous spectrum of the corona. It was at that time estimated as coincident with a bright chromosphere line of approximately the same wave-length, and the element was given to the element from which the light which was the source of the line came. The photographic records of the powerful spectrographs applied to the eclipses of 1896 and 1898 furnished data, however, which definitely separated that element from its neighbor in the chromosphere.

The eclipse of 22 Dec. 1870 was of particular interest to the American observers who had studied that of 1869. This resulted in the despatch of two large parties to Europe, one directed by the United States Navy; the other by the officers of the Coast Survey. If there remained any doubt as to the gaseous nature of the inner corona it was to be dissipated by the fine drawing and description of the inner corona furnished by Professor Watson of Ann Arbor, stationed at Carletinti, Sicily, and observing this gaseous shell to an elevation about 5 minutes; and by Professor Young’s observations in Spain of the now familiar green line of coronium, visible plainly in this area, and traceable as far as 16 minutes from the solar limb. This eclipse will always be peculiarly famous for Professor Young’s discovery of the reversive layer as a thin shell lying immediately above the photosphere. The existence of this reversing layer has since 1870 been repeatedly verified visually, and more recently by photographic records. It comprises an envelope of glowing vapors of an estimated depth of about 600 miles lying at the base of the chromosphere. Its thinness causes the bright lines to appear for but a few seconds, or as a brief flash, unless the observation be made at some station near the edge of the lunar shadow.

The eclipse of 12 Dec. 1871, whose path lay across southern India, and northern Australia, was photographed according to a consistent plan, and photographs were subsequently studied with consummate skill and the delicate results reproduced in detail with masterful accuracy. (Vol. XLI. ‘Memoirs Royal Astronomical Society.’) Here for the first time was available a representation of the corona in all its complex glory of spaced solar rays, dark rifts, filaments straight, curved, and interlacing, and of stupendous synclinal structures with rich veined mantling. The accuracy of the wet-plate process was only equalled by the scientific and artistic manner in which the results were integrated.

The eclipse of 16 April 1874 was visible only in southern Africa, and observed at Klipfontein by Mr. E. J. Stone, the astronomer royal of the Cape Observatory. He confirmed Young’s observation of the reversal of the Fraunhofer lines near the photosphere, and traced the main, green coronal line to more than a degree from the moon’s edge. The inner corona exhibited extended equatorial wings, covering in some parts more than three lunar diameters. The spectroscopic character of the corona, and its unchanged features, as viewed from different stations in Africa, led Stone to insist on the solar origin and cosmical nature of the outer corona.

The path of the total solar eclipse of 29 July 1878 lay diagonally across North America from Bering’s Strait to the Gulf of Mexico, and afforded a memorable opportunity to many American and foreign astronomers. The direction of the line of totality across the Rocky Mountains permitted several astronomers to observe the phenomena at extraordinary altitudes. Langley on Pike’s Peak, at an altitude of 14,100 feet, traced the corona in the direction of the ecliptic for a distance of at least 12 lunar diameters, and felt great confidence in saying that this, though covering a range of over 10,000,000 miles, was but a portion of its extent. The polar rays and filaments of the inner corona received careful study from such experienced observers as Paul, Trouvelot and Upton. The dry-plate photographs obtained by Professor Hall’s party at La Junta, and by Professor Harkness’ party at Creston, were in remarkable agreement as to the details of the inner corona, the same intensities of shading, to great delicacy, being in common, and the pronounced filamentous character of the polar rays, as well as the marked curvature and brightness of the equatorial extensions being clearly shown in both sets of plates. It was the concurrent opinion of many observers that although the corona exhibited vast wings, it lacked, particularly in its inner portions, the brilliancy of the corona of 1869. As to the spectroscopic observations, the gaseous corona manifested, as it seemed, a pronounced sympathetic and intimate relation with the 11-year sun-spot period, giving faint spectroscopic lines at the minimum, 1878, and brilliant ones at the maximum, 1869, 1870, and 1871, of the period. It was also discovered that a greater development of the corona in the equatorial than in the polar regions is one of
ECLIPSE

561

the characteristics of coronas which have been observed during periods when there were few sun-spots.

Thus, during total eclipse of 17 May 1882 the photographs of the corona reproduced the form which it had in 1871, near a sun-spot maximum, being most extended at points away from the solar equator and with no special structure at the poles. It was thus distinguished from the coronas of 1878 and 1867: near sun-spot minima, which were greatly elongated along the sun's equator and of marked structure at the poles.

During the eclipse of 29 Aug. 1886 Prof. W. H. Pickering, of the Harvard College Observatory, made a valuable investigation on the photographic photometry of the corona, the result of which led Holden to employ a similar method in the two eclipses of 1889. The values obtained by these two observers are stated in the following table. From this eclipse also, a study of the largest prominence of the eclipse, which rose in a somewhat spiral form to the altitude of 150,000 miles, the Italian astronomer Tacchini was enabled to verify the discovery of white prominences and immediately announced to the Academy of the Lincei at Rome: "That during a total solar eclipse of the sun there may be seen most beautiful prominences not visible in full sunlight; that the prominences visible only during totality are white, especially in their more elevated parts, and have a special filamentous character, the threads being thin, long and blunt at the top; that the luminous intensity of the white prominences is feebler, and for this reason they are not visible to the naked eye, unless their height surpass that of the more brilliant parts of the corona; and that the other prominences visible in full sunlight appear much wider and higher in a total eclipse, and, when of a considerable height, have their summits white."

The total eclipse of 1 Jan. 1889 was visible in a path that lay across California and Nevada, and was successfully observed by many American astronomers. The photographs taken are notable alike for the fine detail of the inner parts of the corona registered, and for the immense extent of the streamers imprinted. A particularly fine negative by Barnard permitted Holden to trace rays similar in typical character to the polar rays all around the limb of the sun and to present a detailed study of the filamentous character of the corona. An interesting feature of several of the photographs consisted in their showing the outline of the moon's black disc projected on the corona before totality had begun.

From a study of his photographs of this eclipse and of the following total eclipse four years later, Professor Schaeberle deduced his "Mechanical Theory of Solar Corona" by which the corona is caused by light emitted and reflected from streams of matter ejected from the sun, the stream lines of the corona coinciding with elliptical areas having one focus at the sun's centre, the origin of the streams being, in the main, confined to the spot-zone regions. Professor Schaeberle applies his theory to the location of half a dozen solar areas productive of the actual streamers photographed in the eclipse of 1893. Whatever the merit of the particular theory, it has had the advantage of pointing out the importance of dynamical and spatial study of the coronal streamers.

In the eclipse of 16 April 1893 it was shown that the lines of hydrogen and helium, seen hitherto in the corona by a number of observers, must be attributed to a scattering of the prominence light by the earth's atmosphere and possibly by the corona itself, but not to the intrinsic coronal light. An attempt was also made to determine the rotation of the corona by photographing its spectrum on both sides of the sun; the H and K lines were only weakly employed and a speed was found almost equal to that of the solar surface and corresponding to a distance of 20 minutes from the limb.

The eclipse of 9 Aug. 1896 was visible in its total phase in Norway, Nova Zembla and northern Asia, while the path of the following eclipse, that of 22 Jan. 1898, lay across east central Africa, India and the Chinese Empire. Each of these eclipses was successfully observed by a great number of astronomers and furnished a great wealth and variety of photographic material. In the second eclipse Campbell, of the Lick Observatory, employed an objective-grating spectograph which was so arranged as to give a continuous photographic account of the changes in the solar spectrum at second and third contacts. Many interesting results of differences of level and of intensity of radiation in the lines were obtained. The photographs obtained by Campbell with a lens of 40-feet focal length showed also a great wealth of detail. One of two seconds' exposure clearly indicates the ultimate relation of the prominences with the synclinal structure of the corona; another, of eight seconds, gives a fine representation of the polar rays and spots with a coronal form already clearly influenced by the approaching sun-spot minimum.

The total solar eclipse of 28 May 1900 will always be famous for its long course through civilized territory, its path crossing the United States from Texas diagonally to Virginia, and finally threading its way across Spain.
chiefly memorable for the fine weather which prevailed along the track of totality and for the magnificent array of optical and physical appliances employed in its observation. The chief American parties were those of the Lick, Yerkes, Allegheny, Smithsonian, Princeton, Brown, Harvard and United States Naval observatories, conducted respectively under the direction of Campbell, Hale, Wadsworth, Langley, Young, Upton, W. H. Pickering and S. J. Brown. Long focus telescopes either directly pointed at the sun or fed by coldstats for coronal photography, huge Rowland grating spectrophotographs for supposed graphing the flash and the delicate bolometric appliances of Hale and of Abbot characterized the instrumental attack. A great prominence was seen in the southwest quadrant, whose white summit was in eruptive activity. Striking changes in this prominence and in others were seen on comparing the American photographs with those taken at Ovar, Portugal and in Spain about two hours later. The study of the form of the corona as presented by the photographs was of special interest as a test of a "polari- zation" theory of the sun's magnetic field. Of its stress early in the year 1890 some 10 years previously. According to this theory the coronal lines should lie in the direction of the lines of force surrounding a spherical magnet. Such magnetization of the sun though suggested, was then not necessarily assumed. The progress of physical science later made it probable that matter on the solar surface was electrically ionized after the manner of the cathode streams of the Geissler tubes. And these electrified particles, or electrons, require through to be directed by a supposed magnetic field of the sun. Bigelow's "Magnetic Theory of the Corona," supported by Ebert's experiments, seems likely both from the natural assumptions made, and from the deductions allowable, to furnish the master-key to the mysterious "captive arrangement" of the corona at the sun's minimum of activity.

The spectroscopic observations were manifold and in the main successful. Professor Evershed, observing in Algiers, just outside of the path of totality, obtained photographs of the flash spectrum in high solar latitudes, and concluded that, in its main features, it is the same as in low latitudes. He verified the essential identity of the flash spectra as photographed by Shackleton in 1886 and those obtained in 1898 and 1900, and inferred that the flash spectrum is probably as constant a feature of the solar surface as in the Fraunhofer spectrum.

In discussing the detailed spectroscopic results of the flash layer, Evershed infers that the abnormal intensities of the enhanced lines characteristic of all levels and all latitudes of the flash is due to a continuous circulation of the solar gases in a radial direction, while the cooler, more diffused gases, in their subsidence, determine the character of the absorption spectrum. His final conclusion that the flash spectrum represents the emission of both ascending and descending gases, while the Fraunhofer spectrum represents the absorption of the descending gases only, Professor Deslandres, by means of spectographs with optical parts of Iceland spar and quartz, photographed the entire ultra-violet spectrum of the reversing layer from 3,400 to 3,000, the entire ultra-violet spectrum of the upper chromosphere and the entire spectrum of the corona with two new coronal rings. Deslandres, observing visually with a powerful grating, inferred from the inclination of the green coronal line on the east side of the equator that the corona appeared to have a more rapid rotation than the disc. Professor Turner, secured photographs, in polarized light, of the corona, permitting of a quantitative investigation. The polarization of the corona was radial and was "not only shown in the outer streamers, but right up to the moon's limb." An important bolometric measure of the heat of the corona was conducted by Abbot and Mendenhall, of the Smithsonian Observatory, which led to the conclusion that the corona neither reflects much solar light nor in the main gives light of its own on account of high temperature, but seems rather to be giving light in a manner not associated with a high temperature, or at least with the preponderance of infra-red rays usual in the spectra of hot bodies. This result plainly points to the electrical character of the coronal light and is also in harmony with Bigelow's magnetic theory. Deslandres, using *a very sensitive photometer which he developed by himself, low some 10 years previously. According to this theory the coronal lines should lie in the direction of the lines of force surrounding a spherical magnet. Such magnetization of the sun though suggested, was then not necessarily assumed. The progress of physical science later made it probable that matter on the solar surface was electrically ionized after the manner of the cathode streams of the Geissler tubes. And these electrified particles, or electrons, require through to be directed by a supposed magnetic field of the sun. Bigelow's "Magnetic Theory of the Corona," supported by Ebert's experiments, seems likely both from the natural assumptions made, and from the deductions allowable, to furnish the master-key to the mysterious "captive arrangement" of the corona at the sun's minimum of activity.

The total eclipse of 18 May 1901 traced its path across southern Madagascar, the Indian Ocean, Sumatra, Borneo, the Celebes and New Guinea, and, on account of its long duration of over six minutes and the high altitude of the sun at the best points of observation, attracted expeditions from many countries. The general weather conditions unfortunately proved to be unfavorable; at a few of the eclipse stations, however, observations of great value were made. Professor Perrine, observing at Padang, Sumatra, through a partly clear sky, obtained excellent results. His photographs showed conspicuous series of coronal hoods, and also "a remarkable prominence, and an inverted cone of considerable angle" and unlike anything previously recorded. This disturbance associated with a long thread-like prominence, Professor Perrine, subsequently, by means of the Greenwich solar negatives taken at Delhi, India, traced to a sun-spot and associated facule, near the solar limb on the day of the eclipse, and thus plainly exhibited facule, prominences, coronal disturbance, and sun-spots in a common origin and intimate relation. This wonderful phenomenon was without doubt due to a solar eruption which took place near the solar limb and at, or just prior to, the time of the eclipse. The photographs of Mr. Peters, of the United States Naval Observatory, taken at Fort de Kock, Sumatra, confirm Perrine's results, and the flash spectrum and envelopes above some of the prominences, and are replete with structural detail. The corona, according to Perrine's photographic negatives, was polarized in the portions 10 minutes beyond the solar limb in all position angles including the polar regions. In negatives of the English astronomer, Newall, some of the streamers showed greater extension in the polarized than in the unpolarized light. In the special work
on the corona contemplated by Professor Barnard’s long exposure of a very large plate, and by Dr. Abbott’s second attempt to measure the coronal heat bolometrically, there was universal interest among astronomers and universal regret at the compulsory postponement to a future eclipse on account of the clouds. A photograph was taken for the purpose of the planet was conducted by Perrine using four lenses covering a stretch of 19 degrees on either side of the solar equator. The faintest stars on the plate range from 6.5 to 9.3 visual magnitude, and Perrine infers that “unless at the time of the eclipse the planetary bodies were directly in line with the sun or with the brightest portion of the corona, there is no planetary body as bright as 5.0 visual magnitude within 18 degrees of the sun, whose orbit is not inclined more than 77° to degrees of the plane of the sun’s equator.”

In the total eclipse of 30 Aug. 1905, the shadow swept over the earth from central British America, across Labrador, France, Spain and northern Africa, finally leaving the earth at Java. This was a very favorable eclipse, the maximum duration being nearly four minutes, and the path of totality unusually accessible. For these reasons, great numbers of parties were organized to observe it, no less than 80 stations being established. It was planned that a comparison of photographs taken toward the west end of the path with those of Spain and Arabia, taken nearly two and one-half hours later, would throw much light on the changes of the corona during this interval and upon the alteration in appearance of it and of the chromosphere due to the rotation of the sun. Unfortunately it was cloudy in Labrador, but hundreds of beautiful photographs were taken from stations in the Old World. Fabry during this eclipse made a careful determination of the total light emitted by the corona and found that altogether we receive from this object almost exactly as much light as from the moon when this is full.

The shadow in the eclipse of 21 Aug. 1914 swept from the northern boundary of North America across eastern Europe to India. Several parties were formed to observe this eclipse, notwithstanding the very unsettled condition of the countries through which the shadow passed, but the results were, very unfortunately, almost nothing, due to cloudy weather. It was planned to test from this eclipse for the first time the new theory of Relativity, according to which a ray of light passing through a gravitational field should suffer a minute deflection. The measurement of this deflection seems at present to be about the only physical observation which can be made to test the theory, though even with a star which appears at the edge of the sun the deflection should amount to but ninety-three hundredths of a second, and to less than four-tenths of a second for a star 20 minutes away. If found, this deflection would be complicated by the refraction of the rare matter of the corona, the density of which in different portions was also to be investigated by photometric methods.

The eclipse of 8 June 1918 was of special interest to astronomers in the United States because the path of totality extended entirely across this country in a diagonal direction from Washington to Florida. The duration of totality exceeded two minutes in Washington, but this time diminished to less than one minute in Florida, and as the sun was very low in the west when the eclipse occurred to Eastern observers, nearly all eclipse parties were stationed in the far Western States. Owing to world conditions, these were exclusively American. Observers from the Allegheny Observatory, the Chamberlain Observatory, the Lowell and Sprout observatories, the observatory of Drake University and others were located in Colorado; from the Mount Wilson Solar Observatory and from the Yerkes Observatory, the parties were in Wyoming, while the party from the Lick Observatory (whose elaborate instruments, employed in the eclipse of 1914, were still detained in Russia), were in Washington. The party farthest east was from the Smithsonian Astrophysical Observatory: this located in Kansas in order to ensure the spreading out of observers along the path as much as possible and so to increase the chance of avoiding bad seeing, which must be purely local. Observations were also made for determining the rotation of the corona, while photometric measures of its light and many photographs of its form were obtained, the weather being favorable almost throughout the entire path. Photographs were also secured to test the theory of relativity, but the results of this work cannot yet be given.

Bibliography.—The general theory of eclipses and the methods for their computation have been developed by Bessel in ‘Astronomische Nachrichten,’ Vol. 151 and 152, but with the utmost rigor in his ‘Astronomische Untersuchungen’ (Vol. II); a full development of Bessel’s method is given in Chauvenet’s ‘Spherical and Practical Astronomy’ (Vol. I), and in ‘The Theory of Eclipses’ by Roberdeau Buchanan. The most reliable general tables for the computation of eclipses are those of Newcomb, ‘Astronomical Papers of the American Ephemeris’ (Vol. I). Oppolzer’s ‘Canon der Finsternisse,’ published as Vol. II of the ‘Denkschriften’ of the Vienna Academy, contains the elements of 8,000 solar and 5,200 lunar eclipses occurring between the dates — 1207 Nov. 10 (Julian) and 2161 Nov. 17 (Gregorian), and the accompanying charts show the approximate path of each eclipse on the earth’s surface. A valuable accessory to Oppolzer’s ‘Canon’ is found in Dr. R. Schramm’s ‘Tafeln zur Berechnung der näheren Umstände der Sonnenfinsternisse,’ published in Vol. LI of the Vienna ‘Denkschriften,’ in the ‘Sitzungsberichte’ of the Vienna Academy, LXXXV, LXXXVII and LXXXIX, and in his ‘Spezieller Canon der Finsternisse,’ published by the Berlin Academy, has brought together a large array of references to ancient eclipses and compared them with computation. The papers of Airy, Williams, Maguire, and S. Johnson in the ‘Monthly Notices’ of the Royal Astronomical Society are of interest. The physical data and problems of total solar eclipses are treated in a vast modern literature mostly issued by the observatories and learned societies. A highly important compend of physical information concerning total solar eclipses is that of Ranyard, ‘Memoirs of the Royal Astronomical Society’ (Vol. XLII). For the
later eclipses the most valuable discussions are to be found in the publications of the United States Naval, Harvard, Lick, Yerkes and Smithsonian observatories, in the 'Astronomische Nachrichten,' the 'Memoirs' and the 'Monthly Notices' of the Royal Astronomical Society and in the 'Astrophysical Journal'. Revised by Eric Dolittle.

ECLIPTIC, in astronomy, the sun's path, the great circle of the celestial sphere, in which the sun appears to describe his annual course from west to east. The constellations on the ecliptic give their name to the 12 signs of the zodiac (q.v.), each of which covers 30 degrees. The Greeks observed that eclipses of the sun and moon took place near this circle; whence they called it the ecliptic. The sun does not always rise to the same height in the meridian, but seems to revolve round the earth in a spiral, and is in the equator twice a year, about 21 March and 23 September. The points of the equator in which the sun is on these days are at the intersection of the equator with the ecliptic. On 21 June the sun reaches its greatest height in the heavens, and 21 December descends the lowest. The position of the equinoxes on the ecliptic is changing about 1 degree 24 minutes per century. (See Equinox.) The ecliptic has two poles, 90 degrees from it, where it revolves about the north and south celestial poles, respectively, every 24 hours. What appears to be the path of the sun, however, is in reality the path of the earth. The planets and the moon revolve in different planes; but these are inclined at only a very small angle to the plane of the ecliptic; hence these bodies can be but a small distance from the ecliptic. The plane of the ecliptic is very important in theoretical astronomy, because the courses of all the other planets are projected upon it and reckoned by it. By the obliquity of the ecliptic we understand its inclination to the equator, or the angles formed by the planes of these two great circles. This angle is measured by the arc of a third great circle, drawn so as to intersect the two others perpendicularly in the points at which they are farthest apart. The ancients endeavored to measure the obliquity of the ecliptic. According to Pliny, it was first determined by Anaximander. The most celebrated measurement of this obliquity in ancient times was made by Ptolemaeus, at Marseilles. He found it, 350 B.C., to be 23 degrees 49 minutes 23 seconds. A hundred years later, according to Ptolemy, Eratosthenes found it to be 23 degrees 51 minutes 13 seconds. In 1900 the obliquity was 23 degrees 27 minutes 8 seconds; it is diminishing at the rate of nearly half a second a year and is expected to reach a minimum value of 22 degrees 15 minutes in about 15,000 years. It will increase thereafter to about 25 degrees. See Day; Nutation.

ECLOGUE, ɛkˈlɒg, in poetry, at first a term applied to a section of choice poems. Later the word, from its application to the collection of Virgil's pastoral poems, the 'Bucolica,' came to connote a pastoral composition, in which there is a dialogue between two or more shepherds; and, when used loosely, any short, highly finished pastoral poem. See Literary Forms.

ÉCOLE DES BEAUX-ARTS, ā-kōl-dă-bōz-ār' (School of Fine Arts), the French government school at Paris, officially called the École Nationale et Spéciale des Beaux-Arts de Paris. In 1648 Mazarin, under the patronage of Louis XIV, founded the Academy of Painting and Sculpture, and in 1671 Colbert completed Mazarin's work by establishing the Academy of Architecture with its school. The two schools were united under their present title in 1793, although lessons in architecture had actually been given at the former school by François Blondel as early as 1671. Competition for the Grand Prix de Rome was instituted in 1666, and the same year witnessed the establishment of the Collège de France at Rome by Colbert and Charles Errard. In 1796, when the Academy was abolished, the school was established in the hands of the Académie des Beaux-Arts. In 1863 it was taken from the control of the Institute and placed in the charge of a government official, since when the management has remained practically the same.

The school is free to men and women from the ages of 15 to 30 and the courses extend over a period of 8 to 10 years, generally. Courses are given in painting, sculpture, architecture, copper-plate engraving and engraving of medals and precious stones; and supplementary classes are held in drawing (both from the antique and living model), building, architecture (theory and history), design, decoration, history of art, aesthetics, general history, geometry, perspective, science, etc. There are severe examinations for entrance and, likewise, competitive examinations which are held every six months. This competitive system governs the grading of all pupils. In addition to more or less regular attendance at these regular courses, the students work in the various ateliers, or studios, under different professors, to whom they are obliged to pay a small fee.

The location of the school is at the old convent of Petit Augustin, between the rue Bonaparte and the rue Saints-Pères. The present Palais was designed by Debret and enlarged and completed by Félix Duban, the construction being finished in 1863. Opportunities for study are found in the splendid collections, which include all the works which have been awarded the Grand Prix, numerous portraits of the professors, classical copies and originals and valuable drawings by the old masters. The library, whose origin dates from the beginning of the school, is rich in valuable books, engravings and photographs. Statistics show about 2,000 students (1913) and 50 teachers (including those in the ateliers). The governing board and administrator are selected from among the best artists of France.

American students are predominant among the foreigners at the school and American architecture has been greatly enriched as a result of their training. The Congressional Li-
ECONOMICAL GEOLOGY

Non-metals.—Following are listed the more important members of this group. The natural fuels include coal, peat, petroleum and natural gas. Important building stones are granite, marble, slate, sandstone and limestone. Clay and cements may be included under materials of construction. Salt, borax, potash and related compounds are considered under the head of salines. Closely related to these is gypsum. The fertilizers include apatite, rock phosphate, muriate, greensand and potash. Among the abrasives are novaculites, corundum, emery, grindstones, pumice and volcanic ash, tripoli, garnet and quartz. The gems or precious stones include diamond, emerald, beryl, garnet, opal, ruby, sapphire, peridot, topaz, turquoise and many others. Minor unclassified non-metals include asbestos, barite, diatomaceous earth, feldspar, fluorite, fuller's earth, glass sand, graphite, magnesite, mica, monazite, sulphur, soapstone, talc, water and numerous others of lesser importance. See ABRASIVES; BUILDING MATERIALS; CORUNDUM; DIAMOND; PETROLEUM; SLATE.

Metals.—The major metals are iron, copper, lead, zinc, gold and silver. Minor metals include aluminum, cobalt, manganese, mercury, nickel, platinum, tin, tungsten and many more. See COPPER; Lead; Zinc; ALUMINUM; also ORE DEPOSITS; PLACES; MAGMATIC SEGREGATION; VEIN, etc.

Each of the above substances is treated in a separate article which includes the mineralogy and geology of the product.

Transactions of the American Institute of Mining Engineers (New York 1871 to date); "Water Supply" (London 1901); also the publications of the United States Geological Survey, Washington, D. C., and of the various State geological surveys.

C. L. Dake, Professor of Geology, University of Missouri.

ECONOMIC HISTORY. It is a truism that each generation must rewrite the history of the past for its own study. This is because each generation views with particular interest those aspects of life and progress in the past which are of greatest present importance. From the 15th to the 18th centuries men were primarily interested in religious questions and the history written during that period was tinged with theological controversy. During the latter part of the 18th and the greater part of the 19th centuries the formation and development of constitutional government claimed chief attention, and history was written over again from this standpoint. To-day, especially in the United States, our interests have grown to be preponderantly social and economic, and the result is that emphasis is now being laid upon what is called economic history.

By this is not meant what is generally termed the economic interpretation or the materialistic conception of history, which holds that economic factors alone can furnish an adequate explanation of human development. This doctrine of economic determinism was set forth with great force by Karl Marx and has been generally accepted by other socialists. According to them economic activity is the fundamental condition of all life, and consequently all changes in the development and structure of society, whether intellectual, religious, social or what not, must be traced in the last analysis to purely economic causes. Few writers hold this view and it must not be confused with the recent development of economic history.

What is called the Socialist assign, indeed, a much humbler rôle to economic history than that of such a comprehensive explanation of all social phenomena. According to some its chief mission seems to be to hunt up illustrations which the economic theorist may then use to illustrate principles which he has deduced without recourse to historical evidence. Others admit that it is often useful to test the limits of the actual applicability of theoretical economic doctrines. While still another group, notably the German historical school of economics, hoped that by the use of historical research they could establish new economic truths of a theoretical character, arrived at by the inductive method. This last hope has on the whole proved fallacious and the economic historian to-day is content with a limited and often relatively simple construction of economic science.

What then is economic history? It may be defined as an explanation, as complete as may be, of the economic life of a period. Such an explanation is very difficult and for certain periods all but impossible, because of two facts. The first is that the records of the past in so far as they concern economic phenomena—the everyday business of earning and spending one's income—are very meagre; and the second is that the Industrial Revolution (q.v.) so completely changed the course of economic development that even a complete explanation of the past is beset with economic problems. Economic history is more than a narrative, or an account of an industry or an institution; it is an economic analysis and causal explanation of the facts and their interrelations. Such an explanation is not easy, for economic life is very complex; economic phenomena are never isolated, but work together. The special task of economic history is thus a reasoned explanation of causes and tendencies.

E. Estes B. Bogart, Professor of Economics, University of Illinois.

ECONOMIC THEORIES OF LABOR. See Labor.

ECONOMICS. Economics may be defined as the science of the production and distribution and consumption of wealth. It is concerned with the activities of man in the process of earning a living and of applying his income to the satisfaction of his wants. As a science economics is scarcely more than a century old, but economic phenomena must have attracted attention and caused reflection as long as thinking beings labored to gain a living. At first economic thought was inchoate and confused, finding expression chiefly in the moral codes of priestly lawmakers. And when economic doctrines began to be differentiated from moral or political precepts, they were still conditioned by the religious, industrial and social environment in which the thinker lived. With every important social change new economic theories have arisen which have sought to explain the existing situation. Hence economic progress has been accompanied with the development of economic thought and the rise of new theories. And the economic thought organized primarily for economic rather than for military or religious purposes greater attention has been directed to economic problems and to their theoretical explanation. The development of thought shows a progressive comprehension of economic phenomena and a steady development in scientific treatment. To understand the scope and content of the science of economics to-day we cannot do better than to trace its historical development.

Ancient Thought.—The earliest expressions of economic thought are to be found in the moral codes of Oriental peoples, of which the Mosaic and Brahminic codes may serve as illustrations. These were primarily religious and economic concepts and were completely divorced from the logical conception of human relations. Spiritual perfection was the end to be achieved and economic well-being or poverty were held to be ordained by divine will. Everyday life was minutely regulated; custom ruled and change was avoided; the individual was entirely subordinated to society. Under such circum-
stances there was little opportunity for the development of economic progress or of economic thought.

While the Greeks resembled the Oriental people in their confusion of economics with morals, in conceding the dominance of ethical motives and in emphasizing the importance of the state, they yet appreciated more fully the importance of material wealth and analyzed the nature of economic wants more carefully. It has been said that every one is a follower of either Plato or Aristotle, the two leading Greek philosophers. Plato described an ideal state in which the individual is completely subordinated to the state, community of property and of wives and children is established, population is regulated. Aristotle opposed this extreme communism, approved of personal freedom, private property and individual initiative. His analysis of economic activities was rational in contrast with the metaphysical Oriental speculation or the idealism of Plato and marked a considerable advance in economic method.

There was little advance made by Roman writers. Economic doctrines may be traced in the contacts and political, industrial activities were regarded as ignoble — with the exception of agriculture — and consequently little thought was directed to these subjects. The chief writers who directed their attention to economic matters were Cicero, Cato, Varro and Columella, but all of them concerned themselves rather with technical advice about agriculture and laments at its decline than with national economy. In general the Romans followed the Greek writers. Their chief contribution lay after all in the development of the science of jurisprudence.

The slight development of economic thought in antiquity was due to several reasons. In the first place practical economic activities were not far developed. War absorbed a great part of the energy of the people. Agriculture was rude, manufacturing and commerce were in a still more primitive state. Owing to the insecurity of life and property there was little incentive to or possibility of the accumulation of capital. The system of slavery, upon which all ancient societies were based, led to a contempt for labor and prevented real economic progress.

Medieval Thought.— The ill-defined period known as the Middle Ages (400-1500) was one of transition and adjustment. After the downfall of Roman civilization there was a stormy period in which Roman institutions, Christian theology and Germanic customs were blended into a new catholic and hierarchial civil system, followed by another period in which the Western world had to defend itself against the invasions of Eastern nomadic tribes. From the 11th to the 15th century the typical medieval institutions of scholasticism and feudalism developed and dominated life and thought. Throughout most of this period society was disorganized and broken into fragments. The typical economic unit was the independent domestic economy, self-sufficient and practically without intercourse with the outside world. Agriculture was the main and in fact almost the only industry, domestic manufactures being confined to supplying local wants, and commerce was practically unknown for all but river or seaport towns. There was, however, during the later Middle Ages a transition from this domestic economy to a broader town economy, if not to a national economy. Manufactures and commerce encroached gradually upon the ancient institution of slavery was modified into serfdom. Feudalism, however, prevented any considerable economic advance, as its chief office, which must be recognized as beneficent in the chaotic conditions of the times, was to preserve order and defend existing institutions.

Under such circumstances but little contribution could be expected to the world of economic thought. Men's speculations during this period were primarily theological and economic doctrines were controlled by religious considerations. The best exposition of the economic theory developed during the Middle Ages, if we may designate as theory a body of rules of conduct, is to be found in the canon law. Based upon a mass of ecclesiastical legislation and decisions, this was codified in the 12th century. Prescribing as it did rules of right conduct and of atonement for wrong, it necessarily made inquiry into economic relations and activities. The keynote of the economic doctrines may be traced in the concept of just price; this was determined by the cost of production, but to the canonist cost was measured only by the labor involved, as there had not yet developed an adequate conception of capital as an agent of production. A just price then was one that secured a fair return to the worker. Similarly, because of their lack of appreciation of the rôle played by capital in production, they condemned usury or the taking of interest, though this doctrine came to be modified with the growth of trade. But avowal of the pursuit of wealth as an end in itself, was condemned as one of the seven deadly sins. This stands in strange contrast with the modern conception of self-interest as the motive power of economic action. Manifestly there could be no great development of economic activity or of theory so long as such conceptions prevailed.

The Middle Ages were followed by a period of two or three centuries marked by profound change in the world of economic enterprise and by the rise of new ideas in the sphere of economic thought, which paved the way for modern systems of industry and theory. In this transitional period we may distinguish two systems of thought or of policies, namely, Mercantilism and the Physiocratic system. The first of these was a body of economic policies rather than of theory, but the second comprised a coherent system of thought.

Mercantilism.— By Mercantilism is meant the prevailing economic views entertained by European statesmen from the 16th to about the middle of the 18th century. These concerned themselves mostly with money and foreign commerce and were the result of the new economic forces that were making themselves felt in the world. Foremost among these was the importation of gold and silver from America, which facilitated the change from payment in services and kind to a money economy, and helped to break up the old feudal régime. The growth of court expenses, of standing armies and of other governmental expenditures necessitated heavier taxation, which led to the encouragement of manufactures and trade by the central governments; heavier taxation on the other hand was made possible by the greater security and increased production of wealth in the towns.
At the same time a struggle was going on between the local units of government and the central power. As the old feudal economy began to be supplanted by a national economy it was felt that the state must be made strong. It was a period of struggle between nascent states, and Mercantilism, which is defined by Schmoller as state-making, aimed to make the nation strong. In international relations, says this author, those states gained the supremacy "which understood how to put the might of their fleets and admirals, the apparatus of customs laws and navigation laws, with rapidity, boldness and clear purpose at the service of the economic interests of the nation and state."

The Mercantilists, therefore, emphasized the encouragement of foreign commerce and domestic manufactures, of agriculture and fishing. Seeing that those nations were strong which possessed large amounts of the precious metals, they laid great stress upon the importance of amassing and retaining within the national borders every store of money and goods. Money and money were often confused by the typical Mercantilist, though it can no longer be held that they identified them. This was the fundamental Mercantilist doctrine, and as a means of securing bullion, foreign trade was encouraged and regulated so as to secure a favorable balance. As a merchant marine was necessary to carry on trade, all measures that would develop a navy were approved, from navigation laws granting a monopoly of the carrying trade to home shipping to laws requiring the eating of fish so as to encourage fishing and thereby the training of sailors.

But since a nation must have commodities to trade with manufactures were also encouraged within the country, while agriculture was to be developed sufficiently to make the nation self-sufficient. A dense population was desired as an element of military strength. It was an all-around system of protection, regulation, price fixation and state control, which should not be thoughtlessly condemned as it was at the time, but as well suited to the spirit and needs of the times. Charles V is said to have introduced it, but its best-known exponent was Cromwell in England, Colbert, the Minister of Louis XIV, in France and Locke in England, in his "Two Treatises of Government." Among the best-known English Mercantilist writers were Mun, Child, Davenport, and Temple.

The Physiocrats.—Toward the end of the 17th century and more markedly in the 18th, protests began to be urged against the extreme and burdensome restrictions of the Mercantilist policies. This system had performed its work and was outliving its usefulness. The agricultural revolution, already being consummated in England, was demonstrating the profitableness of agriculture when conducted scientifically with sufficient capital and rotation of crops. The growing manufacturers of the towns, too, felt themselves burdened and restricted by obstrue regulations and the monopoly of the guilds. It was France particularly, where the burdens of taxation upon both agriculture and manufactures were especially onerous, that the protests found expression in a new system of thought. This was Physiocracy, which might be defined negatively as a revolt against Mercantilism, though it was much more than this.

At the basis of the Physiocrats' doctrines lay their nature philosophy, as indicated in the name they gave themselves (φυσις κρατος = rule of nature). By this they meant that social activities were subject to natural laws in the same way that nature is subject to physical laws. National well-being could be secured only by obeying these natural laws. The political application of this philosophy led to the social contract theory, according to which government exists for the benefit of the members of society and rests upon their consent. In the economic sphere it led to the free market system, with individual freedom and initiative. The functions of government should be limited to the protection of life, liberty and property, and the individual should be permitted to pursue his own interests and make the most of his labor. There should be freedom of exchange and competition, and all monopolies or restrictive privileges should be abolished. This idea was embodied in their famous maxim, laissez-faire et laissez-passer (let things alone, let them take their own course). This, in short, was the Physiocratic theory, which was negative and aimed to break down the restrictions of Mercantilism. But it contained also positive contributions to economic theory.

The central doctrine of the Physiocrats was that of the free market and the surplus. Only agricultural and the other extractive industries, as mining and fishing, are productive, that is, yield a surplus over the cost of production, and thereby increase the wealth of a nation. Manufactures and commerce are non-productive, for they merely give a new form and location to the materials produced by the extractive industries; the higher value of the manufactured articles is offset by the costs of production, the labor, provisions and materials used up in the process, and therefore there is no net surplus added to existing wealth. Artisans, merchants and the professional classes were regarded by the Physiocrats as sterile or non-productive. This doctrine led, of course, to a demand for the encouragement of agriculture by the state and the abolition of all measures which might be indirectly designed to encourage manufactures or commerce. These should be left to develop naturally. In criticism of the doctrine of productivity it may be pointed out that to the Physiocrats production means the growth of wealth and the wealth of society. According to them, nature worked in a peculiar way in cooperation with the farmer; he alone added to the stores of material wealth. But the manufacturer or trader, who added only a form or place utility, was denied the name productive. This is contrary to modern economic theory.

From their doctrine of the product net followed logically their theory of the impost unique or the single tax. Since land was the sole ultimate source of wealth, all taxes should be levied directly upon it. If they were imposed upon other branches of industry, they would necessarily be shifted as there was no surplus out of which to pay them, and they would all ultimately rest on the land. A single tax on the net income from land was therefore the simplest way to secure the revenue of the state.

The historical mission of the Physiocrats was to break the fetters of Mercantilism and to free industry and trade from the restrictions which were preventing its normal development. It was therefore in large measure a system of reaction and negativism. In its insistence upon
the sole productivity of agriculture it went too far, and a broader system had to be developed by Adam Smith which should give manufactures and commerce their rightful place. Their doctrine of freedom of industry has exerted a powerful influence upon subsequent theory and economic policy. They also made positive contributions to the theory of taxation.

The best-known writers among the Physiocrats were Frenchmen, Quesnay, Turgot, Du Pont de Nemours, Mirabeau and Gournay, though the Englishman Cantillon had anticipated some of their ideas.

Adam Smith.—Adam Smith has been called the father of political economy, and his book "The Wealth of Nations," published in 1776, has undoubtedly had a greater influence and won for its author greater fame than any other book on this or allied subjects that has ever been printed. It was justly famous, for it marked an epoch in the development of economic thought and for the first time presented a distinct systematic and comprehensive treatise on economics. Smith was original, for he built upon the labors of his predecessors,—and under the Physiocrats the science had already made considerable progress,—but he avoided their errors and added much that was his own. He embodied in his work many of the ideas of the Physiocrats, though he avoided their extremes, and was also greatly influenced by contemporary English writers, notably Hume. The great merit of his work lies in its eminent saneness, breadth of view and catholicity.

In his treatment of economics Smith introduced a new viewpoint. Hitherto all writers had considered the production of wealth as the end and aim of economic endeavor. But, though he dealt largely with production, Smith emphasized the importance of consumption: "Consumption is the sole end and purpose of all production and the interest of the producer ought to be attended to, only so far as it may be necessary for promoting that of the consumer." This is the modern standpoint. It was, however, often lost sight of in the immediate followers. Starting with the idea that the labor of a nation is the source of its annual income, "The Wealth of Nations" opens with a classical discussion of the division of labor. Smith, it may be noted, in great measure its productiveness, but when this is introduced each member of society depends upon others for the satisfaction of most of his needs; hence arises the necessity for exchange and the use of money. The exchange of goods necessitates their comparison and hence the idea of value arises. From this point Smith is led to study the component elements of price, wages, profits and rent. These researches fill the first two books and constitute his general economic scheme. The third book is historical in character and contains an account of the economic development of Europe; while the fourth book is devoted largely to a polemic against Mercantilism and Physiocracy; the fifth deals with public finance.

Smith's work, like that of the Physiocrats, was largely destructive; he had to overthrow before he could build up. He advocated the "simple and obvious system of natural liberty" and paved the way for free trade in England. He taught that when each individual pursues his own self-interest the best economic interests for society will be secured. While he stood for freedom of trade and personal liberty and initiative of the individual, he admitted certain modifications in this doctrine, as in his approval of the navigation laws, of a protective tariff for retaliatory purposes and in certain other cases of government interference. There is little doubt that if he could have seen some of the evils which followed this doctrine of non-interference after the development of the factory system, he would have modified his views still more. In spite of some of the criticisms later urged against Smith is his theoretical absolutism. He is also criticized on the ground that he was unduly individualistic and materialistic, but in these respects he reflected the general philosophy of his age. He showed his breadth of view and judgment by taking what was best in the prevailing theories of his predecessors and combining this into a unified system, to which he also made original contributions, notably in his discussion of value.

One reason for the success and popularity of Smith's work was that he wrote just at the beginning of a great industrial revolution. Before this time the system of industry in England was the so-called domestic system, under which the work of production was carried on in the home of the worker by hand methods, though middlemen operating on a considerable scale had already appeared. But beginning about 1760 there occurred a remarkable series of inventions which affected many lines of industry—cotton spinning and weaving, coal mining, iron smelting, manufacture of earthenware, and the improvement of transportation by the construction of roads and canals. The epoch-making change of this period lay, however, not in this series of inventions, important as they were, but rather in the substitution of non-human power for human muscles. This was first made possible on a commercial scale by Watt's improvement of the steam engine. A vast expansion of industry now took place; the factory system supplanted the domestic system, capital found new applications and began to play a more important role, while new labor problems arose with the new conditions of industry. New inventions were introduced which demanded freedom from old restrictions and the new industrial leaders approved highly of Smith's doctrine of non-interference. This accordingly became the cornerstone of English economics for the next generation or so, until the evils of this policy became so apparent as to lead to reaction. We may note some of the followers of Adam Smith.

Malthus.—By 1798 many of the evil effects of the Industrial Revolution were showing themselves and unemployment, poverty and disease were already problems that called for remedial treatment. Thomas Robert Malthus (1766-1834) had his attention directed to these evils while discussing a socialistic scheme of William Godwin and wrote his "Essay on the Principle of Population" to refute such utopian cures. In this he held that population tends to increase faster than the means of subsistence; that this tendency is restrained only by certain "positive" checks in the form of famine, disease and war, or by a "preventive"
check in the shape of moral restraint, such as the postponement of marriage. Any socialistic society, he therefore held, in which there was universal well-being and in which these checks did not operate, would be speedily broken down by his single principle of population. Malthus himself has given rise to enormous amount of discussion and has had an important practical influence in the attitude of economists and others to various schemes of social reform. His principle of population must be held to have stated an important truth, though it was not original with Malthus and was greatly exaggerated by this writer and his followers.

Ricardo.—David Ricardo (1772-1823), another follower of Smith, is best known for his theory of rent. While this was not original with him it was so fully developed in his Principles of Political Economy and Taxation that it has generally been known since as the Ricardian law of rent. Briefly stated the theory is that rent is due to the difference in the productivity of land of different qualities and the poorest land under cultivation. Rent is therefore a differential return which is due to the necessity of resorting constantly to poorer lands. It is a result of high prices and of the niggardliness of nature, which yields smaller and smaller returns to successive applications of labor and capital to the cultivation of the soil. This idea of a resort to inferior soils and of diminishing returns in agriculture, combined with Malthus' principle of population, gave rise to a most pessimistic theory of wages, known as the iron law of wages. As stated by Ricardo, "the natural price of labour is the price which is necessary to enable the labourers, one with another, to subsist and to perpetuate their race, without either increase or diminution" (Ch. V, § 1). If wages rise temporarily population will tend to increase and this will cause a fall again in the rate of wages. Nor will it help the laboring class to exercise thrift or self-restraint, for when wages fall to the low level necessary for their subsistence. The remedies proposed by Ricardo himself were the abolition of the poor laws and the development among the laboring classes of a higher standard of living. Ricardo made important contributions to the theory of money, to which subject his rigidly deductive method and his analytical skill were well adapted. In this respect his influence was unfavorable, for economic method was for many years diverted from the combination of inductive and deductive reasoning employed by Adam Smith to a purely deductive one. A false impression of accuracy and finality was thus given to economic theory.

Perhaps no writer went further than did Nassau William Senior (1790-1864) in narrowing the scope of political economy and treating it as an abstract science. His name is usually associated with the abstinence theory of interest, which was his contribution to economic thought. Ricardo had stated that the value of goods was fixed by their labor cost, but Senior pointed out that cost of production includes the abstinence of the capitalist in saving his capital for production, for which he must be rewarded. His new term was somewhat unfortunate to cause negative reasoning, but his emphasis of the contribution of capital to production constituted a real advance in theory. Most of the other English writers between Ricardo and John Stuart Mill were of minor importance and may be dismissed with a mention of their names. The principal ones were R. Jones, James Mill, J. C. M'Culloch, Robert Torrens and W. T. Thornton.

The Classical School in France.—The influence of Adam Smith and of the so-called English classical school of political economy was, however, not confined to England, but affected France and Germany. The writer who most undeviatingly followed Smith was the French writer, J. B. Say (1767-1832). In his Traité d'Economie Politique, published in 1803, he popularized The Wealth of Nations, but in so doing he reorganized and simplified the subject matter. His work was more than that of a mere popularizer, however, and he made some original contributions of his own. In his hands economics became a purely theoretical and descriptive science, being divorced from the vexed piece of land and the poorest land under cultivation. Rent is therefore a differential return which is due to the necessity of resorting constantly to poorer lands. It is a result of high prices and of the niggardliness of nature, which yields smaller and smaller returns to successive applications of labor and capital to the cultivation of the soil. This idea of a resort to inferior soils and of diminishing returns in agriculture, combined with Malthus' principle of population, gave rise to a most pessimistic theory of wages, known as the "iron law of wages." As stated by Ricardo, "the natural price of labour is the price which is necessary to enable the labourers, one with another, to subsist and to perpetuate their race, without either increase or diminution" (Ch. V, § 1). If wages rise temporarily population will tend to increase and this will cause a fall again in the rate of wages. Nor will it help the laboring class to exercise thrift or self-restraint, for when wages fall to the low level necessary for their subsistence. The remedies proposed by Ricardo himself were the abolition of the poor laws and the development among the laboring classes of a higher standard of living. Ricardo made important contributions to the theory of money, to which subject his rigidly deductive method and his analytical skill were well adapted. In this respect his influence was unfavorable, for economic method was for many years diverted from the combination of inductive and deductive reasoning employed by Adam Smith to a purely deductive one. A false impression of accuracy and finality was thus given to economic theory.

Perhaps no writer went further than did Nassau William Senior (1790-1864) in narrowing the scope of political economy and treating it as an abstract science. His name is usually associated with the abstinence theory of interest, which was his contribution to economic thought. Ricardo had stated that the value of goods was fixed by their labor cost, but Senior pointed out that cost of production includes the abstinence of the capitalist in saving his capital for production, for which he must be rewarded. His new term was somewhat unfortunate to cause negative reasoning, but his emphasis of the contribution of capital to production constituted a real advance in theory. Most of the other English writers between Ricardo and John Stuart Mill were of minor importance and may be dismissed with a mention of their names. The principal ones were R. Jones, James Mill, J. C. M'Culloch, Robert Torrens and W. T. Thornton.

The Classical School in Germany.—German expositors of Adam Smith displayed more independence and originality than did the French writers. Of these may be mentioned K. F. Rau (1792-1870), F. B. Rau (1792-1868), F. Nebenius (1784-1857) and J. H. von Thünen (1783-1850). Rau exercised considerable influence through his encyclopedic Lehrbuch der Politischen Oekonomie, which combined Adam Smith's political economy with much historical, statistical and material for-
His contribution to economic theory consists in his separate analysis of the entrepreneur's gains or losses of management. Thünen has contributed to the study of a number of special subjects, which he treated with great ability. But von Thünen made the most important contributions. In his work 'Der Isolirte Staat' he studied the effect upon rent of situation with respect to the market. His second work, 'Das System der Politischen Oekonomie,' gives the key to his position. It is really a treatise on international trade in which he attacks the free-trade principles of the classical school. His chief contribution was his theory of the stages of economic development. According to his theory, he says, passes through the stages of pastoral life, agriculture, commerce and manufacturing, but not all nations are in the same stage of development at a given time. Hence the government should assist a people who wish to pass from a lower to a higher stage against the competition of those nations which had already attained their full industrial growth. Practically he advocated protection for undeveloped Germany against industrial England. His doctrines had great influence upon German thought.

Henry C. Carey (1793-1879), an American writer, was also a protectionist and a nationalist, and on both these grounds criticized the teachings of the classical school. The best exposition of his views is to be found in his 'Principles of Social Science.' His main arguments in favor of protection are, first, that manufactures would develop association and diversity of interests, by which civilization would be better promoted than by agriculture alone. His second argument was more original, and is based on the necessity of returning to the soil what is taken from it. If a country exports foodstuffs and raw materials in exchange for manufactured goods, it depletes the soil and the land soon becomes exhausted; the ideal is a community where manufactures and agriculture are carried on side by side. He also attacked the Ricardian theory of rent and the Malhustian doctrine of population. Carey exercised considerable influence in the United States by his writings.

(3) Socialist Critics.—The third group of critics of the classical school was the early socialists. Most of these were French. Orthodox economists had always treated private property as an inevitable and inalienable institution. Now, however, we meet a group of writers who attack the ideas of private property and of competition. The Industrial Revolution had wrought sweeping changes in society since the time of Adam Smith and had been followed by many economic maladjustments and evils, such as child labor, low wages and crises. In seeking an explanation of these phenomena the socialists were led to attack the existing system of industrial organization and the economic school which defended it. The most important of these writers were C. H. Saint Simon (1760-1825), Robert Owen (1771-1858), Charles Fourier (1772-1837), Louis Blanc (1813-82) and P. J. Proudhon (1809-65). The first three of these wished to organize the labor force of the country for productive purposes into small associative or co-operative groups by voluntary action. Blanc proposed that the government should assist the establishment of such associations by advancing capital to them and that the government have abolished government. They all attacked the existing institutions of competition, which Blanc insisted was the case of every economic evil, and of private property which Proudhon said was theft. While often utopian and vision-
ary they were important as critics of existing economic theory by their attacks on institutions which had been accepted as matters of fact, while their insistence on the social nature of production won a valuable corrective to the individualistic tendencies of the classical school.

**Mill's Restatement.**—Modern economic science had first been formulated by Adam Smith; since his time Ricardo had added his theory of rent, Malthus his theory of population and Smith his theory of that of abstinence. On the other hand, various writers had attacked certain phases of his teachings or had modified certain conclusions. And more than all the Industrial Revolution had completely changed the economic world which Smith described and had brought new problems to the front. The time was now ripe for a restatement of the principles of economics which should take account of all these changes. In John Stuart Mill (1806–73) such a restatement was found. His book, *Principles of Political Economy*, with some of their Applications to Social Philosophy,* published in 1848, combined and organized all that was enduring in his predecessors’ work. It is extremely logical and well written, but contains little that is original. The clearest statement of English classical economics we may note its main teachings.

Self-interest was accepted as the motive to economic activity. Since each individual is the best judge of his own interests individual liberty is essential to economic progress; state interference was therefore disapproved of save in exceptional instances. Value is determined in general by demand and supply. Mill distinguished between normal and market value; at any given time demand and supply determine market value, but in the case of freely reproducible goods their normal value is set by the cost of production. His theory of value is therefore a cost theory. The Ricardian theory of rent and the Malthusian doctrine of population were fully accepted, and Mill often declared that there was no hope of improvement in the lot of the working class unless they checked the growth of population. His theory of wages is essentially that of the wages-fund, with the qualification that of abstinence. The determinate number of laborers who must work and a determinable amount of capital unconditionally destined to the payment of wages (i.e., the wages fund); this fund is distributed among the laborers solely by means of competition, and the rate of wages depends on the proportion between capital and population. Only by encouraging the growth of capital by means of saving, or by discouraging the growth of population was a valuation becorporably modified and wages raised. Mill made a real contribution to economics by his development of the Ricardian theory of trade—it is not the difference in absolute costs of production as between two countries, but in comparative costs, that determines international trade; foreign trade is therefore an advantage to all countries, but especially to backward ones. He did not give any space in his book to the subject of consumption, which finds a large place in modern works, but he was sympathetic with the demands and aspirations of the working classes. Indeed in his later years he recanted the wages-fund theory and took a long step toward socialism.

With Mill’s *Principles* the teachings of the classical school reached their climax and from now on we meet with increasing dissent from and modifications of its ideas. Exceptions may be made of Joseph Chamberlain (1836–1914) whose chief contribution lay in his theory of non-competing industrial groups, which limited the scope of competition to a much smaller area than that usually assigned it; of Michel Chevalier (1816–79) of France, and of the Swiss A. E. Ch. Jevons (1835–82), of whom it may be said that he showed itself most prominently in Germany, where the teachings of the classical school has never been accepted as fully as they had been in England and in France. To Germany, there fore, we must look for the next forward movement in economics. This was contributed by the historical school.

**The Historical School.**—Three names are usually associated with the rise of the historical school in Germany, those of William von Roscher (1817–94), Bruno Hildegard (1812–78) and Karl Knies (1821–98). They expressed their disagreement first of all with the abstract deductive method of the older school and insisted that the proper method was inductive and historical. Von Schommer and Karl Bücher, have laid less stress upon this point, and modern scholars no longer concern themselves with this barren controversy. As Schmoller says, "Induction and deduction are both necessary for the science, just as the right and left foot are needed for walking." Another point of disagreement was their denial of the existence of economic laws. Influenced by Hegelian philosophy and later by the theory of evolution they emphasized the relativity of such generalizations, and pointed out that so-called economic laws are provisional and conditional. On this point there would be little disagreement to-day; the only question would be as to what name to apply to such economic tendencies. The historical school also criticized the hedonistic psychology of the earlier writers and asserted that man is influenced even in economic activities by other considerations than those of self-interest. Perhaps it is putting the case too strongly to say, as M. Rist does, "that newer historical construction came to the rescue just when the science was about to give up the ghost, . . . infusing new life into the study," but they certainly offered a valuable corrective to the abstract tendencies of the classical school and have led to a great interest in economic history.

**The Psychological School.**—Another school which has played a very important part in the development of recent theory is the Austrian or psychological school. They emphasize the importance of subjective factors and analyze value on the basis of utility. While the first economists to emphasize these features were a German, H. H. Gossen (1810–58), and an Englishman, W. S. Jevons (1835–82), it remained for an Austrian group to develop the subjective theory of valuation to all the factors of production, and to develop consistent theories of interest, wages and profits. The foremost members of this school are Carl Menger, F. von Wieser himself very sympathetic with the demands and aspirations of the working classes. Indeed in his later years he recanted the wages-fund theory and took a long step toward socialism.
it in the words of Wieser, "the value of a single good out of a store is determined by that useful service which is the least important among those afforded by the store." Mill's cost of production theory of value is rejected, or at most cost has only an indirect influence; value is subjective. The Austrian school also extend their theory of value to the means of production and even to problems of distribution. The application of the utility theory to the problem of interest was made by Böhm-Bawerk, but it has remained a subject of discussion among American economists. The subjective theory of money, wages and profits. Among these may be mentioned J. B. Clark, I. Fisher, S. Patten, T. N. Carver and F. A. Fetter. This school has contributed to the advance of economic science by emphasizing the subjective elements in contrast with the classical school, but in sympathy with them and in contrast with the historical school they have reverted to the use of the deductive method. Out of the discussion between the two schools it has become clear that, just as both inductive and deductive methods are needed, so both objective and subjective factors must be considered in the problems of economics.

Consumer theory. Critics and antagonists to all these schools stand the socialists, who, since the day of Karl Rodbertus (1805-75) have become more scientific and less utopian. Rodbertus propounded a notable theory of crises, which he thought were due to insufficient purchasing power on the part of the laboring classes; poverty and crises can be avoided only by the socialization of property. More important was Karl Marx (1818-83) whose book "Das Kapital" became the veritable bible of the socialists. He held a labor theory of value, which led him to conclude that profits and interest and rent are robbery, and that socialism is both inevitable and necessary. Socialist criticism has been valuable in overthrowing the conception of a natural order, in developing the social viewpoint, and in leading to greater emphasis upon distributive justice, which, while never overlooked even by the classical school, had not received the attention it merited.

Economic Thought in the United States. Recent years have seen in the United States a development of economic thought not surpassed in any country. With the exception of H. C. Carey, American economists had usually followed the teachings of the classical school, until the brilliant writings of F. A. Walker (1840-97), who attacked the wage fund theory and developed the idea of enterpriser's profits. The formation of the American Economic Association in 1885 was a sign of the growing interest, and this has been followed by the establishment of half a dozen journals devoted to economic affairs. As might be expected in a new country, which was rapidly developing and whose natural resources were being exploited, there was considerable revolt against the pessimism and abstraction of the classical school. Many of the members of the rising group of writers had received their economic training in Germany and were in sympathy with the historical school. And finally the theories of the Austrian school have been accepted and carried forward by still another group. So that the development of economic thought in the United States parallels that which has taken place elsewhere, but has been characterized by much that is original and noteworthy. Among those who may be mentioned as having established a claim to recognition are H. C. Adams, T. N. Carver, J. B. Clark, J. R. Commons, R. T. Ely, H. H. Davenport, D. R. Dewey, F. A. Fetter, I. Fisher, A. T. Hadley, E. J. James, D. Kinley, J. L. Laughlin, S. Patten, E. R. A. Seligman, F. W. Taussig and T. Veblen.

Conclusion. It is difficult to draw any conclusions from an account of the development of the science of economics, for the one outstanding fact in this study is that it has been full of change and that the end is not yet. Out of the conflict of ideas however there has developed a body of knowledge which affords a common ground for all and constitutes the science of economics of to-day. The subject matter of this science, so far as it is a pure science, has more narrow, having sloughed off such subjects as political science and sociology, now treated it has become clear that, just as both inductive and deductive methods are needed, so both objective and subjective factors must be considered in the problems of economics.

Ernest L. Bogart, Professor of Economics, University of Illinois.

ECONOMICS AND THE WAR. When in the early autumn of the year 1914 the present great war was forced upon the world by the joint action of Germany and Austria-Hungary, the great powers had been at peace with each other for a period of nearly 50 years and during this interregnum of the war lords, economic conditions, including especially domestic production, monetary and banking systems, international trade and the various other institutions of an organized economic life had become stabilized by the relatively unchanging demands of a world at rest. The mobilization for war radically changed, almost in the twinkling of an eye, the conditions under which the economic life was thenceforth to be
ECONOMICS AND THE WAR

carried on, and as a necessary consequence the economic life itself. Economic customs and institutions hoary with age and venerated and perpetuated because they had been useful under other conditions were continued without question, then questioned, then abandoned as the requirements of war were found to differ from those of peace. While war is destructive of human life and the savings of the past, it is also and in no less measure the destroyer of outgrown institutions and customs and the creation of new ones, some of which may prove permanently beneficial, while others may be discarded as mistaken attempts to meet the changed conditions. When the German War Council met at Potsdam on 5 July 1914, it was attended by the great bankers, railway directors and the captains of industry as well as by the war lords and the representatives of the state. The representatives of every line of activity, finance, transportation, trade and industry as well as the army and navy were solemnly asked by the German Government in its account of the historic conference was that the bankers must have time to sell foreign securities and to make such loans as might be necessary to prepare their banking institutions and their other financial interests for the initial shock of the war. The request of the financiers was granted and the Serbian ultimatum postponed for the period named to give the banking institutions time to arrange their loans and to convert their foreign securities into gold or credits as nearly liquid as they might find feasible. This financial moratorium while not so important as many events which have taken place during the war clearly illustrates an important principle. War separates or tends to separate the nations engaged in the conflict from each other, severing the economic ties which bind them, and forcing them to adopt either one or both of the following plans: first, they may seek to establish economic relations with countries other than those with which they have been trading, or second, they may turn to the satisfaction of their own wants by diversifying their own industries until as nations they have become entirely self-sufficient. During the present war both of these expedients were adopted. For the past half century, Germany has, by the conscious effort of her government, adopted the policy of using economic pressure to force her citizens to provide more and more fully and completely for their own wants. During a much longer period, England has specialized as a producer of a limited number of commodities and has relied upon her ability as an international trader to exchange a part of her products for such other commodities as she needed for a fully developed economic life. When war was declared, Germany ordered her navy and merchant marine to seek safety in the most convenient ports and thereafter she and her allies have relied upon their own diversified production together with such neutral trade as has been able to gain access to her markets to provide for the wants formerly supplied by im-
ports from all parts of the globe. England, France and the United States on the other hand adopted, partly by necessity, partly by choice, the policy of keeping the seas open to their merchantmen and developing their international trade as never before. While Germany has been building both battleships and merchantmen as a preparation for the trade competition that will inevitably follow the conclusion of the war, the allied nations have been forced to do the same as a necessary consequence of which may result from the war at all. This in itself has caused a profound change in the economic life of the United States and has intensified the most marked economic characteristics of English industry and trade. The change referred to has already been to have its immediate effects and its after-effects will be even more significant. To carry on international trade, ships are necessary and if a nation is to be at all independent, it must provide its own. At the beginning of the war, the United States possessed a fairly strong navy and a considerable fleet of ships suitable for coastwise traffic. During the first two years and a half of the war, the United States was called upon to supply many of the other nations with food, raw materials and such manufactured products as she was able to supply in ever-increasing quantities. It is of course stating a self-evident fact to say that the United States could not grow wheat and build ships with the same identical labor and capital; that as she built more ships she must grow less wheat and mine less iron and coal and that consequently her creative power was diverted by the demands of war from the production of food and materials to the building and sailing of ships.

That the after-effects of the increase in tonnage and the new avenues of international trade thus opened up by the war will prove to be permanent factors in our economic life is hardly open to doubt. Our ships, built to help win the war, will after peace has come be active agents in promoting the interchange of goods between the United States and every other nation, which by reason of its geographical situation, size and the far training of its people, is able to produce for us goods that we cannot so well produce for ourselves. International trade promoted by the war will not cease with its termination. To sell to others we must in turn buy of them and consequently the stimulation of international trade by the war will after peace has been declared tend to promote freer trade relations with the rest of the world than has prevailed in the past.

The first effect of the war was to check international trade, but not for long. Soon the demands of the nations at war for war material began to be felt and with this demand international trade began to revive but at the same time its character changed both in quantity, in direction of flow and in kind. In the case of the United States the war checked exports to such an extent that for August 1914, the balance of trade was against us by over $19,000,000. Late in September exports began to flow out in ever-increasing quantities until limitations imposed by lack of shipping served

* Morgenthau, the World's Work, June 1918.
to cause a temporary check. In September 1914, the balance of trade was again in our favor and for the last five months of the first year of the war the total excess of exports from the United States over imports was $264,000,000. Despite the submarine warfare, the lack of shipping and the high rates for freight and insurance, both exports and imports continued to increase year by year and generally month by month until at the present time the total of our foreign trade is approaching $10,000,000,000 per year with an excess of exports of over $3,250,000,000. The following table shows the important facts in regard to the quantity of our international trade since the outbreak of the war:

**International Trade of the United States**

(In millions of dollars)

* Decrease; all others increases.

From these tables it may be noted that while our imports increased in each of the four great classes into which the commodities are here grouped, the marked increases are confined to raw materials and food. With regard to the exports the effect of the war has been to lessen the export of raw materials and to increase measurably both foodstuffs and manufactured goods. Comparing the two periods with respect to the quantity of international trade, it may be noted that while the total of both exports and imports more than doubled, the balance of trade for the four years of the war was almost five times that of the preceding four years. The change in the character of the trade necessarily affected our industries by throwing new burdens upon those where the balance of trade in our favor increased most rapidly. How well our agricultural classes and our manufacturers have met the call upon them is evidenced by the partial failure of the railroads and the shipping facilities to move the goods to the ports and across the Atlantic as fast as they are made ready for the transportation agencies.

The increasing balance of trade in our favor, proving our power to assist in feeding, clothing and arming the nation, at the same time providing for our own needs, has raised questions in international finance that before the war had been thought to be of little practical importance. Writers on international trade have generally taught that exports from any country are limited by its ability to purchase goods in exchange, for the reason that otherwise the country exporting becomes short of goods and overstocked with money, thus making goods dear and money cheap. The exporting country then becomes an importer, exchanging its surplus money for the goods which it needs and the balance of trade then turns against it. Before the war the United States was using the credit due it from the excess of its exports in various ways. In the first place, it was hiring its goods freighted across the water in the ships of other nations and it was also to a large extent purchasing insurance of the English and German companies. In the second place, it was paying interest on approximately $10,000,000 of European capital that had been invested in American railways and other industries. In the third place remittances to friends and travel in European countries accounted for another portion of considerable size; and in the fourth place, it imported regularly a small amount of gold, the last resort in settling foreign trade balances. When the balance in our favor continued to grow despite the use of the ordinary methods of settlement it became evident to the American financiers as well as to those representing the various European countries with which we were trading that other means of adjusting our growing credit must be employed. The first means actually used was the repurchase of American securities. At first it was feared that securities held abroad would be dumped in quantities upon the market at a time when conditions for their purchase were so unfavorable that the prices would break far below intraking levels and to guard against such a catastrophe the stock exchanges in all the leading commercial countries were closed for a time. It was, however, found that the European holders were loth to part with their American securities and when after borrowing and purchasing a considerable quantity for the purpose of securing a loan the English government thought it desirable to support sterling exchange by the further sale of securities it was found necessary to impose a special tax of 10 per cent of the face value of all foreign securities held in England in order to encourage their holders to part with them and thus help settle the debts arising from the excess of imports. Mr. Loree's investigations showed that of the $5,000,000,000 to $6,000,000,000 of American securities held abroad at the beginning of the war only about $1,000,000,000 were repurchased before 30 June 1915, and not over $1,250,000,000 were sold here during the period 1 Aug. 1914 to 31 Jan. 1917. The difference between the value of the excess of exports of the imports, plus freights, insurances, remittances to Europeans, travel in foreign countries, the value of purchased securities, and
the importation of gold, notably in the latter part of the year 1916, has been paid for out of the proceeds of loans placed in this country directly or through the medium of the United States government.

Within a country at war, the changes in its economic life are pronounced and permanent. From the economic standpoint, the human life that is sacrificed by war either permanently or for the period of the conflict reduces the productive power of the nation by the amount thus sacrificed. With regard to capital, the same principle holds true. Land, labor power and capital united into working units are the producing agencies in every stage of economic activity. War has a double effect upon all these. It destroys and it diverts. It uses land for war purposes, thus preventing its use for productive ones. Land devoted to camps, cantonments and aviation fields cannot at the same time grow corn and wheat; land over which a battle has raged for some length of time is thereby rendered temporarily unfit for agricultural purposes, as witness northern France and parts of Belgium. War first diverts a considerable portion of the labor power from the work of creation to that of destruction, and during the process the labor power thus diverted is actively engaged in destroying the labor power of the enemy and the capital of both. With capital the same general conditions prevail. A considerable portion of our capital is and for the past four years has been exclusively employed by and devoted to the claims of war. An excellent illustration is furnished by the cotton harvest. The 1914 crop was an unusually heavy one and the sudden interruption of industry caused by the war lessened the normal demands of the trade so much that a cotton pool was formed for the purpose of loaning $135,000,000 to those wishing to hold their cotton and thus prevent the ruinously low prices that would be likely to result. As soon as the war was well under way the demands for cotton for war purposes become sufficiently urgent to counteract the lessened demand from the ordinary trade so that the pool was dissolved after having loaned only $28,000.* Since 1915 the price of cotton, owing to its use for explosives as well as for clothing, has risen to new high levels and the problem has become one of furnishing cotton rather than of providing an artificial market to prevent prices falling below the cost of production.

When land, labor and capital are working together in proper proportions and the units thus formed are wisely directed, not only is production at a maximum, but, what is almost if not quite of equal importance, the three factors of production share the results of their joint efforts in fairly equitable proportions. War as a destroyer does not always act impartially. Sometimes it destroys men faster than it destroys capital. Sometimes the reverse is true. In either case, land as a factor of production suffers less than either of the other two factors. When men and consequently labor power is destroyed faster than capital, the labor element in production becomes deficient in quantity and hence in response to the urgent demand for more labor power, wages rise relatively to the rate of interest; conversely, when capital is destroyed or diverted from productive uses faster than labor power embodied in man, then the interest rate rises faster than the rate of wages. Attention should be called to the fact that it is always the net available supply of labor and capital that is referred to.

If the productive power of the laborers is augmented by an increase of speed, if machines are operated more continuously, each of these methods of increasing efficiency will counteract the absolute loss of men and machines. During the present war, the diversion and destruction of men and capital has caused the interest rate to rise, while rents in relation to wages and interest, except in areas crowded as a result of peculiar conditions, have fallen. Whether wages have risen more rapidly than interest or the reverse has yet been demonstrated owing to the inherent difficulties of determining the rate of wages.

A. The direct effect of the unprecedented destruction of capital is reflected in the rate of interest. A somewhat less direct but none the less important cause is the speeding up of industrial establishments and the increased efficiency with which capital is used. A third effect is found in the various expedients adopted to prevent the investment of new capital in any industries except those which are essential to the successful prosecution of the war.

(1) Immediately after the outbreak of the war interest rates were not only high but were also unduly fluctuating and as a result various means of stabilizing the rate and preventing its rise to abnormal heights were discussed and some attempts to control the rate were in a measure successful. In general, however, the fears of financiers and the large borrowers were never realized, for while the rate of interest has advanced as a result of the destruction of capital by the war, the advance has been much less than was early predicted. Take for example the discount rate of the Federal Reserve Board; 31 Dec. 1914, the New York rates were as follows: for 30-day paper, 4½ per cent; for 60- and 90-day paper, 5 per cent; on 24 May 1915, the rates were: for 16- to 90-day paper, 4 per cent. In the commercial paper market the advance has been somewhat marked especially during the past year. In August 1917 the rate for standard commercial paper was 5½ per cent; one year later, it was 6 per cent. The bond market also shows a gradual increase in the interest rates. In December 1915, 40 standard bonds, selected for comparison by the Wall Street Journal, were selling at an average price of $94.83 per $100. In December 1916, the same bonds were selling at $94.97, a slight advance. In October 1917, they had fallen to 86.23 and on 29 April 1918 to 83.61. During the same period, the return on standard government bonds has advanced from an average of less than 4 per cent to an average of nearly 5 per cent.

(2) It is at this date quite impossible to make any quantitative estimate even of the increased productivity of industrial establishments resulting directly or indirectly from the threatened shortage due to the destructive effects of the war. It is, however, easily demonstrable that during the present great war, as during

those of preceding generations, our own industries as well as those of Germany, Austria, Italy, and Japan. Had the war been fought in youth as it were and in many cases increased their productive power rapidly enough to more than neutralize the loss of capital resulting from the war. When the second great English war loan was floated, at that time called the greatest finance and transaction in history, it was generally assumed in England and feared in this country that a flood of American securities held in England for investment would be thrown upon the market and that as a result our own security market would be thrown into confusion and values established in England and other foreign countries would be suddenly sacrificed. As a matter of fact the loan was floated at 4½ per cent and sold at par without seriously affecting the domestic or international market. So great was the productive power of the people of the United States that during the year 1916 they not only financed their own industries at a fairly reasonable rate of interest, but in addition purchased approximately $1,000,000,000 of foreign securities and repurchased a much larger amount of securities of American corporations held in European countries. And since the United States has been a participant in the war, she has financed her own loans and assisted her allies without at the same time disturbing either her savings bank deposits or her investment in foreign enterprises. Indeed so much had the net income of the United States increased during the war largely as a result of increased efficiency of capital and labor and their more harmonious co-operation that when the third Liberty Loan of $4,170,000,000 was taken in May, 1918, by over 17,000,000 subscribers it was generally remarked that the money market was scarcely ruffled while the price of standard bonds was quoted as firm and advancing. In addition to the repurchase of securities and the subscriptions to foreign and domestic loans, the American investment market absorbed during the year 1916, according to the tables compiled by the Journal of Commerce, over $3,500,000,000 per value of domestic capital issues.

(3) The increase of production and the maintenance of reasonably low interest rates has not been achieved without conscious effort on the part of both citizens and the government. Our citizens quite generally have eliminated unnecessary expenditures and confined their consumption to the essentials of an efficient life. They have thus been able to produce more while consuming less. Those who have been able to save something each month and each year have quite generally used better judgment in investing their earnings, although as yet there is, as always in the past, a strong tendency to take a chance on enterprises supported wholly or almost wholly by the glowing promises of their promoters. It is, however, chiefly by organized effort that the investment of new capital has been more wisely directed. Early in the war, bankers' associations, chambers of commerce, clearing-house associations and other organized groups of the smaller as well as the larger investors began to preach the doctrine that to win the war every dollar must be placed where it could do the most good. In this work the Investment Bankers' Association has performed a most valuable service. It first formed a capital issues committee and then entered upon a campaign to secure the creation by the government of a commission whose function it would be to prevent the investment of new capital in non-essential lines. This movement to conserve capital by directing its investment into the more needed lines was inaugurated by the British government early in the war and through the efforts of the bankers and the Secretary of the Treasury at the Federal Reserve Board established in the latter part of the year 1917 a voluntary plan for passing upon capital issues of $500,000 or over in the case of corporations and $250,000 or over in the case of States, counties and municipalities. This Capital Issues Committee of the Federal Reserve Board was, however, not intended to be a permanent feature, for in the annual report of the Secretary of the Treasury for 1917 a plan for a war finance corporation was outlined, an institution intended to assist in the financing of essential industries as well as to restrict the flow of new capital into the non-essential ones. The plan of the Secretary of the Treasury met with some opposition but after its purposes were fully explained, it was passed by Congress early in April and on the fifth day of the month was approved by the President. The War Finance Corporation Act created a corporation with $500,000,000 capital stock, all of which was subscribed by the government, and empowered it to borrow on its own bonds not more than six times its paid-in capital. With the funds thus secured it was authorized to loan under conditions stated at length in the act to banking institutions and in certain exceptional cases directly to corporations. As a supplement to its financing power, the act authorized the President of the United States to appoint a Capital Issues Committee, three of whose members should be chosen from among the members of the Federal Reserve Board and the committee was authorized by the act to investigate, pass upon and determine whether it is compatible with the national interest that there should be sold or offered for sale or for subscription any issue or any part of any issue of securities hereafter issued by any person, firm, corporation or association, the total aggregate par or face value of which issue and any other securities issued by the same person, firm, corporation or association since the passing of this act is in excess of $100,000.

*From 1 July 1915 to 30 June 1916 a conservative estimate was $1,500,000,000.

ECONOMICS AND THE WAR

struction and after having accomplished its immediate purpose proceeds to kill, maim and invalidate a portion of those whom it has thus destroyed. In this light the effect of war on labor is entirely similar to that to which it has on capital. There is, however, one marked difference that must not be overlooked, viz., the longer period generally required to replace the labor power which has thus been destroyed. At the beginning of 1917 a large number of workingmen were laid off and unemployment threatened to become a serious menace to industrial peace. Just as gold pools and cotton pools were formed by the financial interests, so commissions on unemployment were formed in the larger cities to study and to formulate plans for providing the unemployed with opportunities for earning a living. So early in the war as the winter of 1915 it was estimated that 2,000,000 wage-earners in the United States were without employment, although, as a result of the war, immigration from Europe had almost entirely ceased. This situation was, however, only temporary. By June 1915 the call for skilled mechanics exceeded the supply and common labor began to be short in the mines and the shops of Pennsylvania and West Virginia. By August, labor troubles began to loom up seriously, owing to the scarcity of labor, the consequent high wages offered to secure laborers by rival industries and rival plants, and the failure to advance wages of employees who had been continuously employed by individual establishments for a period of years. In England the labor situation became so menacing to national efficiency that in December 1915 a joint conference was called to consider the labor question and the demands of the wage-earners for increased pay. This conference was participated in by representatives of the government and of the labor unions and served to call attention to the underlying principles of the whole question of rising wages and the effects of such increases upon prices of products. Fortunately for England and the cause of the allied nations the labor situation was considered at this and other similar meetings in connection with its relationship to the national efficiency and the problems of war and as a result a system was gradually adopted of basing wages upon the general average of prices of commodities from month to month. Since the early part of 1916 the expansion of the industries in the United States has been limited more by labor shortage than by the lack of necessary capital. The shortage of labor was especially felt by the iron and steel industries and seizing this favorable opportunity the railway trainmen began a campaign to secure an advance in wages as their fellows in the steel and textile mills had already done. In the spring of 1916, the shortage of labor extended to the farms and by May of that year it was generally considered that the labor shortage was the most important question in the industrial world. The advance in wages was the effect of war on labor. The United States Steel Corporation for the 10-year period ending with the summer of 1916 is illustrative of the movement of wages in an expanding industry in response to a rising price level and an increasing shortage of labor due to the war. On 1 Jan., 1907, the United States Steel Corporation increased wages by 7 per cent; in 1910 by 6 1/2 per cent; in February, 1913, by 10 per cent; on 1 February, on 1 May, and again 1 Nov., 1916, 10 per cent; on 1 May and again on 1 Oct., 1917, 10 per cent; while in March, 1918 the steel companies generally advanced wages of common labor by 15 per cent. Advances in other lines were perhaps less frequent and in some cases less rapid, but in every line the advance was marked, especially so in the essential industries such as the railways, textiles and the mining of coal. As already stated the railway trainmen began their campaign for an increase in wages early in 1916 and in April of that year a conference between their representatives and those of the railways was held for the purpose of modifying the railroad labor unions, which, stated in its simplest terms, was for an eight-hour day. The demands translated into actualities really amounted to an increase of wages owing to the obvious impossibility of rearranging the runs of the trainmen in such a way that each could be given a working day of eight hours. The result of granting the demands of the railway trainmen's unions must necessarily be to increase their pay by increasing the amount of overtime work, a result that was actually achieved in September 1916 by the passage of the Adamson bill and its subsequent approval by the Supreme Court of the United States. In the copper industry, one of those most affected by the war, the demand for labor has exceeded the normal supply and since April 1917 special efforts have been made to prevent the shortage of labor from interfering with the supply of copper necessary for the successful prosecution of the war. For the first three years of the war a plan of increasing wages was introduced which was followed with favorable results. During the past year, owing to German propaganda on the one hand and to the artificial control of the price of copper by the government on the other, the wage situation became alarming in certain districts in the West; strikes and their attendant incidents becoming the order of the day, with the result that a serious shortage of an essential article was feared. Fortunately here as in other industries the good sense and patriotism of our citizens, laborers and managers alike, re-established peaceful relations and the threatened disaster was averted. As for the other industries, such as the manufacture of brass goods not directly used in war, automobiles, hardware, etc., the demand for men in the war industries has been so abnormal that every employer of labor in the less essential occupations has been obliged to advance his scale, following often somewhat behind that established by the essential industries in order to hold his force at all.

The shortage of labor power caused by the
demands of the war has as its direct result checked production and advanced wages. The economic effects however do not end here. There are other results, less direct but none the less important. The more important of these indirect effects are, first, the speeding up of labor's pace; second, the introduction of women into various vocations hitherto exclusively or almost exclusively occupied by men; and third, the forced diversion of labor from the less essential vocations to the more essential ones by the action of the various governments engaged in the war. Each of these movements is so important in the present and in the future that any adequate discussion of its causes and results would call for space beyond the limits permissible here and on this account those interested in such economic developments are referred to the books and pamphlets on the several subjects.*

It is, however, not in international trade, nor in the relationships of capital and labor to each other and to the other economic activities that the present war has had its most far-reaching effects. Of all the economic phenomena, prices of commodities are the most effective in economic changes and on this account it is here that war accomplishes its most important economic results.

The Civil War, it will be recalled, was accompanied by a rapid increase in the price level and was followed for a period of 30 years by a continuous decline. Beginning about 1896, as a result of improvements in smelting and the opening up of new mining districts, the output of gold increased so rapidly that the downward trend was converted into an upward movement that still continues. By 1904 prices had ascended to a level substantially equal to that of 1860 and by 1914 the general level was approximately 50 per cent above the low point of 1896. Since the outbreak of the war prices have continued to rise at an unprecedented rate until at the present writing, September 1918, the general level is estimated by the United States Bureau of Labor Statistics to be over 90 per cent above rates prevailing in 1914. The basic causes of the rise in prices both before and during the war are well understood. Prices are the rates at which goods exchange for money and consequently anything that makes goods relatively scarce and money relatively plentiful causes prices to rise. The primary economic effect of war it must not be forgotten is to cause commodities to be used up more rapidly than before and at the same time to lessen the productive power of the nations at war. Commodities then become less plentiful with respect to wants and prices begin to rise. Under normal conditions the rise in prices induces producers to work harder and as a consequence goods become more abundant and then prices fall. In times of war, and pre-eminently in a war making such unprecedented demands for arms, munitions, aircraft and other offensive and defensive instruments of warfare, a considerable portion of the productive forces are engaged in war activities and the remainder are incapable of fully answering the calls made upon them. Food and clothing then become relatively scarce and despite the efforts of those producing the commodities needed for a comfortable and efficient life, prices continue to rise except where the government intervenes through laws and fixed prices. Beyond laws they may not legally go. When the government fixes maximum prices it must at the same times establish priorities, classifying items into the essential, the less essential, the desirable and the superfluous, and then by the creation of food commissions and the administration of such agencies not only see that its scales of prices are observed but also that production is stimulated or consumption curtailed or both as the occasion demands.

While commodities have been growing, relatively speaking, scarce and dear, money has as a direct result of the war been growing plentiful and cheap. It will be remembered that a part of the balance of trade in our favor has been settled by the importation of gold, thus making the supply of the basic money more abundant than ever before. From the beginning of the war, our financiers as well as those of England and France have been trying to prevent the importation of gold by the United States for reasons that such a movement causes prices to rise and thus interferes with the sale of our foodstuffs and other commodities which we desire to sell and the European nations at war desire to buy. It was for this reason that the British and French governments sent a joint commission to this country in the autumn of 1915 to confer with our government and our financiers with the result that arrangements were concluded by which a series of secured loans were provided for, thus permitting the sale of our exports without at the same drawing gold from England and France into this country. Notwithstanding all efforts made to check the flow of gold toward the United States, so strong are the natural economic forces that the importation of this precious metal, while seriously interfered with, has never been entirely stopped. Between 8 Jan. 1915 and 22 June 1917, over $1,600,000,000 in gold was imported into the United States from various foreign countries, the larger part of it coming from the nations at war. From October 1917 of the war to 10 Aug. 1918, the net gain in our stock of gold resulting from the large excess of imports over exports is over one billion dollars worth.

MAURICE H. ROBINSON,
Professor of Economics, University of Illinois.

ECONOMY, Pa., village in Beaver County, on the Ohio River, and the Pennsylvania Railroad, 20 miles northwest of Pittsburgh. The first settlements were made by a colony of Harmonists who had formerly been in Pennsylvania, then moved to Indiana, but returned and founded Economy in 1825. Pop. 860. See Harmonists.

ECRÉVISE, the French name for cray-fish (q.v.).

ECSTASY, an intense emotional state in which the scope of consciousness appears on introspection to lack all differentiation. It is characteristic of religious devotees. Mysticism is the opinion that ecstasy is a cognitive state, and mystics usually assert that the true knowledge, or even the only true knowledge, is that acquired in a state of ecstasy. Ecstasy is not confined to any one religion nor to any one state of civilization—it is shared by the Buddhist monk, the Hindu yogi, the Moslem dervish, the Neo-Platonic sage, the Jewish cabalist, the early Christian martyr, the Swedenborgian and the medicine-man of the Amazonian savage. It is of the most varied nature as to its causes, its physiological and psychological concomitants, and the interpretation which it receives. Intoxicants, wild orgiastic dances, intent gazing at the navel or crystal globe, the mortification of the flesh, strange postures, the droning repetition of sacred words—all these devices and myriad others are employed to sweep from the field of consciousness all sharply-bounded ideas of particular things, and to lead the soul into a contemplation which finds all its demands satisfied within itself. The state of ecstasy and the ideas of any of these means shows in its concomitants an intimate association with hypnotic phenomena—it is accompanied in certain cases by amnesia, the stigmata of the saints, loud irrepressible cries or frenzied dances and visions of the most varied kinds. In the Occident, ecstasy is oftentimes interpreted as a direct communion with God, an unmediated entrance into the inmost heart of things. The less theistically inclined Hindu regards his ecstatic state rather as a sloughing off of the appearances of Being and even of the will to be, so that the soul floats away into the blissful non-existence called Nirvana. In many cases where states of an essentially ecstatic character have been attributed to demoniac possession.

Ecstasy is closely related to other forms of very intense emotion. The ecstasy of the Moslem fanatic is above all a warlike passion, a desire to carry jehad into the lands of the unbeliever. Ecstasy of the orgiastic variety has very commonly a strong sexual element, as the case may be. The deliberate evocation of ecstasy as a means of inducing a pleasurable excitement is by no means unknown even within the Christian faith, as is shown by the circumstances of many religious revivals. Ecstasy may be associated with objects other than those of religion. Intense aesthetic contemplation often leads to an absorption of the spectator in the work of art so complete as to deserve the name of ecstasy. In such a case the scope of the work becomes so intense as to blot out all thought of the detail by which this effect is conveyed.

The cognitive value of ecstasy is very difficult to determine. It is certainly impossible to refute by recourse to the processes of consecutive thought what purports to be the object of a knowledge higher than thought and independent of its norms. Nevertheless, this logical irrefutability of mysticism is by no means a proof of its validity. The fact that the mystic believes with the utmost assurance in a communication with God does not in the least show that his mystical experience has not merely been a general sense of well-being, combined with the apparently amorphous mental content of one in a state of partial auto-hypnosis. So long as the mystic keeps his worlds of descriptive knowledge and of revelation sharply distinct, whether he follows the course of each to decide for himself. However, much of the discursive knowledge that the mystic accepts as guaranteed by his mystical experience is not contained in the mystical experience itself, which is for the most part non-discursive in nature. The transition between the mystical vision, such as that which appeared to Moses on Sinai, and its interpretation in discourse—the Ten Commandments—is subject to a criticism on the part of reason, to precisely the same extent as any other transition from one item of knowledge to another. The weakest link in the chain that leads from the state of ecstasy to the dogma which claims to have been revealed in this state is the first step from direct immediacy to descriptors knowledge; it has undergone some strong emotional shock. (See MYSTICISM; TRANCE.) Consult Achelis, T., 'Die Ekstase' (Berlin 1902); Granger, F., 'The Soul of a Christian' (London 1906); Inge, W. R., 'Christian Mysticism' (Oxford 1899); James, J., 'Varieties of Religious Experience' (New York 1902); Janet, P., 'L'état mental des hystériques' (Paris 1893–94; tr. New York 1901); Rééjac, E., 'Essai sur les fondements de la connaissance mystique' (Paris 1897); Ribot, 'Les maladies de la mémoire' (Paris 1881); Starbuck, E. D., 'Psychology of Religion' (London 1899); Underhill, E., 'Mysticism' (London 1911).

ECTHYMA, ēk-th'ī-ma, a complication of a number of general diseases by itself as a form of pustular inflammation of the skin, particularly distributed on the extremities, the lower, especially, the neck and trunk also often being affected. As a rule the affection begins as a small pimple which takes a rounded outline unless scratched. This pimple develops into an ulcer which is covered with a thick dark crust. The ulcer heals slowly and there is a small scar resulting. The development of the disease is slow, usually running a fortnight, and the pimple may be single or appear in crops. There is burning and pain. The common cause of ecthyma is diminished bodily resistance, such as is found in starvation or in syphilis, tuberculosis, diabetes or anemia.

ECTODERM, the outer cellular layer of the embryo. See EMBRYOLOGY.

ECTROPION, or ECTROPIUM, a Greek term meaning an everted eyelid, a turning outward; an abnormal eversion of the eyelids. It is most frequent in the lower lid. Acute ectropion is due to swelling of the conjunctiva or spasm of the orbicularis palpebrae muscle. Chronic ectropion is due to scarring, paralysis of the seventh nerve or projection of the eyeball. Sehiz that he has been in communication with God does not in the least show that his mystical experience has not merely been a general sense of well-being, combined with the apparently amorphous mental content of one in a state of partial auto-hypnosis. So long as the mystic keeps his worlds of descriptive knowledge and of revelation sharply distinct, whether he follows the course of each to decide for himself. However, much of the discursive knowledge that the mystic accepts as guaranteed by his mystical experience is not contained in the mystical experience itself, which is for the most part non-discursive in nature. The transition between the mystical vision, such as that which appeared to Moses on Sinai, and its interpretation in discourse—the Ten Commandments—is subject to a criticism on the part of reason, to precisely the same extent as any other transition from one item of knowledge to another. The weakest link in the chain that leads from the state of ecstasy to the dogma which claims to have been revealed in this state is the first step from direct immediacy to descriptors knowledge; it has undergone some strong emotional shock. D., 'Psychology of Religion' (London 1899); Underhill, E., 'Mysticism' (London 1911).

NOBERT WIENER.
Ecuador, a South American republic, bounded on the north and northeast by Colombia, and on the southeast and south by Peru, and on the west by the Pacific Ocean. The area, including the Galapagos Islands, is about 120,000 square miles.

The cordilleras of the Andes traverse Ecuador, running nearly north and south, with elevated plains between the eastern and western mountains, some of the latter forming a sequence that has suggested to geographers two parallel chains. Though there are not here the highest single peaks in the world, or even in South America, there are nowhere else so many peaks of very great height, forming a group. Their equatorial situation gives to these masses of granite, gneiss, schist, trachyte, porphyry, volcanic detritus wholly exceptional contrasts in temperature. This region has been in the past, and is probably to-day, more subject to volcanic disturbances than any other in South America. As an offset to the group of high peaks, the Andean ridges sink downward, forming the lowest pass at any point between Colombia and the southern division of the Andes. The principal rivers of the lowlands of western Ecuador, running from the central region of mountains and high plains to the Pacific, are the Guayas and the Esmeralda. The former empties into the Gulf of Guayaquil. In the eastern lowlands, the Napo and its tributaries belong to the Amazon River-system. There are numerous small lakes.

The mean temperature of the coast at Guayaquil, etc., is 80°F., that of the interior ranges from 95°F. in the lower valleys to 65°F. or even 50°F. on the plateaus, according to the altitude. The lower slopes of the mountains are torrid; the highest crests are snow-clad. The elevated valleys of the Andes have a very salubrious climate. They lie at an altitude of from 7,500 to 9,000 feet, where the temperature is moderate and ever unknown. The climate of the capital is temperate and springlike throughout the year, with little variation and it is said to be one of the best in the world for the cure of tuberculosis. There are two seasons only, the rainy lasting from December to May, and the dry from June to November. The first meteorological station in Ecuador was established in 1915. It has since been in successful operation at the Quinta Normal Agricultural School, near Ambato. Stations are now established at Sangolqui, Saquimala, Latacunga, Pansaleo, Mulalillo, Pilaro, Palate, Pelileo, Banos, Pilahua, La Victoria and El Puyo. They are in charge of the director of the Quinta Normal, where the data are computed and reduced to tables each month, which are published in the Bulletin of the school.

Petroleum, sulphur, gold, platinum, coal, copper, mercury, lead and iron are plentiful in Ecuador, but of these gold alone figures in the list of principal exports. The Zaruma mines, province of El Oro, are worked on an extensive scale by an American company. That district contains numerous gold-bearing quartz veins, which were worked by the Spaniards 100 years ago. Along the Santiago, Cochabibi and Umibi rivers in the province of Esmeraldas there are placer deposits of gold and platinum is found in conjunction with gold in the Esmeraldas washings. Silver is exported to a small extent.

History.—The Quito Indians, who held the country near the present capital, were conquered, perhaps in the 10th century, by a more warlike race led by chief's called Scyris. These in turn yielded to the Incas of Peru. After the death of Inca Huayna-Capac, the empire was divided between his two sons, Atahualpa and Huascar. The former, whose mother was a Scyris princess, received the Quito kingdom; Cuzco and the southern empire were given to the latter. War broke out between the brothers shortly before the Spaniards under Francisco Pizarro arrived upon the scene, and this civil strife made possible the conquest of a great nation by a handful of foreign adventurers. (See Pizarro.) Benalcazar, the famous Spanish captain, completed the conquest of the Scyris kingdom and seized the city of Quito (1534). Between 1564 and 1820 this region was administered as a presidency; and 36 presidents exercised authority there as representatives of Spain before the series of presidents of the republic began. Quito's first demonstration in favor of independence, 10 Aug. 1809, was quickly and savagely repressed. Guayaquil was more fortunate in her belated attempt (9 Oct. 1820). A campaign which resulted in the capture of Quito, after the battle of Pichincha, was organized by a triumvirate whose members were the poet, Josè Joaquin de Olmedo, the merchant, F. Rocaf, and the soldier, Rafael Jimena. The battle of Pichincha was won for the patriots by the Venezuelan general, Antonio de Sucre, Bolivar's lieutenant. The territory thus liberated was naturally drawn into the Colombian federation, which Bolivar dominated for a time. (See COLOMBIA.) In 1830, after the dissolution of that greater Colombia, Ecuador became an independent republic. The convention of Riobamba placed Gen. Juan José Flores at the head of the government. His successor (1835-39) was Vicente Rocafuerte. Flores won his power from 1839 to 1845 and, with the approval of many partisans, tried to secure a much longer term and dictatorial powers. A second triumvirate, composed of Olmedo, Roca and Noboa, carried on the government; a convention was held at Cuenca. This convention elected Vicente Ramón Roca, who served as President from 1845 to 1849. Vice-President Acasúbi assumed the Presidency when Congress and the country could not agree upon a candidate: the country, however, continued to be disturbed until 1851, when Diego Noboa was chosen by a constituent assembly. In the following year he was displaced by Gen. José María Urvina, at the head of a successful revolution. Urvina was President until 1856. Slavery was abolished during his term. Gen. Francisco Robles followed (1856-59). During the next two years the country had a varied experience: war with Peru, the dictatorship of General Franco and the provisional government of Gabriel García Moreno. In 1860 the population of Quito elected García Moreno to the Presidency (1861-65). Gerónimo Carrión, elected in 1865, retired in 1867. Juefí Espinosa served from 1868 to 1869. Garcia Moreno, as
the leader of an insurrection, took office again (1869–73), and in 1873 secured re-election by the use of force. He was assassinated 6 Aug. 1875. Antonio Borrero, his successor, was driven from office by General Ignacio de Veintemilla in 1876. After the expiration of the legal period, President Veintemilla made himself dictator. Joaquín María Vigil Cacháno was President from 1884–88. He was succeeded by Antonio Flores 1888 to 1892; Luis Cordero from 1892 to 1895 — when he resigned to put an end to bloodshed. General Alfaro, at first "supreme chief," was legally elected in 1897. In 1901, he succeeded him in 1901. In 1904 all religions were made equal before the law and eventually the nation was declared to be the owner of all church property. In 1905, the clericals elected their candidate for the Presidency, Lizardo Garcia, but he was overthrown in January 1906 by ex-President Alfaro, who was himself assassinated in Quito, together with a number of leaders. The President elected in 1912 was Gen. Leonidas Plaza Gutiérrez, who had been chief executive 1901–03. In 1913 contracts were made for the sanitation of Guayaquil. In 1914 government forces attacked the port of Esmeraldas, which the rebel leader, Colonel Concha, was holding, and a large part of the city was destroyed by fire. In 1915 difficulties of a serious financial character were discussed in connection with delayed payment of interest on bonds of the Guayaquil and Quito Railway and the lien on the entire customs receipts of the country held by European investors in that railway enterprise. Plaza was succeeded in 1916 by Patricio B. Plaza Tenorio, ex-Minister of Foreign Affairs and president of the Senate.

Government.—Congress meets at Quito every two years, usually on 10 August, for a period of 60 days, which may be extended for another 30 days. The President of the republic may also call an extraordinary session when deemed necessary or expedient. There are two chambers: the Senate of 32 members (two senators from each province; term four years) and the Chamber of Deputies of 48 members (one deputy for each 30,000 inhabitants; term, two years). Both senators and deputies are elected by direct popular vote, every citizen over 21 years of age who can read and write being entitled to vote. The President of the republic, elected for four years by direct vote of the people, cannot be re-elected until eight years have passed after expiration of the term of office. The Constitution now in force, dating from 23 Dec. 1906, is the twelfth promulgated since 1830. According to its provisions, Ecuador is a centralized republic. In the event of the death or disability of the President, the president of the Senate or of the Chamber of Deputies, in the order mentioned, exercises the executive power. The President’s Cabinet is composed of the Minister of the Interior and Public Works, the Minister of Foreign Relations, the Minister of the Treasury and Public Credit, the Minister of Public Instruction, Post Offices and Telegraphs and the Minister of War and Navy. In addition to this Cabinet, there is a council of state which is consulted by the President in all important matters, and which represents interests when the body is not in session. It includes members of the Cabinet, the president of the Supreme Court, the president of the Court of Accounts, two senators, two deputies and three other citizens, the last seven members being elected by Congress. Under the Constitution foreigners enjoy the same guaranties and civil rights as the citizens of Ecuador. Freedom of thought, of worship, and of the press is guaranteed. Women may exercise all the rights granted to Ecuadorians, and also have the free administration of their property, even when they are married. Aliens may acquire property, also public lands, and may establish banking institutions under the same conditions as Ecuadorians. Public credit is guaranteed and funds set aside for the payment of public debt cannot be used for other purposes.

The local government is controlled by the central government. The local administrators, from the governors of the provinces down to the lieutenants of the parishes, are all appointed by the President. Chief towns of cantones have municipal councils, commonly of five members. There are rural (mounted) and urban police, with a director or chief in each provincial capital.

Ecuador’s courts are the Supreme Court, at Quito (five justices, elected by Congress for a term of six years, attorney-general, two secretaries); Superior Courts at Quito, Guayaquil, Cuenca; Riobamba, Loja and Pueblaviejo, the first two being composed of six judges and the last four of three judges each, all elected by Congress for the same term as the members of the Supreme Court; Court of Accounts at Quito (seven judges) empowered to audit and investigate all public accounts and expenditures, its members being elected by Congress for a term of similar length to that of the justices; municipal civil tribunals of the first instance at Quito, Guayaquil and Cuenca; fiscal judges for each province; judges of commerce in large towns; judges of mines, police and parishes. In the republic there are 33 cantonal and 359 parochial justices, and 85 solicitors admitted to practice. In criminal cases, trial by jury is provided for, but only in the larger towns.

Education.—Primary instruction is gratuitous and obligatory for children between 6 and 12 years of age. Among the subjects taught beside the familiar elementary branches are morality, religion and urbanity. In the boys’ schools the Constitution of Ecuador is added; in those for girls, sewing and domestic economy. In 1916 there were about 1,600 public schools of primary grade, with 98,400 pupils. Secondary instruction is provided in 57 «colleges,* with 371 professors and 4,500 students. The school year begins 10 October and ending 30 July. The University at Quito, with associate universities at Cuenca and Guayaquil, has faculties of philosophy, belles-lettres, law, medicine, physical and natural sciences, mathematics and agriculture. There is a Ladies’ College, the Museum, with about 1,228 students. Schools of arts and crafts are found in the provinces of Pichincha, Leon, Chimborazo, Azuay, Loja and Guayas. Bahía has a commercial school. About $600,000 is expended yearly by the government. Congress, when in session, also numerous private schools in the republic.
ECUADOR

1 Old Church at Quito

2 A Pass in the Andes; Guayaquil and Quito Railway
José Joaquín de Olmedo (b. Guayaquil 1780) and Juan Montalvo (b. Ambato 1833) are by Ecuadorians esteemed, the former the greatest poet, the latter the greatest prose writer of South America. The capital of the United States took the place of José Mejía, the "American Mirabeau," and of many historians, theologians, poets, romancers and critics whose works are highly regarded in Spain. The Ecuadorian Academy (founded 1875) is the chief of the literary associations of the republic.

**Commerce, Finance and Agriculture.**—

The value of imports in 1914, the last normal year before the effect of the European War was felt in all Latin-America, was $8,402,767; of exports, $12,464,333; and the principal exports were: cacao, 47,210 tons; coffee, 2,980 tons; gold (in bars or dust), $365,324; bananas, $972,215; cattle hides, 811 tons; ivory nuts, 8,583 tons; rubber, 147 tons. The exports in 1914 were to United States total value of exports valued at $3,588,130; France took $4,438,226; Germany, $860,302; United Kingdom, $1,230,555. Ecuador imported from the United States goods valued at $2,770,599; from the United Kingdom, $2,415,537; from Germany, $1,203,525; and from France, $327,770. The value of imports in 1915 was $8,422,881; of exports, $12,882,402. The principal exports were cacao, 8,171,773 pounds, valued at $9,706,981; bananas, 300,375 pounds, valued at $639,027; gold, $530,591; ivory nuts, 20,924,252 pounds valued at $526,519; coffee, 5,116,161 pounds valued at $463,413; cattle hides, 1,971,243 pounds valued at $289,333; rubber, 564,934 pounds valued at $196,447; leaf tobacco, 584,888 pounds valued at $89,825; leather, 163,803 pounds valued at $27,410; bananas, 3,522,475 pounds valued at $33,575. The exports to the United States amounted to $5,674,291, to the United Kingdom $2,669,280, to France $1,175,972, to Spain $382,834, to the Netherlands $982,410, to Italy $358,590. Textiles other than silk formed the principal import item in 1915, amounting to $1,795,101. Other important articles imported were gold and silver coin to the value of $1,416,232, foodstuffs $1,257,294, hardware $890,857, raw cotton $327,315, machinery and parts $277,970. The imports from the United States in 1915 totaled $3,209,608, those from the United Kingdom $3,353,333, those from Italy $399,961, Spain $330,867, France $246,728. United States ranked first in purchases from Ecuador for 1915, with the United Kingdom second and France third, while in imports the United Kingdom occupied first place, the United States a close second and France a distant third. Heavy ware of materials for the capital and Guayaquil from the United Kingdom were largely responsible for the increased value of shipments from that country. Great increases were made by the United States in the sales of cotton piece goods, laundry soap, ready-made clothing, straw hats, drugs and chemicals, paper, crackers and a number of others, including canned goods, which have secured a permanent entry into this market.

There were 185 vessels of 318,742 tons and 2,709,018 tons entered the ports of Ecuador during 1915, as compared with 162 steam vessels of 335,561 tons and seven sailing vessels of 12,125 tons during 1914. The exports from the port of Guayaquil in 1916 to the United States included 37,227,400 pounds of cacao, 175,143 pounds of coffee, 1,829,200 pounds of hides, 592,997 pounds of ivory nuts and 121,317 pounds of rubber. The United States took 23,772,000 pounds of cacao, 143,730 pounds of hides 62,362 pounds. France took 10,905,225 pounds of cacao, 599,938 pounds of coffee, 29,378 pounds of hides and 219,205 pounds of ivory nuts. Spain took 4,242,700 pounds of cacao, 558,956 pounds of coffee, 42,091 pounds of hides, 78,375 pounds of ivory nuts and 10,683 pounds of rubber. Holland took 4,325,000 pounds of cacao and Chile 2,528,834 pounds of coffee. The total exports of the port were 81,756,910 pounds of cacao, 4,645,218 pounds of coffee, 2,044,399 pounds of hides, 1,101,017 pounds of ivory nuts and 132,000 pounds of rubber.

The monetary system is based on the gold standard, the unit of value being the sucre (weight 0.8136 grammes of gold .900 fine, or 0.73224 grammes of pure gold). The value of the sucre is $0.48605, currency of the United States; and the value of $1.00 American in terms of Ecuadorian currency is $2.05484. The actual currency of the republic is gold, silver and banknotes, but the only legal tender is gold. The new coinage consists of the gold condor of 10 sucre, weighing 8.136 grammes of gold .900 fine, or 7.3224 grammes of fine gold, equivalent to $4.8605 in currency of the United States, or one pound sterling, English money. Consult Cosby, J. T., 'Latin-American Monetary Systems and Exchange Conditions,' New York (1915). Ecuador has four banks of issue: In Guayaquil, Banco del Ecuador (capital 3,000,000 sucre), and Banco Comercial y Agrícola (capital 5,000,000 sucre); in Quito, Banco de Pichincha (capital 1,500,000 sucre); in Cuenca, Banco del Azuay (capital 400,000 sucre). Other banks are the Banco Hipotecario (capital 1,000,000 sucre) and the Banco Territorial (capital 750,000 sucre). These are only mortgage loan banks. The fiscal revenues of Ecuador before the European War amounted to $10,000,000 a year, of which $9,000,000 went in customs duties and the funds of the treasury (on imports of $4,000,000 and on exports $2,600,000, alcohol tax $480,000, salt monopoly $360,000) and internal resources. (Consult 'Proceedings of the First Pan-American Financial Conference,' Washington 1915). The debt of the government to the local banks is partly consolidated, to be liquidated in 1927, and partly in current account. Beside this, the government owes a million of 6 per cent internal bonds and $1,500,000 of floating debt, making a total debt of about $6,500,000. The foreign debt proper amounts to $1,000,000 and the guarantee of the bonds of the Guayaquil and Quito Railway, Ecuador Central Railway and French Railway Company of Ecuador. The total debt of the republic in 1915 was $23,615,000. The cultivated area is limited, owing to the lack of laborers; nevertheless Ecuador has considerable agricultural resources. A large variety of crops are grown and the soil is exceedingly fertile. Ecuador produces more cacao than any other country except Sao Tomé and Principe in Africa. It is grown principally in the provinces of Guayas, El Oro and Manabí. In 1914, 47,210 and in 1915, 40,000 metric tons were produced. Over 40,000,000 pounds of tagua (ivory
nut) are exported annually. Coffee is cultivated in several districts to the extent of several million pounds a year and considerable quantities are exported. Sugar cane and tobacco are grown on the lowlands of the coast. Of the former about 16,000,000 pounds are produced yearly, an amount which about satisfies the domestic demand. Rice, quina, maize, wheat, barley, oats and a number of medicinal and industrial plants are also grown to supply the home market and some are exported. The rubber tree is plentiful and this industry is growing fast, the rubber exported annually reaching nearly $1,000,000 in value. Alfalfa is cultivated and the pastoral industries are thriving.

Communications.—Sixty miles of the railway from Guayaquil to Quito were built between 1885 and 1889, and from the coast to the village of Chimo, at the base of the cordillera. A company organized in the United States completed the road (25 June 1908); passenger trains make the trip (297 miles) in two days. The line starts from Guayaquil, ascends the Guayas River from Guayaquil and ascends the Andes to a height of 11,841 feet, when it descends to a height of about 9,000 feet and continues on to Quito. The gauge is 3 feet 6 inches and the rolling stock consists of about 25 locomotives and several hundred passenger and freight cars. The Central Railway, from Manta on the coast to Santa Ana, is in operation as far as Puerto-viejo, 25 miles, and when complete will be 35 miles long. A railway connects Bahia, Caracas and Quito (186 miles). A number of other lines are authorized, among them being a 125-mile line from Ambato to the Curaray River, a line from Manta to Ambato, a line from Quito to a port on the Esmeraldas coast and one from Guayaquil to the coast. The total extent of the telegraph system is 5,482 miles with 204 offices. The Ecuadorian landing-station of the Central and South American Telegraph Company's cable is at Salinas, which was declared open as a minor port by executive decree 21 August 1902. Quito and Guayaquil have telephone services; the latter a street car system. There are six wireless telegraph stations—two main ones at Quito and Guayaquil each, one on the coast to the north of Guayaquil and one on the Galapagos Islands and one each at Bolivar and Bahia. A score or more passenger vessels ply on the Guayas River and between Guayaquil and other coast towns. English steamships of the Pacific line and vessels of the Chilean line plying between Valparaiso and Panama call regularly at Guayaquil. There are about 200 post offices in the country and they handle yearly over 6,000,000 pieces of postal matter. The postal service is being gradually extended. Some 20 steamers, as well as a number of sailing vessels, steam yachts, steam launch and gasoline launches maintain an active coast and river service, most of the numerous rivers of the country being navigable for considerable distances inland and affording excellent means of communication. The Guayas River, at the mouth of which is the city and port of Guayaquil, is the most important of these waterways, being navigable for river steamers as far as Bodega, 40 miles from Guayaquil, while smaller vessels can, during the wet season, reach Zapatot, some 200 miles. The Daule River is navigable for some 60 miles, the Vines for 50 miles, while the Esmeraldas, Naranjal, Santa Rosa, Santiago and Mira rivers are all navigable during the rainy season for short distances, varying from 10 to 60 miles or more. The Amazón, which in Ecuador is given the name of Marañón River, is navigable almost in its entirety and thus the eastern slope of the Ecuadorean Andes may be reached by way of Brazil and the Amazón River and its tributaries.

Army and Navy.—In time of peace, the army consists of 7,810 officers and men, and reserves numbering possibly 100,000. The regular force is composed of 13 battalions of infantry, one regiment of cavalry, and 12 batteries of artillery, besides some departmental troops. These serve one year and then pass to the reserve and second line. The second line army has 135 infantry battalions, seven artillery regiments and 44 cavalry squadrons. The regular infantry have the Mauser rifle; the artillery have old-fashioned Krupp guns. Military service is obligatory from 18 to 32 years of age in the army, and from 32 to 45 in the national guard. The compulsory law, however, is not generally enforced. A mining and torpedo section, a sanitary section and a telegraph and telephone corps were created in 1910. The national guard includes companies of firemen—organizations which are especially numerous and influential in Guayaquil. The naval vessels are a cruiser of 600 tons, one torpedo gunboat of 56 tons, one torpedo boat destroyer of 1,000 tons and a transport, with three launches, with a total equipment of about 200 men.

The boundaries of the republic being in dispute, and a large part of Ecuador's claim being unexplored territory, estimates of the total number of inhabitants vary; but the republic contains about 2,000,000. Of these from one-half to three-fourths are Indians, about 600,000 half-breeds and only 205,000 pure whites. There is a small number of negroes.

The provinces of Ecuador, with their capitals and populations, are as follows:

MARRION WILDOX.

ECUMENICAL CONFERENCE. An ecclesiastical body meeting once in 10 years. It is composed of representatives of the various Methodist bodies throughout the world; it has no legislative powers. The first one met in London, 7-20 Sept. 1881; nearly 400 delegates represented 28 bodies. The second met in Washington, D. C. 7-20 Oct. 1891. Twenty-nine bodies were represented and the total delegation numbered 485. The third conference met in London, 4-17 Sept. 1901. Twenty-four bodies sent 471 delegates. The fourth conference met in Toronto, Canada, 4-17 Oct. 1911. Twenty-one denominations were represented by 500 delegates. The proceedings include the reading of papers on denominational history, polity and outlook and discussions of the same.

ECZEMA, ek'ze-ma, an acute or chronic disease of the skin, showing a vast variety of changes in the skin itself, and usually accompanied by intense itching, burning or pain. The changes in the skin at first are usually marked by redness, papules, then small vesicles or pustules which later become crusted and dry; or the surface is weeping. Infiltred and scaly patches are common. All forms of eczema (and no less than a dozen varieties are described by skin specialists) have certain definite changes occurring in the skin. There is usually swelling, congestion and increase of temperature locally. There is almost invariably an exudation of fluid into the tissues, with the formation of vesicles and pustules, as described. There is further a certain amount of plastic exudation which produces in the skin papulous areas that are thickened and infiltrated. Finally these are the subjective symptoms of itching, which may be only a slight tingling, or prickling sensation, or may be so intense as to demand continued and deep scratching until bleeding or oozing takes place. This itching is, as a rule, intermittent in character, being almost invariably worse at night when the patient is covered, the heat of the body causing the aggravation. Sometimes exposure to cold brings about intense itching. The disease usually runs an acute course, and may be limited to one region of the body, or may be general. Its general tendency is to progress rather than to get well. It is perhaps one of the most obstinate of all skin diseases, and at the same time one of the most difficult to diagnose and to treat. The causes are probably many. In general the fundamental pathology is an over-active function of autonomic nerve stimuli going to the skin. This over-autonomic (parasympathetic) activity may be a primary one—or be an imbalance from subacting sympathetic stimuli. The study of this lack of balance may involve a wide search for physicochemical, sensori motor or phycbic disturbances, and a truly helpful therapy must take into account these underlying features. Inasmuch as orthodox medicine has found the disorder very intractable it would seem to indicate the lack of deep consideration of the dynamic factors in human pathology—notably the importance of mental as well as so-called physical factors. The treatment of eczema is a particular study. Sometimes the disease is beyond the power of the best skin specialist; usually such cases are psychogenic in their origin and the average skin specialist is too uneducated to know anything about mental causes. At other times correct diet and accurate errors in diet will bring about cure. So far as household remedies are concerned, only those that can relieve the itching are deserving of notice in this place. One of the best of these is carbolic acid in weak solution—2 to 3 per cent. This may be applied on a bit of absorbent gauze, special care being taken not to enclose a particular part completely with the weak carbolic acid. Bland non-irritating powders, such as calamine and oxide of zinc are often useful. When the disease becomes chronic it is apt to be extremely obstinate. Many of the chronic cases rest upon an endocrinopathic basis, which in its turn often depends upon neurotic disturbance.

EDAM, ed'am, Holland, town 12 miles north-northeast of Amsterdam, and about a mile from the western shore of the Zuider Zee, from which it is connected by a canal. This place is chiefly noted for its trade in cheese, of which nearly 1,000,000 pounds are annually sold in its market. Other industries are shopbuilding, leather manufacture, rope and sail making. The town was once fortified, and has still a wall with seven gates. Its Reformed Church of Saint Nicholas, with large painted windows, is among the finest in North Holland. Pop. 6,444.

EDDAS, The. The name given to two collections of early Icelandic literature, very unlike in character. The 'Poetic Edda' consists of a series of lays in various metres, most of them celebrating the deeds of gods and heroes; the 'Prose Edda' is a manual of instruction for poets, in which information in regard to the matter and form of poetry is given in prose with some illustrations in verse. The 'Poetic Edda' is the work of different authors, no one of whom is known by name. Internal evidence shows that the lays which compose it date, in their present form, from the 9th to the 12th centuries inclusive; most of them belong, perhaps, in the 10th. They were united into a collection by an unknown Icelander in the early 13th century. His transcript is lost, but the material is extant in later copies. The best and oldest manuscript is the Codex Regius, now in the Royal Library at Copenhagen. This dates from the end of the 13th century, but was not recovered until the 17th century, by the Icelandic bishop Brynjolf Sveinsson. He called it the 'Edda of Sæmund the Wise,' because he thought that a learned Icelander of the 13th century, Sæmund Sigfusson, might be the author or collector of the pieces. Modern criticism has shown this to be impossible, but the term 'Sæmundar Edda' is still sometimes erroneously used. The so-called 'Snorra Edda' was the Icelander Snorr Sturluson, (1178-1241), a literary man of great distinction. Hence the 'Prose Edda' is often called the 'Snorra Edda,' and sometimes the 'Younger Edda,' to distinguish it from the Elder or
Poetic collection. The term "Edda" belongs properly only to the work of Snorri. It probably means "the book of Oddi,"—a little place in Iceland where Snorri and Saemund lived. "Edda" also signifies "great-grandmother"; hence the collection has been fancifully interpreted as having told by an old woman to her descendants. Again, it has often been understood as "a system of poetry." Whatever its origin, the term has won its way to the best modern usage. Poetic Edda falls roughly into two divisions, treating respectively of gods and heroes. The Lays of the Gods differ a great deal from each other in character and technique. The "Voluspa," or "Prophecy of the Sibyl," is an account of the creation and fated destruction of the world. "Balder's Dreams" has a similar setting; the prophetess gives Odin information about the future, explaining the evil dreams that have afflicted the god Balder. The "Lay of Thrym" is a humorous piece, narrating the story of Thor's marriage and its recovery from Loki. Similar in character is the "Lay of Hymir," in which Thor goes out fishing on the wintry sea with the giant Hymir, and catches the world-serpent which lies at the bottom, encouraging the earth. In the "Word-Combat of Loki," the treacherous god calls, at a banquet from which he has been excluded, disreputable incidents in the lives of the deities, until silenced by Thor. The "Lay of Skörrir" relates a love-affair of the god Frey. Several pieces consist of moral reflections, set in a narrative framework. In the "Lay of Howardin," Odin shows his supremacy in contests of wisdom; in the "Lay of Allwise," the victory is with Thor, who keeps the dwarf Allwise above ground after sunrise, so that he is turned to stone. In the "Lay of Grimnir," Odin utters wisdom in disguise. The "Havamal," the "Words of the Mighty One," is a collection of gnomic material. The "Lay of Rig" and the "Lay of Hymir," of minor importance, and the "Lay of Sigmund," with the setting of a love-story, but uniting the prophecy and the word-content, complete the collection, except for material of little significance.

With the exception of the "Lay of Weland," the "Lay of Holm," and the three "Helgi-Lays," the second section is concerned with the personages connected with the great story of Sigurd, the German Sigriot, which is here much extended. A short prose section, "Sinfjotli's Death," and the "Prophecy of Gripri," lead to the "Lay of Regin" and the "Lay of Fafnir." Sigurd slays the dragon and gets the Nibelungen gold. In the "Lay of Sigdrifa" (Bryn- hild) his meeting with the Valkyrie is described; and the well-known story is continued in two lays centering about Sigurd, three concerned with Gudrun and two describing the tragedy at the court of Atli. The "Lament of Oidrun" deals with the love of the sister of Atli for Gunnar. The "Exhortation of Gudrun" and the "Lay of Hamthir" describe events after Gudrun's marriage to Jarl, particularly the pathetic tale of Swanhlid. The "Lays of the Heroes" often attain a high level of tragic power. Dramatic moments are emphasized and details omitted and the stanzaic structure heightens the effect of intensity much in the traditional ballad-verse. The whole is very different from the tranquil and ample narrative of Anglo-Saxon poetry. Mythological interpretations of the poems as allegories of the processes of nature must be received with caution. The hypothesis of Sophus Bugge that many of the lays have their origins in classical and Christian traditions has not met with general acceptance.

After a Prologue, the "Prose Edda" narrates the "Beguiling of Gylfi," in which, under a narrative disguise, information about mythology and cosmogony is set forth. In the "Narratives of Braug," the god of poetry tells stories of Odin and Thö. The section entitled "The Poesy of the Skalds" treats of methods of poetic expression; and in order to illustrate metaphor and allusion, much of interest in Scandinavian mythology and story is given to the reader. The concluding portion, the "Hattatari," consists, besides explanatory material, of a poem on King Hakon Hakonarson in more than a hundred stanzas, each in a different metre. This latter section is without much interest for the modern reader, but earlier parts of the work, though intended mainly for technical instruction in the making of skaldic verse, are often highly picturesque and of great value in the study of Scandinavian traditions.

Biography.—The Lays of the Gods have been translated by Olive Bray (Viking Club, London 1908); the second volume to contain the Lays of Heroes, has not yet appeared. The German translation by H. Gering of the entire Poetic Edda may be used in default of an English version. The two volumes of the "Prose Edda" have been translated by A. G. Brodeur (New York 1916).

WILLIAM WITHERLE LAWRENCE,
Professor of English, Columbia University.

EDDY, Clarence, American organist and composer: b. Greenfield, Mass., 23 June 1851. He studied under Buck in Hartford, counterpoint under Haupt, and piano under Loechelhorn in Berlin. In 1874-76 he was organist of the First Congregational Church, Chicago; afterward organist and choirmaster of the First Presbyterian Church for 17 years and from 1875 to 1908 was director of the New School of Musical Art. In 1877-79 he gave a series of 100 organ recitals, with entirely different programs, a memorable achievement in American musical annals. He has played at several exhibitions in America and abroad, and has given recitals in the principal American and European cities. He has composed several works for the organ and has written "The Church and Concert Organist" (3 vols., 1885); "The Organ in Church" (1887); "Concert Pieces for the Organ" (1889), and a translation of Haupt's "Counterpoint, Fugue, and Double Counterpoint" (1876).

EDDY, Henry Turner, American scientist: b. Stoughton, Mass., 9 June 1844. He was educated at Yale and later took a further scientific course in Berlin and Paris. After holding a professorship of astronomy and civil engineering at the University of Cincinnati 1874-90, and acting as dean of the academic faculty of that institution (1874-77, 1884-89), he became its president in 1890. He was also president of the Rose Polytechnic Institute at Terre Haute, Ind., 1889-91. The university, when he accepted the chair of engineering and mechanics at the University of Minnesota. He
became dean of the Graduate School of the latter university in 1906, and professor and dean emeritus in 1912. He published 'Analytical Geometry' (1874); 'Researches in Graphical Statics' (1878); 'Thermodynamics' (1879); 'Neue Konstruktionen aus der graphischen Statik' (1880); 'Maximum Stability under Concentrated Loads' (1890); 'Theory of the Flexure and Strength of Rectangular Flat Plates Applied to Reinforced Concrete Floor Slabs' (1913); 'Concrete Steel Construction' (1914); and numerous scientific and technical papers.

EDDY, Mary Baker, discoverer and founder of the religion (theology and practice) which she named Christian Science, and founder of the Church of Christ, Scientist. Mrs. Eddy (at first Mary Baker) was born at Bow, near Concord, N. H., 16 July 1821, the sixth and youngest child of Mark and Abigail Baker. One of her ancestors, John Baker, was among the earliest settlers of the colony of Massachusetts Bay (at Charlestown in 1634). One of her great-grandfathers was Capt. Joseph Baker, who earned his title and gained an honorable name in the service of the colony of New Hampshire. Other soldiers of renown among Mrs. Eddy's relatives were Capt. John Lovewell, hero of a war with Indians during the colonial period, Gen. Henry Knox of the War for American Independence, and Gen. John McNeill of the War of 1812. Her immediate family were people of considerable prominence and prosperity: her father a large landholder and well-known citizen; one of her brothers, Col. George Sullivan Baker, a public man and member of the staff of the governor of New Hampshire; another brother, the Hon. Albert Baker, a lawyer and member of the New Hampshire legislature; a cousin, the Hon. Henry M. Baker, a lawyer and member of Congress from New Hampshire.

The home in which Mrs. Eddy was reared was one of refinement and religious devotion. Her parents were members of the Congregational Church, and their hospitality was frequently enjoyed by the clergy of this and other denominations; and in the discussions of religious subjects which often occurred in the home Mrs. Eddy took an interest and participated in a manner that was seen to be unusual and far in advance of her years. To her mother and her brother Albert, however, Mrs. Eddy gave the most credit for her early training. Her mother was a woman of evident gentility and marked spirituality; her brother Albert a graduate of Dartmouth College, studied law with Franklin Pierce (afterward President of the United States), and became a young man of extraordinary promise before his decease at the age of 31.

As a child, Mrs. Eddy was frail and subject to illness. This kept her from attending school regularly; yet she was studious, and with the aid she gained an education equal to that which was then regarded as liberal. One of her tutors was the Rev. Enoch Corser, pastor of the Congregational church at Tilton, N. H., who supplemented his pastoral duties, sometimes by teaching in the local academy and sometimes by tutoring. Mr. Corser's contact with Mrs. Eddy began soon after she removed with her parents from Bow to Tilton in 1836 when she was 15 years old, and continued for six or seven years. He departed this life before she became famous, but an interesting and significant expression of his opinion was preserved and related by his son, Mr. S. B. G. Corser. Writing from Boston, N. H., in 1902, the younger Mr. Corser said: "My father, the Rev. Enoch Corser, was pastor of the Congregational church at Northfield and Tilton (then Sanbornton Bridge) from 1837 to 1843, with which the Baker family was connected. If I remember rightly, Mrs. Eddy was about 15 when I first met her, she being several years younger than myself. I well remember her gift of expression, which was very marked. As her pastor, and for a time her teacher, my father held her in the highest esteem; in fact he considered her, even at an early age, superior both intellectually and spiritually to any other woman in Tilton, and greatly enjoyed talking with her. She and my father used to converse on deep subjects frequently. I remember her admiration for him, and she stands out in my recollection as his brightest pupil. He predicted for Mrs. Eddy a great future and spoke of her as an intellectual and spiritual genius."

From her childhood or girlhood until much more than a decade after her discovery of Christian Science, Mrs. Eddy was a member of the Congregational Church. Applying for membership at Bow when she was 12 years old, she was examined and given some assurance of acceptance in spite of the issue she took with the then-prevailing doctrine of unconditional election or predestination. Whether she was formally admitted to membership at this time, or not until five years later at Tilton, is a question left uncertain by the records of these churches. It was at this earlier time, when Mrs. Eddy was about 12 years old, that she first experienced the power of prayer to deliver from sickness. Perturbed by the teaching that her brothers and sisters and she were already numbered among those who were to be saved and lost, she became filled with what the family doctor pronounced a fever. In her autobiography, 'Retrospection and Introspection' (p. 13), Mrs. Eddy thus related her healing: "My mother, as she bathed my burning temples, bade me lean on God's love, which would go to Him in prayer, as I was wont to do, seeking His guidance. I prayed; and a soft glow of ineffable joy came over me. The fever was gone, and I rose and dressed myself, in a normal condition of health. Mother saw this, and was glad. The physician marvelled; and the 'horrible decree' of predestination — as John Calvin rightly called his own tenet — forever lost its power over me."

Mrs. Eddy was married three times: first to Maj. George W. Glover, a native of New Hampshire who had removed to Charleston, S. C., and became a successful contractor and builder. His military title was gained by service in the militia and on the governor's staff in South Carolina. This marriage occurred in 1843, when Mrs. Eddy was 22 years old. It was dissolved in less than a year by the death of Major Glover. Ten years later (in 1853) Mrs. Eddy married Dr. Daniel S. Patterson, a dentist of Franklin, N. H. In 1873, after her removal to Lynn, Mass., and when she was a member of Christian Science, she obtained a divorce from him on account of long-continued desertion due
to his infidelity. In 1877, after she had begun the practice and teaching of Christian Science, Mrs. Eddy married Asa Gilbert Eddy of London, Vt., the first of her students to engage in the public practice of Christian Science healing. He died five years later (in 1882) after having helped to sustain Mrs. Eddy during the period in which the Church of Christ, Scientist, was organized and the Christian Science movement encountered its first active opposition.

During Mrs. Eddy's first widowhood (1844–53) she developed her fluency of expression and her earning capacity by writing occasional verses and by contributing articles for periodicals on topics of public interest. Her ability of this kind was recognized by an offer of $3,000 a year (a large salary at that time) to become associate editor of the *Odd Fellows Magazine*, then edited by the Rev. Richard Rust, and by the inclusion of two poems from her pen in an anthology of poems and essays by New Hampshire authors which was published first at Manchester in 1850 and again at Boston in 1856. During the same period, Mrs. Eddy served as substitute teacher in the Tilton Academy and experimented with a school for children somewhat below the modern standard. The period between Mrs. Eddy's second marriage and her discovery of Christian Science (1853–66) was one of following the fortunes of an inconstant or faithless husband and enduring the combined difficulties of desertion and ill health.

The course of events that led to her discovery of Christian Science was described by Mrs. Eddy as follows: "During twenty years prior to my discovery I had been trying to trace all external effects to a mental cause; and in the latter part of 1866 I gained the scientific certainty that all causation was Mind, and every effect a mental phenomenon. My immediate recovery from the effects of an injury caused by an accident, an injury that neither medicine nor surgery could reach, was the falling apple that led me to the discovery how to be well myself, and how to make others so" ('Retrospection and Introspection,' p. 24). The accident here spoken of occurred in the evening of 1 Feb. 1866, as Mrs. Eddy was returning from a Good Templars meeting in Lynn, Mass., to her home in the suburb of Swampscott. The contemporaneous account of it furnished by the *Lynn Reporter* said that she fell on the ice, was taken in an insensible condition to a near-by residence, where she was examined by a physician and cared for during the night; that the doctor found her injuries to be internal and of a serious nature, and that she was removed to her home the following afternoon in a critical condition.

Mrs. Eddy has described her recovery from this injury as follows: "On the third day thereafter the following lines of Matthew ix, 2. As I read, the healing Truth dawned upon my sense; and the result was that I rose, dressed myself, and ever after was in better health than I had before enjoyed. That short experience included a glimpse of the great universe of faith, since tried to make plain to others, namely, Life in and of Spirit; this Life being the sole reality of existence" ('Miscellaneous Writings,' p. 24). This incident was the occasion for beginning years of profound study of the Scriptures. Of this search and research she has said: "I must know the Science of this healing, and I won't rest till I have it. I am not afraid of absolute conclusions through divine revelation, reason and demonstration. The revelation of Truth in the understanding came to me gradually and apparently through divine power. When a new spiritual idea is born to earth, the prophetistic Scripture of Isaiah is renewedly fulfilled: 'Unto us a child is born, and his name shall be called Wonderful'" ('Science and Health,' p. 109).

The next events of major importance in the life of Mrs. Eddy were the writing and the printing of the textbook of Christian Science, 'Science and Health with Key to the Scriptures.' After writing a statement of her discovery and finding no publisher for it, she became her own publisher and brought out the first edition of 1,000 copies (at Boston in 1875). Copies of this edition now sell at many times their original price, then they were difficult to sell at all, and were not always welcome as gifts. Yet the uncompromising idealism and absolute spirituality of the book demanded and gained attention. A Bronson Alcott was the first to give Mrs. Eddy a comforting assurance for the future of her book, and Wendell Phillips said: "Had I young blood in my veins, I would help that woman." At the outset, it was Mrs. Eddy's expectation, and for years her hope, that the existing churches would welcome her interpretation of Christian Science, proved a failure by the restoration of Christian healing. A considerable number of ministers did accept her offer to this profession of free admission to her classes, and some of them invited her to speak in their pulpits. In course of time, however, it became evident to Mrs. Eddy that a distinct church was necessary to preserve Christian Science intact, for the benefit of that and future generations. Accordingly, the First Church of Christ, Scientist, was organized at Boston in 1879. Four years later another step was taken when Mrs. Eddy founded the first of the Christian periodicals, *The Christian Science Journal*. During the ensuing years, the teaching of eight classes of students annually, weekly preaching to eager congregations, editing the monthly organ of her church, and heading all the activities of the expanding Christian Science movement, made her life one of the most eventful in the annals of men. And though Mrs. Eddy, in her later years, trained others to relieve her of some detail and duty and to become the directors of Christian Science affairs, she continued to be the active leader of the movement she instituted until her decease (at Newton, Mass., 3 Dec. 1910). It was characteristic of Mrs. Eddy that she devised the bulk and residue of her estate to be used "for the purpose of more effectually promoting the understanding of the religion of Christian Science as taught by me." Her principal writings are 'Science and Health with Key to the Scriptures,' 'People's Idea of God,' 'Christian Healing,' 'Retrospection and Introspection,' 'Unity of Good,' 'Rudimental Divine Science,' 'No and Yes,' 'Church Manual,' 'Miscellaneous Writings,' 'Christian Science versus Pantheism.'
(1889); ‘Pulpit and Press’ (1898); ‘Messages to The Mother Church’ (1900, 1901, 1902); ‘Poems’ (1910); ‘The First Church of Christ, Scientist,’ and ‘Miscellany’ (1913). Consult ‘Life’ by Wilbur (4th ed., Boston 1913).

Clifford P. Smith.

Eddy, Thomas, American philanthropist: b. Philadelphia, Pa., 5 Sept. 1758; d. New York, 16 Sept. 1827. He entered the insurance business in 1790, in which he made a large fortune. With Philip Schuyler and Ambrose Spencer he presented a bill for establishing a penitentiary system in 1796, which was passed. He had charge of erecting the first building and for four years was its director. In 1793 he was appointed by the Society of Friends to visit the Indians in New York State; was one of the governors of the New York Hospital; and in 1815 one of the founders of the Bloomingdale Insane Asylum. He was also one of the originators of the New York Savings Bank and the New York Bible Society, and a conspicuous promoter of the Erie Canal. He received the title of ‘American Howard’ for these labors, and in 1801 published ‘State Prison of New York.’

Eddy Currents. See Foucault Currents.

Eddystone Lighthouse. The frequent shipwrecks on Eddystone rocks off the coast of Cornwall, England, led to the erection of a lighthouse on them by Henry Wriothesley in 1696-1700. It was a two-sided polygon, 100 feet high, with a stone base; but the great storm of 20 Nov. 1703, completely washed it away, with the architect. Another lighthouse was built in 1706-09, also of wood, with a stone base, and 92 feet high, by Mr. Rudyard, a silk- mercer. This erection was burned in 1755. The next, noted for its strength and the engineering skill displayed in it, was constructed by Smeaton in 1757-59, on the model, it is said, of the trunk of the oak tree. It was built of blocks, generally one to two tons weight, of Portland oölite, encased in granite. The granite was dovetailed into the solid rock, and each block into its neighbor’s. The tower, 85 feet high, had a diameter of 26½ feet at the base and the top 15 feet, and 72 feet above the water, was visible at a distance of 13 miles. As the rock on which this tower was built became undermined and greatly weakened by the action of the waves, the foundation of another was laid on a different part of the reef in 1789. The new lighthouse, completed in 1822 by Sir James N. Douglass, is, like its predecessor, ingeniously dovetailed throughout. Its dioptric apparatus gives, at an elevation of 133 feet, a light equal to 159,600 candles, and visible in clear weather to a distance of 17½ miles. See Lighthouses.

Einfelt, a’del-felt. Albert Gustav Aristid, Finnish painter: b. Helsingfors, Finland, 21 July 1854; d. 1905. He began his artistic studies at Antwerp and afterward became a pupil of Gérôme, in Paris, where he developed a high skill in draughtsmanship, in the depart ment of genre and portrait painting. He gained a second medal in the Paris Salon of 1882, and a medal of honor in the Paris Ex position of 1889. Two of his pictures have been purchased by the French nation for the Luxembourg.

Eiffel, Eiffel. Gustave, French engineer: b. Paris, 15 Dec. 1832; d. 1923. He was the designer and architect of the Eiffel Tower, Paris. For more than 30 years he was engaged in the construction of iron and steel bridges, and his work includes bridges over the Seine at Paris, the Seine at Rouen, the Rhine at Basel, and many others. He also designed the monument to the First World War, the city hall of Paris, and the mausoleum of the Invalides. He was awarded the Gold Medal of the International Exposition of 1889, and the Grand Cross of the Legion of Honor.

Eiffelog, The. See Eiffel Tower.

Eiffel Tower, Paris. The Eiffel Tower, Paris, is one of the most famous landmarks in the world. It was designed and built by Gustave Eiffel between 1887 and 1889 for the Exposition Universelle of 1889. The tower stands 324 meters (1,063 feet) high, including its antenna, and is the tallest structure in Europe. It is made of wrought iron and was the tallest man-made object in the world until 1930. The tower has been the subject of many literary and artistic works and is a symbol of Paris and France. It is now a popular tourist attraction and a famous landmark of the city.

Edelweiss, a’deel-wis, Ger. a’del-wis, (a)Noble-white; (b) Gnaphalium or Leontopodium alpinum), a perennial plant of the order Compositae, growing at great altitudes, in the Alps, the Pyrenees and also in parts of Austria and Siberia. Its flower is white and somewhat star-shaped, the heads surrounded with a characteristic woolly involucre, and its leaves also having the same woolly character. It is comparatively scarce; generally grows in inaccessible positions; is eagerly sought by Alpine tourists, and has become so rare in some of the Swiss cantons that it is protected by law. The supposed difficulty of gathering it is the groundwork of various legends and poems; as the emblem of purity, it is given by the Tyrolean youth to his fiancée bride. It is not difficult to cultivate and is found in American and European gardens, but is apt to lose its distinctive woolly character under cultivation.

Edema. See Dropsy.

Eden, Sir Robert, last proprietary governor of Maryland: b. Windermere Hall, Durham, England; d. Annapolis, Md., 2 Sept. 1784. As captain in the Coldstream Guards he served in the Seven Years’ War. He was appointed governor of Maryland in 1768, where he remained until 1776, when that State committed itself to the principles of the Revolution, and virtually declared the proprietary governorship at an end. He left in an English warship, but returned a few months before his death. Consultant Steiner, ‘Life and Administration of Sir Robert Eden’ (in the ‘Johns Hopkins University Studies in Historical and Political Science,’ 16th series, VII–IX, Baltimore 1898).

Eden, William, 1st Lord Auckland: b. Durham, April 1744; d. there, 28 May 1814. He was educated at Eton and at Oxford, where he received his M.A. in 1768. He studied law and published in 1772 ‘Principles of Penal Law.’ In the same year he was chosen Undersecretary of State. In 1774 he entered the House of Commons and was again chosen in 1778, when he was one of the five commissioners to America. He published a report on his return in the form of ‘Four Letters to the Earl of Carlisle.’ In 1780 he accompanied Lord Carlisle as Chief Secretary to Ireland. In this capacity he was instrumental in establishing the National Bank of Ireland. In 1783 he became Vice-Treasurer of Ireland and a member of the privy council. He was a staunch supporter of Pitt, resigning with him in December 1783 and returning with Pitt’s ministry in the following year. Eden was made Lord of the Committee of Council on trade and plantations, and was sent to France to negotiate the commercial treaty, which was finally consummated in 1786–87. He served as special Ambassador to Madrid in 1788; to the United States and to Holland in the succeeding years. In the latter country he was especially active during the years 1790–93 as Ambassador extraordinary. In the last named year he retired and was created a peer of Great Britain as Lord Auckland of West
Auckland, Durham. His support of Pitt continued, and in 1798, he returned to office in the capacity of joint Postmaster-General. His final resignation came in 1801, when the Pitt ministry collapsed under the disapproval of the king in regard to their Irish policy. The love of Pitt for Auckland's eldest daughter who later married the Earl of Buckinghamshire strained the relations between Pitt and Auckland, and resulted in the latter's refusal to join Pitt's second ministry. In 1796 he was chosen to be chancellor of Marischal College. Besides the publications already mentioned, he wrote 'History of New Holland' (1787), and 'Remarks on the Apparent Circumstances of the War.' His 'Journals and Correspondence' were edited by his son, Robert John, bishop of Bath and Wells (4 vols., 1860-62).

EDEN, the garden of paradise. It would be difficult in the whole history of opinion, to find any subject which has so invited and at the same time so completely baffled conjecture, as the Garden of Eden. The three continents of the Old World have been subjected to the most rigorous search; but no locality which in the highest degree resembles the description of the first abode of the human race has been left unexamined. Philo Judaeus (furnished about 20) first broached the allegorical theory of interpretation, teaching that paradise was a symbol of the glory and the privilege of the soul, and that the tree of life represented religion, the true means of immortality. Origin, adopting a somewhat similar view, regarded Eden as heaven, the trees as angels, and the rivers as wisdom; and Ambrosius considered the terrestrial paradise and the third heaven, mentioned by Saint Paul (2 Cor. xii, 2-4), as identical. Luther taught that Eden was guarded by angels from discovery and consequence proliferation until the Deluge, when all traces were destroyed. Swedenborg, who regarded the first 11 chapters of Genesis as constituting a divine allegory, taught that Eden represented the state of innocence in which man was originally created and from which he degenerated in consequence of the Fall. The ancient Hebrews in Genesis of the situation of Eden is not such as to enable us to identify it with any existing locality. It is said to have had a garden in the eastern part of it, and we are told that a river went out of Eden to water this garden, and from thence it was parted into four heads, which were called, respectively, Pison, Gihon, Hiddekel and Euphrates (Phrat). The Pison is said to compass the whole land of Havilah; the Gihon that of Ethiopia (Cush); and the Hiddekel to go toward the east of Assyria. Of the rivers mentioned the Phrat of the original seems to have been correctly identified with the Euphrates, and the name Hiddekel appears elsewhere in Scripture (Dan. x, 4) to be applied to the Tigris; but it is impossible to say what rivers or places were meant by the names Pison, Gihon, Havilah and Cush.

EDEN, the principal river in the county of Cumberland, England, rising in the hills of Westmoreland, near the northwest boundary of Yorkshire; flows northwest, passing Appleby and Carlisle, and empties into the Solway Firth. Total course, about 65 miles.

EDEN OF AMERICA, a fanciful name bestowed on the island of Aquidneck, on which is situated the city of Newport, R. I., on account of its great fertility.

EDENHALL, the ancient seat of the Musgraves in Cumberland, four miles northeast of Penrith, England. Here is still preserved the famous 'Luck of Edenhalle,' an old painted glass goblet, said to have been snatched from the fairies, on the safety of which the welfare of the house depends. It is supposed to have been a chalice, and its leathern case bears a sacred monogram. Uthland's well-known ballad, 'The Luck of Edenhall,' and Longfellow's translation of it has carried its fame beyond the British islands.

EDENTATA, é-dén-tá'ta one of the smaller orders of mammals, most of which are found in South America. It includes the South America sloths, ant-eaters and armadillos, and two Old World groups, all of which are characterized by an absence of front teeth, and in a few instances by completely toothless jaws, whence the generic name. Where teeth are present they are without enamel, and lack distinct roots; and the teeth generally are not preceded by a set of milk teeth. These animals are ranked comparatively low in the scale of mammals, not only on account of their deficiency in teeth, but also because their brains are relatively small and lack the convolution characteristic of the more highly developed orders. With two exceptions, the armadillos and pangolins, the Edentata are clothed with coarse hair, and they never are completely hairless. The armadillos are peculiar among mammals, in that their bodies are covered with an armor of bony plate; and in the pangolins the entire body is protected by a coat of overlapping, horny scales. The typical edentates are the sloths (Brodyopodidae), the ant-eaters (Myrmecophagidae) and the armadillos (Dasypodidae), all of which are American; the two groups in the order, native to Africa and Asia, are the pangolins (Squamata) and the aard-varks (Tubulidentata), although Lydekker questions the correctness of placing the last two among the edentates, preferring to consider the present and extinct forms as an entirely American order. The sloths live on vegetable food exclusively, the other group chiefly on insects or animal matter softened by decay.

Fossil Edentates.—Of the large and numerous edentate fauna which lived in South American during the Tertiary and Quaternary periods, some (Mylodon, Megalonyx, Glyptodon) spread to North America during the Pliocene and Pleistocene epochs; the armadillo is still found as far north as the Mexican border of the United States. Their earliest ancestors were, perhaps, North American, but their development was exclusively in the southern continent during most of the Tertiary period. The earlier stages in their evolution were less divergent from the normal mammals than the present edentates, and were of small or moderate size; later on they became of huge size and very highly specialized. The most remarkable among them were the Myrmekotherium, ground-sloths, distantly related to the modern ant-eaters and true sloths, but terrestrial animals, very heavily proportioned, with massive hind quarters and tail, and immense digging claws;
EDENTON — EDESSA

and the Glyptodontis, related to armadillos but much larger, with massive unjointed carapace like that of a tortoise and with hoofs instead of claws. The armadillo, both large and small, some ancestral to the modern species, others of extinct races. No fossil ant-eaters have yet been discovered, and fossil tree-sloths are almost equally unknown; but the fossil beds of South America have yielded specimens of this fact is not surprising. See AARD-VARK; ANT-EATER; ARMADILLO; GANDONITA; GLYPHTOON; MANIS; MEGATHERIUM; MYLodon; SLOTH.

EDENTON, N. C., town and county-seat of Chowan County; on the Albemarle Sound near the mouth of the Chowan River; on the branches of the Norfolk and Southern Railroad; about 90 miles north of Beaufort and 115 miles northeast of Raleigh. Four steamship lines enter Edenton, thus making it a good shipping point for the trade of the northeast part of the State. The shallow waters of the Albemarle Sound are a hindrance to more extensive shipping. The name given to the town when founded in 1712 was Queen Anne's Creek, but this was changed to Edenton in honor of a governor of the colony, Charles Eden. In less than a year after the Boston Tea Party, on 24 Oct. 1774, 52 housewives of Edenton resolved not to assist in supporting England by paying a tax on tea; and they formed themselves into an organization, none of whose members should conform to that pernicious custom of drinking tea and "would not promote ye weare of any manufacture from England." In addition to being first among those who held Revolutionary tea parties, they seem to have been pioneers in America in the formation of organizations for women. Its industrial establishments include cotton mills, peanut factories and lumber mills. The herring and shad fisheries are also important. A fish hatchery is maintained here by the government. The municipality owns the waterworks and lighting plants. Pop. 3,000.

EDER, a'dër, Joseph Maria, Austrian chemist: b. Krems on the Danube, 16 March 1855. He taught photo-chemistry at the Technical School, Vienna, and in 1882 was made professor of chemistry at the Industrial School in that city. He has made great contributions to the development of the art of photography, particularly with reference to the use of chloride or bromide of silver. He also invented a photometer for measuring the invisible ultra violet rays by the oxalate of mercury, and the now extensively-used aristo papers (chloro-gelatin papers). Among his works are 'Photographie aux sels de chrome'; 'Etudes sur l'action de la lumiere coloree' (1879); 'Manuel de photographie' (1882); 'Die Momentphotographie in ihrer Entwicklung bis zur Vissenschaft' (2d ed., 1886); 'Arleitigung zur Herstellung von Momentphotographien' (1887); 'Photographie mit Bromsilbergelatine' (1890); 'System der Sensitometrie photographischer Tronckenplatten' (1899–1903); 'Beitrage zur Photographie und Spectralanalyse,' with Valenta (1903); 'Atlas typiert Spektien' (1911). He was from 1887 to 1911 editor of the 'Jahrbuch fur Photographie und Reproduktionstechnik.'

EDERSHEIM, a'ders-him, Alfred, English biblical scholar: b. Vienna, 1825; d. 1889. He was of Jewish extraction and received his education at the university of his native city. He became a tutor in Pest and was there converted to Christianity by the armadillos, both large and small, some ancestral to the modern species, others of extinct races. No fossil ant-eaters have yet been discovered, and fossil tree-sloths are almost equally unknown; but the fossil beds of South America have yielded specimens of this fact is not surprising. See AARD-VARK; ANT-EATER; ARMADILLO; GANDONITA; GLYPHTOON; MANIS; MEGATHERIUM; MYLodon; SLOTH.

The municipality owns the waterworks and lighting plants. Pop. 3,000.

EDES, Robert Thaxter, American physician: b. Eastport, Maine, 23 Sept. 1838. He was graduated at Harvard 1858 and at the Harvard Medical School 1861; served as surgeon in the United States navy 1861–45; was professor of materia medica 1870–84, and professor of clinical medicine 1884–86 at the Harvard Medical School. He was physician at the Boston City Hospital 1872–80 and at the Garfield Memorial Hospital, Washington, 1889–91, and resident physician at the Adams Asylum 1891–97. Among his works are 'Nature and Time in the Cure of Diseases' (1868); 'Physiology and Pathology of the Sym pathetic or Ganglionic Nervous System' (1869); 'Therapeutic Handbook of the United States Pharmacopoeia' (1883); 'Therapeutics and Materia Medica' (1887), and many contributions to medical publications.

EDESON, Robert, American actor: b. New Orleans, La., 1868. He was educated in the public schools of Brooklyn and made his first appearance in 'Fascination' at the Park Theatre, New York, in 1887. Later he appeared in 'A Night Off'; 'The Dark Secret'; 'Incog.;' and 'Under the Red Robe' in 1906. He was leading man in 'The Climbers' and starred in 'Soldiers of Fortune' (1902–04); 'Ransom's Folly'; 'Strongheart' (1905–07); 'Classmates' (1907); 'The Call of the North' (1908); 'The Noble Spaniard' (1909); 'Eagle Feathers' (1913). He also played the role of Ma-Wo-Cha-Sa in his own play, 'Where the Trail Divides' (1910).

EDESSA, the name of two ancient cities. (1) The ancient capital of Macedonia and the burial place of its kings, now Vodhena. It is probably the same with the still more ancient Elasa. (2) An important city in the north of Mesopotamia, which, subsequent to the establishment of Christianity, became celebrated for its theological schools. During the centuries which were affected by the Christianizing of Rome, Edessa became the centre of learning of Syria. (See Syria). The modern city of Urfa or Orfa stands on the site once occupied by Edessa. In 1098, in the first crusade, Edessa came into the hands of Baldwin I, but ultimately became part of the Turkish empire in 1637. It was one of the greatest four cities of Syria, the other three being Antioch, Damascus, and Nisibis. The modern city has a population of about 30,000, mostly Mohammedans. The Mohammedans consider it a sacred city, and maintain that Abraham at one time lived there.

**EDFU**

Edfu, Egypt, town situated on the Nile, 54 miles southeast of Thebes. It contains the remains of two temples, the larger of which is the best preserved monument of its kind in Egypt. It was founded by Ptolemy III Philopator more than two centuries before Christ and added to by his successors down to Ptolemy XIII Dionysus, a period of 170 years. The general plan of the temple resembles that of Dendera. Its length is 451 feet, the breadth of its façade is 250 feet. Its entrance is by a gateway 50 feet high, between two immense truncated pylons, 37 feet wide at the base and 115 feet high, the whole surface covered with sculptures and inscriptions in low relief. This splendid façade is visible from a great distance and is one of the most commanding sights in the Nile valley. Passing through this entrance, a court is reached 161 feet long and 140 feet wide, enclosed by a splendid colonnade of 32 columns of every variety of capital, and surrounded by walls between which and the pillars there is a stone roof, forming a covered portico. From this court a hypostyle hall of 18 columns is joined by an intercolumnar screen, through which access is obtained to an inner hall of 12 columns, leading to the sanctuary, where a great monolith of gray granite was evidently intended to encage the hawk, the sacred emblem of Hor-Hud, the local Horus, to whom the temple was dedicated.

The sanctuary and surrounding chambers, together with the outer and inner halls, are separated by an open corridor from the outer wall of the temple, and both sides of this passage are covered with elaborate reliefs and numerous inscriptions, which present a sort of encyclopedia of ancient Egyptian geography, ritual and ecclesiastical topography, with calendars of feasts, lists of divinities in the various names and cities, and even a species of church directory, including the names of singers and other temple officials. The smaller temple, erected by Ptolemy Physcon and Lathyrus, consists of only two chambers. Previous to 1860, both court and temple were inlaid with rubbish, fallen stone, etc. Nomad Arabs built lean-to sheds against the walls until Mariette, with the consent of the Khedive had all these disfigurations removed and established a semblance of order. Consult Mariette, 'Monuments of Upper Egypt' (London 1877); Breasted, 'Ancient Records of Egypt' (Chicago 1907). The manufactures of Edfu at present are blue cotton cloths, and earthenware similar to the ancient Egyptian pottery. Pop. 2,500.

**EDGAR** ('"THE PEACEABLE"'), one of the most distinguished of the Saxon kings of England, the son of King Edmund. He succeeded to the throne in 958, and managed the civil and military affairs of his kingdom with great vigor and success. He maintained a body of troops to control the mutinous Northumbrians, and repel the incursions of the Scots, and fitted out a powerful navy to protect his subjects from the Danes. Edgar, wolves were nearly extirpated from the southern parts of the island, by exchanging a tribute from Wales for payment in the heads of these animals. He married Elfrida, daughter of the Earl of Devonshire, in 965. It was during his reign that Dunstan (q.v.) was primate of England. He died in 975, and was succeeded by his son, Edward the Martyr.

**EDGAR, SIR JAMES**

Canadian statesman and author: b. Hatley, province of Quebec, 10 Aug. 1841; d. 1899. He was admitted to the bar of Ontario 1864. In 1872 he was elected to the Dominion Parliament; served in 1874 on an unsuccessful mission to British Columbia on the dispute between that province and the Dominion as to the terms of construction of the transcontinental railway; and was elected speaker of the Commons in 1896. He was the author of 'The White Stone Canoe' (1887); 'This Canada of Ours and Other Poems' (1893), etc.

**EDGAR ATHELING**

Anglo-Saxon prince: b. Hungary about 1057; d. toward the end of the 11th century. He was a grandson of Edmund Ironside, and his life may be epitomized as a series of abortive attempts. Selected by Edward the Confessor as his prospective heir, he was kept out of the throne by William the Conqueror (1066); having twice attempted to invade the northern revolts against the Normans, he was twice compelled to take refuge in Scotland, with Malcolm Canmore, who married Edgar's sister, Margaret; then, embracing the cause of Robert, Duke of Normandy, against William Rufus, he was driven away (1091) from the duchy to Scotland; then he embarked (1099) in a bootless crusading expedition to the East; and finally was taken prisoner at Tencleblari (1106) fighting for Duke Robert against his brother Henry I. Almost the only successful achievement of his life seems to have been that of reestablishing his nephew Edgar on the throne of Scotland (1097), which had been usurped by Donald Bane. His last days were spent in obscurity; the date of his death is not precisely known. Consult Freeman, 'History of the Norman Conquest' (Vols. III–V, Oxford 1873).

**EDGARTOWN**

Mass., town, county-seat and port of entry of Dukes County; situated on the eastern shore of the Island of Martha's Vineyard, 27 miles southeast of New Bedford. At present it is a summer resort and once a whaling station of importance. The town was settled in 1642 and was incorporated in 1671. Its harbor is small but well-sheltered. It contains a Carnegie library. Pop. 1,191. Consult Banks, 'History of Martha's Vineyard' (Boston).

**EDGECUMBE,** éd'jē cum, Sir Edward Robert Pearce, English traveler; b. 13 March 1851. He was educated at Cambridge, was mayor of Dorchester 1891, and sheriff of Cornwall 1896. He has published 'Zephyrus, or Travels in Brazil and on the river Plata' (1887); 'Bastian's Popular Fallacies' (4th ed., 1893); 'Popular Fallacies Regarding Bimetallism' (1896); 'The Parentage and Kinsfolk of Sir Joshua Reynolds' (1901), etc.

**EDGE, Walter Evans,** American public official: b. Philadelphia, Pa., 20 Nov. 1873. He was educated in the public schools and began life as a printer's devil on the Atlantic Re- gister of Albany. Later he established a national and international advertising agency, acquired the proprietorship of the At-
lantic City Daily Press and the Evening Union of that city. He also became identified with banking and other lines of business. In 1897–99 he was journal clerk of the Senate of New Jersey; from 1900 to 1904 he served as secretary of that body. In 1904 he was a Republican presidential elector and in 1908 was alternate delegate-at-large to the Republican National Convention at Chicago. In 1909 he became a member of the Legislature of New Jersey and served two terms in the Senate, from 1910 to 1916, becoming Republican leader in 1912 and president of the Senate in 1916. He was chairman of the economy and efficiency committee and a leader in securing passage of the Workmen's Compensation Act and the Central Purchasing Bureau Act. During the Spanish-American War, Mr. Edge served as second lieutenant in the 4th New Jersey Volunteer Infantry and afterwards was made captain in the Third Regiment of the New Jersey National Guard. For the term 1917–20 Mr. Edge was governor of New Jersey.

EDGEHILL, éj'hil, England, an eminence in Warwickshire, 12 miles south of Warwick. On its northern slope was fought the first battle of the war of the French and the Royalists under Charles I and the forces of the Parliament under the Earl of Essex. It was an indecisive engagement.

EDGEWORTH, éj'wé-rth, Maria, English novelist: b. Hare Hatch, near Reading, Berkshire, 1 Jan. 1767; d. Edgeworthstown, Ireland, 21 May 1849. In 1782 her father, Richard Lovell Edgeworth, succeeded to the family estate of Edgeworthstown, in the county of Longford, Ireland, and thither he proceeded and took up his abode. In 1802 she established her position as an author by her Castle Rackrent, a novel of Irish life, in which the manners and customs of a by-gone generation are most graphically and humorously described. A Treatise on Irish Bulls appeared in 1803; Emmie (1810); The Abbe (1811); The Children of the Chatham (1817). About 1803–04 she began to write stories with pointed morals, both for children and adults. Among these may be mentioned Moral Tales; Popular Tales; Tales of Fashionable Life; The Parents' Assistant, and A Collection of Stories for Children, and the well-known series of Early Lessons; Harry and Lucy; Frank; and Rosamond. Belonging to the class of regular novels are Belinda (1804); Leonora (1806); Patronage and Harrington. Miss Edgeworth's lively style and vivid imagination made her extremely popular in her day. In her pictures of Irish and English life she was the precursor of the genre literature of the succeeding generation. But her strong tendency to moralize has led to her eclipse in popular favor. It is on the excellence of her vivid representation of the life of her generation that her place in literature is justly based. (See CASTLE RACKRENT.) Consult Ritchie, Thackeray Anne, 'Book of Sibyls' (1883); Zimmerm., 'Life of Maria Edgeworth' (1883); Hoffmeister, W. D. 'Heroines of Fiction' (New York 1901); Hill, 'Maria Edgeworth and her Circle' (New York 1910).

EGOREN, Anne Charlotte Leffler, än ša-löt’té fel-lér e’dër’en, Swedish novelist and dramatist: b. Stockholm, 1 Oct. 1849; d. Naples, 24 Oct. 1892. A volume of short tales, 'By Chance,' and the dramas, 'The Actress'; 'The Curate,' were a great success anonymously; and she then put her own name to three successive volumes of short stories called From Life, followed by 'A Summer Story,' 'Women and Erotism' and many others. 'Ideal Women'; 'The Struggle for Happiness'; and 'A Rescuing Angel' (the most successful of her plays), are notable among her dramas. Consult Key, Ellen, 'Life of Edgeworth' (1881).

EDHEM PASHA, pash'-ä or pash’a, Turkish soldier and statesman: b. Chios, 1813, of Greek parentage; d. 1893. He studied in Paris, and on returning to Turkey was attached to the staff of the army with the rank of captain; rapidly attained that of colonel; and was appointed a member of the Council of Mines at the time of its formation. Having been appointed aide-de-camp to the Sultan in 1849, he soon was placed at the head of His Majesty's household troops. In 1856 he resigned the functions which he had fulfilled in the palace, and was appointed a member of the council of the Tanzimat, and afterward Minister of Foreign Affairs, with the rank of muchir. Subsequently he played an important part in the wars of 1859 and 1877, and was later made president of the council of state. He was also for some time Ambassador at Berlin. At the conference of Constantinople (1876–77) he acted as the second Turkish Plenipotentiary, and was appointed to succeed Midhat Pasha as grand vizier, 5 Feb. 1877. From 1879 to 1883 he was Ambassador at Vienna.

EDHEM PASHA, Turkish soldier: b. 1851; d. 1909. In 1877 he held the rank of colonel in the Turkish army and rose rapidly during the war with Russia. He was appointed governor-general of the Vilayet of Kossow, and was later made adjutant-general and field marshal. In the war with Greece (1896–97) he had the chief command of the Turkish army. In three weeks he collected an army of 55,000 men, met and defeated the Greeks at Maluna Pass, invested Thessaly and occupied Larissa. In this campaign he displayed great skill as a commander and was no less successful in organizing the sanitary and hospital services of his armies.

EDIT, a public proclamation of laws made by a ruler or superior magistrate. In ancient Rome, the higher officers of state, who were elected annually, publicly declared, at their entrance upon office, the principles by which they should conduct their administration. This was done particularly by the ediles, who superintended buildings and markets, and by the praetors, as supreme judges. These annual proclamations, by which the deficiencies of the general statutes were supplied, and the laws were adapted to the peculiar wants of the period, gradually acquired a certain permanency, as each officer retained, unaltered, most of the regulations of his predecessor (editum tralatitum); and they became, in fact, the source of that branch of Roman law which, being founded on the official authority of the authors, was called jus honorarium, and was of the informal law, jus civile. However, according to Roman jurists these usually indirect forms of legislation had their object in rendering the civil law more expedient to the public welfare, and always received the seal of the people's approval. Editcs were sometimes made for some
EDICT OF NANTES — EDINBURGH

special occasion, in which case they were called *edicta repetenda*. It was against the abuse of this kind of edicts that the Edict of Nantes in 67 B.C. was directed. Those which were applicable in all cases during the tenure of office of the magistrate who issued them were called *edicta perpetua*. The name of *edictum perpetuum* was also given to a collection and arrangement of the clauses which the praetors were accustomed to put into their annual edicts, made under the Emperor Hadrian by Salvius Julianus about 131 A.D. What the exact nature of the work thus done by Julianus was is not known, but the edict prepared by him, and sanctioned by Imperial authority, had unquestionably a special force, and it is likely that it restricted in future the right enjoyed by magistrates of issuing edicts, to such cases as were not provided for in the edict of Julianus. Only a few fragments of the ancient Roman edicts have been preserved by Wieling in "Fragmenta Edicti Perpetui" (Frankfort 1733). See CIVIL LAW.

EDICT OF NANTES, a decree of Henry IV, king of France, published 13 April 1598, by which he conceded to the Huguenots, or Protestants of that kingdom, freedom of religious beliefs, teachings and practices; freedom of public worship and liberty to erect churches, except at Paris and the royal residences, and to maintain the four Protestant universities of Saumur, Montauban, Montpellier and Sedan, and as members of the parliament of Paris and the right to special chambers in the parliaments of Grenoble and Bordeaux; further, the right to hold provincial and national synods. In 1620 the Huguenots in their political congress at Moulins were received as members of the Roman Catholic churches and constituted throughout France a military and civil organization for Huguenot ends.

Before the formal revocation of the Edict of Nantes the liberties of the Protestants were largely restricted by partial acts of revocation, which precluded them from office in the government, from membership in trade corporations, etc., and from marriage with Roman Catholics. The edict was formally revoked by a decree of Louis XIV on 18 Oct. 1685. The Protestant churches of the Huguenots were to be destroyed, forbade the holding of religious meetings and of synods by Protestants on penalty of confiscation of goods; banished all Protestant ministers; ordered the children of Protestants to be baptized and brought up as Roman Catholics.

EDINBURGH, ed·im·búr·ú (Edinboru), the metropolis of Scotland and one of the finest cities in the British Isles, is built on ridges and hollows that run east and west. It is picturesquely situated on the southern shore of the Firth of Forth, 47 miles east of Glasgow, and 400 miles north of London. From the Firth the ground slopes somewhat unevenly upward to the top of the Castle Rock, 438 feet above sea level. The Central Ridge, which constituted the site of the old town, is terminated on the western side by the Castle Rock, restored by the House of Hanover, and on the east by Arthur’s Seat, 822 feet high, which overlooks the whole of the eastern and southern part of the city, and between it and the Palace are the elevations known as Salisbury Crags. The new town lies between the old town and the sea. The houses, streets, squares and gardens are all handsome, built of beautifully dressed freestone found in the neighborhood of the city. The principal streets of the new town are Queen street, George street and Queen street, running parallel with each other.

Geological Formation.—The geological formation upon which Edinburgh is built is of a very interesting character. The rocks which underlie the town belong to the "Princlodynamis" of the carboniferous system, but here and there in the neighborhood, such as in the rocks of the Pentlands, Blackford Hill, and a portion of Arthur Seat, there are several veins of igneous rock. The district is particularly interesting one for the geologist, and several writers of standing have dealt with the subject, among whom may be named — Hutton, Playfair, Forbes, Millar, McLaren and Gelkie.

Principal Buildings, Galleries, Museums, etc.—In Princes street there are some notable buildings, and on the Mound connecting it with the old town is the National Gallery, while near at hand to the east is the Scott Monument. The old town has suffered very much at the hands of the improver, but there are still some cloisters, "*halls,*" and churches to interest the visitor. From the Castle to Holyrood House there is one continuous street, known at different parts as the Lawnmarket, the High street, and Canongate. It is upward of a mile in length, and is frequently termed "the Royal Mile." Among the notable buildings in and around this "Royal Mile" are the Tolbooth Church, the meeting place of the General Assembly of the Church of Scotland; the United Free Church Assembly Hall, Saint Giles’ Cathedral, Parliament House, the Albany, the Signet Library, and the municipal buildings. The Tron Church is at the junction of South Bridge with the High street. Continuing down the Canongate on the left is the house of John Knox, the great Reformer, while on the right further down is the "New Parliament House" built by the Regent Murray, in the garden of which stood, till quite recently, a tree said to have been planted by Queen Mary. In the garden is still existing a summer-house where it is averred that Mary ordered the heads to be fixed. There are other interesting buildings in the Canongate, such as the Tolbooth and Queensberry House. To the north of the "Royal Mile" there are such buildings as the Bank of Scotland in Bank street, and the Scotsman Buildings in North Bridge. From the head of the Canongate a particularly good view can be had of the Calton Hill, with its Nelson Monument and the never-to-be-finished National Monument. To the south the public buildings in George IV Bridge are the County Buildings, the Sheriff Court-house, and the Public Library (the latter erected in 1887 at a cost of £50,000, given by Andrew Carnegie; total stock now is 165,000 volumes); while in Chambers street there is the Royal Museum of Science and Art, the Heriot Watt College, and the University (a.v.). Near at Hyndland is the Students’ Union, M’Ewan Hall, Heriot’s Hospital, and the Royal Infirmary, all of which are distinctive buildings. The Castle contains accommodation for 2,000 soldiers, and the Armory has places for 30,000 stands of arms. The regalia of Scotland is kept in an apartment by itself. Another attraction to visitors, besides this, is Queen Mary’s
1 The Castle and Museum

2 The Old Town, from Princess Street
room, which is visited annually by large numbers. Holyrood Palace and Abbey stand at the east termination of the "Royal Mile," and the former is only now used on the occasion of the visit of the royal commissioner to the general assembly. St. George’s Church, at the end of the 15th century, suffered destruction in Hertford’s invasion in 1544, with the exception of portions built by James V in 1528; was destroyed by fire during the Cromwellian occupation in 1650; and the greater portion of the present building dates only from the time of Charles Second. The apartments occupied by Queen Mary are in the northwest corner of the building, and in very nearly the same state as that in which they were left by that unfortunate princess. The Abbey is supposed to have been founded by King David I in 1128; it suffered at the hands of the English in 1544 and from the iconoclastic zeal of the reformers about 1558; in 1688 the chapel, which had again been set apart for worship in accordance with Roman rites, was completely destroyed by a Protestant mob. Other interesting buildings are the Royal Museum of Science and Art, the National Portrait Gallery and Antiquarian Museum in Queen street; Fettes College, Daniel Stewart’s College, and the Cathedral of Saint Mary (Edinburgh). Saint George’s Church in Charlotte square is a notable modern ecclesiastical building. Along with the University the more prominent educational institutions are the New College, the School of Medicine, Heriot-Watt College, Fettes College, the High School, the Academy, Daniel Stewart’s College, and George Watson’s College. The southern part of the city is modern, but extends now to the foot of the Pentland Hills, including the Braid hills, the golf course of which is one of the best inland courses in Scotland.

Manufactures.—The principal manufactures in Edinburgh are printing, type-making, coach building, ale brewing, and cabinet-making. It is the seat of the principal government departments for Scotland, and the headquarters of the book trade.

Government.—The town council consists of lord provost, magistrates known as bailies, treasurer, a dean of guild, and 41 ordinary councillors. Edinburgh was a royal burgh as early as the time of David the First, its designation at that time being Edinwibsig. The outlying suburb of Portobello on the northeast was added in 1896.

Railways.—The two principal railways connecting Edinburgh with other parts of the country are the Caledonian and North British railways. There are 25 miles of cable tramways throughout the city. The system has been municipally owned since 1893; and in 1910 a beginning was made with an overhead electric system in one of the suburbs. To this system there was at one time a root 1 average of 100,000. It was to preserve the amenity of Princes street; but on the expiry of the present operating company’s lease in 1919, it is certain that the whole system will be electrified.

Electricity.—The city is beautifully lit by an electric installation, which has been one of the most successful in Great Britain. Not only is the public supplied on an extensive scale, but all the private houses of the modern parts of the town have electricity as the domestic light.

EINBURGH 585

Parks.—Edinburgh is particularly well off with open spaces. The King’s Park, including Arthur Seat, Salisbury Crags, etc., is one of the most handsome in the Kingdom, although very little is done to adorn it either by the government or the local authority. The Black Hills and Blackford Hill, on the latter of which is the Royal Observatory, are picturesque resorts in the summer time, while in the very centre of the town there are the Calton Hill, East and West meadows and Bruntsfield Links. Involveth Park on the north, and Saughton Park on the western outskirts, are recent additions — the latter a noteworthy one. A fine zoological garden has been opened on Constance Hill, west of the city.

Climate.—Robert Louis Stevenson, who was constitutionally ill adapted for the climate of Edinburgh, "pays cruelly for her high seat in one of the wildest climates under heaven," and has described the east winds that prevail in spring as making of the city a "meteorological purgatory." Despite these strictures the city is a healthy one, with an annual mean temperature of 47° F., and a rainfall of 27 inches.

Churches.—Edinburgh is noted for its churches. It is distinctively a Presbyterian city, there being in connection with the Church of Scotland some 46 churches, and with the United Free Church, about 65.

Population.—The population in 1901 was 316,479; in 1911, 320,318. The ravalable value of the city in 1915-16 was $16,633,100.

Charitable Institutions and Libraries.—Among benevolent institutions are the Royal Infirmary; Donaldson’s Hospital; Deaf and Dumb Institution; Royal Blind Asylum and many others. There are four large libraries situated in the centre of the old town: the Advocates’ Library, 550,000 volumes, the University Library, the Library of Writers to the Signet, 110,000 volumes, and the Public Library.

History.—The history of the city is largely the history of Scotland. Before the 11th century it did not figure more than as a fortified town, but in the time of David I it begins to be mentioned in charters under the name of Edwinsburg. In 1128 the Abbey of Holyrood was founded by David I and between it and Edinburgh was the Canongate, which had a separate municipal authority down to 1856. The old wall of the city is said to have been built in 1450, and was extended after the battle of Flodden in 1513. The English under Hertford in 1544 burnt the city to the ground, with the exception of Saint Giles Cathedral, and 17 years later, Mary, on her return from France, took up her residence at Holyrood Palace. The modern history of the town is more associated with literature than with commercial and industrial enterprise.

Editorial Staff of The Americana.

EDINBURGH, University of, the youngest of the four Scottish universities, was originally known as "the College of Edinburgh," or "the Town's College," having been founded in 1583. King James VI, in 1582, granted to the town council of Edinburgh a charter, conferring upon that body certain powers and privileges, and under this charter the Town's College, which afterward became known as "the College of James VI," was founded by the town council as a degree-granting institution, and the University of Edinburgh remained under the control of the town council until 1858, when, by the Universities Act, all the universities of Scotland were made practically autonomous. From 1858 to 1889, the senate academicus (that is to say, the principal and the professors) was the governing body of the university, but, by the Universities (Scotland) Act of 1889, the university court became the governing body, having full control of all the property belonging to the university. The senate, however, still regulates the teaching and discipline of the university.

The university consists of the rector (the chosen representative of the undergraduates); the principal; the lord provost of Edinburgh for the time being; three assessors nominated by the chancellor, the rector and the town council, respectively; four assessors elected by the general council; and four assessors elected by the senate.

The university has six faculties, videlicet—divinity, law, medicine, arts, science and music, each presided over by a dean elected by the separate faculties. In 1918 an ordinance constituting a degree in commerce (B. Com.) received the consent of the Privy Council, London.

The general council of the university consists of the chancellor, the members of the university court, the professors and the graduates. The council does not exercise any direct control in the government of the university, but "may make reports to the university court on matters affecting the well-being and prosperity of the university, and the university court shall consider the same, and return to the council their deliverance thereon." The general council, together with the general council of Saint Andrews, and the representatives of the members of Parliament, who represents the two universities jointly. The chancellor of the university is appointed for life by the general council, and acts as president of that body. The general council is represented on the university court by four assessors elected every four years, two retiring biennially.

A students' representative council, elected annually, was founded in 1884, to represent the students in matters affecting their interests, and to afford a recognized means of communication between the students and the university authorities, as well as to promote the social life of the undergraduate community.

Enrolment as a student in one or more classes, the payment of the fees for such classes, the signing of the university album and the payment of a matriculation fee of one guinea per session (or half a guinea for a summer session only) are conditions precedent of matriculation. The matriculation fee entitles students to the use of the university library. The rector of the university, who presides over the university court, is elected by the matriculated students.

The university buildings consist of (1) the college of university (old building) in South Bridge Street; (2) the new buildings (school of medicine) Teviot Place; (3) the music classroom, Park Place; (4) the John Usher Institute of Public Health, Warrender Park Road, and (5) the engineering department, Infirmary Street. The old buildings of the university which were erected on the site of "Kirk o' Field," the scene of the murder of Darnley, contain the library and reading-rooms, the class-rooms of the faculties of arts, divinity and law, the natural history and some of the science classrooms, the examination hall, the physical, geological and pathological laboratories, the Fulton Engineering Laboratory; the physical, geological, fine art and natural museums; the senate hall; the university courtroom and the offices of the senate, the court and the students' representative council. The new buildings, begun in 1878, were partly completed for teaching purposes in 1880, being completed in 1888. They contain the lecture-rooms of the faculty of medicine (excepting those of botany, natural history and public health); the various museums connected with the medical faculty; a students' reading-room and common room; the faculty of medicine reception and reading-rooms, and the offices of the faculty.

Immediately contiguous to these new buildings, there was erected in 1902, the Hughes Bennett Physiological Laboratory, in memory of a former professor of physiology. The laboratory is connected directly with the other physiological laboratories and has been designed on the most modern lines.

The M'Ewan Hall was built between 1888 and 1889, and is a spacious hall of the early Italian renaissance style, capable of holding 2,600 people, and is used for all academic functions.

The John Usher Institute of Public Health was opened in 1902, and is equipped with the most modern appliances for teaching and research in bacteriology and chemistry. It is the gift of Sir John Usher, baronet, and was erected at a cost of over £21,000.

The new block of art classrooms for the engineering department was completed in 1905, and provides extensive accommodation for carrying on the work of that department.

The School of Music was built in 1858 from designs by the late Mr. David Cousin, and contains, in addition to the music classroom, an excellent organ, and museum of musical instruments.

The University Union, with extensions, has
cost over £37,000. It is situated in Park Place, near the M’Ewan Hall, and is held by trustees for the students.

The University Library, which contains over 270,000 volumes, and about 8,000 MSS., many of great value, was founded in 1580 by the transference from the town council to the university of a collection of books left to “Edinburgh and Stirling” by John Mervyn, by Clement Little. In addition to the University Library proper, there are separate libraries in connection with the following departments: Theological, classical, philosophical, historical, physiological, astronomical, modern languages, natural philosophy, engineering and music.

The income of the university is derived from benefactions and bequests for the foundation of bursaries, scholarships and prizes; from matriculation, graduation and other fees; from funds bequeathed for general purposes and for the endowment of chairs; and from parliamentary grants. The salaries of the principal and professors are paid from a fee fund account, the whole of the fees being pooled. The total net annual revenue is about £180,000.

John Minto, Librarian of the Signet Library, Edinburgh.

EDINBURGH REVIEW, the first of the great critical periodicals of the 19th century. It first appeared in October 1802, being started by Francis Jeffrey, Sydney Smith, Francis Horner and Henry Brougham. The original publisher was Constable and the printing was done by Willison. Of the first number 750 copies were printed; the demand soon exhausted this edition and 750 more were struck off. In six years the periodical reached a circulation of 9,000 and in 1813 it had about 13,000. Sydney Smith edited the early numbers but was soon succeeded by Jeffrey who made the Review a potent influence in Whig politics and also in the literary field. Its writers exhibited remarkable keenness of criticism, wit and brilliancy of style and the Review caused a sensation in the world of literature. Among the least pleasing episodes of its early period are its treatment of Southey, Wordsworth and other writers of the Romantic school. After the early period Macaulay was the most brilliant contributor. The Review is now published in London. Consult Napier, ‘Life and Correspondence’ (London 1862).

EDINBURGHSHIRE, or MIDLOTHIAN, a maritime county of southeastern Scotland; area, 234,289 acres. The Pentland Hills cross the country from the southwest, and the Moorfoot Hills separate the southern uplands from the Forth. The southwestern uplands in the south are devoted to pasture; dairying is carried on in the west; and on the lowlands toward the Forth the soil is of remarkable fertility. Oats — for which the county is famous — wheats, barley and potatoes are the principal crops; paper, ale and brick are among the manufactures; coal and shale are extensively worked, and there are important quarries. The county returns one member to Parliament. Pop. 507,666, or exclusive of Edinburgh, Leith and Musselburgh, 80,922.

EDISON, Thomas Alva, American electrician and inventor: b. Milan, Ohio, 11 Feb. 1847. His family moved to Port Huron, Mich., when he was seven years of age, but he obtained no schooling, and at the age of 12 became a trainboy on the Detroit and Pont Huron branch of the Grand Trunk Railway. While in this capacity, in 1862, he bought a small hand press and edited, printed and published a small paper of his own, naming it the Grand Trunk Herald. It had a circulation of 300 among the employees of the road. For the rescue of the son of a station agent he was taught telegraphy by the father and later became an operator at Mount Clemens, but, owing to his dislike of routine work, his fondness for reading and his inventive genius, he lost several subsequent positions and became a "tramp operator," although known to be remarkably proficient. While in Indianapolis in 1864 he invented an automatic telegraph repeater, the first of a long series of improvements and inventions. He soon after went to Boston, where he invented the commercial stock indicator, which he sold to New York capitalists for $40,000. This gave him the long-cherished opportunity of establishing an extensive laboratory, which he did at Newark, N. J., for the special manufacturing of electrical printing, automatic and other apparatus. In 1876 his health failed and he gave up manufacturing, confining his labor to investigation and invention. He established his laboratory at Menlo Park, N. J., and later at West Orange, N. J., gave employment to hundreds of workmen and became known as one of the greatest inventors of the 19th century. More than 300 patents have been issued on his inventions and he has besides produced hundreds of minor contrivances and improvements not covered by patents. Among his more important contributions may be named the phonograph, a telephone for long-distance transmission, a system of duplex telegraphy (which he subsequently developed into quadruplex and sextuplex transmission), the carbon telephone transmitter, the carbon microphotometer, the aerophone, megaphone, the incandescent electric lamp, the kinetoscope and a storage battery for street railway cars and automobiles. There is not an electrical instrument or an electrical process now in use but bears the mark of some great change wrought by the most ingenious of Americans. In 1878 he was made Chevalier of the Legion of Honor by the French government, a commander of the Legion in 1889 and was the recipient of the insignia of a grand officer of the Crown of Italy bestowed the same year by King Humbert. In 1892 he received the Albert medal of the Society of Arts of Great Britain.

Among his commercial ventures were the magnetic treatment of iron ore and a Portland cement plant. The great improvement of his latest invention is the nickel-iron storage cell, which is extremely rugged, is almost incapable of electrical injury and has a very high capacity per unit of weight. Its special use is the propulsion of vehicles and railway cars. Edison also invented a disc phonograph with a diamond-point repro-
EDISTO — EDMONDS

EDISTO, a river in South Carolina, which has its rise in the southern part of the State and which flows in a general direction southeast into the Atlantic Ocean. Its source is at the confluence of two streams called the North and South Forks of Edisto River. The river is 150 miles in length and navigable for 100 miles.

EDITOR, The, (Redaktören), a play by Björnstjerne Björnson, appeared almost simultaneously with 'A Bankruptcy.' Both plays had been written by the author and were published in Norway in 1875. They signaled the beginning of Björnson's career as an author of social dramas. In this respect he came a little earlier than Ibsen. While 'A Bankruptcy' met with a favorable reception both at home and abroad, 'The Editor' was ill received. Since it was a fierce attack upon modern journalism, it naturally roused the ire of the newspaper world, for it shows how the press exerts a most pernicious influence when in the hands of unscrupulous men. Björnson injects much personal feeling into the play. He was himself a liberal and had often been stung by the attacks of the conservative press. The 'editor' is therefore represented as a conservative of the conservatives, and the author takes perhaps too keen a delight in poking fun at the sad man. The 'editor' is held forth as the very incarnation of evil, while his opponents, the liberals, appear like the angels of light. The standpoint of the author is that of tolerance, and the old doctor in the play is the spokesman of this philosophy. But the author combats the doctrine that we must become hardened to the criticisms that are directed against us through the press or otherwise. Consult Jaeger, Henrik, 'Illustreteret norsk litteraturhistorie' (II, 589-659 and 711-768); Brandes, Georg, 'Det Moderne Gjenembruds Maend' (pp. 1-69, tr. by Mary Morison in a volume entitled 'Henrik Ibsen. Bjørnstjerne Bjørnson. Critical Studies. By George Brandes,' 1899).

JOSPH ALEXIS

EDMONDS, Richard Hathaway, an American journalist: b. Norfolk, Va., 11 Oct. 1857. His parents were Virginians of English descent. His father died when he was an infant and his mother removed to Lancaster County, Va., where the family suffered many bitter experiences during the Civil War. In 1871 she removed to Baltimore where the boy received an education at private schools, and for two years at the City College of Baltimore. In 1875 he became clerk in the office of the Journal of Commerce, and was successively bookkeeper, reporter and editor until 1881, when he became identified with the founding of the Manufacturers' Record, devoted to the industrial and commercial interests of the South. As its editor he has been the author of its wonderful growth and powerful influence. Realizing the vastness of Southern resources and the possibilities of developing them, he planned and labored ably and successfully for their development. As editor of the Journal of Commerce he wrote on the world's grain trade, becoming an authority on grain statistics. For the American Historical Record he wrote the interesting and noteworthy history of the American grain trade after 1820. He is a trustee of the Southern Baptist Theological Seminary of Louisville. He has published numerous pamphlets about the South
EDMONSON — EDMUND 586

and its resources; also 'Facts about the South' — an historical review of business conditions in the South. He has been active in advocating technical schools for the South. He is a member of the American Association for the Advancement of Science, and the American Academy of Political and Social Science.

EDMONSON, Thomas William, American mathematician: b. Skipton-in-Craven, Yorks., England, 26 June 1899. He was graduated at London University in 1888, and at the University of Cambridge in 1891, studying later at Clark University, Worcester, Mass. He was assistant professor of physics and associate professor of mathematics at New York University from 1896 to 1905, when he became full professor of mathematics. He has published 'Worked Examples in Co-ordinate Geometry' (1891); 'Mensuration and Spherical Geometry' (with W. Briggs, 1893); 'Deduction in Euclid' (1901), also other mathematical textbooks.

EDMONTON, Canada. The city of Edmonton, capital of the province of Alberta, stands at an altitude of 2,158 feet, and is situated on both banks of the North Saskatchewan River about 800 miles west by north of Winnipeg and 946 miles east of Prince Rupert. It is approximately 300 miles north of the international boundary and lies a few miles south of the middle of the province. The site is picturesque, as the Saskatchewan at this point flows between banks 200 feet high and densely wooded. The name Edmonton is derived from the little town near London, England, to which John Gilpin took his famous ride. Throughout the 19th century the place was an important trading-post of the Hudson's Bay Company and it was only in 1916 that the moldering timbers of the old fort were finally demolished. With the advent of railway communication with Calgary in the early nineties, the town began to develop, and this development has proceeded steadily ever since.

On account of its strategic position at the old cross roads of north and south and east and west trade, Edmonton has become a remarkable railway centre. Thirteen lines of railway operated by the Canadian Pacific, Grand Trunk Pacific, Canadian Northern, Edmonton, Dunvegan and British Columbia and Alberta and Great Waterways enter the city. Two of these are the transcontinental lines of the Grand Trunk Pacific and the Canadian Northern. The new northern railways leading to the Peace River country and to the McMurray district, celebrated for its tar sands, have already made Edmonton the distributing point for the rapidly growing commerce of the northern section of Alberta. Communication between the north and south sides of the city is provided by four steel bridges, the most important of which is an imposing structure crossing the river at a height of 200 feet. The legislative assembly is housed in a fine stone building.

Government. — The city government is composed of an elective mayor and council and a board of appointed commissioners. Municipally, Edmonton has become known as the exponent of the single tax and public ownership of all municipal utilities. The city owns and operates its own street car service, telephones, hospitals and waterworks. Whilst distributing and selling its own light and power, the city has recently surrendered to a private corporation the manufacture of power.

Religion and Education. — All the better known religious bodies are represented by substantial edifices. Edmonton is the seat of a Roman Catholic archbishop and an Anglican bishop. The schools are managed by an elected board of trustees, and education is free and compulsory. There are two high schools, one on each side of the river, and a flourishing technical school. Higher education is provided by the Provincial University, a handsome building occupying a beautiful site of some 250 acres on the south side of the river. Comfortable residential buildings for students and staff have also been provided. Robertson College and Alberta College, occupying its own building on the university grounds, are respectively the theological seminaries of the Presbyterian and Methodist churches and are in close affiliation with the University of Alberta. Edmonton is the site of an important meteorological station.

Industrial Progress. — The most important industry is perhaps coal mining. Lignite coal of a good quality is mined within the city limits and in the adjoining country. This supplies the local coal market, and a large trade is being developed in shipments to remoter centres. Stock-raising provides raw material for three extensive packing establishments, and in connection with these stock-yards have been established. The milling of cereals grown in the rich surrounding country is also a flourishing business and sure of healthful growth. Amongst other industries that have made a good start are brick-making, for which the local clays offer excellent material; dairy products, the manufacture and export of which are assuming large proportions; clothing, soap and biscuits. Natural gas has been found at Viking in territory close to Edmonton and the city will at an early date be furnished with this commodity. Cheap power is soon to be supplied from an extensive hydro-electric plant situated on the Saskatchewan west of the city. Pop. (1911) 24,900; estimate in 1916, 35,000.

Dean of the University of Alberta.

EDMONTON, England, town in the county of Middlesex, on the New River, eight miles north of London. The "Bell at Edmonton" has become famous by association with the adventures of John Gilpin, the hero of Cowper's poem. Charles Lamb died at Edmonton in 1834.

EDMUND, Saint, king of the East-Angles: b. Nuremberg, 841; d. Oxen, now Hoxon, England, 20 Nov. 870. Edmund belonged, by blood, to the English-Saxon kings, but was not a direct heir to the throne. When Edmund was only in his 15th year he was crowned by Humbert, bishop of Elmam, on Christmas Day 855. Butrum, a royal villa on the Site, was called Bures. In the 15th year of his reign the land was attacked by the Danes, and they laid waste all the country through which they passed. The king tried to protect his people, but the Danes outnumbered them and spared none.
He was captured at Oxon and terms, prejudicial to religion, were offered and rejected. Hinguar, the Dane, ordered most terrible tortures to be inflicted. Again he was offered terms of surrender, and again he refused. Hinguar at last ordered his head to be cut off.

EDMUND, Saint, archbishop of Canterbury: b. Abingdon, England, about 1190; d. Soissey, France, 16 Nov. 1240. His first studies were made at Oxford and from there he was sent to Paris, where he devoted himself to the study of theology and the Scriptures, and for a time taught the Scriptures in Paris. Returning to England, after his ordination, he became a teacher at Oxford from 1219 to 1226; he was the first who taught Aristotle’s logic at Oxford. He desired to work among the poor, and at his own request was transferred to Salisbury Cathedral. While at Salisbury he received a commission from the Pope to preach the crusade against the Saracens, which he did with effective results. In 1234 Pope Gregory IX appointed Edmund as archbishop of Canterbury at once entered upon a series of reforms in courts, monasteries and among his clergy. His ‘Constitutions’ in 36 canons, dealing with matters of reform, are still extant. Troubles arose between Edmund and the king, when the king’s greed sought various means to secure Church revenues. Both the archbishop and the king appealed to the Pope, who, failing to finally settle the disputes, left the archbishop almost powerless to cope with adversaries. Fearing that by remaining he might seem to sanction what he could not redress, he left the country secretly and went to France. He was canonized in 1246, only four years after his death. Some of his works extant are ‘Constitutions,’ to be found in ‘Editions of the Councils’ by Linwood, Spelman, Wilkins, Johnson and Labbe; ‘Speculum Ecclesiae,’ or ‘Mirror of the Church’; and several of his works in manuscript, one on the Sacraments, are in the Bodleian Library, Oxford. Consult Wood, ‘History and Antiquity’; Tanner, ‘Notitia Monastica’; Butler, ‘Lives of Saints,’ and the ‘Life’ by Ward, (1903).

EDMUND I, or EADMUND, king of England: b. about 921; d. 26 May 946. He was a son of Edward the Elder and succeeded his brother Athelstan in 940. At the battle of Brunanburh, in 937, he distinguished himself. He subdued Northumbria and the Five Danish Boroughs in 944, and in the following year conquered Cumbria, which he bestowed on Malcolm, king of Scotland, on condition of homage. He was killed at a battle by Lifoia, an outlaw.

EDMUND II, or EADMUND (surnamed Ironside), king of England: b. about 981; d. 30 Nov. 1016. He was a son of Ethelred II, and on the latter’s death in 1016 was chosen king at London, whilst Canute was elected to the same dignity, at the same time the Danish forces under Harald the Hard-Heard were advancing against him. He repulsed the Danes atAssandun and went on to conquer the southern parts of England. On Edmund’s death a few weeks after this treaty, Canute became king of England. Consult Oman, ‘England before the Norman Conquest’ (London 1910).

EDMUNDS, Albert Joseph, American librarian: b. Tottenham, Middlesex, England, 21 Nov. 1857. In 1877 he entered the University of London, was secretary to T. Backhouse, the astronomer, from 1877 to 1882, and emigrated to the United States in 1885. From 1887 to 1889 he was assistant librarian of Haverford College; in 1889–90 he classified the Philadelphia Library, and since 1891 has been cataloguer of the Historical Society of Pennsylvania. He has published ‘English and American Poems’ (1888); ‘Songs of Asia Sung in America’ (1896); ‘Marvelous Birth of the Buddhæ’ (1899); ‘Hymns of the Faith’ (Dhammapada 1902); ‘Buddhist and Christian Gospels’ (1902; 3d ed., Tokio 1905; 4th ed., Philadelphia 1909, with important postscripts in 1912, 1914; Italian translation, Palermo 1913); ‘Buddhist Bibliography’ (1903); ‘Buddhist Texts in John’ (1906; 2d ed., 1911); ‘Fairmount Park and Other Poems’ (1909); ‘Buddhist Loans to Christianity’ (1912); ‘With Omar’ (1913); ‘History Simplified’ (1914); ‘Hoag’s Vision’ (1915).

EDMUNDS, George Franklin, American lawyer: b. Richmond, Va.; Feb. 1828. He received a common school education, as well as the instructions of a private tutor; studied law, and began its practice in 1849. In 1851 he removed to Burlington, Vt. He was a member of the Vermont legislature 1854–59, being speaker 1856–59, and was a member of the State senate, and its president 1861–62. He was by this time very prominent in Vermont politics, and at the opening of the Civil War, when a State convention assembled with the intention of uniting war Democrats and Republicans, he outlined the resolutions which the convention finally adopted as the principles of union. On the death of Solomon Foot, in 1866, Edmunds was elected to the United States Senate to fill Foot’s unexpired term, and was thrice re-elected for full terms, resigning in 1891. During his quarter-century in the National Senate he served on many important committees, displaying the qualities of an able, accomplished statesman. He was a member of the electoral commission in 1877, and was the author of the act of 22 March 1882 known as the ‘Edmunds Act‘ (q.v.), which provided for the suppression of polygamy in Utah and the disfranchisement of any person convicted of practising it. He was also the author of the ‘Anti-Trust Law’ of 1890. During the term of President Arthur he was president pro tempore of the Senate. In 1897 he became chairman of the monetary commission which had been appointed by the executive committee of the Indianapolis monetary conference. After his retirement he devoted himself to his profession, and gained wide fame as a constitutional lawyer.

EDMUNDS ACT, passed by Congress 22 March 1882; an act to root out polygamy in Utah, not only by direct punishment but by barring out votes, while the act of 1890 disfranchised the children of persons found guilty of polygamy and excluded from juries all who either practised polygamy or believed it rightful. The disfranchisement was even more effective, as Utah had woman
EDMUNDON - EDUCATION, ADULT

suffrage, and each polygamous wife was dis-
franchised also. The act made the living with
more than one woman in marital relations a
misdemeanor.

EDMUNDSON, George, English clergy-
MAN and historian: b. Redcar, Yorkshire, 1848.
He was educated at Magdalen College, Oxford,
and entered the ministry of the Church of Eng-
land in 1870. He is best known as a student of
the history of the Low Countries and of South
America. From 1901 to 1904 he was engaged in
the preparation of the British case in the
Guiana-Brazil boundary dispute. He was a
contributor to the 'Cambridge Modern History'
and published 'Milton and Vondel' (1885);
'Archbishop Laud and his Work' (1905);
'Anglo-Dutch Rivalry in the First Half of the
17th Century' (1910); 'The Church in Rome in
the First Century' (1913).

EDOM, Edom, in the New Testament,
Israel, in ancient times, in the country lying to
the south of Palestine in the region of Mount Seir.
The Edomites are said in Genesis to be the
descendants of Esau. They were subdued by
King David, and after the separation of the 10
tribes of Israel remained subject to the kingdom
of Judah, under their own kings, from the time
when this revolted and secured their independence
for a time. They were again subdued by Amaziah
and again in the reign of Ahaz, recovered their
independence, which they maintained till the
time of the invasion of Judea by Nebuchadnez-
zar. They fell under the rule of the Persians,
and latterly their fortunes were merged in those
of Arabia.

EDRED, king of England: d. Frome, England,
23 Nov. 955. He was a son of Edward
the Elder, and succeeded to the throne on the
murder of his brother, Edmund I, in May 946.
He quelled a rebellion of the Northumbrian
Danes, and compelled Malcolm, king of Scot-
land, to renew his homage for his English pos-
sessions. Edred died after a reign of nine
years, and left the crown to his nephew, Eadwy.

EDRISI, See Idrisi, Abū A'balāl Mo-
Hammad.

EDSALL, Samuel Cook, American Prot-
estant Episcopal bishop: b. Dixon, Ill., 4 March
1860. He was educated at Racine College; read
law and was admitted to the bar in 1882. He
soon abandoned this profession, entered the
Western Theological Seminary and was or-
dained to the Protestant Episcopal ministry in
1889, becoming rector of St Peter's Church,
Chicago, in the same year. After 10 years in
this charge he became missionary bishop of
North Dakota; in 1901 was elected coadjutor
bishop, and in the same year was trans-
slated as bishop. He is author of 'Prayer
Book Preparation for Confirmation' (1898).

EDSON, Cyrus, American bacteriologist: b.
Albany, N. Y., 8 Sept. 1857; d. 1903. He was
graduated at the New York College of Physi-
cians and Surgeons in 1881 and in the follow-
ing year was appointed a sanitary inspector. In
1893-95 he was health commissioner of New
York. He discovered a new treatment for con-
sumption, malaria and other germ diseases, in
1896, which he named aspetolin. His publica-
tions include about 80 papers on medical and
sanitary subjects. He was the inventor of many
surgical instruments.

EDUCATION, Abnormal. See Educa-
tion of Feeble-Minded and Mental Defec-
tives.

EDUCATION, Adult. The conviction that
the duty of society in the education of its mem-
bers does not cease with the completion of a
school or college course has gained ground
during the last decade. Because of this, wide-
spread efforts to educate the adult have been
made with varying results. On the whole, the
progress has been satisfactory, yet a co-ordina-
tion of effort and a scientific plan is still lack-
ing. The National Society for Broader Edu-
cation, organized in New York 1910, is the only
organization for adult education that has a
definite plan and actually covers the entire
country. The Society with its headquarters at
Carlisle, Pa., has, however, because of lack of
funds, limited its activities to economic, so-
ciological, literary and musical fields. In 1917
it gave 7,796 lectures to 41,696 persons in
32 addresses for every day of Society's work-
ing year of nine months. Its audiences, includ-
ing classes, numbered 1,339,907, or 5,583 per-
sons every working day. In addition to its field
work, the National Society for Broader Edu-
cation maintains small extension classes in
schools and universities. Its staff in 1917 numbered
176 persons. Adult education has been ham-
pered by the lack of suitable meeting places.
Satisfactory halls existed but the rental charged
precluded their use. The National Society for
Broader Education organized a country-wide
campaign for the open schoolhouse. Various
educators either working with the Society or
independently aided the movement. As a result
of the effort, a canvass of 603 cities of over
5,000 inhabitants made by the Russell Sage
Foundation showed that schoolrooms in these
cities were used after class hours for the in-
struction of the adult. In 294 cities for mis-
cellaneous educational activities, in 219 for lec-
tures, in 207 for meetings of Parent Teachers
Association, 129 as social centres and in 39
for vacation schools. In 11 States in 1917
grants were made for the education of the
alien adult but these efforts have only been a
beginning of a needed work. Minnesota and
Wisconsin are the most successful of the suc-
cessful States in adult education and New
York city has for years stood pre-eminently
first among the cities in its provision for adult
instruction. The 25th annual report of the
supervisors of lecture of the New York
Board of Education showed that in 1917 there
were 174 lecture centres, 676 lecturers speak-
ing on 1,695 topics before 5,405 audiences.
Total average audience was 1,154,066, an
average of 214 per lecturer. For 25 years these
lectures have cost the city of New York about
$150,000 annually. The University of Minne-
sota has carried the University atmosphere over
the State, reaching 25 towns on each year's
assayd. University week is a six-day program
conducted in each of the towns listed through-
out the State, during which time the
State, during which time the
dramatic club gives performance as do musi-
cal organizations and there are talks to business
men at noonday luncheons and women's clubs in the afternoon. The University of Wisconsin is a pioneer among educational institutions in publishing a school film exchange as one of the means of solving the motion picture problem. Motion pictures are used by several churches, among them the Grace Methodist Episcopal Church and Saint Bartholomew's Episcopal Church of New York city. The girls at Student's afternoons pictures of travel through the history of the Church. It is generally conceded that the public has in its hands the ultimate development of the motion picture. The public has been importuned to demand a high grade of pictures. Many public schools and other educational institutions are now furnishing films to students and sending them out to the general public when centers are organized for their reception and exhibition. In 1891 New York State appropriated $10,000 for adult education, it was the first State appropriation. Work was classified under title "Home Education" and included "Study clubs, exchanges, traveling libraries, public libraries and library school." Similar work was begun in Chicago in 1892 but quickly abandoned when the University of Chicago incorporated this work as part of its activities. In December 1891 a National Congress on Adult Education and University Extension met in Philadelphia, at which it was reported that in the four years, 1887-91, 28 States and Territories had begun adult education in some form. This work was relatively unorganized and there was no organized adult education before 1892, and in that year organization in two institutions only, University of Chicago and University of Wisconsin. Between 1906-13, 28 institutions organized adult education and 21 institutions reorganized the work in addition to 12 institutions which had begun the work between 1892 and 1906. Modifications and gradual change of methods have taken place in the last 10 years. It has been decided that the English plan of lectures, class work, syllabi, collateral reading and more or less rigid examinations was not well adapted to the larger part of the adult student body in America, whose need was great for educational opportunity offered out of work hours. Modifications were introduced and in quick succession departments were added including the educational bulletin and package library, and of welfare work covering the entire field of civic and social betterment. Adult education now includes all extra-mural university service, and certain types of intra-mural work. Under the latter head are included institutional short courses and conferences and opportunities to attend classes or lectures out of work hours as are offered sometimes with and sometimes without the customary entrance requirements. Of institutions offering education to adults, 20 give degrees. In addition to the above-mentioned institutions with organized work in adult education, 52 colleges and universities give more or less attention to the subject. In adult education great service has been done by the General Federation of Women's Clubs, with its 9,000 clubs, its 50 or more federations, and 3,000,000 members working through 12-15 departments. The Federation stands for better homes, better schools, better things for men, women and children and a broader vision of life. Among its departments are art, music, literature, civics, library extension, conservation of public health, social and industrial conditions, social hygiene, child hygiene, legislation, home economics and education. One praiseworthy activity is the rural welfare service through which town club women invite the farm women to "get acquainted meetings" at which informal discussions of school and other problems is subordinated to visiting and general social enjoyment. Correspondence has played an important part in adult education. Though organized as business enterprises several of the schools system correspondence may be classed as private educational institutions. As a factor in the educational problem they are of great importance. Several of the correspondence schools serve at one time anywhere from 1,000 to 35,000 students, with faculty running as high as 350 persons, with, in addition, as many as 400 text and lecture writers and examiners. The average age of those taking course is about 30. Music, through the Music League of America and other musical organizations, through such societies as the Drama League of America, have done much for the aesthetic side of adult education. The Drama League of America, now in its seventh year, was founded on the belief, according to Richard Burton, its president, in 1914, that the drama is fast becoming an appreciable and important part of American literature. The league refuses to censor or attack bad plays. It believes that it is most effective to call attention to that which is good. This is done through the agency of a play-going committee reporting through a bulletin system inaugurated in Chicago, the birthplace of the League. The National government is perhaps the most active agency in adult education and this chiefly through public documents. During year ending 30 June 1915, 34,714,186 copies of government publications were mailed free and 3,252,919 copies were sold. These publications report legislative, executive, financial, postal, military and naval functions common to all governments, comments on world activities and the results in popular reading instruction for the instruction and practical use of all the people, of scientific investigation, covered by the United States.

Guy Carleton Lee,
Managing Director, National Society for Broader Education, New York.

EDUCATION, Agricultural. The methods of scientific instruction in all branches of farming.

Historical.—Most of the early attempts to establish systematic agricultural instruction were made through schools of secondary grade. This was the natural consequence of the fact that the early development of agriculture was largely dependent on the development and application of chemistry. The two earliest colleges of agriculture to be established were at Hofwyl and at Amherst. They were started in 1797. The former exerted a marked influence upon the development of agricultural education, especially that of a secondary grade. Its influence was felt in this country through the pupils that were drawn from this country and by the work of
"Association of the Fellenberg System of Education." The first professorship of agriculture in a collegiate institution in the country was held by Samuel L. Mitchell of Columbia College. He also held chairs in natural history and chemistry at the same time. The position was established in 1792. Just when the first school devoted largely to the interest of agriculture was established in the country is difficult to determine. During the early part of the 18th century a large number of agricultural societies were active and many of these organizations were interested in promoting systematic instruction in agriculture. The writings of Washington, Franklin and Jefferson bear testimony to their interest in the subject.

In spite of the fact that it is difficult to determine the beginnings of schools of agricultural instruction, it is relatively easy to decide upon the first institution in this country that attained such a measure of success that it attracted general attention. This honor belongs to Gardiner Academy which was established at Gardiner, Me., in 1821. In the legislative act providing for its incorporation it is stated that it was "designed to prepare youth by suitable instruction in the arts and sciences, including agriculture, mechanics." In 1823 the legislature made provision for some aid from the State treasury. This was undoubtedly the first State aid that was ever granted to an agricultural school in the United States. This institution had a fair measure of success for several years but was finally forced to close its doors in 1823, because of decline in student body and a lack of financial support. Many other attempts were made with varying degrees of success to found schools during the first half of the 19th century, but none met with a marked degree of success. All declined after, at most, a few years of existence. Among these institutions may be mentioned Agricultural Seminary, Derby, Conn., 1824; Cream Hill School, West Cornwall, Conn., 1827; Eastham's College Hill, Ohio, 1833; Fellenberg School, Whitesborough, N. Y., 1831; and Mount Airy Agricultural College, Mount Airy, Pa., 1847.

The movement for agricultural education began to assume more serious proportions when efforts were made to secure State and Federal aid for the support of agricultural colleges. To whom the credit belongs for these suggestions is impossible to say with certainty. It is agreed, however, that through the influence of far-seeing men in several sections of the country pressure was exerted in behalf of State and Federal support of colleges of agriculture at about 1850.

In Pennsylvania the present State College is due to the activity of the State Agricultural Society that took definite steps in 1850-51 to secure an agricultural school. In New York State several attempts were made but all of the early ones were without great measure of success. To the State of Michigan belongs the honor of having the oldest college of agriculture in North America. This institution is also the first to be established entirely on the basis of State support. The State Constitution adopted in 1850 made provision that the State legislature should establish and maintain a college of agriculture. The law providing for its establishment became effective 12 Feb. 1855. Immediately a bitter fight followed over the location of the institution. There was a decided effort made by those who were interested in the State University to have the College of Agriculture made a part of that institution. This movement was opposed by the State Agricultural Society and this organization was successful as the college was finally located at East Lansing. This location, apart from a literary institution, was favored because of the influence that it exerted upon the establishment of "separate" colleges of agriculture after the passage of the Land Grant Act. In the early years of the agricultural colleges the separate institutions had a more substantial development than did those that were made a part of existing colleges or parts of State universities. The colleges that were made a part of a university were very slow to find themselves, but their growth in recent years has been of such a nature as to justify the views of those who believed they should be a part of a university.

On 16 Feb. 1857, the State legislature of Michigan appropriated $40,000 for the erection of buildings, instruction and maintenance for the years of 1854-55. The institution opened to receive students 13 May 1857. State supported colleges of agriculture were established in Pennsylvania and Maryland in 1859.

Land Grant Colleges.— Undoubtedly there would have been a gradual development of colleges of agriculture on the basis of State support, but even before the establishment of the Michigan College of Agriculture there had been proposed plans for Federal aid. To whom the credit for this suggestion belongs is in doubt. Probably it had independent origin in the minds of several men. The first bill introduced in Congress touching on this subject was offered by Justin P. Morrill in 1857. At that time Mr. Morrill was a member of the House of Representatives from the State of Vermont. This bill made provision for granting to each State 20,000 acres of land for each senator and each representative in Congress. It was finally passed 7 Feb. 1859. It was, however, vetoed by President Buchanan. The matter then rested until after President Lincoln's election, when Mr. Morrill again introduced a bill, drawn in lines similar to the previous measure except that it made provision for granting 30,000 acres of land to each State for each senator and representative in Congress. This measure became a law on 2 July 1862, when President Lincoln's signature was affixed.

It provides that the income from these lands shall be used by each State which accepts the benefits of the act "to the endowment, support and maintenance of at least one college where the leading object shall be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to agriculture and mechanic arts, in such manner as the legislature of the States may respectively prescribe, in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions of life. A supplementary act was passed in 1866 by which provision is made so that when any Territory becomes a State it is entitled to the benefits of
the Act of 1862, or the First Morrill Act as it is commonly called.

The Second Morrill Act became a law 30 August 1890. This act provided for an initial allotment to the States of $15,000 per year with an automatic increase of $1,000 annually until the sum of $25,000 was reached in 1900. The purpose of this legislation was for the "more complete endowment and support of the colleges for the benefit of agriculture and mechanic arts established under the provisions of an act of Congress, approved July second, eighteen hundred and sixty-two." Under the terms of this law, there is provision for the division of the funds between colleges for white and colored students in States where separate institutions are maintained.

The Nelson amendment was approved 14 March 1907. This provided for an increase of $25,000 a year to the allotments made under the Second Morrill Act. The initial grant was $5,000 and was subject to an annual increase of $5,000 until the maximum of $25,000 was attained. Under the two acts, the Second Morrill Act and the Nelson Amendment, the annual grant to each State is $50,000.

Through the provisions of the three acts there has been a marked development of State colleges of agriculture. As a result there are at the present time 67 of these institutions including those for colored students. There are 17 of these. In 1915 the total income of the land grant colleges was $31,961,765, of which amount only $3,552,077 came from Federal sources. According to a report from the United States Bureau of Education there were in 1915-16 private colleges to the number of 16, giving instruction in agriculture.

The debates that took place in Congress at the time of the passage of the First Morrill Act showed no clear conception as to what these colleges when established were to accomplish. It is also true that much diversity has been shown in the use of the funds by the States. In some of the eastern States the land grant was turned over to privately endowed colleges that were in need of funds and in the Midwest in some cases used as a basis for the establishment of State universities. In spite of these facts in the half century that has elapsed since the passage of the first act strong institutions have been developed that have come to have clearly defined aims and fairly definite means of attaining those ends. At present, in most of the institutions three lines of activity are clearly defined: viz., resident teaching, research and extension.

Teaching.—The courses offered by the institution are usually of two classes; long courses, four years of the usual length of a college year; and short courses which are commonly two years in length but of only 10 or 12 weeks duration each year. In addition most institutions make special provision for the adult student who cannot meet the entrance standards. The admission requirements to the four-year courses are in general as high as those for admission to other college courses. The completion of the course leads to the degree of Bachelor of Science or B.S.A. The subjects taught include such basic sciences as chemistry, botany, zoology, mathematics, geology and meteorology. In addition English and political economy are usually required subjects. The applied subjects are represented by farm crops, farm management, rural engineering, soils, breeding, agronomy, animal husbandry, and dairy economics, poultry husbandry, rural education, entomology, fruit growing, vegetable gardening, floriculture, forestry, landscape art, dairy industry and agricultural chemistry. The relation between the basic and applied subjects varies in the different institutions but usually it comes between the limits of one-third and one-half.

During the year of 1915-16 there were 16,008 students in the four-year courses and in addition 10,332 students in one- and two-year courses. To these figures should be added 2,053 four-year students in agricultural colleges for negroes. This is quite in contrast with the early experience of the colleges when they had almost no student body. Statistics from bulletin number 10 of the Carnegie Foundation show the student body in these institutions grew rapidly from 1894-95, 2,712, to 1914, 14,844.

Since the land grant colleges are supported by the State and National governments, they have felt the need from an early date of providing instruction through short or winter courses for students who did not have the time to attend during the regular academic year or who may have lacked entrance requirements. Many early attempts were made at courses of this character but the University of Wisconsin is generally credited with having established the short course on its present day basis. This course was opened in 1898 and has run each year since that time. These courses vary in length at different institutions but usually they are from 4 to 12 weeks in length and continue for one or two years. The work that is offered is of an extremely practical nature. That it is meeting a demand is attested by the fact that there were 14,108 short-course students in the colleges of agriculture during the year of 1915-16. It is quite likely that with the development of agricultural instruction in the public high schools and special secondary schools that this phase of the grants will take on a new significance.

In recent years many of the colleges are offering summer courses of 6 to 12 weeks duration to teachers. The need for this work has been especially pronounced as a result of the development of agricultural instruction in the elementary and secondary public schools.

Research.—Almost from the beginning of instruction in the colleges of agriculture some of the instructors devoted a portion of their time to investigation. This was made necessary by the relatively small body of agricultural knowledge that was established on a scientific basis and organized for teaching purposes. As a result of provisions of the Federal acts encouraging agricultural research most of the experiment stations are organized at the State colleges of agriculture. Obviously, the investigator is a member of both college and experiment station staffs. The results of the experimental work are usually distributed by means of bulletins that are published both in technical and popular form. See AGRICULTURAL EXPERIMENT STATION.

Extension. This term is usually applied to the instructional work that is conducted with students who are not resident at the college.
EDUCATION, AGRICULTURAL

It covers a wide range of activities such as correspondence courses, which have been especially developed in Pennsylvania and California, demonstration schools, farmers' institutes, demonstration plots, lectures, reading courses, county agents, home demonstration agents and boys' and girls' club work. Almost from the beginning colleges of agriculture have felt the pressure for such work, because they are State supported and also as they had to establish themselves with the farmers.

The first State law making specific appropriation for extension work was probably the Nixon Act which was passed by the New York State legislature in 1894. At the present time practically every college of agriculture has an extension department with a head who is usually designated extension director. There are approximately a thousand extension specialists on the faculties of the agricultural colleges. Much of the stimulus for this work and plans for its organization have come through the Smith-Lever Act which became effective 8 May 1914. This law differs from the previous acts in which Federal funds were granted to the States for the development of agriculture, in the fact that the National government retains a larger measure of control than in any previous opposition. This is done by making the funds available only for co-operative extension work that is carried on by the land grant colleges of agriculture and the United States Department of Agriculture. The nature of this co-operative work is set forth in section 2 of the law as follows:

A co-operative agricultural extension work shall consist of the giving of instruction and practical demonstrations in agriculture and home economics to persons not attending or resident in said colleges in the several communities, and imparting to such persons information on said subjects through field demonstrations, publications, and otherwise; and this work shall be carried on in such manner as may mutually be agreed upon by the Secretary of Agriculture and the State agricultural college or colleges receiving the benefits of this act.

By the provisions of this act, $480,000 were appropriated for the first year, $10,000 of which went to each State accepting the provisions of the act. For the succeeding year there was an appropriation of $600,000 and this will increase annually at the rate of $500,000 until the sum of $4,500,000 is attained. These grants, except the $480,000, are 'allotted annually to each State by the Secretary of Agriculture in the proportion which the rural population of each State bears to the rural population of all the States as determined by the next preceding Federal census.' In order to secure the benefits of the act an amount equal to that coming from the Federal government must be appropriated from sources within the State. The law is administered through the States Relations Service of the United States Department of Agriculture.

The most notable developments under this act have been the systems of county agents home demonstration agents, and boys' and girls' club leaders. March 1, 1918, there were co-operatively employed 2,645 county agents, 1,514 home demonstration agents and 441 boys' and girls' club workers. Not all of these persons are employed on permanent funds as 2,950 are emergency agents put into the co-operative

work for the purpose of stimulating agricultural production and food conservation after our entrance into the war with Germany. This act was made possible by an emergency appropriation of $200,000, which was furnished through the courtesy of the States Relations Service, shows the growth of the co-operative extension work since the passage of the Smith-Lever Act.

The various Federal acts relating to instruction in agriculture have resulted in the development of a group of strong institutions that are making their influence felt throughout the entire country. In 1918 there were 67 state and federally supported institutions of college grade giving instruction in agriculture, 17 of which were for negroes. In 23 States and Porto Rico the college of agriculture is a part of the university. Tuition is free to residents of the State in which the college is located in most cases. There were 766 persons engaged as instructors or investigators in these institutions.

Foreign Countries.—The most widely known college of agriculture in Canada is the Ontario Agricultural College at Guelph. This institution was established in 1874. Several other colleges have been established since that time. In addition to its collegiate instruction in agriculture Canada has done much to encourage the introduction of agriculture into the rural high and elementary schools. The first chair of agriculture in England was established in the University of Edinburgh in 1790. In 1838 the Albert Agricultural College was founded at Glasnevin, Ireland, as a state-supported institution. The Royal College of Agriculture was established at Cirencester, England, in 1845. There have been other colleges opened for the purpose of giving instruction in agriculture and in addition there are a considerable number of other colleges giving agricultural instruction. National aid is given to this work through the Board of Agriculture and Fisheries.

The Institut National Agronomique de Paris, which is supported by the national government, stands at the head of the French system of collegiate instruction in agriculture. In addition to the national schools, one each at Grignon, Rennes and Montpellier. France has an excellent system of secondary schools of agriculture, some of which are specialized in their work and others give general instruction. There are also lyceums and colleges. Since 1879 instruction in elementary agriculture and horticulture has been obligatory in the normal and primary schools. Institutions for giving instruction in agriculture both of college and secondary grade are to be found in most of the civilized countries of the world.

Secondary Schools.—As has been noted most of the efforts to give instruction in agriculture were made in schools of secondary grade. Numerous attempts were made to establish "farming schools" in the East and Middle West during the first half of the 19th century. While some of these met with a measure of success, sooner or later they were compelled for one reason or another to close. It was not until 1888 that a permanent secondary school of agriculture was established. This was the Minnesota State School of Agriculture, located at Saint Anthony's Park, in connection with the State College of Agriculture. Following the opening of this school there came a period in which there was considerable development of special secondary agricultural schools. In 1915-16 only 394 special agricultural schools receiving State aid and 12 private agricultural schools of secondary grade. These special schools have in some cases been supported entirely by State aid and in other instances by a combination of State and local funds. The unit of territory that they attempt to serve varies greatly. In some cases, e.g., New York and Minnesota they have been supported entirely by the State, and in some cases a combination of State and local funds. The unit of territory that they attempt to serve varies greatly. In some cases, e.g., New York and Minnesota they have been supported entirely by the State, and in some cases a combination of State and local funds.

The length of the courses varies from one to four years with the most common length two years except in the district schools of Alabama and Georgia where four years is the rule. The admission requirements very properly are not high for most of these institutions. Completion of the elementary school is expected, except for students over 16 who are commonly admitted regardless of previous academic preparation. In most of these schools the instruction is designed to meet the needs of boys who have come from the farm and who expect to return to it without further opportunity for study. In addition to the instruction in such agricultural subjects as farm crops, soils, animal husbandry, farm management, fruit growing, poultry husbandry, and dairying, the students have work in English, civics, arithmetic, and some basic science work. In these institutions the tendency has been to follow too closely in the footsteps of the colleges of agriculture so far as organization and presentation of the work are concerned. Most of the schools are provided with a farm.

It was noted in connection with the "separate" colleges of agriculture that in the early stages they developed more rapidly than did those that were a part of a university. When the later class finally started they had a more substantial growth. A striking parallel occurs in the development of agriculture instruction of secondary grade. The first few years of its growth the special schools were prominent and there were few agricultural departments in high schools. These, however, are developing rapidly in recent years. In 1915-16 there were 421 State-aided vocational departments of agriculture in public high schools and 2,981 public high schools teaching agriculture. In the vocational departments the course of study is commonly four years in length, although frequently short courses are also offered. In other high schools the courses commonly run from a half year to two years.

February 23, President Wilson signed the Smith-Hughes bill for vocational education. This move is a close ally of the legislation for Federal aid to the States for vocational education in agriculture, trade and industrial subjects, and home economics, is certain to exert a marked influence upon the development of secondary
agriculture. Like the Smith-Lever Act this law makes the development of vocational education in agriculture a co-operative enterprise between the various States and the Federal government. The law went into operation 1 July 1917 and provides Federal funds to the amount of $500,000 for the stimulus of vocational education in agriculture. This amount is increased by $250,000 annually until $2,000,000 is reached when it is increased to $3,000,000, which is the maximum, by annual increments of $500,000. This money is appropriated among the States in the proportion that the rural population of each State bears to the total rural population of all the States. In order to receive the benefits of this act there must be expended from sources within the State an amount equal to the amount received from the National government. The instruction must be designed for pupils over 14 years of age but it must be below college grade. The law further provides that the funds must be expended through State supported or supervised schools, and arrangements must be made so that pupils obtain at least six months of practical experience each year. The law makes it an obligation of the State to prepare teachers of vocational agriculture.

This act is administered by the Federal Board for Vocational Education which consists of a representative of labor, a representative of agriculture, a representative of trade and industry, and the following ex-officio members; secretary of agriculture, secretary of commerce, secretary of labor and the commissioner of education.

In all of the early attempts to develop agricultural instruction in secondary schools it was considered necessary to maintain a farm. In recent years the home project plan, which has been developed largely through the efforts of R. W. Stimson of Massachusetts, has proved more satisfactory as a means of affording vocational experience. The home project is ordinarily a productive enterprise that is an outgrowth of the school instruction but is carried on by the pupil at his home under the supervision of the agricultural instructor. The next 10 years the study of related academic subjects is to be continued and the development and extension of the home project method in agricultural teaching in high schools.

Elementary Schools.—Agricultural instruction in the high schools raises many problems that are difficult of solution but the problem is even more serious in the rural elementary school. There are a number of States in which such instruction is required by law but in a large measure it has failed to function because it has been too haphazard. This is chiefly due to the fact that in most States there is no regular system for the preparation of rural teachers. They are unable to go into the school and utilize the experiences of the country child and the opportunities of the farming community for educational purposes. However, some very good results have been attained in spite of the many difficulties. The consolidation of schools has greatly increased the possibilities of instruction in agriculture for pupils of the upper grades. This is also true of the intermediate schools and the general commercial arts of New York State; and the junior high schools to be found in the rural communities of Vermont. The latter have had a very marked development since 1915 when provision was made for them by special legislation. (See AGRICULTURAL COLLEGES; AGRICULTURAL EXPERIMENT STATION). Consult Bailey; L. H. (ed.) Cyclopaedia of American Agriculture (New York 1910-13); Carney, M. 'Country Life and the Country School' (Chicago 1912); Bulletins of United States Department of Agriculture and of State Experiment Stations.

EDUCATION, Catholic. See CATHOLIC EDUCATION IN THE UNITED STATES; CATHOLIC EDUCATION IN CANADA; CATHOLIC CHURCH AND SCIENCE; PARISH SCHOOLS, etc.

EDUCATION, Commercial, a general system of modern education to prepare youth for commercial pursuits which follows the usage of many European schools and colleges, where the selective courses for pupils on entry are designated as either "commercial" or "classical." The commercial high schools of the public system of education of the United States are organized with industrial aims to give such general education as best fits youth for commercial pursuits. Supplemental or higher commercial education is furnished by extended scientific training in university departments, in schools of technology, or in independent trade and business schools and colleges.

About one-third of the pupils in high schools in the United States in 1917 were taking commercial courses. Government reports from 31 cities of 100,000 population and over show that from 10 to 60 per cent of all high school pupils take commercial courses, and that of these Boston and Milwaukee have the largest, and Cincinnati, Cleveland, Columbus and Dayton have the lowest per cent. There were special high schools in 1916 in Boston, Cleveland, Columbus, New York, Portland (Or.), San Francisco, Springfield, Syracuse, Washington and Worcester. The pupils who receive special commercial instruction in the government high schools, and in the special commercial high schools, continue the study of related academic work with the other pupils from which they are not separated; for commercial instruction is looked upon as general education and is treated as such. While the private business schools have had very definite, if narrow aims, to which they have adhered strictly and logically, the commercial education of the government secondary schools has been more or less a concession to the demands of business interests and practical life; and of late educators have begun to insist that the commercial education of government institutions should be better organized and that its aim be more definitely stated. At present (1918) pupils taking commercial courses in secondary schools give only about 25 per cent of their time to technical commercial education. Another 25 per cent is devoted to "related work" and 50 per cent to "general culture." The private business schools, on the other hand, go direct to the goal they have set for themselves. The result is that they cultivate in from six months to one year, the same commercial work that the secondary schools require from two to four years to accomplish; and the pupils of the private business colleges are taught in a more exact
and businesslike way. Hence the popularity of the latter, though they charge comparatively high fees. In other words, commercial education in the government schools has not yet become individualized, as it has in Germany, where it has developed into a system by itself and not a comparatively unimportant part of a general system, as it still is in the United States. Hence the need of a general reorganization along pedagogical and practical lines; for the necessities of business life continue, from year to year, to make more imperative and extensive demands upon the public school system. Owing to the fact that commercial education forms a part of the ordinary school curriculum of secondary importance, most public schools are poorly equipped as to organization and the other machinery necessary to meet the ever-increasing demands made upon them by the business world, which is still pinning its faith in the private business college, which to keep its ear close to the ground.

The commercial courses of the government secondary schools may be divided as follows: General office work and bookkeeping; stenography; typewriting; shorthand; the operation of office appliances; secretarial work, which requires more careful training and higher academic requirements on the part of the pupils; and salesmanship. The program of the commercial education of the secondary schools is theoretically good, but in practice it has a decided tendency to be too technical at the expense of accuracy and practicability. On the other hand the private business schools aim, above all things, at speed, accuracy and practical results, and trouble themselves very little over questions of technical nature, when they are not absolutely necessary to the end in view. The demand being made upon secondary schools is, therefore, that they study more carefully the needs of commercial life and that they impart more practical knowledge of the construction and practice in each individual section of commercial education so that their pupils may be enabled to step from the schools into subordinate positions in business concerns. To this end it is necessary to increase and improve the office appliance departments of the secondary schools and to place them in the hands of trained practical teachers, as the better class of business colleges have already done.

Commercial high schools in the United States are confined, for the most part, to the larger cities. They differ very little except in name and the number of pupils taking commercial courses, from the ordinary secondary school with attached commercial courses. Not one of them is primarily a commercial school whose aim is, first and foremost, the teaching of commercial subjects and the preparation of pupils for business life. Even in these schools the equipment of other departments is generally favored at the expense of the commercial. In other words, the commercial education of the United States secondary schools has no traditions to live up to and no definite aims to assure definite results. Until these are attained it must continue to live on sufferance, with other branches of education which have traditions of their own. But the hope can be held for in the teaching of commercial subjects in the government schools until such time as the ordinary high school and the commercial school are divorced and the latter is allowed to follow its own life and maintain a teaching staff trained to keep the needs of commercial education in mind.

Students.—There were, in 1917, approximately half a million students in commercial courses in the United States. The Bureau of Education had the names of more than 1,300 independent commercial and business schools, exclusive of the hundreds of other business schools forming departments of normal schools, private schools and other institutions. Only 843 of the independent business schools in 1916 responded to the request of the Bureau of Education for statistical information. The reports thus furnished show that there were in the 843 business schools reporting 183,286 students, an increase of 15,223 over the preceding year. The reports of 762 private high schools show that they had, in 1916, 17,705 students in business courses. The 2,863 public high schools of the country, during the same period, had 208,605 students in their commercial departments. Of the pupils reported in the private business schools 130,431 were in day and 32,855 in night courses. The total number of students reported to the department as in commercial courses was made up as follows:

Thus it will be seen that the hundreds of business colleges and other institutions having commercial courses, but not reporting them to the department, should easily have increased the number of students in commercial courses to 500,000 in 1917, when the demands of the war had given an added impulse to this ever-growing department of education. Massachusetts led with the highest number of pupils in the public high schools, 28,489, New York coming second with 27,887; but as the latter had more students than the former in private high schools and academies, the total of students of both commercial courses, exclusive of private business colleges, was New York, 29,563; Massachusetts, 29,485. Pennsylvania reported 17,544 commercial students in the public high schools, and 2,539 in private high schools and academies, a total of 20,083; Illinois, 13,923 in public high schools, and 1,349 in private high schools and academies, total 15,272; New Jersey, 12,444 in public high schools, and 319 in private high schools and academies, total 12,763; California, 11,567 in public high schools, and 582 in private high schools and academies, total 12,149; Ohio, 10,191 in public high schools, and 995 in private high schools and academies, total 11,086. Michigan and Wisconsin had each about 8,000 commercial high school students; Connecticut about 7,000; Indiana, Minnesota, Iowa, Missouri and Wisconsin, each about 6,000; Maine, Rhode Island and Kansas between 3,000 and 4,000; New Hampshire, Nebraska, Maryland, Texas, Colorado, Tennessee and Oregon between 2,000 and 3,000; while Vermont, Virginia, West Virginia, Georgia, Kentucky, Louisiana, Oklahoma, Montana, Utah and the District of Columbia had each over 1,000.
The trend of business education in the public schools is shown by the reports of the Bureau of Education for sections of the country as follows: In the North Atlantic States, in 1915, 1,248 schools and 70,406 students; Western States, 564 schools and 26,690 students; South Central States, 315 schools and 10,551 students; and the South Atlantic States, 250 schools and 9,369 pupils.

In 1916 there were 54,871 students and 1,511 teachers in the 241 private commercial schools of the North Atlantic States; 76,769 pupils and 1,664 teachers in the 344 schools of the North Central States; 22,926 pupils and 530 teachers in the 116 schools of the Western States; 16,515 pupils and 318 teachers in the 84 schools of the South Central States; and 12,265 students and 286 teachers in the 64 schools of the South Atlantic States. The total number of students reported taking commercial courses in public and private high schools and business colleges, in 1916, was: North Atlantic States, 164,169; North Central States, 147,115; Western States, 49,616; South Central States, 27,066; South Atlantic States, 21,631.

Education. In 1915 there were over 10,000 students studying commercial work in the colleges and universities of the United States. At the head of these was New York University with 2,260 students. The University of Pennsylvania had 916 students of commercial subjects; North Western University, Wisconsin, 484; University of Illinois, 423; Boston University, 378; University of California, 320; University of Chicago, 220; University of Pittsburgh, 213; and Saint John's, Ohio, 207. In all 60 colleges and universities were reported as having instruction in commercial education; and of these 25 had 100 or more pupils each.

By the middle of the last century, owing to the vast increase of business throughout the civilized world, business men had already come to feel the need of special technical commercial education for their employees. As early as 1855 Gustav von Mevissen, the great European financier, in a report to the Chamber of Commerce of Cologne, advocated the higher education of business men with the surplus capital in business to supply the needed business education. But it was not until the universities turned their attention to this field that the dream of von Mevissen might be said to be in a fair way to become realized. He himself began the good work by founding a commercial college at Cologne. But the real pioneer in higher commercial education was the University of Pennsylvania which in 1881 established the Wharton School of Finance and Commerce.

Seventeen years later the University of California founded a similar course leading to the degree of B.S. And in the same year the University of Chicago also added a commercial department with the degree of B.P.H. In 1900, New York City, in the following year, Columbia University, and in 1902, the universities of Illinois, Indiana and Michigan established commercial courses with the bachelor's degree. Now (1918) most of the important universities of the United States have more or less complete commercial departments. The Harvard Graduate School of Business Administration, established in 1908, and the Amos Tuck School of Administration and Finance, opened in 1900, in connection with Dartmouth College, go further in this respect than the other universities, admitting to their courses only college and university graduates whom they train for business and public affairs.

John Hubert Curnyn,
Editorial Staff of The American.

Education, Compulsory. The doctrine of the democracy of Calvinism from the beginning of its teachings contained the fundamental principle that each person should be able to read. Under that doctrine religious matters were held to be of vital concern to every person as well as to the nation and each individual was held to be personally accountable for his own conduct. The Bible contained the rules of conduct which should regulate the lives of all people. Each person was, therefore, expected to be able to read that book and not to be dependent upon others for a knowledge of its teachings and of the personal obligations which such teachings imposed. In the countries, therefore, which were under the control of the Calvinists, the basic principles of compulsory education laws, so general in all the progressive countries of the world at the present time, were first established. The general feeling of the people in the Netherlands in relation to education was such that more than 150 years before the Dutch began to make settlements in America public schools had been maintained in that country. The education of the masses through these schools which were public schools had been the bulwark of the
EDUCATION, COMPULSORY

liberties of the people and the national freedom of the country. The country was prosperous and happiness prevailed among its people. When the Calvinists settled in America they brought with them the spirit and the institutions of their native country and wherever the Dutch settled in America they established schools which were of the type of the schools in the fatherland. These schools were administered under the same general plan on which the schools of Holland had been operated. All children were required to receive instruction. This instruction was provided by members of the family at the home in many cases, often at private schools but generally in the schools established by the authority of the company which were responsible for the regulation of the affairs of the settlement. The West India Company which made settlements at Manhattan and at Albany adopted an ordinance in 1629 providing that all colonists "shall endeavor to find out ways and means whereby they may supply a minister and a schoolmaster." Under this ordinance, schools were maintained and children were required to attend them. The Dutch, therefore, during their period of control in the colonies planted the germ of the foundation on which compulsory attendance laws are based.

The General Court of the Massachusetts colony issued a decree in 1642 which has also exercised an important bearing upon the development of compulsory attendance statutes. The decree of the Massachusetts court and the preamble upon which it is predicated were as follows:

"Forasmuch as the good Education of Children is of Singular behoofe and benefit to any Commonwealth, and whereas many Parents and Masters are too indulgent and negligent of their duty in that Kind;

"It is Ordered, that the Select men of every Town, in the several Precincts and quarters where they dwell, shall have a vigilant eye over their brethren and neighbours, to see, First that none of them shall suffer so much Barbarism in any of their families, as not to endeavor to teach, by themselves or others, their Children and Apprentices, so much learning, as may enable them perfectly to read the English tongue, and the Capital Lawes; upon penalty of twenty shillings for each neglect therein."

This law did not specify where the children were to be instructed and such law was amended in 1647 by specifically providing that in each township containing 50 families an instructor should be employed to teach all children to read and to write, and the law further provided that in a township containing 100 families, a grammar school should be maintained and masters employed who were able to fit young people for entrance to a university.

Thus, there were in the very beginning of the establishment of organized society in this country two great forces, one Dutch, and the other, English, in different sections of the country, which enacted decrees or statutes which are the basis upon which compulsory education laws of the several States have been established.

When the Republic was founded, no provision was made for a national system of education. Education, therefore, became a subject which was controlled and administered by the several States. It took many years for the development of public opinion which required the establishment and maintenance of public schools. When school systems were established in a State under general laws, and when independent schools were organized under special acts in various communities, provisions were not generally incorporated in such laws or acts which made attendance upon school compulsory. The parent of a child generally assumed that the cost of education of such child was a matter entirely personal with such parent. During the early years of the nation there was a common feeling which was repugnant to all mandatory statutes. The opposition to the enactment of such laws must not be regarded as a lack of interest in public education, but as the leaders of the nation had an appreciation of the value of education and the national necessity for its promotion and development.

The economic and industrial conditions of the country were passing through a stage of development which influenced the whole social organization of the state. The cities were increasing in population. The number of cities and large villages were also increasing. The industrial and commercial affairs of the country were expanding and developing. Children were being employed in the industries. The increase in immigration was bringing large numbers of foreigners into the country. Young children under the apprentice system were bound out to labor which deprived them of school privileges. These conditions prevailed quite generally in the New England and Middle States. Great evils grew out of these conditions. Hardships were imposed upon children of tender ages. These conditions could be remedied through legislation only. The first effort along this line appears to have been in Connecticut in 1813 when a law was enacted providing that all children employed in factories should be taught reading, writing and arithmetic. In 1836 Massachusetts enacted a law prohibiting the employment of children under the age of 15 in manufacturing establishments unless they should have attended a public or private school for at least three of the 12 months during the year preceding such employment. The law did not place adequate responsibility upon parents, the period of instruction was too long, and the penalty of a fine of $50 imposed upon owners, agents or superintendents of factories was ineffective, as no provision was incorporated in the statute defining who should prosecute violations of the law.

The statutes of Connecticut and Massachusettset were undoubtedly modeled somewhat after the English factory laws. Laws regulating the employing of children in factories and providing for the education of children thus employed were enacted in England in 1802 and in 1833. Under the first act all apprentices in the cotton and woollen mills were required to be taught reading, writing and arithmetic, or either of them, during the first four years of their apprenticeship and every day during the hours of work. The employer was required to provide the teacher. In the provision of this act is the germ of the modern continuation school. The act of 1833 greatly strengthened this law. It provided for factory inspectors to enforce the law. The employment of children under nine years of age was prohibited. Children between 9 and 13 years of age were required to attend school two hours each day for six days each week. The parent possessed the right to select the school. If the parent failed to make such selec-
tion the factory inspector made it. Parents who violated the law were subject to a fine of 20 shillings; Employers who violated such laws were subject to a fine of $20. In this legislation of Connecticut and Massachusetts the right of the State to require a child to attend school, to compel the employer of a child to provide educational facilities for such child and to penalize a parent or the employer of a child for failing to provide a child with educational facilities is first asserted in this country. These laws were not general compulsory education statutes but they were a step in that direction.

The next important legislation in this country bearing upon compulsory education were the truancy laws of Massachusetts enacted in 1850 and 1852 and of New York in 1853. The Massachusetts Act of 1850 conferred power upon the cities and towns of the State to prescribe ordinances to provide for the education of children who were habitual truants or who were not attending school and who were not employed in regular or lawful occupation. The law applied to children between the ages of 8 and 14 years of age. The law was indefinite and cumbersome. The general purpose was to compel children who were not receiving instruction and who were not employed in accordance with the provisions of the factory laws to attend school. The ineffectiveness of the law was recognized and in 1852 a broader and more effective law was enacted. Under the provision of the act of 1852 certain definite provisions were made mandatory. Parents were made responsible for the education of their children. All children between the ages of 8 and 14 were required to attend some public school in the town for at least 12 weeks and 6 of these must be consecutive. A penalty of $20 was prescribed for violation of the law. The statute, however, contained one clause which expressed conditions under which a person who had not complied with the law should not be regarded as having violated it. Children who were "otherwise furnished with the means of education for a like period of time" were regarded as having complied with the terms of the law. Attendance upon private or parochial schools for the required period of time was held to be a compliance with the law. It was not required that the instruction should be the equivalent and as thorough as that given in the public schools. The burden of enforcing the penalty for violating the law was placed upon town treasurers, and these officers generally refrained from making prosecutions. The New York Act of 1853 followed somewhat the lines of the Massachusetts law. It provided that "if any child between the ages of 5 and 14 years, having sufficient bodily health and mental capacity to attend a public school, shall be found wandering in the streets or lanes of any city or incorporated village, idle and truant, without any lawful occupation," such child and its parents were required to be brought before a magistrate for examination. The court possessed the power to put a parent under written obligation to cause such child to attend school. Provision was also made in the Massachusetts and the New York law for the commitment of truants in suitable institutions. These laws were written upon the theory that children who were not truants did attend school and that it was necessary to enact laws relating to the attendance of those children only who were truants. The experience of the States which first enacted truancy laws was that it was difficult to enforce such statutes because of defective machinery provided for their administration. These defects were gradually remedied and the laws gradually strengthened. The experience of the country also showed that laws aimed solely at truancy could not be effectively enforced. This experience further showed that a statute on this subject to be made effective must be a clean-cut law requiring every child within certain ages to attend upon instruction for a definite period of time.

The only American States which enacted a compulsory education law previous to the Civil War were Massachusetts and New York. In 1874 New York substituted an entirely new act for the act of 1853. This law was not denominated a law relating to school attendance or to truancy but it was given the following significant title, "An act to secure to children the benefits of elementary education." It was mandatory in its terms and required every parent and every guardian of a child between 8 and 14 years of age to require such child to attend school or receive instruction at home for 14 weeks each year and 8 weeks of this attendance must be consecutive. The law specified spelling, reading, writing, English grammar, geography and arithmetic as the subjects in which the children should receive instruction. Children were exempt from the provisions of the law for physical or mental unfitness. The law contained the required restrictions with penalties to prevent the employment of children in labor who had not received the instruction required thereunder. The act contained all the necessary provisions to make it effective except one and this one defective feature resulted in the act not being enforced. That one defect was the conferment of duties in the collection of fines for the enforcement of the law upon city treasurers and supervisors of towns. These officers were elected annually by the people and they were unwilling to incur the displeasure of their constituents and neighbors by the performance of a disagreeable duty in no way logically associated with the functions of the offices to which they had been elected.

The general trend of the development of public education in the United States, the settled policy in America that public education is a State function and that public policy requires the maintenance of public schools, the extension of public school work so as to include modern high school courses, and the further action of the several States in making these educational facilities free to every child in the land, inevitably meant that the authority of the State would be exercised to compel all children to attend school. If the welfare of society and the State depends upon an educated citizenship and if the State possesses the legal authority to tax the property of all its citizens for the accomplishment of this result, then the State must exercise and must exercise the authority to compel the children who are to become its future citizens and upon whom its welfare in the future depends to attend upon the instruction provided for them. Following the Civil War, which had exer-
cised a liberal influence upon the country, there was a general development of educational systems in the several States on the principles above outlined. In this same period there was a great increase in the immigration of foreigners and there was a large development in manufacturing and industrial affairs. The use of the unskilled labor of children had grown to an alarming extent. These conditions created social and economic problems of which the American fathers were unable to find a solution. There was a general demand for more stringent laws regulating the employment of children and providing for their education. Labor unions which were honestly endeavoring to improve social conditions were being discouraged, and the condition gradually became understood by the public generally. This fact became an effective agency which enabled society to cope with the ignorant and unscrupulous parent willing to impose improper burdens and even hardships upon his children for financial profit and with the greedy employer who was anxious to avail himself of the cheap labor obtainable through the employment of children. Thus we find that immigration, labor and the industries have been important factors in procuring the enactment of compulsory education laws.

The ordinance of the West India Company in New York in 1629, the decree of the General Court of Massachusetts in 1642, the enactment of the truancy laws of Massachusetts in 1850 and 1852, and the enactment of a similar law in New York in 1853, the amendments to the Massachusetts law in 1867 and 1873 and the new act in New York in 1874 show that these two States assumed the leadership in the attempt to enforce school attendance in America. The statutes of these States have been the models upon which attendance laws in the other States of the Union have been constructed.

There is now an effective compulsory attendance law upon the statute books of every State in the Union except Mississippi, and in Mississippi a compulsory attendance law, permissive in character, was enacted in 1918. The law confers upon the school authorities of any county in that State power to enforce compulsory attendance. The large number of illiterates in the country and the social and economic conditions existing because of the lack of these laws and of proper child labor laws aroused the public conscience and enabled the leaders of the nation who espoused social reforms to obtain the enactment of these laws. In Great Britain, until within the last quarter of a century that these laws were made effective or were properly enforced. The official action of Governor Pattison of Pennsylvania in 1891 and in 1893 illustrates to some extent the public feeling toward laws of this type. In those years he vetoed compulsory attendance measures upon the ground that they were un-American in principle and interfered with the personal liberties of the parent. The effect of the enactment of compulsory education laws in the American States has been to reduce rapidly and materially the number of illiterates in these States.

Compulsory attendance laws have generally been enacted in the European and Latin States of North America and in Central America but they have not been enforced. Such laws are practically dead letters in those countries.

England, Ireland, Scotland, France, Switzerland and the Netherlands have effective compulsory attendance laws, and they are generally well enforced in these countries. The compulsory ages are from five or six years of age to 13 or 14 years of age. Japan is the only country in Asia which has a compulsory education statute and such law applies to children between the ages of 6 and 12. While Italy has a compulsory education law its provisions are not enforced. This is also true of Turkey.

The Balkan states have each declared elementary education compulsory and some progress had been made previous to the outbreak of the War in their enforcement.

The number of illiterates in a country indicates to some degree the effectiveness of its compulsory education laws. In the countries having a military system requiring service from all men there will be found few illiterates. In these countries, however, an illiterate is given special instruction before he enters upon his military service. The mandatory features of the military training laws therefore are in effect compulsory education provisions.

The latest available statistics of certain European countries enforcing compulsory school attendance show the percentage of illiterates in the population of these countries to be as follows: German Empire, .03; Denmark, .2; Sweden, .3; Switzerland, .5; Netherlands, 1.4; Great Britain, 1.5; France, 2.97. On the other hand, the latest statistics available also show that in those countries not enforcing compulsory school attendance the per centages of the population who are illiterate. The percentage of illiterates of the whole population in such countries is as follows: Russia, 70; Spain, 59; Italy, 48; Hungary, 40; Austria, 26. The percentage of the population of certain European countries which are enrolled in the elementary schools is as follows: Russia, 2.5; France, 14.24; Great Britain, 16; Germany, 16.87. The general result in the European countries and in the American States has been that the adoption of an effective compulsory education law has greatly increased school attendance and rapidly reduced the number of illiterates.

Compulsory attendance laws have been in operation in Prussia for more than two centuries. Such laws and child labor laws have been more effectively enforced in the German Empire than in any other country in the world. Frederick the Great's general law of 1763 clearly asserts the principle of compulsory education. The law of 1794 reduces the terms of such statute to two very
simple provisions: First, "Every inhabitant who cannot or who will not provide the necessary instruction for his children in his own household is required to send them to school after completion of the fifth year." Second, "The school instruction must be continued until a child has learned one of his spiritual guide, has obtained the knowledge necessary for an intelligent person of his station in life." The authority to determine the amount of instruction which a child shall receive was transferred in 1872 from the "spiritual guide" to the "school inspectors." In some of the German states the attendance of children upon school is controlled by regulation and not statute enactment. The Prussian Act of 1891 and the acts and regulations of the other German states, in relation to compulsory education and to child labor, are stringent measures and are rigidly enforced. There are practically no illiterates in Germany, and in many of the leading cities of that country the number of persons who do not complete the eight-year-elementary course is less than 1 per cent. The largest percentage of the population of the people in any country in the world which is in attendance upon school is in Germany.

There are two modern movements in connection with compulsory education statutes. These are the court order and the provision for enforcement of attendance upon continuation schools. The court order provides for the issuance of a court order in cases where a child is dropped from school because it is impossible to bring the child back to school. The court order is a last resort to aid in the enforcement of attendance. The provision for enforcement of attendance is made for those who cannot or will not send their children to school. The court order and the provision for enforcement of attendance upon continuation schools is compulsory for boys between the ages of 14 and 18, and for girls between the ages of 14 and 15.

The English education bill before Parliament seeks to establish compulsory attendance for all young persons under the age of 18. It provides for an increase in the number of secondary schools and for the establishment of part-time secondary schools. It provides that children between the ages of 14 and 18 shall not be employed in the industries unless they have attended a full-time secondary school until they become 17 years of age, or unless they attend a part-time secondary school for not less than nine hours per week.

There has been such a large increase in the number of adult illiterates in this country and the total number of such illiterates has assumed such proportions that there has been much public agitation for the enactment of a compulsory education law which will apply to these illiterates. There are more than 3,000,000 adult white illiterates in the country. Of course, the Congressionals have assumed that if they have not a knowledge of English sufficient to admit them to the fifth grade of a public school. New Jersey also has taken advanced action on this subject. The most recent action, however, is the mandatory statutes enacted by the legislature of New York in 1918. Under this law, all illiterate minors are compelled to attend upon instruction. Penalties run against minors' parents and employers who do not conform to the provisions of the law.

The experience of America as well as the experience of the European countries shows that a compulsory attendance law to be effective and accomplish the results sought must contain the following provisions:

1. The law must be supervised by the State educational authorities. These authorities must be given broad powers in the disciplining of local officers who fail to perform their duties.

2. Each local administrative school unit must be charged with the responsibility of enforcing the law and with the authority to appoint and remove attendance officers. The local administration must be under the general direction of the school authorities and not the municipal authorities.

3. There must be a registration of all children above four years of age. The addresses of these children must also be recorded. School authorities must know the number of children becoming of school age each year, so as to make provision for their entrance in school. This registration must be constantly revised so that there shall be at all times an accurate record of the names, ages, addresses and parents of children within compulsory ages.

4. The attendance of children within the prescribed ages must be rigidly insisted upon. A child must be compelled to account for a single day's absence. Physical disability or some other reason equally satisfactory should be the only excuse for an absent pupil.

5. Attendance should be required from the time the child becomes of school age until the child has completed in a satisfactory manner the prescribed elementary school course.

6. Provision should be made for attendance upon co-operative continuation schools for a period of at least two years beyond the completion of the elementary course.

7. Provision should be made for the imposition of fines upon parents or guardians who fail to respect the law.

8. A city, town or school district which fails to enforce the law satisfactorily should be refused grants of State funds until said law is properly enforced.

9. Attendance laws should be operative during the entire period in which a public school is in session in a city or other local administrative unit.

10. These laws must contain restrictive provisions in relation to employment of children within compulsory ages in mercantile, manufacturing and other occupations.

11. In America, instruction in English in the entire curriculum for the compulsory attendance period should be mandatory, and the subjects in which instruction is required should be specified.

12. When instruction is given a child within compulsory ages at home or in a private or parochial school, this instruction must be substantially the equivalent of that given in the public school and by qualified teachers.
EDUCATION, COURSES OF STUDY IN

13. Attendance officers and other representatives of the school authorities must be given the right to enter shops, factories and other industrial and commercial places, to ascertain for themselves in relation to the employment of children, to determine whether or not employers violate the attendance and labor laws.

14. Provision should also be incorporated in such laws requiring all adults who are unable to speak and write the English language to attend evening or other schools until they have acquired such attainments.

THOMAS E. FINEGAN,
Deputy Commissioner of Education and Assistant Commissioner in Charge of Elementary Education, State of New York.

EDUCATION, Courses of Study in. The course of study which forms the outline of work in the best schools of to-day is a broad, socialized program, having little resemblance to the brief course in the schools of 50 years ago. Reading, writing and arithmetic were then the subjects of instruction covered in the elementary schools. In the "academies" Latin and Greek were principal subjects, as the purpose of the instruction was preparation for college. In many States there are now certain statutory requirements relative to the course of study such as the teaching of physiology and hygiene and instruction in reading, writing, spelling, arithmetic, geography and history. The emphasis to be given to these different subjects, the assignment of time allotments, and the teaching of other subjects such as music, drawing or science are fixed largely by local superintendents and boards of education.

During recent years courses of study have been "enriched" and "vitalized" by the introduction of many new subjects. Some have held that too much new matter has been added with the result that thorough work is no longer possible. On the other hand, the vast changes in the social and economic life of the day demand a closer relation between the program of studies and the immediate daily life of the child. The scientific study of the progress of pupils has established the fact that there has been considerable waste in useless repetition in the elementary grades. The activities which have been introduced through play and games, storytelling, dramatization, handwork, weaving, sewing, cooking, wood-working, modeling, gardening and other means have been added largely because of their interest. They were considered helpful devices in the monotony of the daily routine. Only recently has their social value been appreciated. The importance of these activities in the growth and development of the child has given them a definite place in the course of study. The evidence of waste in effort and of undue time allotments for the fundamental subjects makes the argument of the principal subjects work more easily accomplished. The schools are an important part of the social life of the community, not apart from it. In the process of education the course of study must present in rational sequence type form the principle of mental development. The vast changes in our social conditions have reacted on the whole theory and practice of education. Courses of study are, therefore, not definite and final, but subject to constant modification.

Health education was not thought of yesterday, but is all-important to-day. Physical training, supervised playgrounds and recreational centres are provided in the educational program of every primary school. As the school day is being lengthened, and the time is not far distant when the course of instruction will be continuous throughout the year.

Too often this enrichment has resulted in mere multiplicity of subjects and congestion of the program. It should not mean this if the entire course is unified and the common aims of the instruction determined. The study of the relative values of the different subjects of instruction and the elimination of useless material has resulted in the consensus of educational leaders that six years is ample time in the elementary grades to be given to the study of the so-called common branches. At least it is thought that the problem in the first six years has been too much a matter of giving the child a vast accumulation of facts, that he should master the fundamental processes of reading, writing and arithmetic, and form a proper mental attitude toward his social environment.

The thought has been held for several years that many of the so-called secondary subjects should be begun before the ninth year. The several reports on this subject which appeared around 1900 emphasized the unreasonable rigidity of the system which fixed eight years for the elementary course and four years for the secondary course. These discussions largely centered on the necessity of economy of time and a thorough instruction in subject matter. The epoch-making treatment of the subject of adolescence by Hall was a new and compelling factor in the consideration of the reorganization of the course of study. It became clear that the psychological break came too late; that the eight and four plan for the elementary and secondary school work was illogical as well as uneconomical; that the development of the youth, physically as well as psychologically, demanded the reorganization of the school work on the six and six or the six-three-three plan of pupil work. School work in the course of study and methods of instruction might be made after the sixth school year. The great elimination of pupils in the seventh and eighth grades and the failure of the course of study to function compelled remedial action.

Hall's complete discussion of adolescence and Dewey's emphasis on the relation between the course of study and the social environment have resulted indirectly, if not directly, in the development of the intermediate school, covering the seventh and eighth grade. In the six-three-three plan the elementary work is followed by a three-years' intermediate course, and that in turn by the secondary course of three years. The course of study in the intermediate school, or junior high school as it is sometimes called, is to assist the boys and girls to find themselves; the work is slightly differentiated into groups to meet individual needs and to give an acquaintance with the first principles of a few fundamental occupations. The work is done in the vast changes which are made by subjects. The courses are in a sense provocative in that the pupil has the opportunity to test his inclinations and capacity through the socialized grouping and co-ordination of
subjects. He is given more freedom than in the elementary school but is not left on his own resources as in the secondary schools. The organization of the intermediate school with the development of the course of study best suited to the peculiar needs of the pupil in his relation to his social environment is only a step in the solution of a large educational problem; it is far from being solved.

In the secondary field courses of study are more fixed, and the college preparatory aim persists not only in the course of study but in the treatment of separate subjects of instruction. In very few of the courses of study in the secondary schools has there been any complete correlation of work or definite aim. The subjects are too often unrelated to each other and bear little relation to the social environment. The mortality in the secondary schools is very high, as only 20 to 25 per cent of first year pupils complete the course. When no one factor is responsible for this condition, the failure of the course of study to function has been a determining element.

School courses have been planned for the graduate, not for the pupil who goes part way through, overlooking the fact that the three-fourth majority do not complete the course. The aim of the eight-year elementary course has been the completion of the requirement for admission to high school. The aim of the high school course has been the college or professional school requirement. The needs of scarcely 5 per cent of secondary pupils have determined the course of study for the other 95 per cent. The relation of the school work to the social environment has been almost entirely overlooked in both the general outlines of courses of study and in the method of treatment of the subjects of instruction.

The solution seems to be in the shortening of the elementary course and in the modification of the work in the seventh, eighth and ninth grades, or intermediate school, so that a slight differentiation in work may begin before the adolescent period, and that the secondary course of three years furnish opportunities for the development of the different types of individual pupils. Each pupil should be based on definite needs and have a definite and specific aim. It should furnish the pupil the opportunity to carry forward the particular work in which he showed or developed interest in the intermediate school.

The more logical break which comes at the end of the three-year period at the close of the intermediate courses does not leave the pupil wandering aimlessly. He has been given an opportunity to find his bent. The diversified course of study in the intermediate school holds the pupil much better, and even if he should leave school at the end of this period, he has had the advantage of an additional year beyond the eight grades, with a course of instruction planned to meet his needs.

A reconstruction of the secondary course is under way. In part the needs of pupils are being met through the organization of technical high schools, commercial high schools, vocational and continuation schools, and in some high schools courses in technical, commercial or vocational subjects are offered along with the so-called academic work. There are two schools of thought with regard to the vocational courses; one, that there should be set up an independent educational organization for this vocational work, and the other that such a program is undemocratic, that the courses in vocational, technical and academic subjects should be carried along side by side with no separate educational administrative organization.

This adjustment with the environment is being worked out and courses are being evolved with definite social aims. There will be no fixed courses of study, but they will always be subject to modification as the needs change. There will be no final differentiation between academic and vocational, as technical or cultural training will depend upon the needs of the pupil rather than on any mere arbitrary classification of studies. Courses of study must be adjusted with the whole environment in terms of individual and community needs.

GEORGE M. WILEY,
Director, Division of Examinations and Inspections, State Education Department, Albany, N. Y.

EDUCATION, the Development of the Office of School Superintendent. Supervision of schools by educational experts is an American idea. In ancient Athens, it is true, the teachers were to some extent under the supervision of the State. Overseers were appointed to enforce the laws respecting morality. The State, however, exercised but little supervision over the qualifications of tutors or their methods of teaching. Charlemagne visited the school of the palace and placed the schools for the education of the clergy under the care of the bishops and the parish schools under the care of the priests. They had so many that they could not exercise a close oversight over the teaching in the schools which were thus placed under their care. Luther and Melanchthon visited schools and churches under the direction of the Elector of Saxony, but their time and strength were devoted to duties other than those of supervision. When the king of England and the nobility made liberal subscriptions for the establishment of a system of charity schools, in which the German children of Pennsylvania might be taught English, and thus through the instrumentality of language be attached to the English Crown, Rev. Michael Schlatter was in 1754 made superintendent of those schools at an annual salary of £100. He was succeeded by Dr. William Smith, who was outspoken in his loyalty to the British government. The former was a missionary of the Reformed Church, and the latter was provost of the university. Hence neither of them could devote much time to the work of supervising the schools under their care.

City Supervision.—The idea of appointing a person who was to devote all his time to school supervision first took shape in Buffalo, N. Y., and Louisville, Ky. In the winter of
1836-37 a law was passed by the legislature of New York authorizing the appointment of a superintendent of common schools in Buffalo. R. W. Haskins received notice of his appointment, but finding the law defective, he resigned before the expiration of the year, and was succeeded by Oliver G. Steele, who has always been known as the father of the public schools of Buffalo.

The city of Louisville, Ky., appointed a superintendent of schools in 1837. He was called Agent of the Board of School Visitors and began his work in the month of September. Two years later Saint Louis, Mo., and Providence, R. I., appointed superintendents. The last of the great cities to create the office of superintendent was Philadelphia.

State Administration and Supervision.—

New York also led the way at a still earlier date in provisions for State administration and supervision of schools. The law of 1795, which appropriated $100,000 each year for five years, provided for the annual election of not less than three, nor more than seven, commissioners in each town who were to supervise and direct the schools. By the act of 1797 the regents were empowered to charter colleges and incorporate academies, and to exercise supervision over them, being authorized and required to visit and inspect them, to examine into the condition of education and discipline in them, and to make an annual report thereof to the legislature.

On 14 Jan. 1813 Gideon Hawley was elected superintendent of common schools of New York and retained the office until 22 Feb. 1821, meanwhile having been appointed secretary of the board of regents, 25 March 1814, and continuing in that capacity until 1841. When he was removed by the "Counsel of Appointment" just prior to the expiration of its own life, as provided by the constitution of 1821, public indignation rose to such a pitch that the legislature promptly abolished the office of superintendent and devolved the duties upon the secretary of state. But the office has been continuous from 1812 to the present time and has been held by several of the most distinguished men of the State.

In Maryland a State superintendent in 1825, and Vermont in 1827, but in neither was the office continuous. In Pennsylvania the duties of State school administration were, in imitation of New York, devolved upon the secretary of the commonwealth, and Thomas H. Burrows achieved lasting fame by his work for the common schools while serving as secretary of the commonwealth. Most of the time, however, the function of school administration was assigned to a clerk or deputy until 1857 when the office became independent of and co-ordinate with the other departments of the State government. Michigan filled the office in 1836, and Massachusetts in 1837 with Horace Mann under the title of secretary of the State Board of Education. Kentucky came next (also in 1837), and then Connecticut with Henry Barnard under the same title as that adopted in Massachusetts. His successor was Daniel B. Fish in 1842, but resumed by himself in 1849. Since that time the establishment of the office has been rapid, and in the newer States the office dates from the beginning of their organization, either as a Territory or as a State.

County and Local Supervision.— In 1841 New York passed a law for the appointment, by the Board of Regents, of superintendents for the counties, except that in counties having more than 200 school districts they were to appoint two deputies. These deputies came to be known very soon as county superintendents, and the arrangement lasted until 1847. In 1841 provision was made for the election of town superintendents and this lasted till 1856. In 1854 a State Department of Public Instruction was again established, and the office of superintendent of public instruction was created. In 1904 the Department of Public Instruction and the Board of Regents were consolidated, and at the head was placed a State commissioner of education. The powers lodged in this department of the State government have been surprisingly large. Its decisions cannot be questioned and reviewed in any court or in any other place. Thus school disputes can be settled promptly and without much expense.

In Massachusetts there have been several great epochs in the development of the policy of school supervision. The ordinance of 1647 obliged all towns of a given number of householders to provide and support schools. The law of 1789 authorized the employment of a school committee to look after the schools. In 1826 such oversight was made obligatory by law. The people of Massachusetts have always been jealous of their rights and correspondingly slow to delegate power to persons in office. The high-water mark of democracy and the low-water mark of the Massachusetts school system was reached when prudential committees and district committees began to be in collision or collusion. The law of evolution under which the people gradually demand the best in education for their children brought on the period of supervision by experts. At first school committees appointed one of their own number to inspect the schools. The school committee of Cambridge in 1836 and of Gloucester in 1850 delegated to one of their members certain supervisory duties and designated him superintendent of schools. The first instance of the appointment of a superintendent other than that of a member of the school committee in Massachusetts was in Springfield in 1840. He remained in office but two years. The first permanent appointment of such an official was made in Boston in 1851. The experiment was successful, and in 1854 a law was passed (amended in 1857 and 1860) authorizing towns and city councils to require the school committee to appoint a superintendent who should have the care and supervision of the public schools. The cities and large towns, one after another, adopted the plan until in 1879, 25 years after the permissive bill was passed, 35 cities and towns employed superintendents for full or nearly full time. In 1888 a law was passed permitting the employment of a superintendent by two or more towns, the expense therefor being largely borne by the State. Permissive measures were followed by mandatory laws. Massachusetts in 1865 passed an act obliging the school committees of all towns and cities to employ a superintendent of schools after 1 July 1902. The towns having a valuation of less than $2,500,000 to be governed
by the law under which two or more districts could join in the employment of a superintendent, 19 New York and Massachusetts are typical States, and their example was followed elsewhere, especially in the Northwestern States and in Pennsylvania. In the latter State the office of county superintendent was created in 1854. Popular indignation rose to so high a pitch over the creation of so many new offices that it helped to defeat Governor Bigler when he came up for re-election. But his successor, Governor Pollock, took a bold stand in favor of school supervision, and the superintendent of schools whom he appointed, Henry C. Hickok, made it his chief aim to show the people that they would get more in return for their school taxes if the schools were placed under the supervision of men fitted for the office by literary and professional qualifications. The law in Pennsylvania has always been a schoolmaster of public opinion, and in no long time the advantages of school supervision were recognized, and the policy of electing county superintendents at a competitive examination by school directors specially called for this purpose has been left unchanged although the term has been lengthened to four years. The requirement that the superintendent must possess literary and professional qualifications in order to fill the office has been adopted in other States.

Ohio created the office of county superintendent in 1914. He is elected for a period of from one to three years by a county board of five members who are themselves elected by the presidents of the district boards.

Salary.—The higher compensation which the superintendent receives, as compared with the teachers under him, has raised in the public mind the question: "How does the superintendent earn his salary?" To answer the question the school system may be likened to a manufacturing establishment whose operating expenses exceed the income by $20,000. The deficit caused the stockholders to employ a more efficient superintendent, who by organizing the workmen, rearranging the work and saving the waste or raw material not only prevented this loss but made a profit of $50,000 by the end of the next year. Did the new superintendent earn the $5,000 salary which he received? To ask the question is to answer it. But in school work there is far more serious than the waste of raw material. The most valuable asset of a commonwealth is brains, and this goes to waste through inefficient teaching. The time and effort of pupils is too valuable to be wasted during the most plastic period of human life. It is the function of the superintendent so to organize and oversee the work at school that the people may get the largest return for the taxes gathered for educational purposes. The results of school supervision have established in public favor the office of superintendent and the policy of school supervision in every State of the Union.

Duties of the Superintendent.—Various functions are assigned to the superintendent. If he is responsible for the efficiency of the schools he must have a voice in the selection, suspension and dismissal of teachers, the promotion of pupils, the making of the course of study, the selection of the textbooks, the purchase of apparatus and furniture, the erection and condemnation of schoolhouses. In smaller towns difficult cases of discipline are referred to him for adjustment; in the cities and larger towns such cases go to the principal who assumes many of the functions of a supervisor. Where a superintendent's powers are based upon statute it is easy for him to exercise these functions. When he must exercise them through committees the situation becomes very complex and requires the greatest tact and personal force.

Methods of Teaching.—The superintendent is everywhere expected to improve the methods of teaching. Hence he is charged with the duty of conducting teachers' meetings, and in some States he has charge of the annual teachers' institute. He makes reports to the Board of Education, stands between the schools and the newspaper reporter bent on mischief, between the teacher and the unreasonable parent, as well as between the schools and the ill-advised reformer. It is also the duty of the supervisor to protect the child from over-pressure in school work and from other unreasonable demands on the part of the teacher. He may, by holding frequent examinations, ruin the methods of teaching and unnecessarily worry the minds of teachers and pupils. It is now recognized that children have rights as well as duties, that one of these rights is the right to be happy at school, that children cannot be happy unless the teachers are happy in their work, and that no teacher can be happy if he or she is constantly annoyed by rude or unreasonable demands from the superintendent. Hence the educational leaders of America have insisted that the superintendent shall be courteous in manner, always pleasant to parents, teachers and pupils and capable of sending them away satisfied, even when he must refuse their requests.

Assistant Supervisors.—Where the administration of schools absorbs most of the time of a superintendent it has become imperative to appoint supervisors who take charge of special lines of work, like drawing, music, manual training, primary instruction. In the selection of these assistants it is important to get experts who can get things done. Mere inspection for the purpose of reporting what is done falls far short of the real purposes of school supervision.

From the nature of the case, county superintendents cannot exercise as close supervision as is possible in cities and towns. Various duties have been assigned to them in different States, namely, to examine teachers, issue certificates, visit schools, conduct the annual institute, make reports to the Department of Public Instruction, see that the schools are kept according to law, that the State school appropriation and other school funds are wisely expended, and that schoolhouses unfit for use are replaced by modern structures. The preparation of questions for the examination of teachers and the employment of talent for the annual institutes has in many States been delegated to the superintendent and his assistants.

The Selection of Superintendents and Public Opinion.—Of the various plans for the selection of State or county superintendents, that by popular vote is least satisfactory. Nominating conventions are apt to select candidates for geographical reasons or political services and not on the basis of fitness for the duties of the office. This may be prevented by public opinion.
EduCATION, Elementary.—In all the elementary schools of the United States, public and private, there were enrolled in the year 1914 over 99,000,000 pupils,—17,500,000 of these in public schools. The average number of days attended by each pupil enrolled in the public or common schools and including rural schools was 115.6 days, and the average length of the school term 138.1 days. The total expenditure per pupil was $36.31 for sites, buildings, salaries and all other purposes as compared with $15.91 for the same items in 1875.

Rural Schools.—By the increasing concentration of industrial and commercial life and the resultant growth of railways and other modes of rapid transportation during the past 50 years, the suburbs of cities were greatly extended, the urban population vastly increased and the rural population diminished. Rural schools suffered correspondingly. Within later years, however, a reaction has set in favor of agricultural life by which rural schools have begun to profit. There still are rural schools in sparsely settled districts that continue the old practice of holding winter schools with limited sessions of 50 to 90 days and taught by itinerant teachers. Yet lingering shortcomings are steadily yielding to the establishment of union schools, to the consequent more generous extension of school terms and to increasingly successful efforts to secure more adequate preparation of prospective teachers through special normal courses in State and county normal schools and in high schools. In the union schools a number of districts are consolidated; the children are conveyed to these at public expense; the courses of instruction are graded; the teachers comparatively well prepared and more permanent. Moreover, they have offered rallying points for the people of the community for lectures, entertainments, discussions, exhibitions, institutes, social gatherings, etc. In a number of instances, increased interest in education was stimulated and led to the establishment of township and county high schools. Township high schools are common in New England and in some of the Middle Atlantic and Middle Western States; Kansas and Oklahoma and several of the Middle Western States have county high schools. Much fresh stimulus, too, has come from the extension and increased stringency of compulsory school attendance laws. Since 1899 such laws have been passed or amended in the direction of greater stringency by all the States save two, and 28 of these require attendance during the full school year for from 6 to 9 years. The beneficial effect of such legislation will appear in the fact that the percentage of illiteracy has sunk from 7.1 per cent in 1900 to 4.1 per cent in 1910. Furthermore, it appears that out of 100 persons enrolled, approximately 92 pursue elementary studies, 6 are enrolled in secondary schools, and 2 are in higher institutions.

From the general character of courses of study, it is fair to assume that the average schooling in all but the most backward rural district is sufficient to secure for each normal person enough to enable the future citizen to read and write and cipher within the practical needs of life, and to enjoy in addition some geographical knowledge, some acquaintance with the history and political organization of his country and, in many instances, some skill in singing, in drawing and other handwork, and a measure of literary taste.

Trained Teachers.—Consideration of the reasons for increasing the length of the term of the elementary school and the adoption of a graded course of study, reveals the most important item of improvement in the recent history of American schools, namely the introduction of professionally trained teachers. The first normal school in the United States was established at Lexington, Mass., in 1839. The number of normal schools supported by state or municipal governments has increased since that year to 235; in addition there are 46 private normal schools and a number of schools of higher grade where the training of teachers in high schools and colleges. The advantage of professionally educated teachers above others lies in the fact that they have learned to use methods and devices intelligently and in thoughtful adjustment to the needs and interests of children. They have learned to distinguish between the essential aid the accessory in the subjects of instruction and know how to lead the pupil to inspiring uses of his knowledge in deliberate research and in successful application to varied purposes of achievement.

But much is yet to be done, if teaching is to become a profession with adequate permanence of tenure on the part of its votaries. Thus, with regard to rural schools, Harold W. Foght, rural school specialist of the United States Bureau of Education, reports that the average rural school teacher remains in the profession less than four years of 140 days each. This means that the entire personnel must be renewed every four years or that about 92,000 new teachers must be prepared each year. In 1913-14, 94,455 students and graduated only 19,438. The burden of providing for the largest immediate supply of rural teachers falls upon the training departments of high schools and upon county and township training schools in some of the States. Nor do these sources seem to be adequate in view of the fact that in 1913, according to the commissioner's report, there were in the teachers' training courses of public and private high schools, only 3,767 boys and 23,284 girls. Nor is the dearth of satisfactorily trained teachers confined to rural schools; for of 1,350 cities reporting to the Bureau of Education in 1914 only 474 require elementary teachers to be normal school graduates, 630 require only a high school education, and the remainder fail to specify what qualifications are demanded.

Probably the most serious obstacle to the professionalizing of teachers is to be found in the comparatively low salaries paid them. In 1914 the average wage of elementary teachers
in cities of 25,000 and less than 50,000 inhabitants was $641; in cities of 5,000 and less than 10,000 inhabitants the average wage was $333; both wholly inadequate to secure normal graduates and continuous tenure. With similar importance, the investigations of the National Education Association committee on teachers' salaries discloses the fact that the annual wage of farm laborers in 1913 was $257, while the average wage for rural teachers was but slightly more, although the exact figure was not available. More to the same point, the average wage of rural mail carriers was $1,150. The average salary of elementary teachers in cities of 100,000 and fewer than 250,000 population in the same year was $791, and in cities of 5,000 and fewer than 10,000 population the average salary reached only $533.

Under such conditions permanence of tenure and the choice of teaching as a life work become almost unthinkable. One-third of the men and one-half of the women engaged in teaching work under 24 years of age. One-half of the teachers have had but four or fewer years of experience, and one-fourth can claim only one year of experience. At the same time, because of the more varied and wider opportunities for profitable vocational employment, men are more and more turning away from and leaving the field of teaching to women. Thus it has happened that the percentage of men teachers, which in 1870-71 amounted to 41, has steadily declined so that in 1911-12 it had fallen to 29, leaving 71 per centule of the school to women. Unfortunately, this situation is still further complicated by the fact that, all but universally, married women are excluded from eligibility. Consequently, to the characteristic of the great majority of elementary teachers there has to be added the qualification that they are unmarried women. This qualification each teacher, up to a certain age, hopes to escape, thus adding a new factor to the uncertainty of tenure and a new limitation to the growth of professional spirit.

The modern organization of the elementary school which will be discussed later on in full, presents among other welcome features the fact that it brings into the life of the child at an earlier period the influence of men teachers. The value of this cannot be overstated. It furnishes the boy realizable ideals and examples he can emulate, and to the girl it furnishes the opportunity to gain respect for the masculine factors in life on the ground of merit. I direct attention to this without prejudice to the equally valuable influence of women in the school; for I am aware of the fact that the all but exclusive employment of men as teachers in former days had as weakening an influence upon the effectiveness of schools as their excessive feminization has upon the schools of to-day. As in the ideal family we find mother and father, sister and brother, so in the school both elements should be found in vital proportion, if the children are to grow into ideal relationships in a social organization involving both women and men.

Under the circumstances indicated, it is evident that small rural districts cannot secure professionally trained teachers. Such, indeed, find ready employment in cities and villages; for these, too, as a whole cannot show in their graded schools an average of more than one teacher in three that holds the diploma of a normal school.

Urban Schools.—Another great advantage belongs to the schools of the village or city. They are graded schools, have a regular course of study, proper classification of pupils and uniformity of textbooks. In the small district school 15 to 40 pupils are brought together under one teacher. Their ages vary from 4 to 20, and their degree of advancement ranges from beginners to those who have attended for 10 or 12 winters and attempt secondary studies. It still may happen that there is no uniformity of textbooks except, perhaps, in the speller and reader, each pupil bringing such arithmetic, geography or grammar as his family may possess. This was the case universally in the old-time district school—such as existed in 1790, when 29 out of 30 of the population lived in rural districts, and 50 years later when only 1 in 12 lived in a city. As the railroad has caused villages to grow into cities, so it has virtually moved into the city a vast population living near railway stations in the country by giving them the morning newspaper and rapid transportation. In 1890 one-third of the population was living in pursuits of business or unemployed, but in 1910 almost 20 per cent of the population in the city had changed to the rural districts. But the suburban populations made urban by the railroad swell the city population to one-half of the whole nation. Hence the great change now taking place in methods of building schoolhouses and in organizing schools.

With this change in the composition of the population, the method of individual instruction was supplanted by class instruction. The individual did not gain much under the old plan, for the reason that his teacher had only 5 or 10 minutes to examine him on his daily work. In the graded school each teacher has her grade divided into two sections and hears one recite while the other prepares a new lesson. All pupils learn more by such class recitation than by individual recitations, for in the class each can see the lesson repeated in the minds of others, and understand the teacher's views much better when drawn out in the form of a running commentary on the recitation.

Textbook and Oral Teaching.—It is supposed that the chief work of the pupil is the mastery of textbooks containing treatises that give the elements of branches of learning taught. The evil of memorizing words without understanding their meaning or verifying the statements made in the book is incident to this method, and is perhaps the most widely prevalent defect in teaching to be found in the schools of the United States. The oral method escapes this evil almost entirely, but encounters another. The pupils taught by the oral method exclusively are apt to lack power to master the printed page and to get from it the full meaning; they need the teacher's expert phrases and definitions. The American method of textbook instruction, it is claimed, throws the children upon the printed page and holds them responsible for its mastery. The pupil is taught to assume a critical attitude toward the statements of the book and to test and verify them or to disprove them by appeal to other authorities or by actual experiment. It is evident that this system of instruction is feasible only in
graded village and city schools and can find no place in the ungraded small rural school. Where such schools have made the attempt to classify their pupils, e.g., in arithmetic or geography, they were obliged to unite in one class children of very different degrees of attainment with unavoidable injury to the dull by overpressure, to the gifted by neglect, and with but doubtful benefit to the average.

The chief objections to this method of work in graded schools has been found in its tendency to degenerate even in the hands of well equipped teachers into spiritless “machine” work and mass-teaching with their disregard and suppression of individual needs and interests, as well as of the claims of spontaneous social intro-ordination. It proved to be economical financially, it is true, but wasteful educationally. The shortcoming is further emphasized in 24 States by the fact that these have made uniform textbooks mandatory. In some of these States the adopted books must be used and in others, work is assigned by districts; in others, high schools are permitted to select for themselves; and in still others, city districts and special tax districts may adopt whatever books they may desire. In a few instances, where the State prints its own texts and modifies them from time to time on the basis of advancing professional insight, possible evils of the measure are greatly mitigated.

A concomitant of the “machine” work and mass-teaching to which large graded schools have been subjected is found in so-called discipline or government. The establishment of order, regularity, silence, concerted action and general obedience to authority offered great difficulties and invited measures that seemed arbitrary, out of relation with the object in view, and without even indirect appeal to the children’s good will and insight.

The New Pedagogy.—However, under the inspirations of Froebel and Herbart, of Spencer and Wundt, of Dewey and Hall, and many others, a new psychology and a new pedagogy are coming to the rescue. More and more, in the life of the school, the needs of the child with reference to his individual and social development are coming to the front. The treatment of subjects in these schools reflects the new tendencies, place stress upon touching interest on the basis of the learner’s experience, upon striving the desire for independent research, upon utilizing new knowledge in fresh individual achievement or generous social endeavor. Similarly, disciplinary measures are judged more and more by these considerations. Incentives are adapted to individual nature and need. Encouragement is taking the place of relentless pedantic criticism. Good will, insight and self-respect are appealed to and, in growing proportion, deliberate self-control and even organized pupil-government take the place of ospitive waywardness and inadjustment by teachers.

Much is due in the gradual reorganization of the elementary school to the influence of the kindergarten, of manual training, drawing and certain phases of nature study. In all of these the value of the hand as man’s chief organ in exploring the world and in adjusting his thoughts to his needs is fully revealed. With their introduc-

I. tion the motto, “learn by doing and in order to do, acquired appreciable meaning. At last, the whole child—head, heart and of him—went to school. The liberal and the practical lost their antagonism, became indeed the two indispensable poles of full culture which carries men, ask whether it is the useful, through the true, to the beautiful. The progress of the kindergarten as a factor in elementary education has been quite rapid. The first public school kindergarten was established in 1842 in 1873. In 1892 the Commissioners of Education reported 459 public and 852 private kindergartens in the United States. In 1898 there were in 389 cities of 8,000 inhabitants or over 1,365 kindergartens supported by public funds. The number of teachers employed in these was 2,532, and under their care were 95,867 children. At the same time, information had been obtained concerning 2,998 private kindergartens, with 6,405 kindergartners and 93,737 children. Thus the total number of kindergartens, public and private, was 4,563 with 8,937 teachers and 389,604 children. Kindergartens were authorized in 14 States, but a number of cities had established kindergartens through powers conferred in their charters. For 1914 the commissioner reports that in all States but one establishment and maintenance of kindergartens is either required by law under certain conditions, specially permitted by law, or permitted under general authorizations. There were reported in this year 7,254 public kindergartens in 1,135 cities with an enrollment of 391,143 children. In addition there were reported in 677 cities and villages 1,571 private kindergartens with an enrollment of 74,725 children; yielding for this year a grand total of 8,425 kindergartens with an enrollment of 465,868 children.

It is the general consensus of opinion on the part of superintendents, principals and primary teachers that the kindergarten child has advantages over the non-kindergarten child, other things being equal, in good school and life habits, in wealth of ideas and power of expression, in powers of observation and concentration, in perseverance in a task once begun, in control of the hand in manual work, in social co-operation and sense of responsibility in common work, in memory, in a number of other minor points. So beneficial, indeed, has been the influence of the kindergarten upon the spirit and work of the primary school that deliberate movements for the mutual adjustment or even conciliation of the two are becoming more and more urgent. It is proposed—and sporadically carried out—that the transition from one to the other be made less abrupt and that in normal schools student teachers for the kindergarten and others for primary work be taught to be prepared for all essential things; in short, that the kindergarten be no longer treated as a separate department, but be made an integral part of primary instruction.

A further development brought to the elementary school the “kindergarten training” in the fact that it directed favorable attention to the value and need of modeling, drawing and other forms of constructive and creative handwork in connection with the educative activities of the school. This prepared the way for slogan and other forms of manual training which later on came to the upper gramm
EDUCATION, ELEMENTARY 611

grades and to secondary schools, largely under the pressure of the growing industrial needs of the country.

Certain of these forms of manual training had been advocated long ago by Locke and Franke, by Rousseau and Pestalozzi; but the recognition of its full value as a factor in education was reserved for Frebel. He, first fully and clearly revealed the law that the end of mental activity is not knowledge, but the use of knowledge in some sort of self-expression or doing; that as the acquisition of knowledge rests largely upon the activity of the exploring hand, so the application of knowledge to the needs of life is largely dependent upon the activity of the achieving hand; and, furthermore, that full normal interest in learning can be stimulated only by the achievements it serves. To Frebel, the manual training he had in mind was not a new subject of instruction, nor was it a concession to the industrial need of the time, but an immanent factor in every phase of educational work, adding nothing new to intellectual effort, but simply giving ethical and aesthetic aspiration. In a measure, then, it includes all the workshop and sketching-room, the kitchen and sewing-room features of current manual training departments of the elementary school, but it also includes the manual work of the kindergarten and of the modern primary school, the laboratory, the studio and the school-garden. In a broader sense, looking upon the hand as the symbol of deliberate muscular activity, it even may include the new attitude of the school to physical training, to play and playgrounds, to dramatization, to song and rhythmic motion.

Inspiration for manual training of a technical and industrial character came to European countries from Finland and the Scandinavian countries. To Uno Cyngeus, whom his countrymen fondly name "father of the school," belongs the honor of first introducing work of a technical character in the urban schools and to Jakob Bock, in the rural schools. Similar and almost simultaneous movements for the extension of slojd and home industries in the schools of the people were carried on successfully in Sweden and Norway and more particularly in Denmark. In our own country, work of a technical nature, as part of the manual training is traced to an exhibit of a Russian institution at the Centennial Exposition in Philadelphia in 1876. The value of the system of manual training, there suggested, appealed to such men as John D. Runkle and C. M. Woodward who introduced it into the institutions under their charge and became forcible advocates of its value. The advanced technical features of this phase of manual training — including various forms of woodworking and ironwork — are confined to high schools and in some instances, to the upper grades of the grammar schools. The manual training of grades below the 7th deals with extended kindergarten material, with paper and cardboard work, plastic materials, raffia, bookbinding, simple forms of slojd, etc.

Industrial Vocational Training.—Within recent years the problem of manual training has been much complicated by movements for the establishment of courses for industrial and vocational training, which are not merely a less complete preparation for distinct callings, coupled with the opportunity for the pupil to find under so-called vocational guidance what particular vocations or group of vocations it is most profitable for him to choose. While in the original manual training, which still persists in elementary schools, the stress is upon its cultural value, industrial and vocational training emphasize the distinctively practical outcome in fitting the pupil for some definite calling, for some domestic, agricultural or other industrial work. In 1898 manual training was an important feature in the public school course of 149 cities. In 339 institutions other than city schools, there was training that partook more or less of the nature of manual training. These institutions embraced almost every class known to American education, and the manual features varied from the purely educational manual training of the Teachers' College in New York city to the specific trade instruction of the apprentice school. In 1914 there were approximately 1,200 public high schools that offered courses in manual or technical training, in agriculture, and in domestic economic pursuits as well as the extent of educational or other hand-training in the elementary schools at this time.

Within the last two decades, the attention of legislative activity has been directed to the importance of hand-training, more especially with reference to industrial and vocational needs. To Massachusetts belongs the honor of leading the way in this matter in a law 20 years old, requiring every city of 20,000 inhabitants or over to maintain manual training courses in both elementary and high schools. Later on, Massachusetts again led in legislation aiding the establishment of industrial and vocational schools. By 1915 24 States and the District of Columbia had found it necessary to pass laws providing for courses in a variety of vocational work: for continuation schools, evening schools, trade schools, special classes, etc. Thus, by way of illustration, New York provides for courses in agriculture and home-making in her consolidated rural schools, for continuation schools, for trade schools, and for evening vocational schools; New Jersey provides for all-day industrial schools for boys over 14, household-arts schools for girls over 14, part-time continuation schools for boys over 14, part-time vocational schools for boys over 16, art classes, evening industrial classes for boys or girls over 15 who are employed as apprentices, evening household-art classes for girls over 17, and vocational agricultural classes. Indiana makes provision for "fitting each individual in the State for some useful form of work" in the public school work of the State; for this purpose, the law requires that elementary instruction in domestic science and in the industrial arts be given as part of the regular course of instruction in all the schools — in the 7th and 8th grades and in the high schools — of the State. Moreover, the law provides for vocational departments and schools conducted for the sole purpose of preparing for efficient and productive work in the shop, in the home, and on the farm.

The highly organized graded school of to-day is quite young. The War of Independence and the subsequent need for organizing and extending the new territory and of establishing means of intercommunication and other economic facilities had deflected attention to the scanty
provisions for public education. At the same time immigration brought many poor and ignorant families, and illiteracy was growing apace. A movement toward an intensively popular education, however, set in when in 1837 Horace Mann and Henry Barnard began their educational work, the one in Massachusetts, the other in Connecticut and later (1843) in Rhode Island. From these beginnings and within less than 80 years, the elementary division of our public school system has been evolved. Within the past 40 years, there have come to our public elementary schools among many other commendable features grouping by grades, trained teachers, enriched study programs, care for the health of the children and for their general well-being. The most significant steps in the functional reorganization of the elementary school came within recent years: in the first place through efforts of the college to shorten the time required for college graduation by reducing the elementary school period to six years instead of eight or nine; and, subsequently, to free the public school generally from its all but exclusive subervience to college ideals in the belief that it might be as free of the needs of industrial, commercial, agricultural and domestic life. With this in view, the course of the elementary school is being more and more generally shortened to six years, to be followed by an intermediate course of two or three years and by a high school course of four or three years.

Six-three-and-three Plan.—Among the various plans proposed and set in operation for the purpose indicated, the six-three-and-three plan is probably the most favored. It reduces the elementary school to six years, establishes an intermediate school, or "Junior High School," of three years and a full-fledged high school of three years. In both the intermediate and the high school the courses are flexible and promotion is by subjects not by grades. Instruction throughout is departmental and in the hands of persons who combine the qualities of the teacher with those of the expert. The curriculum of this intermediate school affords much opportunity for differentiation. All, it is true, share in pursuits that reveal the duties of citizenship and open avenues to the appreciation of the refinements of life. Yet, for each one there is opportunity to emphasize what talent, genius, necessity, or even inclination may demand. This flexibility of the course with its wealth of opportunity enables the student under the teacher's guidance to "find himself," his capacities and enthusiasms with reference to the choice of a life-career. Thus the intermediate schools of Los Angeles offer five distinct courses: the literary-scientific course, the engineering preparatory course, the mechanical arts course, the home economics course, and the commercial course. Aside from its many internal advantages, this coming intermediate school confers the great boon of holding the children under instruction for a longer period and of bridging the fatal chasm between the elementary and the high school. Leading a greater number of children better prepared in its academic, scientific, technical, commercial and other quasi-professional departments. The work assigned to the elementary grades remains practically the same. Courses of study deal with reading, writing and arithmetic, spelling, the use of the vernacular, nature study, the history of our country (biographical and chronological), some geography, hygiene, physical culture, music, drawing, and some practical manual work, mostly in connection with other subjects of instruction or with the plays of the pupils.

Problems.—The problems of truancy, retardation and varying endowment are destined to become important factors in the reorganization of the elementary school. These problems became urgent with the sincere and consistent enforcement of compulsory education laws about 1890. It soon became evident that the physical and mental conditions of children are not uniform and that individual differences in children demand serious consideration in their education. The fact that children vary widely in their natural gifts and inclinations and the clear discovery of eye, ear and motor-mindedness in children, forced upon the school demands of greater flexibility in method and organization. At first, the attention was chiefly upon mere truancy and certain disciplinary faults. Then, and until quite lately, the stress was upon ability to perform the tasks of the home, of the classroom and of the public, the needs of industrial, commercial, agricultural and domestic life. With these in view, the course of the elementary school is being more and more generally shortened to six years, to be followed by an intermediate course of two or three years and by a high school course of four or three years.

Gary Plan.—A new departure in school management which is attracting much attention proceeds from Gary, Ind., under the direction of Superintendent William A. Wirt. The city of Gary is a high-density industrial community about 30 miles southeast of Chicago. When it was founded in June 1906 the site was a waste of shifting sand dunes dotted with marshes. To-day it is a flourishing city of approximately 50,000 inhabitants, with all the public utilities
and aspirations of a modern city. In 1906 four teachers taught 120 pupils in its first schoolhouse; in 1916 the number of teachers had risen to 30, and that of pupils to more than 6,000. The Gary plan of a school plant is "a playground, garden, workshop, social centre, library and traditional school combined under one management." For these purposes the new Frezel School, erected near a railroad track on a tract of 10 acres; one-half of this is used for playgrounds, two acres for schoolgardens, and three acres for park. There are also two conservatories for nature-study work, the botany work in the high school, and for subjects, such as home work in the schoolrooms. Among the striking features of the work, the following are the most notable:

1. The schools are open the year round, or for four quarters of 12 weeks each. Pupils are held to attend school for three of these quarters, choosing for vacation the one that suits them and the home best. During the free quarter the pupil may attend voluntarily any of the activities of the school or, with the help of the school, find employment in the industrial life of the city.

2. The elementary school and the high school are in the same building. This, it is claimed, removes the chasm between the two departments and tends to hold pupils in the school for longer periods. Moreover, it establishes the same standard of discipline for all grades, increasing sense of responsibility on the part of the older pupils and stimulating worthy ideals on the part of the younger.

3. Throughout, the teaching is departmental. This renders it possible to promote pupils by subfields of special teachers and to do away with supervisors.

4. The school plant is open on Saturdays. Pupils come and go as they please, work or play as they choose under teachers who receive extra pay for this work. The responsibility placed upon pupils who avail themselves of this stimulates initiative and has a tendency to "transform the play impulse into the work impulse."

5. Similarly, certain schools are open four evenings per week for continuation school work and for "social and recreational centre" activities.

6. Constant utilization of the school plant by double the number of classes as compared with the number of available classrooms. This involves the constant use by successive classes of the auditorium, the basements, the library, the gymnasium, and various portions of the playgrounds in such a way that no part of the plant is ever idle during the entire schoolday.

Other phases of the work, still in progress of evolution promise equally valuable contributions to school management. Indeed, the results already attained by Superintendent Wirt have induced a number of cities to seek at least partial enjoyment of the benefits of the Gary plan. Prominent among these is New York which is making extensive experiments with it under the direction of Superintendent Wirt, not without prospects of success.

Among a number of other features in the progressive development of schools within the past two decades, a prominent place belongs to increasing attention to sanitation, to the care for atypical children, the organization of parent-teachers associations, the use of schools as community centres.

Sanitation.—With reference to sanitation, it is reported that in 1914 there were over 500 open-air schools in the United States and that throughout open-window ventilation is gaining ground. Forty States have enacted laws relative to the sanitation of school plants, involving the inspection of schools and supervisors of new buildings, and the right to compel improvements. In a number of instances, these laws extend to rural schools empowering the county superintendent to condemn faulty structures and to inspect and pass on plans for new buildings. Medical inspection laws relate to compulsory health supervision of school children; to examination of teachers and janitors and to regular inspection of buildings, premises and drinking water in order to insure sanitary conditions; inspection to control contagious diseases; annual tests for sight and hearing; provision for the employment of school nurses; penalties or other provisions for the enforcement of the laws. That steady gain is being made in cities appear, from a summary of returns made by 1,406 cities to a questionnaire, sent out by the Bureau of Education in 1914. These returns show, among other things, that 750 of these cities have some form of medical inspection; that 570 have inspection of ears, eyes and teeth; 62 of ears and eyes only; 90 of eyes only; and 20 of teeth only; that 268 have school nurses, and that in all 923 school nurses are reported; that 130 cities have dental clinics and 195 treat the teeth of school children through other agencies; that 74 have general clinics and 33 psychological clinics under expert direction. On the other hand, the sanitary condition of rural schools still is described as deplorable. Indeed, it is pointed out on the basis of comparative statistics concerning defects of school children of the cities and rural districts of five of the older States that for all defects except two, the prevalence of defect was much greater among the children of the rural schools. This is attributed largely to low architectural and sanitary standards in rural regions; ignorance regarding the physical, mental, social, and moral effects of unattractive and insanitary school buildings; false economy of school boards; and lack of State supervision and assistance. However, as indicated above, intros are being made by means of suitable legislation, by normal schools and educational associations, so that improvement cannot tarry long.

Surveys.—The tendency to secure improvement of schools in both rural and urban districts through the agency of careful surveys of existing conditions and needs is steadily extending. In tracing the development of the movement in an address delivered in 1915, Dr. Leonard P. Ayres, director of the division of education of the Russell Sage Foundation, gave an account of the important features of the 30 surveys made up to the time. The following data are culled from this report. These surveys were carried on: seven by individuals, six by universities, five by bureaus of education, three by State departments of education, three by foundations, two by the United States Bureau of Education, two by municipal departments, and two by national societies. The directors of the surveys were professors of education, 13; special investigators, 11; direct-
ors of foundations, four; the United States Commissioner of Education, one; superintendent of schools, one. The cost figures for the different surveys ranged from $500 (Montclair, N.J.) to $125,000 (New York City). The time required varied from three months to two years and two months. From 1 to 12 individuals were engaged in each survey; and the published reports varied from six pages to 2,573 pages in size. Much good has come to the systems thus surveyed in the relation of supervising and teaching forces to each other and to boards of education; in the vitalizing of courses of study and methods of work; in securing minimum standards for dol work, notably in the three R's, setting free much time for work of greater value. As a result many new surveys are being called for by city and rural school authorities. A number of cities, indeed, have established permanent bureaus of efficiency. Notable among these are Boston, Detroit, Kansas City, New Orleans, New York and Oakland.

Parent-teachers' Associations.—Ideally, the public school is an organic factor of our democracy. By it the coming citizens are to be fitted in knowledge and character for the performance of their duties. On its work depends the political and economic welfare of the state, as well as the individual and social welfare of each coming citizen. It is obvious, therefore, that fathers and mothers should feel a direct and personal interest and civic responsibility in the organization and work of the school, an interest and responsibility that cannot wholly be delegated to representatives. To such considerations the school owes the organization within recent years of mothers' clubs, parent's guilds and parent-teachers' associations which by their very existence have been and are exerting a highly beneficial influence upon the progressive development of the school. In a general way, the object of these associations is co-operation between the home and the school, to induce the school to consider in its work the needs of the home and to induce the home to aid the school in its attempts to meet new conditions and civic needs. In a city of 100,000 inhabitants in the Middle West such associations provided pianos, valuable art objects, stereoscopic lanterns and slides, and other physical apparatus, thereby declaring emphatically and in most amiable fashion that in the opinion of the people music, art and science had a legitimate place in the curriculum. Elsewhere the schools owe to such organizations in a large measure the establishment of kindergartens, the teaching of domestic arts, the enrichment of school libraries, the introduction of school lunchrooms, the encouragement of schoolgardens, of school festivals and school exhibits. They arrange for round table discussions of topics relating to the children's health, their conduct in and out of school, the nature and value of play, the influence of environment and every phase of child-study (q.v.). They invite experts to lecture on similar and other timely topics.

Social Centres.—Of deep significance for the public is the fact that the school have, as well as for the other departments of the public school is a correlated movement of recent origin, namely, the wider use of school buildings for *social centre* and *community centre* activities. Aside from the fact that it utilizes the costly school plants for worthy purposes of public import at times when they are not needed for the direct purposes of the school, this movement means that the people are beginning to realize the deeper fact that the school has not completed its work when it has bid its pupils to enter upon some way to earn a living and that these young people still need opportunity for further social and character development as well as for additional instruction under wholesome influences. The movement originated in efforts to vitalize the work of rural schools by a variety of social occasions interesting to parents and in the needs of parent-teachers' associations in cities; but within less than a decade it has assumed wider proportions. In 1915 the Bureau of Education reported from 603 cities of 5,000 inhabitants and over, detailing the more or less extended adoption or admission of social, civic and educational activities in their schools. Among the activities mentioned the following are prominent: meetings of mothers' clubs, parent-teachers' associations, women's civic clubs, musical organizations, art clubs, Chautauqua circles, Boy Scouts, Campfire Girls, gymnastic clubs, dramatic and literary clubs, debating societies, lectures, evening schools for adults, various courses. Already 18 States have secured legislation permitting the use of schools for the purposes indicated.

The management of these activities still is in an inchoate condition. In Youngstown, Ohio, the local playground association provides for supervisor and supports social centres in the schools. In Trenton, N.J., it is the Social Centre League, assisted by the principals and teachers. In Plainfield, N.J., there is a citizens' committee on evening recreation in which the Board of Education is represented by its president and the superintendent of schools. In Grand Rapids, Mich., the park and school boards together maintain a department of municipal recreation. Philadelphia has a municipal recreation commission and in Kansas City, Mo., the public welfare board co-operates with the board of education. Quite steadily, however, the responsibility is passing into the hands of schoolboards and its employees. Thus, in Pittsburgh, Pa., the direction is in the hands of the director of evening schools; Cincinnati, director of social centres; in Boston, a similar official works directly under the superintendent of schools and has the advisory assistance of the Women's Municipal League; in Milwaukee, a special department of school extension controls the after-school activities.

Increasingly, too, we find in new elementary school plans adaptations to the new uses of the buildings. Prominent among these are auditoriums, gymnasiums, lunchrooms, plagues, library rooms, swimming pools and a plex of bowling alleys. In the equipment movable the Women's Municipal League; in Milwaukee, the social centre directors are provided with amply furnished private offices; many of the rooms intended for recreational work are in the basement and have been made attractive through the use of paint, pictures, book cabinets and a supply of suitable chairs and tables. The assembly rooms are provided with large electric lamps of high power and sturdily screened to adapt the room for basket ball and similar games. In most of these large rooms there are
also through footlights and sliding curtains, as well as motion picture booths.

EDUCATION, Engineering. One of the most marked features of recent educational history is the increasing attention given to engineering education. Engineering has been defined as the direction and control of the forces of nature for the use and convenience of man; but until comparatively recently there was no systematic attempt to formulate the principles of engineering nor any organized effort to instruct beginners in these principles.

Engineering education, the application of the sciences to the needs of man, in this country has been a growth entirely within the past 100 years. At the beginning of the 19th century, organized instruction in engineering was confined to two or three schools on the continent of Europe. The United States Military Academy was founded in 1802, and for about 30 years was the only organized agency for engineering education in America. For three-quarters of a century a surprising proportion of the graduates of this institution practised engineering in civil life, not because the education there given was what would now be called engineering instruction, but because it was the best preparation for engineering practice that could then be obtained. At Troy, N. Y., between 1825 and 1835 was established the first institution in the world for giving instruction in engineering not military. In the next 30 years only four engineering schools were founded, of which only two were really entitled to the name engineering. At the close of the Civil War the graduates of the engineering schools, exclusive of West Point, numbered less than 300.

In 1862 Congress passed an act giving to the several States public lands for the benefit of "instruction in the arts and sciences relating to agriculture and the mechanical arts"; and shortly after the close of the Civil War many of our engineering schools were organized under the provisions of that act. Since 1878 the number of schools of engineering has increased more rapidly than our population. The number of institutions in which engineering is taught has increased with astonishing rapidity in recent years; in 1889 there were 3,043; in 1899, 9,659; in 1900, 11,874; in 1901, 15,753; in 1910, 30,329. The rate of increase is most remarkable; during the first decade above the average annual increase was about 660, while during the last three it is practically 2,300. The increase in the number of students pursuing an engineering course is much greater than the increase in the number of schools. In 1899 the former increased 444 per cent, while the latter increased only 48 per cent. At present the engineering students constitute 21 per cent of the total number of male students pursuing a collegiate course.

But the most significant fact connected with the growth of engineering education is the improvement in the methods employed and in the scope of instruction. The teaching force of the engineering schools has been increased and the material equipment has been extended, thus permitting a radical change in the methods employed and in the scope of the instruction given. The best engineering colleges of America are offering unexcelled opportunities for the acquisition of the fundamentals of an engineering education. Few, if any, Americans now attend European engineering schools, for it is generally conceded that the American schools, in equipment, methods and scope of instruction, are superior to any European schools — at least for American engineers. German and British engineers quite generally concede the greater effectiveness of American methods of engineering instruction, particularly in the use of fully equipped laboratories and shops and in the value of various forms of practical instruction. The curriculum of the engineering college at present consists of about 10 per cent of English or modern foreign language, usually the latter; 30 to 40 per cent of indirect technical studies, as mathematics, physics and drawing; and 50 to 60 per cent of technical work. Over half of the engineering students are in institutions requiring for entrance the completion of a four-year high-school course, and another quarter require a three-year high-school course.

At the beginning of the specialization of engineering education practising engineers doubted or denied the value of a technical training for young engineers, and distrusted the engineering graduate; but now general managers and chief engineers prefer technical graduates, since they have been trained in scientific methods of working, and have a knowledge of the fundamental principles underlying all engineering practice, and look upon the world of truth from the view point of a man of science. The national engineering societies now give
credit for training in the engineering school toward the requirements for admission to membership, and the most cordial relations now exist between instruction in the schools of engineering. Within recent years, largely if not mainly through the influence of the technical colleges, engineering has ceased to be traditional and has become scientific; and engineering has come to be recognized as a learned profession.

The wonderful growth of engineering education is of interest to the young man who is trying to choose a livelihood; but it is of vastly greater importance to the citizen who is interested in the continued growth and prosperity of the country. For the past few years our newspapers and our magazines have had much to say about our rapidly increasing foreign trade, chiefly in the way of recording its marvelous growth, but with little attention to its facts, and the Englishman who believed it possible to the humblest to rise to the highest position; (3) the fact that we are a great nation, speaking one language, with no barriers in the way of the freest social and commercial intercourse; (4) our great and varied natural resources of mine, forest and soil; (5) the high price of labor, which stimulates the introduction of labor-saving machinery; and (6) the general dissemination of education, which made possible the effective use of labor-saving machinery and permitted the nation to profit by the capable and ambitious workers of all classes.

But since 1900 we have entered upon a new phase of national and industrial life. Until then we had been engaged in subduing the great West, in establishing homes, in founding cities, in building railroads. By legislation we barred out foreign competition and preserved the home market for our own products; but now the new land in the West is occupied and there is no longer an outlet in that quarter for our surplus labor. Our industries have found the home market. If prosperity is to continue in the future as in the past, we must have new markets; and in these markets we must meet the competition of the world. What are the conditions necessary for success in that field?

The modern commercial history of Germany and Great Britain is significant.

For many generations Great Britain was preeminent in manufactures and in commerce. In 1870, she did one-quarter of the world’s business, and she believed that their industrial supremacy was secure; but in a single generation they were awakened to the fact that they were rapidly losing ground and in some respects were already third in the race. With Germany the almost exact reverse was true. Thirty years before she had a comparatively unimportant place in the commercial world, but in a single generation all this had been changed. The power employed in manufacture had increased four times as rapidly as the population, and the tonnage of the ships engaged in foreign trade had increased ten-fold. From 1870 to 1895 German foreign trade increased 42 per cent, while the English increased only 13 per cent; and from 1895 to 1900 German foreign trade increased $200,000,000, while England’s increased only $30,000,000. Why is it that Germany, with one of the poorest seaboard in the world, with a poor soil and with a degenerating political condition, was thus able to in a single generation to outstrip England—the mistress of the sea and the foremost manufacturing nation of the world?

The modern marvelous industrial development of Germany was coincident with and dependent upon the development of industrial education. About 30 years ago Germany reorganized and strengthened her technical schools and established many new ones, until the provision for technical education became the wonder and admiration of all who know the facts. In the number and equipment of her technical schools Germany led the world. She was fully alive to the commercial importance of scientific investigation and technical education.

England, too, was a sensitive, was confident in the superiority of her own manufactures, passed a law that all foreign-made goods should be labeled with the name of the country from which they came. This stamp was intended to be a mark of excellence, and the Englishman, the British, the label “Made in Germany” appeared on the highest grade of goods, which the Englishman had assumed to be of home manufacture. England received another shock when she found her street railroads being supplied with electrical apparatus made in America, and when she discovered that her manufacturers were importing American machine tools, and when America obtained the contract for bridges in her African and Indian colonies. After vainly endeavoring to convince herself to the contrary, England is ready to admit that she is being distanced in the industrial and commercial race, because she has not kept alive to the intimate relation between science and industry, and that in neglecting the technical education of her people she has failed to train her industrial army. In these days of sharp competition and small margins, when the entire world is in the market, the nation that most carefully trains its industrial army will gain industrial supremacy. Of course, there are antitaxagist, antiunion and tariff; but not one of them is of such transcendent importance as that training of the individual which enables him to produce the most in the least time and at the smallest cost.

What is the lesson for the United States? It is, that if this country is to extend or maintain its foreign trade it must look carefully to higher education. We already have a goodly number of technical colleges, but in number and equipment they are inferior to those of Germany, and in 1895, they are better adapted to American conditions than would be the German type. Most of our technical schools are in need of additional equipment and more instructors. Technical education in this country was inaugurated about 30 years ago, and the engineering education given now is vastly better than that of 25 years ago; but there is still opportunity for improvement. The one thing necessary is adequate financial support. Technical education, especially engineering education, is very expensive. A large and costly equipment is required, and machines and apparatus wear out or become antiquated and must be replaced by new. Our technical schools need a more generous support, so that they may add to
their facilities and extend their courses. Any money given for this purpose will be more profitably expended, for abundantly proves that money given to technical education is returned many fold in the increased productive-ness of the nation's industries.

To be most effective, technical education must be practical. Without less it is, many will be debarred from its privileges, and society will be dependent upon a few workers from a favored class. One of the main reasons why the United States has been so prosperous in the past is that the nation has been free, and consequently the higher ranks have been continually recruited from the lower. The way should be open that the humblest may rise from the lowest to the very highest rank. Education should not be bestowed as a charity, nor as a means for helping the recipient to earn a livelihood, but because the proper education of the people is the only basis for social security, economic prosperity and the highest national development. The conclusion almost certainly follows that the new world will not be free until the nation has been free, and consequently the higher ranks have been constantly recruited from the lower. The way should be open that the humblest may rise from the lowest to the very highest rank.

At present the engineering college is engaged chiefly in giving the rudiments of an engineering education, but it should do more than simply impart knowledge. It should be a service to the nation, and provide for the adequate technical education of the people. The Federal government and the States, particularly the North Central ones, have made magnificent provisions for technical education, and others seeking it require increased equipment and the change in industrial life demands a higher grade of work.

There are numerous scientific and practical subjects that are very much in need of investigation. The practising engineer frequently encounters problems which ought to be investigated experimentally, but it is seldom that he can command the necessary laboratory equipment or find the time for such work. There should be some place where such problems could be sent for solution; and where is a better place than a research laboratory established in connection with a technical school? Much of the equipment required in the work of instruction could also be used in research work. The professors now do more or less such work, but they are usually, and rightly, employed because of their instruction. The research part of instruction consumes so much of their time and energy that they cannot do much in the way of investigation. There should be trained corps of men engaged in original research in matters relating to engineering and manufactures, much as is the case with agricultural experiments and investigations now being carried on at most agricultural colleges. Many such investigations are returning to the public each year benefits equal to more than a hundred times their cost. Of these a few are: The breeding of cotton and of corn, the prevention of smut in oats, and the spraying of apple trees for the destruction of harmful insects. Why should not similar aid be given to our manufacturing interests?

The following are the words of a prominent practical engineer: "The cost of duplicating the land, buildings, equipment and endowment of the largest and most complete technical school in the United States, training more than 1,500 young men, is little more than half the cost of one of the latest battleships, and the running expenses of one of the largest technical schools are about the same as for keeping a battleship in commission. The technical school has a far more important part to play than the battleship in the 'first line of national defense.' The time has already come when the commonwealth and the nation should contribute more liberally to the burden of its support and help it to ever broader usefulness. The demonstration of its great value to the prosperity of the state is already complete. With the increasing numbers of students and with the rapidly increasing cost of laboratory facilities needed for the best training, the need of funds is greater than private munificence can be relied upon to meet. In the reawakening of the old spirit of commercial adventure in foreign lands, we must look to-day for our hope of success on superior excellence and economy of manufacture and in the calling of our engineers to foreign lands. The growth of our cities is laying a burden of new and larger problems on our departments of public works, a burden which only those trained in the schools of engineering can carry wisely and well. The time has come to see that every enterpriser clearly, will urge again and again a generous support to schools of engineering by city, state, and nation when private munificence falls short."

The increase in the number of engineering students attending college has not been as great in recent years as in the period covered by the statistics in the earlier part of this article. The number of engineering students reached a maximum about 1910, and fell off about one quarter during the next five or six years. This falling off occurred in all engineering courses, but was most marked in civil engineering; and was due to legislation affecting the rates of railroads and public utilities and the development of water powers which caused a curtailment of expenditures in those lines. However, in the meantime, the number of engineers finding employment in other lines greatly stimulated the demand for engineers in new fields; and before the world war disturbed industrial and financial conditions in this country, the demand for engineers exceeded the supply. It is generally and confidently believed that after the close of the war there will be a greatly increased demand for technically trained engineers.

Since the advent of the automobile, the peace of the world, there has been a general tendency to look with suspicion upon anything of German origin; and hence a few words concerning the reference above to German technical education may not be out of place. Unquestionably Germany for a generation before the great war had a marvelous industrial and commercial development, and also unquestionably it was largely due to the attention given to higher technical education. The rest of the world may profit from a study of the causes of Germany's great development without approving some of the commercial methods and social results or her military motive.

Professor of Civil Engineering, University of Illinois.

EDUCATION, Health. See Health EDUCATION.

EDUCATION, Higher, in the United States. In the transit of civilization from the Old World to the New, higher education played
an early and conspicuous part. The proportion of university men among the colonists of Massachusetts Bay was larger, but in either 90 and 76 English university men were among the emigrants prior to 1648, or 1 in each 200 or 250 of the total population of the colonies. Seventy were graduates or former students of Cambridge, 20 of them from St. John's College, England. The rest had attended Emmanuel and Peterhouse, and there learned the love of truth and sense of duty that signally characterized their later lives.

These men became the leaders in church and public affairs in New England, and one of their earnest desires was the creation of a new Cambridge University near Boston. It was only six years after the founding of Boston that their dream had partial realization in the founding of Harvard College, for on 28 Oct. 1636, the General Court agreed to give 400 pounds towards a school or college.3

"After God had carried us safe to New England," writes the historian, "and we had builded our houses, provided necessaries for our livelihood, erected convenient places for God’s worship, and settled a civil government; One of the next things we longed for and looked after was to advance learning and perpetuate it to posterity, having been taught to leave an illiterate ministry to the churches, when our present Ministers shall lie in the Dust." Two years later John Harvard, a clergyman who had been a year in the colony, died and bequeathed one-half of his estate and his precious library of 300 volumes to the enterprise. This, with other gifts, enabled Harvard College to open.

Founding of the First Colleges.— Attempts to found a college in Virginia began before the Mayflower sailed to Plymouth, in the grant of 10,000 acres for a university made by the Virginia Company, but it was not until 1693 that the planters, suffering from sickness, poverty and massacre, were able to obtain sufficient aid from England to found their "place of universal study." The entire population of the colony, if gathered together from the scattered plantations, would hardly have filled a sizable city, and the college could hardly have profited from the liberal aid which it received as a child of the Church of England: aid to which the dissenting colleges of the northern colony could not appeal. Had the English sovereign and the High Churchmen who lent substantial assistance been able to foresee the infant college becoming the mother of rebellion and the "training ground of democracy," inspiring the students, Jefferson, Monroe, Tyler and Marshall and their colleagues with faith in the inalienable rights of man, and granting Washington his surveyor's license, they had perhaps been less prompt with their gifts.

Tradition has it that the third American college, Yale, had its origin in the bundles of books which the founders are reputed to have carried to Branford as endowment for the little collegiate school that held its commencement at Saybrook. A child of Harvard, the school was founded in 1701, that the youth may be instructed in the Arts and Sciences, who . . . may be fitted for Publick employment both in Church and Civil State. The college found a permanent home in New Haven after more than a decade of migratory existence. It received firm foundation in the liberality of Gov. Elihu Yale, a wealthy English colonial official born in Boston and resident in London, who shipped consignments to be sold for the benefit of the college and gave also many books to the college library. Equally generous was the great English philosopher, George Berkeley, who gave the Puritan foundations, that collection of books ever brought to America at one time as well as the "Dean's" farm which he had occupied in Rhode Island. The colonists gave from time to time as they were able, sometimes land, sometimes books, material, labor or plants, apparatus, and the general assembly appropriated annually £100 or £200 besides special appropriations. Successful foundation came to Yale, as to all the other colonial colleges, only at the price of common sacrifice, and liberal public policy at home, and generous aid from England.

Benjamin Franklin in his 'Proposals Relating to the Education of Youth in Pennsylvania' laid the framework of the future University of Pennsylvania. The narrow curriculum of the English colleges, the Latin and Greek declamations and recitations seemed insufficient to Franklin. "It would be well," he wrote, "if they (the pupils) could be taught everything that is useful and everything that is ornamental. But that their time is short. It is therefore proposed that they learn those things that are likely to be most useful and most ornamental, regard being had to the several professions for which they are intended." Thirty-four citizens of Philadelphia undertook to establish an academy of the type suggested and to lay foundation for a seminary to erect a more extensive and suitable seminary. In January 1751 the academy formally opened. It embraced an English, a Latin, and a mathematical school with wide range of studies.

William Smith, author of a broad plan of education for an Utopian college of "Mirania," was chosen provost of Franklin's academy, and guided the institution through its notable, if tumultuous, early history. He bitterly disappointed Franklin, quarreled with the provincial assembly, and was believed to be insane, but he built into fact enough of his own and Franklin's early ideals to make the college of Philadelphia a model for all later American colleges.

Princeton, founded in 1746 as the College of New Jersey, had for predecessor the Log College of William Tennant, near Philadelphia, a college of the simplest type where, with Ten-ant's four sons, future clergymen of the Presbyterian Church received instruction and council. Princeton influence was active in the foundation of Brown University in the Rhode Island colony, organized by the Philadelphia Baptist Association under the agency and presidency of the Rev. James Manning, a graduate of the New Jersey College.

Kings College in New York (now Columbia) owes its origin to the joint interest of the colonial assembly and Trinity Church. The assembly declared its belief that a proper and ample foundation for the regular education of youth would greatly tend to the welfare and reputation of the colony and voted an annual appropriation of £500, in addition to author-
EDUCATION, HIGHER

izing lotteries, believing "so good and laud-
able a design must readily incite the inhab-
ity to bestow contributions on a lottery." Trinity Church offered "any reasonable quan-
tity of the church farm" for the college build-
ings on condition that the president be forever a member of the Church of England and that the liturgy and collect of the Church be used. Both, however, survived the stormy party and the minority who seem to have had in mind the erection of a non-sectarian univer-
sity under the direct control of the assembly. If the plan for the new college was not as lib-
eral as the minority wished, it was in practice less sectarian than any milage erected.

Dartmouth, established by the Rev. Eleazer Wheelock in 1769, was an outgrowth of Moor's Indian Charity School. Ten thousand pounds were collected for it in England. Situated on the frontier of the Indian country, remote from populous towns and white settlements, it early worked out a rough sort of vocational training that was prophetic of a later day.

Rutgers, established by royal charter as Queens College, in New Jersey in 1766, com-
peted with most of the colonial col-
leges. Twelve were founded in the colonies prior to the Revolution, but the others did not survive.

The colonial colleges were not mere copies of English prototypes. Each has an individu-
ality of its own. Each is a product of its own primitive community. Each retained permanent characteristics given by the groups of able and independent men that founded and presided over them. Their achievement is a great one. They realized the hopes of their founders and more than any might not have been realized in the new world and that able leaders in church and civil affairs might not be wanting, but they did more.

They furnished the leadership in the great debate with England and legislature in parliam-
et and newspaper that preceded the Revolutionary War; they furnished a notable proportion of military leaders and soldiers in the terrible struggle, and they supplied largely the practi-
cial statemanship that joined the discordant colonies into the state that was to become one nation. Without the colleges the Revolu-
tion could not have succeeded or would have been deferred for a generation.

The colleges paid the price. All but one or two were forced to close their doors for a time. For a time Harvard's dormitories resounded with the heavier footsteps of provincial troops. Washington took command within a few rods of the college yard and occupied the president's house as his headquarters. The scientific appar-
atus was removed to Andover and instruction was given. Concord Yard formed her work interrupted and resumed for a season a migratory life. Her president was subjected to indignities and the students suffered from shortage of food.

Nassau Hall was the scene of a crucial battle of the war: Nassau Hall still bears the scars of battle and gave shelter in turn to provincial and British troops. Brown's Hall was used as a barracks and hospital. Kings students drove the Tory president into exile, but the col-
lege buildings were later occupied by British troops and no commencement was held be-
tween 1777 and 1786. William and Mary was used by Washington as a hospital, and Queens College was forced to evacuate a branch of the Raritan to escape active hostili-
ties. Remote Dartmouth alone seems to have continued undisturbed in her scholastic pur-
suits, but suffered the loss of her Indian stu-
dents, allies of the British. These colleges all, however, survived the struggle and before the close of the 19th century closed their number was increased by 17 new foundations, among which were Hamp-
den-Sidney (1776), Washington and Jefferson (1787), Dickinson (1783), Georgetown (1791), Williams (1793), Bowdoin (1794), Union (1795), University of New Hampshire (1789), University of Vermont (1791), and Middlebury (1800).

Government Aid.—Although generally founded as independent, self-governing corpora-
tions closely related with some religious de-
oxination, practically all the early colleges received generous aid from the colonial or home government either in gift of money, grant of land, lottery, privilege or special tax. The provision was, however, pitifully small. The total property to all colleges by the end of the 18th century has been estimated as not in excess of $1,000,000 in value. The present property of the colleges and universities is nearly 800 times as great. The equipment of the early colleges was of necessity of the sim-
plicity. A few books were the most essential, as the gifts of John Harvard, Elihu Yale and Bishop Berkeley abundantly indicate. Food and dormitories for the students, a house for the president, simple apparatus for those col-
leges which offered courses in natural philos-
ophy and astronomy, and an unpretentious col-
lege hall were the usual requisites. Wil-
liam and Mary had for the time a notable build-
design by Sir Christopher Wren. Nas-
sau Hall was esteemed one of the finest build-
ings in the colonies. College Hall in New York was "exceedingly handsome, the most beautifully situated of any college in the world." But these were the exceptions. The president's house often served as place of reception. He was often the sole member of the faculty, teaching all the subjects of the curriculum. The faculty and tutors were always few in number.

A New Era.—The close of the Revolution ushered in a new educational era. Some of the colleges, as Kings, were virtually defunct and required refounding. Others had suffered so severely that larger appropriations were needed than the impoverished States could well afford. But chiefly significant is the new patriotism that preferred education at home to education in Europe and the new conception of education as not primarily a church function but as an instrument of national spirit and national life. The new impulse came: in part from France and was in part the natural result of newly-won national independence.

The University of the State of New York was founded 1784-87 to serve an organized system of higher schools adequate to the needs of the State. The State of Georgia provided in 1784-85 that all public schools instituted or to be supported by funds or public money shall be considered as parts or members of the Uni-

versity of Georgia. Thomas Jefferson be-
lieved profoundly in the new educational faith. As press of other duties permitted, he concerned himself with the project of developing in Virginia, as a model for all the States, a true organized system of schools crowned and controlled by a State university. The plan was proposed in 1779 and partly carried out in 1796. It was not until his old age that he found time to incarnate his idea in the foundation of the University of Virginia. Jefferson founded in the university a new type of institution. The purpose of a State university he considered to be (1) To form statesmen, legislators and judges; (2) to expound the principles and structure of government, the laws which regulate the intercourse of nations and a sound spirit of legislation; (3) to promote industry, agriculture, manufacturing and commerce; (4) to develop the reasoning faculties of the youth, enlarge their minds, cultivate their morals and instil in them the precepts of virtue and order; (5) to enlighten them with mathematics and physical sciences.

Washington in his plan for a national university was moved by the same impulse. He thought a national foundation the surest way to establish American education equivalent to that formerly taught by many American youths of good family in the English universities, and he believed that the gathering of students from all the colonies into one institution would foster a common national spirit. The plan of Washington has never yet been realized but it has found support in the opinion of many of our wisest Presidents and most experienced educators.

So strong was the democratic impulse and the influence of Jefferson's university that private foundations came to be viewed with something like distrust. In some States the legislature vainly sought to obtain control of existing colleges by offer of financial support. In three States, at least, the colleges were for a brief period converted into public institutions, but soon reverted to their original character. The famous Dartmouth College Case put an end to this attempt, it being decided that the charters granted educational foundations were inalienable. The effort had greater success in the States where private or public foundations had not a firm foothold. Provision was made in the constitutions of most of the new States for the establishment of State colleges or universities to crown the system of public schools. The national government laid substantial foundation in land grants. The grants of the Continental Congress in 1787 reserved perpetually two entire townships to the States to be erected in the Ohio country for the purpose of a university. One or two townships of public land were granted each of the newer States for educational and were usually devoted to the establishment of a State university. The Morrill Act granted public land for instruction in agricultural and mechanical subjects in proportion to population: 30,000 acres for each member of Congress representing the State. By the acts of 1890 and 1902 $30,000 annually was given each State annually for the same purpose, and by acts of 1887 and 1906 $30,000 annually was granted each State for Agricultural Experiment Stations, which were usually made part of the State university or agricultural college. The effect of these grants was to stimulate the growth of State institutions and to broaden their curriculum. The great universities of California, Illinois, Minnesota and others owe their origin to the Morrill act. In other States agricultural colleges were established, as in Massachusetts, Michigan and Iowa; and in others the proceeds were devoted to the maintenance of departments in connection with the university. The idea of the national policy, joined to liberal State appropriations, was the creation of "the most comprehensive university foundation the world has ever seen" in the newer Western States. The annual appropriation of several exceeds $1,000,000 each for current expenses. In States the proceeds of a permanent mill-tax assures a fixed minimum of income. Generally no tuition fee is charged residents of the State, in no case is the fee more than nominal except for professional study. These institutions are educational. Of the 100,000 women attending colleges and higher schools about 30,000 are in State universities. The State universities are maintained as an integral part of the State system of public schools and graduates of standard high schools are admitted without examination. Thus the States provide a democratic system of education aiming to make available to each of its future citizens as complete a training as the mental equipment of each makes possible.

Recently the State universities have taken upon themselves much greater tasks. They have attempted to see to it that the expert knowledge of which they are the accredited custodians shall become embodied in the practical affairs and industry of the State: that the current practice of agriculture shall apply the expert knowledge of the agricultural sciences; that actual government shall embody the principles of political and social science; that actual teaching shall embody the principles of pedagogy and hygiene.

They further interpret their obligations to the State to include not only the student body in the university but all residents of the State with intellectual interests and aptitudes. The attempt is made to extend the university over the entire State and carry knowledge directly to the people. University centres are organized in whatever a sufficient number of people can be interested and instruction and lectures are given far from the campus by members of the university staff. Instruction is given by correspondence and an information service is operated by which any resident may consult the experts of the university in reference to his practical difficulties. The intelligent discussion of public questions is fostered, music, pageants and libraries are made available to any community.

Recently "surveys" have been made of several State universities. A survey is a thoroughgoing but sympathetic and constructive examination of the equipment, administration, standards, methods and ideals of the institution to determine the relative efficiency of its organization, the value of its service to the community and the potency of its ideals. Surveys may at times degenerate into "investigations," but when true to their mission are practical and constructive. The State universities investigated not only have stood fairly well the test of the
searching examination of the survey experts, but have been quick to adopt their suggestions for improving and strengthening the educational plant. A survey may extend to the entire educational resources of a State, and suggest a new alignment of educational institutions.

The Municipal University.—A type of college of municipal development asked in spirit to the State university, is the municipal university. The most conspicuous and purest examples are the College of the City of New York and the University of Cincinnati. The College of the City of New York was organized as an "Academy or College" in 1847. Under the presidency of John H. Finley it was developed into a great institution of collegiate standards supported by direct appropriation from the municipality. Nearly $6,000,000 was appropriated for new buildings, grounds and equipment and the annual appropriations are over $600,000. The college is distinctly city minded, and takes as its chief function the task of producing a higher type of citizen for the great city-state.

The University of Cincinnati is organized more in the pattern of the new State university. Its relation to the city government is very close. The political science department of the university conducts a municipal reference bureau in the city hall; the college for teachers uses the public schools for the training of its students in cooperation with the superintendent of schools in the supervision of teachers and in investigations and reports. The department of psychology co-operates with the schools in the study of backward children. The department of social science co-operates with the city department of charities and the courts. The college of medicine conducts a free dispensary, maintains milk supply stations and sends out visiting nurses. It also conducts the laboratory of pathology of the City Hospital. The engineering college conducts a city testing bureau and co-operates with the various city departments doing engineering work. These are a few typical co-operative activities. Students study in the university and do practical paid work in city departments and manufacturing plants in alternate weeks. Eighty-five per cent of the men and 30 per cent of the women earn the whole or part of their own support. They participate in the things they are studying. The university conducts evening and external courses, and makes every effort to reach the larger number of men and women who but for the university would be debarred from an adequate education.

The rapid growth of city universities is evidenced by the organization in 1914 of a national association of urban universities consisting of forty institutions. Several of these are properly public municipal colleges. There are now nearly 100 State and municipal colleges and universities. In them are educated approximately 40 per cent of the college and professional students of the United States. Some day the college of private foundation, of which there are 474 offering instruction of college grade or higher as measured by the United States Bureau of Education, college of private foundation has been as phenomenal as the evolution of the State university.

The colonial college developed into the modern university chiefly under European influence. German influence in American higher education began with George Ticknor, Edward Everett and George Bancroft who were students at Göttingen early in the 19th century. They were followed by an increasing number of American students who pursued advanced studies at the great universities, especially at Berlin, Göttingen and Leipzig. On their return to America these men introduced the new methods of research into their advanced classes and through the influence of students profoundly affected the methods, structure and ideals of the American university. The lecture system was developed. Productive scholarship became the common aim. The University of Michigan was remodeled in 1852 on the continental plan. Johns Hopkins was in its fundamental ideas founded on foreign practice and many of its professors were foreign trained. It was primarily a graduate school devoted to the development of research and publication, in science, history and medicine.

Organization and Work.—The chief marks of a complete university are (1) that it is a place of universal studies representing the entire field of knowledge; (2) that it is devoted primarily to research or the training of men for research from which follows (3) that it is devoted largely to experimentation and the elaboration of methods of research and the technique of the science; (4) that it offers the highest possible training for the great professions, law, medicine, theology and engineering. The university thus becomes a "center of free inquiry," a "seat of true learning," a place where thought is freed from all fetters, where life takes cognizance of science to the advancement of both.

The international character of the higher learning is reflected in the development of international exchange of professors. Harvard and Berlin entered into such reciprocal relations in 1904. Harvard and the Sorbonne began a similar exchange in 1911, followed by Columbia and Berlin and The University of Chicago and Göttingen.

"On the maintenance of the university," says Daniel Gilman, former president of Johns Hopkins University, "modern civilization depends. No tradition, no dogma, no hypothesis and no theory can escape from scrutiny, and none can long survive if it is found to rest upon false premises, imperfect knowledge or fallacious reasoning. The universities are the discoverers and explorers of new domains. They are the modern judges of the world. The very processes they employ in ascertaining the truth are favorable to the development of sciences and the education of acute and independent intellects. ... Rare minds will first perceive the truths, and then will teach others. In due time the advanced positions of the philosophers and scholars will be occupied by the multitude and forward will go the progress of the universities to make new conquests in the dark continents of ignorance and uncertainty till there are no new fields to conquer."

The Association of American Universities represents fairly those institutions that have
approached to the requisite facilities for universal studies and the advancement of learning. The Association includes 22 institutions, one-half of which are State universities. The universities of private foundation holding membership are Johns Hopkins, Columbia, Harvard, Cornell, Chicago, Yale, University of Pennsylvania, Princeton, Leland Stanford, Clark and the Catholic University of America. These great endowed universities make and maintain the highest intellectual and scientific standards of this country. The higher degree conferred by the universities are usually the M.A. degree and the Ph.D. degree. The M.A. degree usually represents one year of graduate work and passing of a general examination and the writing of a brief thesis. The Ph.D. degree represents three or more years of graduate study, one, at least in residence, the passing of an extended examination and the writing of a dissertation based on individual research and constituting a contribution to knowledge. In 1861 the first doctorate was conferred; in 1914 over 500.

The richer private institutions have established numerous scholarships and fellowships. In this policy they have been influenced by the desire to make the private college a real democracy of talent as the State universities do by free tuition. The University of Chicago reports over 1,000 scholarships and fellowships, Yale over 400, Harvard 600, the University of Pennsylvania nearly 700. The State of New York has established a comprehensive system of State scholarships, yielding each $100 for four years in the approved colleges of the State, awarded to those who obtain the college-entrance diploma with highest rank. Seven hundred and fifty scholarships are awarded each year, making 3,000 in force, at a cost to the State of $300,000 a year. The motive in this important legislation is the same that influenced the Western States in the establishment of State universities.

The general establishment of graduate and professional schools has placed the college in a position of real danger. The development of the university has complicated its problem and confused its status. Many colleges are in organization not colleges but low grade universities, properly speaking, the place between the high school and the graduate university or higher professional school. It may be an independent institution or one of the several schools forming a university group. A college of standard grade requires for admission the equivalent of eight years' elementary school work and four years of high school work. It requires for the bachelor's degree a four-year course or its equivalent. This brings the normal student to the higher professional school or graduate school at an age of 22 or 23, and delays the practice of his profession to the age of 26 or 27. There has been constant complaint of the length of the educational sequence and repeated efforts have been made to save time somewhere in the process. Differentiation between a junior college and senior college, by which college work may be ultimately limited to two years and university work begun in the senior college, is an interesting experiment. A three-year college course has been tried, and in some institutions, at a cost of $1,200, it permits professional work in the fourth college year, but defers the granting of the bachelor's degree until the end of the fourth year.

Course of Study.—The influence of the university has operated to introduce into the college a greatly modified curriculum. Until 1870 most colleges provided a four-year course of prescribed studies. So rapid was the growth of the sciences, natural, social, political and applied, as well as history and philology, that the old course of study did not serve to orient the student into the modern world of thought. The problem was met by the multiplication of courses, the multiplication of professors and instructors and the introduction of a greater or less liberty of election between courses. The larger colleges offered in 1914 10 or perhaps 20 different courses for every one offered in 1875. The extreme elective system is generally recognized to have been a failure in the college as it has been a success in the university. The present tendency is to prescribe those subjects which are regarded as essential to a liberal education, to permit election between courses of related courses rather than between individual courses and chiefly in the last two years of the college course. Much has been done to introduce a greater degree of unity, continuity, breadth and profundity into the curriculum. A promising venture was the establishment of the perceptorial system at Princeton and since adopted in part by a number of colleges. The preceptors enter into close relationship with small groups of students, guide their reading, give personal attention to their difficulties and are able to influence their choice of studies from personal knowledge of individual aptitudes and deficiencies. Honors courses are provided in some colleges for students desiring to attain high rank in carefully selected sequences of courses. A general examination is sometimes substituted for term examinations and tests a more permanent deposit of knowledge.

The position of the college, however, is not yet secure. Its final articulation with the high school below and the graduate and professional school above has not been finally determined. That it is destined to have a permanent place in the educational system seems certain, and the solution of the crucial time problem may come with a relief reform of the college has the process now arbitrarily divided into four distinct and different educational stages and four types of schools, elementary, secondary, college and university.

Professional and Technical Schools.—There is space but for a few brief sentences concerning the professional and technical schools. During the colonial period many American-born lawyers sought a legal education in the English inns of the court. Equal interest in jurisprudence was not manifested after the Revolution. Even the great ability of James Kent failed to attract students to Columbia University after his first year of service in 1794. The Harvard Law School was not successful until Justice Joseph Story in 1830 lent an impetus to the influence of his great name. Not until after 1890 was it firmly established that the apprenticeship system of legal education was inadequate to the increasing volume and complexity of the law; and that adequate preparation could be had only in the better law schools connected with the large universities. There are now approximately 122 law schools with over 20,000
students. Not more than one in four of these students has taken a college degree, although many have had the one or two or three years required for admission by some of the better schools.

Medical education did not attain a high standard until the founding of the medical school of Johns Hopkins University in 1893. There are now about 100 medical schools with about 17,000 students, of whom approximately one in six hold collegiate degrees. The course is usually four years. The efforts of the Carnegie Foundation and other institutions to raise the minimum standard of medical education has resulted in a considerable decrease in the total number of medical colleges and of medical students. Some of the weakest institutions have been eliminated. In 1900 there were over 150 medical schools; in 1914, 100. In 1900 there were 25,000 students; in 1914 not quite 17,000. In addition there are 50 schools of dentistry with about 9,000 students; 72 schools of pharmacy, with nearly 6,000 students, and of more recent establishment 1,250 schools for nurses with 36,000 students. The theological faculty in the United States is a part of the university as in the German, but schools of theology abound. In 1914 there were 176 theological schools with 11,000 students and nearly 2,000 graduates annually. Less than 50 were integral parts of colleges and universities. About half the schools require a college degree for admission, and the length of the course is usually three years.

Education in engineering begins with the foundation of Rensselaer Polytechnic Institute in 1824. The creation of the Lawrence Scientific School in 1847 at Harvard and Sheffield Scientific School at Yale a little later brought a much higher standard. The influence of the National Land Grant Law in 1862 on engineering education was profound. Able schools are connected with most of the larger State universities. The leading school is the Massachusetts Institute of Technology affiliated with Harvard University. Most technical schools require four years of residence, and grants of college degree are given in time-value with the B.A. and B.S. degree. There are more than 200 public training schools and colleges for teachers with over 90,000 students, but in only a few of the States are the requirements for admission sufficiently high to permit their classification as of college or university grade. In addition there are 46 private normal schools with nearly 6,000 students and a few teachers' colleges of high grade, of which the most notable are at Columbia University and at the University of Chicago. The rapid advance in the application of pedagogical principles to educational practice is due in considerable part to these teachers' colleges.

The deep popular interest in higher education has tangible expression in private gifts to various institutions. In the decade from 1890-1900 an amount was given equal to the entire estimated value of the college property and productive funds in 1890, or $115,500,000. In 1914 gifts from private sources aggregated $31,375,000. Nearly $600,000,000 have been given since 1870.

Mention has been made of the fact that State universities are almost universally coeducational. Most of the colleges of private foundation in the Central and Western States also admit women in equal terms with men. Oberlin Collegiate Institute, now Oberlin College, admitted women from its opening in 1833. In the Eastern and Southern colleges for women grew from the female seminaries founded in large numbers before the Civil War. Elmira College in New York was the first institution for women to receive a college charter in 1855. Vassar began a notable history in 1865. Wellesley received a college charter in 1870, and Smith in 1871. Smith College opened in 1875. There were in 1915 nearly 19,000 undergraduates attending women's colleges.

The problem of military education has frequently demanded the attention of the Congress, the colleges and the people of the United States. Out of the experience of the Revolutionary War and the recommendation of Washington came the military academy at West Point, founded in 1802, now a college and engineering school of the highest type for the training of officers for the United States army. The Naval Academy at Annapolis, founded in 1845 by George Bancroft, the historian, performs a like purpose for naval officers. The number of cadets is strictly limited by Congress, and the President makes the appointment. The present law (1916) provides for the designation of three midshipmen to each member and delegate of Congress, and in addition 10 at large and 15 from the enlisted men of the navy to the Naval Academy. Appointment to West Point will be on the basis of two cadets to each member and delegate of Congress, four from each State at large, 80 from the United States at large. The President may appoint, in addition, not to exceed 100, from the enlisted men in the army. The government maintains in addition a number of special military schools for the training of soldiers in various branches of the service.

Out of the early experience of the Civil War came the provision of the Morrill act requiring military drill at the "land-grant colleges." The National Defense Act of 1916 reorganized the provisions for military education at the State universities and agricultural colleges. Reserve officers enrolled for service in case of war are to be trained in reserve officers' training corps units by United States army officers detailed as professors of military science and tactics. Adequate instruction in military science as part of the regular course of study is provided. The college training is supplemented by the six weeks' summer training camps conducted by the War Department. Similar provision is made for private colleges which agree to maintain at least a two-year course of military training. College regiments or batteries exist at many universities either as independent organizations or as units of the State militia. The demand for more adequate recognition of military science and military practice by the colleges has its origin largely in the student body and is receiving much attention from the college faculties. The introduction of an element of military discipline into the free life of the college is looked upon with favor by many college presidents.

In the history of higher education in America the first 15 years of the present century represent an area of criticism and reconstruction. Out of this era our universities and colleges emerge confident, potent, alert, with a quickened sense of their high responsibilities, a
clearer vision of their mission and an immensely increased knowledge of educational methods. A new world epoch in educational history will dawn with the close of the European War. What the characteristics of the new epoch will be no one can foretell, but it is a reason for confidence that America can enter the new era with great universities and noble colleges reshaped and strengthened by 15 years of thoughtful self-examination and the close experiment of the War. What the characteristics of the new epoch will be no one can foretell, but it is a reason for confidence that America can enter the new era with great universities and noble colleges reshaped and strengthened by 15 years of thoughtful self-examination and the close experiment of the War.

FRANK L. TOLMAN,

EDUCATION, History of. The history of education begins with primitive man—in fact even with the lower animals, for any training which is given by one being to another to enable it to do something better than it would otherwise be able to do may be designated education. We might distinguish between the education which is given by animals, which is instinctive, and which is given by human beings, which is partly instinctive and partly consciously and deliberately worked out into a system.

The earliest system, if it may be called such, that of primitive man, had, perhaps very much of it instinctively, as its end the object of teaching others, particularly the young, methods of procuring the necessities of life, particularly food, clothing and shelter. In other words, savage education adapted itself to the immediate needs of life. To estimate how widely it extended itself along such lines one only has to think of the actually widely extended domain of savage activity: the making of arms, boats, clothing, huts, the manufacture of articles used in the catching and preparation of food, fishhooks, spears, traps and pottery of all sorts.

From the first times of which we know anything, considerable attention was given by primitive man to self-adornment, sometimes with a sex motive, at others with motives of protection and religious belief. The training given in making gaudy articles of decoration did not have that close relationship to the most immediate needs of life, and thus man, at the beginning of things education was unconsciously divided into training for the doing of those things which were useful and those which we may denominate as luxuries or superfluous—although what one merges into the other it is difficult to determine.

As man progressed from his extreme simplicity, and great industrial changes gradually took place, such as came with the domestication of animals and the discovery of agriculture, new things for which training or education was to be given arose. The more complex civilization has become, the more numerous have become the various elements for which the individuals have had to be trained, and thus every educational or training system should have adapted itself to the needs of the civilization in which it was existing. The natural conservatism of man has, however, as history shows, led him frequently to cling to an educational system adapted to earlier ages.

The influence of religion among all early peoples was so great that those of the community into whose hands the religious ceremonies gradually fell exercised an enormous influence. Training for their particular class became an end in itself and those who succeeded in training members not only determined the training which future entrants should have, but also by virtue of the peculiar influence of their profession succeeded in influencing all other training given—even for ends other than religion.

So powerful has been the influence of religion on education that beginning with the earliest people, of whose history we know much, the Egyptians, it continued to be the dominantly determining and usually reactionary and conservative factor right down through the middle of the 19th century, in a measure accounting for the fact that systems of education have so frequently lagged far behind the demands of civilization, and have given a training in one century of a sort adapted to a condition of man's development of some centuries before.

The earliest teachers were with primitive peoples the parents, and they continued to be a very large factor in all ages. The professional teacher, however, had already come into existence at that time. Among the priests were the most important of them, though there were many private teachers for teaching practical trades and professions. The methods employed in teaching were those largely of mem-
orizing and imitation. Writing by the stylus on wood or with ink on papyrus was taught as was always reading and numbers. The discipline was severe, corporal punishment resorted to and the teacher held in respect.

Variations of the system in vogue among the Egyptians were to be found among the Chinese and Hindus. The Semitic peoples—the Babylonians, Assyrians, Hebrews, Phenicians, showed less rigidity and fixity in their systems, probably due to less and lesser involvement in the social organization than was the case with the former peoples. The studies given were reading, writing, arithmetic, history, religion, psalms, domestic arts, music, dancing and trades. Law, ethics, astronomy and geography were studied by those who went above the ordinary trades and went into the professions. The teaching was dominated by the priests and they exercised a restraining influence on that breadth of education which might have come from bringing in Greek and Roman methods.

The history of Greek education extended over many centuries and during that time the educational system, beginning in Homeric times and closing with the Roman conquest, underwent many changes in its ideals and content. Even over the period when the Greek world was supreme there were within its boundaries states that had very divergent systems of education. The two extremes are usually represented by Athens and Sparta and the difference between their educational ideals may be in a measure accounted for by differences in tribe and environment. The Athenians, sprung from the Ionians, were highly imaginative, artistic and literary. The Spartans, sprung from the Dorians, were lacking in imagination, were extremely practical and highly military. The former lived near the sea and in their maritime trade got a breadth of view and culture by trading with foreign nations, while the latter lived in the interior surrounded by their mountains, cut off from the broadening influence of contact with others. The educational ideal of the Athenians therefore came to be that of leading a complete life, beautifully and happily. The individual and his opinion made much of. Ever with the idea of beauty in mind the young were taught grammar, poetry, style, oratory, rhetoric, music, mathematics, physics, economics and politics. The teachers, who were more or less free lances, overdeveloped themselves in their individualism and let their pupils up to be unduly forward and disputatious and lacking in reverence for the state and religion.

In Sparta the ideal was to develop strength, courage and obedience—to subordinate the individual to the state. Much less stress was laid on literature and the artistic. To accomplish this ideal the state was turned into a military school, and each citizen was trained accordingly. As the individual was not trained as such he was lacking in moral force.

It was from Athens rather than from Sparta that the first great teachers and writers on educational systems and theories came: Socrates, Xenophon, Plato and Aristotle, and probably no four men from any one people have exercised greater influence on educational history of the world.

The Romans by nature were much more similar to the Spartans than to the Athenians. Their early educational work was very practical and centred in the home in which the father was the dominating and all-powerful factor. Training was thus given in the Laws of the Twelve Tables, in business, farming, civic duties, reading, writing and arithmetic. Girls received instruction in household duties.

After the conquest of the Greeks by the Romans the former began to exert a powerful influence on Roman education. Greek teachers came over in large numbers and the former purely practical education of the Romans began to take on a literary and artistic turn. The study of Greek prose and poetry was introduced even for the younger children, and in the higher schools training in history and science, philosophy, oratory, declamation and debate was given. Rome like Athens produced some profound students of education, the most important being Cicero, Seneca and Quintilian. Schools were multiplied and state support was given widely and generously. With the incoming of the barbarian Teutonic hordes from the north and the disruption of the Roman Empire, the culture and the educational work of the Greeks and Romans largely disappeared. Education suffered a shock from which it did not recover for centuries and the world had in a way to begin all over again.

The Church assumed leadership not only in matters of religion but also in matters of state. For a time very little could be done about general education. As the ideal of life was ascetic and all things which pertained to man's life on this earth looked down upon, the education which was given was, in the ideal at least, to prepare men for the life to come. In the monasteries, where such teaching as was given was carried on, time was devoted to prayer and contemplation. The past was revered for its spiritual and religious teachings and books containing them were carefully copied. To this end largely the novices were taught reading, writing, singing, the church service and a little arithmetic. Then they were given the trivium (grammar, rhetoric and dialectic or logic) and the quadrivium (arithmetic, geometry, astronomy and music) which made up the Seven Liberal Arts.

Though some outside of the religious order might enjoy the privileges of this education, the chief object of all of this instruction was religious. Even the attempts of Charlemagne in his Palatine School under the headship of Alcuin could not make the educational ideal very different. After his death as during his life the only educated class was the clergy. The people generally and even the nobility received very little education in the ordinary acceptance of the term in ancient and modern times. Such training of the noble classes as was given that might be called educational is to be described under the title of chivalry. A youth was trained as a page in attendance on a knight or lady, was given some instruction in music and poetry, and taught how to play chess. Later as a squire he was given military training and instruction in hunting, riding, jousting, swimming, religion and singing. As a knight he was taught ethics, to practise the virtues, to defend the Church and protect women. See Chivalry; Education.

Out of the monastic schools there grew up a certain type of scholarship known as scholas-
ticism (q.v.), whose object was to use Greek knowledge for religious ends. Great stress was laid by its devotees on dialectics, the object of which study became not to discover new but to prove old truths. Aristotle and his works became to these students the chief source of knowledge.

During the 11th, 12th and 13th centuries there was a remarkable growth of cities, due to the activities of the artisan and commercial classes. These people were organized into trade and merchant guilds and it became the object of each guild to have its prospective members educated. The guilds employed teachers, usually drawn from the clergy, to give the children of members instruction in reading, writing, arithmetic. Even the cities as chartered bodies established schools for the same purposes. In each of the guilds there was a system of teaching boys a trade by the system of apprenticeship.

Toward the end of the 11th century and during the course of the 12th, universities began to grow up. At first these universities were banded together for a common purpose, such as the study of medicine at Salerno or for law at Bologna. In Paris the university grew out of a school attached to the cathedral and was an organization of masters or teachers. The instruction there was at first mainly in theology. A university in our sense, with a large plant and numerous buildings, these were not. The students met for lectures in private houses or rented halls.

During the Middle Ages art, love of beauty, literature, poetry, science thrived as contributions to the support of religion and the Church. One important result of the Crusades (q.v.) was that they broadened men's minds, and subjects of study which had been formerly condemned because of the influence of the Church and the clergy came to be taught during the Renaissance. The study of the Greek and Latin languages for the knowledge of the literature and wealth of learning which the Greeks and Romans had was revived. The development of the individual became an object. The Church ceased to be everything and the men now thought of fame and glory for themselves. Teaching still remained in the hands of the clergy, but instruction was broadened. These Renaissance teachers in their turn fell into narrow ways and came to emphasize linguistic training to the exclusion of physical, social, artistic and scientific elements. Petrarch was such a teacher, whereas his fellow countryman, Vittorino da Feltre, emphasized history and civilization.

The Reformation and Counter-Reformation (qq.v.) brought about considerable changes in education as well as in religion. Luther and Melanchthon both demanded that education should be provided for all and that the state should maintain and control the schools and see that children attended them. Thus the idea of compulsory education was initiated. Stress was laid on teaching the mercantile, on providing simple instruction in the elementary schools to meet the immediate needs of the people. In the secondary schools, or Latin schools as they are called in England, instruction was given in the classics, history, mathematics, grammar, music and gymnastics. Though in theory these schools were to supply leaders of thought, in practice they became preparatory schools for the universities, whose main object was the preparation of teachers and ministers. The liberalism in education which was at first promised by the Renaissance failed to materialize during the Reformation and education took on the form of supporting the various sects which had grown up after the revolt from Roman Catholicism. Corresponding to the Protestant schools were those of the Jesuits whose insistence on thoroughness and on well-trained teachers has become proverbial.

During the last half of the 16th and the whole of the 17th century this religious control and formalism dominated education. In content the curriculum was humanistic, but in spirit it was almost as ascetic and scholastic as in the Middle Ages.

This kind of education met with protests from certain scholars like Rabalais, Milton, Montaigne and Sir Francis Bacon, who have been denominated realists because they insisted on the study of practical things, not literature, instead of the words and grammar, and on the study of nature, law, arts and trades by means of actual observation. The curriculum of studies, however, still remained literary and linguistic, and this met with little opposition. The object of its supporters came to be to justify it and this they did through the theory of formal discipline, so well enunciated by the Englishman, John Locke. According to him it is not so much what is learned as how it is learned. The value to the pupil is in the discipline obtained in the process of learning.

The stiffness and formalism which had held sway in religion and education for so many centuries led, in the 18th, to a revolt best illustrated by Rousseau. His was a cry "back to nature" — to doing things in a natural way — to permitting the development of a child according to its nature.

The influence of Rousseau was not immediate, but it left an indelible impression on the educational progress of the 19th century. Formalism gradually gave way to a natural treatment of the child and training was adapted to age and individuality. Following him came Pestalozzi, who preached that in order to give proper educat matter of the pupil taught must be studied and his needs, interests and abilities taken into consideration; Herbart, who emphasized the importance of education as a science and of the proper training of teachers to teach; Froebel, who was responsible for the establishment of the kindergarten and the development of the ideas that self-activity, initiative and individuality are important ends of education.

In the 19th century there has been a steady if slow development toward the theory that the proper education is that which enables the student to turn that which he acquires by learning to immediate use — that mental power is best developed by learning those things which are of most use in life. Herbert Spencer was the best exponent of this "turn to use" education. Children should be taught those subjects which will enable them to earn a livelihood and be good citizens. His influence was responsible for bringing science into the school curriculum and for a look back on the formal discipline theories of Locke.
Down to the 19th century education had been generally considered from the point of view of the individual. The great growth in industries and in democracy during that century emphasized the need of educational systems which would take into consideration the position of the individual in society. The individual must be educated mentally, physically and morally, and he must be trained for the professions, or the trades, or in agriculture or commerce, for if he is not he will in a way be a drag on society and the body politic. For such an education all means known must be placed at the disposal of the child and citizen: schools, elementary and secondary, manual and vocational, colleges, academic and technical. Nor is the question as to whether the individual shall take the education one for voluntary action. Society has the power and the right to compel him to get an education.

To justify its place in the curriculum a study must be shown to have some immediate and practical relation to life. In the first quarter of the 19th century, a visit to our schools and colleges shows the extremely practical turn which education has taken. In addition to instruction in the mother tongue, reading, writing, arithmetic, geography, history and other subjects familiar in earlier centuries, are to be found an array of such subjects as woodwork, ironwork, cooking, sewing, printing, drawing, architecture, engineering of all kinds, agriculture, horticulture, forestry, dairying, bookkeeping, business practice, civics, commercial law, stenography, typewriting, economics, banking, finance, transportation, insurance, sociology, carpentry, blacksmithing, molding, plumbing, machine-shop work, bricklaying, plastering, textile industries and many others. Thus the authorities in charge of public schools and universities have taken over many studies formerly left to private employers or agencies, and now by the establishment of playgrounds, nurseries, recreation centres, camps and many other activities are tending toward a control by the state in the interest of society which is cramping the freedom of action by the individual. The latest innovation advocated along such lines is that of compulsory military training in a democracy like the United States. This started about by the Great War which began in 1914. How far this sociological method in education will go only the future can tell. See Education, Theological; Religious Education in the United States; Education, National Systems of; and related subjects.

James Sullivan, State Historian, The State Education Department, Albany, N. Y.

Education, Industrial. See Indian, Education of.
students still devote their energies mainly to literary instruction and to training in both agriculture and the mechanic arts and not at all to technical education.

Along with this evolution of the aim and organization of the land grant institutions, many experiments in industrial education for both men and women were tried in a great variety of schools and courses which were designed to fit students for immediate betterment of their condition as wage earners and independent producers. Both technical and industrial types of education were at first considered as competitors with the general or liberalizing education of the elementary or secondary schools; both suffered from the lack of specially trained teachers and of a body of organized and tested materials for instruction. The necessity for using teachers trained in the old order caused many a failure but ultimately both types have been recognized as auxiliaries or supplements, not rivals, to the older types of schools and both now receive liberal support on the same basis, namely, the common differentiation of the whole school community in the promotion of an industrial efficiency in America equal to the best in Europe without class distinction and without closing the door of opportunity to any student.

The centennial exhibition of 1876, especially the Russian exhibit, stimulated the introduction of manual training or manual arts into the elementary and secondary public schools of the United States. (See Manual Training.) The object of this form of education, however, was not the production of industrial workers, but the training of the pupil's hand and eye, as well as his brain, as vitally related to his full personal development. But the demands of the industries in a rapidly expanding, competitive order, which was no longer provided with an apprenticeship system, could not be met by this form of training, and institutions sprang up to provide various forms of special training for vocations like agriculture, carpentry, cooking, iron-working, machine work, painting, plumbing and stenography. By 1900, 144 manual and industrial training schools reported to the United States Bureau of Education from 38 States and Territories showing 41,736 pupils under instruction. From 1900 to 1917 the number of schools devoted primarily to industrial and trade education greatly increased, both through tax support and through private foundation on a generous scale, for example, the Dunwoody bequest of approximately $3,000,000 for the Dunwoody Institute for free instruction in industrial and mechanic arts for the youth of Minneapolis and Minnesota, a worthy successor in the long line in which Girard College (q.v.) was a pioneer. In 1917 public and private high schools to the number of 2,610 reported 130,734 students in technical and manual training courses. Three thousand five hundred and ninety schools reported 260,413 students in commercial courses and 145,727 students in courses in domestic economy. In the same year, 912 private commercial schools or business colleges enrolled 192,888 students.

The following courses of instruction in Wentworth Institute opened in Boston in 1911 as a purely industrial, endowed school "for the purpose of furnishing education in the mechanical arts," will illustrate the scope and method of an extremely and immediately practical type of industrial education confined to building and manufacturing and to printing and graphic arts. Admission to the one-year day course is open to students "at least 16 years of age . . . thoroughly in earnest"; to the two-year day courses, to those who pass examinations in arithmetic and English. One-year day courses are offered in carpentry and building, electric-wiring, plumbing, machine-work, pattern-making, foundry practice, forging, hardening and tempering. The weekly schedule for three terms in the course in machine-work calls for 20 hours of shop practice in machine-tool work, machine construction, bench-work and tool-making; 6 hours of mechanical drafting and blue-print reading; 9 hours of practical mechanics, materials of construction, power transmission, etc.; 5 hours of practical mathematics, machine shop computations. The two-year day courses are for persons who wish to become master mechanics, foremen, etc., and provide instruction in machine-tool design, electrical construction, steam and electrical power plant practice, foundry management and operation, and architectural construction. Evening shop courses are provided for persons employed during the day, and are selected from the list just given, together with tool-making, foundry chemistry and advanced plumbing; evening technical courses are for persons employed in building and manufacturing industries and give instruction in practical mathematics, mechanical drawing, machine design, architectural drawing, architectural design, practical mechanics, reinforced concrete and modern fireproof building, applied electricity, care and operation of steam boilers and engineering. There are also day and evening courses in printing and graphic arts, including typographic printing and composition, book printing and etching. Similarly detailed curricula would be found in specialized schools in cities like Lowell, Mass., where textile industries predominate, and Scranton, Pa., in the mining region.

Another form of industrial education is found in the 101 State industrial schools, which reported in 1916 36,976 males and 9,567 female students learning some trade or occupation. Of the type wholly supported by the State and the Iowa Industrial School for Boys and the New Jersey State Home for Boys; of the co-operative type, privately managed but subsidized by the State, for the care and instruction of orphans and delinquents, is the Roman Catholic Home of the Good Shepherd in New York, in which girls are prepared for various occupations.

Still another important group of schools for industrial education is that for special groups or races, as schools for negroes and Indians. The number of institutions in colored schools, however, has not been equal to that in white institutions. Among the most notable of these industrial schools is the Hampton Normal and Agricultural Institute of Virginia, opened in 1868 under the great leadership of Gen. S. C. Armstrong for training of negroes in academic, industrial and agricultural subjects. The institution has national recognition as a pioneer in
the development of the educational value of manual labor and in the correlation of academic subjects with industrial training. As a model or imitator is the Tuskegee Normal and Industrial Institute of Alabama (q.v.), built up, under the leadership of Booker T. Washington, from nothing to a plant and endowment worth $4,000,000, an attendance of nearly 1,400, and a teaching staff, all colored, of 184. These two have been followed in some degree by the 16 land grant schools for negroes and by more than 200 smaller institutions scattered all over the South. One hundred and sixty-three counties in Southern States provide county industrial teachers. Washington, D. C., Charleston, S. C., and Columbus, Ga., are the only cities which maintain industrial schools for negroes. Important among the 109 boarding schools under Federal management, for the general and industrial education of Indians, are the Indian Industrial School of Carlisle, Pa.; The Haskell Institute of Lawrence, Kan., and Sherman Institute, Riverside, Cal., in all of which the industrial element is kept eminently prominent.

To provide for industrial education in process of organization and standardization are the special schools, continuation schools and corporation schools for workers in service. The motto of these schools is: "Learn while earning, and earn while learning." They are conducted as day schools, evening schools or correspondence schools, frequently as parts of the public school system of cities, and for their four objects (1) the advancement of the individual by special training for a more technical work, (2) the prolongation of the period of education for those who would otherwise not go to school at all, (3) the increased efficiency of the student in his present position, (4), the discovery for each student of the kind of work for which he is best fitted. The lower age limit for all of these schools is 14 years. The co-operation between school and employer takes varying forms. In some instances the student is detailed from his regular task to the school for certain hours on his employer's time; in other cases instruction is in the shop with the aid of a paid instructor in addition to the shop superintendent. In still others like the recent "vestibule schools" the employee is intensively trained for a brief period before admission to the shop. Twenty-four big corporations in 1917 had special training schools for men in preparation for service of the corporation, the largest of these schools being that of the General Electric Company, which admits 250 to 300 college men per year for a training period of 12 to 15 months. In a similar manner the American Bridge Company receives about 60 college men per year for a course in bridge engineering from one to two years' length. The Boardman Apprentice Shops, part of the public school system of New Haven, Conn., provides industrial education in co-operation with corporations in that city on a plan providing for eight hours of instruction per day, 5½ days per week, and 50 weeks of the year; a twelve-year period, approximately one-quarter time being devoted to academic subjects and three-quarters to actual trade practice under the instruction of skilled mechanics for the production of salable articles. In some cases in this school, as in others, the boys in paid alternate between school and the factory in which they are employed, one working in the factory while the other is in school. The significance of this form of industrial education is attested by the formation of the National Association of Corporation Schools in 1913, which had in 1917 104 company members, including such corporations as the Atchison, Topeka and Santa Fe Railway, which reported 37 railway shop schools for apprentices; the American Telephone and Telegraph Company and the International Harvester Company.

The incorporation of industrial or vocational education into the State systems, with provision for State subsidies to vocational or industrial schools, had been provided for in 10 States in 1916: Massachusetts (Department of Vocational Education), New York (Division of Agricultural and Industrial Education), Connecticut (State Superintendent of Trade Education), Pennsylvania, Wisconsin, New Jersey, Indiana, California, New Mexico and Maine.

The movement for industrial education received its greatest recent reinforcement in the passage of the Smith-Hughes Act of Congress, 23 Feb. 1917,* which provided for the promotion of vocational education; to provide for co-operation with the States in promotion of such education in agriculture and the trades and industries; to provide for co-operation with the States in the preparation of teachers of vocational subjects,* which made an initial appropriation in 1917 of $1,860,000 to be gradually increased to an annual grant of $7,367,000 after 1926. The allotments to the States for the various purposes of the act are made in the proportion which the rural, urban and total population of each State bears to the corresponding totals for the United States, the allotments to be administered through State boards in accordance with plans approved by the Federal Board for Vocational Education.

EDUCATION, Moral. Instruction in morals, whether merely informally by parents or formally by teachers, dates from earliest antiquity. This is true largely because of the nature of the subject, for morals, strictly defined, comprise as subjects the customs (Latin mores), laws and practices which have grown up among a tribe, people or race.
Out of this kind of moral instruction grew another which went beyond a content which had only included those things as moral which were clearly evil. This view questioned certain moral standards which had grown up and, taking a more advanced ground than that which made mere custom determine a moral standard, declared that certain rules of conduct should be followed because they were better than custom. The determination of what was better was generally arrived at by the experience of realizing that a condemned custom was detrimental to general physical or mental welfare.

Moral instruction along this higher plane became most prominent among the Hebrews and the Greeks, was carried on by the Romans and has continued down to our own day.

It was quite natural that from earliest times moral instruction should become closely interwoven with religion and the clergy. The latter as a class were the preservers of custom and the speculative philosophers on improvement. Great moral teachers other than the clergy did arise and brought about what were sometimes termed great revolts in moral ideals, but generally throughout ancient and medieval times the dominating importance of religion and the priesthood made the religious organization the determining factor in moral instruction. Particularly in the Middle Ages the close association of education with ecclesiastical institutions made the clergy the almost sole teachers of morals.

Beginning with the Renaissance and the Reformation there began to grow almost imperceptibly and very gradually a separation between religion and education which has culminated in their practically absolute divorce in the public schools of France and the United States. In the course of this long movement moral instruction largely remained in the hands of the churches, as those in control of state-supported schools felt that because of the variety of religious sects no form of religion should be taught. The close connection hitherto existing between the teaching of religion and the teaching of morals was probably responsible for permitting the teaching of morals to drop out of state-supported institutions.

In countries like England and Prussia, where the church and state maintained and still maintain a close relationship, and the public schools are still strongly under the religious influence of the Church, moral instruction was continued. The tendency to drop it from the state-supported schools in the former country led in 1906 to the formation of the Committee on Moral Instruction and Training in Schools for work both in the United Kingdom and in the United States.

In France the government in 1882 put into operation a course of study in morals for use in the public schools. In the United States the Religious Education Association, organized in 1903, has begun an agitation for the introduction of moral instruction in the public schools and the efforts of the teachers of the second grade in a recently established (1911) National Institute for Moral Instruction with headquarters at Washington, D. C.

These movements in the United States have had particular reference to the public schools. Schools, conducted by or in conjunction with churches or religious sects, and ethical culture societies, including all, private schools, consciously attempt to give moral instruction. The colleges, generally speaking, the public elementary and the public high schools do little or nothing in an avowedly formal way with moral instruction.

The problem presents great difficulties particularly in the United States. The heterogeneous character of the school population comprising as it does children from scores of different peoples foreign to each other in language, religion, institutions and moral ideals, makes it extremely difficult to get a common meeting ground. A course of study in morals comparatively easy to carry out in a New England or Southern village, where all of the people are of a common ancestry for generations, encounters unexpected difficulties in New York City. A course now used in France, for example, can, in some particulars, be shown to be ill adapted to the United States.

Again, the teachers, though all agreed that something along the lines of moral instruction ought to be done, are in no agreement at all as to how it should be done. Those who believe that formal lessons in morals with a definite allotment of school time ought not to be given seem to be in a majority. They feel that some suggestive course of study ought to be drawn up so that teachers would be enabled to give training in character and morals in conjunction with the studies already in the curriculum, particularly those of English, history and civics. They feel, however, that each study may be made to answer the purpose, when skillfully and deftly handled, and that everything in connection with school life should be utilized: the playground, sports, the assembly, the school city, self-government, dramatics, pageants, home visits, parents' meetings, etc. They lay emphasis on the personality of the teacher and on the necessity that normal schools and other teacher training agencies are under, to develop teachers who will exercise a good will, and a tone of persuasiveness that will imbue the mind and will in the subject matter, spirit and example. They also urge that those who employ teachers should place the element of personality more strongly to the fore than formerly.

The teaching body as a whole may be said to be passive with reference to moral instruction. Though perhaps acknowledging its worth they are willing to do nothing active to bring it into the course of study. Some meetings of the National Education Association (1907 and after) have had papers read upon it and they have met with a favorable reception. In some communities the courses of study in the elementary schools point out the opportunity for giving moral instruction, but this is not general.

A considerable negative element is found which doubts the utility of moral instruction. Members of this group maintain that it cannot be shown that the moral condition of the people in countries where religious and moral instruction is given is any better than that in the United States. They say that it cannot be shown that the graduates of church and private schools, where more or less formal moral instruction is given, are superior to those of
the public schools, where virtually no or very informal instruction is found. They maintain that it is the duty of the teacher to guide the children, that the personal influence of the teacher that good results are obtained and that all efforts should be directed toward the preparation of the teachers. They seem to overlook, however, the fact that the teacher is an outgrowth of the boy or girl, and that to get effective teachers a systematic instruction for the children is necessary, as the pupil of to-day is the teacher of to-morrow. In spite of this negative attitude on the part of some the outlook at present is that courses of study for morals and character building will have a great growth in the future. See ETHICS; and related topics on EDUCATION.

JAMES SULLIVAN,
State Historian, The State Education Department, Albany, N. Y.

EDUCATION, National Systems of. The system of education maintained by any nation must be the result of three groups of factors; (1) a group of national ideals; (2) a group of fundamental conceptions of the relationships of citizens in their economic, political, social and religious activities, and (3) an accepted attitude toward childhood and a group of accepted views with reference to the nature of educational processes. All of these may be vague and ill-defined or they may be clearly formulated,—the result of a philosophy of life, consciously worked out in a more or less scientific way. The first two groups of factors are most influential in determining a nation's educational aim and in selecting the content of the curriculum, or material to be taught; the second and third groups contribute most to the form of organization perfected for carrying on educational work; to the third group we look for the explanation of the methods of instruction employed. In order to fully understand a nation's education, then, there must be taken into account facts with reference to its history, industrial life, government—particularly in its legislative and administrative phases—temperament of the people, organization of society, religion, and, finally, the degree to which scientific principles have been developed and applied to problems of education.

Such completeness is impossible here. With these facts in mind, however, we may in a general way characterize the leading national educational systems of the present by presenting their most prominent characteristics and indicating the conditions upon which they depend. France, Germany and Great Britain, because of their size and importance, deserve the fullest treatment. We shall treat them first, following with very brief sketches of other European nations, then those of the principal nations of the far east, China and Japan, and finally, of Latin-American countries.

France.—France possesses a national system of education in the truest sense. Its most marked characteristic is centralization. Politically, the country is made up of 89 départements, each under a prefect appointed by the President, a small advisory council and a general council of elected members. Each department is divided and subdivided again into arrondissements, cantons and communes. For educational purposes the country is marked off into 17 académies. The authorities in all these divisions, both political and educational, play a part in carrying into effect the educational laws, all of which are national. Some of the characteristics of the system resulting from these laws are: (1) opportunity for free elementary education; (2) compulsory attendance; (3) absence of religious instruction in public schools; (4) requirement of moral instruction; (5) a completely organized system of normal schools; (6) recognition of teaching as State service and provision for teachers' pensions.

Administration centres in a government department under a Minister of Public Instruction. Assisting him are four directors; one each for elementary, secondary and higher education and one for accounts, under each of whom are a number of bureaus with special functions. In each academy except Paris a rector has charge of educational affairs in general, though prefects hire elementary teachers on recommendation of academy inspectors, and certain other affairs are left to a departmental council of teachers, inspectors and general councillors. In the academy of Paris the Minister is nominally rector, but a vice-rector performs the duties of the office. Inspection of the system is organized to the last detail. For example, in case of primary education there are general, departmental and arrondissement inspectors, each of whom must possess special qualifications.

Instruction may begin at a very early age in the maternal schools (écoles maternelles), where children from two to six years of age attend. Infant classes for children from five to seven years are provided in some places. Schools of primary and secondary grade are not closely co-ordinated. The former are practical and are directed toward life work; the latter (les lycées and collèges) are pointed more in the direction of higher training.

Lower primary schools, adapted to fit the compulsory school period (ages 6 to 13), are organized wherever possible as elementary, intermediate, and higher grades. The fundamental elementary subjects are taught, strict stress is put upon manual work, and the teaching of morals is compulsory. Special classes are organized in many places for backward and subnormal children. Where necessity warrants it, books, pencils and even clothing are provided. Supplementing the primary instruction described above are various courses. There are: (1) the "supplementary courses" (cours complémentaire) provided in some places; (2) the "higher primary school," which is a separate school with a practical course; (3) professe-
sional schools offering special instruction, as agriculture; and (4) continuation schools which are somewhat similar to the evening classes in American cities.

A normal school for each sex in each department, except where departments are allowed to combine their efforts, provides a three-year course for training elementary teachers. The work includes theoretical pedagogy and practical teaching. A higher normal for men and one for women are provided for the preparation of teachers to supply the departmental normals.

Secondary instruction is given in the state institutions called lycées, and in the communal colleges, which may receive state aid. Both may charge tuition fees. They admit boys at the age of 10 or 11 years and give courses of seven years. Most have preparatory schools for boys under 10 associated with them, so they do not draw their attention from the primary schools. The first cycle of four years is arranged to allow a choice of a classical course or a modern language and science course. The second cycle of three years offers four possibilities: (1) a Greek-Latin; (2) a Latin- modern language-science, and (4) a science-modern language course. Completion of any course of the four gives a baccalauréat degree. Teachers in these institutions must have special training along both academic and pedagogical lines. Secondary instruction for girls is carried on in lycées and colleges for girls, but the course is of five years instead of seven. They too have their own preparatory schools.

For higher education a university has been established in each of 15 of the academies, but they do not all have the complete four faculties. Appropriate degrees for higher work are given in the name of the state. There are also some special institutions, among which are the Collège de France, which dates from 1530, certain private institutions, and some "free faculties" of the Roman Catholic Church. Private institutions may not take the name of university.

Great Britain and Ireland.—England, Scotland and Ireland may best be treated in a group because all are more or less directly under the control of Parliament and all receive contributions from parliamentary money grants. Let us take them up in the order given above.

England's education is best approached from the historical viewpoint. Its organization has been slow and only in recent times has begun to warrant the use of the term "system." The leading universities and some of the secondary schools are several centuries old, and still maintain curricula which suggest the Renaissance. They have always been the fitting schools for the best classes of English society. For a long period the education of the common people was, in accordance with accepted views, the business of the Church. Schools were controlled by ecclesiastical authorities. Two or three centuries of change along industrial, social and political lines, however, brought a change of view. Education began to be thought of as the business of the state, and was promoted by various parliaments. In the Parliament, appropriations and the appointment of a special committee for administering educational grants. But the first of a series of really effective measures was the educational act of 1870.

Under this act, existing voluntarily established denominational schools were to be recognized as public elementary schools and receive apportionments from parliamentary grants on condition that they (1) conform with regulations of the education department, (2) submit to government inspection, and (3) reserve religious instruction for hours outside those of the regular school day. They might charge fees but could not share in any local tax. The act provided further for a school in every district not already supplied, provided the electors requested it. Such a school was to be established by a local elective school board, and came to be designated a "board school." It might, on meeting government requirements, receive support from both parliamentary grants and local taxes. Thus was laid the foundation upon which has been built England's dual system of schools, supported by moneys from endowment incomes, parliamentary grants and local taxes. A summary of some of the most important characteristics resulting from legislation since 1870 would include (1) compulsory school attendance; (2) a central board of education; (3) the right of voluntary denominational schools to participate in local tax funds; (4) abolition of the old committee and organization of a central board of education; (5) elimination of local boards and placing of local school affairs in the hands of the *county councils*; (6) extension of government support and inspection to include secondary schools of all classes. Government schools are now called "provided" schools, while others are called "nonprovided" schools. Supervision is left to supervisory boards, and in case of "nonprovided" schools a majority of the members may represent the Church under which the schools were established. Secularization is therefore not complete.

In the elementary schools, the lower grades, or "infant schools," for children of five or less to eight years of age, lead up from play exercises to easy reading, writing and number work. Upper grades, for aged 8 to 13, carry on the work in the usual elementary subjects. Additional classes for vocational training may be organized under certain conditions. Where a need for them exists, "higher elementary schools" of three grades may be established for the continuance of instruction along the lines of elementary subjects with special vocational training added. Children who attend must be 12 years old and must have completed at least two years of elementary school work. They may not remain after completing the third year of the course nor after attaining the age of 16, except to complete a grade.

Technically, among secondary schools are included all day and boarding schools maintaining courses of wider scope and more advanced degree than elementary schools and attended by scholars up to and beyond the age of 16. Pupils may enter as early as the age of eight or nine. These schools may charge fees but also receive parliamentary aid on meeting government bills presented. Breadth of training is insisted upon and Latin may be omitted from the course only with the consent of the school board. Considerable variation in organization
and means of support exists. The best known types are the classical "grammar schools" and "public schools," many of which rest upon very old endowments. (Public school does not mean free to the public. It is the designation for secondary boarding schools like Rugby, Harrow, etc.). These schools fit boys from the best classes of society for the university. Secondary schools for girls are very modern institutions. During the last few decades many have been established with financial foundations and study courses similar to those in institutions for boys.

Elementary and secondary schools are not closely co-ordinated. Most children who attend the broader secondary schools prepare under tutors or in special preparatory schools, then enter at an early age. Some pupils go from elementary to the secondary schools, but the number is small, and there has been official expression of the opinion that preparation in elementary schools for transition to the secondary is a "subsidiary object." When made, the transition is at the end of the course. That is to say, the two groups of schools differ in aim and are designed to meet the needs of different classes of society. Most children who go through and beyond the elementary schools enter day or evening continuation schools or vocational or technical schools.

Universities, university colleges and higher technical and professional schools provide for advanced training. They are not free institutions, but may receive government financial aid. Teachers in secondary schools usually come from the universities. Elementary teachers get their training through a kind of apprenticeship known as "pupil teacher training," or by a method of "student teacher training" in which secondary training to the age of 16 or 17 is followed by a year of practical work and one to four years in teacher training colleges which are maintained in connection with universities or may be established by county or city councils.

Scotland's education is under supervision of a separate board of education, with committees for secondary education in large educational districts and localities. Elementary education is generally free. Compulsory attendance is demanded of children between the ages of 5 and 14. Practically all types of schools may receive parliamentary aid on compliance with government standards.

Primary schools (infant, junior and senior divisions) carry the child to the age of 12, when a "qualifying examination" is given. Beyond this he may enter a supplementary course or he may begin an intermediate course. The latter is a kind of lower secondary course of three years, broader in scope than the primary and including a foreign language. On completing it a child receives an intermediate certificate. A secondary school parallels the intermediate course and adds two more years, and may give a choice of more than one course. On completing such a course a child receives a leaving certificate. Higher training is given in the universities and technical institutions.

Teachers prepare under the direction of committees for the training of teachers, of which there are four, and must take work in both academic and professional subjects, usually in selected institutions, not in separate normal schools.

The educational history of Ireland is similar in some respects to that of England. A group of voluntary elementary schools has been placed under control of a National Board, which administers education, supervises inspection of schools and distributes parliamentary grants of money. Elementary education is free and compulsory. Religious teaching is permitted, but may not be enforced by any denomination upon a child against the wishes of his parents. Teacher training is provided in denominational colleges. Little progress has been made in providing higher elementary schools. Most secondary schools, known in Ireland as intermediate schools, are endowed, private or denominational. These have been brought partly under supervision of an intermediate board, which cares for distribution of grants of money to those schools which conform with government standards and submit to inspection. Denominational contentions have retarded the progress of higher education. However, there are a number of denominational colleges, and reorganizations of rather recent origin have resulted in the combination of some colleges into universities with a view to securing greater financial aid from parliament.

Germany.—Germany is a federation of some 25 states, in which are included monarchies, grand duchies, duchies, free city republics and small principalities. The King of Prussia holds the title of Emperor. Imperial legislation covers only affairs with which the states are jointly concerned. Other affairs,—and education is included among them,—have been left largely to the control of individual states. Education is sometimes affected by actions of imperial authorities, but there has never been an imperial educational code. There has therefore been no "system" of education in the empire, but systems, provided and administered by the several states, with consequent lack of uniformity in methods of providing and supporting schools. On the other hand, there has been similarity through not identity of educational aims; other states have tended to follow the example of Prussia; and since the historical background has been nearly the same for all, their schools bear remarkable similarities of content and organization and serve the various classes of society in much the same way.

Some states have series of educational laws, others only general legislative provisions supplemented by ordinances or decrees of central authorities. Administration has been highly centralized, particularly in Prussia. Most of the larger states combine education with religion under one ministry. This is true in Prussia, Bavaria, Württemberg and Saxony. Some others include education in the Interior or in the Department of Justice. Central authorities may be assisted by local bodies, sometimes civil authorities, sometimes special provincial and local school councils. Military training is universal, but the requirement decreases with increase in educational accomplishment. School attendance is compulsory, usually to the age of 14. Religion is taught in elementary schools. Much has been
done to raise efficiency of teaching and to induce persons to make it a life work. Pensions for teachers are now authorized. Great progress has been made along the lines of hygiene and the sanitation of school buildings.

As stated, schools are similarly organized in the several states, though there are variations. Those of Prussia come nearest to being typical, and may be characterized as follows: A longitudinal separation prevents continuity and keeps distinct the schools patronized by different classes of society. A child's school and the length of his course is determined almost entirely by the class of society into which he is born. Transition, after the first two or three years, is very difficult.

The "Volkschule," or people's school, is a free school of eight grades admitting children at the age of six, in which are taught the elementary subjects and religion. It is patronized by the lower classes of society. Most children go from here into industrial life. Supplementary courses in evening or Sunday "continuation schools" exist in many places, and there has been a movement in the direction of making attendance a requirement, up to the age of 18, wherever possible. Teacher training is thorough, including three years in preparatory classes above the Volkschule, three in a normal school, and then practical work, aside from the passing various examinations.

Secondary institutions are tuition schools of nine grades, or classes, admitting boys (girls very rarely) at the age of nine or 10 years. Preparation for entrance is either privately or in a special preparatory "Vorschule." There are three types: (1) the "Gymnasium," characterized by its strictly classical course; (2) the "Realgymnasium," with a Latin—modern language—science course; and (3) the "Oberrealschule," with a science—modern language course. A special examination at the close of the gymnasium course (the Abiturientenprüfung), if successfully passed, fulfills the requirements for entrance to the university, in part the requirements for state service, and in addition secures certain privileges with reference to any service. The same is true for "Realgymnasium" and "Oberrealschule," except that language deficiencies must be made up in order to enter certain university courses. Communities unable to maintain nine-year courses have six-year courses, paralleling the first six years of the schools just described, under the names, "Progymnasium," "Realprogymnasium," and "Realschule." Secondary schools for girls, similar in organization to those for boys, but with less extensive courses, are found in many places. Secondary schools are patronized only by the aristocracy and the professional classes. Secondary school teachers must have thorough training, including university work and special pedagogical training, both theoretical and practical.

Between the lower and secondary schools are the "middle schools," with courses somewhat longer than that of the lower, or people's school. They are somewhat exclusive, charge tuition and are attended by children of the middle classes. But they do not articulate with the secondary schools.

Universities and higher technical institutions are state institutions, controlled by the state and maintained largely by state funds.

Austria and Hungary.—The educational systems in these countries are very similar to those of the German states. Hungary has included denominational schools under an arrangement similar to that in England, but in both these countries the organization of classes and the curricula in elementary, secondary and higher institutions parallel very closely those in the schools of Germany. Hungary also has a group of inspectors, assisted by the bishops of the state (Evangelical Lutheran) church. Education is free and compulsory between ages seven and 14 years. Religion is taught.

The school system includes (1) the elementary school ("Volkskole") for children of six to 14 years, supplemented by continuation schools; (2) the middle school ("Mellenskole"), with a four-year course which may be entered from the elementary school after the age of 11, and supplemented by a "real class" leading into a group of "middle professional schools"; (3) the three-year "special schools," offering three courses based on the classics, mathematics and modern languages, and leading to the higher technological schools and the university. The university is considered a part of the state system. Schools above the elementary are not free. Middle and secondary schools for girls exist, but they are fewer than those for boys. Normal schools, both public and private, give courses of from one to three years for the training of elementary teachers. Teachers are considered as in state service, and teachers' pensions are provided on a graded scale. Denmark deserves the credit for originating the special supplementary school for adults known as the "people's high school." It gives a short course, for men in winter, for women in summer, for which a tuition fee is charged, but there are no examination requirements.

Sweden.—Education in Sweden is controlled through the ecclesiastical department of the government, working in co-operation with the popular assembly.

Elementary education is compulsory for children from seven to 14 years of age. Schools are subdivided into "infant schools" (ages 7 to 9, and elementary schools (ages 9 to 14). Teachers are prepared in training colleges with four-year courses. Continuation schools, held usually in the evenings, "higher elementary schools" and "people's high schools," modeled after those of Denmark, supplement the elementary schools.

Secondary institutions are (1) the practical six-year "realschool"; (2) the four-year "gymnasium" for boys, offering both classical and modern courses; (3) the higher girls' school, usually a private school with preparatory classes attached; (4) the special technical school. A lower secondary examination is given at the close of the realschool course, and a higher secondary examination at the close of the gymnasiu course. Children may go from elementary to realschool, also from "middle school" or "realgymnasium at the end of the fifth year of the course. "Middle schools," in some communities, give a practical four-year course which
may include the work of the higher elementary schools.

Three state universities and two private universities, known as high schools, provide for higher training.

Norway.—In Norway schools are under general control of the Department of Education and Ecclesiatical Affairs, but local control is left to county and local school boards in which the state (Lutheran) church is well represented. Primary education is free and compulsory to the age of 14 and religious instruction is required. A well co-ordinated system allows continuous progress from primary school through, first, a lower secondary school of four classes (*Middelskole*), and a higher secondary school of three classes (*Gymnasium*), to a higher professional school or a university. Secondary schools may be state, municipal or private. Most of them are coeducational. Continuation schools supplement the primary schools. Lower secondary courses articulate with technical courses of lower professional schools. Training colleges are provided for preparation of teachers. Local committees of special state institutions provide for abandoned and delinquent children and for defectives.

Netherlands.—Administration here is under the Minister of the Interior, under whom are ranged groups of general, district and arrangement inspectors. Some local affairs are regulated by local civil authorities and communal school boards. Classed as elementary schools are: day schools for children 7 to 13 years old—the compulsory school age,—continuation schools and evening schools. Secondary institutions are both public and private. They include burgher schools with a two-year practical course, higher burgher schools with a five- and a three-year course, agricultural schools, industrial and technical schools, and a group of very special training schools. Higher burgher schools are the only ones giving broad training. They close with a state examination giving admission to higher institutions and to various kinds of state service. Gymnasia, with courses for ages 12 to 18, and fitting for the university, are classed along with the university as higher institutions.

Training of teachers is carefully supervised and the law provides for minimum salaries of elementary teachers and for pensions in cases of disability and long service.

Belgium.—Belgium, like a number of other European nations, has had a long denominational struggle. There exists an educational department under the Minister of Science and Art, who is assisted by general directors and a corps of inspectors, but in each commune there is a board possessing considerable authority, and in these denominational influences is considerable. Local independence accounts for considerable variation in the schools. Above the elementary schools, there are lower and higher secondary schools. The lower are practical schools maintained by the government and giving a transition that free schools for boys and girls are established. The higher are seven-year schools (*athénes* and a few *collèges*), and lead up to the university. Aside from these two groups, secondary schools may be established by local authorities. Higher education is provided for in four universities, two of which are state institutions, and in numerous special institutions.

Switzerland.—Because each of the 25 Swiss cantons controls its own educational affairs there results considerable lack of uniformity in the school system. Free education is provided for in the constitution. Some cantons provide free books and material. Compulsory education is common, sometimes for seven, sometimes for eight years, beginning usually at the age of 6½ or 7 years. Continuation schools are provided in all cantons. Various kinds of schools above the elementary grade exist, some giving general, others technical courses. Commercial education is stimulated by giving federal grants. The universities, of which there are seven, and the *Federal Polytechnikon* are institutions known world wide for their standards of work.

Italy.—Administrative machinery for control of Italian education is very complex. Under the Minister of Public Instruction are an undersecretary of state for public instruction and a higher council with the minister as chairman. A vice-president of the council is appointed by the king. The council is divided into different permanent and special committees. There are also a number of special bureaus. In each province there is a special administrative head and an educational council. Some localities have a degree of independent control.

Elementary schools vary in number of grades from two to six, and may or may not be free. Under certain conditions they may receive state aid. Attendance is compulsory to the age of 12, or, in communities with the poorer schools, through the grades which are provided. Many evening and Sunday schools for illiterate adults have been established.

Secondary schools provide classical, technical, nautical and normal training in courses ranging from two to five years in length. An examination, for which a fee is charged, admits children to secondary schools at the end of the fourth elementary year. Few limits are placed upon the establishment of secondary schools, but government credit may be had only by taking the government examinations.

Universities are state institutions with separately organized administration. Various other higher special schools and institutes for higher training may receive contributions from state funds.

Spain.—The Spanish government seems to have taken over for inspection and support many schools, whether founded by the state itself, the provinces, towns or religious corporations. These it controls through a general director, who, with an advisory council, is under the Minister of the Interior. A number of inspectors are employed, and in each province and town there is a school board which has considerable authority.

Attempts have been made to classify the elementary schools, but they are poorly graded, except in a few cases, and in such a state of transition that few definite opinions concerning them may be made. *Institutes* admitting boys at the age of 10 and giving courses leading to the bachelor's degree, and *colleges* with shorter courses from which boys may go into the *institutes,* are classed as secondary.
institutions. Secondary and university education are closely related, the two being under the control of "rectors," of which there is one for each "university district." Professors in both types of institution are appointed by the king and must be university graduates. Education of girls has been for the most part in private schools or in convents owned by the Roman Catholic Church.

Oriental Countries.—Oriental education was for centuries characteristically memoriter, imitative, nonprogressive. The two most important nations, Japan and China, have for a number of decades been making a transition to a more progressive education, largely on account of western influences.

Japan started the movement first. For about half a century she has been busy with the problem of modernizing and "westernizing" her education. At present education is controlled entirely by the state, through a Minister of Education who is a member of the Cabinet, and an educational council. Much of the regulation is by means of imperial ordinances.

Parents are compelled to send their children to primary school, which is the duty of the community to provide. Above the primary schools are middle schools and secondary schools of various types. The former are practical and lead toward technical schools or toward the secondary. The secondary schools are divided into the university, special colleges, or other higher institutions. Some provision has been made for the education of girls in special girls' higher schools. The problem of the proper co-ordination of the various institutions is not yet completely solved.

A fairly well organized system of normal schools for training elementary teachers has been developed, and also a method of certification, either on graduation from one of these schools or by examination.

China's transition has been made almost within the present century. An ancient educational system consisting for the most part of memorization of a group of Chinese classics and the passing of a series of state examinations has been overthrown. A system modeled somewhat after the western system has been put in its place, but many of the problems are yet unsolved. Teachers educated under the old system tend to fall back into a memorization method, disregarding the teaching of the meaning of material. Governmental changes and the changes incident to rapid adaptations being made make definite statements difficult. In general it may be said that China is fast developing elementary, middle and secondary, and higher institutions to meet the needs of education throughout the nation.

Both China and Japan find difficulties arising out of the nature of their written language (a character for each word), and both meet the difficulty of finding the proper place for the classical Chinese, which bears a similar relation to their modern life that Greek and Latin do to the modern life of western nations.

Latin-American Countries.—Space permits only a general characterization of education in Latin-American countries. In all of them the development of public educational systems has been slow. The causes for this are found in their extended territory, scattered rural population, differences in the grade of culture of the several classes of inhabitants, and the tendency to patronize private institutions. Early schools were almost entirely those of the Catholic Church, and there is still a large measure of Church control. With the acquisition of independence and establishment of republican forms of government, most of these countries began building public schools. The majority of them have provided ministries of education, although education may be administered, in individual cases, through the Department of Interior or Department of Justice. Usually responsibility for education is in the hands of provincial and local authorities, but in Chile there is government support of all classes of schools and the control is highly centralized under a system somewhat similar to that of France. Many of the countries have taken steps to provide free elementary education, and there have been a few partially successful attempts at compulsory attendance. Compulsory education is not the rule, even in elementary schools, but exists in the lower grades of government schools in a number of countries. Elementary education is liable to be of a low standard in rural districts, but in the larger cities, and especially in the government capitals, much has been done to build up model institutions and stimulate the development of efficient schools. Normal schools have also received much governmental attention. In practically all of the leading countries some form of government secondary school may be found, supported by national, provincial or municipal funds, but much of the secondary education is carried on in private or Church schools. Secondary schools are liable to articulate poorly or not at all with the elementary schools, as is the case in some European countries. Universities are also found in most countries, although in a few cases higher training has been given by special faculties—of medicine, law, etc.—the instructors being professional men who gave part time only to teaching. The influence of the world's modern industrial development has been felt in these southern countries, and the old literary and classical tendencies have tended to give way to more practical education, as is shown by the efforts of educational ministers to introduce reforms into the school systems. Education of Negroes in several European countries have been studied, sometimes by special commissions, and in some cases scholarships have been provided to allow young men to study abroad. See Latin America.

United States in Relation to Other Nations.—In both the period of their establishment and the later periods of development the schools of the United States have been greatly influenced by the educational situations in the various European countries. The methods and forms of organization have in a way been echoes of those in the countries whose people first settled America. The development of our Federal government, however, with its characteristic democratic spirit, has made for an educational system in which the paternalism and social distinctions characteristic of so many nations in Europe are almost entirely lacking. And so it is that the business of education is left for the most part to the several States, and is only indirectly influenced by the Federal government. The way in which all of the States have set themselves the task
of providing a co-ordinated system of elementary, secondary and higher institutions through which any child of ability may go is remarkable. Schools which parallel the "middle schools" of European countries have been slow in coming, but in recent decades have been making their appearance rapidly, as have also those similar to European "lower" or "middle technical schools." What will be their effect upon American life and society is a question full of interest and deserving careful thought. A similar and perhaps more vital problem arises from a tendency present in many quarters to push specialization down into the elementary grades.

The Present Situation.—Practically every nation's educational system is disturbed, even reorganized temporarily just at the present, as a result of the European War begun in August, 1914. Undoubtedly the outcome of that war will bring radical changes in many a nation's economic, political and social philosophy, followed by changes in both the mental philosophy and educational practice. The foregoing statements are based upon conditions as they were at the beginning of the conflict and, in so far as known, as they have continued since. But habit is strong, and the probability is that any changes in national educational systems resulting from the war will be in the nature of modifications and gradual evolutions, not sudden breaks from the old habitual courses. The general outlines here given will probably in the main hold true thereafter, especially if reviewed years after the conclusion of the just peace for which the world waits.

Instructor in Education, State College for Teachers, Albany, N. Y.

EDUCATION, Negro. See NEGRO EDUCATION.

EDUCATION, Professional. Professional education as distinguished from elementary, secondary, industrial or liberal education, is that form of higher education specially designed as a preparation for "learned" technical, commercial, or social professions or callings in which men and women deal with their fellows, with institutions, or with material things, according to abstract principles, with an understanding of natural or social forces and the ways in which they have been or may be applied. To the "professional" of the older time, other professions have been added to meet the need of a developing civilization. Hence professional education takes account of dentistry, chemistry, engineering, education, pharmacy and veterinary medicine, while as published by the United States Bureau of Education for the years 1900 and 1916, is shown in the accompanying tabulation, from which are omitted statistics of schools which train for the professions of engineering (see TECHNICAL EDUCATION), chemistry, commerce, and social service, for the reason that such training is still carried on largely in the usual four-year undergraduate course, either in close co-ordination with other undergraduate divisions or in parallel separate schools, with the inclusion of a considerable amount of fundamental or buttressing material of a non-professional character in the quasi-professional curriculum. Statistics of training schools for nurses are likewise omitted because these institutions are not, by organization, faculty, curriculum or special equipment, quite comparable with professional schools which are independent establishments, not merely adjuncts or accessories to major enterprises like hospitals which exist for an entirely different purpose. The standards of admission, instruction and graduation in professional schools have markedly improved since 1870, notably in medicine, engineering and education. In the case of medicine the changes since 1904 have been almost revolutionary under the firm and statesmanlike guidance of the Council on Medical
Education of the American Medical Association and the Association of American Medical Colleges, two voluntary organizations within the medical profession, which have neither legal nor coercive authority over schools, licensing boards or individual teachers or students. Organizations quite similar to these two have exercised in a smaller degree an elevating influence on corresponding forms of professional education during the last two decades. Legislation by the states now regulates more or less effectively the practice, and hence the education to practice, of the last five of the six tabulated professions, and in some degree also the quasi-proessions of accountancy, nursing, etc.

Several specific examples are here given to illustrate the progress just described and the present state of certain forms of professional education. The law school of Harvard College required no previous course of study in 1857; male students, 19 years of age and of good moral character, were eligible for admission. Not until 1870 was the course extended; yet in 1877 it was raised to three years; since 1899 only graduates of approved colleges are eligible for admission. Yet in 1916 this law school had 791 students, more than any other law school in the country except certain evening schools in Chicago and Washington, D. C.

By 1916 all but 20 of the 124 law schools reporting to the Bureau of Education prescribed three-year courses and only one remained on the one-year basis; all but 26 maintained a standard year of at least 35 weeks. The requirements for admission, until after 1870, were merely a knowledge of English and the common branches; by 1880 they were the completion of a four-years' high school course; at the present time nearly all the better schools require the completion of at least two years of work in a college of liberal arts. Though the content of the work of these two years is not prescribed, students are urged to choose such subjects as history, politics, English literature, logic, philosophy, economics and public speaking.

Professional work in law is usually quite closely prescribed during at least the first year, including contracts, torts, personal property, real property, domestic relations and criminal law; for the remainder of the course a varying degree of freedom is accorded the student. The methods of instruction have been remodeled along with the changes just noted; the original lecture system was succeeded by the textbook system, and this in turn by the "case system," in which the student makes analytical studies of actual cases decided in courts, discusses these cases in the classroom, and passes examinations on them and upon lectures dealing with the principle involved. The degree of bachelor of laws (L.L.B.) is generally conferred upon the completion of the regular course; certain schools, e.g., the universities of Chicago, Michigan and Yale, confer instead the degree of doctor of law (J.D. or J.U.D.) upon those graduates who entered with an A.B. or B.S. degree from an approved college. For a fourth or more of the degree of master of laws (M.L.) is sometimes given.

Medical education has undergone even more striking evolution than law. The early medical schools were usually connected with colleges, but, beginning in the early 19th century, came a period of about 75 years when the independent proprietary medical school flourished, to the grave detriment of the profession. In about a century 437 medical schools appeared in the United States and Canada, of which 162 were in operation in 1906 when the campaign for improvement began. The Flexner report on "Medical Education in the United States and Canada," published in 1910 by the Carnegie Foundation for the Advancement of Teaching, is a landmark in both medical and professional education in North America. Concerning the majority of these numerous schools the report states:

Nothing was really essential but professors. The laboratory movement is comparatively recent. Little or no investment was therefore involved. Occasional dissections in time supplied a skeleton—in whole or in part—and a box of old bones. Other equipment there was practically none. The teaching was, except for a little anatomy, wholly didactic. The schools were essentially private ventures, money-making in spirit and object. Many of the schools had no clinical facilities whatever. The schools had two sessions of 16 to 20 weeks each; the courses were ungraded, the two classes met together. The student had two chances to hear one set of lectures—and for the second set of fees. State boards were not yet in existence. The school diploma was itself a license to practice.

From this chaotic and almost standardless condition, medical education moved up in 25 years that the best American schools are quite the equal of the best European schools. The universities have resumed actual and vigorous control; graded courses of medical studies, adequately based on two years of college training, including chemistry, physics and zoology, and covering four schools of approximately nine months each, are the rule. Six medical schools have already taken still more advanced ground by requiring before graduation the satisfactory completion of a fifth year to be spent in an approved hospital or in other acceptable clinical work—Minnesota, Stanford, Rush, California, Northwestern and Vermont, and six State boards have established a requirement of one year's internship for licensure to practice. Numerous full-time salaried teachers have supplemented the voluntary voluntary lecturer, even in important clinical chairs. Great laboratories for instruction and research, supplemented by extensive hospitals for clinical teaching, have been built at enormous expense, sometimes by individual gifts, as in universities like Harvard, Cornell, Washington and Leland Stanford Jr., and sometimes by State or municipal appropriations, as in universities like Minnesota, Michigan, Iowa and Cincinnati, thus setting the highest standards now known in the profession. The degree of doctor of medicine (M.D.) is almost invariably conferred upon graduates. A special degree in public health (Dr.P.H. or Gr.P.H.) is given by several institutions, e.g., Michigan, Harvard and California.

Such progress meant inevitably not only the death of many weak and scandalous schools; by 1917 the roster of medical schools showed 96 names, of which 29 were integral parts of State universities. Proprietary, profiteering schools could not live when the common spent annually on each student in 82 schools on which an estimate was made in 1917 was $419, and the corresponding return from the student in fees was about $150, the fees ranging from $25 in Oklahoma to $275 in Columbia.
Out of 48 schools of dentistry only 12 are independent institutions. The dental curriculum covers three years of professional work based upon four years of high school, and leads to the degree of doctor of dental surgery (D.D.S.). A movement to raise the course to four years, comparable with medicine, has attained considerable momentum with the cordial support of the leaders of the profession. Tuition fees range from $60 to $200, averaging about $100.

The schools of theology represent a wide variety of standards, from the full salvation school (in Kentucky) to the great group of seminaries about the Catholic University of America, the Union Theological Seminary of New York, Princeton Theological Seminary, or Boston University School of Theology, all of which as a rule require a bachelor's degree or its equivalent for admission and a three-years course for graduation. The degree usually conferred is bachelor of divinity (B.D.) or bachelor of sacred theology (S.T.B.). The theological schools reporting to the bureau of education in 1900 and 1916 are summarized in the accompanying table. The attendance of 11,227 in 1916 included 760 women. But the figures do not include the considerable number of students in semi-professional Bible schools and institutes for training evangelists, missionaries and other church workers. Theological schools in 1916 were located in 32 States, New York, Pennsylvania, Ohio and Illinois having each more than 15. By denominations the distributions of 1900 and 1916 were:

All but 15 of the 71 schools of pharmacy have university or college connection. Admission requirements to the two-years course are two to four years of high school; the four-years course, usually the full high school course of four years. The former leads to the title of graduate in pharmacy (Ph.G.) or pharmaceutical chemist (Ph.C.), the latter to bachelor of science in pharmacy (B.S. in Phar.).

One of the chief reasons for the rapid development of veterinary medicine is found in the great demand by the Federal government for inspectors of food animals and by the farmers for the prevention or cure of swine and cattle diseases. Nine of the 22 veterinary schools are connected with state agricultural colleges. The course of four years is generally based on a high school education and leads to the degree of doctor of veterinary medicine (D.V.M.). The largest schools are those of Iowa, Cornell, Ohio, and Kansas City.

The training of teachers for the elementary schools does not fall under the heading of professional education, but the last decade has seen a gradual standardization of really professional training of teachers, comparable with the other professions in scope and severity of requirements. Few of the normal schools and colleges of education do more than incorporate into the regular undergraduate curriculum considerable courses in psychology, history of education, educational organization, and practice teaching in neighboring schools, or in college-controlled or laboratory schools as at the Universities of Wisconsin, Missouri and Minnesota. The better institutions limit the seminary studies in education to the last two years. Teachers College of Columbia University, which has been a graduate school since 1914, and the education divisions of graduate schools like those of Chicago, Harvard and California, are the best examples of professional courses in education, though they may not, with the exception of the first, be known technically as professional schools. The volume and significance of the researches of this group of institutions augur well for the further development of the profession.

Illustrative of the newer type of professional schools which require more than a four-years high school course for admission, are the Graduate School of Business Administration of Harvard University, New York School of Philanthropy, the Tuck School of Administration and Finance of Dartmouth College and the Yale School of Forestry.

So enormously expensive has the maintenance of professional education of all kinds become, that it must more and more depend upon tax-support or upon generous endowment, and less and less upon student fees and the free services of lawyers, doctors and dentists. No first class professional school can be content with mere teaching; it must engage in investigations of new conditions and new problems, in medicine, theology and education as well as in journalism, chemistry and social service, in the strenuous endeavor to master alike the social and natural forces which affect human welfare. Hence the graduate professional school and the research institution or endowment are new integral parts of professional education at the present time. Examples of these are the Graduate School of Business Administration of Harvard, medical endowments for research in cancer at Columbia and Harvard and in urology at Johns Hopkins, the Mayo Foundation for Medical Education and Research at Minnesota, the Veterinary Investigation Department of Iowa State College, the Engineering Experiment Station of the University of Illinois, and the Mellon Institute of Industrial Research and School of Specific Industries of the University of Pittsburgh.

To meet these multiplying and mounting needs of professional education, men and states have poured out during the last decades a veritable stream of gifts and appropriations as evidence of approval of the soundness and progressiveness of the management of such schools. In 1917 the University of Chicago received nearly $5,500,000 for its medical schools, Vanderbilt, Washington, Johns Hopkins and Yale have each recently received $1,000,000 or more for medical work; Pennsylvania received more than $1,000,000 for dentistry; the Pulitzer donations to Columbia for journalism were $2,000,000. The endowments
of eight theological schools are above $1,000,-
000 each, three passing $2,000,000 and one
(Princeton), passing $3,000,000, while the
grounds, buildings and library of the General
Theological Seminary of the Protestant Episco-
pal Church are reported to be worth more than $2,000,-
000. The building and library of the law school
of the University of Chicago are estimated at
$500,000, and the properties of the Harvard
Law School (including $600,000 of endowment)
at Cambridge.

EDUCATION, Psychology of. In some
branches of the subject, educational psychology is differentiated clearly from the general
science of psychology, while in other branches
the two subjects overlap. The investigation of
the laws of memory, of learning, of the deter-
minants of attention or of individual differen-
tes in endowment, has been carried on by psy-
chologists whose interest is in the theoretical
development of the science, as well as by those
whose interest is in the application of psychol-
yogy to education. But even in such cases, in
which there is an overlapping in subject matter,
the aim of the educational psychologist, which is
to discover how mental growth may most
effectively be promoted, usually causes him to
emphasize different questions than those upon
which the pure psychologist dwells. Certain
branches of educational psychology, such as the
psychology of learning to read, write and spell,
or the construction of tests of proficiency in the
school subjects, or the technique of tests of in-
telligence or maturity, belong wholly to this
field.

The education of the child is the product of
the sum of the external influences which are
brought to bear upon him, and of the reactions
which he makes to these influences. The study
of these reactions and of their laws is the scien-
tific foundation for rules of practice in attempt-
ing to guide and modify them. In so far as
these reactions are mental their study constitu-
tes the subject matter of educational psy-
chology.

The differences in the child's interests and
 capacities as he advances from babyhood to
maturity are important factors in his reactions.
For the treatment of this phase of educational
psychology, see the article on CHILD PSY-
CHOL OGY.

Principles of Learning.— In the second
place the child's reactions are governed by the
laws of learning,— both those which are gen-
eral in their application and those which depend
upon the child's stage of development. The
effect of practice upon skill or excellence of
performance has been studied in the case of a
variety of types of learning. One of the earliest
and most valuable studies was made upon the
growth of ability in the telegraphic language.
A number of studies have been made of the
somewhat allied process of typewriting. Some
light has been thrown on human learning by
studies of the behavior of animals in escaping
from a cage or learning to find their way
through a maze. In the field of sensory discri-
mination and the development of perception a
number of studies have been made — as, for
example, in learning to discriminate between
tones or colors, to overcome illusions, to apprehend and draw unusual figures. The progress
in learning a foreign language has been traced.
Numerous studies have been made of associa-
tive learning and memorizing. Memorizing has
been investigated to discover the best mode of
presentation, the best way of dividing material
— e.g., into large or small parts, the effect of
the learner's attitude, the permanence of
memory under various conditions, etc. Finally
the process of problem solving, as in the solu-
tion of puzzles, has been studied.

One of the characteristic features of the
study of learning is the construction of the
practice curves, which represents graphically
the rate of progress at different stages. The
form of some practice curves indicates a rapid
progress in the early stages, followed by a
gradually decreasing rate until progress almost
cesses. In other cases, however, the progress
is nearly uniform while it lasts; while in a few
the progress is slow at the beginning and more
rapid later on. The difference may perhaps be
explained by the varying ease with which old
habits may be adapted to the new task.

There are various sorts of fluctuations in
the curve of progress, some of short duration
and some lasting over weeks or even months.
A cessation in progress over a number of prac-
tice periods has been termed a plateau. Plateaus have been found to exist in several
forms of learning. A number of explanations
have been suggested. The earliest was that the
learner develops first certain simple habits and
later more complex ones, and that while he is
perfecting the simpler habits as a preparation
for the complex habits no apparent progress is
made. Another explanation is that the learner
either spurns and hence makes errors and
becomes confused, or becomes lazy and fails
to push ahead.

The extent to which practice or learning
produces not simply special habits or ability but
also general habits, attitudes, abilities or ideas
which are operative in other fields than the one
in which the training has taken place has been
the subject of many experiments and much
debate. It is now generally agreed that there is
some transfer of the effects of practice, but the
amount, the nature and conditions under which
it occurs and the importance of transfer are
matters of considerable divergence of opinion.
Among the factors which control the rate of
progress is the distribution of the practice
time. In the case of the rather simple types of
learning in reference to which this has been
studied rather short periods of 10 to 15 minutes
have proved favorable, but it is unsafe to apply this rule very widely.

The importance of mental fatigue in hindering progress in learning or in impairing mental work has been variously estimated. A distinction must be made between true mental fatigue, as represented by an actual falling off in ability to do mental work, and the mere feeling of weariness, which may or may not indicate real reduction in ability. What has often been thought to be fatiguing may not be. True fatigue may be merely loss of interest or suggestion. But the modicum of true mental fatigue which remains when this illusory fatigue is allowed for, probably hinders learning and interferes with the more difficult mental operations.

Learning in the School Subjects.—The third branch into which education psychology may be divided deals with the processes of learning which are characteristic of the school subjects. Important studies have been made of reading which reveal the nature of the behavior of the subject in the reading matter. The eyes are shown to move along each line of print intermittently, the words being perceived during the pauses only. The pauses vary in number and duration according to the subject matter, the most important fact, however, being that perception in reading is that it is by word wholes or groups of words. Some attention to the letters must be given in the early stages of learning, but the letters are soon subordinated by their organization into words. A factor in this organization is the association of printed words with spoken words, and even in silent reading there is a more or less distinct accompaniment of inner speech.

The writing movement has been studied chiefly by making records of the movements of the fingers, hand and arm as they contribute to the total movement as it appears at the pen point, and by measuring the speed of the pen movement and the pressure which it exerts. The fingers, hand, forearm and upper arm unite in various ways in different individuals to form a very complex and difficult movement co-ordination. Some diversity among individuals is desirable. Changes in pressure and in the speed of the stroke accompany the production of the particular letter forms. The speed changes determine the rhythm of writing which is closely related to ease and good form.

In the field of number some work has been done, particularly with the early stages of learning. The child gets his abstract idea of number through such concrete experiences as counting money, measuring, manipulating grouped objects, and there has been a good deal of discussion of the relative advantage of these experiences. Among other subjects of discussion are imagery types and their bearing on number operations, the nature of the mental process in calculation, and the amount and conditions of improvement in reckoning. Little study has been made of the mental process in solving complex problems.

The problem of spelling has been attacked from several angles, to determine, for example, the relative advantages of the drill method and the incidental method of learning, the best method of presentation of spelling words, the advantages of class study in comparison with individual study, etc. Elaborate studies have also been made of adult writing vocabularies in order to discover what words should be taught.

Studies of drawing have been directed chiefly toward the development of drawing ability and interest in the child. There have shown that the young child uses drawing as a language to express his ideas with a great deal of freedom, and have led to the acceptance of much crudity in his early work, in the knowledge that greater faithfulness of representation will come later.

There has been discussion of the psychology of other subjects, such as language and literature, history, geography and science, but little experimental investigation.

Tests in the School Subjects.—Besides experiments which are designed to discover the nature of the learning process in school subjects there have been in the past few years — for the most part since 1910 — many attempts to devise standard methods or tests to make possible comparable study of proficiency of children in the school subjects. These tests in some cases are made by the help of scales or series of specimens of pupils’ products in the subject in question, graded so as to represent regularly ascending degrees of excellence, with which individual work can be graded may be compared. Of this sort are several handwriting scales, a scale for judging English composition and a scale for drawing. Such scales do not by any means eliminate judgment in grading, and it is found necessary to give graders training before their scoring is uniform or comparable to the scoring of other grades; but it is possible by the use of such scales to obtain more accurate comparisons of the work of different groups of pupils than without them. The handwriting scales have proved the most successful on account of the greater ease with which excellence can be defined in handwriting than in such subjects as composition or drawing.

The other type of test consists of a series of tasks which are carefully selected so as to represent essential phases of a subject of study, and which elicit responses from the pupils which can be definitely and objectively graded. The units which enter into such a test are carefully graded by preliminary application. Sometimes they are made of as nearly equal difficulty and sometimes of progressive difficulty. The latter arrangement is desirable when pupils of a wide range of ability are to be tested. Tests of this general nature have been used chiefly in the subjects of arithmetic, reading, spelling and algebra, while beginnings have been made in some of the other subjects.

Among the questions which are being vigorously attacked by the use of tests are individual differences in the attainment of pupils in their mastery of the school subjects and the accompanying large overlapping in the learning of pupils of different ages and school grades, the large variation in the results obtained in different classes, schools or school systems, the causes of these variations and the relation of
methods of teaching or of supervision to the pupil's attainments.

General Tests.—Finally a branch of educational psychology which has been energetically pursued within the past 10 years and in which there has already been considerable development both in methodology and in outcomes, consists of tests which are designed to measure some phase of a mental function of a more general sort than is involved in one of the school subjects. Tests of sensory acuity — as of vision and hearing — and of keenness of sensory discrimination have been developed and used for a much longer period than 10 years. But apart from the detection of special sensory defects, for which elaborate technique and special instruments have been devised, and from the interests of theoretical psychology, the study of these elementary mental functions has in large measure given place to the attempt to measure the higher mental processes. Exception should perhaps be made of tests of pitch discrimination, which has proven significant as a means of detecting capacity for musical education, and of some other simple processes which may be important as means of determining vocational fitness. But in general the burden of opinion is that tests which involve such processes as memory, association, reflective thought and originality in meeting problems give much more valuable insight into intellectual capacity.

The recent revival of mental tests is due in large measure to the work of the French psychologist, A. Binet. Binet was given a commission to prepare a method of selecting children from the schools of Paris who were to be put into special schools for retarded pupils. In collaboration with T. Simon he arranged a series of tests graded in difficulty and designated certain points in the series as corresponding to the capacity of children at particular stages of development. In the first revision of the series in 1908 a group of tests was chosen to represent each age from 3 to 13. A still further revision in 1911 brought some rearrangement but no change in the principle of construction.

The Binet-Simon graded tests have stimulated very extensive trial of the series itself and very many attempts to standardize other single tests or groups of tests. The fundamental principle, which is that the child's advance- ment with age is accompanied by the attainment of the ability to perform tasks of regularly increasing difficulty and that the ability of a child to perform tasks above those which are found to be typical for his age indicates superior intelligence while his inability to perform tasks which are typical for his age or for a lower age indicates inferior intelligence — this principle of age standards has proven to be very fruitful, although many questions of detail have arisen in the application or interpretation of the tests. A more radical reconstruction is represented in the Yerkes-Bridges point scale which uses almost entirely Binet tests but discards the arrangement by ages. The child is given a certain number of points of credit for successfully passing each test (or partial credit for partial success) and his score is obtained by adding all his points of credit. The score is then interpreted by comparison with age, sex, etc., norms.

It is obviously of advantage to have convenient means of determining in an examination of an hour or less the degree of intelligence of the child. Imperfect as the methods thus far developed admittedly are, they are already very useful in selecting children for special education, either because they are retarded or advanced — and in examining delinquents in the courts to determine whether the delinquency is due primarily to intellectual defect.

The very extensive recent experimentation with single tests has resulted largely from the use of tests of the higher mental processes as already noticed and from the derivation and adoption of the more refined methods of calculating correlation. The significance of a test can only be determined by working out the relation between ability in the test and ability in some other test, or general ability as measured for example by the estimate of teachers or acquaintances. A test is useful according to the closeness of the correlation between attainment in the test and some other attainment representing the ability which it is designed to measure. Besides tests of general intelligence some attempt has been made of securing only limited success up to the present, to devise tests of the special sorts of ability which are required in the various vocations. Tests of general intelligence themselves have proved to be of some value for vocational guidance.

EDUCATION, Retardation. See Education of the Feeble-Minded and Mental Defectives; Retardation of Pupils.

EDUCATION, Rural. When school systems were first organized in America, the people of this country were almost wholly engaged in agricultural pursuits. The social and civic life of the people was extremely simple. The increase in population, our great development in industrial and commercial activities, the rise
of great cities in all parts of the country, and the advancement in science and invention have been the means of establishing advanced standard of civilization which require complicated services from the social and civic institutions of the community.

Administration of Rural Schools.—The great agency in America which is to prepare our citizens for the highest possible kind of service and which is to enable them to meet successfully the great problems of democracy is the public school system. The enlarged scope of the function of the school has brought prominently to the attention of the public many problems which affect the economic and efficient administration of our school systems. One of the most difficult of these problems and one of paramount importance to the country at large is the proper organization and administration of rural schools. This question is, of course, one of primary importance to the agricultural sections of the country and, yet it is not exclusively related to the interests of rural communities. The number of people residing in the cities of the country has constantly increased until nearly one-half of the entire population now reside in cities. The number of the cities in the country and the population of these cities will constantly increase. There has been a decrease in the population of the agricultural sections of nearly every State in the union. The prosperous and growing cities and villages with their increasing millions of people and their great industrial plants turning out billions of raw materials which are distributed throughout the civilized world are placing additional burdens and affording greater opportunities and advantages to those who are living upon the farms.

The agricultural lands of America must supply not only the food products for the people living in the cities as well as the country and certain raw materials which are needed in the great manufacturing establishments, but they should also be able to reap the financial reward which will come from supplying the demands of the foreign trade. The results achieved in the past must be the goal set for the future. There must be more intelligent and scientific management in our agricultural pursuits. The administration, therefore, of rural schools must have a direct and vital bearing upon the economic, industrial and commercial activities as well as upon the social and civic progress of the nation. The interdependence of the people living in the cities and of those living in the rural sections must be recognized, and the schools maintained in the rural or agricultural sections must be administered from the broad standpoint of the general needs of the nation.

There has not been the same measure of improvement in the rural schools of the country that there has been in the advancement of the schools of the cities and populous sections of the nation. The general trend of educational movements in the cities for a long period of years has been to enable the schools maintained therein to meet the living conditions and necessities of the people whom such schools serve. Unfortunately, this general object has not been in the case of the rural schools. There has, however, been a great change in school administration and in public sentiment in this respect within the last 15 years. Many of the leaders in national movements have come to see that the rural school problem is one of the great constructive problems in the public affairs of the country. Great energy is now being directed to an effort to make the country schools the equal of the city schools. There has been much legislation in all parts of the country to accomplish this result. The school term has very generally been extended; compulsory education laws have been made more effective; there has been an enlarged use of school rural life and grounds with the idea of organizing the school itself as a social center; provision has been made for organizing instruction in agricultural courses in all schools; consolidation of small schools has been encouraged by the payment of larger quotas of state funds; medical inspection of school children has been authorized as a means of conserving life in agricultural communities, and provision has been made in various ways to afford boys and girls living in the remote farm sections the advantage of the high school training. This is a long list of important legislative measures which have been considered in many of the States. The effect of the enactment of these laws upon the efficiency of rural schools is now yielding results. However, to make the work of the rural school as efficient and as well adapted to the needs of the people as the city schools are, several important things must be done. Among these are:

1. The courses of study maintained in the rural schools must be adapted to the social and economic conditions of rural life.

2. The schools maintained in the rural sections must be in operation for a period of time equal to that which schools are maintained in the city or more populous sections.

3. The same care must be taken to conserve the life of the child in the rural community which is now generally exercised in the city.

4. The school buildings, grounds and equipment of the rural school must be as adequate and as attractive as those of the city schools.

5. The teachers employed in the rural schools must be as capable in the work of scholarship, professional training and experience of the teachers employed in the city schools.

In recent years there has been a great expansion in the courses of study intended to meet the conditions of industrial centers. The theory is that the school is not only to teach children the fundamentals of an education but it is intended to train them so that the instruction which they receive shall be of service to them when they leave school to assume their obligations of citizenship. To meet the necessities of boys and girls who go into industrial life, manual training, industrial and vocational schools have been authorized. If courses of study are to be maintained in populous centers for the purpose of meeting the needs of the industrial workers, the obligation rests upon the State to make provision for equal opportunity in the education of boys and girls who are to assume the responsibility of the future operation and management of the agricultural interests of the country. Instruction in industrial art and in vocational courses must be satisfactorily in the rural schools as in the city schools. Agriculture is the greatest industry of the nation. The schools maintained in the
agricultural regions contain the great bulk of recruits for farm life in the nation. Practical courses should be given in these schools along the lines of scientific agriculture. Potato clubs, corn clubs, canning clubs and other similar clubs related to agricultural work should be organized in every rural school. Home project work will be an important feature of a modern, efficient rural school. To illustrate: the pupils in a corn club could be shown what soil is adapted to the growing of corn and what fertilizers are essential. They could be shown how to prepare the soil for planting corn; the selection of seed could be carefully determined; the planting could be done at the proper time, and the crop could be properly cultivated; the value and necessity of frequent cultivation and of rotation in crops could be illustrated. The harvesting could be done at the proper time and under the best approved methods and the method of placing the crop in the market with the least expense and the greatest advantage to the school could be learned. The farm located in every school district in the country should be made the great laboratories on which experimental work in farming could be carried out. The parents of children in the schools will generally be willing to cooperate with a successful teacher in the experiments which such teacher desires to make in the real live, active management of a farm. The same process could be pursued in sections where potatoes are the principal crop. Similar experiments could be made in relation to all farm products, fruit growing, etc. Matters pertaining to the management and care of the home will interest the girls; the canning of fruit, preserving vegetables, making bread, etc., are activities in which they may be interested and given instruction. In most of the great agricultural States, a State college of agriculture is maintained at public expense. These institutions are all doing great research work and are making scientific experiments and are producing information for the benefit of the farmer. This information, however, will not be of great service to the State unless there is some medium able to bring it to the general knowledge of the farmers of the State and to make of such knowledge a practical application. Fruit exhibits and contests, vegetable exhibits and contests, similar exhibits and contests in grain and other products, the common rules to be observed in caring for poultry, and a dairy are matters which may be included in courses of study in rural schools and increase the interest in school work and make the work of the school more effective, practical and efficient. In the year 1917 800 boys pursued in the schools of New York State what is known as home project work. After paying all expenses incurred in their experiment and being assigned for their own labor $20,000, these 800 boys had a net profit of $40,000. Each of these boys earned on the average $75. Of course, some of them earned more than $75; some received less than $75. Is not this, however, the rule in the actual affairs of life including farming? Does not this experiment present the opportunity to show the boy who failed the causes for such failure, to point out to him how much failure to success, and to offer to him the necessary encouragement to achieve this result? These illustrations are sufficient to indicate the type of work which is to form a prominent feature of the courses of study in the future work of the rural schools of America. It is not the custom in any of the States to maintain rural schools for the same period of time which schools are maintained in cities. In most of the States there is a provision of law which requires the school to be maintained in every district and city of the State for a certain number of months. This period of time varies from six months to nine months. It is the custom, however, in cities to maintain school for ten months. Four weeks is usually considered a month. It is not possible to give the boy or girl in the country districts the same opportunity to obtain an education which is afforded to the boy or girl in the city unless the period of time which school is maintained in the country district is equal to the period of time that the school is maintained in the city. Supervising and directing the health interests of children is now regarded as essential as the supervision and direction of matters pertaining to their intellectual development. This work has been organized as a part of the regular school work in nearly all rural schools in the country. It should be extended to all rural schools. The conditions of children in the country districts is generally at a lower standard than the health of children in cities. The child who is compelled to attend a country school is just as much entitled to the benefits of health instructions as the child residing in the city. A child in the country district is subjected to the danger of contracting a contagious disease and is, therefore, entitled to every precaution which the State can afford to protect him from this danger. There is not the same careful supervision of the physical condition of children living in the country that there is of those living in the cities. The rural school should, therefore, be made the great agency not only in the development of health regulations, but of a knowledge of sanitary principles in all rural communities. Physical training should form a part of the curriculum of every rural school. The children in the country should be made to realize the difference between children living in the cities. This does not mean, however, that they do not need physical training which is provided for the children in the cities. The children in the country districts are generally in greater need of systematic training in physical education than the children living in the cities. The children of the cities are afforded greater facilities for play purposes than the children of the country. It is argued that children of the country have the entire farming area in which to play and to obtain recreation. They may not obtain these privileges, however, without becoming trespassers. The children living in the country are entitled as a matter of right to playground facilities. The sites on which schools are erected should contain a sufficient amount of land so that a playground, croquet ground and other necessary recreation and play may be organized and maintained for the benefit of the children attending school. Such sites may be turned over to the school district to be maintained at small cost. It is entirely within the financial ability of school
districts to provide these facilities for the children. The most progressive communities are giving this subject attention. The tendency throughout the country is to erect attractive school buildings in the country districts. It costs but little more to make a country school building attractive, sanitary and to conform to the modern principles of lighting, heating and ventilating. The State school authorities of each State in the Union should possess the authority to approve the plans and specifications of every rural school building which is constructed. The grounds should also be made attractive.

There is no factor in a rural school so important as the teacher. Proper courses of study, suitable and attractive buildings with adequate equipment, the maintenance of schools for a longer period of time will not lead to the progress required in the administration of the rural schools unless teachers of better qualifications are employed in such schools. Lower salaries must be a sufficient condition for the teachers employed in rural schools than in the city and village schools. The children in attendance upon these schools will not receive the efficient instruction to which they are entitled until teachers are employed in these schools who have qualifications substantially equivalent to the qualifications provided for teachers in the populous centres. The teachers in these schools should, therefore, be required to show the completion of a four years' academic course of training and thereafter the completion of a professional course of two years which relates especially to the conditions and needs of rural life.

Consolidation of Rural Schools.—To effect the general change in the administration of rural schools to enable these institutions to accomplish the purposes which are now demanded of them, there must be a reorganization of rural school systems. Two elements are essential for the maintenance of successful rural schools. There must be a sufficient number of children to create the interest essential to the school and a sufficient amount of property to support such school without the taxation becoming burdensome. The modern idea in all parts of the consolidated small rural schools into central schools so that these schools may be properly graded and advanced instruction be provided. The daily rural free delivery, the telephone, electric lights, good roads, the automobile, the auto bus and the trolley line are the advance agents of the consolidated rural school.

The first State in the Union to enact a law providing for the consolidation of school districts was New York. That State took such action as early as 1833. The action taken, however, applied to cities and villages. It did not extend to country districts. Massachusetts provided for the consolidation of schools as early as 1869 and made provision at the same time for the transportation of pupils. The consolidation of Massachusetts with its rural schools. About 1890 Massachusetts paid less than $23,000 for the transportation of children who lived so remote from schools that they could not walk to and from school daily. The Western Massachusetts was paying for the same purpose $500,000. The movement for the consolidation of schools and the transportation of children has gradually extended until it has reached every State in the Union. Indiana, North Dakota, Ohio and many of the central western States have been leaders in this movement. Indiana has undoubtedly done more in the matter of consolidation of rural schools than any other State. The success of the great effort which is now being made throughout the country to improve the rural schools depends very largely upon the consolidation of schools and the transportation of pupils. It has been established in all parts of the country that it is feasible without injustice to the taxpayer or hardship to the children to organize consolidated rural schools which will afford the country children practical, cultural and advanced courses of instruction which are the equivalent in every particular of courses which are maintained in cities and villages. It is just as feasible to maintain courses in these schools which will prepare a boy for admission to college or for industrial or professional life as in the courses in the cities and villages. Agricultural and industrial arts and home economic courses should form an important part of the curriculum of a school of this type, and the boys and girls desiring to pursue vocations along these lines are entitled to the same aid and encouragement that is given to the boys and girls who desire to pursue the long established traditional courses.

Transportation.—There is now an extended system of transportation of school children in operation in all parts of the country. Many agencies are now utilized extensively in taking children to and from school when these children reside too far from the school to walk to and from it daily. Boys and girls go to school portions of the year on bicycles. Various types of individual conveyances are used. The automobile has been brought into extensive use for this purpose. Automobile busses are employed in several communities. Electric lines, steam lines, motor boats, etc., are also employed. Where transportation is provided systematically and with good business regulations and supervision, the objections that have been raised are generally overcome. A child may ride from two to four miles in a comfortable wagon or other conveyance and still reach a good school without hardship. Under proper regulation it is just as safe for children to be conveyed to school as it is for them to walk to school. Where busses or conveyances are employed for the transportation of children, they must be operated under definite regulations which are strictly observed. There should be an established route with scheduled hours for arrival and departure and drivers should carry watches and be required to maintain this schedule. It is possible to arrange schedules so that children will be on the road the minimum period of time and be required to travel a minimum distance. These matters are being arranged in all parts of the country without inconvenience to the home and with little hardship. The established hours which regulate farm life. No person should be employed as a driver to carry children to and from school who has not the full confidence of the community. He should be made responsible for the conduct of the children during the time they are under his care to the same extent that a teacher is re-
sponsible for their conduct while they are in school. Transportation should be provided at public expense. In many States appropriations are made to communities which provide transport.

Highways and the Schools.—There is another important factor which enters into the ability to provide better educational facilities in country districts and this is the improved system of highways which is being established in many of the States. Not only are the States developing improved highways, but the national government is making appropriations for the construction of highways. These roads have made rural life more attractive, have made agricultural pursuits more profitable by bringing the farm in closer touch with the markets, and they afford those living in the rural regions the opportunities of social life which prevail in the village and city. These roads have also enhanced the value of farm property. We may, therefore, confidently expect that improved State roads will be extended and developed in the future.

The greatest obstacle in the way of better rural schools is the increased cost involved in their maintenance. The relation of the country district to the city and to the State at large is such that States may with propriety and with justice to all parts of the State appropriate more money in proportion for the maintenance of rural schools than it does for the maintenance of schools in cities. The relation of the maintenance of proper rural schools to the needs of the nation itself is such that the national government has instituted a plan which contemplates national aid for rural education. The results which could be accomplished for the national service through appropriations by the national government justify the government in making such appropriations. The rural school systems of the several States should be made as practical and as efficient as the schools maintained in any of the populous centres of the country.

THOMAS E. FINEGAN,
Deputy Commissioner of Education and Assistant Commissioner for Elementary Education, State Department of Education, Albany, N.Y.

EDUCATION, Secondary, in America.
The history of American secondary education presents three stages of development: First, the colonial period, with its Latin grammar schools; secondly, the period extending from the Revolutionary War to the middle of the 19th century, with the *academy*; and, thirdly, the period down to the present, chiefly characterized by the growth of public high schools.

THE COLONIAL PERIOD

1. The Founding of Grammar Schools.—
The influences which most vitally affected the early development of secondary education in America were the example of the *grammar schools* of England and the rising spirit of democracy. England was largely at the time in its modes of thought and kept in touch with Calvinistic portions of Europe.

Early in the history of the colony of Virginia, funds were raised and lands set apart for the endowment of a Latin grammar school. But these promising beginnings were swept away by the Indian massacre of 1622 and the school seems never to have been opened. The town of Boston set up a Latin school in 1635, which has had a continuous existence down to the present time. This school was established by vote of the citizens in a town meeting; it was supported by private donations and by the rent of certain islands in the harbor, designated by the town for that purpose; and a town rate seems to have been levied when necessary to make up a salary of $244.50 a year for the master. Other Massachusetts towns followed the example of Boston. School fees were commonly collected. A town rate, which was depended upon at first only to supplement other sources of revenue, gradually came to be the main reliance; and by the middle of the 18th century most of the grammar schools of Massachusetts charged no fee for tuition. Latin schools were early established in Connecticut; one at New Haven in 1641 and one at Hartford not later than 1642. A notable bequest of Edward Hopkins, sometime governor of Connecticut colony, available in the middle of the 17th century, was devoted to the maintenance of Latin grammar schools in Hartford and New Haven, and also in the towns of Hadley and Cambridge in Massachusetts. The Dutch at New Amsterdam opened a Latin school in 1659, continued for some years after the colony passed under English rule. Secondary schools were established in Pennsylvania in the latter part of the 17th century. One of these, the William Penn Charter School at Philadelphia, has continued down to the present day. King William's school at Annapolis was erected by the legislature of Maryland in 1696, and similar schools were established in different sections of the same colony. The 18th century saw schools of like character opened, partly by legislative enactment, partly by private initiative, in these and in the remaining colonies. Some of the number, like the University Grammar School in Rhode Island and the Free School at New York, were the forerunners or the accompaniments of colonial colleges.

2. Character of the Grammar Schools.—
The chief emphasis in these colonial schools was laid on preparation for the college entrance examination and the admission to college determined the course of study. The colonial grammar schools accordingly taught Latin, a little Greek, religion and little else. Both grammar schools and colleges were intended especially for the directive and professional classes and had little connection with such elementary schools as there were. In Massachusetts, towns which maintained grammar schools were not required to maintain reading schools. Sometimes pupils were taught to read in grammar schools, but the grammar school teachers objected to this burden; and, too, the mixing of the two grades of instruction in one school was recognized as an evil. The grammar schools exercised a kind of selective function, discovering latent capacity for the higher studies and sending talented youth on the way to college. Those who showed capacity of a lower grade or of a different sort received little attention or encouragement.

3. The Organization of Colonial Systems.—
In the organization of colonial systems of sec-
secondary education important beginnings were made. In 1647 the colonial legislature of Massa-
chusetts ordered that every town should be maintained in every town of 50 fam-
ilies; and that in every town of 100 families there should be a grammar school, in which students might be fitted for the university. This provision was copied by the colonies of New England and New Hampshire, and in Con-
necticut the provision was afterward changed to require a grammar school in each county town. These New England colonies maintained and enforced such provisions down to and after the Revolution. Maryland also established by law a system of county grammar schools. When the colonies were transferred into States, after the Declaration of Independence, the sys-
tems of schools in the four colonies mentioned were continued with little change, but no other of the 13 States had anything that could be called a system of public instruction.

THE PERIOD FROM THE REVOLUTIONARY WAR TO THE CIVIL WAR.

1. The Founding of Academies.— As we approach the Revolutionary period, we find new social conditions giving rise to a new order of schools. With the growth of sectarian differ-
ences there appeared a decided tendency toward the separation of governmental from eccle-
siastical affairs and thus the position of edu-
cational institutions was disturbed. This change lessened the prestige of colonial systems of education among the adherents of the religious de-
ominations and a growing distrust of the col-
leges appeared among those who most in accord with the secularizing tendency of the time. The old grammar schools were weakened by these influences and in their stead there grew up a new type of secondary school, com-
monly known as the academy.

Both the name and the character of the new institution were suggested by precedents in Eng-
land, where the Dissenters were excluded from grammar schools and universities. In the lat-
ter part of the 17th century the non-conformist bodies first established “academies,” schools in the main secondary, which, however, undertook to prepare candidates for the non-conformist ministry. The fame of these English academies seems to have influenced the thought of the American colonists in the matter of public edu-
cation; first the strong theological bent of their English prototypes reappeared in the new Amer-
ican schools; and then the resemblance was more obvious in the wide range of studies of-
fered, for the English academy had been more practical and technical than the university. But the American academies soon came to have a well-defined character of their own, apart from any conscious imitation of English models.

In 1720, a school for classical and theological studies was established by a Presbyterian minister at Neshaminy, in Pennsylvania. It was commonly known as the “Log College,” as its home was a building made of logs. This school in the wilderness was the centre of deep and widespread interest in classical studies as well as in the religious life. It sent out large numbers of zealous pastors and teachers, who established “log colleges” all over the highlands of the middle and southern colonies. The Neshaminy Log College itself was later incor-
porated with what is now Princeton Uni-
versity. Through the efforts of Benjamin Franklin, a school was established at Philadel-
phia, legally incorporated as an academy in 1753, and probably the first institution in Amer-
ica formally designated by that title. It was under the control of a self-perpetuating board of trustees. A fund raised by private subscription for its establishment and maintenance was supplemented by a grant from the New York treasury and by tuition fees, which were re-
mitted in the case of those unable to pay. This academy organized in three departments or schools; namely, the Latin, the English and the mathematical, put little stress on the theological element and much on English language and lit-
erature and the mathematical sciences. The school ultimately developed into the University of Pennsylvania. Within two or three decades after the founding of this school at Philadel-
phia, a number of schools somewhat similar in character, and some of them bearing the name academy, were established in the middle and southern colonies. In New England the two Phillips academies, one at Andover in Massa-
chusetts and the other at Exeter in New Hamp-
shire, were incorporated in 1780 and 1781, re-
spectively. The influence of these two schools extended to remote States, especially in the growing West; and they still rank among the strongest and most influential secondary schools. The academy movement begun in Revolutionary times grew apace even down to the period of the Civil War. More than 150 were incorporated in Massachusetts alone between 1780 and 1865.

Dexter in his ‘History of Education in the United States’ tabulates 6,085 academies in the United States in 1850, employing 12,260 teachers and giving instruction to 263,096 pupils.

2. The Character of the Older Academies.— The old academies were generally endowed in-
stitutions, organized under the control of self-
perpetuating boards of trustees or of religious bodies, established to serve the need of a wide constituency and not merely of a single com-
munity, and often located in small country places. Many of them made provision for boarders as well as for day pupils. They were not intended in any exclusive sense for the training of future members of the learned pro-
fessions, although many of them developed into preparatory schools. In the Western States preparatory schools attached to colleges were commonly called “academies.” But such was not the earlier purpose of the academies, which were largely schools for the middle classes and answered to a growing desire after learning for its own sake, or for the increased efficiency it would give in other than profes-
sional pursuits.

Their training was more “practical” than that of the colleges, wider and more liberal than that of the grammar schools, or of some of the colleges. They laid new stress on the study of the English language, together with grammar, rhetoric and public speaking. They taught mathematics, often including surveying and navigation; began the study of natural science, especially of natural philosophy (phys-
ics), of which astronomic large was a dominant division; gave courses in geography, an-
cient history, English and above all American history, French often and German seldom. Latin and Greek were the substantial core of the instruction offered. In the earlier days, the
course of study was not well defined. In English, Latin and mathematics a good degree of continuity of work was apparently maintained, but in others, classes were formed at irregular periods, because of the exigencies of rural life which demanded certain courses be confined to a short winter term not interfering with farm labor. When finally definite courses of study were laid out, they varied in length from three to four or five years. Parallel courses were offered. That including classical studies and covering the requirements for admission to some college was commonly regarded as the standard course of the school. With this might be found an English course. Afterward a scientific course was often provided.

Many of these schools were established by religious bodies. Catholic secondary schools began to appear in this period, established by the several teaching orders. The Society of Jesus founded institutions of secondary and higher education in the United States after the Revolutionary War; the Brothers of the Christian Schools opened their first school in America at Montreal in 1838; soon after set up establishments within the United States, at Baltimore and New York, and followed these elementary schools with secondary courses; and besides many conventual schools for girls were established, which drew a large clientele from other than Catholic families. The academies established by Protestant bodies usually terminated their formal connection with ecclesiastical societies upon their legal incorporation. The religious instruction which they carried on concerned itself for the most part with the broad underlying principles of Christianity, so that the non-Catholic academies, even such as had arisen from the initiative of religious societies, tended toward the non-sectarian character which has been more fully exemplified in the public schools of later times.

The grammar schools had been exclusively for boys. Such was the case with many of the academies. But others were coeducational, and there grew up also a large number of academies for girls, which were too often without the title of "female seminary." The last two prepared the way for two types in higher education, appearing in the fourth decade of the 19th century; namely, the coeducational college and the college for women exclusively.

The academies broadened the intellectual horizon of families and communities and reinforced the protest which was arising against the narrow curriculum of the American colleges. In the absence of special schools for the training of teachers, the better elementary schools were for a long time in the hands of academy graduates. Special classes were organized in New York and Pennsylvania academies for instruction in the art of teaching and a seminary for teachers was opened in conjunction with the Academy at Andover. When State normal schools began to be established in Massachusetts in the year 1839, suggestions for their organization and management were drawn from this seminary and from the current practice of academies. With the introduction of normal schools in this country a new means of secondary training of considerable importance was added, since these institutions began and continued to devote a large share of their time to work essentially academic in character and of secondary rank.

3. The Rise of the Public High School. In the early part of the 19th century there appeared a strong demand for schools under the exclusive control of the State. The Calvinistic view of the civil power had prepared the way for State agency in education, and the steadily advancing separation between church and State kept alive the question as to the relation of the schools to both. The well-established theory that the State should grant charters to colleges, authorizing them to manage their own affairs under close corporations, with incidental aid from the State in the shape of gifts of land or money, was long applied to secondary education as well. The first step in the establishment of public secondary schools was taken by the larger towns and municipalities, under the lead of Boston, where in 1821 was established an "English Classical School" which soon took the name of "English High School," probably imitating the style of the Edinburgh High School. The report to the school committee made at the time of its founding said: "The mode of education now adopted, and the branches of knowledge that are taught at our English grammar schools are not sufficiently extensive nor otherwise calculated to bring the powers of the mind into operation nor to qualify a youth to fill usefully and respectably many of the stations, both public and private, in which he may be placed. As the course was adopted, embracing English language and literature, mathematics, navigation and surveying, geography, natural philosophy (including astronomy), history, logic, and moral and political philosophy. Latin and modern languages were added afterward and the course was extended to four years. Students were received into the high school from the elementary schools of the city, but at first were not prepared for admission to college, that being the function of the Latin school. But with the addition of foreign languages and the study the English High School fitted its students for admission to certain higher institutions."

Other Massachusetts towns followed the lead of Boston in this matter. Philadelphia, in 1838, established the Central High School, under special authorization from the Pennsylvania legislature. Baltimore followed with the establishment of a "city college." Providence opened a public high school in 1843. Hartford, in 1847, transformed her old grammar school into a school of the new type. New York opened a "free academy" in 1848, the name of which was afterward changed to the College of the City of New York. This school was established in accordance with a special act of the State legislature, ratified by vote of the people of the city. The growth of public high schools prior to the Civil War was not rapid. The exact number established in the first 40 years of the movement has not been accurately determined, due to the inaccuracy and meagerness of data upon the question. Ingles, compiling from data given in the report of the United States Census, estimates the total number established prior to 1860 at 321, indicating, however, that the esti-
mater is probably very inexact. Cubberley, following a table prepared by William T. Harris while United States Commissioner of Education, says that as late as 1860 but 69 of our present cities are regarded as organized a clearly defined high-school course of study. Prior to the Civil War, and for a long time after it, the public high school movement encountered hostility from those who regarded the academy as the final or best solution of the problem of public secondary education. It also encountered hostility from those who were opposed on principle to the recognition of secondary education as a proper field for governmental agency.

4. The Beginnings of State Systems of Secondary Education.—Soon after the close of the Revolutionary War, new State systems of education began to be established, in which special provision was made for secondary schools. The University of the State of New York, erected in 1784, was an example of the strong influence which French thought then exercised in American affairs, as it realized the conception of a university put forth by Diderot and others of the great French writers of the eighteenth century. The University embraced the whole provision for secondary and higher education within the State, with the exception of schools of a purely private character. Its control was vested in a Board of Regents, consisting of the governor and the lieutenant-governor, ex officio, and 19 members elected by the State legislature. The reorganization of 1787 made the Board of Regents distinct from the Board of Trustees of Columbia College, with which it had been identical. This university exercised great influence on later systems; and in Georgia, by an act passed in 1785, "All public schools instituted, or to be supported by funds or public moneys in this State, shall be considered as parts or members of the university"; and in the territory of Michigan an act passed in 1817 established a university of imposing character. The latter establishment existed mainly on paper, and the act incorporating it was repealed in 1821. The Georgia "university" also never amounted to much. In the United States a comprehensive type of university organization was not widely adopted, there was a general desire in the early part of the 19th century to establish complete and well-rounded systems of public instruction. The legislature of Tennessee declared in 1817 that "Institutions of learning, both academies and colleges, should ever be under the fostering care of this legislature, and in their connection with each other form a complete system of education." Even more significant is the provision of the constitution of Indiana, adopted in 1816, that "It shall be the duty of the general assembly, as soon as circumstances will permit, to provide by law for a general system of education, ascending in regular gradation from township schools to a State university wherein tuition shall be gratis and equally open to all.

For the most part, however, actual State agency in secondary education was as yet limited to the subsidizing of privately managed academies. In Massachusetts provision for grammar schools under town control was continued after the colony became a State, but the law was so changed that only the larger towns were left subject to this requirement. At the same time academies established by private initiative were endowed by the legislature with grants of public lands. In Kentucky the State legislature granted 640 acres of public lands to an academy in each county. In Pennsylvania colleges and academies received financial aid from the State for many years, culminating in 1838 in a general State system of educational subsidies. Five years later such aid was discontinued. In other States the granting of State subsidies, in money or lands, to secondary and higher schools was customary for many years. For the most part there was but little system or consistency observable in the distribution of such aid; and the State-aided institutions were not subjected to any sort of State control.

It would seem an easy transition from the State policy of granting subsidies to private secondary schools to the policy of providing by law for the establishment, and even the support, of such institutions. In 1824, however, readily made, since, as has been mentioned, many objected to the principle involved regarding secondary education as a proper field of governmental agency. The legal questions wrapped up in this later stage were not settled until 1874, when the Supreme Court of Michigan, in what is known as the "Kalamazoo Case," decided: "Neither in our State policy, in our constitution, nor in our laws do we find the primary school district restricted in the branches of knowledge which their officers may cause to be taught, or the grade of instruction that may be given, if their voters consent, in regular form, to bear the expense and raise the taxes for the purpose." The principle involved was applied long before this decision, however. As early as 1798 Connecticut authorized the opening of higher schools by the local authorities ("school societies"). In Massachusetts the law requiring grammar schools in the towns was so far weakened, in 1824, that towns having a population of less than 5,000 were allowed to substitute therefor an elementary school. But three years later, 1827, it was enacted that every town having 500 families should provide a master to give instruction in the history of the United States, of geography, geometry, surveying and algebra; and every town having 4,000 inhabitants a master capable of giving instruction in Latin and Greek, history, rhetoric and logic. Due to the strong entrenchment of the "district system," this law was modified and even weakened many times prior to the Civil War; but in the revision of 1859 all of the essential provisions were re-enacted and even bettered. Iowa adopted a provision in 1849 expressly permitting the aiding of higher grades to the district schools; and in 1858 authorized the establishment of county high schools. In New York, systematic grading of schools went steadily forward; and the "academic departments" of these schools corresponding to the high schools of other States, formed a part of the University of the State of New York and received financial aid from the literature fund. In Maryland, the county academies, which had displaced the grammar schools of colonial days, continued for many years to receive financial aid from the State. Prior to the Civil War, therefore, all later types of State interest in secondary schools of a public character were at least represented;
the *permissive* type; the obligatory type; and the type in which a complete and well-rounded system was sought.

THE PERIOD FROM THE CIVIL WAR TO THE PRESENT.

1. Statistics of Growth.—From the Civil War to 1890 data upon this point are very incomplete and inaccurate. The United States Bureau of Education, formally established in 1866, almost immediately began to collect statistics regarding secondary institutions. Difficulties were at once met in classifying such institutions and in getting reports from them. Work of secondary character was done in schools bearing all sorts of titles: academies, high schools, seminaries, female seminaries, institutes, grammar schools, preparatory schools, colleges, universities, schools of science and normal schools. It was well into the eighties before the public high schools began to rival their competitors in numbers of students. Since 1890 the growth in such schools as well as in the number of students enrolled in them has been phenomenal. The following table is compiled from the report of the United States Commissioner of Education for the year 1914:

The tremendous growth shown has been the result of a large number of factors. In the first place, social changes of great significance have been taking place since the Civil War period. A number of these changes peculiarly important in their bearings upon secondary education need not be mentioned: the rapid increase of population containing a large percentage more or less unacquainted with our political conditions; the growth of science with resultant discoveries and inventions; and, largely in consequence of these, the multiplication of industries and vocational opportunities requiring special training. Along with these, the increase in wealth, both public and private, the growth of cities, the systematization of business and the opportunities afforded for leisure have produced far-reaching results upon secondary and higher education. In the second place, education as a study has taken a place among the sciences. In this development secondary education has received attention, especially in the field of adolescent physiology and psychology. G. Stanley Hall's notable work on 'Adolescence' (q.v.), published in 1865, started a new interest in both the kind and the extent of education which youth should receive. All of these factors are extremely complex in their bearings; and in spite of the great advances so far made, the principles of secondary education both in their administrative and theoretical aspects constitute problems rather than fixed conclusions. Some of the most important of these problems may be reviewed.

2. The Relation of Secondary to Higher Education.—While the public high school grew up primarily to serve the students who did not plan to enter college, the new institution did not long remain uninfluenced by the demands of higher institutions. In the seventies and eighties, much discussion took place relative to the wisdom of high schools emphasizing preparation for college; but the question was soon dropped as a problem of division. The relation between these institutions became probably the most important question in secondary education for the ensuing three or four decades.

One of the earliest methods of adjusting this relationship, and one which remains to-day as probably the most effective, is the so-called *accrediting system.* This system was inaugurated by the University of Michigan in 1871. Under it the university admitted to its freshman class, without examination, such graduates of private universities and colleges likewise recommended for that purpose by the principals of those schools. It depended upon a purely voluntary agreement between the secondary schools and the higher institutions, so that the school rather than the individual was examined; and the inquiry related chiefly to the vitality, intelligence and general effectiveness of the instruction. A large number of other State universities have adopted this general plan; some have developed elaborate and rigid means of inspecting the secondary schools, while others have failed to do so because of the large amount of work and expense involved. Some have resorted to a large extent upon written reports; others have insisted upon first-hand inspection by a university officer. In 1914, according to the bulletin of the United States Bureau of Education on *Accredited Secondary Schools in the United States* (Bulletin, 1915, No. 7), at least 19 State universities relied upon lists prepared by their own authorities. A number of private universities and colleges likewise build their own lists; some examples of these are University of Chicago, Johns Hopkins University, Catholic University of America and Saint John's College.

In a considerable number of cases State laws have empowered their own State departments of education to classify and standardize secondary schools. Some erect very elaborate systems of grading and employ an adequate inspection force. In 1914 New York had an inspections division under the Board of Regents consisting of a chief and 13 assistants, of whom 10 at least gave their whole time to the work. Ohio and Minnesota are other notable examples of this system, but with a less highly developed technique than New York. In many cases, State universities accept the lists of accredited secondary schools made by the State departments; such is the practice at present in at least 10 States. In some of the Southern States the success of this system has been marred by failure to maintain any inspection with the General Education Board of New York city. These State lists have served other accrediting boards throughout the country and have exerted a powerful influence toward raising standards within the States preparing them.

A third series of agencies influential in developing the accrediting system may be found
in a number of associations formed in different sections of the country and made up of representatives from both secondary schools and higher institutions. These grew up primarily to bring these representatives together for the purpose of discussing common problems; and while retaining the original purpose, they have added the work of preparing lists of accredited secondary schools for the use of the institutions represented. The parent society of this sort is the New England Association of College and Preparatory (now Secondary) Schools organized at Boston in 1885. This organization prompted the establishment of the New England College Entrance Certificate Board in 1902. This is now made up of representatives from all the leading colleges and universities of New England and has a list containing the names of more than 400 accredited secondary schools. The Association of Colleges and Preparatory Schools of the Middle States and Maryland came into existence in 1892. Out of this grew the Middle States College Entrance Examination Board in 1900. While this board relies for the most part on the examination of the individual student, its influence upon the relation between secondary and higher education is essentially the same as that of the accrediting system. The North Central Association of Colleges and Secondary Schools was formed at Evanston, Ill., in 1895; and the Association of Colleges and Preparatory Schools of the Southern States at Atlanta, Ga., in the same year. Both of these associations have extensive lists of accredited schools.

The criteria used by these different accrediting bodies differed widely in the demands they made upon secondary schools, and they still continue to do so. For example, at the present time the College Entrance Examination Board recognizes but 11 subjects as permissible in a standard high school course while the University of Minnesota recognizes 22. Some means of securing uniformity, therefore, became a significant problem; and this subject is as vital to-day as it was in 1890. Inasmuch as no mechanical adjustment between secondary schools and colleges can settle this problem, the important attacks that have been made upon it have attempted to go to the bottom of the educational advantages of both, to get a basis for determining the details of relationship. The first and one of the very most significant attempts at solution was made by the Committee on Secondary School Studies, appointed by the National Education Association in 1892 and known as "Committee of Ten." Nine sub-committees of 10 members each were appointed to prepare reports on the several ordinary departments of secondary school instruction; namely Latin, Greek, English, other modern languages, mathematics, physics (with astronomy and chemistry), natural history (biology, including botany, zoology and physiology), history (with civil government and political economy), geography (physical geography, map work, and meteorology). The Committee of Ten, having secured carefully prepared reports from its sub-committees and having examined a large number of the courses in actual use in secondary schools, drew up a report in which was published the United States government in December 1893, together with the reports of the several sub-committees. Great stress was laid on the correlation of studies in secondary schools, the unifying of many subjects into a well-knit course of instruction, through the recognition of their numerous inter-relations. The committee would have continuous instruction in the four main lines of language, mathematics, history and natural science. In particular they recommended that in the first two years of a four-year course each student should enter all of the principal fields of knowledge, in order that he may fairly exhibit his quality and discover his tastes; and urge the postponement of the beginning of Greek to the third year, in order that the student may not find himself at the bifurcation of the course into classical and Latin-scientific courses before he is ready, or his advisers sufficiently informed as to his capabilities, to make an intelligent choice. The committee would require in each course a maximum of 20 recitation periods a week; but they would have five of these periods devoted to unprepared work; and would reserve double periods for laboratory exercises whenever possible. With reference to requirements for admission to college, the committee recommend "that the colleges and scientific schools of the country should accept for admission to appropriate courses of their instruction the attainments of any youth who has passed creditably through a good secondary school course, no matter to what group of subjects he may have mainly devoted himself in the secondary schools." "A good secondary school course," they describe as consisting of any group of studies from those considered by the sub-committees, "provided that the sum of the studies in each of the four years amounts to 16, or 18, or 20 periods a week,—as may be thought best,—and provided, further, that in each year at least four of the subjects presented shall have been pursued at least three periods a week, and that at least three of the subjects shall have been pursued three years or more." The next attempt at an adjustment of the relations of secondary schools and colleges to the educational advantages of both, is contained in the report of the Committee on College Entrance Requirements, appointed in 1895 by the National Educational Association and consisting of 14 members, representing the high schools and universities of different parts of the country, under the chairmanship of the superintendent of high schools of the city of Chicago. The first important service rendered by the committee was the preparation and publication of a table showing the actual entrance requirements of 67 representative colleges, universities and higher technical schools in the United States. The committee's final report, presented at the meeting of the National Educational Association in July 1899, is mainly devoted to the attempt to establish "national or local norms," in the several subjects taught in the secondary schools as preparatory to the college course. The fundamental problem is to formulate courses of study in each of the several subjects of the curriculum which shall be equal in value, the measure of value being both quantity and quality of work done. In the determination of these norms the committee received assistance from several bodies of expert scholars in the United States. The supplemental papers received from these bodies are published in connection with
the committee's report. The committee adopted 14 resolutions, of which the following are of the greatest general significance:

1. That the principle of election be recognized by the several secondary schools.

2. That we favor a unified six-year high school course of study, beginning with the seventh grade.

3. That while the committee recognizes as suitable for recommendation by the colleges for advanced studies, the several studies enumerated in the report, and while it also recognizes the principle of large liberty to the students in secondary schools, it does not believe in unlimited election, but especially emphasizes the importance of a certain number of constants in all secondary schools and in all requirements for admission to college.

4. That we recommend that any piece of work comprehended within the studies included in this report that has covered at least one year of four periods a week in a well-equipped secondary school, under competent instruction, should be considered worthy to count toward admission to college.

In more recent times a number of attempts have been made to solve the problem of the relation between secondary and higher institutions. One of these has accomplished considerable good on the side of the mechanical aspects involved in the adjustment; namely, the National Conference Committee on Standards of Colleges and Secondary Schools, formed in 1906. This committee is composed of representatives from the accrediting associations mentioned earlier in this section, together with representatives from the National Association of State Universities, the Carnegie Foundation for the Advancement of Teaching and the United States Bureau of Education. This committee has defined the unit for purposes of accrediting as follows: "A unit represents a year's study in any subject in a secondary school, constituting approximately a quarter of a full year's work. This statement is designed to afford a standard of measurement for the work done in secondary schools. It takes (1) the four-year high school course as a basis, and assumes that (2) the length of the school year is from 36 to 40 weeks; that (3) a period is from 40 to 60 minutes in length; and that (4) the study is pursued four or five periods a week; but under ordinary circumstances a satisfactory year's work in any subject cannot be accomplished in less than 120 60-minute hours, or their equivalent."

The Carnegie Foundation for the Advancement of Teaching gave very serious consideration to the question of the relation of high school to college in the annual reports of 1910, 1911 and 1912. These reports make rather severe attacks upon certain practices in both the high school and the college. The former is criticized for the lesser work — the covering of too many subjects with thoroughness in none. The college is criticized for insisting upon too rigid prescriptions in traditional subjects for admission; they ignore changing social conditions. The burden of solving the problem is placed on the higher institutions; they must insist upon solid four-year high school courses, but must permit a wider range in the subject-matter in them.

The National Education Association has been giving renewed attention to the problem in the past five years. In 1910 the Committee of Nine on the Articulation of High School and College was appointed. The report which was presented to and adopted by the Secondary Education Department of the Association the following year. In basic principles this report is in sympathy with the position of the Carnegie Foundation. Adopting the "squares" set forth in the National Conference Committee on Standards of Colleges and Secondary Schools, it recommends the following standard high school course: Nine specified units; three of English, two of one foreign language, two of mathematics, one of social science, including history, and one of natural science; two additional academic units, and four units left as a margin for whatever work best meets the need of the individual. A much more radical and fundamental solution of the question has been under consideration for the past four years by a committee of the National Education Association known as the Committee on Economy of Time in Education. A report of this committee was published by the United States Bureau of Education in 1913 and remains essentially unchanged as it is being discussed to-day. So far as the question here at issue is concerned, the following of its recommendations are most significant:

The elementary school should take the child from 6 to 12; the high school period should be from 12 to 18 or 12 to 16, and the college period from 18 to 20 or 16 to 20. The report, says the report, "to make the high school period 12-18 or 12-16 and the college period 18-20 or 16-20 will adjust itself in the following ways: (1) It begins high school work at the proper time and continues it to the recognized age of college admission or of beginning life (12-18); (2) it provides for a large number who will enter vocations at 16 and adjusts itself to the idea of an intermediate industrial school (12-16); (3) it provides for the contingency that the college course in the younger will end with the sophomore year and that the two years of college may be done in the university or in the larger high schools, and that the independent colleges may make a four-year course (16-20), admitting from the smaller high schools at 16."

3. Relation of the High School Course to Social Conditions and to the Needs of the Student.—In spite of the so-called "domination" of the college over the high school, the latter institution has at no time in its history suppressed its original ideal of serving the youth of all classes. The lack of an energetic response on the part of the high school to changing social demands has been due in part to a basic principle of social psychology; namely, custom. The Renaissance ideal of a liberal education was the ideal of a select coterie everywhere. It was well into the last half of the 19th century before the modern social view of education affected practice to any significant extent. Certain important changes in the course of study responding to this view have been made; many others are in the process of adoption.

One of the earlier movements of this character was the manual training movement, inaugurated by the foreign exhibits at the Phila-
delphia Centennial Exposition in 1876. The first manual training high school established in the United States was that opened in 1880 in connection with the School of Design at St. Louis. In 1884 the Commercial Club of Chicago established the first private independent manual training high school in the country; the first public high school of this character was opened the same year at Baltimore. By 1900 at least 38 cities had such high schools; and by 1905 at least 63 cities had followed the example. Besides these, many academic courses had included the subject. In these schools and courses the idea of manual training for the purpose of general culture was usually uppermost, their projectors disclaiming any intention of establishing schools for the teaching of trades. At present there is a tendency to view the subject from the social and practical standpoint rather than from the disciplinary.

The commercial branches had their first appearance in secondary school courses very early in the form of bookkeeping and commercial arithmetic. In the second quarter of the last century these courses flourished; and during the period from 1850 to 1890 they multiplied rapidly and furnished practically all of the training demanded for purely clerical positions. The first Commercial High School, now in existence, was established by the city of Pittsburgh in 1872; the next was the Business High School of Washington, D. C., established in 1890; Los Angeles, Calif. came third in 1895. Other large cities followed: Louisville, Ky.; San Francisco, Calif.; Philadelphia, Pa.; Syracuse, Brooklyn, and New York City. Commercial courses were multiplied in academic high schools, and private business colleges waned in popularity for a time. In 1914 the United States Bureau of Education reported 2,914 public and private high schools offering commercial courses to 178,707 students. Very recently criticism has begun to the effect that commercial courses in public high schools do not after all really fit students for business; they approach their work from a point of view too academic. Some of the better commercial high schools are attempting to overcome this weakness by articulating the courses directly with commercial life; Boston and Cleveland furnish good examples of this tendency.

The preparation for agricultural pursuits through the high school began about 20 years ago, when Alabama established a school of this character in each of the nine congressional districts of the State. Five years later Wisconsin instituted its system of county schools of agriculture and domestic economy. This movement has gone steadily forward, and there are now at least 1,677 high schools, either public or private, giving courses in agriculture to 34,367 students.

At present there is no more important problem facing secondary school administration than that relative to the extension of vocational work in the high schools. States, cities and even the National government are taking an active interest in the question. Some States are encouraging the establishment of such courses by means of appropriations; many of the larger cities have already established or are making elaborate vocational surveys looking toward their extension; and the question of Federal support to the movement in smaller places is being discussed. This whole movement centers for the most part in the secondary school period; and in this country the fixing of this period between the ages of 14 and 18 and the almost universal adoption of education essentially liberal in character cause the movement to be attended with tremendous difficulties which bid fair to produce far-reaching and fundamental reorganization within the whole secondary system. Significant steps in this reorganization have already been ventured. One of these may be found in the newer type of technical or vocational high schools. In these the older kinds of manual training work have been given a distinctly new turn toward the practical; trade courses of a high order have been added; and the academic subjects retained have in large part been treated from the standpoint of their bearing upon the practical work. Notable examples are the Albert G. Lane Technical High School of Chicago, opened in 1908; the Technical High School of Cleveland, opened in the same year; the Technical High School of Newton, Mass., opened in 1909, and the High School of Practical Arts for Girls, opened in 1909. This type of readjustment, which has received at least a trial, is the so-called Part-Time Cooperative Plan, well illustrated in the High School at Fitchburg, Mass. In 1908 a number of manufacturers together with the school authorities agreed upon the establishment of a combined shop and school course four years in length. During the first year the student spends his whole time in the school; for the next three years, he alternates weekly between shop and school, getting pay for the time he spends in the former. By this method the student gets actual shop training under shop conditions and secures a type of school work bearing directly upon the problems to be faced later in the calling. The Continuation School, so prominent in Germany, seems to offer a third type of desirable reorganization suitable to the needs of this country. Under this plan the employers permit their employees to attend vocational courses from four to six hours a week without loss of pay. Cincinnati began a high school course of this character in 1909. A fourth form of readjustment seems destined to give prominence to a kind of secondary school which is at total variance with the traditional ideals; namely, the Trade School. Such schools take boys and girls 16 years of age or over and, with little regard to their previous training, aim to provide them with skill in a particular trade. Examples are the Manhattan Trade School for Girls in New York City; the Philadelphia Trades School; the Milwaukee Trade School for Boys and a like one for girls, and the Worcester Trade School in Massachusetts.

Another form of adjusting the relation between secondary education and vocational life is so significant that it deserves special mention. For a long time it has been a question among educators whether our secondary school period did not begin too late; evidences of this feeling have been mentioned in connection with the discussion relative to the articulation of high school and college, notably the report of the Committee on Economy of Time in Education. In more recent times, studies in retardation and elimination have brought the question distinctly to the foreground. It boys and girls who need it most are to get any school training at all
which is directly correlated with the demands later to be made upon them, they must begin before the close of the elementary school, as it now exists. To meet this situation, what is known as "prevocational work" has been established in the seventh and eighth grades. In some schools a ninth grade has been instituted and shares in this kind of work. At present there is a strong movement toward giving these grades, in whole or in part, a distinctive organization and name. So far as the titles are concerned, two are struggling for distinction, "The Intermediate School" and the "Junior High School." According to Briggs's treatment of the movement in the report of the United States Commissioner of Education for 1914, at least 193 cities have effected an organization of the upper grades in some ways corresponding to the ideas contemplated in the movement. By many it is hoped that the next step in the movement will be the general adoption of a junior high school, taking the student from 12 to 15, to be followed by a senior high school carrying the work on to the 18th year.

By the nature of the limitation the differentiation of the one school would be directly articulated with those of the other. Just what this differentiation shall be is now under discussion; four types of courses are already prominent: the academic, the commercial, the household arts for girls and the industrial arts for boys.

Numerous as the difficulties of mechanical adjustment are in this whole movement for vocational training, they by no means exhaust the problems. The internal make-up of the courses is hard to effect, due to the lack of texts and to the lack of first-hand knowledge regarding the demands of the numerous callings; teachers who combine teaching ability with wide vocational experience are rare; and the relative amounts of attention to give to theory and to practice are very difficult to determine. Experience in the field has led to an increasing number of new needs and possibilities. The Vocational Guidance movement may be cited as one of the most significant. For the student to decide upon a calling he needs to have a rather wide knowledge about the demands of numerous vocations as well as a knowledge of his own capabilities and tastes. His location in a proper position, too, requires organization. Such a system must provide for the first and a capable director is needed for guidance in the latter two. A few cities have made great advance already in attacking the question; the best known of these are Boston, Mass., and Grand Rapids, Mich. The vocations bureau of the former city was established in 1908 by Mrs. Quincy A. Shaw under plans worked out by the late Dr. Frank Parsons. Meyer Bloomfeld, the present director, has extended the work greatly and has described the results and problems in his "Youth, School and Vocation." The developments in Grand Rapids have been largely due to the work of the principal of the high school, Jesse B. Davis, whose book on "Vocational and Moral Guidance" is exceptionally strong on the side of practical application.

The traditional secondary school course has not remained uninfluenced by the social and vocational movements in education; the course of study is receiving severe attacks from many quarters. The older problem of articulating high school and college is being supplanted by the problem of adjusting courses of study to the needs of the school person as it now exists. The conception of liberal education is undergoing change; and in partial response to it, the "general course" is appearing among the parallel groups. Certain new studies have begun to appear, likewise, such as "general science," "community civics," a history of art and music appreciation. Two very significant criticisms of the high school course have been issued recently by the General Education Board of New York city; one prepared by Charles W. Eliot, entitled "Changes Needed in American Secondary Education," and the other by Abraham Flexner, entitled "A Modern School." The former would, aside from the introduction of vocational subjects, have more emphasis placed upon sense training through the sciences and drawing and more time for music. The latter article would have four fields represented in the curriculum—science, industry, aesthetics and civics; and within some of the subjects, radical reforms are contemplated in the differentiation of subjects, a direct bearing upon cultural and social life. Such reforms are proposed in particular for mathematics, ancient history and the modern languages; grammar, Latin and Greek would be eliminated entirely.

4. Problems in Method and Management—

The great changes in the aim and course of study have been accompanied by changes equally significant in method and management. The laboratory method which came with the introduction of the sciences, needs but mere mention. Means for vitalizing these subjects, as well as of others, have multiplied greatly: pictures, charts, diagrams, museums, models, and moving picture appliances are examples.

For the past 10 years New York State has appropriated annually $20,000 for visual aids to instruction. The numerous criticisms of the results obtained in modern language instruction have led to the partial adoption of the "Direct Method" in these branches. Dissatisfaction with a "recitation" program has led to an interest in the "Co-operation Plan," whereby all of the teachers in a given school submit part of their written work to the English teachers. Analytic and drill methods in history and literature are another. A course of study, "Appreciation Lesson" is receiving a place in the newer books on high school method.

Wider reading, fewer technical questions, dramatic presentation and more flexibility in general are required in this type of recitation. The learner, finally, is coming to be looked upon as a more important item in discussions of method than the teacher, and "teaching the pupil how to study" has come to be one of the newer efforts in the high school. A part of this involves library instruction or how to use books. All of these advances in method are virtually attempts to avoid a part of the cramming procedure which grew up while college entrance was looked upon as the chief purpose of the high school.

Changes quite as important are taking place in the field of management. The rapid growth of high schools has resulted in the bringing together of a large number of students in a single school; and athletic associations, dramatic societies, debating teams, fraternities, and all kinds of clubs have grown up. Both the social

EDUCATION, SECONDARY
and educational philosophy of the past two or three decades have pointed to the "Self-government" scheme as the wisest solution of most of the questions of control involved. In New York city, a "General Organization" has been effected to which a large number of the high schools are now made subscriber. Each student in a given school, upon payment of twenty-five cents, becomes a member of this organization as affected in his own school. Such student members then adopt a constitution and by-laws to govern all the societies and clubs of the school. In some high schools, school savings banks are instituted and placed under the management of students. Cooperation with the home, with the authorities of the local government, and with other associations or societies in the community may be cited as added evidences of the ideal to bring the high school into close connection with all the better forces in society.

5. The Preparation of Secondary School Teachers.—A committee of the National Educational Association held a conference on the training of teachers for secondary schools. The committee declared that "The degree of scholarship required for secondary teachers is a subject of great importance. Each country should have a college education." They proposed a course of special training for such teachers, consisting of instruction during the senior year of the college course in psychology, methodology, school systems and the history, philosophy and art of education; and a graduate year of practice in teaching, under close supervision, supplemented by advanced studies in educational theory. That this proposal is far in advance of common practice or requirement no one acquainted with general conditions can doubt. To just what extent States and cities are tending in the direction of this early proposal — which still remains the ideal — can be determined only through a study of the widely varying and detailed laws and regulations now in force in the various States and closely approximate these ideals with the exception of the graduate study requirements; and the latter are often rewarded though not required. The very general "experience" requirement in large cities makes practice teaching unnecessary. One State — California — has very nearly met all of the requirements set forth in the proposals of 1895; a college degree from a recognized institution, graduate study both academic and professional amounting to one year or its equivalent, and practice teaching in the absence of experience are demanded. The State Board of Education is empowered by law to fix the details of certification regulations. In a considerable number of States, professional study of an undergraduate character is required of applicants qualifying under certain conditions. In general, the teaching force in the smaller high schools is not specifically prepared for the work it has to do. In New York State in 1914 very nearly one-half of all the high school teachers in the towns (as opposed to the cities) had obtained only a high school diploma licenses. In most sections of the country a strong tendency exists to employ only college graduates for high school teachers; but definite and serious study in the pedagogy of secondary training appears very rarely as a requirement either through custom or law. What pedagogy that is required is usually of the general kind. About 50 per cent of the high school teachers of Vermont in 1914 had not even had this. The State Commissioner of Education for Massachusetts in the report of 1912-13 complains that while most of the high school teachers of the state are college graduates and that while many have taken pedagogical courses in such institutions, they "are, in relation to the work they are expected to do, deficient in professional training" and "approach their work as learners, as apprentices, to whom methods of effectively teaching boys and girls are as yet almost wholly unknown." Definitely planned systems for the training of secondary teachers do not exist in this country. Aside from the State College for Teachers at Albany, N. Y., which makes the preparation of high school teachers its main purpose, and several specific courses in other normal schools of the country looking in the same direction, the only means generally prevalent is that of the college and university department of education and in which there are now some 350 of recognized standing. These, however, emphasize for the most part the general courses in education; secondary method in some of the branches taught in the high school; but not usually from the professors in these subjects in the college; and few have well-organized practice teaching. Other means in the improvement of secondary teachers are summer school courses, reading circles, teachers' associations, teachers' meetings within a given school, travel bureaus, sabbatical years, and the like; but these must be considered only a very small part of the solution to the larger problem to be faced in the systematic professional training of instructors for high schools.

6. Tendencies in the Organization of State Systems of Secondary Education.—Nothing closely approximating the highly centralized system of French and German secondary education exists in this country. While the State is the legal unit of the school system in this country, powers with reference to detail in organization are usually delegated to State boards of education, cities, counties, or even smaller units. The real test of the centralizing tendency in this country, therefore, resides in the extent to which the State, either by law directly or indirectly by delegation to the State Board of Education, takes a hand in the vital detail of organization in schools. The application of this test to current practice shows results of a widely varying character so far as secondary education is concerned. A large number of the States provide for inspection of schools of this kind through an officer usually called "high school inspector"; in a few States deputy commissioners of education are appointed and assigned to secondary schools; in some cases, inspection is little more than a formality, while in others it is very careful and results in approved lists of schools that are accepted by the State universities; some half-dozen States employ systems of school commissions of high schools into grades and set minimal course requirements for each; in very few instances, are actual courses of study directly controlled by State boards. The laws relative to the establishment of high schools are in most of the States "permissive" in character; and while
State aid is quite general for schools in rural districts, it is usually small in amount and cautiously guarded. Complete State certification of secondary schools and localities constitute a class by themselves, and central control is almost unknown to them. Neither uniformity nor the centralized systems of Europe would necessarily mean efficiency in America. What is most needed are State boards of education, free from political influence, composed of men with large views and expert knowledge, and devoting themselves to vital questions of policy and vital questions of organization too large for the local administrative units.

A number of States began early to take certain steps toward efficient control, and recent times have added to the number; three or four among these may be mentioned. Massachusetts has already been discussed; the compulsory establishment of high schools, State aid to the poorer districts, and minimum course requirements of earlier years have persisted; and new extensions have been made in the way of State certification of teachers in the State-aided schools, State support for vocational education and inspection. Minnesota began a State system in 1883, headed by a school board which still exists and exercises such powers as approving courses of study, inspecting all high schools once a year, and determining what institutions shall receive aid. California and New Jersey have made notable advances in methods of certifying teachers and prescribing requirements for the same. New York, however, represents the most complete State system of control yet developed in this country. This system has been described in part already. Under it, all incorporated secondary schools and the State manages the State funds to be distributed to secondary schools. Such funds, amounting to nearly $60,000, were added to the legislature until in 1913 the total sum contributed to secondary schools was $650,000. Approximately $140,000 of this was given for books and apparatus and $322,398 for the payment of non-resident tuition, the remainder being apportioned on the basis of attendance of academic pupils. The Board also prescribes rules for awarding the State scholarships of $100 each to graduates of high schools to aid them in pursuing college work. Ultimately there will be 3,000 of such scholarships; in 1914 awards were made to 750 secondary school graduates. A large force of inspectors, assigned mostly according to branches of study, exercises supervision of instruction; and an assistant commissioner of secondary education devotes his whole time to this branch of education. For the purpose of instituting a uniform basis for the apportionment of the so-called literature funds, the Regents adopted in 1864 a system of examinations of elementary pupils. In 1878, this system was extended to the academic branches; and in 1913, such examinations were held in 859 schools, with 408,786 pupils examined. Of these, 288,244 were accepted. These papers were first graded at the schools and then regraded under direction of the Regents at Albany. A special examination board under control of the Regents now prepares the questions. Each school falling under control of this central Board of Regents must report quarterly to it and get a rating in the annual report. By these four means—apportionment, examinations, inspection and reports—the Board of Regents exercises most of its far-reaching control over the secondary schools of the State.

EDUCATION, Study of. The study of education is, on the one hand, the study of a profession—the profession of the teacher, of whatever grade; and, on the other, the study of a social force—the force that preserves and improves the civilization of each generation, and transmits it to the next—and of the institutions which society has developed for the organization and administration of this force. It goes without saying that these two aspects of the Study of Education are not independent of each other. Further, it is clear that the study is either a professional or a liberal study in accordance with the object with which it is pursued. In this article no pains will be taken to keep these two aspects of the subject distinct. The context will make it clear which aspect is under consideration, and also when both aspects are considered together.

The systematic study of education is now carried on in the United States chiefly in normal schools (State, city or private) and in colleges and universities. Less extended but often valuable opportunities for the study of education are afforded by county training schools for teachers, by classes in some high schools and academies, and by some other institutions: as, for example, training schools for kindergartners; some departments of the so-called Institutes (like Drexel Institute of Philadelphia, Pratt Institute of Brooklyn); and by Teachers' Institutes. Teachers' institutes are carried on in towns or counties, for a few days or weeks, usually during the long summer vacation, and commonly receive support from the State treasury; they have been described as normal schools with very short courses of study. This article deals only with the study of education in normal schools, and in colleges and universities; because the work done by these is typical, and sufficiently comprehensive to cover the special work done in the other institutions mentioned. It may be said, however, that in general, the normal school aims only at the professional study of education; whereas the college or university department of education aims at both a professional and a liberal study of the subject, but of a higher grade than that of the normal school; and that the university School of Education aims at a professional study of education only, but, at present, of the grades undertaken with both at the university departments of education. University schools of education are of recent origin, but they are already numerous.
Normal Schools.—The systematic study of education in this country has a rather brief history. Although some beginnings had been made in the academies of New York and New England, and the methods of instruction that were employed in the State normal schools for the training of elementary school teachers, of which the first was founded in Lexington, Mass., in 1839. It began there with the study of methods of teaching the common branches of the elementary school curriculum, and the methods of running and managing a class or a school. That is to say, the study of education began with the study of methods. For a long time the study of methods comprised the whole of the study of education, although it did not cover the whole work of the normal schools. Most of these schools gave, from the very beginning, and many of them still give, more attention to the study of the branches that the prospective teachers are to teach, and to extending the range of their scholarship beyond those branches, than they gave and give to the study of methods. At the same time they naturally emphasized the study of methods from the beginning, and they still do so. This was natural and, within reasonable limits, desirable. The needs of the normal schools pursued the study of methods with such exaggeration of emphasis and such minuteness of detail that they are chiefly responsible for the development of an erroneous conception—namely, that the study of education is still practically identical with the study of methods; and this conception has done much to discredit the proper study of education and to prevent its appropriate development. How narrow and inadequate this conception is has already been suggested. It is not strange that the normal schools should emphasize the study of methods. Their function is to train teachers; and to teach well and govern wisely is the first duty of the teacher. But a good teacher not merely possesses a good method; he uses that method with discriminating insight into its efficiency and with careful adaptation to the needs of every pupil. He not only commands the technique of his art, but he understands the principles on which his art is based, and has a clear conception of the ends which his methods are to serve. Moreover, it is not often, merely the study of a particular way of doing a particular thing—how to teach reading, spelling, writing, arithmetic and so on; or how to secure conformity to this, that or the other rule of conduct; and this was (and is still) too often done in such a way as to convey the impression to the neophyte that there is no other correct way. The tendency of such instruction is, of course, to mechanize and not to vitalize instruction. In the hands of the less capable the mechanized technique that enables it to obscure other fundamental aspects of the study of education and of the right training of teachers. Instruction in methods did, however, develop systematic teaching where before there had been little or no training at all. By and large, the teachers trained in the normal schools proved their superiority over their untrained predecessors and contemporaries. The normal school study of education, in spite of its narrowness, did bear good fruit. But the results were still unsatisfactory. The means and methods of education were still considered by the tendency to use them blindly and mechanically was too obvious to be overlooked. The study of education, thus far, had not penetrated to the root of the matter.

The conventional scheme of education as expressed in existing programs ("courses") of study, and equally conventional methods of teaching and discipline, had been accepted without critical analysis of what it was all for, and to what extent the means and methods employed were adapted to the nature of the children to be taught and to the demands of modern life. Accordingly, it began to be clear that the study of education must mean more than the study of methods—the devices of teaching and governing. It was perceived that the mere acquisition of these devices often failed to impart life and purpose to the teacher's work. Gradually it was perceived that what was lacking in the study of education was the assimilation of guiding principles which should forever prevent the teacher from treating his work as a mere routine, but should enable him to conceive it throughout as a rationalized endeavor. It was natural that these guiding principles should be sought, first of all, in psychology, which, as the science of mind, should reveal the process of learning; and by implication should therefore give an insight into the process of teaching. "As we learn, so must we teach." Moreover, the Prussian normal schools, which had served as models for our own, had long incorporated the study of psychology into their programs of study, and the feature of their programs, which, to be sure, had also found its way into our own but had been without special significance, was now seized upon as the chief source of the guiding principles we were seeking. This was about 1885. Before that time psychology or "mental philosophy" had been pursued in our normal schools as an independent study without vital relation to the study of education. Now, however, this relation was perceived, and an extraordinary devotion to psychology as the key to all educational problems was the result. Before long, also, certain phases of psychology or particular psychological theories, notably the Herbartian theory of "apperception" and the derived theories of the "concentration" or "correlation" of studies, were heralded as the very gospel of educational salvation. There is truth in the theory of apperception and of the correlation of studies; but these theories were pursued and applied for a time with such extravagant and misguided enthusiasm as to obscure the more fundamental aspects of the study of education and of the right training of teachers. Instruction in methods did, however, develop systematic teaching where before there had been little or no training at all. By and large, the teachers trained in the normal schools proved their superiority over their untrained predecessors and contemporaries. The normal school study of education, in spite of its narrowness, did bear good fruit. But the results were still unsatisfactory. The means and methods of education were still considered by the tendency to use them blindly and mechanically was too obvious to be overlooked. The study of education, thus far, had not penetrated to the root of the matter.

The most extravagant development of the
study of psychology by students of education was "child study" which swept the country over from border to border some years ago. For instance, teachers of elementary students of education were discredited unless they endeavored themselves to make some contribution to the psychology of childhood, and these contributions were actually attempted by teachers of all grades and by other persons of all degrees of intelligence. This effort was, however, short-lived—it lasted 10 years at most. This was because a large part of the data which had been so enthusiastically collected, together with most of the "scientific" conclusions to which it was alleged they pointed, were held in slight esteem by the real psychologists. Such a result was inevitable. The psychology of childhood can be developed as a science only by persons trained for that purpose, just as physical science can be developed only by trained scientists. It was then seen that the chief advantage to be derived from the study of children by untrained observers was the effect on the observers themselves. Not to extend the boundaries of the science of psychology, but to interest the observers in children, to enable them to get into relation with child-life—that is the real value of child-study for most persons. And wherever this conception of its value prevails the study of children is to-day rendering good service to students of education. The acute stage of extravagant devotion to psychology as a part of the study of education is now happily past; and only good can be expected of the sober pursuit of it, which is fast becoming the rule.

From the foregoing it is already clear that far more was expected of psychology than could be realized. But more needs to be said on this point. Psychology is even yet in its formative stage as a natural science, and 30 years ago was just emerging from its thralldom to metaphysics. It was, however, assumed to be a perfected science—a complete and accurate account of mental phenomena and their interdependence; and hence the extravagant expectations entertained of deep insight into educational problems and a command over teaching processes. These expectations could not be realized; for, as has just been said, psychology is still a formative science and cannot therefore guarantee the complete insight into mental life—especially the mental life of children, which it was believed to yield; and even if it were to-day all that it was then thought to be—a perfected science of mental life, and particularly of mental development—the acquisition of that science would not necessarily ensure technical skill on the part of the teacher. Insight and the practical application of insight are two very different things. Nevertheless, the widespread devotion to the study of psychology in normal schools and by teachers was a great gain to the study of education. It established the fact once for all that methods of teaching and governing have a rational basis in the constitution of human nature, and that it is the duty of the student of education and the teacher to ascertain what this basis is as nearly as he can. The study of educational psychology, and education beyond the study of methods as mere devices to a study of these devices as based on the nature of the minds subjected to them. That is to say, the study of education had gradually come to include "educational psychology," and in particular the psychology of childhood and adolescence.

Meanwhile, again following the lead of the Prussian normal schools, light for the path of the student of education was also sought in the records of the past. The history of education was appealed to for guidance in solving contemporary problems of teaching and governing. It was only natural that a narrow conception of the significance of the history of education should have been entertained, because the study of education itself was still quite generally interpreted as the study of methods. Naturally, therefore, educational biography and "educational classics" or monographs setting forth the educational theories of individuals of the past—both usually without reference to the social setting in the general history of their time—constituted nearly all that was studied as the history of education. In spite of this narrow interpretation of the history of education, the study of that subject, like the study of psychology, was a great gain to the study of education. The recognition of the kinship of contemporary education with that of the past necessarily broadened and dignified the conception generally entertained of the meaning of education itself and naturally enhanced the value of the study of that subject. For, although the history of education was at first inadequately conceived and taught, it was inevitable that it should ere long be recognized at its true value, namely, as a part of general history; and hence that the student of education should come to realize that in studying the history of education he was studying nothing less than the history of culture—of the training of each generation to assume its share in preserving, improving and transmitting to the oncoming generation the resources of our civilization, and in so doing actively to promote the progressive solution of its problems. This true conception of the history of education is, however, of value in giving the insight into educational problems and a command over teaching processes. These expectations could not be realized; for, as has just been said, psychology is still a formative science and cannot therefore guarantee the complete insight into mental life—especially the mental life of children, which it was believed to yield; and even if it were to-day all that it was then thought to be—a perfected science of mental life, and particularly of mental development—the acquisition of that science would not necessarily ensure technical skill on the part of the teacher. Insight and the practical application of insight are two very different things. Nevertheless, the widespread devotion to the study of psychology in normal schools and by teachers was a great gain to the study of education. It established the fact once for all that methods of teaching and governing have a rational basis in the constitution of human nature, and that it is the duty of the student of education and the teacher to ascertain what this basis is as nearly as he can. The study of educational psychology, and education beyond the study of methods as mere devices to a study of these devices as based on the nature of the minds subjected to them. That is to say, the study of education had gradually come to include "educational psychology," and in particular the psychology of childhood and adolescence.

Meanwhile, again following the lead of the Prussian normal schools, light for the path of the student of education was also sought in the records of the past. The history of education was appealed to for guidance in solving contemporary problems of teaching and governing. It was only natural that a narrow conception of the significance of the history of education should have been entertained, because the study of education itself was still quite generally interpreted as the study of methods. Naturally, therefore, educational biography and "educational classics" or monographs setting forth the educational theories of individuals of the past—both usually without reference to their social setting in the general history of their time—constituted nearly all that was studied as the history of education. In spite of this narrow interpretation of the history of education, the study of that subject, like the study of psychology, was a great gain to the study of education. The recognition of the kinship of contemporary education with that of the past necessarily broadened and dignified the conception generally entertained of the meaning of education itself and naturally enhanced the value of the study of that subject. For, although the history of education was at first inadequately conceived and taught, it was inevitable that it should ere long be recognized at its true value, namely, as a part of general history; and hence that the student of education should come to realize that in studying the history of education he was studying nothing less than the history of culture—of the training of each generation to assume its share in preserving, improving and transmitting to the oncoming generation the resources of our civilization, and in so doing actively to promote the progressive solution of its problems. This true conception of the history of education is, however, of value in giving the insight into educational problems and a command over teaching processes. These expectations could not be realized; for, as has just been said, psychology is still a formative science and cannot therefore guarantee the complete insight into mental life—especially the mental life of children, which it was believed to yield; and even if it were to-day all that it was then thought to be—a perfected science of mental life, and particularly of mental development—the acquisition of that science would not necessarily ensure technical skill on the part of the teacher. Insight and the practical application of insight are two very different things. Nevertheless, the widespread devotion to the study of psychology in normal schools and by teachers was a great gain to the study of education. It established the fact once for all that methods of teaching and governing have a rational basis in the constitution of human nature, and that it is the duty of the student of education and the teacher to ascertain what this basis is as nearly as he can. The study of educational psychology, and education beyond the study of methods as mere devices to a study of these devices as based on the nature of the minds subjected to them. That is to say,
It includes (1) Theory of Education or General Principles of Education, sometimes called "Science of Education" or "Philosophy of Education," pursued as a means of awakening interest in and developing insight into the general problems of education; distinct nor separable from (4) below; (2) Methods; (3) Kindergarten Theory and Practice; (4) Psychology and the Study of Children, pursued as a source of information about the development of mental life and the processes of learning and as a rational basis for methods of teaching and discipline—that is, psychology pursued as a science on which the art of teaching and managing children might be based and the study of children pursued chiefly as a means of developing a comprehending and sympathetic attitude toward children on the part of future teachers; (5) The Study of Teaching by observation and practice in "model schools" or "training schools"; (6) School Organization and Management, chiefly internal organization and class work, therein; (7) The History of Education, usually pursued as a source of suggestions for planning contemporary studies and methods of teaching and management and, to a limited extent also, as a means of developing a broader professional outlook and a critical and judicious insight into educational problems as problems of social evolution; (8) School Hygiene; (9) School Laws as a source of practical information concerning the teachers' legal rights, privileges and duties.

As was pointed out above the work of normal schools is not confined to the study of education; but so far as that study itself is concerned the foregoing enumeration covers the ground, although not all of it is necessarily found in all normal schools. The foregoing description also reveals the aim of the study of education in normal schools. That aim is primarily the technical preparation of the classroom teacher. Finally, it should be said that many normal schools are far inferior to others in the above-mentioned respects. The study of teaching and the thoroughness with which that study is carried on.

Colleges and Universities.—Great as are the services which the normal schools rendered it gradually became clear that they were alone unable to cope with the rapidly growing need of a more comprehensive as well as a more intensive study of education than they could supply. Some time before the end of the 19th century the normal schools had made clear the great distinction between a trained and an untrained teacher, as was pointed out above; and they had, accordingly, made good progress in the gradual transformation (still going on) of the calling of the elementary teacher from a mere routine into a profession. But the increase of the population, the great influx of foreign immigrants, the geographical expansion and the much more important and very great commercial and industrial development of the country have been followed by our huge modern schools, our varied and complex systems of cities, the enormous and steadily increasing need of trained and efficiently instructed teachers, and the programs of studies, our immense city school systems; and hence a host of new educational problems have come into the field—problems with which the mere classroom teacher of limited academic training and narrow, even if thorough, technical training, is manifestly unable to cope satisfactorily. We have, fortunately, many efficient grammar school principals and superintendents to-day who have had only a normal school training; but in no case are they efficient because their training was originally limited, but in spite of that fact. Moreover, the general public, particularly the educated and the reading public, now take an interest in educational problems heretofore unknown, and this interest is increasing daily. This interest demands satisfaction and seeks educational leaders among the teaching profession as well as good classroom teachers. At the same time it had long been apparent that many college-bred men of excellent scholarship were poor teachers. The college offered them no opportunity to learn how to teach. The problem was to secure, in addition to adequate scholarship, appropriate insight into education and technical skill in teaching. This the collegegraduate could not get nor can he get ordinarily secure in the normal school—first, because the normal school was and is naturally and properly concerned chiefly with the training of teachers for elementary schools and, therefore, has generally neither the teaching force nor the equipment generally necessary to deal separately with college graduates who usually seek preparation to teach in secondary not elementary schools; and second, because it was not and cannot be profitable in most cases to teach in the same classes college graduates and normal school students. The college-bred student are too far ahead of the normal school students in maturity and scholarship to make a satisfactory combination class. For similar reasons the normal schools are generally unable to provide adequate opportunities for teachers already in service who seek preparation for work as principals or superintendents of schools. Out of these considerations arose the university department of education which has undertaken to provide the college graduate with the opportunities he needs for the development of his professional career as a classroom teacher, or whether as an experienced teacher he returns to the university for the study of his profession under direction with a view to becoming a principal or a superintendent; or whether as an interested layman he seeks enlightenment as to the meaning of education and the means and methods of organizing and directing it as a branch of State or municipal affairs.

The history of the study of education in the colleges and universities of the country is even more brief than the history of that study in the normal schools, for it does not really begin until 1879, when the University of Michigan founded a chair of "the science and the art of teaching" of co-ordinating rank with other chairs and departments. Education before that time (from about 1850) had been studied in "normal departments" established at a number of colleges and universities (more commonly of the Middle West than elsewhere), in which the study of education did not differ materially from that pursued in the normal schools. Such a normal department, for example, existed at Brown University from 1851 to 1854. It was discontinued in consequence of the establish-
EDUCATION. STUDY OF

ment in Providence of the Rhode Island Normal School, so says the university catalogue for 1854-55. Another example was the normal department of the University of Iowa, which was, at first (1855), a department of the preparatory school of the university. It had a varied career and was gradually transformed into the present "School of Education" of the university. It exemplifies a not uncommon process of development of these "normal departments" into the university Departments of Educational Science or Schools of Education or "Teachers Colleges" of to-day.

Not infrequently the courses in education instead of being grouped in a department or school of education or teachers college were, and are still, associated with and made a part of the department of psychology or philosophy, usually to the disadvantage of the study of education. This affiliation followed the lead of the German universities and dates from the time—not far back—when pedagogy rather than education was the subject studied. It has been found possible, however, in only a few college or university departments of education to solve the problem of technical training for neophytes. Teachers of experience and other persons who resort to the university to study the theory and history of education and the organization and administration of school systems find the instruction of any good professor of education decidedly profitable. But beginners who need to learn how to teach under direction usually fail to get what they most need—their hard work in seeking the teaching and management under the usual conditions that prevail in the classroom. A few college and university departments of education, like the department at Harvard University, have provided such opportunities from almost the very beginning; but, except in some of the larger urban universities, it has generally been found impracticable. But the university department or chair of education has accomplished and is accomplishing a most important task, quite apart from what it may or may not accomplish in the training of young teachers, or in the training of principals or superintendents. It has made education in all its phases a university study. Apathetic and even hostile faculties have slowly yielded the false position that they once held, namely, that among all the fields of human thought and activity education is the only one it is not profitable to study; and this is a great gain. The gradual abandonment of false views concerning the study of education by members of the faculties of our higher institutions has naturally been followed by some progress on the part of the students. To-day university courses in education are attended by an increasing number of future lawyers, doctors and business men who do not care for the technical courses pursued by future teachers or school administrators, sometimes called "Philosophy of Education," or "Science of Education." The specific aim of these courses is to enable the student to gain a just conception of the scope and meaning of education and to make a critical examination of such generally accepted educational principles as will serve to guide him in his further study of educational questions. (2) Educational Psychology and Child Study. While this subject could be appropriately regarded as a subdivision of the preceding topic, it is usually offered in separate courses, the special aim of which does not differ materially—although the method of treatment does—from similar courses in normal schools. The work done in such courses in colleges and universities is usually divided into two: the study of the corresponding normal school courses. (3) General principles of method and special methods of teaching the several school subjects, without and with practice teaching, particularly the methods of teaching secondary school rather than elementary school subjects. The instruction in the courses in special methods is given by instructors belonging to the department of education, but often by specialists chosen from

is, it has helped to determine a professional attitude and temper of mind of great importance for immediate efficiency and steady professional growth; and, at its best, it has done and is still doing this, and provides, also, actual laboratory work for the young teacher—classroom teaching under direction amid normal surroundings, over a sufficiently long period of time; and it provides suitable training for principals and superintendents of schools on the basis of good instruction and a comparative study, under direction, of schools and school systems in actual operation; and, finally, it has established the study of education among the branches of a liberal education. At the present time more than half of the colleges and universities of the country make more or less provision for the study of education, and many more are preparing to do so. But the development of this study has naturally been more rapid in the State universities than elsewhere, save in the few cases noted above, that is, in the universities that have developed "Schools of Education" of their own, in only a few college or university departments of professional schools. The scope and general aims of the college or university study of education, as now carried on, may be summarized as follows: (1) To study education as an important function of society as well as of individuals, and hence of interest to all university students, whether they intend to become teachers or not. (2) To offer to university students who look forward to teaching the necessary technical training for their vocation; and to teachers already in some teaching posts, the opportunity to study their profession under direction. (3) To offer to university students who have already had experience as teachers, and to all teachers of suitable age and attainments, appropriate training for future activity as principals or superintendents of schools. (4) To offer opportunities to advanced students for research in the field of education.

While the courses of study offered for the realization of these aims vary greatly, they may be briefly described as courses in: (1) Educational Theory or General Education, sometimes called "Philosophy of Education," or "Science of Education." The specific aim of these courses is to enable the student to gain a just conception of the scope and meaning of education and to make a critical examination of such generally accepted educational principles as will serve to guide him in his further study of educational questions. (2) Educational Psychology and Child Study. While this subject could be appropriately regarded as a subdivision of the preceding topic, it is usually offered in separate courses, the special aim of which does not differ materially—although the method of treatment does—from similar courses in normal schools. The work done in such courses in colleges and universities is usually divided into two: the study of the corresponding normal school courses. (3) General principles of method and special methods of teaching the several school subjects, without and with practice teaching, particularly the methods of teaching secondary school rather than elementary school subjects. The instruction in the courses in special methods is given by instructors belonging to the department of education, but often by specialists chosen from

other departments of the college or university. (4) History of education studied as history. This is the study of the historical development of modern schools and universities, with especial reference to their ideals, studies, modes of teaching and organization; together with the effect of economic, political, social and religious ideals on the spirit and direction of education; and the influence of school methods and curricula of the general progress of the arts and sciences. Such a course should therefore give the student a view of the subject in its relation to the history of civilization, as well as a historical and sociological criticism of the more important elements of modern schools and school systems. (5) The educational importance of play and recreation. (6) Education in practical arts for boys and for girls. (7) The education of exceptional (anemic or tubercular, crippled, deaf, blind, truant and delinquent, mentally defective) children. (8) Vocational (industrial, commercial, agricultural) education. (9) The vastly important allied subject of vocational and educational guidance for school and college youth, and for young people after graduation. (10) Organization and management of schools and school systems. The purpose of courses covering this last subject is to study both the internal organization and management of schools and school systems with special reference to the duties of principals and superintendents within a given school or school system, and also the organization and management of education as a branch of State and municipal affairs, at home and abroad. Accordingly, they deal with the problems of the development of education, powers and duties of State and city boards of education; the powers, duties and opportunities of superintendents, principals and teachers in cities and towns; the work of elementary and secondary schools, including the construction of programs of study; and, in general, everything pertaining to the organization and efficient administration of our vast, complex and costly provision for public education; and sometimes also a similar study of the educational organization and administration of private schools. (11) School hygiene; the hygiene of school buildings and the hygiene of the pupils. (12) Seminary courses or research courses. Such courses offer opportunities to the most advanced students for prolonged study of particular educational questions. As the whole field of educational theory and practice abounds in unsolved problems and vast areas in the history of education are as yet untouched, it is easy to see how important such courses are. Not all of these courses are found in every college or university department of education, but they are all found in some of them; and in the university schools of education, to which reference has been made, all these courses are offered. The scientific examination of a minuteness of differentiation that should eventually promote a very thorough study of the topics involved.

Progress in the study of education has been greatly facilitated in recent years by the rapid growth of a considerable body of good educational literature both in books and periodicals. is still common, a large number of good books have been published in recent years and several periodicals have appeared worthy of a place beside the best educational literature that has been produced anywhere.

In addition to the study of education already described, mention should be made of the study of educational psychology. The National Educational Association is not only a vast forum for the discussion of educational questions, but since 1893 it has stimulated and subsidized educational research through committees appointed to report upon selected problems, and for the reports submitted by these committees have been of great value and more may be expected in the future. The State teachers' associations and other local associations throughout the country also occasionally carry on educational investigations of more than local significance. Mention must also be made of the studies in education now undertaken by associations of laymen and by some of the non-professional magazines.

Recent and very important developments in the study of education may be described as statistical and experimental studies of educational procedure and approximately scientific studies (quantitative measurements) of educational results. The purpose of these studies is to obtain objective standards whereby contemporary educational practice can be directed and results measured with an accuracy approximating the direction and measurement of results in the natural sciences; and thereby to confirm or refute (as the case may be) educational opinion. Such standards, when attained, constitute unassailable organization and opinion will always be worth studying, but the conviction that scientific method in education is essential to satisfactory progress, which has been slowly forming during the past decade, is now firmly established in the professional mind; and the statistical and experimental studies and the measurement of educational results above referred to are the result. The literature of this important development in the study of education is growing rapidly. Apart from books, such studies are energetically promoted by several contemporary periodicals and by researches carried on by colleges and university departments and schools of education, working independently, but often in cooperation with progressive supervisory officers and teachers in neighboring school systems. The conviction that such studies are essential to progress in education has also led to the establishment of departments of research in about a dozen of the larger school systems of the United States. Such departments serve the same purpose in school activities that research departments and departments of design serve in industry and commerce. That they do serve such purposes, several of them have already proved.

Many important studies of entire school sys-
tems, called school surveys, have been made by specialists usually not connected with the systems studied on the invitation of State, city and rural school authorities. The reports of these surveys, now numerous, constitute a vast mine of information for all students of education; indeed, the student of education in the United States will find no more important body of educational literature than is embodied in those reports.

Paul H. Hanus, Professor of Education, Harvard University.

Education, Supplemental. See Supplemental Education.

Education, Technical. Technical education is a very modern form of educational enterprise which is concerned with the training of men to make an organized practical application of a knowledge of the principles of chemistry, physics (especially mechanics, heat and electricity), mathematics, astronomy and bacteriology to the design, construction and operation of machines and structures of all kinds, and the material conveniences of life. It aims to produce men of broad understanding of the field of applied science, who have insight, organizing power and leadership, not merely surveyors, draughtsmen or superintendents. Viewed in this light it is an important new phase of professional education (see Education, Professional), always mindful of the need of increased production, but distinguished from industrial education (see Education, Industrial), which is destined primarily to prepare men and women for maximum production with a minimum expenditure of time and human energy. Broadly speaking, technical education is engineering education, but the term engineering now includes a variety of divisions which would have been entirely incomprehensible to the founders of the early schools of applied science; it applies rather to the expert direction of organizations which utilize the forces and materials of nature through large combinations of human units than to the actual labor of production. In addition to the usual branches of engineering — civil, electrical, mechanical, mining and architectural — there must now be included chemical, railway, marine, ceramic, sanitary, textile, agricultural, metallurgical and aeronautic engineering.

The scheme of technical education for all of these specialized engineering professions provides for firm grounding of the student in the processes of the fundamental pure sciences appropriate to the specialization, whether chemical, ceramic, textile or aeronautic. In the usual four-years technological course leading to a Bachelor's degree this is accomplished largely in the first two years, in which instruction in mathematics, chemistry, physics, surveying, etc., is given, sometimes by basing the two years engineering curriculum upon two years of liberal arts, as in the University of Missouri. In the case of five-years engineering courses or six-years combination courses the fundamentals may occupy the first two years or the first three years in the Columbia School of Mines, School of Mines, in which the three-years technological courses in mining, engineering and chemistry are based upon the three years of study in a collegiate or scientific school. After these fundamental sciences and additional instruction in English, economics, politics, etc., the curriculum of the last two or three or four years of technical courses follows divergent lines of study preparatory to or leading to such professional and paraprofessional engineering professions, which aim to meet corresponding specialized demands arising out of the unparalleled development of mechanical, structural and industrial needs of a nation of 110,000,000, complex in its interests, rich in its resources and impatient in its demands.

The first school of engineering in the United States was the Rensselaer Polytechnic Institute (q.v.), founded at Troy, N. Y., by Stephen van Rensselaer in 1824, as a School of Theoretical and Applied Science, to furnish "instruction in the application of science to the common purposes of life." No further provision of the kind was made until 1847 when the Sheffield Scientific School at Yale and the Lawrence Scientific School at Harvard were founded. In the same year the University of Michigan voted to establish a course in civil engineering. These four schools, concerned almost exclusively with civil engineering, were the only schools of the kind opened before the Civil War. After the passage of the Morrill act in 1862 (see Education, Agricultural) many states provided by the act and proceeded to organize new schools of agriculture and the mechanic arts, or to add these types of technical education to existing schools. Many of the State universities, like Illinois, Wisconsin and California, which now offer a well-equipped instruction in technical lines received very large impulse from the Morrill act. The great expansion of construction and industry after the Civil War caused the rapid multiplication of engineering schools. The four schools of 1860 increased to 17 in 1870, 41 in 1871, 70 in 1872, 85 in 1880 and 126 in 1917; the graduates numbering 100 in 1870 reached 4,300 in 1917. Besides these schools there are 43 other institutions giving more or less attention to engineering work, either in the form of two years of engineering or of single courses like civil engineering in connection with other curriculum. Of the 126 schools of 1917, 46 were connected with land grant colleges, 44 were professional schools in universities, 20 were attached to colleges and 16 were independent. Midway between the group of technical schools and industrial schools are to be found certain excellent institutions giving more or less technical or engineering education to men and women, for example, Pratt Institute in Brooklyn, Lewis Institute in Chicago and the Cogswell Polytechnic Institute in San Francisco.

Following the period of rapid multiplication of technical institutions from 1870 to 1890 came a period of standardization of requirements for admission and for graduation, for it was clear that technical education was a complex problem with an easy and uniform solution, especially if the engineer was to become the professional equal of trained lawyers and doctors. The formation of the Society for the Promotion of Engineering Education in 1890 and the organization of the joint committee on engineering education of the national engineering societies in 1908 promoted the process of elevation and standardization of curricula. By 1917 practically all of the first class technical schools required at least four years of high school work
for admission and at least four years of collegiate work for the specialized degree, whether that of B.S. in some division of engineering, as Bachelor of Science in Mechanical Engineering (B.S. in M. E.), Bachelor of Civil Engineering (B.C.E.) or Civil Engineer (C.E.). With few exceptions, e.g., Massachusetts Institute of Technology, the technical schools, like other colleges, receive their students out of the great system of public secondary schools by certificate rather than by examination. Students thus received are given approximately the same work during the first year with later differentiation as discussed above. The extent of this specialization is illustrated in the curricula offered at the University of Illinois and the Massachusetts Institute of Technology.

UNIVERSITY OF ILLINOIS.

Degree of B.S. in special curricula: architecture, architectural engineering, ceramic engineering, civil engineering, electrical engineering, mechanical engineering, mining engineering, municipal and sanitary engineering, general engineering, physics, railway civil engineering, railway electrical engineering and railway mechanical engineering.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY.

Degree of B.S.: civil engineering, mechanical engineering, mining engineering and metallurgy, architecture, chemistry, electrical engineering, biology and public health, physics, general science, chemical engineering, sanitary engineering, geology, naval architecture and marine engineering, electro-chemistry and engineering administration. Further specialization is permitted within these courses in the Massachusetts Institute of Technology, for example, in mechanical engineering along the lines of engine design, locomotive engineering, mill engineering and steam turbine engineering.

A summary of the requirements for admission and the curricula for graduation, for the course leading to a degree in mechanical engineering in the Massachusetts Institute of Technology, the Rensselaer Polytechnic Institute and the University of Illinois will serve as an illustration of the standardized technological course in an institution of the highest class. The specifications for admission are given in terms of units (one unit is approximately one-fourth of the work of a high school year).

The proportions between shop work, or practice work, and theoretical work in the curriculum of technical schools, vary widely in different institutions and at different times. The most progressive have abandoned the requirement of many hours of manipulative laboratory work and the presentation of completed machines, and now require sufficient shop work for an understanding of the processes and tools, but without insistence upon the attainment of skill. On the other hand there is stronger and stronger emphasis upon the mastering of the fundamental subjects and theory behind the technical courses. Many strong institutions like those whose curricula are given above require also a considerable proportion of liberal, non-technical study in order to develop the man as well as the engineer, so that the student who graduates from the institution shall understand the importance of both the human and the technological factors which enter into the practice of his profession. In place of the narrow technical education of 1890 or 1900 with slender foundation in the sciences and the inclusion of large quantities of shop practice, technical schools now seek to develop at the same time an accurate working knowledge of the principles and practices of engineering subjects and personal qualities of judgment, initiative, responsibility and an understanding of men. Such a curriculum as that noted above in engineering administration requires quite as much knowledge of "human engineering" as of mechanical or chemical engineering.

The co-operative type of technical education, sometimes known as the Cincinnati co-operative plan, is the most recent attempt to co-ordinate theory and practice under conditions approximating those of the shop and of the field. First formulated in 1899 by Hermann Schneider when instructor at Lehigh University, it had its beginning in 1906 at the University of Cincinnati which established under his direction a co-operative agreement with industrial plants, railways, etc., by which students who are admitted to the university, as are other students, work on a schedule by which, during bi-weekly periods, one-half of the class is at the university, and one-half is in the factory. During the next period of two weeks the sections change about. The co-operative course is of five years' duration, 12 months in the year. While in factory or
shops students are regular employees, receive regular pay and must report satisfactory service in the shops as well as in the classrooms in order to be continued in the university. The co-operative plan has been adopted at other technical institutions, and in some cases by secondary institutions, which are advantageously located near shops and industrial plants of various kinds, with which co-operative arrangements may be made. It is claimed that this combination of scientific and theoretical study at the university with practical experience results in a better mastery of facts and of manual skill since it is secured under conditions which compel a maximum of independent thinking along with an appreciation of the social significance of the studies and the practice.

Technical education has its upward reach into graduate courses for professional degrees like Civil Engineer (C.E.), and Master of Civil Engineering (M.C.E.); organizations for research like the Engineering Experiment Station of the University of Illinois, the Federal Products Laboratory located at the University of Wisconsin and the Mellon Institute of the University of Pittsburgh; and investigations in subjects like industrial chemistry leading to the Ph.D. degree at universities which are recognized organically parts of a technological college, as at Cornell University and the University of Chicago. The steady emphasis of the stronger technical schools upon investigation and contributions to the solution of intricate new problems is one of the latest and most significant aspects of technical education in the United States and in Europe.

KENDRICK C. BARCOCK,
Dean of the College of Liberal Arts and Sciences, University of Illinois.

EDUCATION, THEOLOGICAL. A system of training for the work of the ministry. From remotest times religion centred in ritual acts and gave rise to a system of training men to fill the office of the necessary priesthood. The priests of the great temples in ancient Babylonia, Egypt and other lands, as well as those at the prehistoric shrines, naturally took pains to train young men to perform the duties of the sacred office which eventually they had to surrender. When religion consisted in the main of the public performance of ritual acts the training of the priest was a simple affair. It consisted, of course, in imparting a knowledge of the performance of the ritual acts, but mostly it was a course of ritualistic instruction. The case of Samuel (1 Samuel c. i ff) brought up at the shrine of Shiloh is an illustration of this early sort of training for the priesthood. When religious systems clashed in a strife for supremacy in the world, the priest had not only to administer the ritual of the altar but to defend and proclaim the doctrines of his faith with converting power. This was conspicuously the situation when Christianity sought to get a foothold. Among the early Christians the preaching of doctrine outranked the performance of ritual. With the increasing importance of doctrine a fuller and more thorough instruction on the purely intellectual side of religion necessarily entered into the preparation for the ministry. During the first few centuries of Christian history individual enthusiasm was so intense that the ministry was adequately supplied by men who in a sense were self-educated, self-prepared. As churches multiplied and the need of uniformity in Church teaching and practice became more urgent, systematic efforts had to be made by the bishops to train men to fill the priestly office. The way was for the bishops to take young men into their own homes and educate and train them. In New England it was for a long time quite the common thing for young men who thought of entering the ministry to take up residence with a rector with a view of becoming clergyman and read divinity with him very much as a young man preparing for the law entered the office of a lawyer and read law there. Eventually the monasteries became the training schools for priests and the universities naturally became a place of theological education. Down to as late a time as the Council of Trent theological training was in an exceedingly chaotic condition, a condition greatly emphasized by the events of the Reformation. One of the steps taken by the Catholic Church to meet the situation of this stormy period was the establishing of the theological curriculum for the diocesan seminaries, a curriculum which has continued practically unchanged to the present time. In Europe where the Protestant religion became the religion of the state Protestant theological education was from the first provided by the great public universities. The Protestant denominations dissenting from the established Church provided schools of theology.

The United States.—The earliest educational institutions in New England were theological in purpose and inspiration as is evident from a contemporary account (1643) of the founding of Harvard University: "After God had carried us safe to New England and wee had builded our houses, provided necessaries for our livelihood, rear'd convenient places for God's worship, and settled the civil government: One of the next things we longed for and looked after was to advance learning and perpetuate it to posterity; dreading to leave an illiterate ministry to the churches, when our present ministers shall lie in the dust." That this purpose might be doubly ensured against miscarriage free tuition was offered to candidates for the ministry, while students for other purposes were charged a fee. This practice has been almost universally followed. These early institutions did not confine themselves to the teaching of theological subjects and by the end of the 18th century, several universities outran divinity that it became necessary to create within these old universities separate schools of theology. When toward the end of
the 18th and the beginning of the 19th centuries different denominations began to establish their own theological seminaries there was manifest a wish to turn over the responsibility of the training of clergy from all institutions of higher learning by building them at considerable distances from such institutions. This guarded against secularization and helped to make the minister a more ardent denominationalist. Of the existing theological schools there were established before the 19th century: the seminary at New Brunswick, N. J., of the Dutch Reformed Church, founded in 1784; the Roman Catholic Seminary of Saint Mary's, Baltimore, Md., 1791; and the United Presbyterian Seminary, established 1794, at Service, Beaver County, Pa., and later removed to Xenia, Ohio. Later other denominations established seminaries. The first Congregational seminary was opened in Andover, Mass., 1808 (now located in the neighborhood of Harvard University). The Protestant Episcopal Church founded its first seminary in New York city in 1819. At Hartwick Seminary, N. Y., the Evangelical Lutherans built their first theological school in 1815, Colgate Seminary, now a part of the Colgate University. Baptist Seminary in Newbury, Vt., the Methodist Episcopal Church opened its first theological school in 1841; this school is now a department of the Boston University. In 1819 the divinity school of Harvard University was organized as a separate institution and became the first non-sectarian divinity school in the country. During the first 25 years of the 19th century 18 seminaries were organized representing 11 denominations. Four of these were Presbyterian; three Congregational; Baptist and Protestant Episcopalian 2 each. The period of greatest activity in establishing theological schools was from 1850 to 1875, 71 being the number of new schools founded. Of the 169 theological schools reported by the United States Commissioner of Education for the year 1916 26 were organized after 1899. Of the 165 seminaries reported in the statistics of 1899, 38 are not found in the statistics for 1916, having disappeared by amalgamation or otherwise. The 169 theological schools reported in 1916 represent 27 denominations. (For statistics see Education, Professional). In 1916, seven were listed as non-sectarian, four as interdenominational, three had no sectarian designation. Since the beginning of the 20th century three important theological schools have abandoned sectarian designation: Union Theological Seminary, New York city, changed its designation from Presbyterian to interdenominational; Yale from Congregational to undenominational; the theological school of Vanderbilt University, Nashville, Tenn., from Methodist Episcopal to non-sectarian. Of these 169 schools 41 admit both men and women. In 1890-1893 were graduated from 165 schools and in 1921-1928 were graduated from 169 schools. The practice generally followed for over a century was to establish theological schools fairly remote from other institutions of higher learning. It has come to be realized that this practice has seriously impaired the scholastic and practical value of these schools. The past 20 or 25 years has witnessed an increasing movement toward bringing these schools into closer touch with colleges and universities. As instances of this, the mov-

ing of Andover Theological Seminary to Cambridge, Mass., and its affiliation with Harvard; the affiliation of the Chicago Theological Seminary with Chicago's Union Theological Seminary; the effect of the Meadville, Pa., Theological School to send its students to the Chicago University for a part of their course may be cited. A century ago the importance of this plan was recognized by Thomas Jefferson and advocated by him in his report as rector of the University of Virginia.

Roman Catholic.—In the diocesan seminaries for the training of men for the priesthood the curriculum of to-day is but little changed from that outlined by the Council of Trent. The course extends over a period of six years divided into a philosophical course of two years followed by a theological course of four. Candidates for admission to the seminary must offer a B.A. from some recognized standing or a satisfactory equivalent. This latter provision is made so that the Church may not lose the services of a man peculiarly fitted by nature for the office of priest who has not been able to secure a collegiate training. Unlike Protestant seminaries, where the number of students is much larger, the number of Roman Catholic seminaries is limited. The courses are alike in all Catholic seminaries though the quality of scholarship may not be uniform. The first two years are devoted to logic, ontology, psychology, natural theology, Church history, general history, Old and New Testaments, Latin, Hebrew, Greek, science, biology and chemistry. The purpose of science in this curriculum is well explained by Leo XIII: "It is enough that their (the seminaries') pupils have an accurate knowledge of the main principles and summary conclusions (of physical and natural sciences), so as to be able to solve the objections which infidels draw from these sciences against the teachings of Revelation."* These two years are designed to furnish a sufficient preparation for the rigorous and intensive study of theological subjects of the next four years. The subjects pursued are apologetics (an exposition and defense of the grounds of Catholic belief), dogmatic and moral theology (the aim of moral theology is to prepare the future priest for the competent and practical care of souls, teaching him how to judge and estimate the morality of the actions of those who may fall within the province of his direction as a priest and confessor), pastoral theology (the proper care and government of the charges entrusted to him and the faithful and successful discharge of his sacred ministry), homiletics, canon law, Church history, biblical exegesis. Sociology is a seminary subject and is intended to afford an opportunity for the students who so wish to secure a thorough knowledge of modern social and economic problems and movements. By constant participation in the ritual the young priest is trained to the proper administration of the Church's sacraments. Similarly the student is prepared to organize and manage the Church's many social activities through service in those societies which have to do with the immediate work of the Church. Jewish.—Theological education for the Jewish ministry differs somewhat from the Christian scheme. The course at Hebrew Union College extends over a period of nine years—four years preparatory and five years in the
collegiate department. In the preparatory department the students are given a thorough grounding in the grammar and vocabulary, which enables them to read the unnotated text of the Pentateuch and other Hebrew literature. A general knowledge of Rabbinical literature and history of the prayerbook and Psalms and the doctrines and ceremonies of Judaism is also aimed at. The collegiate department is divided into two parts, the lower grade being devoted to the acquisition of material and the upper two to systematic and specific theological knowledge. The principal subjects of study are Bible Exegesis and the Talmud and all the important Hebrew literature, as well as the New Testament; the history of the Jewish people. The study of the origin and development of Mosaic and Rabbinical Judaism paves the way to systematic theology. The study of comparative religions is pursued to be a foundation for Jewish apologetics. Practical theology divides itself into the study of homiletics and the rites and ceremonies of Judaism. Ethics and pedagogy are important subjects, the latter being designed to prepare the student for the task of religious instruction. Applied theology or the science of philanthropy forms a part of the curriculum, and is of the New Covenant and the precise word of the latest inspiration. Dogmatic theology "weaves into a single system the separate strands of truth gathered from Scripture and tradition. Apologetics is studied that the preacher may go out equipped to defend the established doctrines against critics and heretics. The study of Church history acquaints the student with the way in which previous dogmatic theologians have done their work; including the forms and institutions in which the Christian truth has found embodiment. Homiletics is the art of fitting a doctrine to a text and proclaiming it convincingly. Practical theology is studied to prepare the student to conduct and administer properly the services of the particular Church the ministry of which he is to enter. While in a considerable number of theological schools this is the extent and character of the education given in these days, the modern minister must come to his position prepared to manage, initiate, inspire many secular or semi-secular enterprises as well as fill the place of a spiritual administrator. The services of worship and spiritual instruction have become the smaller part of a minister's activities. The order of philosophy forms a part of the curriculum, and is designed to teach the rabbi "how to combine the new method with the ancient spirit of Judaism in the field of practical righteousness and Social Service."

Protestant.—In the education for the Protestant ministry the strictly theological subjects differ little from the major subjects in the Catholic curriculum. Systematic, dogmatic, practical theology, exegesis, church history and homiletics—these for many generations were the sum of Protestant theological education. A recent writer has summarized the instruction given in the leading theological schools until recently in such a way as to indicate the different values assigned to these subjects. Out of a possible 1,536 hours of study the time is actually divided in this way: Theology and apologetics, 480 hours; Hebrew and Old Testament, 288 hours; Greek and New Testament, 224 hours; ecclesiastical and Biblical history, 256 hours; preaching and social problems, 96 hours; rhetoric and elocution, 144 hours. A word or two by way of explanation will help to a better understanding of the actual significance and purpose of these studies. The study of Hebrew is designed to enable the student to get the text of "the divine law and covenant." Greek is required that he may get "the letter, banquets, sociables and many other activities designed to aid in the development of community life. In response to these new demands the theological seminaries are radically changing their curricula, not by abolishing the old subjects but by the addition of new ones, or rather by changing the rank of the subjects—studying the old subjects from an entirely different angle. To quote from one seminary's catalogue, "The social teachings of the Old and New Testaments are studied with the purpose of estimating the nature of the contribution of Biblical history and theology to moral and social progress." The sociological now ranks with and in some cases ahead of the theological in an increasing number of schools. The much-debated question whether Hebrew and Greek should be required is being answered by putting these subjects in the elective groups. In some instances students are allowed to present themselves as candidates for the degree of B.D. by offering as substitute for Hebrew and Greek a satisfactory acquaintance with scientific, philosophical, or historical method. The course on "Social Ethics" offered by the Divinity School of Harvard University is a good illustration of how the theological schools are trying to educate the minister to meet the
problems which confront the clergyman of
today. The subjects explain themselves.
"Social Problems in the Light of Christian Ethic,
"The Development of Philanthropic Theory and
Practice," "The Minister's Relation to Social
Agencies," "American Population
Problems," "The Housing Problem,
"Unemployment and Related Problems," "Rural
Social Development." The intimate
association of the student with the
Chicago Commons Social Settlement and
the Chicago Institute of Social Service
are indicative of the attempts now made to
teach the student by introducing him while in
the seminary into the midst of the complex
human problems — a sort of sociological
clinic. The preceding table presents a brief survey of
the course of study planned out for a candidate for
the ministry in some of the leading Protestant
seminaries.

The emphasis in much of theological education
today is put on "Psychology, sociology, philanthropy, legal principles, and practical
problems involved in applying the spirit of
Christianity to modern life." In some schools
the comparative study of religions is given an
important place in the work of religious education
in all its branches and for such other callings and/forms of service as seek to promote Christian
worship and work; to train men and women
for service in such institutions as are
established for the social welfare of mankind in
the name and spirit of the Christian faith; to train
men and women for service in the foreign
field." To this end there has been added to
some of the seminaries a school of religious
pedagogy which aims to offer its theological
student further opportunities to prepare himself
on the Sunday school and social service work
of the church, and also to educate men and
women to fill what might be called the office of
assistant to the pastor. A school of missions
has been added to give those who plan to enter
the foreign field a chance to specialize in studies
peculiarly fitted to that end. Another feature is
the summer schools of theology, which offer to
men already in the regular work of the ministry
an opportunity to pursue the old seminary
studies or take up new ones in the hopes of
better fitting themselves for the tasks met with
in their parishes. The work pursued in these
summer schools, conducted by several of the
leading seminaries, may be credited toward a
degree. Another and not less useful innovation
is the correspondence courses in theology
which have been carried on by a few of the seminaries. These correspondence courses afford the man in the
field an opportunity to secure the education he feels in need of under the guidance of competent instructors. In some instances the work done
in these courses may be credited toward a de-

gree. All this is simply indicative of the desire
on the part of the seminaries to create a finely
educated ministry for the churches.

The question of educational qualification for
admission to theological seminaries has been
previously thoroughly debated for many years.
While there is evidently a constant stiffening of
these requirements, a college training being
more and more in demand, it is felt now, as it has
been all along, that the theological seminary
should be flexible enough to let in persons who,
lacking college training, nevertheless have
intellectual and spiritual qualifications which
make them desirable additions to the ministry.
To compensate for this lack of scholastic prepa-
ration most of the seminaries provide courses in
essentially preparatory subjects, and so pass
these students on into the regular courses or else
the students are admitted to special courses.
However, many of the seminaries award de-
grees only to those who enter with a collegiate
degree; though usually any student is allowed to
present himself as a candidate for the degree
if he submits evidence of scholarship fully
equivalent to a college training. In most instan-
tances tuition is free in the theological schools,
and financial assistance readily available to needy students. This has been severely criticised.
But whether it deserves the criticism or not, it is
difficult to break up a long established custom and
one that has been productive of some excellent results.

REV. CHARLES GRAVES.

EDUCATION, United States Bureau of,
a bureau under the Department of the Interior
since 1868, whose chief activities are given to
the collecting and dissemination of educational
information. It was originally created a de-
partment by act of Congress 2 March 1867. But
the opposition of the States was so pronounced
against the interference of Congress in educa-
tional matters that the newly-created depart-
ment was reduced to a bureau the following
year and its province limited almost altogether
to the encouragement of education through the
collection and dissemination of educational in-
formation. The work of the bureau naturally
fell far short of that done by the Department of
Education in countries where such bodies are
given the direction of educational matters for
the whole nation. In 1864 efforts were made
by teachers and others interested in the advance-
ment of education for the establishment of a
Bureau of Education. But owing to the attitude
of Congress and the various State legislatures,
which were unanimous in their agreement to
leave all educational matters in the hands of
the State officials, the Bureau of Education was
not taken very seriously by the United States
government and its efficiency was hampered by
a lack of funds and of freedom of action. The
bureau began to make its efforts more concrete and effective by the issuance of 'Annual Reports.' In 1870 a series of 'Circulars of In-
formation,' dealing for the most part with the
history of educational progress in the various
States of the Union, was published; the reports
1903, indicated increased activities. A
step in advance was made in 1906 by the institution of the 'Bulletins,' dealing with a wider variety of interesting educational subjects. In 1910 the
bureau broadened the scope of its work still
more by the publication of 'Circulars of Infor-
EDUCATION OF THE BLIND

EDUCATION OF THE FEEBLE-MINDED

EDUCATION OF THE DEAF

EDUCATION OF THE DWAP

EDUCATION OF THE FEEBLE-MINDED OR MENTAL DEFECTIVES

EDUCATION OF THE BLIND

EDUCATION BOARD, General
ENCE, the imbecile is the next higher and the moron is the highest.

The importance of the subject of feeble-mindedness will be appreciated by considering it in the light of its social significance. There has been no general census in Europe or in this country which reveals the exact number of feeble-minded adults or children. Various studies and surveys have been made, however, under government direction and by reliable organizations, and it is estimated that the number of feeble-minded persons within a given area and a specified population. From the information which has been obtained through these investigations and surveys, it is possible to make a fairly accurate estimate of the number of feeble-minded people and also the number of feeble-minded children in the country.

The Royal Commission of Great Britain made surveys in several sections of England, Ireland and Scotland, and it estimated with careful thought for four years. Its report was made in 1909 and showed that, on the basis of its study, 1 in every 217 persons in England was feeble-minded. Surgeons of the United States Public Health Service studied in Porter County, Ind., in 1915, which showed that 9.55 per cent of all the children in that county were feeble-minded. The same authority made a survey of Newcastle County, Delaware, in 1916, which showed that 1.3 per cent of all the children examined were feeble-minded. A survey made by the Nassau County Association assisted by the National Committee for Mental Hygiene, the United States Public Health Service and the Rockefeller Foundation, in Nassau County, N. Y., in 1916, showed that on the basis of its study, 1 person in every 183 of that county was feeble-minded. The investigation by the Massachusetts Society for Mental Hygiene in that State in 1914 indicated that there was one feeble-minded person in every 278 of the population. The estimates made by such experts as W. E. Fermlid, H. H. Goddard and E. K. Johnstone place the number of feeble-minded in the United States at 1 in every 250 people. These figures and the estimate of the Committee on Mental Hygiene and the New York Committee on Feeble-Mindedness to the population of the United States, we should have in this country about 400,000 feeble-minded persons and about 100,000 feeble-minded children. The presence of this large number of feeble-minded children in the country at large is a condition which demands that every effort possible be made to educate and train as many of these as may be possible in order that they may be self-supporting. It is estimated by Mr. George Hastings, secretary of the New York Committee on Feeble-Mindedness, that about one-third of the feeble-minded break the law and nearly one-third of the law breakers are feeble-minded.

About 1850 the States began to give consideration to the education of the feeble-minded child. State institutions were organized and the care and education of this type of child has received extended consideration since that time. Many State institutions and several private institutions have been established for the care, education and training of children of this type. It is not feasible to undertake the education of the classes of mental defectives known as idiots or imbeciles in the public school. These types of mental defectives must generally receive their training in institutions established in accordance with the most modern standards of education and care of such children. The children who are classified as morons may be segregated and educated in special classes provided for them in the public schools. Mentally defective children who come from homes which are able to give them proper care and attention are not under the influence of the school and who may be trained to become either wholly or partially self-supporting may generally be afforded necessary educational facilities for their proper education in the public school system of the city or district in which they live. All mentally defective children who come from homes which cannot give them the protection and care which is essential to the best interests of society should be educated in institutions organized for this type of children. The tendency throughout the country is to utilize to the greatest extent possible the public school system for the education of this type of children.

There has been recent legislation upon this subject in the States of New Jersey and New York. In 1911 the legislature of New Jersey enacted a law making it the duty of the State board of education to ascertain the number of children in the public schools of the State who were three years or more below the normal grade. This law further provides that in each district in which there are 10 or more such children the board of education for that district shall establish such special classes as may be necessary for the education of these children. No class may contain more than 15 of such children. An important feature of the New Jersey law is the State aid which is accorded each district in the State which organizes one of these classes. The State authorizes an apportionment of $500 for each teacher employed in giving instruction to a class of children of this type. This State aid offers great encouragement to a community to organize such classes and enables a community to meet the expense of maintaining such classes without burdensome taxation. The commissioner of education reports that, for the school year ending 31 July 1917, 162 classes had been organized. The establishment of these classes in New Jersey is compulsory. This appears to be the first State in the Union which has enacted a statute making it mandatory upon the local school authorities of an administrative unit to organize classes for children of this type. The training school for normals at Vineland, N. J., is one of the notable institutions of the country for this type of children.

The New York law enacted in 1917 is also a mandatory statute and is modeled somewhat after the New Jersey act. The commissioner of education is authorized to prescribe regulations to govern the taking of a census by the school authorities by each city and each school district. The local school authorities must take such census. The law further provides that each city and each union free school district shall establish such special classes as may be necessary to provide instruction adapted to the mental attainments of children who are three years or more below normal. This, of course, requires provision for all mentally
defective children as well as for the retarded children. No more than 15 pupils may be placed in one of these special classes. The school authorities of a city or district which has less than 10 children are required to provide for their instruction in industrial arts in a school which establishes classes or schools for such children. The financial aid given by the State is $300 for each class organized in a city or district.

The major work in a course of study for this type of children is industrial training. This type of child may be trained to become an efficient domestic worker and may be also trained to do very satisfactory work in agricultural lines. The institution and the public schools which maintain courses for these children have demonstrated that large numbers of them may be trained to become self-supporting. To illustrate the type of course of instruction which is maintained for such children, I quote the following from the official report of the Superintendent of the Rome Custodial Institution:

"4Kindergarten; sense training; form, color, co-ordination and numbers; articulation and language; weaving; sewing, knitting and crocheting; sloyd; carpentry; painting; gardening; farming; domestic arts (dressmaking); music (vocal and instrumental); dancing; entertainment; Sunday School; chapel; farm colonies; domestic colonies; parole; discharge (or failure and permanent custody).

The institution located at Waverly, Mass., the one at Vineland, N. J., the Rome Custodial Institution, Rome, N. Y., and the State Normal School at Oswego, N. Y., maintain courses for the training of teachers for this type of school. Undoubtedly other institutions for this type of children also maintain such courses.

THOMAS E. FINEGAN,
Deputy Commissioner of Education and Assistant Commissioner for Elementary Education, State Department of Education, Albany, N. Y.

EDUCATION IN THE HOUSEHOLD ARTS. See HOUSEHOLD ARTS, EDUCATION IN THE.

EDUCATION OF IMMIGRANTS. During the 14 years preceding the outbreak of the European War 11,726,606 immigrants over 14 years of age were admitted to the United States. Of this number 3,116,182 or about 25 per cent were illiterate. During a year of ordinary immigration preceding the war more than 1,000,000 immigrants came to this country. In the year 1914 the number was 1,218,480. Illiteracy has been on the increase in 18 States in the Union. These States are the leading industrial and mining States, and include New York, New Jersey, Massachusetts, Connecticut, Pennsylvania, Illinois and California. These are the States in which the great majority of immigrants settle. Under the first selective draft law 1,245,801 alien males registered who were between the ages of 21 and 30. Under the military ages fixed in the amended draft law, 18 to 45, there are 3,000,000 unnaturalized alien males in this country. About 20 per cent of these cannot speak English. When they enter the United States army they will be unable to understand the commands of their officers until they are taught to understand English. There are 5,500,000 people in the United States who are unable to speak English.

In the last decade there has been a large decrease in the number of illiterates under 14 years of age. Under compulsory attendance laws illiterates under this age have practically disappeared. The number of negro illiterates is rapidly decreasing. The number of native-born white illiterates is also rapidly decreasing. The only class of illiterate which has been increasing during recent years is the one which are able to read, but are unable to write. This large number of citizens unable to speak the language of the United States exceeds the number of soldiers which the government expects to send to Europe to fight in this war. The number equals about one-twentieth of the population of the country. These immigrants come to the United States for the purpose of obtaining larger opportunities for themselves and their children. They naturally drift to the sections of the cities which are inhabited by former residents of their native lands. Thus there are to be found in all the large American cities a particular section inhabited by Italians and known as the Italian section, another inhabited by Poles and known as the Polish section, etc. These immigrants do not get the spirit of the life of American or democratic institutions. They retain to a very large extent the customs and habits of the country from which they emigrated. It is difficult for them to learn to speak English and they are not able to communicate readily with Americans. This fact is to their disadvantage in obtaining employment. Then, too, they do not acquire so readily a knowledge of the laws of the United States, of their rights in and their obligations to the country. About one-third of the prisoners in penal institutions in the United States are aliens. The number during the decade preceding the war had constantly increased. They have in many instances been here but a short period of time and have committed minor offenses. They are in many cases the leaders in riots and in other movements of disorder and lawlessness.

President Wilson in addressing several thousand aliens made the following statement: "You cannot become thorough Americans if you think of yourselves in groups. America does not consist of groups. A man who thinks of himself as belonging to a particular national group in America has not yet become an American... America was created to unite mankind by those passions which lift..." Immigration is a national affair and has always been regulated by the Congress. The action of the Congress in passing a measure over the veto of the President in 1917 prohibiting immigrants from coming to this country who are illiterate has given rise to the question of adult illiteracy. While no additional illiterates will be admitted to this country there will still be large numbers of immigrants admitted who are not able to read or write English. In the problem therefore of illiterate immigration there is an immigration who must have consideration. First, the illiterate alien, and second the literate alien who is unable to speak English. It is as important to educate the non-English-speaking literate alien as it is to educate the English-speaking alien for preparation for citizenship by informing him upon the fundamental features of the social,
industrial and civic questions upon which the progress and prosperity of a democracy depends.

This subject has never been approached as one of the great national problems which the country must solve. For many years such a charitable, philanthropic, religious and civic organizations, in various parts of the country, have done very much toward the education of the illiterate alien. The North American Civic League for Immigrants, The Baron De Hirsch Men's Educational Association, The York Men's Christian Association and many civic, religious and charitable societies have done much pioneer work of great value in this field of education. The great railroad corporations and many of the industrial and manufacturing corporations of the country have maintained schools at their own expense for the education of their alien employees. In many cases large corporations have found it to be a matter of economy to maintain such schools and therefore reduce the number of accidents, thus insuring insurance and increasing the efficiency of the employees. The developments of this field of education are similar to the developments in all the new fields of education, which are ultimately assumed by the general and religious societies, and usually take the initiative in such fields. Over half a century ago some of the American States, which had begun to realize the importance of this problem, because of the number of immigrants coming into such State, authorized the establishment of night or evening schools. The establishment of such schools was not mandatory but was wholly in the discretion of the community or its educational officers. This type of legislation has increased until most of the States having large numbers of aliens have authorized such schools. In most States attendance upon these schools is free. In some States small appropriations are made by the State but very generally the burden of the maintenance of such schools is placed upon the city or district.

The problem is not a local problem and local authorities should not be compelled to meet the expense of maintaining such schools. The problem is a National problem and a State problem. The National government should make appropriations which, supplemented by appropriations by the States, would be adequate to provide schools where all aliens might receive the degree and type of education which is essential for newcomers from other countries who intend to make America their adopted home. An effort has also been made to reach the alien through the organization of camp schools. In cases where cities and municipalities have been engaged in large constructive problems, notably in New York, in connection with the construction of the Barge Canal, the building of the State roads and of the Ashokan Dam, where large numbers of aliens have been employed for long periods of time, temporary or camp schools have been established for the education of such aliens. The aliens employed in these labor camps do not remain in one place a sufficient period of time for the establishment of permanent schools. Experience in maintaining camp schools shows that if such schools are to be made effective there should be portable school buildings with equipment which may be moved from one place to another. The expense of maintaining these camp schools should be borne by the municipalities or the corporations or jointly by the agencies employing such aliens.

Massachusetts, New Jersey and New York have done pioneer work in alien education. Massachusetts enacted a law on the subject in 1887 requiring all illiterates between the ages of 14 and 21 to attend some school if they were continuous residents in the municipality where they were living. An evening school was held. An examination was prescribed to be given after the close of the instruction as a literacy test. In 1906 this test was that which was required in reading, writing and spelling for admission to the second grade in the public school. In 1907 for admission to the third grade and in 1909 to the fourth grade. The requirement now is admission to the fifth grade. The law prohibited the employment of a minor unable to pass this test unless he attended an evening school. The New Jersey law of 1907 provides that the board of education may establish and maintain a public evening school or evening schools for the instruction of foreign-born residents of said district over 14 years of age in the English language in the form of government and the laws of this State and of the United States.

The most recent and comprehensive legislation on this subject is that of the State of New York. Three laws were enacted in 1918 by that State. One provides for the appointment of special teachers to instruct illiterate adults, under the supervision and direction of the State Education Department and an appropriation was made by the State for the purpose of holding summer institutes in which teachers so adapted to this work might receive instruction on the most natural and modern ways of approaching the foreigner and teaching him not only the English language but his relations and obligations to the government. Another of these laws makes it mandatory upon the cities and school districts to maintain night schools on three nights per week for two hours each night. In cities of the first class these schools must be maintained during the duration of the period that day schools are maintained. In cities of the second class such classes must be maintained for 100 nights. In cities of the third class they must be maintained for 80 nights. In school districts outside of cities and which have 20 or more persons above the age of 16 years who desire instruction, such school must be maintained for 75 nights. Attendance upon these night schools must be free. The purpose therefore of these two acts is to provide the necessary facilities for the maintenance of schools where illiterates may receive instruction and also to provide trained teachers who will go into the community for the training. The third law makes it obligatory upon certain minor illiterates to attend these schools. An illiterate minor who cannot speak, read and write the English language sufficient for admission to the sixth grade of the public school if he is in proper physical and moral condition must attend the evening school or a day school until such minor is able so to use the English language. Unless a minor satisfies these requirements of the law he may not be
employed in industry. Provisions, with suitable penalties for the failure thereof, run against such minor, his parents or guardian and the employer.

In the State of California a plan has been adopted to reach the immigrant women and through them the home. This plan involved the establishment of a Home Education Department under the direction of the State authorities. Through this plan visiting teachers go to the homes of all the immigrant women who are illiterate and who need instruction in modern home making and in the customs and practices of this country. If laws similar to the statutes in New York and California could be enacted in every State and the National government and each State would make appropriations upon an equitable basis illiteracy in this country could be practically eliminated within the next decade.

THOMAS E. FINNEGAN,
Deputy Commissioner of Education and Assistant Commissioner in Charge of Elementary Education, State of New York.

EDUCATION IN MUSIC. See Music, Education in.

EDUCATION AND NATIONAL DEVELOPMENT. Education has been an important factor in influencing our national development, our institutions, ideals, habits, efficiency, and general mental attitude. It has in turn been shaped by those permanent factors that determine, in large part, the nature and progress of any civilization—the geographical, physical and racial factors—and the institutions resulting, particularly those of a political, economic, religious, and social character. It is the interaction of all these factors that accounts for the peculiar relation of our education to our national development.

Nations that have a national system of education, directly controlled by the central government, have the power to influence conspicuously the character and legislation so as to produce a definite type of national life. Many of the important nations of the past have, through state aid, established, encouraged, and controlled to a greater or less extent their educational institutions,—elementary, secondary, and especially higher. They have likewise fostered and protected libraries, art, literature, and science. Their purpose was to raise the tone of national life, to train leaders for service in church and state, and to teach men their duties to the state, to each other, and to themselves.

In the United States, however, from the founding of the colonies until the present time, education has not been in the hands of the central government. During the colonial period of our history each colony acted independently, in this matter, and when our Constitution was framed the States retained supreme authority to regulate education. Moreover, during the colonial period and until the second quarter of the 19th century, with few exceptions, both colonies and States left the subject almost wholly in the power of the local units of government, of which the district was the most characteristic, or trusted to private or other agencies. This led to extreme variations in educational ideals, institutions, and practices, with the result that the direct influence of education on national, as distinguished from State or local, life, was small. By this we mean there was little tendency to educate the individual in a way to prepare him for efficient citizenship, with an eye to the welfare of the communities toward the nation. Indeed this was hardly possible until there was a realization that the local communities were to become parts of a great whole or until the national spirit was born. Since a political basis for national education was lacking schools were maintained largely for the moral and religious development of communities, and the preservation of learning for its own sake. After the State systems were formed there was some improvement, but educational policies and institutions were necessarily largely determined by local or sectional needs.

In spite of this diversity, it is true that gradually the spirit of American education, and to a considerable extent its forms, have tended toward uniformity, with the result that the same forces that led to the substitution of the principle of union and nationalism for particularism. In the case of education the process has been voluntary, without the compelling force of general laws issued by the central government. In other words the individual States have been guided by similar ideals and forms of education, because they best express the needs of their people. The more that various sections of the country become one in spirit and institutions, the more the State systems of education have tended to become similar in spirit, practice, and form.

Before the American Revolution two movements of all these forces prepared the way for a greater influence of education on national development. First, the tendency to recognize the responsibility of the state for education, rather than some other agency like the Church or agencies of a private character. This notion appeared first in 1647, in legislation establishing the educational system of Massachusetts. Second, those forces tending toward the sentiment for and feeling of nationality, based on common political institutions and language, literature, habits of thought, aspirations, and especially on the influence of environment in producing democratic tendencies.

The American Revolution was the first great event which increased the influence of education on national development. It stimulated a desire for institutions which would express national character more local or national, and placed emphasis on subjects expressing national rather than local sentiments. The Revolution hastened the decline of the Latin Grammar School, already an institution failing to meet the needs of the generation before the Revolution, and ushered in the academical institution, better suited to the needs of the people and more democratic in aim, type and distribution than was the Latin Grammar School. The Academy was the forerunner of the still more democratic institution of the next gen-
eration, the public High School. The Revolution also stimulated an interest in English, the mother tongue, which was the beginning of serious study of this subject. It stimulated patriotic sentiments which led to an interest in our national history and hence the study of history and civics, the foundation of political education.

With the formation of our first national government, the Congress of the Confederation passed the first act that emphasized the national aspect of education. This was the Green land Act of 1785, which provided for the reservation of lot number 16 of every township surveyed, in the newly-acquired western territory, for the maintenance of public schools within the township. The ordinance for the government of the Northwest Territory, 13 July 1787, contained an important article, number three, which reads,—"Religion, morality, and knowledge being necessary for good government and the happiness of mankind, schools and the means of education shall forever be encouraged and aid be furnished for the sale of land to the Ohio Company and authorized the reservation of land, lot number 16, in each township, for schools, but also provided the two townships desmated by the company, and for the support of a literary institution." The precedent thus established was followed, and in all territory later included in the public domain, reservations for elementary and higher education were made in a similar manner. Thus provision was made for the endowment of the State universities, a type of educational institution that has had great influence on national development.

Later the Congress of the national government granted additional tracts of land to the western States for educational purposes, culminating in the Morrill Act of 1862. This act provided for large grants of land to each State to endow "at least one college where the leading objects shall be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to agriculture and the mechanic arts, in such manner as the legislatures of the States may respectively prescribe, in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions in life." The importance of this attitude of the Federal government toward education consists in the fact that it is an acknowledgment that the Federal government has a right and duty toward national education, notwithstanding the delegation of the power to the States. The educational institutions resulting from these acts have had great influence on our national development.

In the second quarter of the 19th century the forces engendered by the industrial revolution reacted on education. The rise of manufacturing the factory system, the new grouping of population, and the humanitarian and democratic movements following, brought insistent demands for free elementary and secondary education at public expense. It is principally from this period, 1830 on, that education has had an increasing influence on national life. This relationship was further stimulated by improvements in intercommunication, by means of the steamboat and the railroad, and in agencies for the transfer of intelligence, the newspapers, libraries, telegraph and telephone.

The public school has been the chief instrument for influencing national life. The State systems of public instruction have as their basic idea, that it is the duty of the State to make education available and free for all, at public expense. Other principles gradually adopted include State support and administration, compulsory attendance and supervision, and fixed standards for the subject matter of the curriculum and for qualifications of teachers. The tendency toward uniformity in these matters has made it possible for public education to influence greatly national development. One important effect, for example, has been the secularization of public education, and hence a marked decrease in the religious element in the curriculum, and a decline in the influence of church supported schools. After the middle of the 19th century legislation prevented public funds, with few exceptions, from being used to promote sectarian education.

Public education was also reacted in a way to give a certain mental attitude to the nation. As America has been a synonym for opportunity, and freedom for the development of the human spirit, public education has absorbed this spirit and practiced it in instruction which encourage individual initiative and independence of thought. This attitude tends to perpetuate the spirit of democracy and opposition to autocratic political systems.

The development and extension of the notion of public democracy has been most important in its influence on national life. The reasons for, and justification of, the principle are as follows: First, the basis of free institutions in any nation is the intelligence and integrity of its citizens. Our government in the last analysis is based on public opinion, and it is only through an enlightened public opinion that the permanency and success of the Republic are possible. The more universally the people are educated, the less need there is of restraint, and the greater is the check against corruption or unwise legislation by representatives.

Public education directly affects national development, because through this agency national interests are best promoted. With the extension of the suffrage and the tendenc to channel the government more and more on the hands of the people, or their directly elected representatives, both voters and leaders needed education to act intelligently. Again, public education promotes national well-being, because it leads to greater economic efficiency, and hence greater national wealth. It promotes industry because it awakens desires for more and better goods. It promotes discoveries and inventions. It leads to greater social efficiency because it reduces crime, and turns thought in the direction of social service. Essential for the preservation of the nation, public schools become the principal means of teaching pupils their duties and obligations to the State, as well as their rights and liberties. Public education leads to more rapid progress, as civilization can advance permanently only as the mass advances. Public schools give opportunity to teach the masses to appreciate and desire the best in literature, art, and music. In
short national life as a whole could hardly be enriched to any great extent except through public education. Finally, education has as its chief aim the formation of character, and hence the national character can be best formed through the public school. It has for its aim the promotion of the educational and moral development of the masses — the ethical as well as the material aspects of life.

In spite of the many ways in which public education has influenced national life, it falls far short of what is possible. After all is said, the State systems of public instruction, in their origin, development and present conditions, tend to express very largely the local or sectional needs of the communities in which they are placed. The educational policies adopted are not primarily national in character, nor in harmony with each other. There is too much variation in types of educational institutions, emphasis or lack of emphasis on various kinds of education, and attention paid to the problems of the whole nation. In both nations, like others, was developed through conflicts, three in particular; the American Revolution, the Mexican War, and the Civil War. Each left prejudices which have been perpetuated in the educational system. The first against England, the second against Mexico and Latin America in general, and the third the antagonism between the North and the South, still perceptible in certain features of the education in the two sections. The first two prejudices interfered with our international relations and intercourse, causing a lack of sympathetic knowledge of the progress and problems of England and Latin America. These prejudices affect teaching of history in the public schools, as well as geography, and lead to provincialism from the standpoint of the relations of the United States to world conditions. The third prejudice affects particularly the teaching of history and tends to perpetuate the disintegrating force of the Civil War, because it interferes with national unity. All these difficulties are inherent in the State systems of public instruction, but could be remedied in large part through greater national control or by the placing of emphasis on problems of national life.

Another serious fault of our public system of education is its failure to give equal opportunity to all sections and classes. The more backward sections, or those less fortunate in their economic life, cannot give the same opportunities for education as the more advanced and wealthy sections. From the standpoint of the influence of education on national life this is unfortunate. To nationalize education in this respect, it is proposed that the national government should equalize these variations so that part of the wealth of the whole people will be available for those portions of the country and to develop public education to the highest standard.

It is proposed that the national government should consider not only the matter of support but also that of control, at least so far as to establish minimum standards of education and teaching and to develop the principles on which public education should be based. For to promote national in place of local, provincial, and sectional development and interests, the principles must be determined at one centre, and not at 48 centres. It is recognized that this will be even more necessary in the future, because of the revolution in the industrial and social systems of the country, and the great importance of national development and life in connection with the world interests and responsibilities of the nation. As the old notions of State rights have been overthrown in the economic and political world, and as the nation has taken over many of the early powers of the States in these respects in order to gain greater efficiency in national development, so it is necessary that the same policy should be pursued in the matter of education. For it is only through the resources of the whole nation that the expense of nationalizing education can be met, and only through national control can those principles, and minimum standards be established which will best promote national interests.

A third weakness of the public school system under individual State control is the failure to hold a good proportion of the pupils for the full course of study in secondary schools, and to train them efficiently. About two-thirds of the pupils, boys and girls, leave the public school before they reach the age of 14, and enter industrial, commercial, and agricultural, the first so-called the first grade. 10 per cent of the 12 or more millions of persons engaged in agriculture have received adequate training for this pursuit. Much the same can be said of the 14 millions engaged in manufacturing and mechanical pursuits. Similarly the State systems maintain great inequality in the teaching force. Of the 212,000 teachers for rural schools nearly one-third have an education in quality below the ninth grade, and another one-third not above the 10th grade. That is, 150,000 out of 212,000 rural teachers have inadequate preparation for teaching and the remaining one-third have only an average high school course with one or two years of normal school training. Here again it is only through greater national aid and control that we can secure the greatest influence of public education on national development.

Recent tendencies in American public education have tended to emphasize still further the close relationship of education and national life. There is more and more effort to make education richer and broader; to provide more opportunities for the masses for a complete education from the kindergarten through the university; to increase the number and variety of agencies and institutions for education and development, such as playgrounds, lectures, continuation schools, correspondence, evening, and summer schools; to use school plants as community centres; to extend the benefits of free education not only to all children but to all the people; to pass beyond the older conceptions of moral and book education, to new types; to emphasize not physical training but free medical examination and care of health — in short, to develop the physical as completely and with as much care as the mental being; to give opportunity not only for general education but also for types that will fit for specific vocations, and to provide special teachers for vocational guidance in order to help pupils select the vocation for which they are best adapted. A demand for a special type of education, military educa-
tion, is due to the emergency brought on by the world war; but it is advocated by many as a matter of right and as necessary to provide for national safety. It is evident that these tendencies are certain to have important effects on our national life. The effort to extend the control of the national government over education, through the proposal to create a department of education with a cabinet officer, is another plan to relate education still more closely to national life.

EDUCATION IN PAINTING. See Painting, Education in.

EDUCATION OF THE PHYSICALLY HANDICAPPED. For a long period of years, a child who was born deaf or blind or who did not possess the full normal use of any of the organs or members of the human body has been called a defective. It has also been the practice to classify children who have lost the use of any of the organs or members of the body through disease or other causes over which they have no responsibility as defective children. This classification is not regarded by those who have had the largest experience with these types of children as either wise or proper. A child who has not the full normal use of any of his organs or of any part of his body is generally sensitive about his condition and needs the sympathy of his fellows who have not suffered the loss and disadvantages that grow out of such physical conditions. If there is a psychological or other advantage in the term of ‘defective’ it is for the use of children of these types, it seems wise and desirable to employ such terms in all references to or discussions of such children. It is not generous nor fair to these children to speak of them as defectives. The common meaning of the word ‘defective’ is too broad. Such term has a tendency to bring a degree of reproach upon such children which they do not merit. This is especially true when consideration is given to the general view which prevailed until within the last century and a half in the civilized countries of the world, in respect to these children. One hundred and fifty years ago they were generally looked upon as children who did not possess the mental capacity for training or for citizenship, who were not generally capable of self-support and who must remain a burden upon society. The belief that the deaf and blind could not be educated was so universal that within the last century they were actually referred to as children of silence, solitude and darkness, sorrow-stricken children of silence.

abandoned to his hard fate of wandering in darkness, the pitiable object of dismal despair.

The results achieved by statute and by court in protecting the children their inherent rights to an education and the standing which the deaf and the blind have attained for themselves in the general affairs of life, when given the same opportunities which have been afforded other children, have led to the adoption of an entirely different policy on the part of society and the state in relation to them. It is now universally recognized that these children are entitled to certain privileges as a matter of right which must be respected by the state and that there are certain definite obligations imposed upon the public which must be discharged. These children should not therefore be classified as defectives or wards of the state. The modern and the most appropriately just classification for these children is to designate them either as deaf children, blind children, or crippled children, or under the general term, physically handicapped children.

The most reliable information obtainable shows that there are in the United States approximately 46,000 deaf persons and 60,000 blind persons. More than 35 per cent of the deaf are born in that condition and about 75 per cent of the deaf become so before they reach legal school age, which is generally, in the American States, five years. Eighty per cent of the deaf children are not able to speak. Less than 2 per cent of the blind are born in that condition and about 12 per cent become blind before they reach the age of 20 years. Statistics show that these several classes of physically handicapped children are distributed through the several States fairly proportionate to the population thereof. The number is so large that it is necessary to provide a comprehensive, well-organized system of education adapted to their needs and conditions, if they are to be afforded the opportunities to prepare themselves for the responsibilities of citizenship which are at all comparable with the opportunities which are afforded the children of the country who labor under no physical handicap whatever.

There is not that uniformity of policy pursued in the several American States in relation to the education of these types of children that is pursued in relation to the education of normal children. There are two fundamental questions which have not been definitely settled in America in relation to the education of these physically handicapped children. These questions are: 1. What is the legal and moral obligation of the State in providing educational facilities for these types of children? Is the education of these children to be looked upon as a matter of charity or a matter of State obligation?

2. Are the facilities which shall be provided for these types of children to be institutional or as nearly like those provided for normal children as may be possible?

The schools first organized for these types of children were established largely by efforts of men and women interested in such children either from the charitable or philanthropic standpoint. Men and women interested in the subject, persons of means with the philanthropic spirit, civic organizations desiring to promote social welfare and religious
organizations were the first promoters of institutions for the education of children of these types. In 1907 the State of Oklahoma incorporated its constitution with the following provision: "The legislature shall establish and maintain a system of free schools wherein all the children of the State may be educated." (Section 1, article 13).

The constitution of nearly every State in the Union contains a provision similar to that of the State of Oklahoma. This mandatory provision of the fundamental law of each State makes no discrimination between types of children. The provision is that these schools shall be maintained for the purpose of educating all the children and not simply the normal children. There should therefore be a settled policy on the part of every State in the Union to make suitable provision at State or community expense for the education of these children. Children who are so unfortunate as to be afflicted as these children are should be relieved to the same extent that normal children are relieved of the stigma of receiving their education as a matter of charity. The administration of public institutions for more children in every State in the Union is upon the basis that such schools are institutions of the State and must be supported and maintained by public taxation. The same principle should be applied in the maintenance of institutions in which children of these types are educated. The institutions which are maintained for the education of these children should be regarded in every way as educational institutions and they should not be classified nor grouped with charitable, reformatory, correctional or other institutions of this character which are maintained by the State.

The purpose in educating these children is to make them self-respecting, self-supporting and law-abiding citizens of the State. They are to be trained to assume their positions in organized society as other children are trained for that purpose. If this is the conception of the State in authorizing the maintenance of institutions for the purpose of educating these children then it is the obligation of the State to divest from such institutions every element which signifies that such institutions are a part of the charitable system of the State and that the persons educated therein are therefore objects of charity. To instill into their characters the element of independence essential to success in life the State must avoid the maintenance of institutions for their education which compel those who are trained therein to feel and believe that they are dependents.

There are many reasons why these types of children should be afforded educational facilities in the public schools of the city or district in which they reside whenever it is possible to do so. This is the modern trend in connection with the education of these children. Of course, this was not possible in the early history of the development of institutions for the education of these children, when such children were so sparsely distributed throughout the country. In large and prominent cities of the country, there are now a sufficient number of children of each of these types to warrant provision for special classes in the regular public schools. It is not possible to provide for the establishment of such classes in the States which do not have large cities or in the territory of many of the States outside of their large cities. It will be necessary therefore to provide for the education of such children as live in these remote or more sparsely settled parts of the country. In about one-third of the States, however, there are public day-schools for children of these types. They have the advantage therefore of association with normal children and the personal consciousness that they are being educated for citizenship under the identical plan provided for the education of other children. The thought that these children are different from other children is thus largely avoided. An argument of great weight in favor of this mode of educating these children is that they are afforded the opportunity of remaining at home and therefore of having the influences and pleasures which home life provides. The feeling generally is somewhat repugnant to the idea of taking children at these tender ages, who possess such afflictions, from their relatives and homes and placing them among strangers in an institution. Such action may not be held to be economical for the education of these children in the regular public day-school than to pay for their education in institutions especially maintained therefor. The whole trend in modern school organization is in favor of this idea. The introduction into the schools of industrial education makes it possible to provide the facilities for the education of children of these types which are afforded in the special institutions.

The most advanced expression of public opinion upon this subject will be found in the law enacted in the State of New York in 1917. This law requires the board of education of each city and of each union free school district to take a census of all the physically handicapped children in such city or district. In those cities or districts in which there are 10 or more children of one of these types, the law makes it obligatory upon school boards to establish a special class and to provide instruction adapted to the mental attainments of the children and to their physical condition. This law also authorizes the school authorities of a city or district in which there are less than 10 children of one of these types to contract with the board of education of another city or district or with an established institution in the State for the education of such children.

Deaf Children.—There are recorded many early efforts on the part of individuals to teach some deaf friend or relative. The earliest record is probably that of a deaf person taught by Bishop John of York in 691. It is also recorded that Girolamo Cardona, a distinguished physician of Pavia, invented the first manual alphabet about the middle of the 10th century. The first organized class of deaf pupils to receive instruction, of which there is a record, was probably in the convent of San Salvador de Oña in Spain, and was taught by Pedro Ponce de Leon in 1550. It is claimed that this method of teaching the deaf began to receive general attention in the countries of Europe. Schools had been established in England, Scotland, France, Ger-
masy, Italy, Switzerland, Spain and Holland before the demand for their organization in America was created. In America as in Europe, the first effort was in an individual case when Philip Nelson of Rawley, Mass., was taught by Isaac Kilbourne in 1639. John Harrower, a teacher in Fredericksburg, Va., wrote in his diary that from 1773 to 1776 he had a deaf boy in his school. The real foundation of the education of the deaf in the United States was begun in this way. Twelve thousand and dollars had been expended by subscription previous to the opening of the school at Hartford, on 15 April 1817, and soon after an additional $12,000 was raised by the same method. The institution soon obtained a national reputation. Gallaudet went to Washington in 1819 to interest Congress in the movement. He met Henry Clay and, through the influence of that Southern statesman, Congress appropriated 23,000 acres of public land. From this appropriation the institution realized the sum of $100,000. The school was particularly regarded as a New England institution. Massachusetts instituted the policy of sending its deaf children to this school to be educated. Each of the other New England States followed the example of Massachusetts. Georgia and South Carolina did likewise. And many private pupils were sent to the school from different parts of the country. Within the next decade institutions were founded in New York, Pennsylvania, New Jersey and Kentucky. These were all organized as private institutions. In 1823 Kentucky established an institution which was the first State school for the deaf in the country and this may be regarded as the beginning of a change of policy in the education of the deaf. Congress gave aid to this institution. For many years the deaf children from the Southern States and from many of the Western States were sent to this institution to be educated. From this time on the State recognized its obligation in providing for the education of these children by the establishment of institutions as State institutions in nearly all the States of the Union. The schools thereafter established, except in Maryland, New England and some of the Eastern States, have been organized as State institutions.

Every State except Delaware, New Hampshire, Nevada and Wyoming maintain an institution for the education of the deaf. Because of their small population these States find it more economical to provide for the education of their deaf children in the institutions of other States. There are 65 State institutions in the United States. Forty-eight of these are owned by the States which have erected them. In Connecticut, Massachusetts, Vermont, New York, Pennsylvania and Maryland there are 17 institutions owned by private corporations but under the general supervision and inspection of the State. Many of these institutions have been endowed. Appropriations are made by the State for the construction of new buildings for these institutions and for repairs and improvements to their plants. A per capita allowance is also appropriated by the State to the institution for the maintenance of students.

When institutions were first organized by the States it was the policy to restrict the number of students who might be taught to a certain number of indigent pupils from a political division. The number was gradually increased and
the language modified which classified them as indigent pupils. Finally no limitations were imposed but the right of any deaf child in the State to attend was clearly specified in the law and provision made for meeting the expense.

An examination of the census of the United States shows that the deaf are generally employed in the chief industries of the country known as trades and in about the same proportion as hearing people. The number of deaf employed in the occupations which are classed as manufacturing is about one million, and the average of men and women, blind, is about four million, or about three per cent of the able-bodied population. The number of deaf persons employed in mercantile and commercial pursuits is much less. The percentage of the deaf who either own or give direction to the business in which they are employed is about the same proportion as the hearing people.

There appears to be no discriminatory action on the part of the employer in employing the deaf. He is employed under the same conditions and at the same compensation that others are employed. About 80 per cent of the deaf are employed in gainful occupations and about 90 per cent are self-supporting. The character of the instruction which the deaf children receive therefor does not differ from the instruction given to a well-trained normal child. The courses of instruction in reading, language, history, arithmetic and all book-work as well as courses in vocational work for children are suitably adapted to the needs of deaf children. The method of instruction must, of course, be different.

The sign language has been used in the instruction of the deaf since special schools have been organized for their education. This system is called the manual or sign method. There is a second method known as the oral method. Many teachers employ a combination of the two methods. The sign language has always been the chief vehicle through which the deaf express themselves. There is a great disadvantage in this method, since the deaf are not generally able to use it or to interpret it. The deaf have therefore been unable to communicate readily with those with whom they must transact their business affairs. There have been advocates of another method, the lip-reading or the deaf, and in 1669, Dr. William Holder published a work on the Elements of Speech. In this work Dr. Holder advocated the teaching of the deaf by a process of articulation. At this early date the foundation of the two rival methods of the present day for the instruction of the deaf was established.

Samuel Heinicke opened a school in Hamburg in 1754 and in 1778 on invitation of the government he removed the school to Leipzig. The State supported the school and this appears to be the public method which had been established. It was one of the great deaf teachers, an advocate of the oral method and influenced the method of teaching the deaf in European countries and in America. Charles Michel, Abbe de l'Epee, was the founder of the school at Paris, which was established in 1755. He probably exerted a greater influence on the instruction of the deaf in America than any other teacher.

The New York institution is said to have been organized as a day school in protest against the alphabet method of instruction and to have been conducted as a school until the 19th century. In 1869 the Board of Horace Mann school was organized as a day school and since that time day schools for the deaf have been established in 14 States. Such schools have been organized extensively in Wisconsin and Michigan. In the former State such schools have been organized in 23 cities or villages with an enrolment ranging from 5 to 150. In the latter State schools have been established in 14 cities or villages. The large cities are organizing such schools and they will be found in New York, Chicago, Cleveland, San Francisco, Los Angeles, Saint Louis, Saint Paul, Newark, Atlanta, New Orleans and others.

About 72 per cent of all the deaf pupils are taught the combination method, 26 per cent the oral method and 2 per cent the manual or alphabet method. About 83 per cent of all the deaf children under instruction or about 12,000 are in attendance upon institutions, about 14 per cent of the children or 2,000 are in attendance upon day schools and about 4 per cent or 600 in private schools.

High school courses for deaf students are generally provided. Gallaudet College, an institution for the deaf and named in honor of the American champion of the rights of the deaf, was organized in Washington in 1864 and is supported by the national government. See also DEAF; DEAF; EDUCATION OF THE; DEAF-BLIND.

Blind Children.—The efforts to develop a system of education for the blind have paralleled in many ways the efforts to develop a system of education for the deaf. For centuries the blind were regarded as objects of pity and as unfortunate beings. There is authority for the statement that a hospital for the blind was established by Saint Paul at Cesarea in the 4th century and that a refuge for the blind was established in Syria in the 5th century. There is no record of consideration of any importance having been given to this type of institution until the middle of the 13th century. It is recorded that King Louis IX of France established an institution for the blind about 1200. There are numerous records of individual efforts to teach the blind to read in the early centuries. These records show activities in Italy, Austria, Switzerland, France, England and Germany. It was not, however, until the close of the 18th century that success was attained in efforts to establish schools to be devoted to the teaching and training of the blind.

The one pioneer in this great work, to whom the blind are indebted most for the laying of a foundation for a system of education which has resulted in training thousands of blind people to become self-supporting and to get pleasure out of life, is Valentin Hauy, a Frenchman, who was born in Picardy in 1745. M. Hauy became interested in a blind boy by the name of François Lesueur. He had been much interested in the blind because of various experiences which had impressed him. He had even made an investigation as to the methods employed by other persons who had attempted
to teach the blind. M. Haüy is the inventor of the first system of embossed printing for the blind. It was through an experience with the boy, Lesueur, who was employed in his office, that led to the invention of this system. When engaged in sorting papers on M. Haüy's desk, the boy obtained a card which had been deeply indented by type. The boy was able to trace out several of the letters on this card with his finger and was, of course, greatly delighted to show his master what he had discovered. M. Haüy then made several experiments with the boy and in this way obtained the idea of devising a system of training for the blind. He submitted to the Academy of Science at Paris in 1785 a plan outlining his method of giving instruction to the blind. A committee was appointed by that body to examine into the matter, and, after making due investigation, they gave M. Haüy credit for inventing the relief printing for the blind. In submitting its report, the committee stated: "We propose to the academy to give its approbation to the system that M. Haüy has presented to it and to encourage him to make it public and to assure him that it will willingly receive any account that he may give of its effects so as to arrive at the degree of perfection of which he is susceptible." He undoubtedly established the first school in the world for the education of the blind. This school was known as L'Institution Nationale des Jeunes Aveugles and was established in France in 1784. In 1791 this institution, due to the Napoleonic wars, was discontinued and was not again opened until 1815. Doctor Guillelme was then made the head of this institution. Industrial education was the basis of instruction given in this early school and it was continued under a larger and more practical plan by Dr. Guillelme. He obtained much new equipment for the institution. The principal handicrafts which were taught in this school were spinning, weaving, sewing, knitting, chair caning, rope making, shoe making, harness making, etc. When the institution was closed under Napoleon's rule M. Haüy accepted an invitation from Tsar Alexander I to go to Saint Petersburg for the purpose of organizing an institution for the blind in that city. On his journey through Germany and Belgium he met distinguished teachers and others through whom he became much interested in mathematics. He invented the abacus. He used this in determining mathematical problems. He later became a professor of mathematics at Cambridge. Other distinguished blind persons who were very influential in developing interest in the education of the blind were Milton, the Scottish preacher Blacklock, and the engineer John Metcalf.

Schools were well organized throughout Europe before America gave this question much consideration. There were three schools in this country where the pioneer work in the education of the blind took place. The first school in America opened for the education of blind children was the New York Institution for the Blind. This institution was chartered by the State legislature in 1831 and has been in continuous operation since that date. A group of citizens in New York recognized the need of providing educational facilities for blind children. The founders of the school desired to provide facilities for the children whose parents were unable to pay for their education and at the same time to receive students whose parents were able to pay for their instruction. The school was started as a charitable institution. Its doors were open to all children, with only three blind children. Soon after two other children were admitted... The prime
movers in the foundation of this school were
Dr. Samuel Akerly and Samuel Wood, a well-
known philanthropist. Dr. John D. Ross had
discovered several blind children in the almsh-
house and had the genius to organize a school when he learned of the
work which the other two men had already
done in this direction. He co-operated with
them and was chosen as the head of this primiti-
ve school for the blind in America.

Dr. John D. Fisher of Boston was pursuing
medical studies in Paris and he frequently vis-
ited L'Institution Nationale which had been or-
ganized by M. Haüy. He became interested in
the subject and was desirous of establishing a
similar school for the benefit of blind children
in America. He returned to Boston in 1826 and
began to urge the plan upon his friends. A
meeting of those interested in the subject was
held in 1829. A committee was appointed by
the meeting and Thomas Dartmouth, Samuel G.
Bowles, and others went to Paris to get a char-
acter for an institution to be called the New England Asylum for the
Blind. This charter was granted 2 March 1829.
It appears, however, that no action was taken
toward the organization of the school until 1832.
Samuel G. Bowles was elected the first super-
intendent. He was sent abroad to familiarize
himself with methods of instruction. He
returned in 1832 and opened a school at South
Boston with a class of six children. The school
in New York had been opened a few months
before the one in Boston was opened by
Dr. Howe. In 1833 the Pennsylvania Institu-
tion for the Instruction of the Blind was estab-
lished in Philadelphia. These institutions were
organized by contributions from private sources
but have for years received appropriations from the
State.

In 1830 the United States government took
its first census of the blind. This census showed that there were 5,444 blind persons in the
country. The superintendent of the blind
schools at New York, Boston and Philadelphia
took groups of their pupils to different parts
of the country to demonstrate to the people the
feasibility of educating the blind. These tours
created a profound impression upon the people
all over the country and developed a sentiment
which resulted in the establishment of other
institutions. In 1837 an institution for the blind was established in the State of Ohio. This
was the first school organized purely as a State
institutions. Other States followed in the estab-
lishment of such institutions until at the present
time there are about 50 State institutions
attended by more than 5,000 blind children. The
last Federal census shows that there are about
60,000 blind children in the United States and
that 10 per cent of these are of school age. In
nine of the States provision is made for the edu-
cation of the blind children who are under school
age. The best modern thought is that children
who are born blind should be placed under in-
struction at the earliest moment possible and
that all children who become blind before they
reach school age should also be placed under in-
struction as early as possible. The institutions
for the blind are generally under the control of
the State and the boards of trustees select the superintendent or principal of the in-
stitution. The institutions generally are subject to
inspection by the State educational authorities.

Great interest has been manifested all over
the country in the education of the blind within
the last 20 years. The modern trend of thought
is to provide for the education of blind children
in the public school system. The first city in
this country was taking measures to organize a
school when he learned of the
work which the other two men had already
done in this direction. He co-operated with
them and was chosen as the head of this primiti-
ve school for the blind in America.

Dr. John D. Fisher of Boston was pursuing

done in this direction. He co-operated with
them and was chosen as the head of this primiti-
ve school for the blind in America.
and Dr. Wait will always be associated in America with the development of methods for teaching blind children. They did a great work in this field.

The line alphabets which were used for many years in giving instruction to the blind have been abandoned. The point systems have come into general use. These are known as "braille." The base is a cell of six points. The characters used are made by various combinations of these six points; 62 characters are used. These characters each represent a letter, a mark of punctuation or a contraction standing for several letters. The system is named after its author, Louis Braille, who devised it in 1829. There has been a long controversy between teachers of the blind as to whether the braille system or certain modifications devised by American teachers is the better. There appears to be no great fundamental difference in these systems. The American modification of the system differs from the other simply in the assignment of the letters to the various combinations. The American idea was that such letters as E, O, R, S, T, which occur most frequently in words, should be made easier to read. One of the best noted teachers of the blind states that the New York point system is as legible as braille by its characters being two points high and three wide instead of three points high and two wide. This author states that while the New York point system has many advantages, it has many disadvantages.

Most attention in the education of the blind has been given to the education of blind children. Although the great majority of the blind become so after the age of five, there has been an apparent neglect in the education of the adult blind. Various organizations have been formed in recent years which are giving the needs of the adult blind special attention. State commissions have been organized by legislative authority in certain States supported by State funds, to provide for the education of the adult blind. In some instances, as in New York, the commission makes provision for home teachers. Under this method a teacher goes from home to home and gives instruction to the blind adult in his home.

A potent factor in the education of the blind adult is the work done through libraries. In March 1890 a library section for the blind was incorporated in the New York State Library. In the same year the Detroit Public Library selected 110 volumes and made these available for the blind of the city. The Library of Congress at Washington established a reading-room for the blind in 1879. There are now (1914) about 70 libraries maintaining divisions which contain embossed type books which are circulated among the blind people.

Crippled Children.—It was not regarded necessary to provide separate schools for crippled children until many years after schools had been founded for the other types of physically handicapped children. In recent years the number of crippled children has increased, owing to the prevalence of tuberculosis and infantile paralysis and to other causes.

The first institution established at Munich the first institution in the world for the education of crippled children. Up until 1890 only five institutions had been established in the United States. Three of these were in New York city and two in Philadelphia. Since 1890, 31 institutions for the education of crippled children have been established in this country.

Children's hospitals and orthopedic institutions have been organized for the purpose of providing for the treatment of crippled children. In many of these institutions, provision has been made for their instruction during the period of time they have been under treatment therein. In Massachusetts, New York, Nebraska and Minnesota State hospitals have been established, and graded schools maintained by the State in connection with such institutions. However the means afforded for the education of this type of unfortunate children are not adequate to provide for the treatment and the education of the crippled children of the country. There is a large class of these children whose parents cannot afford to meet the expense of their maintenance in private institutions, and whose education is being neglected. Many crippled children who are physically able have always attended the public schools. A crippled child, possessing his mental faculties and being physically able to attend school, will make better progress by associating with normal children than by attending a special institution. The large cities of the country, special schools are maintained by the municipality and in some cases in co-operation with contributed funds, for the education of this type of children. In other cities, the public school authorities, set apart rooms in the public school buildings for the purpose of providing educational facilities for these crippled children. Each city and school district in the State of New York in which there are 10 or more crippled children is obligated, under the law of 1917, to establish a special class and to provide instruction adapted to the mental attainments of the children and to their physical condition. In a city or district in which there are less than 10 of these children, the school authorities are authorized to contract with the board of education of another city or district, or with an established institution in the State, for the education of such children.

The cities of Chicago, Cleveland, Boston and New York maintain day school buildings which have been designed, constructed and equipped with special reference to the needs and comforts of crippled children. These buildings are not all of the same type, but in them will be found such conveniences as inclines and elevators in stead of stairways, movable chairs instead of desks, rubber or cork floors and handrails at low levels. Special chairs and seats accommodated to the physical defects of the children, couches, air cushions, folding chairs, blankets, sweaters, etc., are also provided. The Crippled Children's East Side Free School of New York city accommodates 200 and is the largest institution of the kind in the country.

Provision must be made for taking these children from their homes to the schools and for returning them to their homes. They cannot, of course, return home at the noon hour and it is necessary, therefore, to provide luncheon for them. The transportation and the luncheon are items of additional expense. In some of these schools, in most cities the children are taken to and from the schools which he attend in large omnibuses drawn by horses. The tendency now is to change to the auto-bus. The seats in the buses used for this purpose are
constructed to meet the physical defects of the children. Attendants accompany all buses to see that the children are properly taken in and out of the buses, the school buildings and their homes. Attention is given to the maintenance of the buildings.

In the larger cities, where rooms in the public school buildings are set apart for these children, an orthopedic surgeon or a nurse is provided to give such special treatment to the children as may be needed. The city of New York maintains 60 schools or classes for the crippled children of that municipality.

Those children who are suffering from bone tuberculosis should be segregated from the other children and provision should be made for their maintenance, if possible, in a separate building. Open-air schools should be established for all children of this type.

All these different agencies for the education of the crippled children still fail to provide facilities for some of these unfortunate children. There are many children who are badly crippled that they are prevented from attending institutions or schools even with all the comforts and conveniences which are provided for them. The only way by which such children may be instructed is through a teacher who visits them at home. To meet the needs of these children it is proposed in New York city, through funds provided by the Association of Public School Teachers, to employ visiting teachers who will go among the homes of the children and give them instruction.

Through proper funds provision is made by some of the organized institutions for the care and education of crippled children whereby such children are given an opportunity to spend a few weeks in the country. Summer homes have been established for this purpose by some of these institutions in New York, Baltimore and other cities.

The work in these special classes for crippled children is based upon that of the regular elementary school work of the city in which the schools are organized. This work includes a large amount of handwork such as basketry, weaving, sewing, etc. Only in exceptional cases is there an effort made to carry the pupils beyond the elementary grades.

This movement of recent years to provide special classes in the public schools and home teachers for those unable to go to school, thus making an elementary education accessible for all the physically handicapped children of the country and at the same time affording them the associations and influences of home life, is a manifestation of the broad, humane, democratic spirit of the philosophy upon which American public education is founded.

THOMAS E. FINEGAN,
Deputy Commissioner of Education and Assistant Commissioner for Elementary Education, State Department of Education, Albany, N.Y.

EDUCATION OF TEACHERS. See Teachers, Professional Training of.

EDUCATION IN THE UNITED STATES. Every nation has its social ideals and by these its civilization may be measured. Education is the instrument by means of which a nation hopes to realize its ideals. Because different nations have different ideals, there exist different systems of education. In Europe the ideals are the resultants of historic forces. Society has developed in strata and the classes in control of the destinies of the various nations believe in the maintenance of their position in society. As an individual is born into a class of society his education is organized chiefly to fit him for the various vocations of that class. This conception of education has been successfully maintained not only because of the organization of society into castes, but because of the relative stability of the population. Most people live in the community in which their parents lived and it is natural for their children to take up the vocation of their parents. These two factors explain to a great extent the remarkable success of the industrial education movement in Germany. Neither difference in political ideals nor in the age of a national system of education seems to affect this attitude toward education. Prussia with its centuries-old system of education, is but little more representative of this type of education than is England which is organized politically as a democracy and which developed a national system of education but a generation ago.

THEORY OF EDUCATION in the United States. The theory upon which education is organized in the United States is the very opposite of that which holds in Europe. There are as yet no castes here and few parents are content to have their children continue in the station in life in which they were born. For the first time in history there is an attempt made to realize the educational ideal portrayed by Plato in his 'Republic.' viz.: That every individual should be doing that in life for which he is best fitted; that education should be so organized as to discover for what the individual is best fitted, and then to provide him with the proper and necessary training. This is done, it must be admitted, crudely and haltingly, but the American democracy is practically the only great state in which there exists an educational ladder reaching from the kindergarten to the university, in which all parts, elementary, secondary and higher, are so closely connected that any individual may freely pass from one to the other. In the European systems of education only elementary education is free and it does not articulate with secondary education. The elementary school carries the child to 12 or 14, giving him a rounded elementary education and the secondary school begins at nine and commences to teach subjects not considered in the elementary school, such as mathematics and foreign languages. Even should a child of the masses when he completes the elementary school, then have the ambition and money to continue his education, he would be unprepared to enter the secondary school. There is nothing for him to do but to enter one of the vocational schools for training in some trade or industry. And that is what is expected of him. The American democracy is by no means perfect in all its aspects; but as far as education can accomplish it, it aims to give every individual the opportunity to make the most of his native abilities and to assume the place in society which his abilities justify. This was not always so, and to understand the American system of education as it exists to-day it is necessary to make a brief survey of its development since colonial times.
THE COLONIAL PERIOD.

History of Education in the United States. — The Reformation principle that the individual should be guided in life by the Bible had as an educational corollary that he should at least be taught to read it. Where the Reformation was chiefly a religious movement and was carried to logical conclusions, the effect upon the development of universal education was quite direct, but where the Reformation was political and ecclesiastical rather than religious, and halting rather than thorough, the attitude toward education was one of comparative indifference and neglect. The former condition was true wherever Calvinism prevailed, as in the Netherlands, Scotland and among the Puritans in England. The latter condition was true in England generally, where the Anglican Church was in the nature of a compromise. The United States was settled in the 17th century when religious antagonisms were most bitter and, moreover, it was largely settled by groups of people who fled from Europe because of religious persecution and because of their desire to worship in their own peculiar way. The kind of educational system that would be established in any part of the new land would be determined chiefly by the kind of religious opinions held by the people settling there. We find three fairly distinct types of education developing in the colonies:

1. The Selective Type prevailed in the southern colonies where distinctions of classes developed and the Anglican Church was established. The gentry employed tutors for their own children or sent them to England to be educated. They were not only not interested in the education of the masses who were in many instances indentured servants and convicts, but believed solely in the system of apprenticeship as a preparation for the trades which were to be the life-work of these lower classes. Hence, down to the Revolution, the character that was early impressed upon education in the southern colonies remained, i.e. fair provision for secondary education through the voluntary and parochial schools, and little provision for elementary instruction beyond the system of apprenticeship.

2. The Parochial School Type prevailed in the middle colonies. These colonies were settled chiefly by various Calvinistic sects like the Dutch Reformed in New York and the Presbyterians in New Jersey, or by other sets of the advanced Protestant type, like the Quakers and Mennonites of Pennsylvania. They all believed in the need of everyone to read the Bible, and all, therefore, favored elementary education. But as each sect denied the efficiency of any other's way to salvation, this elementary education took the form of parish schools attached to the church. In all the middle colonies in addition to the parochial schools for elementary education there existed grammar schools for secondary education.

3. The Town School Type prevailed in New England. The people who settled there were more homogeneous than in any other part of the country. There was little distinction of classes among the people of the southern colonies and there was no distinction of sects as in the middle colonies. They were mostly of the middle class socially, were generally well educated and had university graduates for leaders; were thorough believers in democratic government and were strong upholders of the Calvinistic-Genevan principle of the church-state form of government. Holding firmly to the necessity of everyone being able to read the Bible, the General Court, i.e., the legislature of Massachusetts, passed the famous law of 1647 by which "the Puritan government of Massachusetts rendered probably its greatest service to the future." The law provided that every town that contained 50 families should maintain an elementary school and a town that had 100 families should maintain in addition a grammar school to fit the youth for the university. The religious motive that prompted the law is stated in the preamble, namely, to prevent "that old deluder, Satan, keeping man from a knowledge of the Scriptures." Unfortunately, subsequent developments resulted in the decline of education in New England because of the decay of the town school. The chief cause was the spread of population into unsettled regions and the attainment of local government by districts within the town. The houses of the early settlers were clustered around the meeting house of the town, partly for protection against Indians and partly because of religious devotion. As religious fervor decreased in the 18th century and fear of the Indians passed away with their diminution in numbers, settlers moved into parts of the towns that were inaccessible to the town school or they moved into entirely new regions that had no town school. Hence arose the district school, which could afford only a poor teacher who "kept" a school a few months in the year. In all the colonies the colleges that had been founded, such as Harvard and Yale in New England, Columbia, Princeton and Pennsylvania in the middle colonies and the College of William and Mary in Virginia, supplied the higher education needed by the members of the learned professions.

THE PERIOD OF TRANSITION.

The Revolution had both a bad and a good effect on education. It destroyed not only the central government, but many of the state governments. The British fleet had destroyed colonial commerce; its blockade had brought industry to a standstill and thousands were reduced to poverty. In hard times education is generally one of the human activities that is first to suffer. Moreover, other obstacles to the development of a national system of free schools existed. (1) One was the practice of granting public moneys to private schools. This practice was general throughout the colonies but can be best illustrated in connection with the academy movement. The decadence of the town school and of the Latin grammar school in New England due to the growth of the district school was much hastened by the poverty resulting from the Revolution. But the willing-to-do classes would not let their children go without secondary instruction and the policy was inaugurated of establishing private secondary schools called academies. Though these academies were private corporations through the influence of the supporters they were usually able to secure subsidies of public moneys either from the State government or the towns. They performed a splendid service, for they
were generally well organized and administered, were responsive to the needs of their constituents and introduced modern subjects like English literature and science. But they were pay schools and hence not open to the children of the masses; they withdrew the attention of the influential people from public education, just when it was most needed; and they created vested interests which were often opposed to public interests. When one considers that by 1840 Massachusetts alone had 50 such private academies supporting 2,600 scholars, it becomes evident that if the movement had spread throughout the country, one can realize the extent to which they were a hindrance to the growth of public secondary schools. (2) A second obstacle to the development of a system of free public schools was the existence of sectarian religious jealousy. Nearly all the sects opposed a movement which would prevent the teaching of their own peculiar form of religion and which would also render valueless the school property which they had accumulated. (3) A third obstacle was the prevailing notion of the idea of pauper education. The idea that free schools were only for the poor prevailed generally throughout the country south of New England. (4) Another obstacle was the claim that the public school was based upon an undemocratic principle, that it was unjust to compel people without children to pay for a service from which they received no benefit, or to compel parents who sent their children to private schools to pay for the education of other people's children. This view explains the resistance of New England during the early decades of the 19th century by which local areas were permitted to decide how much support they would give to public schools. For example, in 1831 an act was passed by the legislature of Indiana which permitted the voters of school districts into which the counties were divided to decide the amount of local tax to be levied for the support of public schools. But the act contained the proviso "no person should be liable for taxation who does not or does not wish to participate in the benefits of the school." But if there existed numerous obstacles to the development of a system of free public education, there developed counter movements stimulating its development. (1) The principles of liberty and equality for which the Revolution was fought combined with the growth of a new political and social order to develop a belief in the need of universal education to realize those principles and that order. With the opening up of the West there developed a condition of society in which social influence, religious affiliation and wealth counted for much less than in the East. (2) Moreover, the Federal government, even before the adoption of the Constitution, adopted a policy the influence of which in the development of American education cannot be overestimated. The Northern territorial and finally national views of the Federal government by the various States claiming parts of it and from which the States of Ohio, Indiana, Illinois, Michigan and Wisconsin were carved, was organized under the famous Ordinance of 1787. In accordance with the provisions of the Ordinance, the entire territory was divided into townships six miles square, and of the 36 sections into which each town was subdivided, section 16 was reserved for the support of public schools. Moreover, two whole townships were reserved for the support of a State university. This admirable policy was continued in all the territory secured by the United States through purchase or conquest. (3) The introduction from England of Lancaster's system of monitorial teaching whereby one teacher with the assistance of older pupils (monitors) could instruct hundreds of pupils with funds and the introduction of the idea of public school systems, because its cheapness was influential in securing appropriations from legislatures for the establishment of public schools. (4) The infant school movement and the Sunday school movement were also steps in the direction of accustoming people to think of education for all. Though, as the result of the interplay of these opposing influences, education was everywhere becoming less aristocratic and sectarian and more democratic and secular, the advent of a public school system came only as the result of a great awakening. THE PUBLIC SCHOOL REVIVAL. Massachusetts established its State Board of Education in 1837 and Horace Mann, with whose name the public school revival is inseparably associated, was made its first secretary. As a result of his 12 years of service in that position and by means of his annual reports, his Common School Journal and his speaking tours throughout the State, he was able to secure the reforms in the public school system of Massachusetts which were little less than amazing in their extent and value. These included the establishment of normal schools for the proper training of teachers, the extension of the school year by a month, the gradual substitution of the public high school for the private academy, the doubling of appropriations for public education, the increase in pay for the teachers by more than 50 per cent and the adoption of new agencies for improving the efficiency of instruction such as teachers' institutes and school libraries. These admirable reforms were not secured without bitter opposition from conservative schoolmasters and sectarian religious interests. But the movement spread to other States and under the leadership of Henry Barnard of Connecticut, David Page of New York, and a number of enthusiastic educators in the Middle West, by the close of Reconstruction it had resulted in all the States of the North organizing a public educational system providing free elementary and secondary education and in many States higher education also. In the South, the principle upon which the movement was based was adopted but its realization was delayed by the deplorable conditions resulting from the Civil War.

A National System of Education.—The period since Reconstruction has been one of educational rationalism devoted to the practical eradication of sectarian jealousy and the conception of free public education as fit only for those who could not pay tuition fees never appeared and the first constitution of each of those States provided for a complete system of free education extending from the common school to the university. Everywhere the principle
of unification and centralization won. This victory for centralized State control was due to a great many causes, but chief among them were the following: (1) The approximation in the federal millions of acres of land directly to the State for the support of elementary schools and of higher institutions for agricultural and technical education. (2) The distribution of State moneys by the State educational department to the local geographical areas, provided the latter would meet requirements laid down by the former. (3) The unifying and standardizing influence of the State university into whose hands the control of secondary education has in some States been placed. (4) The growing faith of the American people in public education to solve the political, social and economic problems which confront them and hence the necessity that it should be centralized in order to be efficient.

In the United States, each State has exclusive control of its educational affairs and the question naturally arises whether there exists in the United States a national system of education. The Federal Constitution does not by any means speak of national education, that being one of the governmental activities reserved to the States. But the policy of the central government over since its organization has been to assist the extension and development of education in every way possible. It has done this in two chief ways. (1) By means of gifts of land to the several States for educational purposes. This has amounted to 81,064,000 acres with an original value of $103,000,000 for elementary schools alone and 14,775,475 acres for higher education. In addition to this munificent gift the National government by act of Congress in 1887 provided for a perpetual appropriation of $15,000 a year for each agricultural experiment station connected with a State agricultural college and by the Act of 1890 appropriated $25,000 a year to each of the colleges themselves. (2) By means of the Bureau of Education established in 1867 by act of Congress largely through the efforts of Henry Barnard for the purpose of collecting statistics and for the advancement and progress of education in the several States and Territories and of diffusing such information respecting the organization and management of school systems and methods of teaching as shall aid the people of the United States in the establishment and maintenance of efficient school systems and otherwise promote the cause of education throughout the country. Barnard became the first United States Commissioner of Education and organized the Bureau under the laws then in force which has ever since been administered. The Bureau has no control over the educational policies of the States and must work entirely through the force of suggestion and exposition. But by means of its collection of statistics, its comparison of systems, its description and evaluation of experiments in education, it has wielded an enormous influence in securing improvements simultaneously throughout the country and unifying the State systems of education. Other northern States would here to mention that the great confidence everywhere displayed in the work and recommendations of the Bureau is due to a great extent to the splendid personal and professional influence of Dr. William T. Harris who was Commissioner from 1889 to 1906.

Another unifying influence upon education in the United States is the Educational Association (q.v.). The 25,000 members are enrolled in every State of the Union and represent all parts of the educational system, elementary, secondary, higher and professional. The meetings of the association which are held alternately in the East and the West provide an opportunity for exchange of opinion upon the results of educational experiments, for the putting forth of new ideas upon organization, administration curricula and discipline and for decision as to the policies and principles which shall guide the teachers of the country in their efforts to promote the public welfare. One of the most efficient contributions of the association to educational progress consists in the reports made on particular problems by special committees which have sat between annual meetings. The report of the Committee of Fifteen has become the basis of the course of study for elementary schools in every State of the Union and the report of the Committee of Fourteen for high schools. It can be readily understood why as the result of the influence of a number of agencies, chief among which are the National Educational Association and the Bureau of Education, there exists in the United States a truly national system of education. In their general features and in many of their details the State systems of education show a remarkable resemblance. A comparison of the curriculum of a city school system in the East with one in the West or North or South would show almost an identity. Where differences exist it is usually due to the willingness of progressive communities to undertake experiments which, if they turn out successful, will be rapidly imitated by other communities.

SUPPORT OF SCHOOLS.

The munificence of the support given to public education in the United States is as great a source of amazement to foreigners as it is of pride to ourselves. It has been described the generosity of the Federal government to this activity, but the large sums given by it are small in comparison to the amounts raised for it by local and State taxation. The major part of the money devoted to education is raised by local taxation and averages from 20 to 25 per cent of the total amount. What this means for the cause of education is made clear when one learns that the appropriation for school purposes by the municipal government of New York City in 1916 was $42,000,000. The State government adds to the local appropriations grants for a variety of purposes provided the localities maintain standards demanded by the State Department of Education. In the case of New York State this amounted in 1912 to over $5,000,000 distributed in such a way that poor or small districts receive an advantage over large and wealthy ones, and New York State is no more generous in this respect proportionally than other northern States. With the total amount spent for public education in any year it is difficult to say accurately, because uniform standards of estimating costs have not been adopted by all States or localities, e.g., some.
local areas include interest on bonds and others do not. But according to the reports of the United States Bureau of Education (from which all statistics appearing in this article have been taken) the total estimated cost of education in the United States for 1914 was $794,-
459,968. What is undoubtedly true is that there has been a remarkable increase in the cost of education during the past two decades, amounting according to conservative estimates to $100 per pupil. This has been due not only to the high cost of buildings and equipment and to increase in salaries, but to improvements in school organization and equipment to which we must now turn our attention.

EDUCATIONAL ORGANIZATION.

There were, in 1914, 19,561,292 children in the elementary schools, of which 17,934,982 were in public schools. The school curriculum under which these children are taught is practically the same everywhere in the United States. The elementary school maintains a course of eight years preceded in many cities and towns by a year in the kindergarten. The child usually enters the elementary school at six and graduates at 14, if he passes through according to rule. But careful studies of elementary education made by experts during the past decade have demonstrated the existence of excessive retardation and elimination of pupils. This discovery has resulted in two movements which are gaining in strength daily. One is a change in the subject matter of the elementary school curriculum with the object of emphasizing the useful and eliminating the purely academic. The amount of time allotted to the so-called disciplinary subjects like formal grammar and arithmetic has been reduced in favor of such subjects as manual training and domestic science. The other movement which is a corollary to the first, is to complete the general elementary course in six years and devote the last two years to vocational courses, commercial, industrial and academic, leading respectively to business, the trades and the professions. This in turn has caused, as we shall now see, changes in the organization of the secondary education.

About 7 per cent of the children who enter the elementary school pass on to the high school. In 1914 there were 1,373,661 pupils in the secondary schools, of which 1,218,004 were in public high schools. Until about the beginning of the 20th century the curriculum of the high school was everywhere the same, being organized for the few who intended to go to college. In other words, the high school was a preparatory school whose content of study was dictated by the college, although less than 10 per cent of those who entered the high school went to college. As a result of the strong movement in favor of industrial and vocational education that arose about 15 years ago, out of the larger cities now maintain, in addition to the regular academic high school which prepares for college entrance, a commercial high school and a manual training high school designed respectively for business and technical pursuits. Some of the larger high schools commercial and technical courses in addition to the academic course and most States are now supporting agricultural high schools. Until about six years ago, the standard high school course of all kinds was four years in length and was built upon the eight-year elementary school course, but as a result of the movement to differentiate vocations the standard elementary school, viz.: to finish the general elementary course in six years, another movement has arisen in the past few years which bids fair to have an important influence. This is the junior high school movement sometimes referred to as the six-year movement. The principle at the basis of this movement is excellent pedagogically as well as administratively. It is felt that the study of certain subjects should be begun earlier than in the present academic high school, e.g., algebra and geometry, and particularly languages in order to take advantage of the greater plasticity of the vocal organs. Our practice would then conform to that of the European countries. It is also maintained that were the courses leading to vocations differentiated at 12 years of age and their elements well organized for the three-year period, many boys and girls who find the ordinary academic course unattractive would remain to the close of the period and perhaps be induced to continue their studies in the three years of the senior high school. In a large city the junior high school would also have the administrative advantage of relieving the congestion in many elementary schools by removing the boys and girls who must stay under compulsory education laws until they are 14 into a few buildings scattered about the city. Although the junior high school is a recent experiment in secondary education and chiefly popular in the West, it is in accord with present tendencies and will probably be generally adopted in its present form or in some modified form.

Higher education in the United States is closely articulated with secondary. In 1914 there were 216,493 students in the colleges and universities of the United States, of which but 72,920 were in public institutions. Of the 146,963 students in professional schools, but 2,269 were in public institutions. The graduate of the ordinary high school who wishes to continue his education may go to college where he spends another four years in general education before taking up his professional studies or he may go directly to the professional school and finish his scholastic career in three or four years and enter upon his life work at 21 or 22. A few of the large universities of the East demand the bachelor's degree for admission to their professional schools, which means that the student can hardly get on upon his career until 25 or 26. In conformity with the recent demand that young men and women be prepared to earn a livelihood at an earlier age, some of these universities permit the first year of the professional course to be elected as the senior year of the undergraduate course, and Columbia University now grants both the bachelor and the professional degree for a six-year course. This has given additional stimulus to the junior college movement started some years ago by a number of Western universities particularly Chicago and California. These schools plan the first two years of the college course is formed into a junior college with a prescribed course of study looking toward pro-
fessional studies. The junior college movement has also afforded an opportunity to some small and poorly endowed colleges to restrict their efforts to the work of the freshman and sophomore years and affiliate with a large institution having a college, e.g., a considerable number of colleges in the Mississippi valley have entered into junior college relations with the University of Chicago.

The development of the junior college is only one evidence of the spirit of social service that stimulates the higher institutions of education in the United States to-day. The college is no longer content to be a place devoted solely to giving students culture and mental discipline, and the university a place to train men for the learned professions. Curricula and organization are constantly undergoing revision in order better to meet the needs of society and to solve its problems. The development of graduate schools, research departments, schools of commerce and finance, summer schools, extension work, correspondence schools, and seasonal courses, show the extent to which the college and university are being socialized. Although this is particularly true of the State universities which exist west of the Alleghenies, it is becoming increasingly true of the urban institutions that have grown up in the East whether under private or public support.

One of the most important features of public education in the United States is the training of teachers. This is done chiefly by the State normal schools, city training schools and departments of education of colleges and universities. In 1914 there were 95,286 students in the normal and training schools, of which 89,537 were in public institutions. In every State, public school teachers must be certified under State laws, and, although in some of them positions in the rural elementary schools may be secured with a minimum of preparation, the tendency is everywhere to demand professional training. This training is becoming uniformly a two years' pedagogical course based upon high school graduation. Until a decade ago the only requirement to teach in the public high schools was an ability to pass an examination in the subject which the applicant wished to teach. But the National Education Association has gone on record in favor of requiring the bachelor's degree and most of the larger cities now require that and some professional training in addition. In 1914 in all departments of education there were 706,152 teachers, of which number 537,123 were women and 169,029 were men.

Parochial and Private Schools.—In the United States there is no monopoly of education by the State. Churches, corporations and individuals are permitted to maintain schools, the State merely demanding that these schools maintain a certain standard of work. Several of the religious denominations have thoroughly organized systems of schools, especially the Roman Catholics and Lutherans, both of which maintain that religious and secular education must be given at the same time and by the same agency. In support of this principle the Roman Catholics spent last year approximately $35,000,000 of their income in 67 colleges and 983 schools, and the Lutherans a proportionately large sum for the instruction of one quarter million children. The Roman Catholic schools are most numerous and strong in the New England and the Middle Atlantic States, the Lutherans in the Middle West. But in the beginning of the 20th century, the appropriation of public funds for the support of these sectarian school systems was in many States a burning question, but in almost every case where it came to an issue it was defeated, and now more than half the States have constitutional provisions prohibiting the appropriation of public funds for any sectarian purposes.

There is no general system of private schools in the United States such as exists in England, and the number of private schools engaged in elementary education is comparatively small. But about one-fifth of all schools engaged in secondary education are under private endowment. Though a few of these are vocational in character, the great majority are preparatory schools fitting young men for college. In higher education the proportion of public and private institutions is reversed, less than 20 per cent being upon public endowment, though among these are the great State universities like Wisconsin and Michigan. Of the 800 institutions in the United States which bear the name "college" but 261 have an endowment of more than $100,000 and a student body of more than 100. About half of the others are glorified high schools which may in time become junior colleges. Too much credit cannot be given to the remaining small colleges scattered throughout the country which give a higher education to the young men and women of the immediate locality who would have been unable to go to a university at a distance. For this and other reasons there will probably always remain an important place for the small college in American education despite the immense growth of the State universities and of the endowed universities.

One of the most significant features of American education as compared with foreign systems is the immense sums of money given for educational purposes by private benefactors. Because of the splendid public support of elementary education, practically all the money goes to that form and only a comparatively small per cent to secondary education. But in 1915 almost 25 per cent of the entire income of the 550 institutions deserving the name of college or university came from private benefaction. What is still more remarkable is that for the past 20 years the average annual gifts to education amounted to 50 per cent of the gifts to all forms of philanthropy in the United States. These gifts vary in size from a few hundred dollars to the many millions necessary to establish a fully equipped university like Chicago, founded by John D. Rockefeller, and Leland Stanford, founded by Mr. and Mrs. Leland Stanford. The amount contributed during 1914 was $31,357,998, the largest in our history. Not all this money has been given to teaching institutions. In some instances new education agencies have been established, like the General Education Board organized in 1903 by Mr. Rockefeller with an endowment of $32,000,000 for its work in helping education in the South and assisting higher education generally; the Carnegie Institute (1902) with an endowment of $12,000,000 to encourage research
and discovery; the Carnegie Foundation for the Advancement of Teaching (1905) with an endowment of $12,000,000 to pay retiring pensions to college professors; the Russell Sage Foundation (1905) with an endowment of $10,000,000, a large portion of which is devoted to educational purposes. These and similar organizations have had an incalculable influence in fostering education in the United States.

Iliteracy.—It may seem very strange after reading this story of public and private munificence to education to learn that according to the Federal census of 1910, the percentage of illiteracy in the whole United States is 7.7 per cent considerably higher than the percentage of illiteracy in the countries of northern and western Europe with which the United States is usually compared in matters educational. Two things, however, should be remembered in connection with this matter, viz., that whereas the illiteracy among whites is but 3 per cent, among foreign-born whites it was 12.8 per cent and among negroes it was 30.5 per cent. The South is working heroically to reduce illiteracy among negroes, and the North is spending immense sums of money for the same purpose with the newly arrived immigrants. The latter burden can readily be appreciated when one considers that of the 383,172 immigrants who came to the United States in 1912, over 177,000, or 20 per cent, were unable to read or write an English language and very few were well educated. Fortunately the immigrants have so far shown a great desire to have their children go to school and the statistics of 1910 show that the percentage of illiteracy among the children of native-born parents is greater than among the native-born children of foreign-born parents. The fear of an ignorant citizenship which has been one of the great impelling forces to the generous support of education in the United States will continue to be a necessary incentive, now that our borders of immigrants come almost exclusively from the ignorant population of southern and eastern Europe.

The Outlook.—In no country is education so active and vital an element in the life of the people as in the United States. Nowhere else do teachers show so strong a desire for self-improvement, parents so great a determination that their children shall take advantage of the opportunities offered, or citizens so great a willingness to bear the necessary expense. Education is everywhere marked by experiment: to determine the best system of organization, as the Gary System, or the best method of teaching, as the Montessori Method. And these experiments are not without philosophical justification. No other country is so much under attention being given to the reorganization of educational theory as in the United States by such thinkers as John Dewey, G. Stanley Hall, E. L. Thorndike, C. H. Judd and others. Not only has astonishing progress been made in providing proper education for those who differ widely from the normal, such as the blind, the deaf, the dumb, the crippled, and the feebleminded, but the experiments of to-day have as their object the discovery of the best methods and organization to meet the different needs of individual normal children. In other words, real progress is being made toward the realization of the American educational ideal, viz., to organize education that the capacities of every child shall be discovered and the necessary training given to develop those capacities to the utmost, to the end that every individual shall be doing that in life for which his native abilities fit him.

STEPHEN PIERCE DUGGAN,
Professor of Education at the College of the City of New York.

EDUCATION AND THE WAR. The present European War is affecting education to a far greater extent than wars of the past. This is inevitable because never before have the foundations of world civilization been so shaken. Inasmuch as education, its philosophy, institutions, and practices must in the long run express the spirit and forms of the civilization on which it acts, any far-reaching changes in the nature of that civilization will be reflected in education. The immediate effects of the present war on education are similar to those of previous wars, but on a much larger scale, due to the magnitude of the conflict. The essential external elements of education are teachers, pupils, and money needed to carry on the work of educational institutions. War demands the service of teachers and pupils for the army and navy and for the industries upon which these fighting forces depend—agricultural, manufacturing, and extractive. The immediate result is a shortage of teachers, a decrease in the enrollment of pupils in all classes of schools, particularly in secondary and higher institutions; and an actual decline in the number of institutions) for not a few have been obliged to close their doors entirely for the period of the war at least. The increased cost of carrying on education in a régime of rising prices, a common phenomenon in war time—the cost of labor, supplies, salaries, etc.—affects education adversely. Moreover, the shifting of labor to those industries where wages are high draws from educational institutions both teachers and others connected with the schools. The rise in the cost of living also prevents parents from keeping their children in school, so that there is a tendency for fewer pupils to pass out of the elementary to the secondary higher schools. These factors tend to increase the quantity and quality of education and the number of courses and subjects available for study. In the higher institutions less promising material remains from which the leaders of
future must be trained. Thus the war has brought on a national emergency in education which has led to earnest efforts to provide, in part at least, adequate remedies.

Higher institutions of learning, for example, have very generally modified existing and introduced new courses. Even in their modified courses, taught with a view to making them contribute directly to the war, are those in topography, chemistry, physics, medicine, engineering, psychology and French. In these subjects emphasis is laid on the construction and interpretation of military maps, telegraphy and telephony, war surgery and infectious diseases common in war, sanitation and hygiene, bridge and highway engineering and surveying, chemistry of foods, gases used in warfare, dietetics, psychological tests, and military conversational French. New courses, not before customary, include those in military tactics, ordinance, storekeeping, military history and historical courses directly on the war, both from the European and American point of view. A large amount of research work along special lines has been carried on as a result of direct requests of the government.

Remedies suggested by the government to meet the emergency, in many cases already adopted, include appeals to elementary, secondary and higher schools, and educational policies to war needs. That of the Commissioner of Education, 22 May 1917, is notable, "Suggestions for the Conduct of Educational Institutions During the Continuance of the War," urging enforcement of school attendance laws, application of military maps, telegraphy and telephony, and continuation classes and evening schools for minors and adults, requesting normal schools to double their efforts to train teachers, and advising higher institutions to reduce expenses, keep open all the year, to lay special emphasis in summer schools on not being adapted to war needs to stimulate research, and to prevent the scattering of the faculty or student body so far as possible.

The President, on 20 July 1917, urged colleges and technical schools to maintain their courses on the usual basis in order that every opportunity might be given for the training of the leaders on whom must fall the serious work of reconstruction. Likewise we may note the appeal of March 1918, signed by the Secretary of War, Secretary of the Navy and others, urging that boys and girls be kept in elementary and secondary schools until 18 years of age, because the future requires that these pupils have more and better education to cope with the problems of peace.

A second remedy is the plan to use school plants to their maximum capacity, that is, all the year around, with the year divided into four quarters of 12 weeks each. Moreover greater use of school plants is urged for late afternoon and evening classes, both for minors and in the use of school rooms for lectures connected with the problems of the war, such as conservation, production, savings and thrift. Numerous school plants have been used for the training of those entering the war, for both military and industrial services and for the production of war materials—for use of the Red Cross, for example. There is also greater use of the school plant as community centres and as meeting places for the various organized bodies directly or indirectly connected with the school, whose work contributes to the war. This intensive extension of the functions of the school is seen in the formation of such organizations as the Junior Red Cross, Boy Scouts, War Savings, Liberty Loan, and War Garden clubs.

A third remedy is to change the point of view in teaching so far as it centres on local, State, or sectional interests rather than on national interests. President Wilson, in his letter of 23 Aug. 1917, asked the school officers and teachers of the country to stress the problems of community and national life because they are the most pressing problems now before us and will be still more so in the future. This tendency to emphasize national ideals is one of the most important of the changes brought on by the war. The fact that we do not have a national system of education has tended to divert attention from national interests and ideals. One of the immediate effects of the war, however, is to place emphasis on the duties and obligations of citizenship rather than the privileges and rights of the individual. Considering the origin of the nation, the importance attached to individual rights in the period of the American Revolution, the slow growth of the national ideal, and the fact that education itself is under State control, it was natural that this point of view was neglected. But war is one of the greatest integrating and unifying forces, and tends to counteract racial, religious, party, sectional and class divisions, the disintegrating forces in national life. The whole strength of the people may be used to overthrow the common foe. It places first the interests of the largest group, the nation, instead of individual interests, or those of a group seeking some selfish or local end.

Another principle affecting education is the new conception of the relation of the individual to the nation because of the immediate demands of the war. As public opinion changes, as the lessons forced on the people by the war are learned, education necessarily reflects these changes. The war has emphasized not only the matter of duties and obligations, but the principle of obedience and the performance of definite and often disagreeable tasks. This is in contrast to the notion present in the educational philosophy of the past generation, that pupils should do only those things which interest them. The exacting demands of war and the performance of uncongenial tasks required as a part of the training to gain skill and knowledge; the subordination of the individual to the group, to gain efficiency and success—these principles tend to react on educational philosophy, methods of instruction and the requirements made of the pupil. The effect on public opinion of the campaign for saving and economizing in money, time, food and clothing tends also to influence school practice and ideas.

Broadly speaking, the war has emphasized two types of education which compete more and more with the older cultural variety. The first grows out of the emphasis on national ideals and interests, and the duties and obligations of citizens in peace and war. This may be called the new social-civic education which has for its basis the socializa-
tion of the pupil through the study of the social sciences, history, civics, economics and sociology. It is through emphasis on these subjects that the pupils can be taught to take the social rather than the individual point of view; to become interested in, and to sacrifice for, the interests of the group. The new interest in history and the old interest in the history of the country, the old history of the country, and in foreign affairs. It is agreed that the subject of history assumes great importance because the ideals for which we are fighting must necessarily be taught to the present generation. This calls for a revaluation of our own history as well as a broader study of the history and development of our cultural and political institutions, and the development of democratic ideas. It also calls for a more complete knowledge of the history of the nations opposed to us, their psychology, philosophy, political systems and aims. It calls for a broader study of the history of those nations with whom we are allied in the war. It calls for a restudy of our own history, especially with respect to an understanding of our indebtedness to English-speaking problems brought up by the war, up to and much of our culture, to remove false prejudice and to show how under the forms of monarchy England is a democracy. The final attitude of the United States at the peace conference and in future efforts to preserve the world's peace must be, in the last instance, determined by public opinion. An enlightened public opinion is impossible unless historical conceptions are present in the minds of the people, sufficient for them to recognize what is just and right for the future existence of the nations and the world. The history of the United States is concerned with the world peace. If the people of the United States are to help safeguard the world for democracy, it is obvious that the historical background of the struggle for democracy in the past and the manner in which nations have reacted to that struggle must be thoroughly understood.

Similarly, the necessity of studying civics, economics and social science is acknowledged, because citizens must know something of these subjects in order to react intelligently to the serious problems brought up by the war, up to and much of our culture, to remove false prejudice and to show how under the forms of monarchy England is a democracy. The final attitude of the United States at the peace conference and in future efforts to preserve the world's peace must be, in the last instance, determined by public opinion. An enlightened public opinion is impossible unless historical conceptions are present in the minds of the people, sufficient for them to recognize what is just and right for the future existence of the nations and the world. The history of the United States is concerned with the world peace. If the people of the United States are to help safeguard the world for democracy, it is obvious that the historical background of the struggle for democracy in the past and the manner in which nations have reacted to that struggle must be thoroughly understood.

Similarly, the necessity of studying civics, economics and social science is acknowledged, because citizens must know something of these subjects in order to react intelligently to the serious problems brought up by the war, up to and much of our culture, to remove false prejudice and to show how under the forms of monarchy England is a democracy. The final attitude of the United States at the peace conference and in future efforts to preserve the world's peace must be, in the last instance, determined by public opinion. An enlightened public opinion is impossible unless historical conceptions are present in the minds of the people, sufficient for them to recognize what is just and right for the future existence of the nations and the world. The history of the United States is concerned with the world peace. If the people of the United States are to help safeguard the world for democracy, it is obvious that the historical background of the struggle for democracy in the past and the manner in which nations have reacted to that struggle must be thoroughly understood.

The intricacy of modern industrial processes, the greater and greater skill needed to obtain the required amount of wealth out of resources continually growing less, and the necessity of providing the great mass of industrial workers with the kind of education which will not only increase their skill and earning power, and hence the wealth of the nation, but also give them that broader vision and wider knowledge of their position and work, their privileges, duties, and obligations—all this is at the foundation of the demand for vocational education. It is significant that Congress passed the Smith-Hughes bill for Federal aid to vocational education in 1917, under the influence of the war and because of its effect on the type of education needed for a greater bill. This bill provided for the appropriation of large sums from the Federal treasury to stimulate the teaching of agricultural and industrial education, and home economics, and calls for an equal appropriation from the States taking advantage of the bill. It also created a Federal board for vocational education which has important powers of supervising the systems
established. This bill, if not directly a result of the war, was greatly influenced by it. It is the beginning of a new era in the United States, and these have important effects on national life, such as providing for the industrial skill needed for national defense, and for industrial competition likely to follow the war. It also lays the foundation for the vocational education of those soldiers who return. Particular subjects in the curriculum, such as geography, have been affected by the war. The result is a new interest in world geography, both as to the ownership of land areas and especially the economic resources of nations and their trade and commerce. The decline in the study of German in schools and colleges, and the increased attention to French and Spanish, is another important effect of the war on education.

The problems developed by the war, and the preparation for it, have led to increased study of the defects of our educational system with proposals to remedy them. One of the first results of the medical examination of those called to the colors was to reveal the fact that a large and economic number of our young men, especially those who have served in the army, suffered from physical defects and diseases. That many of these could have been prevented, or, at least, discovered by medical inspection of school children, by greater care of their health, and by more attention to physical training by the schools is admitted. The question of the duty of the State to pay equal attention to both the physical and the mental well-being of its future citizens is more and more recognized. If this view is not one of the direct results of the war at least we may say that it has been greatly stimulated.

A second discovery growing out of the war was the fact that there was a large element of our population which had not only not been Americanized, but could neither read nor write English. The newly arrived immigrants who later became voters, as well as those who from choice remained aliens, were hardly touched by our public school system. The absurdity of granting citizenship and the franchise to one class, and allowing both classes to perpetuate their own foreign languages and culture, and even to those who by the exclusion of our own language and culture, is now seen and appreciated. To expect that such a policy would make the United States safe for democracy, or to expect as a result of this policy that the nation would become united in spirit, language, and ideals, so that it could act as a unit in a great crisis for its own self-protection, was foolish. Accordingly it is recognized that the function of the school must be extended so as to prevent such a condition in the future; that the school must extend its opportunities to immigrants and alien, and indeed that education of emigrants must be made compulsory through continuation schools.

The problem of a teaching force that will be all American, loyal, and in sympathy with the ideals of this country has been brought to light by the war. The tendency to require public teachers to be citizens, and to be free from any taint of disloyalty or antagonism to the ideals of America, is an effect of the war. To teach successfully the ideals for which America now stands as well as the relation of these ideals to our historic past is obviously possible only for one who believes in no other ideals. Finally there is the relation of education to the reconstruction period following peace. New political, economic and social conditions inevitably mean a new philosophy of education. The old order has even now actually passed, and it is hardly possible for it to return, because the conditions on which the old order was based have disappeared. The real compelling power of education is the prevailing political, economic and social forces of a period, plus environment. As these change so must education, its philosophy, its ideals, institutions, and practices. The war has already forced changes which must inevitably affect the future. Those changes which have taken place, such as governmental regulation of production, distribution and consumption of food and fuel, the principle of co-operation between the government and private industry, governmental regulation of labor supply and wages, and control of transportation facilities — all these mark the beginning of a new political, social and economic order and hence a new order of education for the future.

National development in the immediate future will be determined largely by the educational plans and practices set in motion by the war — a new physical, industrial, and social training, extension of the principle of universal elementary to universal secondary education, so far as possible, with a corresponding increase in the proportion of those receiving a higher education, and the attempt to reach the whole adult population, through extension of the use of the school plant, various courses of education, and continuation schools. This program may be supplemented in peace times by use of the great cantonments established by the government, for training men for the problems of peace as well as war, and for the rehabilitation of the disabled soliders, the proposed national department of education would do much to correlate existing agencies, to lay down the guiding principles which would standardize minimum requirements and make proposed improvements.

MARCUS W. JERNEGAN,
Associate Professor of History, University of Chicago.
EDUCATION OF WOMEN. The changes during the 19th century include none more significant than those in the history of education for women. So swift has been the transition that it is hardly possible to give dates to this revolution practically the only opportunities for a girl's education were found in the so-called "Dame Schools," where she was taught to read and sew, the 'New England Primer' being the chief textbook. Even the art of writing was not universal, as is shown by the number of wills, left by women of property, which were signed with a cross. The grammar schools, providing instruction sufficient to prepare young men for college, only occasionally admitted girls until the beginning of the 19th century. The exceptions were less than 12 in the first century of our colonial history, as shown by the records of nearly 200 towns in New England. The town of Medford, Mass., voted in 1706 that "The Town hath power to agree with the School Master to instruct girls two hours in a day after the boys are dismissed;" Dorchester in 1784 voted "that such girls as can read the psalter be allowed to attend the grammar school from the first day of June to the first day of October." Northampton in 1796 passed the following resolution: "And also that the master be directed to begin his school from the first day of April to the last day of September at 8 o'clock in the morning and close at 6 o'clock in the afternoon, or any 8 hours in the 24 as shall be thought the most convenient, but that two hours, or a proportionate part of that time, be devoted to the instruction of females—as they are a tender and interesting branch of the Community, but have been much neglected in the Public Schools of this town." In Norwich, Conn., they were admitted "from 5-7 A.M.;" and Nathan Hale, school-master in New London in 1774, writes, "I have kept during the summer, a morning school between the hours of 5 and 7, of about 20 young ladies: for which I have received 20 shillings a scholar by the quarter." This admission of girls at times during the day and year, when the schools were not needed for the boys, seems to have been common during the last years of the 18th century. Northampton, which had voted in 1788 "not to be at any expense for teaching girls," four years later voted "by a large majority to admit girls between the ages of 8 and 15 to the schools from May 1st to October 31st." In 1790, opened the schools to girls during the summer months, when there were not enough boys to fill them.

One of the first advocates of education for girls was a graduate of Yale College in 1780, William Woodbridge, who took up the subject of his graduating essay on "Improvement in Female Education," and afterward opened an evening school for them in which he dared to teach such abstruse subjects as grammar, geography, and the art of composition. The founding of academies, to which girls as well as boys were admitted, is another evidence that in the latter part of the 18th century and the early part of the 19th, there was a new sentiment concerning their education. The first quarter of the 19th century might well be called the "Academy Age," since the most distinctive advance was in the founding of these institutions. The first one was at South Byfield, founded by bequest of a certain William Dummer, who died in 1761. Leicester, incorporated in 1784, Westford (1793), Bradford (1803), Monson (1804), were all coeducational at the beginning, although Bradford later excluded boys and has been for many years. The first in New England for girls only, but was followed by others which became more famous such as Adams Academy in Derry, N. H. (1823), Ipswich Academy, in Massachusetts (1828), and Abbot Academy in Andover (1829).

Before the close of the 18th century there were efforts for the education of girls in other parts of the country, by the Friends in Rhode Island, by the Friends and Moravians in Pennsylvania, the latter founding schools in Nazareth, and as far south as Lexington, Ky. None of these institutions, however, aimed to give higher education to women; the academies prepared boys for college, but 200 years after the founding of Harvard College there was not a college for women in the country.

A movement for the higher education of women began about 1820. The Rev. Joseph Emerson, principal of the Academy at Byfield, had become a Unitarian and had attracted to the Academy women like Zipah Grant and Mary Lyon, whom he inspired with zeal for learning as a preparation for service. In 1820 Emma Willard's 'Plan for Improving Women's Education' attracted the attention of Governor Clinton of New York, who secured the passage of two acts, one the incorporation of a proposed seminary at Waterford, and the other, "To give female academies a share of the literary fund," probably the first law passed by any legislature, expressly favoring women's education. The seminary was opened in 1821, not at Waterford, but at Troy, N. Y., as the Troy Female Seminary, later known as the Emma Willard School.

In 1822 Catherine Beecher opened a seminary at Hartford, Conn., in the upper room of a store. Beginning with 7 pupils, it soon grew to more than 150, and attracted students from all the States, but after 10 years was discontinued on account of Miss Beecher's removal to Cincinnati. Her interest in education was transferred to the Middle West, where for a generation she helped to mold public opinion on the subject.

From 1830-39 several institutions for the education of women were established, most of them in the South, the Wesleyan Female College at Macon, Ga., being authorized to grant degrees. In 1835 Wheaton Seminary in Norton, Mass., was founded by Judge Wheaton in memory of his daughter. But 200 years in-law, Mrs. Eliza Wheaton, instrumental in the founding of the school, lived until June 1905, its constant benefactor and a significant figure, as representing the last of the little group who, in the 30's, were laying the foundation of higher education for women.

Adviser and helper in the founding of this school was the woman who holds a foremost place among pioneers of higher education. Mary Lyon's reputation as student and teacher had already been called the "Academy Age," being the last of the little group who, in the 30's, were laying the foundation of higher education for women.
town of South Hadley, Mass., the seminary realized the ideal for which the founder had been working for years, that of a permanent institution for women which should furnish every advantage that the state of education in the country will allow. The first curriculum, including the natural sciences, higher mathematics, logic, moral philosophy, ancient and modern history, evidences of Christianity and Butler's 'Analogy,' shows a decided advance since the days when a college course was considered eccentric because he believed that women should be allowed to study grammar, geography, and composition. It marks an era in higher education, in the establishment of a permanent endowed institution, which should furnish to women, at moderate rates, as good educational opportunities as the colleges for men then offered. Its founding is not less significant in its influence as the "mother of schools." Among the institutions established on the same plan, with its four-year principal and teachers, are the Western College at Oxford, Lake Erie College at Painesville, Ohio, and Mills College in California. Michigan Seminary at Kalamazoo and the Cherokee Seminary, in what is now Illinois, are for women. Also Mount Hope Seminary schools, while across the water they were founded in Persia by Fidelia Fisk; in Turkey at Marsovan and at Bitlis; in South Africa, where the Huguenot Seminary now Huguenot College, at Wellington, Cape Colony, is the most famous; and in Spain, in the form of the International Institute of Madrid, founded at San Sebastian, by Alice Gordon Gulick. Miss Lyon's influence is seen also in the establishment of Wellesley College, for Mr. Durant was a friend and trustee of Mount Holyoke and included many of its features in his own institution.

The intervening period before the Civil War saw the rise of numerous schools for the education of women, but only two of full collegiate rank to-day, Rockford College in Rockford, Ill., opened as a seminary in 1849 and chartered as a college in 1892, and Elmira College in Elmira, N. Y., founded in 1855 and authorized from the beginning to confer degrees. It is interesting to notice that most of these newer institutions, to put it as they have been developing, have only a development short of the war. Within the last 30 years, three colleges for women of collegiate rank have been established in the following: Randolph-Macon College for Women at Lynchburg, Va. (1893), Agnes Scott College at Decatur, Ga. (1889) and Sweet Briar at Sweet Briar, Va. (1906).

The last 35 years of the 19th century were marked by an advance movement in women's education such as the world had never before seen. During this period three types of institution were developed:

1. The separate women's college.
2. The women's college affiliated with the university or with the college for men.
3. Coeducation in the universities for men.

The first and second types are characteristic of the East and the third of the West, although the distribution is not entirely along sectional lines.

The Separate Women's College.—The conviction of Matthew Vassar, that "woman, having received from her Creator the same intellectual constitution as man, has the same right as man to intellectual culture and development," led in 1861 to the incorporation of Vassar College, opened in Poughkeepsie (1865) with more than 300 students, the first of the distinctive colleges for women authorized to confer degrees, with curriculum and endowment sufficient to realize its ideal of collegiate work. In 1872 two other colleges for women followed, Wellesley College at Wellesley, Mass., founded by Mr. and Mrs. Henry F. Durant, in memory of their son, and Smith College of Northampton, founded by Sophia Smith of Hatfield.

Within another 10 years a fourth college was established, Bryn Mawr at Bryn Mawr, Pa., founded by Joseph W. Taylor, and opening its doors to students in 1885. In 1888 Mount Holyoke Seminary was incorporated as Mount Holyoke Seminary and College, and in 1893 became Mount Holyoke College, the seminary course being withdrawn. The development of these colleges for women has been phenomenal. Each one has a beautiful campus, with fine academic buildings, an endowment ample to maintain the educational standard, and a well-equipped, and offers a wide choice of elective courses, in addition to the required work, which varies somewhat in the different institutions. The faculty of each includes both men and women, with the latter taking a prominent position. Smith and Vassar, have had only men for presidents; two, Wellesley and Mount Holyoke, have had only women; and one, Bryn Mawr, had a man for the first president and a woman, the present executive, for the second holder of the office. The large number of applicants for admission has made it possible for these colleges to maintain a high standard of entrance requirements. Bryn Mawr admits only on examination; the other four colleges have admitted on certificate from accredited schools, a system which will be discontinued in 1919, in order to substitute the Comprehensive Examinations of the College Entrance Examination Board, although the Old Plan Examinations will also be allowed.

Other colleges in the East, somewhat smaller, but of high collegiate rank, are Goucher College in Baltimore, founded in 1888 as a Methodist institution, and Wells College in Aurora, N. Y., beginning as a seminary in 1868, but chartered as a college in 1879. Then, too, there are several in Ohio, Ohio, Lake Erie College at Painesville, Ohio, Milwaukee-Downer in Wisconsin, and Mills College in California, all beginning as seminaries but later chartered as colleges, are doing excellent collegiate work, although their numbers are small, as might be expected in sections of the country where coeducation is almost universally accepted.

More recent foundations in the East are Simmons College and the Connecticut College for Women. Simmons College, established by the will of John Simmons of Boston "as an institution in which might be given instruction in such branches of art, science and industry as would best enable women to earn an independent livelihood," was granted a charter in 1899. Its course of study is arranged in "programs " grouped in seven schools"—including Household Economics, Secretarial Studies, Library Science, General Science, Social Workers, Industrial Teaching and Salesmanship. The plan of instruction provides a fellowship for students meeting its entrance requirements, a one or two year technical training for college graduates and provision for special students.
The Connecticut College for Women, located at New London, received its charter from the Connecticut legislature in 1911 and was opened in 1915. Its course for the degree of Bachelor of Arts in 1918 included several branches of technical training, thus standing midway between the college of liberal arts and the more distinctive vocational colleges like Simmons. The college "owes its foundation to the wish and purpose of a group of Connecticut women to provide within the State adequate facilities for the higher education of women." The movement for its establishment was begun by members of the College Club of Hartford.

Another New England College for Women receiving its charter since 1910 is Wheaton College, formerly Wheaton Seminary.

The Women's College Affiliated with the University.—The college for women affiliated with the university, although the latest development, holds a place midway between the college on a separate foundation and coeduction.

The first to be established (1886) was the H. Sophie Newcomb Memorial College for Women, affiliated with Tulane University in New Orleans. Under the same board of trustees that controls the university, the college is on a different part of the city, its productive funds are in part separate, and it has a distinct faculty, including the president. The graduate department of the university has been entirely open to women since 1890.

The Women's College of Western Reserve University, Cleveland, is the outgrowth of an informal system of coeducation, established at Adelbert College, the undergraduate department of the university, in 1872. Sixteen years later women were excluded from Adelbert College, and provision made for them by the establishment of the Women's College. The fine buildings of the college, although separate, are near the other university buildings, and some of the laboratories of the men's college are open to women. The faculty, with the exception of the president, is distinct, but the university confers the degrees and opens all its graduate work to women.

Barnard College, affiliated with Columbia University, was opened in 1889, although 10 years before that President Barnard had urged the adoption of coeducation at Columbia College. As a result of his efforts and of a large popular petition in 1883, asking for the admission of women to Columbia College on the same terms as men, a system was inaugurated known as the "Collegiate Course for Women," which proposed to grant degrees to those who passed the college examination, but made no provision for instruction. The unsatisfactory character of this arrangement led to the establishment of the college, which, with a separate charter and an administrative autonomy, received Columbia degrees, took the university examinations and had university instructors, or those approved by the president. In 1900 another change was made by which Barnard bears the same relation to Columbia University as Columbia College, having its own faculty, endowments, and examinations, but receiving the university degree and being represented on the university council.

In 1891 the corporation of Brown University voted to admit women to the university examinations, but made no provision for instruction and took no action concerning the conferring of degrees. Unofficial instruction, however, was given by some of the faculty of the university during the first year and at least one woman evidence includes several members of the faculty. In the regular classroom, a beginning which resulted in a vote of the corporation in June 1892 opening the degrees and all graduate courses to women. At the beginning of the second year a dean was appointed and a building for recitation purposes secured, where regular undergraduate classes were conducted by members of the university staff under the name of "The Women's College in connection with Brown University." The numbers had largely increased and four classes were graduated before the corporation formally recognized the college, by constituting it in 1897 a department of the university. The affiliation is a close one, since the faculty is composed of members of the university faculty, and the requirements, courses, examinations, and degrees are the same, thus carrying out the plan of the founder, President Andrews, who designed it not as an "Annex," but as "part and parcel" of the university.

Radcliffe College, in affiliation with Harvard University, was opened in 1894.

The students who completed the course received a degree, but a certificate stating that the holder "had pursued a course of study equivalent in amount and quality to that for which the degree of Bachelor of Arts is conferred in Harvard College, and has passed in a satisfactory manner examinations on that course corresponding to the college examinations." There was no official relation with the university until 1894, when the society commonly known as "Harvard Annex," was incorporated as Radcliffe College and authorized to offer Bachelor's and Master's degrees, subject to the approval of the president and fellows of Harvard College. The president and fellows constitute the Board of Visitors having the general administration of the college, but the immediate government is in the hands of a council and an academic board, chosen mainly by the associates, who form the corporation. Thus its management is, in general, distinct from that of Harvard, although its instructors are entirely from the university staff.

To the list of affiliated colleges should be added William Smith College of Geneva, New York, opened in 1906 as a "co-ordinate" college. William Smith College is under the board of trustees and the president of Hobart College, the same faculty teach in both colleges, with the exception of instructors in the department of household arts and the degrees are the same. It has its own dean, and its classes, collegiate activities, and commencements are entirely separate.

In 1910 Tufts College in Massachusetts partially gave up the system of coeducation and opened Jackson College as a "co-ordinate" col-
\[\textbf{E D U C A T I O N \ O F \ W O M E N}\]

College, with general segregation the first two years of the course.

The affiliated colleges show certain differences in the character of their connection with the university. The chief administrator is generally the dean, only Radcliffe and the H. Sophie Newcomb Memorial College having a president distinct from the president of the university. All these universities open their graduate courses to women, and all, with the exception of Harvard, grant degrees on the completion of that work. In their development much has been done by endowment for dormitories or cottages of women, who have collected funds for endowments, erected buildings, acted as advisers, and in many ways promoted their interests.

\textbf{Coeduction in the Universities for Men.}

To Oberlin College, Oberlin, Ohio, belongs the honor of being the first institution of collegiate rank to admit women. Opened in 1833 as Oberlin Collegiate Institute, it was coeducational from the start, although at first women entered the so-called "Ladies' Course," and were not considered for advancement. The new departure aroused less comment, since from the outset the new institution stood for so many unpopular ideas, social and theological, that the mere fact of the admission of both sexes attracted little attention. 1 Its example was not followed for two decades, the second institution in this pioneer work being also in Ohio, Antioch College at Yellow Springs, founded by Horace Mann in 1853, and coeducational from the beginning. The movement, however, did not gain before the period of the Civil War; various reasons have been suggested for its rapid development since that time, such as the growth of the public school system, generally coeducational, and thus influencing public opinion in favor of the same policy in higher education, and the rise of the factory, relieving the home of many duties and leaving women more free for other interests. Throughout the country the demand for "practical education" was felt and the passage of the Land Grant Act in 1862, appropriating 10,000,000 acres for the establishment of colleges "to teach such branches of learning as are related to agriculture and the mechanics arts" is most significant in its influence upon women's education, since it was interpreted as providing for them as well as for men.

The West and the State universities have been the leaders in coeducation, only three of the latter, Virginia, Georgia and Louisiana, being still closed to women; but the East is not without representation in this class. When Cornell University was opened at Ithaca, N. Y., in 1868, the interest of Mr. Cornell and President White in favor of giving equal advantages to young women resulted in the offer from Henry W. Sage of a generous endowment on condition that "instruction shall be offered to the young women by the Cornell University as broad and thorough as that now offered to young men." In 1872 this offer was accepted and Cornell became coeducational.

The movement, however, had spread farther east than the State of New York. In 1868 Boston University was opened, welcoming young women on precisely the same conditions as young men, the first institution in Massachusetts to take this step and, according to the report of the president, the first in the world to open the entire circle of post-graduate professional schools to men and women alike.

Several other universities and colleges in the East are coeducational, among them Johns Hopkins, the universities of Pennsylvania and Maine, New York, Rochester and Syracuse, and Swarthmore, Adelphi, Bates and Adelphi colleges.

The opening of the University of Chicago in 1892 added another endowed institution of rank to coeducation; but in 1902, by the so-called segregation policy, which means separate instruction for women during the first two years of their undergraduate course, the university provision for them comes partially under the head of the affiliated college. This action, together with the limitation of the number of women admitted to undergraduate work at Leland Stanford Jr. University in California and at Northwestern University, Evanston, Ill., might be interpreted as a certain reaction in the West against coeducation were these policies not explained by the institutions themselves as efforts simply to preserve a proportionate relation in the undergraduate body. In the light of statistics the fear that the women students may outnumber the men is unfounded.

The Commissioner of Education reports that in the academic year 1915-16 there were in the United States 144 colleges for men, with 43,851 undergraduate students; 89 colleges for women, with 20,638 undergraduate students; 341 institutions for both sexes, with 109,009 undergraduate men and 69,543 undergraduate women—in all, 574 institutions, with a total of 152,860 undergraduate men and 90,181 undergraduate women. The degrees conferred upon women by universities, colleges and technological schools in 1915-16 were as follows:

- First degrees—
  - Arts and Sciences: 9,309
  - Agriculture: 135
  - Architecture: 4
  - Commerce: 46
  - Education: 591
  - Fine Arts: 14
  - Household Economy: 639
  - Journalism: 17
  - Music: 311
  - Oratory: 74

The higher degrees conferred upon women were as follows:
- Master of Arts: 909
- Master of Science: 56
- Doctor of Philosophy: 81

The total number of bachelors' degrees received by women was 11,240; by men 20,596. The total number of graduate degrees received by women was 1,062; by men 3,462.

In professional schools the numbers were as follows:

The tendency toward the utilitarian is more marked in the coeducational institutions than in the separate women's colleges, a difference easily explained, since the step is a natural one, from the opening of a work-shop for the men students to the establishment of courses in both men and women. The universities endowed by the land grant were the first to introduce the last-named subject and now form the majority of the institutions which include it in their curricula.

Early specialization is also more common in the coeducational colleges, placing greater emphasis in its undergraduate course upon liberal culture. The general tendency to-day, however, is away from unrestricted elective toward more required work, a "group" system, or a system of "majors," by which the student may have in her undergraduate course something more than a purely technical and hence one-sided training.

The results of education for women are shown in the large increase of numbers in the professions, the census of 1890 giving the number of women in professional service as 311,689, that of 1900 as 430,576, that of 1910 as 733,885, 44.1 per cent. of all the people in professional service. One of the chief reasons urged by the early champions of the movement was that women might be better qualified to become teachers and to-day their representation in that profession outranks all others.

The number of women who are given the higher positions in the profession of teaching, however, is not in proportion, as the following report for 1915-16 shows:

Professors and instructors in universities, colleges and technological schools:

Within the last few years there has been a large increase in the number and variety of employments which college women enter. They are not only teachers and physicians, but also nurses, superintendents of hospitals, secretaries, registrars and keepers of records, librarians, social workers, in settlements and associated charities, professional housekeepers, asbestos and poultry-raisers. They have opened laboratory kitchens, laundries and greenhouses, have engaged in scientific and historical research, published books, become musicians and artists, deans and presidents of colleges. Nor has their interest been confined to the professions by which they might earn a living. A recent writer says that "between the two broad oceans there is hardly any significant movement outside of trade and politics which is not aided by unpaid women who work purely out of ideal motives." Educated women are interesting themselves in the problems of the cities in which they live, serving on boards of education and of sanitation, making possible public playgrounds and vacation schools, agitating the questions of their own votes, pure water supply and clean streets. The experiment of college training for women has already justified itself by what they have accomplished in promoting public health and morals.

The Great War has intensified this call for college women. Laboratories which two or three years ago had no place for them, are demanding more trained workers than the colleges can supply. Positions as draughtsmen, accountants, social workers, government employees, farmers, dietitians, nurses and organizers for different women. The colleges can provide a faster and when the colleges can send out graduates to fill them. Never was there such real need of the educated woman.

The fear that academic training would unfit women physically and divert them from the home by the attraction of other careers has proved unfounded. The women's colleges and many of the coeducational institutions provide gymnasia and regular physical training, require out-of-door exercise, and have careful physical examination. These provisions, together with the regular hours and systematic life of the college, mean a better physical condition than in the case of the average non-college woman.

To those who know the college woman in her home the question concerning her fitness for it is not debatable. The supreme test of the college training is the development of character and the cultivation of self-control, of consideration for others and of a more rational outlook, means preparation for the home as well as for the professional character.

MARY E. WOOLLEY,
President of Mount Holyoke College.

EDUCATIONAL ASSOCIATIONS. The beginnings of educational associations in the United States may be dated to the public school system. Long before the organization of State school systems and before the days of the railroad when travel was of necessity by stagecoach, the great need of conference and exchange of thought was slowly being realized and in several States, particularly in New England and New York, county or other local gatherings of teachers and those interested in education were organized.

Of the educational associations in the United States having a national character, the American Institute of Instruction is probably the earliest. This association was organized in August 1830. The first meeting was held in the State House, Boston, Mass., and President Francis Wayland of Brown was the presiding officer. The first
seven meetings were held in Boston. They were marked by the presence of great leaders and educational statesmen rather than of those actually engaged in classroom teaching. Horace Mann, one of the most notable representatives of the Massachusetts legislature, attended the first meeting at Boston and became greatly interested in the discussions. The program attracted his attention and active support. As a result he turned from the law and from legislative halls and became one of our greatest educational leaders. Among those in frequent attendance on the early meetings were Horace Mann, Thomas H. Gallaudet, Henry Barnard, Samuel G. Howe, ASA Gray, Ralph Waldo Emerson, Theodore Parker, Charles Sumner, David P. Page, Edward Everett and many others whose names are equally familiar. The first few years these meetings in Boston were epochmaking, but discordant elements brought about a change in plan, and for the next seven years the annual meetings were held in various New England cities. Through the influence of Horace Mann Massachusetts made an annual appropriation, at first $300 and later $500 for the expenses of the meetings. This was discontinued in 1874. With the state associations in 1845 the interest in the organization declined. It was desired to make the new state organizations more representative and popular but the dynamic influence of the great leaders who had been active in the meetings of the institute was lost. The interest in the institute was continued through the efforts of Rhode Island leaders. It was commercialized through the excursional idea which was made a feature of the meetings, and thus was enabled to continue from year to year, but unusual expenses and a very limited income from the membership proved a serious embarrassment. More recently, however, the membership has increased and the expenses have been reduced so that the period since 1900 has been more encouraging than at any time since the great leadership of its early days. The contributions of the American Institute of Instruction through the educational statesmen who were in attendance at the movement were a greatly in developing public thought toward a rational educational program. In comparison with the larger State and national meetings the annual meetings of the institute have been small. It has seldom exceeded 2,000 members in enrollment. Although its history has been largely associated with New England, yet its membership has been drawn in part from many other States.

The Western Literary Institute and College of Professional Teachers, which was organized in 1831 drew its membership largely from the four States — Ohio, Indiana, Illinois and Kentucky. Of the 15 annual meetings, 12 were held in Cincinnati, and 3 in Louisville. This association was very active and was supported by the strongest teachers in this section of the country. The spirit and thought of the meetings were progressive. The remarkable development of the new country reacted on the educational thought. There was a freedom from conservatism which took a prominent part in the deliberations. The association continued until 1845 and exerted a wide influence on the schools.

The American Lyceum Association held its first national convention in New York city in 1831. It continued for nine years, when the last meeting was held in Philadelphia. The association was interested in general educational problems but more particularly in improved methods, in creating an interest in the study of the natural sciences, in providing the schools with books and apparatus, and in emphasizing the importance of the education of women. Among the papers presented on the programs were "Manual-Training Schools," "The Education of the Blind," "Vocal Music," "Eye Training," "Education of the Deaf," "Geology," "Female Education," "The Embellishment and Improvement of Towns." The programs were prophetic in character. The association created a wide interest in libraries and lyceums.

The American Association for the Advancement of Education was organized as the result of a meeting of the National Association of the Friends of Education which held its first meeting at Philadelphia in October 1849. The conference was presided over by Horace Mann, then a member of Congress from Massachusetts. The purpose was to discuss the administration of public education in its relation to the needs in different sections of the country. The second meeting, also held in Philadelphia, convened in August 1850, under the presidency of Eliphalet Nott, president of Union College. At this meeting a new constitution was adopted, and the organization became the American Association for the Advancement of Education. The eighth, and probably the last, meeting of the association was held at Detroit in August 1856 under the presidency of Chancellor H. P. Tappen of the University of Michigan. The various meetings of the association were marked by the attendance of superintendents, supervising officers and college presidents. The representation from the actual teaching staff was probably small.

A close relation is observed between the American Association for the Advancement of Education and the new State school systems which were being organized at that time.

The National Teachers' Association, organized in Philadelphia in 1857, absorbed the American Association for the Advancement of Education. The purpose of the new association was to include in one organization "all the teachers of our whole country." The original "call" was made to all practical teachers in the North, the South, the East, the West and was signed by the presidents of 10 of the State associations. It was to be an organization of the rank and file of the teaching profession, to bring together into one unit the common thought of the practical teachers, and through the national association to bind all the State associations together into one structure. The spirit of the new organization was in every sense in harmony with the efforts of the earlier associations both State and national. It conceived the need of a national conference representing the popular teaching body. A pregnant phrase in an address by William Russell at the first meeting at Philadelphia — 'harmonious co-operation of educational skill with scientific progress and human interest'— indicates the breadth of view of these early leaders. Two conditions made this the psychological time for the organization of the National Teachers' Association: the growing strength of
the several State associations, and the liberal legislation by which systems of public education had been established in several States. Moreover, the rapid economic development of the country through the application of scientific discovery and invention to the everyday life of the people, such as the marvelous extension of steam railroads and telegraph lines as well as the use of industrial machinery for the farm and home, made possible a real national conference and furnished a greater opportunity for the interpretation of the common thought. The strength in the association was in its appeal to popular membership. Its weakness was due to lack of educational leadership and statesmanship. The great impending national crisis overshadowed the activities of the embryo organization. There was, therefore, lack of popular interest and no conventions were held in 1861, 1862 and 1867. In 1866 an important change was made in the constitution whereby women were admitted to full membership on the same terms as men, and in 1869 two women were elected on the executive board of 35.

At the meeting in Cleveland, Ohio, in August 1870, D. B. Hagar of Massachusetts, who drew up the call for the convention, and Philadelphia in 1857, was president of the association. In his opening address he outlined certain changes in the organization as a result of which a new constitution was adopted and the following departments were created: normal schools, school superintendence, elementary education, and higher education. By this action the American Normal School Association and the National Association of School Superintendents became, under the new constitution, departments of the National Education Association. From time to time other departments have been added until there are now 21. The breadth of activity is indicated by the names of some of the departments more recently organized: vocational education and practical arts, rural and agricultural, child hygiene, physical, school administration, library, special, promotion of wider use of schoolhouses. The growth, however, was slow. The registered membership at the Cleveland meeting in 1870 was only 170, and for several years the attendance continued small. The funds were frequently insufficient to print the proceedings. In 1884 an unusually successful meeting was held in Madison, Wis., with an enrolment of 2,729. This marked the beginning of a new era for the association. From that time it has properly been regarded as a leader in national educational matters. In 1886 the association was incorporated for 20 years.

The following year at the Chicago meeting the membership in 1870 was only 170, and for several years the attendance continued small. The funds were frequently insufficient to print the proceedings. In 1884 an unusually successful meeting was held in Madison, Wis., with an enrolment of 2,729. This marked the beginning of a new era for the association. From that time it has properly been regarded as a leader in national educational matters. In 1886 the association was incorporated for 20 years. The following year at the Chicago meeting in 1899, 13,656; and at Boston in 1903, 43,953. In 1906 an act was passed by Congress incorporating the National Education Association. A permanent fund founded in 1884 has grown to nearly $200,000.

At the Philadelphia meeting in 1891, Dr. W. T. Harris, United States Commissioner of Education, presented a noteworthy paper on the organization and functions of the association, in which he reviewed its purpose, to *concentrate the wisdom and power of numerous minds, and distribute among all the experiences of one mind,* and pointed out the salutary influence of the departments provided for the needed specialization of work with the suggestion that others should be added.

Since 1870 there has been a permanent paid secretary who gives his entire time to the service of the association, and since 1917 the secretary's office and the headquarters of the association have been located at Washington, D. C. It has always been the policy of the organization to support broad national policies. To formulate a program of education during and after the war, the association designated a Commission on the Emergency in Education. This commission contemplates no less a program than a national department of education, with a secretary who shall sit in the President's cabinet, and the transfer of all bureaus or agencies relating to educational affairs to the new department.

These have been organized in recent years several societies interested in the scientific study of education. The National Herberian Society for the Scientific Study of Teaching was organized in 1895, and in 1902 it was reorganized and the title changed to the National Society for the Scientific Study of Teachers. The National Society for the Promotion of Industrial Education, organized in 1906, has also made large contribution to educational thought and progress. Local teachers' associations had become general before the organization of the National Teachers' Association in 1857. A teachers' association was organized in New York city as early as 1798. An association of teachers known as the School Association of Middlesex County was formed at Middletown, Conn., in 1799. The earliest record of a State gathering of teachers is that a "State Convention of Teachers and Friends of Education" was held at Utica, N. Y., in January 1831. It was not until 1845, however, that there was a formal organization. Actively interested in the work of the State associations were many educational leaders. These men gave strength to the organizations, and every effort was made to secure a large attendance on the part of practical teachers. In Rhode Island, Massachusetts and New York State associations were founded in 1845. The Ohio association was organized in 1847; Connecticut, in 1848; Vermont, in 1850; Michigan and Pennsylvania, in 1852; Wisconsin, Illinois and New Jersey, in 1853; Iowa, New Hampshire and Indiana, in 1854; Missouri, in 1856. The meetings of some of the State associations soon became large and enthusiastic. Dr. Hagar of the State Normal School at Salem, Mass., stated that the attendance at the meetings of their association in the late 60's was from 2,500 to 3,500. He attributed this interest to the reorganization of the meetings into special sections. There is now a State teachers' association in every State except Delaware. The meetings are usually held annually. In the larger organizations the program generally covers several days. At the general sessions the topics are of broad interest, while the sectional meetings are given over to the discussion of special activities. In New York the State association is very strongly organized. Every member is made to attend a large membership. The cities, villages and the supervisory districts are the separate units of the State organization and are represented by delegates who control the poli-
cies of the State organization. Previous to the reorganization of the New York State Teachers' Association in 1913, the meetings were largely village or rural in the locality where the annual meeting happened to be held. The renewed interest and enlarged activities of the new organization have fully justified the change made in 1913. The association is now representative of the entire State and every supervisory unit, city village or rural, of the locality where the annual meeting happened to be held. The renewed interest and enlarged activities of the new organization have fully justified the change made in 1913. The association is now representative of the entire State and every supervisory unit, city village or rural, of the locality where the annual meeting happened to be held.

In some States the interest in the State association is much greater than in others. This is indicated in part by attendance and membership, which varies from nearly zero to 90 per cent of the teaching body of the State. Most of the associations are growing much stronger and teachers are becoming alive to the opportunities of an active professional organization. The economic conditions are rapidly becoming better for the teacher in those States in which the association is supported by a loyal membership. The indifference so often found is due in part at least to the short professional life of the teacher.

In general there are two types of teachers' voluntary associations: (a) the general associations which aim to promote all the interests of teachers, such as the National Education Association and the State teachers' associations, and (b) specialized associations which are limited to some special subject or to some particular activity of school work, such as kindergarten, industrial training, English, music, agriculture, domestic arts, science, health and hygiene, playgrounds, or others.

The early associations were largely cultural. They were not subdivided into sections, in fact, the attendance was so small that this was not possible, even if it had been considered. In recent years the national and State associations have differentiated their work until the sections have become highly specialized. Women play a much more prominent part than formerly. In 1911 the National Education Association had its first woman president. It was an incident worthy of mention that in the same year the National Education Association of Wales had a woman presiding officer for the first time. Little thought was given at first to the economic and material needs of the teacher. In the State associations there is a great interest in educational legislation and also in the raising of professional standards. The teachers' associations in some of the larger cities are largely concerned with the economic betterment of their membership and related legislation.

Teachers' voluntary associations, both general and specialized, have made a noteworthy contribution to educational progress. To the teachers these associations mean renewed enthusiasm, professional growth and material improvement. To the State they are often the "greatest single educational factor." Active teachers' associations are essential to progressive educational policies.

In England a much larger percentage of teachers is represented in the associations than in America. The National Union of Teachers, which was organized in 1879, has a membership of over 70,000. More attention is given to economic conditions and material needs. It has actively supported candidates for Parliament and for a time its secretary was a member of Parliament. The membership was originally limited to teachers in elementary schools, but more recently the union has been open to other teachers. The Headmasters' Conference, organized in 1869, and the Association of Headmasters, organized in 1890, give special attention to questions relating to school management and professional matters. The Assistant Masters' Association is an organization of secondary school teachers and is interested in part in the economic betterment of its membership.

The largest general association in Scotland is the Educational Institute of Scotland. The Scottish Class Teachers' Association also has a large enrolment. The Association of Headmasters of Secondary Schools and the Secondary Education Association of Scotland are organized in the interests of teachers in the secondary schools.

There are various types of educational associations in France. Many of them illustrate the power in co-operation between teachers and others interested in educational problems. The League of Doctors and Families organized in 1902 for the improvement of scientific and hygienic conditions in the school includes in its membership teachers, parents, physicians, and others. The Society for the Psychological Study of the Child, which was organized for the study of child psychology and general educational methods, includes not only teachers but scientists and others interested in a theoretical as well as practical study of educational questions. The work of these associations has brought about the organization of international congresses for the scientific study of educational questions. Associations of teachers and instructors in France have a wide influence. The discussions as to instruction, curriculum and discipline brought out in the meetings are published in their bulletins and principals are quite free as to the adoption of new methods in their schools.

The largest organization of its kind in Germany is the German Teachers' Association formed in 1871. Over 90 per cent of the teachers in the elementary schools are members of the association. It is highly organized throughout the country, including local associations of a general character and sections for teachers in special subjects. The chief interest is the professional and economic betterment of teachers. Its strength is in the centralized organization. There is also an association of secondary school teachers, the aim of which is to improve the conditions of teachers in schools of secondary grade. Associations which enlist the interests of the public-spirited citizen as well as the teacher and which aim to promote general educational activities are not found.

EDUCATIONAL ATHLETICS. At the outset it must be borne well in mind that athletics in an educational institution is not an end but a means to an end. The end in view is to furnish a healthy habitation for a healthy mind, for without a sound body to carry out its work the mind certainly cannot do what nature intended it to do. Certain minds incorporated in crippled bodies, it is true, have risen to remarkable heights in the various fields of human activity, but not on account of deformities, but in spite of them. Perhaps there is nothing so detrimental to a good healthy body—not even the use of stimulants—as excessive sedentary pursuits. When a young man is bent on winning scholastic honors, he unconsciously falls into this excess. Of course the natural result follows. Good rich blood is denied the parts; they become starved, and in a short time degeneration sets in throughout the entire body. Then it is that we have a terrible spectacle of a strong intellect unable to do even ordinary work on account of a pain-racked body.

It is to counteract this tendency to starve the body in order to feed the mind, that school authorities have encouraged physical and mental training among students. Thus we see that to-day the gymnasium is as important a part in a group of school buildings as a hall of science or of arts.

Although educational athletics is found at its best in the university, and there is little difference between the systems employed in our leading institutions of learning, the question is far from settled as to the best way of exercising the boy in the elementary and high school. It is a generally accepted fact that the exercise—we can hardly dignify it by the name "athletics"—in the elementary school is the one which, apparently, has the least system about it.

Athletics reduced to a system is for the first time found in the high school. The games played are much the same as in the college, namely, baseball, football, track sports, tennis and basketball, while in some of the high schools we find indoor baseball. As a rule all interscholastic competition is under the control of the principal, or a member of the teaching force appointed by the principal.

All over the country there are interscholastic associations made up of high schools in adjacent counties. The winners in the respective meets compete in larger meets under the auspices of the athletic associations of some nearby university. In many of the Western States, State high school track meets are held annually by the various State universities. Beside the rivalry between high schools located in the same section, there have been contests between the champion football teams of the Middle West and those of the East.

Generally speaking, every university in the United States has the same routine. Each student is required to undergo a physical examination, so that a correct knowledge of his bodily condition is obtained and proper exercises prescribed. Regular classes are formed for drill in ordinary arm, body, leg and wand calisthenics, and then on the various gymnasium appliances and apparatuses. During the high school year at least, gymnasium work is compulsory. Exceptions, however, are made in the cases of those who make athletic teams. Besides the exercises themselves, lectures are given on personal hygiene. If the college is a co-educational institution, the female students take physical training under a competent woman instructor. In several institutions, young women have taken part in basketball, and in rarer cases in track athletics, and on several occasions have made enviable records.

All competitive athletic games are given under direct university supervision, and examination is required to show that the team members of a student body team will not cause injury to the student, but will tend to improve his physical condition. No student, whose class work is unsatisfactory, is allowed to play on a university team. No student is permitted to play on an athletic team more than four years. All those who take part in collegiate sports must be amateurs.

Of all intercollegiate sports the most popular and the one most distinctlyively a college sport is football. The football season begins in the middle of September and ends with Thanksgiving day. Intercollegiate contests begin about the first of October, since the last half of September is taken up with the training and conditioning of the players. Football, as it is played in physical as well as mental, as the Rugby game. This country first saw it at Harvard in 1875. A match was arranged with Yale that year, and the latter was beaten. However, the lesson seemed to have been a good one, for since then Harvard's victories over Yale have been few and far between. To Walter Camp, Yale 1880, sometimes called "the father of football," do we owe much for football as it is played to-day. It was due principally to Mr. Camp's efforts that the number of players on a team, and positions were fixed in their present condition. Without going into a discussion, on the roughness of the game, let it be considered that what is rough—nay, brutal—for a man in no condition to play, is merely a trial of strength, courage and cleverness, in which all unnecessary roughness is eliminated, for the trained athlete.

After the football season is over, beside work in the gymnasium, there is nothing done in the way of exercise until after the holiday vacation, then for a time the various gymnasium sports are taken up. The principal winter sport is basketball and gymnasium work. It is very important, among other things, in that it brings out a part of the student body which takes no part in the other branches of sport. Gymnasium teams practise in tumbling, trapeze, horse and bar work. Many of the students also take special interest in wrestling, fencing and boxing. Although there is none or little intercollegiate competition in handball, this beneficial exercise is for recreation for a great many of the student body.

Although it is long before the season of competition, the training season of both the baseball and track teams start immediately after the Christmas holidays. Baseball brings out more candidates than any other branch of sport, and the reason for this may readily be seen. Although there are many boys in college who have never played football, or sprinted, there is hardly one, physically able, who has not played the national game. The indoor work in this branch consists of batting, throwing, picking up grounders and pitching. The squad, which in some instances numbers
more than a hundred men, is gradually cut down, so that when they are able to play out of doors, in March, there remains probably not another man in the university than the men who are trying for pitching positions.

In the East, Brown, Yale, Harvard, Princeton, Georgetown and Holy Cross have always been among the leading schools in baseball. The baseball squads in almost all of these colleges are coached by professional players. In the West, Illinois and Michigan have divided all the diamond honors in recent years.

Training for a track team starts in the winter. Almost every university gymnasium is fitted up with a running track. There, day after day, the candidates for the team get out and run under the eye of the trainer. Intercollegiate indoor track matches begin as early as February. They take place in the gymnasium, and consist of short dashes, hurdle races, middle and long distance runs, shot put, pole vault and high jump. To this list is often added a relay race. As soon as the weather is warm enough the track candidates are taken out on the athletic field. During the spring drills a meet is held, and in June, at the close of the collegiate year, a meet is held to which all the track teams of the colleges of a section are invited to compete.

Harvard, Pennsylvania, Yale and Georgetown do the best work on the track in the field among the eastern colleges. In the West Michigan and Chicago usually fight it out for leadership.

The following are the best records made in the respective events by the college track athletes of the country in collegiate meets:

- 220 yards — 21.5 s. — W. M. A. W. M. A.
- One-fourth mile — 47.2 s. — J. E. Merrihod, Pennsylvania.
- One-half mile — 1 m. 53 s. — J. E. Merrihod, Pennsylvania.
- One mile run — 4 m. 14.2 s. — J. P. Jones, Cornell.
- Two mile run — 9 m. 22.6 s. — B. Hoffmire, Cornell.
- 220 yard hurdles — 23.5 s. — A. C. Kraenzlein, Pennsylvania.

- Running high jump — 6 ft. 43 in. — W. M. A. Yale.
- Running broad jump — 24 ft. 41 in. — A. C. Kraenzlein, Pennsylvania.
- Polo vault — 13 ft. 1 in. — R. Gardner, Yale.
- Putts of one hundred feet — 101 in. — P. Beatty, Columbia.

Beside the sports already mentioned, rowing takes an important place in the athletic catalogue of many universities. Perhaps a man has to train longer and more strenuously to make a college crew than if he went into any other branch of sport. Often the man on the crew starts to work in September and continues throughout the entire college year. The swimming tank in the gymnasium leads to many water games, such as racing, diving, water polo, etc., all of which tend to mould a man along healthful lines. Lawn tennis occupies a very important place in college athletics. It is one of the most beneficial sports we have, but as it is not a game which is very interesting to spectators, it will never rank with football, baseball, rowing or track athletics as an intercollegiate sport. Golf is being taken up more and more by the colleges and this most excellent game in popularity, and we will hear of many intercollegiate matches where now there are but few.

The good of athletics in institutions of learning is incalculable. Between classes and lectures, when there is nothing to take up the student's mind, the temptations are manifold. If he is of a studious disposition, there is the danger of excessive sedentary life. If he is not studiously bent, there are many temptations to attract the idle. If he is of a weak constitution, disease and its consequences soon follow; if he is robust, although he may stave them off longer, the consequences are the same. Then again, the athletic field is a place where all classes of students can meet on a common ground. It is the place where they can get rid of a superabundance of youthful enthusiasm. As a result, the town and gown riots, which formerly characterized every college town, are things of the past. One is thus inclined to agree with an eminent college president when he said, "the athletic field does more toward keeping order in the student body than all our rules and regulations combined."

EDUCATIONAL LAND GRANTS. See Land Grant Colleges; Education, Agricultural — Land Grant Colleges.

EDUCATIONAL PERIODICALS. Professional publications designed for the use of teachers first appeared in the early part of the 19th century. Their development has been closely associated with the organization and growth of educational associations. The pioneer educational magazine of which records are kept was the Academician, a semi-weekly edited by Albert and John W. Pickett and published by the Incorporated Society of Teachers of New York. The first number appeared 7 Feb. 1818. It published a series of articles on grammar and another series on mathematics; articles on Pestalozzi's methods and accounts of various institutions of learning. It continued for two years, the last number appearing on 29 Jan. 1820. The second in the field, The American Journal of Education, a monthly periodical edited by William Russell, W. C. Woodbridge and William A. Olcott, was begun in January 1828, and until 1838 exercised marked influence on the educational thought of the country. In the latter year, Horace Mann, then secretary of the Massachusetts State Board of Education, commenced the publication of the Common School Journal. As the mouthpiece of the great educational reformer this magazine did much to advance the teaching profession. It was discontinued in 1852. In the meantime several minor educational publications had sprung up in different States. Most of these exerted but a local and transitory influence. The most remarkable educational periodical ever produced in this country was Henry Barnard's American Journal of Education, which was started in 1855. This was more than a magazine; it was rather a compendium of the educational thought of the day. It continued with some irregularity until 32 volumes had been completed. The plates were preserved and the whole work was reprinted for many years. The expansion of the teaching profession educational periodicals have multiplied until every department of education has its special journal. The best known of the current journals covering the general pedagogical field in America are The Educational Review, (1880), The School Review (1893), School Journal of Education (1875), School Bulletin (1874), American Education (1897), Catholic Educational Review (1904). Among the magazines
covering special phases of educational work the following have a prominent place: Administration \textit{- The Elementary School Journal (1900); Primary Education (1898), American Primary Teacher (1870), Normal Instructor and Primary Plans (1891); psychology - The Journal of Educational Psychology (1910), The Pedagogical Seminary (1896), The Psychological Clinic (1905); physical education - American Physical Education Review (1896); kindergarten - The Kindergarten Magazine (1889), The Kindergarten and First Grade (1916). In addition to these there are many state and local educational periodicals of much merit. Consult Bardeen, C. W., 'The History of Educational Journalism in the State of New York' (Syracuse 1893); 'Report of Commissioner of Education, U. S. Bureau of Education, 1910'; Severance, H. O., 'A Guide to the Current Periodicals and Serials' (1914).

EDUCATIONAL TEST FOR SUFFRAGE. See Electoral Qualifications.

EDWARD, THE ELDER, king of England: b. about 945; d. Falstone, Northamptonshire, 925. He was a son of Alfred the Great, and succeeded his father in 901. Ethelwald, the son of his father's elder brother, claimed the crown; and an insurrection took place in his favor, but it ended with the death of Ethelwald in battle. The crown was not long vacant, for Edward was today chosen by success over the Angilcised and foreign Danes. He fortified many inland towns, acquired dominion over Northumbria and East Anglia, and subdued several of the Welsh tribes. Consult Oman, 'England before the Norman Conquest' (London 1910).

EDWARD (surnamed the "Martyr"), king of England: b. about 963; d. Corfe Castle, 18 March 979. He was a son of Edgar, and succeeded his father in 975. His stepmother, Elfrida, wished to raise her own son, Ethelred, to the throne, but was opposed by Dunstan, through whose exertions Edward was peaceably crowned. His short reign was chiefly distinguished by the disputes between Dunstan and the foreign monks on one side, and the secular clergy on the other. Hunting one day in Dorsetshire he was separated from his attendants, and repaired to Corfe Castle, where Elfrida resided. He requested a glass of liquor, and as he was drinking on horseback one of Elfrida's servants gave him a deep stab behind. He immediately set spurs to his horse, but fainting from loss of blood, was dragged in the stirrup until he died. The pity caused by his innocence and misfortune induced the people to regard him as a martyr.

EDWARD (surnamed the "Confessor"), king of England: b. Ipswich, Oxfordshire, about 1004; d. 5 Jan. 1066. He was an elder son of Ethelred the Unready. On the death of his maternal brother, Hardicanute the Dane, in 1041, he was called to the throne, and thus renewed the Saxon line. He was not the immediate heir, as his brother, Edmund Ironside, had left sons; but as Ethelred the Young, Earl of Kent, on condition of marrying his daughter, Editha, his claim was established. Edward was a mild and virtuous prince, who acquired the love of his subjects by his sanctity and care in the administration of justice. It was under his reign that Westminster Abbey was built. Having been educated in Normandy, he introduced so many natives of that country to his court that the French language and manners became prevalent in England, to the great disgust of Earl Godwin and his sons. A rebellion took place, and Edward was forced to dismiss his foreign favorites. Perceiving that the youth and weakness of his chosen heir, Edgar Atheling (q.v.), would not secure the succession against the power and ability of Harold, the son of Godwin, he turned his eyes upon his kinsman, Wiliam of Normandy, in whose favor it has been asserted that he executed a will. He died leaving the point of the succession undetermined; and with him ended the Saxon line of kings. He caused a body of laws to be compiled from those of Ethelbert, Ina, and Alfred, which is the supposed source of the common law of England. He was canonized by Alexander III in 1166. Consult Hodgkin, 'History of England to 1066' (London 1906).

EDWARD I, king of England: b. Westminster 17 or 18 June 1239; d. Burgh-on-Sands, near Carlisle, England, 7 March 1307. He was the son of Henry III (his mother being Eleanor of Provence, the wife of Henry), and the contest between his father and the barons called him early into active life. In 1252 he became Lord of Gascony, and after his marriage to Eleanor of Castile in 1254, his father made him ruler of Ireland and Wales, and the towns of Bristol, Stamford and Grantham. The officials whom he appointed in Wales were resented by the inhabitants who revolted with the Scotch. Further discontent was manifested by the barons who were likewise indignant at the favors granted to foreigners. King Henry and Edward were finally forced to consent to the Provisions of Oxford which limited the royal power in regard to such appointments and war was declared in 1263. Edward finally quelled all resistance to the royal authority by the decisive defeat of Leicester, at the battle of Evesham, in 1265. In 1268 he joined the Crusade to Palestine, where he inspired so much terror that an assassin was employed to murder him; but he whom he received a wound in the arm. In 1271 he set out toward England, stopping at France to acknowledge his homage to Philip III for his French possessions. He was crowned King of England with Eleanor on 19 Aug. 1274. On assuming the government he acted with great vigor in the repression of the lawlessness of the nobles and the corruption in the administration of justice; but often evinced an arbitrary and grasping disposition. In 1274, and again in 1276, he summoned Llewellyn, prince of Wales, to do him homage, and upon his refusal, except on certain conditions, began the war which ended in the annexation of that principality to the English crown in 1283. Edward then spent some time abroad in mediating a peace between the crowns of France and Aragon, and on his return commenced his attempts to destroy the independence of Scotland. After his return from the Scottish expedition, in 1296, which terminated in the capture of Batiol, he became involved in a quarrel with the clergy, who, supported by the Pope, refused to submit to a tax which he had imposed upon them. Edward forced their compliance by placing them out of the protection of the law. His frequent expe-
dients to raise money at length produced great discontent among the nobles and people also, which obliged him to confirm the great charter and charter of forests, and also to give other securities in favor of public liberty. He then made a campaign in Flanders against France, which terminated with the recovery of 100,000 men. The ignominious execution of the brave Wallace, in 1305, as a traitor, forms a blot in the history of Edward. Neither did it avail, since Robert Bruce was able, in 1306, to place himself at the head of a new confederacy. Indignant at this determined spirit of resistance Edward vowed revenge against the whole Scottish nation, and, assembling another army, was on the point of passing the border when he was arrested by sickness and death. Few princes have left to posterity a more brilliant name than Edward II. His enterprises were directed to permanent advantages rather than to mere personal ambition and temporary splendor. Nor was he less intent upon the internal improvement of his kingdom than upon external importance. The laws of the realm obtained so much additional order and precision during his reign that he has been called the "English Justinian." He passed an act of mortmain, protected and encouraged commerce, and in his reign first originated the society of merchant adventurers. The manners of this able sovereign were courteous, and his person majestic, although the disproportionate length of his legs gave him the popular surname of "Longshanks." He left a son and three daughters by his first wife, Eleanor, who died in 1290, and two sons by his second wife, Margaret of France. Consult Stubbs, 'The Early Plantagenets' (1877); Tout, 'Edward I' (1893); Jenkins, 'Edward Plantagenet' (New York 1911).

EDWARD II, king of England: b. Carnarvon Castle in 1284; d. Berkeley Castle, 21 Sept. 1327. He was the first English Prince of Wales and succeeded his father, Edward I, in 1307. He was of an agreeable figure and mild disposition, but indolent and fond of pleasure. His first step was to recall Piers de Gaveston, a young Gascon, whom his father had banished, and whom he created Earl of Cornwall, and married to his niece. He then went to France to espouse the Princess Isabella, to whom he had been contracted by his father, leaving Gaveston guardian of the realm. Soon after his return the barons associated against the favorite, whom they more than once obliged the king to send away. He was, however, as constantly recalled when the immediate danger was over, until an open rebellion took place, and Gaveston was captured and executed as a public enemy. In 1314 Edward assembled an immense army to check the progress of Robert Bruce, but was completely defeated at Bannockburn. After the battle Edward selected another favorite, Hugh le Despenser, upon whom he lavished favors of every kind, until the barons again rebelled, and the Parliament doomed Despenser and his father to exile. The king was obliged to confirm the sentence. Edward, however, on this occasion, in concert with the Despensers, contrived to raise troops and attack the barons, at the head of whom was his cousin, the Earl of Lancaster, who, being taken prisoner, was executed at Pomfret. Edward subsequently made another fruitless attempt against Scotland, which ended in the conclusion of a truce of 13 years. In 1324 Queen Isabella went to France, and while there entered into a correspondence with several English fugitives, in whose hatred to the Despensers she participated. Among these was Roger Mortimer, a young baron of the Welsh marshes, who, after the death of Isabella, a criminal intercourse followed, in consequence of which the queen was still more determined upon the ruin of her weak and unhappy husband. Having formed an association with all the English malcontents, and aided with a force by the Count of Hainault, she embarked for England in September 1326, and landed in Suffolk. Her forces seized the Tower of London and other fortresses, captured and executed both the Despensers without trial, and at length took the king prisoner. Edward was confined in Kenilworth Castle, and in January 1327 his deposition was unanimously voted in Parliament, on the ground of incapacity and misgovernment. A resignation of the Crown was soon after extorted of him, and he was transferred to Berkeley Castle, where Mortimer dispatched two ruffians, who murdered him, in the 20th year of his reign and 43d year of his age. Consult Vickers, 'History of England, 1272-1485' (London 1912).

EDWARD II, an historical tragedy by Christopher Marlowe (1598). It follows history closely in its main lines and is a powerful representation of the tragic history of that king.

EDWARD III, king of England: b. Windsor, 13 Nov. 1312; d. Richmond, Surrey, 21 June 1377. He was a son of Edward II, and on his father's deposition in 1327, was proclaimed king under council of regency, while his mother's paramour, Mortimer, really possessed the principal power in the state. The pride and oppression of Mortimer now became so intolerable that a general confederacy was formed against him. The result was the seizure of Mortimer, who was tried and executed by a parliament at Westminster, and was executed 29 Nov. 1330. The queen, although treated with outward respect, never again during the remaining 28 years of her life recovered any degree of authority. Edward now turned his attention to Scotland. Assisted by some principal English nobles, Edward Baliol, son of the John Baliol to whom the crown had been awarded by Edward I, raised a force, and defeating the Scots in a great battle, set aside David Bruce, then a minor, and was crowned at Scone in 1332. Baliol being driven away on the departure of his English auxiliaries, applied to Edward, who defeated the regent, Douglas, at the famous battle of Halidon Hill, in July 1333. This victory produced the restoration of Baliol, who was, however, again expelled, and again restored, until the deposition of Edward was called off by a still more splendid object. The crown of France, by the Salic law, having devolved to Philip de Valois, cousin-german to the deceased king Charles the Fair, Edward was induced to claim it in right of his mother,
that monarch’s sister. Edward, in order to obtain supplies, made concessions to Parliament which he never intended to keep; and finding his territory of Guienne threatened, sent over a force for its defense, and quickly followed himself, accompanied by his son Edward, the famous Black Prince, all his chief nobility, and 30,000 men. This meant battle of Crécy followed, 25 Aug. 1346, succeeded by the siege of Calais. In the meantime, David Bruce, having recovered the throne of Scotland, made an incursion, at the head of a large army, into England, but being repulsed by a much inferior force, led by Queen Philippa, and headed by Lord Percy, was totally defeated and taken prisoner, with many of his principal nobles. Philippa went over to her husband at Calais, and, by her interference prevented the barbarous execution of Eustache de Saint-Pierre and five other citizens, whom Edward, on the capitulation of the place, had determined to execute, in revenge for his long detention in the siege. In 1348 a truce was concluded with France. The year 1349 was distinguished by the creation of the Order of the Garter, which soon became one of the most illustrious orders of knighthood in Europe. Philip, King of France, dying in 1350, was succeeded by his son John, the commencement of whose reign abounded with intestine commotion, and in 1355 Edward again invaded France on the side of Calais, while the Black Prince at the same time led a large army from Gascony. Both these expeditions were attended with much plunder and devastation; and Edward, being recalled home by a Scottish inroad, soon repelled it, and retaliated by carrying fire and sword from Berwick to Edinburgh. During this time the Prince of Wales had penetrated from Guienne to the heart of France, where he was opposed by King John, at the head of an army nearly five times greater than that of the English. The famous battle of Poitiers ensued, in which the French monarch was taken prisoner. Edward held at the same time in captivity the kings of France and Scotland, the most dangerous of his enemies. John was taken to England and treated with the greatest respect; and David was soon after liberated upon ransom. A truce had been made with France after the battle of Poitiers, at the expiration of which, in 1359, Edward once more passed over to Calais with a large army, but at length consented to a peace. Besides the stipulation of a large ransom for King John, several provinces and districts in the southwest of France and neighborhood of Calais were yielded to Edward, who in turn resigned his title to the crown of France and duchy of Normandy. Quarrels with his Parliament, the opposition of the Black Prince and personal affairs dissipated the rest of his reign. The successor of John, Charles V, invaded the provinces entrusted to Prince Edward, and Edward had the mortification of witnessing the gradual loss of all his French possessions, except Bordeaux and Bayonne, and of all his conquests except Calais, Consult Longman, ‘Life and Times of Edward III’ (1869); Mackinnon, ‘History of Edward III’ (1900); Vickers, ‘History of England, 1272-1485’ (London 1912).

EDWARD IV, king of England: b. Rouen, France, 29 April 1441; d. 9 April 1483. His father, Richard, Duke of York, was grandson of Edward, Earl of Cambridge, and Duke of York, fourth son of Edward III, while the Lancaster branch descended from John of Gaunt, the third son. The York line had intermarried with the female descendants of Lionel, the second son, which gave it the preferable right to the crown. Edward, educated at Westminster, was taken by his father at the battle of Wakefield, assumed his title, and having entered London after his victory over the Lancastrians at Mortimer’s Cross in February 1461 was declared king by acclamation. Soon after a much fiercer conflict it was necessary for him to fight for his crown against an army of 60,000 Lancastrians, assembled in Yorkshire; and the field of Towton confirmed his title by a decisive victory. Although the high-spirited Margaret was enabled by the aid of Louis XI of France again to take the field, the result of the battle of Hexham, in May 1464, obliged her to return to Flanders, and leave her husband, the imbecile Henry VI, a prisoner in the hands of his enemies. By a marriage with Elizabeth Woodville, widow of Sir John Grey of Groby, of the Garter, he incurred the ablest opponents whom he had to face himself into very serious difficulties, since at the same time he had despatched the Earl of Warwick to negotiate a marriage for him with Bona, sister to the Queen of France; so that he at once offended two royal houses and his powerful friend Warwick. Aided by France, Warwick, who had contracted his daughter to the Lancastrian Prince Edward, landed with Clarence and some other lords at Dartmouth; and quickly saw himself at the head of 60,000 men, with whom he marched to encounter Edward. The king left Warwick in full possession of his kingdom, 11 days after he had set his foot in it. Henry’s title was again recognized by Parliament, and Warwick and Clarence were declared regents of the kingdom. Edward subsequently invaded Yorkshire, where he was met by the victorious Edward, who totally defeated her at Towkesbury. The story is told that the queen and her son Edward being taken prisoners and brought into the presence of the victor, Edward asked the latter how he dared to invade his dominions. On receiving a spirited answer he basely struck the captive prince on the face with his gauntlet—the signal for immediate massacre by the king’s brothers and other nobles attendant. Margaret was thrown into the Tower, where Henry VI soon after died, but whether by violence or by disease is uncertain. The latter part of his reign was disturbed by his jealousy of his brother Clarence, whom he put to death, it is said, by drowning in a butt of Malmsey wine. He had ten children, seven of whom survived him. His reign was marked also by commercial enterprise, notably the introduction of printing and silk manufactures; and by prog-

EDWARD V, king of England: b. Westminster, 2 or 3 Nov. 1470; d. London 1483. He was the eldest son of Edward IV, and was on his 13th year when he succeeded his father in 1483. He fell into the hands of his uncle, the Duke of Gloucester, the regent who caused the young king and his brother to be sent to the Tower, and, it is said, had them smothered by murder. Two boys whose deaths, it is said, were buried at the foot of the stairs of their apartment in the reign of Charles II and were taken up by that king's order, and deposited in Westminster Abbey.

EDWARD VI, king of England: b. Hampton Court, England, 12 Oct. 1537; d. Greenwich, 6 July 1553. He was the son of Henry VIII by Jane Seymour. At his father's death he was only ten years of age, and as he did not live to attain majority, the public acts of his reign are to be deemed those of his counsellors. His education was entrusted to men of the finest character for learning, among whom was Sir John Cheke. He was studious, somewhat retiring, devout, and showed a decided preference for the reformed doctrines, and antipathy to those of the Roman Catholic Church. Protestantism made rapid advances in the kingdom. The churches were divested of images, Henry's 'Bloody Statute' was repealed; Crammer and Ridley were ordered to prepare a new service book which was authorized for use in the kingdom. On his father's death his maternal uncle, the Duke of Somerset, became protector. He sent forces against Scotland under Seymour to punish that government for its refusal to consent to the marriage of Mary Queen of Scots to Edward. The Scots were defeated at Pintock. He raised up such powerful enemies, among them John Dudley, Earl of Warwick, that he was brought to the scaffold with the king's consent (1553). After his death, Dudley, who had boasted of Northumberland, became all-powerful, and through his influence Edward, in a declining state of health, was induced to set aside the succession of both his brothers, and to settle the crown upon Lady Jane Grey, claiming through his father's youngest sister, the Duchess of Suffolk. Edward's principal benefit to the kingdom was in the restoration of the grammar schools. Consult Innes, 'England under the Tudors' (London 1905).

EDWARD VII (Albert Edward), King of Great Britain and Ireland and Emperor of India, b. Buckingham Palace, 9 Nov. 1841; d. 6 May 1910. He was the eldest son and the second child of Queen Victoria and the prince consort, Prince Albert of Saxe-Coburg. After receiving a careful education under private tutors he studied at the universities of Edinburgh, Oxford, and Cambridge. In the summer of 1860 he visited Canada, where he was enthusiastically received and by special invitation of President Buchanan extended his visit to the United States, where his reception was no less splendid. He was appointed to the ranks of the army in 1858 and three years later was attached to the Curragh Camp in Ireland. In October 1861 he was made a bencher of the Middle Temple. In 1862 he was promoted to the rank of general and in the spring of that year he set out on a visit to Egypt, Palestine, Syria and Athens. After the Prince's return from the East he was introduced at the privy council, in 1863 he took his seat in the House of Lords and about the same time formally gave up his right to succeed to the Duchy of Saxe-Coburg-Gotha. On 10 March 1863, at St George's Chapel, Windsor Castle, he was married to the Princess Alexandra, eldest daughter of the King of Denmark. Near the end of 1871 he was attacked by typhoid fever and for a time it seemed as if his death was imminent. In 1875-76 he made a tour in India and was everywhere received with the utmost cordiality and respect. With the Prince he made an extended tour through Ireland in 1885. The establishment of the Imperial Institute as a memorial of the jubilee of Queen Victoria (1887) was mainly due to his suggestion.

In 1893 he sat on the Poor Law Commission. In the diamond jubilee year (1897) he established the Prince of Wales Hospital Fund for the better financial support of the London hospital. By the death of his mother on 22 Jan. 1901, he became King of Great Britain and Ireland and Emperor of India and elected to be known as Edward VII.

Elaborate national and international preparations for the coronation ceremonies in Westminster Abbey were made from 26 June 1911; but owing to sudden illness these had to be postponed and were carried through in a modified form on 9 August.

The new king thus came to the throne in his sixtieth year. He found foreign opinion alienated by the Boer War and he set himself strenuously to promote international amity. In some measure at least the growing friendliness between his country and France and Russia was due to his efforts to promote good will and in his last years he viewed with deep concern the coolness that was springing up between Germany and England. Owing to his close family kinship with most of the crowned heads in the Old World, French wits styled him the "uncle of Europe." Brought up on a very narrow system of education in which even the perusal of history was forbidden, he was never acquired a taste for reading, but possessed uncommon natural powers of observation. Denied intercourse with boys of his own age and disciplined with a Spartan severity, it was only natural that his manhood and freedom came he should travel far from the rigid traditions in which he had been reared. The breath of scandal did not leave him unscathed, but his charm of manner, his frankness of disposition and his punctilious discharge of the somewhat formal duties that fell to him as Prince of Wales endeared him to the British public. During the long years of Queen Victoria's widowhood, her growing isolation from public life made of her throne a lonely splendor, and the state of tutelage in which she kept the heir of the British throne and access to confidential documents, prevented him from developing any aptitude for affairs of state. When he came to the throne he revived in a very real sense the ceremonial splendors of the monarchy; he was fond of pageantry and the observances associated with

VOL. 9—45
the stately ordering of court functions, and during his brief reign he completely won the hearts of his people and the respect of the civilized world. His last years were clouded by the feud between Lords and Commons over the rejection by the former of the Budget of 1909 and his untimely death (5 June 1910), due to heart failure supervening on an attack of bronchitis, evoked a wave of sympathy that was worldwide. He had an ideal consort in Queen Alexandra, who performed the duties of her high station with an elegance, sympathy and tact that won her a special place in the hearts of the British public. Consult Sir Sidney Lee's contribution to Vol. I of the second supplement to the 'Dictionary of National Biography' (1912); also Legge's 'King Edward in His True Colours' (1912). To King Edward and Queen Alexandra were born Albert Victor Christian Edward, Duke of Clarence and Avondale, b. 8 Jan. 1864; d. 14 Jan. 1892; George Frederick Ernest Albert, who succeeded to the throne 3 June 1936; married 6 July 1893, to the Princess Victoria Mary of Teck; Princess Louise Victoria Alexandra Dagmar, b. 20 Feb. 1867, married 27 July 1889, to the Duke of Fife; Princess Victoria Alexandra Olga Mary, b. 6 June 1868, and Princess Maud Charlotte Mary Victoria, b. 26 Nov. 1869, married 22 July 1896, to Prince Charles of Denmark, now King Haakon VII of Norway.

EDWARD, Prince of Wales, surnamed the Black Prince, English prince: b. Woodstock, 15 June 1330; d. Westminster, 8 June 1376. He was the eldest son of Edward III and Philippa of Hainault, and at the age of 15 accompanied his father in his invasion of France, and received from him the honor of knighthood. The victory of Crécy, 26 Aug. 1346, which King Edward left principally to the exertions of the force under his son's command, to use that warlike king's language, "showed that he merited his spurs." It was on this occasion that he assumed the motto of Ich dien (I serve), used by all succeeding princes of Wales, and derived, it is said, from the crest of the King of Bohemia, slain in that battle, which tradition, however, later antiquaries seem disposed to discredit. In 1335 he commanded the army which invaded France from Gascony, and the next year fought the great battle of Poitiers, and distinguished himself by the courtesy with which he treated his prisoner, King John. By the Peace of Bretigny his father had obtained the provinces of Poitou, Saintonge, Périgord, Limousin, etc., which he annexed to Guienne and formed into a sovereignty for his son, under the title of the Principality of Aquitaine. There the prince took up his residence; and at his court Pedro the Cruel, the deposed king of Castile, sought refuge, when driven from his throne by his natural brother, Henry of Trastamare. Edward undertook the re-establishment of this tyrant, which he accomplished. Disappointed by the perfidy of Pedro, of the stipulated reimbursement of his men's arrears he was obliged to levy on his new subjects rendered his government unpopular; and an appeal was made to the king of France, as his liege lord, who summoned him as his vassal to appear at Paris. "I will come," replied the monarch, who possessed at the head of 60,000 men. His health, however, was too far declined to enable him to take the field, when the king of France invaded his dominions; and having suffered the mortification of seeing his generals defeated, he withdrew into England, and after lingering some time died in his 46th year, leaving an only son, afterward Richard II. He was buried in Canterbury Cathedral, where portions of his armor were still suspended above his tomb. Consult Dunn-Pattison, 'The Black Prince' (London 1910); Wickers, 'History of England 1272-1485' (ib. 1912).

EDWARD, Thomas, Scottish naturalist: b. Grosport, 1814; d. 27 April 1896. As the apprentice of a shoemaker he spent the early part of his life in Aberdeen, and in 1837 married and settled in Banff. Here he struggled for 40 years in a ceaseless effort to acquire a close knowledge of natural history, while at the same time he supported his wife and 11 children on wages that never exceeded 15 shillings a week. Apart from his laborious work as a shoemaker he collected, described and exhibited numerous specimens of natural history notably of birds and of crustacea. In 1866 he was elected an associate of the Linnean Society of London. A biography of his life by Samuel Smiles (q.v.), appeared in 1876, 'Life of a Scotch Naturalist,' and being thus prominently brought before the public, a pension of £50 a year was conferred upon him by the queen.

EDWARDS, Sr Herbert Benjamin, British soldier and administrator: b. Frodsham, Cheshire, 1819; d. 1868. He received his education at King's College, London, and entered the Indian army in 1840. He served on the staff of Sir Hugh Gough in the First Sikh War in 1845-46 and in 1847 became first assistant to Sir Henry Lawrence, the British resident at Lahore. In 1848 he suppressed an uprising in Mooltan and for his services received the thanks of Parliament and was brevetted major. He rendered splendid services during the Indian Mutiny of 1857 by securing the neutrality of Afghanistan, thus permitting troops to be withdrawn from the northwest border and rushed to the relief of Delhi and Lucknow. Because of falling health he was obliged to decline the governorship of the Punjab, tendered him in 1862 and to return to England. In 1865 he was made a major-general a short time before his death. Banu, Punjab, was renamed in his honor, Edwardesabad.

EDWARDS, Amelia Blanford, English Egyptologist and novelist: b. London, 1831; d. Weston-super-Mare, Somerset, 15 April 1892. Her novels include 'My Brother's Wife' (1855); 'Hand and Glove' (1859); 'Half a Million of Money' (1865); 'Lord Brackenbury' (1880); 'Barbara's History,' and 'In the Days of My Youth' (1873). Later she achieved great celebrity through her writings and lectures in Europe and the United States on the antiquities of Egypt; her best-known works in this field are 'A Thousand Miles Up the Nile' (1877); and 'Pharaohs, Felkahs and Explorers' (1891). She also translated Maspero's work on 'Egyptian Archaeology,' and was secretary of the Egyptian Exploration Fund.

EDWARDS, Arthur, American clergyman and editor: b. Norwalk, 1834; d. 1901. In 1858 he was graduated at Ohio Wesleyan University and in the same year entered the ministry of
the Methodist Church. In the Civil War he served as chaplain of the First Michigan Infantry until after the battle of Gettysburg. In the following year he was made assistant editor of the Northwestern Christian Advocate of Chicago and from 1872 until his death he was editor. He attended seven general conferences of the church and the ecumenical Methodist conference at London in 1881, before which he read a paper on 'The Status of Methodism in the Western Hemisphere.' In 1876 he was a member of the committee which revised the Church manual. He also served as secretary of the Detroit Conference for about 12 years. At the general conference of 1868 he edited the Daily Christian Advocate.

EDWARDS, Bryan, English historian of the West Indies: b. Westbury, Wiltshire, 21 May 1743; d. Southampton, 15 July 1800. On the death of his father he was taken under the care of an uncle in Jamaica, who left him a large fortune. After a successful mercantile career he returned to England, and in 1796 took his seat for the borough of Grampound, which he represented until his death. He is remembered for his 'History of the Civil and Commercial History of the British Colonies in the West Indies' (1793). A new edition of this work (1801) includes a history of San Domingo. He also published 'Proceedings of the Governor and Assembly of Jamaica in regard to the Maroon Negroes' (1796).

EDWARDS, Charles Lincoln, American scientist: b. Oquawka, Ill., 8 Dec. 1863. He was graduated at Lombard University in 1884; Indiana University, 1886; and the University of Leipzig 1890. He was fellow of biology in Clark University, 1892-93; associate professor of biology in the University of Texas, 1893-94; professor of biology in the University of Cincinnati, 1894-1900; professor of natural history in Trinity College, 1900-10; and associate professor of biology in the University of Southern California, 1911-12; professor of embryology and histology, medical department, University of Southern California, 1912-13; director of nature-study, Los Angeles city schools after 1912. He was president of the American Folk-Lore Society in 1896. He has published 'Ballads, Songs and Stories' (1895), and many papers and monographs on subjects in biology, embryology, folk-lore, etc.

EDWARDS, Clarence Ransom, American military officer: b. Cleveland, Ohio, 1 Jan. 1860. He was graduated at West Point in 1883; professor of military science and tactics at Saint John's College, Fordham, 1890-93; commissioned first lieutenant, 1891; captain, 1898; lieutenant-colonel of volunteers, 1899; served on the staff of General Lawton in the Philippines, and was recommended for brevets of major, lieutenant-colonel, and colonel in the regular establishment, and brigadier-general of volunteers; accompanied General Lawton's body to the United States; chief of the division of insular affairs, War Department, 1900-02; commissioned colonel, 1 July 1902, and chief of the bureau of publications, 1904; formed the bureau of publications, until 1912. He became brigadier-general 30 June 1906; transferred to line in 1912, and later commanded the Sixth Brigade, Second Division at Texas City, Tex., and the First Hawaiian Brigade at Honolulu, H. I. In 1915 he was placed in command of the troops in the Panama Canal Zone.

EDWARDS, George Wharton, American artist and author: b. Fairhaven, Conn., 1859. He was educated in Antwerp and Paris, and has received many medals and honors for his work at American and European exhibitions. His watercolors are particularly praiseworthy and his magazine illustration is well known and of a high quality. He has published 'Thumbnail Sketches' (1886); 'P'tit Matinici and Other Monotones' (1887); 'The Rivalries of Long and Short Codiac' (1888); 'Break o' Day, and Other Stories' (1889); 'Holland of Today' (1910); 'Reading Journey in the Hollow Land, Chautauqua' (1910); 'Brittany and the Bretons' (1911); 'Marken and its People' (1912); 'Some Old Flemish Towns' (1913); 'The Forest of Arden' (1914); he has illustrated Oliver Wendell Holmes' 'Last Leaf' (1885); Austin Dobson's 'Sun Dial' (1892); Spenser's 'Epithalamion' (1895); 'Old English Love-Songs' (1896); 'Old English Ballads' (1897); 'Hans Brinker and the Silver Skates' (1915). He is a member of The American Society of Water Colorists; New York Water Color Club; The Authors Club, and the Society of Arts. He painted the mural decoration 'Henry Hudson' in the West Point Military Academy.

EDWARDS, Harry Stilwell, American journalist and novelist: b. Macon, Ga., 23 April 1855. He was graduated from the law department of Mercer University but in 1881 entered journalism in his native city. He is well known as a writer of magazine stories most of which relate to life in the South, and of numerous songs and poems. Among his works are 'Two Runaways and other Stories' (1889); 'His Defense and other Stories'; 'Sons and Fathers' a novel that won a prize of $10,000 in a worldwide contest over 800 manuscripts; and 'The Marbeau Cousins.' His lullaby song 'Mammy's Little Boy' and poem 'The Vulture,' have a more than national reputation. In 1894 in Chicago he seconded the nomination of Theodore Roosevelt in a notably eloquent oration. He was reeve in Georgia for the seven years of Roosevelt's administration and served as postmaster at Macon, Ga., for 13 years, to which office he was appointed first by President McKinley. He is a member of the National Institute of Arts and Letters.

EDWARDS, Henri Milne-. See MilnE-EDWARDS.

EDWARDS, James Corson, American poet: b. Philadelphia, Pa., 17 July 1802; d. Macon, Ga., April 1861. He moved to Georgia in 1821, and was a poet at one time. He was author of 'An Ode To Music' and much verse preserved chiefly in southern school readers; also of many campaign songs in Whig circles.

EDWARDS, James Thomas, American educator: b. BarNEGat, N. J., 6 Jan. 1838; d. Randolph, N. Y., 20 Aug. 1914. He was graduated at Wesleyan University in 1850. He served in the National army in the Civil War, was afterward principal of several schools, and in 1892-93 was field-secretary of the Chautauqua System of Education. He was a senator in the Rhode Island legislature, 1865-69, and a mem-
ber of the New York legislature, 1892–93; was chairman of the committee on education of both bodies; and was a member of the University bill and Library and Traveling Library bills. He was a trustee and director of the departments of physics and chemistry of the Chautauqua summer schools 1883–93, and was prominently identified with other educational movements. He published 'The Grass Family' (1872); 'The Silva of Chautauqua Lake' (1892); 'Addresses—Educational, Political, Scientific, Religious' (1896); 'Pen and Picture' (1896); 'Rhymes from a Reclining Chair' (1902); 'The Edwards Family' (1903); and articles to various periodicals.

EDWARDS, John Passmore, English newspaper proprietor: b. Blackwater, Cornwall, 24 March 1823; d. Hampstead, 22 April 1911. The son of a carpenter, he began life as a publisher's clerk, became absorbed in public questions, and was a delegate to the peace conferences at Brussels, Paris and Frankfort, 1848–50. His early publishing ventures were failures; but success came to him after he acquired in 1876 the London Echo, the first halfpenny evening Journal in London, which he edited with marked success for 20 years, and kept 'clear of all doubtfull matter and betting news. He represented Salisbury as a Liberal 1880–85, but seceded from Mr. Gladstone on the Home Rule issue, and retired from politics. He showed a wise discrimination as well as generosity in the use of his wealth, and founded upwards of 70 public institutions, including libraries. His autobiogaphy was privately printed in 1905, under the title 'A Few Footprints.'

EDWARDS, Jonathan, American theologian: b. in South (then East) Windsor, Conn., 5 Oct. 1703; d. Princeton, N. J., 22 March 1758. His father, the Rev. Timothy Edwards, a graduate of Harvard, was parish minister at Windsor for nearly 60 years. His mother, Esther Stoddard, a daughter of the Rev. Solomon Stoddard, minister in Northampton, Mass., is celebrated for force of character and native wit. There were 10 other children in the family, all girls. Jonathan, the fifth child, was brought up with his sisters in an environment peculiarly adapted to his development. The quiet beauty of the landscape about Windsor and the outward simplicity of the life in the village and the home, where the interests of recognized supremacy were those of the spirit and the mind, exerted congenial influence on a character pre-eminently disposed to reflection and to the feeling and practical acknowledgment of things invisible. Religion, both in its experimental and in its theoretical aspects, early became his absorbing preoccupation. The precocity of his intellectual development is shown in his first essays, a metaphysical tract on the nature of the soul, written when he was 10, and a paper, remarkable for accuracy of observation and acuteness and breadth of reasoning, on the habits of the "flying spider," written some two years later. At 13 he entered the Collegiate School at Saybrook, afterward Yale College, from which he graduated at New Haven, with the valedictory in a class of 10, shortly before his 17th birthday (1720). The event of greatest intellectual significance for Edwards, and one which may even be said to mark a turning-point in the history of philoso-

phy in America, was his reading, in his sophomore year in college, of Locke's 'Essay on the Human Understanding.' The book made an impression on him a profound impression. He read it, he tells us, with a pleasure far higher than that of the greediest miser gathering up handfuls of silver and gold from some newly discovered treasure. He also wrote a series of notes with a view to a corresponding treatise on natural science. These notes, some of which probably belong to the years immediately following his graduation, though some of the most important almost certainly go back to an earlier date, throw a flood of light on the whole subsequent development of his thinking, as well as on the character and workings of his mind at the period of their composition. The notes on natural science, indead, as valuable as they are as evidence of his genius, express in their main contents only an incident in his thinking. But the psychology and philosophy of both series of notes, especially the notes on the mind, are intimately connected with his theological interests. Here the influence of Locke is marked, but more striking still the originality of the writer's response to it. Edwards accepts Locke's empiricism only in part. He makes all our ideas 'begin from' sensation; he recognizes distinctly the influence of the mechanism of association and the part played by 'images' in the higher intellectual processes. But he is very far from regarding mind as constituted of passively received impressions and their copies. He emphasizes rather the intellectual elements in Locke's doctrine; his tendency is toward Kant rather than toward Hume. The mind is, in his view, essentially active, in pleasure and pain, in sentiment and emotion, as well as in judgment and choice. In its intellectual constructions, moreover, the mind is guided by intuitively certain principles (being, cause, finality, etc.) and is capable, by reflection, of rising above all things sensible to the contemplation of things spiritual and eternal. Universals are not all of pragmatic origin and capacity for judgment; the most considerable species have their foundation in 'the order of the world.' The most noteworthy metaphysical advance beyond Locke lies in the idealistic theory of matter. The general conception was not new; already in the 18th century, before the earliest of these notes were written, Norris, Collier and Berkeley had propounded similar views. Edwards may have heard of their writings, but it is doubtful if he had read any, and practically certain he had not then read Berkeley. However suggested, the doctrine is worked out in a thoroughly independent fashion and the expression of it is wholly original; the true substance of the material universe is declared to be God and its esse not percipi, but an 'infinitely exact and precise divinity.' It is also made possible, perfectly exact and stable Will, with respect to correspondent communications to created minds, and effects on their minds.
JONATHAN EDWARDS
With him the fundamental ontological verity is "that God and Real Existence are the same." "That God is" and that "there is none else." Created spirits are "emanations" or "communications" of his Being. What other conception than his, a love for the beauty of too, like material things, consist in God's distinguishing Thought and stable Will?

Edwards seems to have had no occasion to refer in his later writings to the idealistic theory of matter so pronounced in these notes of his youth. He was, however, traditionally exposed, like too, like material things, consist in God's distinguishing Thought and stable Will.

Edwards then remained two years in New Haven studying for the ministry. He then preached for several months to a small Presbyterian church in New York. He was admitted to New Haven, took his master's degree, and preached for two years (1724-26) in the college. He had declined several invitations to a settlement in the ministry and seemed definitely committed to the academic career, for which by training and intellectual gifts he was eminently qualified, when the call came to him from the church in Northampton, Mass., to become the colleague of the venerable Solomon Stoddard, his grandfather. He was installed at Northampton, 15 Feb. 1727. A few months later he married Sarah Pierrepont, of New Haven, then 17, of whom four years before he had written an admiring description, celebrated as one of the most perfect and charming of its kind in literature.

The moral and religious development of Edwards up to this period was as remarkable for richness and intensity of spiritual energy as was his intellectual development for originality, acuteness and speculative power. In a narrative of personal experience, written for his own use, we have the intimate record of his religious life from its early beginnings, when as a boy he built with other boys a booth in a swamp for daily prayer and had other places for his own devotions besides, through its decline and revival—his "conversion," it has been called, though, as he notes with some misgiving in his diary, he was never converted in the manner of certain more traditionally exposed, like too, like material things, consist in God's distinguishing Thought and stable Will.

On the dead of Mr. Stoddard in 1729, Edwards, then 23, became sole pastor of the church in Northampton, which was the reputed largest and wealthiest in the colony outside of Boston. In 1731 he preached in the public lecture in Boston the sermon, "God Glorified in Man's Dependence," with which he achieved a notable success. The sermon is an eloquent and impressive proclamation of one of the most fundamental articles of the faith, of God's "absolute sovereignty" in the work of salvation: it was a prophet's call to the Puritan churches to return to the old high Calvinistic faith. The counterpart to it is the sermon, published in 1734, on the "Reality of Spiritual Light," which proclaims the mystical principle of a supernatural illumination directly imparted and experienced. The emphasis on religious experience becomes still more pronounced in the two great revivals with which the fame of Edwards as a preacher is associated; he wrote the story of the earlier revival, that of 1735 in Northampton, in his "Narrative of Surprising Conversions" (1736), with confident, even exultant, assurance; the excesses of the "Great Awakening" of 1740, more extensive and tumultuous, led him to reflect on such experience between a genuine and a false experience ("Distinguishing Marks of a Work of the Spirit of God," 1741), and then to an apologetic defense of the movement against the objections of its opponents ("Thoughts on the Revivals," 1742). It was in the height of the excitement
that he preached in Enfield, Conn., his sermon on 'Sinners in the Hands of an Angry God' (1741), the extreme representative of a type not uncommon with him, indeed, yet not the most common nor the most representative even in his most usual preaching (consult for example the sermons 'Justification by Faith,' etc., 1738). More noteworthy and far more original was the treatise on the 'Religious Affections' (1746), in which the distinctively new note in Edwards, the new emphasis on subjective experience, received its most striking expression. In the reaction which followed the revival, a case of discipline arose in his parish—many of the young people being charged with reading and circulating immoral books—the unfortunate management of which caused strong re- sentment and permanently undermined his influence. This was in 1744. Four years later, on his attempt to set aside the established custom—an extension of the old 'Half-way Covenant' of which Mr. Stoddard had been the chief advocate—for full communion, a credulity of godliness, the disaffection became a bitter and determined opposition. The controversy ended finally in his dismissal, 22 June 1750, after a ministry of 23 years, perhaps the most laborious and dis- tinctively his in the annals of the American churches. His 'Farewell Sermon,' the greatest of his discourses, is a noble expression of his character and the dignified apologia of his ministerial life. Early in the following year he removed with his family to Stockbridge, Mass., from a settlement on the frontier, to do the double work of pastor of the village church and missionary to the Indians. It was while thus engaged that he wrote, during the seven years of his residence in Stockbridge, the theo- logical treatises and essays which are the solid foundations of his fame. In the autumn of 1757 he accepted, with some misgivings, a call to the presidency of the college in Princeton, N. J., made vacant by the death of his son-in-law, the elder Aaron Burr. He had scarcely entered upon the duties of this office when he fell a victim of inoculation for smallpox, 22 March 1758.

The least episodical of thinkers, Edwards wrote no system of philosophy or body of divinity. His scattered sermons and treatises can be gathered from the large proportions of his various writings on special topics, mainly contro- versial. The professed aim of the major part of these writings is to defend the dis- tinctive doctrines of Calvinism against the rising tide of Arminianism in the churches inheriting the Calvinistic tradition. He brought to this task a power of keen and relentless dia-lectic that left no loophole of escape to one who accepted his premises and that fairly wearied and overwhelmed the opponent with the multitudinous array of the argument. He brought also, what more contributed to the originality of his thought, the spirit and pro- found insights of the speculative philosopher, seeking to ground his theology in metaphysics. Finally, the rich religious experience which gave the sys- tem for him perpetual practical verification and which certainly, with his moral enthusiasm and vivid imagination, gave it, in his hands, much of its vitality. The central conception about which all his thinking moves is the conception of the absolute sovereignty of God. Metaphysically, God is the sole Reality. Neither Par- menides in ancient, nor Spinoza in modern, phi- losophy, is more emphatic in the assertion of the One Absolute Reality than Edwards. He, however, is the Deity, God, the Abs- olute Reality, is with him—it is easy to see that the tradition here blends with his metaphysics —spiritual, personal—tripersonal—and su- premely excellent. In his 'Essay on the Trini- ty' (1903) he develops the doctrine that the Father is a perfect in prime subsistence, the Son the Deity sustaining in the act of God's Knowledge of himself and the Holy Ghost the Deity subsisting in the act of God's infinite Love and delight in himself. This Love of God, which is thus his consummating, essen- tially Excellency, is primarily the love of com- placency in the perfection of his Being; but it may be viewed also as benevolent, so far, namely, as it embraces the complete content of the divine Idea in God's Knowledge of him- self, and so far as the creative idea of the Father is, in itself the creative plan of the world and the evolution of its history. Now it is the pro- found thought of Edwards' dissertation on the 'End for Which God Created the World' (written 1755), the most speculatively philosoph- ical treatise of the 18th century, that every truth, the fact, God finds in himself a disposi- tion to produce an emanation from himself in which to reflect his glory and express outwardly his delight in his own excellency. The final end of creation is, therefore, the manifestation of the divine glory in a perfect spiritual soci- ety. In his 'History of Redemption,' Edwards endeavors with, to be sure, very inadequate knowledge and, for us, impossible dogmatic as- sumptions, but with a genuine philosophical pur- pose, to trace the process through which this end is realized in time. The *emanation,* or passage into time, of the eternal world-plan, he represents, in his essay on 'Decrees and Election,' as an act of divine Will, the preser- vation of the world being a perpetual and con- tinued creation. Beyond this indication of a nexus in the divine Will between the world-plan in idea and in process of realization, Ed- wards does not go; he develops no theory of the metaphysical relation of the temporal and eternal. Of his ideas that are preserved, note that the divine Decree conforms to, indeed is determined by, the divine Wisdom—what must evidently be taken into account in interpreting the many passages in his writings in which he speaks of God's *arbitrary* Will and of his *mere good pleasure.* Edwards' early idealism with respect to matter is in thorough agreement with this doctrine of creation, but is not now in question. His whole concern now is with the divine plan relative to man. The problem of supreme interest here, of course, is the problem of moral evil. No one has depicted the nature, extent and consequences of sin in stronger lan- guage than Edwards. Sin is with him literally a guilty disposition inherent since the Fall in man's very constitution, as that even infants, that seem innocent and the young vipers, so that the whole race inherits it, and, in the absence of *special* grace, which is bestowed only on the definite number of the elect, inevitably tends to horrible and everlasting destruction. Notwithstanding that all this is held to be included in the creative plan, Ed-
wards nevertheless strongly insists on the sinner's responsibility. In his treatise on 'Original Sin' (1758), he brushes aside the legal fictions with which that doctrine was commercialized, and carries the Augustinian position that the whole race was really present and really participated in Adam's transgression—a notion which involves him in curious and intricate speculations concerning personal identity. Thus, notwithstanding his warnings, the treatise on 'Freedom of the Will' (1754), discusses from other points of view the same general problem of the relation of the creative Decree to the moral life of man. His object in this work was to refute the notion that the will in choosing is so undetermined with respect to its motives as to be able to initiate acts really contingent and, therefore, incapable of being included in God's determinate foreknowledge and decree. He does not deny the fact of choice; 'faculty of choice,' indeed, is his definition of will. But he contends that this faculty is always determined in its preferences by the strongest motive, 'is always as the greatest good is.' The connection of such motive and choice is necessary. But the necessity of this connection can only be considered in the liberty to do as one pleases, without hindrance or impediment. He modifies, indeed, the usual Calvinistic doctrine, declaring in one of his letters that man now, even after the Fall, has all the liberty that God had. His chief attack is against the notion that will is self-determined, that is, that it determines itself to will, a notion which, thus stated, leads, as he shows, to the infinite regress. But there is nothing in his contention to preclude the idea that it is the whole concrete nature of a self which determines the act of choice. His whole argument, in fact, is based on the thorough-going application of the law of sufficient reason. Each act of will has its reason, or, as Edwards, suggesting a naturalistic interpretation not intended, says, its "cause," from which it follows with "logical" or "moral" necessity. God's Will even is no exception. Human responsibility for sin is not dependent on the way the volition is motivated, but on the evil nature of the decision. The ultimate ground or reason of all volition is the divine Idea, comprehending the world-plan, within which every finite being has his place and the realization of which is the effect of the divine decree. God is thus, in a sense, the author of sin, yet not so, as in the case of the human will, that his Will is evil, but so that He, being sovereignly good and perfect and creating the world for a supremely good end, permissively decreed the evil foreseen as comprehended in this purpose.

Thus Edwards, absolutist in metaphysics, ever comes back in his theology to the conception of God as sovereign Power, Wisdom and Love, whose "decrees," determining that the world-plan shall be realized, are the foundation of an all-inclusive optimism. Had he developed his thought to a pure philosopher, his system would doubtless have assumed a very different character in details and in some of its main conclusions. As it was, he blended his philosophy with his theology and his theology with his philosophy and both with a conception and interpretation of Scripture that modern criticism regards as untenable. And although the sharp antitheses in which his system abounds are all reconciled in his thought of God's goodness and eternal decrees, as he lacked the mediating conceptions with which some more modern doctrines have made us familiar, this reconciliation is at the cost of faith rather than of reason. These defects, however, will not blind the sympathetic student of opinion to the essential strength and largeness of his general scheme of thought. His historical influence extended mainly into two directions. On the one hand, the speculative and logical power with which he worked out his fundamental conception made him the chief of a school of theologians in New England—Hoppin, Emmons, the younger Edwards, Dwight, etc.—who, with less logical acumen and less speculative ability, sought to carry out his principles and particularly so to formulate the Calvinistic system as to make it appear better accords with popular notions of the goodness of God and human responsibility. On the other hand, by his doctrine of "spiritual light" and by the emphasis he put on conversion and the religious affections, he powerfully furthered the movement which, laying special stress on religious experience, tends to discard dogmatic assumptions altogether, with the liberty to do as one pleases, without hindrance or impediment. He modifies, indeed, the usual Calvinistic doctrine, declaring in one of his letters that man now, even after the Fall, has all the liberty that God had. His chief attack is against the notion that will is self-determined, that is, that it determines itself to will, a notion which, thus stated, leads, as he shows, to the infinite regress. But there is nothing in his contention to preclude the idea that it is the whole concrete nature of a self which determines the act of choice. His whole argument, in fact, is based on the thorough-going application of the law of sufficient reason. Each act of will has its reason, or, as Edwards, suggesting a naturalistic interpretation not intended, says, its "cause," from which it follows with "logical" or "moral" necessity. God's Will even is no exception. Human responsibility for sin is not dependent on the way the volition is motivated, but on the evil nature of the decision. The ultimate ground or reason of all volition is the divine Idea, comprehending the world-plan, within which every finite being has his place and the realization of which is the effect of the divine decree. God is thus, in a sense, the author of sin, yet not so, as in the case of the human will, that his Will is evil, but so that He, being sovereignly good and perfect and creating the world for a supremely good end, permissively decreed the evil foreseen as comprehended in this purpose.

HARRY NORMAN GARDINER, Professor of Philosophy, Smith College.
filled at the time of his death. He was the author of a treatise on ‘Liberty and Necessity’ (1797); and ‘Discourses on the Atonement’ (1783), which were published with a memoir by Thomas Edwards of Cheddar, 1842.

EDWARDS, Matilda Barbara Betham-See Betham-Edwards, MATILDA.

EDWARDS, Ninian, American political leader: b. Montgomery County, Md., March 1775; d. Belleville, Ill., 20 July 1833. He was graduated at Dickinson College, moved to the Green River district, Ky., studied law, and was admitted to the bar in Kentucky and in Tennessee. He rose rapidly in his profession, was judge of the General Court of Kentucky, of the Circuit Court and of the Court of Appeals, and chief justice of the State Supreme Court. In 1809 he was appointed governor of the newly organized territory of Illinois, and held that office till Illinois was admitted as a State. During his administration he organized companies of volunteer rangers and built a line of stockade forts which were of special value in the border wars with the Indians and in the War of 1812. In 1818 he was one of three commissioners appointed to treat with the Indian tribes. In 1818 he was elected to the United States Senate from Illinois and served six years; and in 1826 he was elected governor of the State, holding that office till 1830. Consult Edwards, ‘History of Illinois and Life of Ninian Edwards’ (1870).

EDWARDS, William, American inventor: b. Elizabeth, N. J., 11 Nov. 1770; d. Brooklyn, N. Y., 1 Dec. 1851. After receiving a common school education he learned the tanning trade and built his own tannery at Northampton, Mass., but eventually settled in Hunter, Greene County, N. Y. Here he opened a model tannery, with improvements in manufacturing appliances originated by himself. His principal invention was a leather-rolling machine which saved the labor of hammering. He invented other machines and utilized water power to such an extent as practically to revolutionize the tanning business in the United States, improve the quality of shoe leather and cheapen its cost. His ‘Memoirs’ were published in Washington (1897).

EDWARDSVILLE, Ill., city, county-seat of Madison County, on the Illinois Terminal, the T. St. L. & K. C. and the Wabash railroads, about 70 miles southwest of Springfield and 20 miles northeast of Saint Louis, Mo. It is the centre of a coal mining and agricultural region. The chief industries are the manufacture of tools and hardware. Edwardsville was the former location of the Kickapoo Agency, which was the instrument in accomplishing the transfer of a large part of the present central United States from the Indians. Pop. 5,014.

EDWIN, king of Northumbria: b. about 585; d. 633. He was the son of Ella, who seems to have ruled that kingdom from 559 to 589. Being an infant at his father’s death the crown was seized by Ethelrith of Bernicia. The young prince was sent for protection to the king of Mercia, but in 616 Edwin, king of East Anglia, by whose aid he was eventually put upon the throne (617). He organized the kingdom of Northumbria and greatly extended his dominions, until they reached Edinburgh on the north. He married Ethelburga, daughter of Ethelbert of Kent, and by her influence and that of Paulinus, a Roman missionary whom she had brought from Rome, he caused his court to embrace Christianity and make it the religion of his people. He was baptized in 627 at York, where he built the first church of wood. The Mercians, under Fenda, revolted against the supremacy claimed by the Northumbrians, and the war which ensued was decided at Heathfield or Hatfield in Yorkshire, in which Edwin was defeated and slain. Consult Green, ‘The Making of England’ (London and New York 1881).

EDWIN DROOD. See MYSTERY OF EDWIN DROOD.

EDWY, or EADWY, king of England: b. about 938; d. 955. He was the son of Edmund I and succeeded his uncle Edred in 955. Taking part with the secular clergy against the monks he incurred the confirmed enmity of the latter. Having called Dunstan to account for his share in the administration in 952,670 he was one of three commissioners appointed to treat with the Indian tribes. In 1818 he was elected to the United States Senate from Illinois and served six years; and in 1826 he was elected governor of the State, holding that office till 1830. Consult Edwards, ‘History of Illinois and Life of Ninian Edwards’ (1870).

EDWY, or EADWY, king of England: b. about 938; d. 955. He was the son of Edmund I and succeeded his uncle Edred in 955. Taking part with the secular clergy against the monks he incurred the confirmed enmity of the latter. Having called Dunstan to account for his share in the administration in 952, he was one of three commissioners appointed to treat with the Indian tribes. In 1818 he was elected to the United States Senate from Illinois and served six years; and in 1826 he was elected governor of the State, holding that office till 1830. Consult Edwards, ‘History of Illinois and Life of Ninian Edwards’ (1870).

ECKHOUT, erekhout, or ECKHOUT, Gerbrand van den, Dutch painter: b. Amsterdam, 19 Aug. 1621; d. there, 22 July 1674. He was one of the pupils of Rembrandt and in some measure successful in imitating his manner, especially in the early part of his life. He excelled chiefly in painting portraits and these as well as his historical pictures abound in the best collections of Holland, while several of them are to be found in Germany. Among his most representative portraits are ‘A Man and a Woman in Black’ (Dresden Gallery), and the portraits of Dapper, the historian (Frankfort), and Jan de Witt (Grenoble Museum). Of his religious subjects may be mentioned ‘The Presentation in the Temple’ (Dresden Gallery); ‘Jacob’s Dream’ (ib.); and ‘The Raising of Jairus’ Daughter’ (Berlin Museum).

EECLOO, ereklo, Belgium, town in province of East Flanders, 11 miles northwest from Ghent, near the Liéue. The manufactures are chiefly woolens, cottons, lace, hats, tobacco, chocolate, soap and starch; and it has breweries, distilleries, salt-refineries, dye-workshops, and an active trade in grain, linen, cattle and timber. Pop. 13,536.

EEDEN, a’den, Frederik van, Dutch author: b. Haarlem, 1860. He was educated at the University of Amsterdam and settled as a practising physician at Büssum. His first work, ‘De kleine Johannes’ (1887; 6th ed., 1900), was a very popular story of animal life. Other important works from his pen are the poems ‘Johannes Viator’ (1892); ‘Ellen’ (1891); ‘De passiebloos Lelie’ (1901); ‘Enkel in een hoeren’ (1898); ‘Van de Koele Man die des doods een novel (1900); and the dramas ‘Ysbrand’ (1910) and ‘Lioba’ (1912).

EEKHOUD, erekhowt, Georges, Belgian novelist and poet: b. Antwerp, 27 May 1854. He
first published two volumes of poetry, 'Myrtes et cyprès' (1876) and 'Les pittoresques' (1877); then became a newspaper literary critic in Brussels and wrote several short stories. His first noteworthy novel, 'Le miracle de Saint-François' (1886), is a masterly portrayal of Flemish peasant life, especially its naive mystic religiousness. His masterpiece, 'La nouvelle Carthage' (1888), paints Antwerp life in broad strokes. Other notable works of his are 'Les fusillés de Malines' (1890), a story of the peasants' uprising against the French in 1798, and 'La faneuse d'amour' (1900), and 'L'Autre yue' (1905). In poetry he has developed from romanticism to pronounced realism.

**Eel**, the general name given to a variety of teleostomous fishes of diverse structure and resembling one another chiefly in their elongated form, soft rayed fins and the tendency for the paired fins to become reduced in size. Although their so-called habitat of which the eel-like fishes are liable to be overlooked, and it is evident that many remain undiscovered, the number and diversity of those already known are very considerable. Ichthyologists have arranged them in numerous families and several orders, which Prof. E. D. Cope regarded as forming a series degenerate in respect to the gradual loss of the paired fins and certain ossifications of the skull, and in the simplification of the gill arches. According to the classification of Jordan and Evermann, most of the eels fall within the order Apodes, the others chiefly within the Plectrobranchia and Carencely. The common eel or fresh-water eel (Anguilla chrysa) belongs to the first order and the family Anguillidae. It is doubtfully distinct from the European fresh-water eel (Anguilla anguilla). Both species are characterized—in addition to the serpent-like elongated body, the absence of ventral fins and the continuity of the dorsal and anal fins round the extremity of the tail—by the wide interval between the dorsal fin and and the head, the projecting lower jaw, well-developed pectoral fins, well-ossified jaws and gill covers and nearly perfect gill arches. Contrary to the common belief, eels are not scaleless but small scales are embedded in the skin. The life history of the eel is very remarkable and in some respects unique. During the spring and early summer multitudes of young eels several inches long migrate up the rivers from the sea and distribute themselves throughout every accessible body of water, whatever its size or character, frequently traveling overland to reach these. Here they remain concealed in the mud or beneath stones and feed on all kinds of animal matter, living and dead. In which they are relentless. Many eels appear never to leave the fresh waters in which they have developed, but most of them after several years return to the sea and enter comparatively deep waters, where sexual maturity and spawning takes place. From the egg a peculiar, compressed, transparent, pelagic larva (Leptocephalus brevirostris) is produced, which in due time generally metamorphoses into the young eel which in turn leaves the sea. Some individuals, however, appear to remain permanently in salt as others do in fresh water.

Both in America and in Europe eels are an important and very excellent food fish, and great quantities are caught in a variety of ways. In the United States use is made of hand and set lines, eel-spears, eel-pots and weirs. The last is the most efficacious method, but owing to its serious destructiveness of shad and other fishes, its use is frequently prohibited by law. A V-shaped fence or net is arranged across the stream with a basket placed in a small opening at the apex, into which the eels are guided by the leads and from which they are unable to extricate themselves. In England river eels are caught in great numbers by means of eelbucks, or eel-pots, traps consisting of a kind of basket with a funnel-shaped entrance composed of willow rods converging toward a point, so that the eels can easily force their way in but cannot return. A stocking or tube of coarse cloth hanging from an aperture of a box down into the interior is also used. A kind of trident, called an eel-spear, is used also for taking them. A fisherman wades to the shallows, and, thrusting his spear in the mud in every direction around him, the eels reposing on the bottom are caught behind the prongs. Except a few other species of the same genus as the common eel, all eels are strictly marine and are found in great numbers in tropical seas where, in the interstices of coral reefs, as also in the deep sea, some very remarkable kinds occur. For an account of the species consult Jordan and Davis, Report United States Fish Commission for (1887); Jordan and Evermann, Bulletin United States National Museum, No. 47, Part I, and Goode and Bean, 'Oceanic Ichthyology.' See also articles Conger Eel; Electric Eel; Snipe Eel; Morays; Pelican Fish; Snake Eel, etc.

**Eel-grass, or Grass-wrack**, a common name for a marine plant, Zostera marina, of the pondweed family (Nauadaceae). The leaves are narrow and ribbon-like, blunt at the end, sometimes six feet in length. The flowers are crowded in a spadix. It is found in bays or streams along the Atlantic coast from Greenland to Florida and on the Pacific, from Alaska to California, also on the shores of Europe and Asia. The genus Zostera (from the Greek, referring to the ribbon-like leaves) comprises six species, of which two besides the eel-grass are found in America. They are all marine plants, and are found on the coasts in the north temperate zone.

**Eel-pout**, the name of various fishes. It is applied in the United States to the burbot or ling of the Great Lakes and to the mutton-fish; in Great Britain to the burbot and in northern Africa to the electric catfish (Malapterurus).

**Eelworm, or Vinegar Eel** (Anguillula aceti), a small Nematoidea worm of the family Anguillulidae, often found in immense numbers in good cider vinegar or in sour paste, where it feeds on the mucilage and organic fluids. It is just visible to the naked eye and wriggles very actively. Like many related species it is very resistant to dessication and other influences ordinarily destructive to animal life. A vast number of similar species live in the earth and feed on decaying organic matter, others are parasitic on plants, in which they are at least the partial cause of certain very serious diseases; thus Tylechnus devastatrix causes the "clover disease" and Heteroder schachtii the still more destructive "beet sickness," which

**EFFENDI.** a title of respect among the Turks, bestowed on men of education and on educated persons generally, in contradistinction to the military title of ağa. It is nearly equivalent to Mr., Sir, or the French *Monsieur,* but is suffixed to the personal name. It is often attached to official titles.

**EFFICIENCY.** See *INTERNAL COMBUSTION ENGINE.*

**EFFICIENCY, Mechanical.** See *LOCOMOTIVE.*

**EFFICIENCY ENGINEERING.** Efficiency, a word comparatively modern in use, for which there is no equivalent word in French, Italian, Russian, Swedish, German. It can be defined as the industrial relation between what is and what ought to be, between the actual and the standard. To find time efficiency divide the standard time by the actual time. The standard time for a toning process is 3 minutes. If the actual time is 2 minutes 30 seconds, the efficiency is 80 per cent. To find output efficiency, divide the actual by the standard. If for an hour the walking standard for a man is four miles and the actual performance is five miles, the man's walking efficiency is 125 per cent. Another definition of efficiency is to do the standard performance in the standard time, at the standard place, for the standard cost.

To an almost incredible degree railroads operate to efficiency standards. The time table sets up thousands of time standards for standard performances at standard costs, reaching particular places with standard equipment. Efficiency standards can be applied to all the seven great divisions of human activity, which are: Production commanding a price; manufacture taking a profit; transportation exacting a toll, rate or tariff; storage, for which rent is charged; exchange, earning a commission; personal service, exacting a fee; parasitism, which steals or robs.

Efficiency engineering belongs in the personal service group. There is a subclass in this group, the ethical class, whose service consists in lessening the wastes in the use of the already appropriated resources of the universe, in order that humanity may be better. The prophets and priests, by inculcating morality, have tried to lessen the wastes due to wickedness and sin. The physicians and surgeons have tried to lessen the wastes due to sickness, disease, early decay and death, bodily defects. The scholars, students, teachers have tried to lessen the wastes due to ignorance. The efficiency engineers have tried to lessen the wastes due to unscientific control and direction of the great divisions of activity in their three elements of materials, personnel and equipment. Everybody realizes the immense wastes due to wickedness. The general loss in the great war brought about by recent diplomacy, by violations of treaties, by ambitious and unscrupulous men, by disregard of what we had come to believe were accepted principles of humanity, of religion, of civilization. Everybody realizes the immense wastes due to disease which again and again has almost depopulated the world, which to-day makes infant mortality a greater drain on human life than the casualties of the battlefields and of the seas. Everybody realizes that an illiterate and un schooled population produces little wealth. Before the World War, in 1913, the uneducated workers in the United States, due to industrial inefficiency, amounted to not less than $40,000,000. In a manufacturing plant the difference in productive value between two men, one of 50 per cent efficiency and the other of 120 per cent efficiency, quite usual variations, may increase to $20,000 a year, even if each is using similar equipment.

Modern efficiency is much lower than that of former ages. By this is meant that although modern man has much more at his disposal than his ancestors, he nevertheless uses his greater resources far more wastefully. The Chinese coolie delivers a maximum all the time. The cause of modern inefficiency is the operation of the law of dependent sequences. Many modern operations are in dependent sequence. In printing, with one color 10 per cent of the sheets may be spoiled. Add another color and in the second run we have another loss of 10 per cent. If there are four printings the efficiency falls to 90 x 90 x 90 x 90 equals 65.61 per cent. If there were eight colors the end result would be only 40 sheets. Ninety per cent is a very high efficiency yet in reduction it sinks. The remedy is possible also through dependent sequence. Improve each step 5 per cent and for four operations of 95 per cent in sequence we have the end result of 81.45 instead of 65.61. Increase the sequences to eight of 95 per cent and the end result is 66.34 instead of 43. A gain in efficiency of 5 per cent gives an end gain of more than 50 per cent.

It is the function of efficiency engineering to eliminate or at least lessen industrial losses, especially those due to dependent sequences. Efficiency engineering, the accomplishing of results with less materials, less human effort, less equipment, is very old. Jethro, a rank outsider, gave Moses excellent efficiency counsel: 'Thou shalt teach them ordinances and laws, and shalt show them the way wherein they must walk and the work they must do. So Moses harkened to the voice of his father-in-law and did all that he had said.' Christ constantly both by precept and example showed how to accomplish much with a minimum of effort. Hideyoshi, the great Japanese reformer of the 16th century, originated and put into practice many efficiency engineering methods, reducing the castle fuel cost to one-third; building a wall in three days instead of three weeks, although he abolished overtime and paid a bonus; conquering a strong castle single-handed, although his lord had lost 5,000 men in a previous futile attempt.

Efficiency engineering began to emerge as a distinct branch of science when the doctrines of the correlation of forces and conservation of energy were accepted. It acquired solid footing when Joules experimentally and Meyer deductively established that 774 foot pounds could be converted into a rise of temperature of one degree Fahrenheit in a pound of water, or, vice versa, that this amount of heat would raise 774 pounds one foot. Yet development of these feats was attempted experimentally, there was great loss. It became the duty of
the efficiency engineer to discover the losses, then to minimize them. The standard had been established, accepted. This was the aim or ideal. The next step was to examine and set forth the actual conditions, so different from the standard. The next step, the peculiar function of efficiency engineering, was so to better actuality, so continuously and intelligently to remove the friction and other losses, as to force the actual gradually to approximate the ideal. The standard there was. It could be exceeded. In the 1912, the efficiency engineer was to create an estuary on the incoming tide, who crossed by means of a sail and who came down on the ebb utilized in succession moon, sun and earth as his motive powers and neither of his prime movers could be improved in efficiency. The white man, too impatient to wait for tide and wind, uses coal, utilizes at best only one-fifth of its power.

The efficiency engineer regards all results as made up of material contributions, personal contributions and equipment contributions. These three differ in delivery and storage, and are subject to very different laws and cannot be treated in the same manner. Materials require storage and careful use. Equipment requires storage, careful use, and in addition continuous, high-grade maintenance. Personnel requires housing, direction, high-grade maintenance, but in addition a far-reaching psychological control. Everyone owning a motor car knows that the fuel, the car and the chauffeur are different problems.

In the subclass United States railroads of the larger division of transportation, the relation of materials, personnel and equipment charges are 3:5:7. In the packing industry materials (cattle, hogs) are overwhelmingly important, personnel comes next and equipment last. Because of these differences railroads turn over their capital once in five years, have to operate at low ratio, 60 per cent to 75 per cent, and are lucky to pay 5 per cent or 6 per cent dividends, while the big packing industry turns over its capital five to six times a year, operates on a margin between cost and sales of 2 per cent or 3 per cent, and can pay 20 per cent dividends. In these combinations of material, personnel, equipment, any one or more may be high in efficiency, any one or more may be low. A first class man may be running a very poor machine or vice-versa. To a good furnace poor coal may be fed or good coal may be fed under a poor boiler. But the combination to be controlled and regulated is not only of materials, personnel and equipment, it is as to each a further combination of quantity and quality, each with its own efficiencies. This leads to the universal formula for production, a formula that equally applies to all the battling hosts of Europe, or to the operations of all the railroads or to the making of a pin.

### Universal Formula

**Costs**  
\[ \text{Costs} = \text{Materials} + \text{Man Costs} + \text{Equipment Charges} \]

**Materials**  
\[ \text{Materials} = Q \cdot P \]

**Personnel**  
\[ \text{Personnel} = T \cdot W \]

\[ \text{Universal Formula:} \quad \text{Costs} = Q \cdot P + T \cdot W + IR \]

**Equipment**  
\[ \text{Equipment} = I \cdot R \]

When the efficiency engineer has thus stated...
his problem he attempts to bring about that combination of $Q$, $P$, of $T$, and $W$, of $t$, and $R$ which will make the cost of each group a minimum. What combination of materials, of personnel, of equipment is under the circumstances most rational? Shall it be little equipment and many men, or shall it be much equipment and few men? The sand along the Suez Canal was removed in part by young women, digging with their bare hands, carrying it away in baskets on their heads and dumping it on the bank. At Panama immense steam dredges were used, scraping 10-ton loads at a stroke, yet the cubic yard of excavation may have cost more at Panama than at Suez. Which was the better method? The cheapest transportation the world has perhaps ever known was of ivory, hides, etc., from the interior of Africa to the sea coast. But it was one-way traffic. The means of transport, slaves, bought for a few dollars in the interior, were worth hundreds of dollars each at the coast. In this case in the universal equation $PQ$, materials is very small, $TR$, equipment, is less, $TW$, wages is negative, since the sale of the slave brought a revenue. But after the questions of relative proportion of materials, of personnel, and of equipment have been settled the next problem is to determine whether large quantity and low quality is better than small quantity and high quality. Is it cheaper to build a bridge out of cast iron blocks at $20$ a ton or of piano wire at $300$ a ton? Efficiency engineering is immediately concerned with industrial wastes not with moral wastes. It may be a great moral shortcoming to use up frivolously the coal, the natural gas and the crude oil of the world but from the point of view of the efficiency engineer the Diesel engine in a submarine may be efficient and a burden bearing Buddha be inefficient. Is it cheaper to walk 500 miles barefoot in 25 days or to go through in a night on a fast train? If wages are $0.10$ a day and meals cost nothing it might be worth for some men to walk the tramps do. With boarding and lodging at $0.25$ a day and wages at $0.40$ a day it is cheaper to ride.

Usually economy is secured by increasing the rate, hence the output per man-hour, increasing the rate, thus reducing the quantity items of weight and of time. The best result is when the value produced is a maximum with $Q$, $P$, $T$, and $R$ very small, but $W$ very large. An infinitely bad result is when $Q$, $P$, $T$, and $R$ are a maximum, millions of costly shells, millions of hours of daily with low wages, 24 hours a day of almost infinitely costly equipment, all to produce unmeasured and unmeasurable destruction. There are different summarized efficiencies for each of the six factors $Q$, $P$, $T$, $W$, $t$, $R$. There are different efficiencies for each separate part of each. Each of a thousand men in a plant will have a different average efficiency and each man will have a different efficiency for each different item of work. When all these million possibilities of wastes and leaks becomes as necessary as to have every joint tight in a 100-mile pipe line, to have every rail in a 1,000-mile road, sound and in line, or to have every item right in the deposits and withdrawals from a bank or to have every word, every letter, in a book proofread.

Nevertheless it has been found efficient to attack inefficiencies under group headings rather than individually on the same principle that it is better to prevent any yellow fever mosquitoes rather than to kill those that fly around. The systematic application of a few principles, some ethical, some practical, brings about general improvement: (1) What is the main idea? Stick closely to it. Eliminate clashes and interference. Fast trains can run on the principle of the free and unobstructed track. (2) Is common sense being used? Mostly it is absent, as in the adoption of a cost plus profit plan by the United States government, for its war orders. (3) Has the best advice been sought, been considered and been followed? (4) Is there the strict discipline, the spirit, that makes the difference between army and mob? (5) Is the fair deal practised toward all? (6) Is there a direct and tangible connection between individual excellence of performance and individual pay? (7) Are all operations minutely planned in advance? (8) Are they carefully and scientifically scheduled as to time and cost? (9) Are all operations dispatched, i.e., put through in accordance with plan and schedule? (10) Are all conditions standardized? (11) Are all operations standardized? (12) Are there permanent written standard practice instructions? (13) Are there records, necessary, reliable, immediate, adequate, convenient? It is the method of group attack that has proved important rather than the particular principles for which others might be substituted.

An able teacher has enunciated the three principles of picking the right man, giving him power, letting him alone. This is excellent but it leaves us without means of detecting results. Not so many years ago, some blacksmiths pretended to be able to smell the quality of iron and to judge of the heat by the color. To-day steel quality depends on alloy and heat treatment. We still depend on the good man but we check him by presenting his excellence by analysis and pyrometers, and for efficiency work a few principles are very useful. In considering the human element in production it is important to encourage everybody man to make the most of his own abilities. There are noble chiefs in Indian villages. It is not less important to so establish conditions that each man whether inferior, average or superior can accomplish most. The wise Indian chief had he been in different surroundings might have been a Lincoln, a Lloyd-George.

A diagram often used by teachers of efficiency consists of a series of rectangles illustrating by their height the excellence of conditions and by dots above the base the achievement of the individual.

**Very Bad Conditions and an Averaged Group of Men. Average Attainment 10 Per Cent.**

![Diagram](image)

Each individual starts along the life line AD at A. Some get no farther than 1, others...
progress as far as 2, still others press on to higher positions until the best man of all, a superman (9) makes D. The position on the line AD is determined by the characteristics of the individual, by heredity, is the same kind of difference as exists between the eagle and the rooster, in the egg scarcely distinguishable. If all the 9 men that entered at A were of the quality of number 9, they would all ultimately bunch about D.

**Very Bad Conditions and a Group of Supermen. Average Attainment, 20 Per Cent.**

![Efficiency Scale Graph]

Under the same conditions the superior group of very unusual men will average twice as well as an average group of unselected men.

**Best Possible Conditions and the Effect on an Averaged Group of Men.**

![Efficiency Scale Graph]

This diagram illustrates that owing to improved conditions each man will have risen perpendicularly so that the average efficiency is now 50 per cent instead of 10 per cent. Under these bettered conditions it is no harder for man 9 to reach 100 per cent absolute than it was under bad conditions to reach 20 per cent absolute. Under both conditions this man is doing twice as much as a normal standard (half of the best record) and any unusual performance is not a matter for expectation or of requirement but of free will. Men ought not to be permitted to be slackers and we can consider all workers below the average of their class and group as slackers and near-slackers. Neither has the community any right to demand a performance above the average. In war when extra-hazardous work impends volunteers are called for. Similarly in industrial life, it is a matter for the individual to decide whether he will be 20, 50, 100 per cent better than the average. The obligation of the community not to discourage, hinder and prevent super performance is even greater than to prevent slacking. The world owes its advances and the progress of civilization to the superman, to the Columbus, the Newton.

It is of course possible to collect a group built of superworkers, as in a league base ball team, or in the best college football teams, or in an orchestra, or in a circus, where every living performer is a star. Such groups will always be abnormal, but the superman of one age may be the average man of a better age. The performance of supermen under best conditions is about 10 times as productive as that of the average man under bad conditions.

It is as distinctly the province of efficiency to discover and state best industrial methods as it is the province of moralists to discover and attain universally highest morality, the province of educators to outline and attain universally highest knowledge, the province of health specialists to outline and attain for us all highest physical soundness. Efficiency is not a new phenomena, it has, however, only recently been clearly defined and studied. Some of the best examples of efficiency practice have been outside of industrial lines. An orchestra is one of the best instances of efficiency organization and efficiency attainment. The leader is a trained and experienced specialist of great and unusual aptitude. Every worker is a superman, of special aptitude, training and experience. He is equipped with marvellously perfect tools or instruments. The work is also planned in advance, with written standard practice instructions, scheduling it most minutely not only as to time but as to quality. The work is dispatched and executed to the fraction of a second. No man plays independently but all are exactly adjusted to each other, yet the players like it and thrive under it and the best are abundantly rewarded. But orchestras are very old.

A more modern example is that of the trotting horse. The trotting horse men, who may not know what the word efficiency means, have nevertheless elaborated the very best plan for attaining it: (1) They began with heredity, counting more on blood and descent as a foundation than on everything else; (2) the dam of the colt and the colt itself are given the best of environment; (3) the training begins early and is continuous; (4) actual experience and tests follow; (5) there is the most skilled leadership.

So much for the physiological and psychological problems. Lastly, conditions are standardized to the utmost. Harness in all its parts, sulky in all its parts, shoes, tracings (shape, balance and surface). Operations are then standardized. The stop watch was first used on trotting horses. Race horse men were familiar with tenths of seconds and their value long before time studies were thought of in industrial shops. The first photographic motion studies
ever made were by Muaybridge of trotting horses. Since the record of 2.40 of Flora Temple about 1840, the improvement has been steady to the present record of 1.58. Probably one-half of this is due to improved heredity, the other half to improved environment, training, education and accessories. As a consequence the performance of the trotter is the performance of the superhorse under best of conditions. The best trotting horse can travel an average of a mile in two minutes. Under the less favorable conditions of road work, a horse or mule does well to travel a mile in 20 minutes.

The need of consistent application of modern research methods to the problems of economic production and consistent improvement of basic units whether materials, personnel or equipment, have attained growing importance during the last 50 years.

Mr. Taylor thus outlines Functional Type of Organization. "Throughout the whole field of management the military type of organization by far the most universal type instituted. Functional Management consists in so dividing the work of management that each man, from the assistant superintendent down, shall have as few functions as possible. The most characteristic of functional management lies in the fact that each workman secures his daily orders and help directly from eight different bosses. Four of these are in the planning room. Four others are in the shop. The four shop bosses are gang boss, speed boss, inspector, repair boss. The four planning room bosses are order of work clerk, instruction card man, time and cost clerk, shop disciplinarian."

In machine shop practice F. W. Taylor made epoch-making demonstrations of the gains to be realized from improvements in both cutting and finishing the art of cutting metals, which virtually scrapped all the machine shop equipment of the world, and improvements of shop management. Taylor expanded from a shop man into a world teacher. It is not without importance that Taylor had had the benefit of French school training, the passion for the new, the logic and precise. About the same time, 1900, as Taylor was breaking from the shop into world prominence, other men who were old with world ideals of principles, of organization, of administration, of selection. Taylor rejected the old military line that had existed in shops, president, manager, superintendent, foreman, gang boss and substituted what he called functional management. He points out that whereas it would be very difficult and expensive to secure any single man with all the nine qualities required in a foreman, it is easier and cheaper to find a foreman with some of the qualities so that four men may cover and to spare the nine functions which in his work on shop management Taylor defines. The Emerson school developed the practical application, to modern industry, of natural organization as it occurs in the animal and plant life. Nature animal organization falls into four parts: (1) the fundamental organs of growth and upkeep, working continuously at low intensity and almost automatically; (2) the counsellors, or the sense organs which look ahead and note both the exceptional and the infinitely minute; (3) the central brain, which constantly counsels, correlates and directs; (4) the doers, creators, whose law of action is directed spasmodic intensity. Natural plant organization covers time and relations. A plant rooted to one bleak spot survives 5,000 years with 3,000 generations of leaves. The humble plants render service to insect and animal that in turn greater service may be rendered them. These facts are a source of inspiration and information only beginning to be recognized and utilized. The natural types of organic life are models for both functional and staff and line organization. The brain and the hands are in the line. The brain correlates and directs, the hands execute. The senses and the interior organs are functional therefore in the staff. A line man must know how to direct. A staff man must furnish all the knowledge available. The line man usually makes the mistake of thinking that he knows. The staff man makes the mistake of thinking that he can direct. It is no part of the plan for the functional organization to overstrain materials, to break down equipment or to overwork men. There is a rational load for either of the three. A man can always do more foot pounds of work in 16 hours than in 12, 10 or 8. Therefore deliberately prefer the shorter intervals because economy is subsidiary to human welfare.

EFFICIENCY SOCIETY

THOMAS C. EMERSON.

Efficiency Engineer, New York.

EFFICIENCY SOCIETY, a nation-wide movement, not for promoting efficiency in the first place, but for making more of what has already been done, and doing it much, but rather for extending the principles of efficient engineering to all other relations of life. The 18th was the theologic century, when man's chief thought was his relations to the Deity. The 19th was the scientific century, when man was much concerned with his relation to nature and its forces. The 20th century will be known as the efficient century, when the world demanded of every man and institution, as it demanded of every approved machine, the better, quicker or cheaper, under penalty of discard, and this meant raising the ratio of results achieved to efforts expended, which is the engineer's definition of efficiency. From creation whenever any man made a distinct effort to improve his methods or his tools so as to get greater results from the time and labor spent, he had in him the elements of the efficiency expert. Steam is as old as the first hot fire under water, and electricity is coeval with the lightning, but the age of steam and electricity is recent. This is the century of efficiency; for in its early years attention was widely drawn to the fact that the progress to which the world aspired was possible only by applying to all of life the lessons learned from machines. Every method, man or institution that maintains its place must prove ability to do something that the busy world wants either better or quicker or cheaper. America leads the world because she studied profoundly her machines. She standardized, and thus both improved output and greatly reduced cost. She cut out every useless part and every needless pound. She added power and speed and eliminated every false motion. As a result she made thousands of useful articles at 50 per cent, 20 per cent, 10 per cent or even 1 per cent of their previous cost in time and labor, i.e., she increased that efficiency 2 to 100 fold. Man with his machines became as a god. Instead of a birch bark canoe he built ships that would carry all the inhabitants of 20 villages of 400 people each and cost as much as all the lands and houses of 100 such villages. He sent trains carrying a thousand people through tunnels and solid rock, under cities and rivers, at 10 times the speed of a footman. He sails under the sea or through the air with the speed and accuracy of fish and bird. He talks as if in the same room across a continent or under the Atlantic. He omits the wire and in a few seconds can send his message to every part of the boundless sea. In his phonograph we hear the voice of a thousand, and on the screen their pictures move exactly as they did in life. Man saw these miracles of efficiency on every side and began to question strongly everything in life: 'Are we giving this more time, thought, labor, or capital than absolutely necessary to produce the desired result? Are we working up to efficiency standard, or what the golfer would call bogey?' Modern life is more or less a race or struggle in which only the fittest can survive the fierce competition between individuals, corporations, communities, states or nations. They keep adding speed and power and looking for any useless pound of weight that can be thrown overboard. In the great contests of life the leaders strip like athletes in the Olympic games. But still in a time of coal famine experts startle us with their claim that we often really use only 5 or 10 per cent of the heat locked up in the coal we burn. Many food supplies yield the farmer who produces perhaps half what he should have, yet the laborer who buys in small quantities pays double what he can afford for that same article. This means low efficiency in the farm-to-family machine. See FARMERS' CO-OPERATIVE MOVEMENT.

College graduates often show unfitness to transact simple business after giving 16 years to training for life, and we cry for more efficient education. We have countless millions in our churches and they have done nothing, yet in great crises of war, panic or plague, we deplore that more of the efficiency of the American machine is not found in our churches. We hear of millions dying for lack of food and shelter and learn that with our boasted efficiency in many lines we are the most wasteful nation the world has known. The new idea was that by persistent, systematic study and comparison of experiments and experience we might approximate in the manifold relations of life an increased efficiency comparable to that so obvious in our machines. This great idea appealed to leaders and thinkers in many fields. Over a thousand joined the Efficiency Society organized at a national convention held in the Engineering Building, New York, 18 March 1912. J. G. Cannon, president of the Fourth National Bank, was president, and its officers and committees included many of the best known men in America. Its constitution says "its object is to promote efficiency or percentage of results obtained relative to effort expended in every activity of man and in everything he employs." On 12 Feb, 1916, the National Institute of Efficiency was incorporated in Washington to supplement the work of the older society by making the country the results of research and experiments as developed and focalized by its committees. On its board of governors were leaders from a dozen different States. The general absorption in the Great War led both Society and Institute to defer much of the work planned, and later they were combined in a single National Efficiency Society incorporated in Washington but with headquarters at 119 West 40th street, New York, we are fuller information can be had. It publishes a quarterly and has made The Independent its official journal, sent weekly to all members. It also publishes efficiency monographs from time to time and provides free or at reduced cost books and pamphlets of special interest to its membership. It plans meetings and provides speakers, and through its officers and committees tries to focalize and disseminate for the public good anything likely to be widely useful to those specially interested in increasing efficiency. It does not assume to give the final answer to any calling, which are best treated by their own
local and national associations. It is thus a union of those willing to turn over for the common good the results of their own studies, and all such are welcomed to its membership. In friendly co-operation with the leaders of other enlightened nations its ultimate goal can be safely prophesied as "The Federation of the World for Greater Efficiency."

MELVIL DEWEY,
President, National Efficiency Society.

EFFIGY, formerly EFFIGIE, (1) a copy or imitation of an object, an image or likeness; in sculpture frequently applied to the figures on sepulchral monuments; (2) to execute or degrade, as the execution or degradation of a condemned criminal, when he cannot be personally apprehended, by subjecting his image to the formalities of an execution; for instance, affixing the image with a rope around the neck to the gallows (hanging in effigy). This practice is not altogether extinct in Prussia and in other countries, but in England it has become merely a mode in which the populace expresses its anger, regarding an obnoxious personage, such as the English custom of parading and burning the effigy of Guy Fawkes on 5 November.

EFFINGHAM, Ill., city, county-seat of Effingham County, on a branch of the Wabash River, about 240 miles south by west of Chicago, and on the Illinois Central, the Wabash and Vandalia railroads. The city is the trading point of an agricultural region and has some small manufactory. It contains Austin College and a large photographic school. Pop. 3,898.

EFFLORESCENCE, a term applied to crystals, which, on exposure to the air, lose their water of crystallization and crumble down into a powder. The most familiar instance is that presented by the glassy crystals of washing soda, which become white and pulverulent in the air. The same phenomena is also presented by phosphate of sodium, borax and other compounds. Another application of the word is to the fine white, feathery crystallization of sulphate and carbonate of sodium which appears on porous walls, or similar crystallizations on the surface of the earth, in decomposing rocks, etc. These exudations are due to the crystallization of the saline solutions existing in the pores of the surface on which the efflorescence appears. Another use of the term is to designate the creeping up of crystals on the sides of a vessel containing a saline solution, often overrunning the edge and down the outside. This action is very noticeable with sal ammoniac as used in battery jars. Efflorescence is in some respects the opposite of deliquescence, and the difference is shown by placing an efflorescent and deliquescent body under a bell-jar. The former gives up its water, which the latter absorbs, becoming thereby fluid. See CRYSTALS.

EFFUSION (Lat. "to pour out", in physics and chemistry, the escape of a gas into a vacuum, through a small opening (such as a pin-hole) in a thin partition. So long as the temperature of the gas is constant, the velocity of effusion is independent of the pressure. For the same gas at two different temperatures (but at the same density), the velocity of effusion varies directly as the square root of the absolute temperature. The velocities of effusion of two different gases (both at the same constant temperature) are inversely proportional to the square roots of the densities of the gases; the densities being determined by comparison under convenient but identical conditions of temperature and pressure.

EGAN, Maurice Francis, diplomat; b. Philadelphia, 24 May 1852. Mr. Egan's family came to Ipswich, Mass., in 1763. His father Maurice Egan of Philadelphia came when quite young to Philadelphia in 1825. Mr. Egan was educated by private tutors and in the Latin School of Saint Philips, at Philadelphia. He graduated from LaSalle College—A.B. and A.M.—his doctor's degree was given to him by Georgetown University. Mr. Egan studied law under John I. Rogers in Philadelphia, but after the success of his first novel, 'That Girl of Mine' (1879) and his little volume of poems, 'Preludes' (1880), he adopted literature as a profession. He has almost 30 books to his credit, the best known of which are 'Songs and Sonnets' (1886); 'The Wiles of Sexton Maginnis'; 'Everybody's Saint Francis' (1912); 'The Ivy Hedge' and the translation of the sonnets of Jose de Heredia. Mr. Egan was professor of literature and English at the University of Notre Dame and at the Catholic University at Washington. He has been since 1907 in the diplomatic service as Minister at Copenhagen. His first diplomatic nomination was during President Cleveland's second term. He was successively ambassador to Vienna, but preferred to remain at his present post.

EGAN, Patrick, American political: b. County Longford, Ireland, 1841. He became identified with the Nationalists and the Home Rule Movement in 1871, and was one of the organizers of the Irish Land League. He was tried in Dublin in 1880 for conspiracy and sedition, going to Paris upon his acquittal. He came to the United States in 1883, and was president of the Irish National Land League of America 1884-86. He testified before the Parliamentary Commission 1889, and was instrumental in securing the failure of the case of the London Times against Parnell. He was appointed Minister plenipotentiary to Chile as a reward for his speeches in the campaign of 1888. In Chile his espouls of the cause of Balmaceda, the Liberal dictator, brought upon him severe criticism. Later he left the Republican party, becoming what was known as the Silver Democrat, and taking part in the subsequent campaigns in favor of that issue.

EGAN, Pierce (The Elder), English sporting writer: b. London 1772; d. there, 3 Aug. 1849. A prolific "historian of the ring" and
kindred institutions, he wrote 'Boxiana' (1818); and the widely popular 'Life in London' (1821), which was illustrated by Cruikshank. He edited in 1824 Pierce Egan's 'Life in London and Sporting Guide', which was later absorbed by Bell's 'Life in London'.

EGAN, Pierce (The Younger), English novelist: b. London 1814; d. there, 6 July 1880. He was a son of the preceding. At first an artist and illustrator, he turned to fiction, winning fame with 'Robin Hood' (1840); 'Wat Tyler' (1841), and similar conceived romances; while his later and more sensational tales ('Imogen' (1844); 'Fair Lilias'; and others, appeared for the most part as serials only.

EGAN, Juan, hoo-án ē-γā'ña, Chilean author and statesman: b. Lima 1769; d. Santiago, Chile, 13 April 1836. After being graduated from the College of Santo Toribio, he was made professor of philosophy at the age of 16; and at 21 succeeded to the chair of theology and law. He practised the latter profession at Santiago and was chosen to the professorship of oratory at San Felipe. He took an active part in the revolution, was a member of the first Chilean Congress, was captured and imprisoned on Juan Fernandez Island, but was liberated in 1817, after which he was made professor of literature at the National Institute and a member of the Board of Education. He was again a member of Congress until elected President of the Republic in 1823. He was a voluminous writer, both of poetry and prose, his works including several educational textbooks. He exercised a great influence in shaping the character of the people and the policy of Chile. He published a translation of his own work in English under the title of 'Pebuchemar Letters' (1819).

EGBERT, king of Wessex: b. about 775; d. 837. On the death of Alcmund, the former king, Brihtric, a powerful noble, succeeded in ousting Egbert, who had the best claim to the throne, and was confirmed en de facto refuge first in the court of Offa of Mercia, then in that of Charlemagne. On the death of Brihtric he succeeded him as king of Wessex, in 800. He reduced the other kingdoms, and rendered them dependent on Wessex, and remained there till 874. He then returned to Copenhagen, and afterward was appointed bishop of 'Greenland'. We have from confidants his account of the country, from which many native names, including those of the 'Greenland Cove', have been derived. He died, 877, having been in the service of King Charles the Bald. His works are: 'Account of Greenland,' extracted from a journal kept from 1721-88; 'Dictionary Grienlandicus'; 'Grammatica Grienlandica'; and translation of the Gospels, the 'Imitation of Christ,' etc., in the Greenland tongue.

EGERTON, James Chidester, Roman archaeologist and epigraphist: b. New York, 3 May 1859. He was graduated at Columbia University in 1881, and held a prize fellowship (1882-85). He began to teach in the university in 1885 and was adjunct professor of Latin 1885-90. In 1890 he was appointed professor of Roman archaeology and epigraphy in Columbia, and has done much to promote the study of these special subjects. He has published 'Introduction to the Study of Latin Inscriptions' (1895); and has also edited 'Cicerone de Gentius' (1895) and written 'Macmillan's Shorter Latin Course' (1892); 'Livy XXI and Selections from XXII to XXX' (1913). Professor Egerton was appointed director of the summer session at Columbia University in 1902 and subsequently directed the extension lectures of the same institution.

EGEDE, á-ğē'dē, Hans, Danish missionary, termed the apostle of Greenland: b. Harstad, Norway, 1666; d. Falster, Denmark, 1755. In 1707 he became a preacher at Wogen. Having heard that Christianity had been once established in Greenland, but had become extinct in the country for want of teachers, he resolved to visit the country, and to preach the gospel to the inhabitants. Having received from the Danish government the necessary permission and funds, he sailed on 21 May 1721 with 46 persons under his command. Egede landed on 4 June, and the conversion of the Greenland Eskimos was now undertaken, but offered great difficulties. Egede took up his residence with his two sons among the natives, in order to learn their language, and so be able to carry out his project of conversion. He carefully noted down every word of which he discovered the meaning; often performing long journeys, at the peril of his life, to visit the remotest Greenlanders, for the purpose of gaining their confidence, in which he succeeded by a thousand acts of kindness. He succeeded in winning many converts, established trade relations with Groningen and founded the colony of Godthaab. After spending 15 years in Greenland, amid innumerable discouragements, he returned in 1736 to Copenhagen, to make new exertions for the support of Christianity in that country. For this purpose a seminary was founded at which missionaries were trained for work in Greenland. He served as principal of this school for six years. The government appointed him director of the Greenland missions, and established his son Paul in the office of missionary there. His writings are in Danish, and relate to the natural history of Greenland, and his sufferings and adventures there.

EGEDE, Paul, Danish missionary: b. 1708; d. Copenhagen 1789. He was a son of Hans Egede and was his assistant from the time he was 12 years old. Notwithstanding a strong inclination for the naval service, he submitted to the wishes of his father, studied divinity, joined the mission in Greenland in 1734, and remained there till 1740. He then returned to Copenhagen, and afterward was appointed bishop of 'Greenland'. We have from confidants his account of the country, from which many native names, including those of the 'Greenland Cove', have been derived. He died, 877, having been in the service of King Charles the Bald. His works are: 'Account of Greenland,' extracted from a journal kept from 1721-88; 'Dictionary Grienlandicus'; 'Grammatica Grienlandica'; and translation of the Gospels, the 'Imitation of Christ,' etc., in the Greenland tongue.

EGELHAFF, á-ğēlli-fā, Gottlob, German historian: b. Gerabronn, Württemberg, 1 March 1848. He has published 'A History of Germany During the Reformation' (3d ed., 1893); 'Emperor William' (3d ed., 1888); 'A History of Germany During the Sixteenth Century until the Peace of Augsburg' (1898-92); and other works.

EGER, á-ğēr, Bohemia, town in the northwest, on a rocky eminence above Eger, 91 miles west of Prague. It was once an important fortress, founded in the 12th century. Six lines of railroads converge at Eger. There are various industries, including machinery, iron and leather manufactures, and a flourishing trade. The celebrated Wallenstein was assassinated at the Stadthaus here (1634). Frantzensbad, a watering place, is connected
with Eger by an avenue three miles long. There is an interesting ruin of a castle built by Frederick Barbarossa; and the inn in which Schiller wrote his 'Wallenstein' is still standing. Pop. of the commune about 25,000.

EGER, a river which rises in Bavaria, in the Fichtelgebirge, 12 miles northwest of the town of Freyung, flows first southeast, then takes a northeasterly direction into the Elbe, near Leitmeritz in Bohemia, after a course of about 190 miles.

EGERIA, e-jë-rê'-a, (1) a nymph who received divine honors among the Romans. Her dwelling place was near the Porta Capena, Rome, where a grove was consecrated by Numa to the kindred Camenian goddesses. Numa is said to have had secret conversations with her and to have received from her the laws which he gave to the Romans. Some say Egeria was the wife of Numa. (2) A genus of spider crabs of the family Matidae; (3) a genus of bivalve shell of the family Donacidae; (4) in astronomy the thirteenth planetoid, discovered by De Gasparis at Naples (1850).

EGERTON, e-jër-tôn, George (pseudonym of Mrs. Mary Chavelita Dunne Melville Clairmonte Bright), English novelist: b. Australia, 14 Dec. 1800. She was married in 1838 to H. Melville, who died in 1859; in 1859 to R. G. Bright, who died in 1901; and in 1901 to R. G. Bright. She has published 'Keynotes' (1893); 'Discords' (1894); 'Young Ole'se Ditties' (1895); 'Symphonies' (1897); 'Fantasies' (1898); 'The Wheel of God' (1888); 'Road Amorosus' (1901); 'Flies in Amber' (1905); and several plays and adaptations.

EGERTON, Hugh Edward, English historian: b. 19 April 1855. He was educated at Rugby and at Corpus Christi College, Oxford. In 1885 he was assistant private secretary to the Hon. E. Stanhope, M.P., and from 1886 to 1906 he was a member of the managing committee of the Emigrants' Information Office. In 1905 he was appointed Beit professor of colonial history at Oxford. His publications include 'A Short History of British Colonial Policy' (1897; 4th ed., 1913); 'Sir Stamford Raffles' (1897); 'Passage, Progress and Growth of the English Colonies' (1902); 'Canada under British Rule' (1908); 'Canadian Constitutional Development,' with W. L. Grant (1907); 'Federations and Unions Within the British Empire' (1911); an edition of 'Sir W. Molesworth's Speeches' (1903), and of the 'Royal Commission on Loyalists' Claims 1783-85' (1915). He contributed to Palgrave's 'Dictionary of Political Economy,' Poole's 'Historical Atlas of Modern Europe,' 'Cambridge Modern History' (Vols. IV and IX), 'The Oxford Survey of the British Empire,' 'The American Cyclopedia of Government,' 'English Historical Review' and other publications.

EGG, Augustus Leopold, English genre painter: b. London, 2 May 1816; d. Algiers, Algeria, 26 March 1863. He became a contributor to the Academy exhibition in 1838 and was elected a member of the Royal Academy in 1860. He painted a great number of pictures illustrative of humorous scenes from Shakespearian, Le Sage and Walter Scott.

EGG. The fundamental cell, technically called the ovum, from which each individual living animal of every species is developed. The egg is the product exclusively of the female organism. It may or may not be developed into another individual being; the potentiality of such development is inherent in the egg. It is not to be understood, however, that a single egg may develop into but one individual. In many known instances the single egg divides and subdivides before it reaches the stage of developing the individual, so as to produce from 8 to 16 individuals—as in Aurelia; or even 32 individuals—as in varieties of Natica. Segregation previous to individual development has been observed also in the frog, the rabbit, the guinea pig, the dog and the deer, as well as in some birds, reptiles, fishes and lower animals.

So far as minute observation goes all eggs of every species are alike in structure and composed of the same primary elements, and at the beginning develop by the same processes of growth. There comes a time in the progressive growth when each egg assumes a character peculiar to the species to which it belongs in the scheme of animated nature. The egg-cell has a constant form of structure. There is an outer sac of cell wall containing a spongy network, filled with a more or less transparent fluid, in which is suspended an interior sac known as the nucleus, filled with a different network and a clearer fluid, and within this the germinal *dot* or *spot* called the nucleus. As the purpose of this article is the discussion of the production of the egg the reader is referred to the article EMBRYOLOGY for the consideration of the processes by which the egg is developed into the specific animal.

Animals in which the egg passes out of the body before it is hatched, that is, before the maturity and escape of the embryo, are said to lay eggs, or to be *oviparous*; those in which the egg remains inside the body to hatch are called *ovoviviparous*; those whose eggs are retained in connection with the parent by means of a placenta and an umbilical cord, so that the young are brought forth alive, are called *viviparous.* These distinctions, and especially the first two, are of secondary importance, and in some cases it is difficult to classify an animal according to them; or varying conditions may lead to change in the same species or individuals at different times. In practically all the mammalia the egg after being produced by the ovary attaches itself to the body of the mother and is developed directly by the vital processes of her system. The only exceptions are a few lowly mammals (the Monotremata, q.v.). All birds and most other animals lay their eggs. The ovoviviparous ones are to be found chiefly among reptiles and fishes. The production of eggs by an individual female varies within the limits (so far as known) of one to a time, as in the human race; the horse, cow and many other species of animal; the penguins and many other seabirds; to the 9,000,000 laid by the cod and 14,000,000 laid by the turbot. Science has offered an explanation of this great disparity, that as the object of the egg is the perpetuation of the species the number of eggs produced corresponds to the natural danger of destruction of

either the eggs or the young in the particular environment of each species. This theory seems well established by the observed facts, but it is evident that nature in so providing for the success and downfall of all living species failed to take into account the depredations of man. It is easy to mention a dozen species which have suffered complete extinction within historic time because their reproductive functions were not gauged to make good the wholesale need of the wholesale slaughter perpetrated by the human species.

Eggs of Birds.—The eggs of birds are so much more in evidence than those of other living creatures that it seems the natural procedure to discuss them as first in order. The eggs of birds are larger in proportion to the size of the mature parent than is the case with any other division of the animal kingdom. This peculiarity has been "explained" by saying that the bird "must be" hatched at an advanced stage of development and therefore much food for it while it is growing "must be" stored within the shell of the egg, and that for this the comparatively large space is required. The matter is mentioned here only to point out that the statement of these facts does not constitute a "reason" and the statement is not necessary — it is the normal fashion of development for the bird; that is all there is to it. The egg of a bird originates in the ovary of the female parent. At the very beginning of its course toward the oviduct it is surrounded with a very small or smaller envelope of yolk. Chemically this is an emulsion containing varying percentages of fat, lecithin, lutein (the coloring matter), cholesterol, the phosphoprotein vitellin and a small quantity of the coagulable protein livetin. The vitellin and lecithin are in some form of combination and are generally joined (for discussion) under the term lecitho-vitellin. This yolk lies in concentric layers about the whitish germinal vesicle or "tread" of the egg, which is the protoplasmic part where alone development processes occur. This plate resides upon the surface of the food-yolk and remains on top by reason of its lightness no matter how the egg is turned. The eggs of many of the lower animals contain food-yolk, but it is usually colorless. The egg of a hen or other bird is further furnished with layers of albumin (the "white") placed upon it in the narrow upper part of the oviduct. Chemically the white of the egg is a coagulable protein fluid of a slightly yellowish tint enmeshed within a network of fibrinous matter. It is feebly alkaline and is 85 to 86 percent water. Of the solid matter 12.2 percent is protein — mostly albumin, with smaller proportions of egg-globulin and ovo-mucoid, — glucose 0.5 percent, inorganic salts 0.06 percent and traces of fat, lecithin and cholesterol. Outside of the albumin is a fibrous membrane in two distinct layers (the "egg-pod"), the separation of which later forms the "air-chamber" at the end of the egg where the head of the chick lies. The stages of ovi-duction is a period of about four hours. In a further stage of the descent along the oviduct there is deposited in and upon the egg-pod an external covering or "shell," calcareous in various degrees. The process of depositing the shell occupies 18 to 20 hours. This shell is porous so as to admit air to the embryo, which also exposes it to bacteria so that eggs are liable to quick decay when living influences cease to operate within it.

Eggs of birds differ greatly in size, color and markings, and this varies with the different birds of the same species. Although the yolk of the egg is spherical the outer shell is rarely so. It ranges from nearly elliptical or ovoid to a shape almost conical, known as conoid. It is to be noted that eggs which are laid in exposed places, on rocky ledges, on bare ground, are much more sharply pointed than those which are laid in deep nests or in holes in trees, and this goes to bear out the theory that the shape of eggs is protective — to prevent their rolling away from the nest. In color as a rule they are white, but many are tinted with cream, pink, blue, green or brown, and they may be plain or spotted, speckled or blotched. These blotches and markings are of varying colors and sometimes of several colors on the same egg. They are deposited in the shell of the egg by certain pigment ducts active as it is making; and while the eggs of the whole species have a close general resemblance, so that an ornithologist recognizes them at once, the eggs of individual birds of the species have an individuality of marking which is often to be observed a double spotting, as if a second layer of shell with another system of spots had been deposited outside of a first layer. It has been suggested that the theory of protective coloring will not fully explain these markings, and that the individuality of these patterns should be ascribed rather to the fact that it affords the mother-bird opportunity for instant recognition of her own nest. The widest variation in this respect has been noted as to the guilemot. 30 distinctly different patterns of markings being shown in some collections. It has been observed also that the markings on the eggs of birds in captivity vary with the state of health and as to conditions of mind, as fear, anger and the like. It is notable that eggs which are laid in dark nests have a more uniform surface than eggs with markings, and it is to be expected as a matter of course that eggs would differ in size just as do the parent birds. A novice in the study of bird lore, however, is not prepared for the wide disparity in relative size with which eggs of different species are compared. The smallest egg known among birds is that of the humming bird, the smallest of the birds. This is quite as one would expect. But the cuckoo lays an egg which is but one-fifth of the size of that laid by the jackdaw, although the two parent birds are of the same size. The mature guilemot is about the same size as the raven, but its egg is three times larger. The egg of the New Zealand wingless bird, the kiwi, has a prodigious weight, fully one-fourth that of the parent, while the egg of the bird of paradise, a male or hen, which may be taken as typical, weighs about one-thirtieth as much as the adult fowl. The largest known bird's egg is that of the now extinct epyornis of Madagascar, which was 10 inches in its solid and was the largest egg of species now in existence that of the ostrich. Variations in the size of eggs, moreover, may occur in the same species in a different habitat. Thus the eggs of the great white heron in Europe are 40 percent larger than those of the same species in India.
The number of eggs laid in each clutch is constant for the individuals of the same species, but differs widely for different species. Many of the sea-going water birds lay but one egg a year — occasionally two. Those waterfowl whose young are brooded by parents lay from 2 to 12. The song birds and field birds generally lay four or five eggs in each clutch, but some few species do not lay more than two (as the pigeon) or three, while a few lay more — up to 10 or 12, or even 20, as is the case of the common partridge. Where two broods are raised in a year, of course the yearly production is doubled; and this, too, may happen in the case of birds which commonly rear but one brood, if the first nesting is destroyed by accident or otherwise. In several cases on record birds have laid the regulation clutch number again and again until exhausted, in the persistent endeavor to raise the yearly brood. The case of the common hen is in point: under natural conditions she would raise two broods of chicks during the year, from 13 to 15 eggs, hat a time. But under the exploitation of the poultryman, who removes the eggs from day to day, she continues laying for months at a time, producing up to 200 eggs per year.

Notable differences are found also in the texture and relative thickness of the shells of birds' eggs. Some are so highly burnished as to resemble polished metal — as the tinamous. The eggs of kingfishers and of some wood-peckers are glossy; those of ducks are waxen in appearance. Some are chalky and others are coated with a chalky crust of a different color from the hard smooth shell underneath — as with the cormorants and gannets, in which the egg is blue and the incrustation white. The shell of the ostrich's egg has the peculiarity of being deeply pitted. Reference to the accompanying plate will give a clearer idea of the principles cited than can be conveyed by mere explanation. See also Eggs.

**Eggs of Reptiles.** — Reptiles, like birds, are distinctly oviparous, with few exceptions. Their eggs are, however, laid by the heat of the sun, or of the fermentation of decaying vegetable matter. In the few exceptional instances referred to the young break out of the eggs as soon as they are laid, and in at least one instance — the stumpy-tailed lizard of Australia — the young complete their development and leave the eggs before they are laid. Among the snakes, too, most of the boas bring forth their young alive, and so do some of the deep-sea snakes. An exception to be noted in the case of the python, which lays from 15 to 100 eggs at a time and broods them until the young emerge.

The eggs of reptiles differ from those of birds in two respects — they are without a calcaceous shell, having a parchment-like skin instead. In shape they are more or less spherical, not ovoid or conoid. In size they are much smaller proportionally to the parent than is the case with the birds. The egg of the crocodile, for example, is about as large as that of a goose. The eggs of the giant tortoises of Galapagos are spherical and about the size of hens' eggs, and in contrast to those of other reptiles have hard calcaceous shells. Crocodiles as a rule lay their eggs in sand, in some cases digging out a pit two feet deep and depositing the eggs in two layers, with sand in between. The whole "nest" is then smoothed over and left to the sun's heat for hatching. The mother crocodile does not infrequently dig up the eggs a day or two before they hatch, excited by the noise and tumult of the hatched young in the shells. Sea turtles lay their eggs in holes scraped out of a sandy shore well above the reach of high water. The number laid sometimes reaches 100, and they are carefully covered with sand. The eggs of marine turtles are generally esteemed as food in the countries where they are plentiful.

**Eggs of Amphibia.** — Among the frogs and toads the eggs are spherical, with a thin membranous envelope, in which the embryo is distinctively visible surrounded with the yolk and with one or two outer coatings of a gelatinous substance. The latter is not noticeable when the eggs are first laid, but as they are laid in water the gelatinous substance swells into a relatively thick layer of slippery, non-soluble jelly. The eggs vary in size from one-twenty-fifth of an inch (with the ordinary toad) to nearly one-half an inch in diameter with the *Megaleophys longipes* of the Malay Peninsula, the eggs of which are not laid in water but hid in damp moss, the little frogs emerging in a "condition of complete development." The number of eggs laid by these frogs and toads which lay them in shallow pools is very large, reaching 12,000, and, as might be supposed, the destruction of these unprotected eggs in enormous. Some species of tree-frogs lay their eggs in a mass of froth on the leaves of branches which overhang a pool. When the young hatch out they drop into the water to complete their development. These frogs lay about 200 eggs at a time. A small New Guinea frog lays 12 to 18 eggs enclosed in a small elliptical sack which is set adrift in the waters of a running stream. Several of the toads and frogs are noted for carrying their eggs about with them, in the water or on land, as the case may be, until they hatch.

Amphibia, of which include the animals popularly called "lizards" and more correctly, newts and salamanders, the aquatic species lay their eggs in water. They are deposited one in a place, or in small clusters, and generally attached to water-weeds or bits of wood or stone on the bottom of the pond. The land varieties lay their eggs in a damp hole in the ground or in a hole in a tree trunk, sometimes as high up as 30 feet above the ground. The eggs are spherical for all species and generally about one-fourth of an inch in diameter. The giant aquatic salamander of Japan and China lays up to 500 eggs, which are in several separate clusters, the members of each being connected together by a membranous string. This same peculiarity has been noted in the case of a salamander or ray-finned fish in the streams of the eastern United States. There are, however, quite a number of species of these animals which do not lay eggs but bring forth their young alive.

**Eggs of Pisces.** — Some species of fish are oviparous, some are viviparous and a few ovo-viviparous. Owing to the obvious difficulty of observing animals whose habitat is deep water, there are many species about which nothing is known concerning their modes of reproduction.
EGGS OF FISHES AND LOWER ANIMALS

1 Egg of Shark
2 Egg of Crustaceps
3 Egg, with embryo of Goby
4 Spawn of parasitic Flatworm
5 Egg with embryo of Starfish
6 Egg of Garfish
7 Spawn of a nudibranch
8 Spawn of Squid
9 Spawn of Sea-squill
10 Spawn of Octopus
11 Egg of Cuttlefish
12 Egg of a flat-worm
13 Egg-capsule of Mantis
14 The same in cross-section
15 Egg of a butterfly
16 Egg of Bedbug
17 Egg of Beetle-mite
18 Structure of eggshell of a phyllo-pod crustacean
19 Egg of branchipod crustacean
Most of the shark-like fishes are viviparous, but in those cases in which they do lay eggs the latter are of considerable size, and, as with the common ground dog-fish, they are provided with a "shell" of tough, horny structure. Within is found a yolk surrounded with an albuminous layer, so that there is a close resemblance to the eggs of birds. The shell of the dog-fish egg is quite a well-known seashore object, with its oblong cushion shape and the long spinous hooks at each corner. It is only in fishes of this class that an envelope worthy of the term "shell" is produced. The eggs of other fishes have only a thin membranous covering, although in some cases this is hard to a degree and often adhesive, fixing itself to the first solid object that it comes in contact with. A few species lay their eggs on rocks or in clumps of weeds between high and low water, so that they are exposed to the atmosphere twice a day by the fluctuating tides. Others, among which are some of our common cat-fishes, lay but a few eggs and carry them attached to the gills, where they soon hatch. Reference has already been made to the great fecundity of the cod and turbot. In the same classification belong the salmon, shad and herring and many others who come up from deep water to lay their eggs in a wholly unprotected condition in the shallow shore or inland waters. The eggs of the herring, like those of the perch, are adhesive, and in this respect have a certain advantage against destruction. Most of the deep-sea fishes, however, lay egg-masses which are buoyant, and float about on the surface of the sea not only to the appetites of other dwellers in the sea but also to those of sea birds, so that comparatively few eventually reach maturity.

The eggs of several kinds of food fishes are esteemed as food delicacies, notably the roe of shad and herring, and caviar (caviar) made from the eggs of sturgeon and other fish.

Eggs of Insects.—When it is recalled that there are upwards of 300,000 known species of insects it will readily be seen that no befitting mention of the well-nigh innumerable variations in egg production and egg forms can be attempted within the necessary limits of this section. The student must be referred to the appropriate volumes noted in the bibliography below.

Most insects are oviparous, but within a few species the eggs are hatched within the body of the mother. The number of eggs laid as a "brood" ranges from one or two up to thousands. As a rule the number laid by the commoner insects is from 100 to 300. They are laid generally in groups of detached eggs or in small masses, though often singly, and attached to a leaf or twig of the plant which will furnish suitable food to the newly-hatched larva. The habits of bees and wasps in this respect are well known, and it needs only this passing mention to an instinctively out of the water surface, on the sub-surface, or the mud cells in which these insects lay their eggs and raise their young. The cluster of eggs rolled up in silk by the common house and garden spiders is a familiar sight. Doubtless the eggs of the butterflies and moths are the most interesting of all among the insects. They are very small, and within the outer membranous coating they contain the egg-cell and a supply of liquid food for its development. In form there is the greatest possible variety—globular, thimble-shaped, pear-shaped, cylindrical, purse-like, lens-shaped, turban-shaped and a multitude of other forms for which no simile can be found. Under the microscope they exhibit a wonderful variety of flutings, sculpturings, lacework and other forms of decorative surfaces. Although most of them are white or greenish their colors range into cream, yellow, red, blue and brown. Generally but one laying is made, but there are a few species which produce two or even three broods in the season. In tropical countries there may be several more than this during the longer life of the adult females.

Eggs of Crustacea.—The eggs of the crustacea are notable as containing a larger quantity of yolk in proportion to their size than do those of any other animal. In nearly all species the eggs are carried around by the female during the early stages of their development, either attached to some portion of her body or in a brood pouch. They do not always hatch into the complete form, but shed. Reference has already been made to the great fecundity of the cod and turbot. In the same classification belong the salmon, shad and herring and many others who come up from deep water to lay their eggs in a wholly unprotected condition in the shallow shore or inland waters. The eggs of the herring, like those of the perch, are adhesive, and in this respect have a certain advantage against destruction. Most of the deep-sea fishes, however, lay egg-masses which are buoyant, and float about on the surface of the sea not only to the appetites of other dwellers in the sea but also to those of sea birds, so that comparatively few eventually reach maturity.

The eggs of several kinds of food fishes are esteemed as food delicacies, notably the roe of shad and herring, and caviar (caviar) made from the eggs of sturgeon and other fish.

Eggs of Insects.—When it is recalled that there are upwards of 300,000 known species of insects it will readily be seen that no befitting mention of the well-nigh innumerable variations in egg production and egg forms can be attempted within the necessary limits of this section. The student must be referred to the appropriate volumes noted in the bibliography below.

Most insects are oviparous, but within a few species the eggs are hatched within the body of the mother. The number of eggs laid as a "brood" ranges from one or two up to thousands. As a rule the number laid by the commoner insects is from 100 to 300. They are laid generally in groups of detached eggs or in small masses, though often singly, and attached to a leaf or twig of the plant which will furnish suitable food to the newly-hatched larva. The habits of bees and wasps in this respect are well known, and it needs only this passing mention to an instinctively out of the water surface, on the sub-surface, or the mud cells in which these insects lay their eggs and raise their young. The cluster of eggs rolled up in silk by the common house and garden spiders is a familiar sight. Doubtless the eggs of the butterflies and moths are the most interesting of all among the insects. They are very small, and within the outer membranous coating they contain the egg-cell and a supply of liquid food for its development. In form there is the greatest possible variety—globular, thimble-shaped, pear-shaped, cylindrical, purse-like, lens-shaped, turban-shaped and a multitude of other forms for which no simile can be found. Under the microscope they exhibit a wonderful variety of flutings, sculpturings, lacework and other forms of decorative surfaces. Although most of them are white or greenish their colors range into cream, yellow, red, blue and brown. Generally but one laying is made, but there are a few species which produce two or even three broods in the season. In tropical countries there may be several more than this during the longer life of the adult females.

Eggs of Mollusks.—As a rule the mollusks are oviparous, but there is a considerable number, among them many of the land and fresh water snails, which are ovoviviparous. The number of eggs laid at a time varies greatly. Helix aspersa lays from 40 to 100 in a little depression hollowed out between the roots of a tuft of grass and covers them with earth. The oyster lays from 300,000 when young to 60,000-000 when a full-grown adult. These eggs are almost microscopic in size, and they are devoured in thousands by fish and other marine animals. Some of the tropical mussels lay eggs as large as those of pigeons, but with a "shell" of tough membrane without a lime deposit to harden them. One of the peculiarities of egg production among the mollusks is their fashion of laying them in small clusters in capsules or egg-pods. These capsules are usually joined together in curious ways by fibrous bands or strings or ribbons, which sometimes are three feet in length and in others are an inextricably tangled snarl. One of the most curious of all is the cochlolysta of the Philippines, which lays its eggs in a folded leaf at the tops of the highest forest trees. For an intimate study of this most interesting section of animal life the books mentioned below are of advantage.

Eggs of Lower Animals.—Among the higher worms may be mentioned the leech, which burrows into the soft mud above the level of the edge of the pool in which it lives and lays several eggs with yolks in a capsule. The tiny leeches upon hatching find their way out of the burrow and into the water. The tapeworm develops a clutch of eggs in each of the lower joints of its long body. As the eggs approach the larval stage the joints break loose and become simply egg-pods, similar to those of the mollusks. Many of the lower worms lay eggs which are relatively large and are protected by an enveloping capsule. The starfish and sea-urchin pass their eggs out through pores at the base of the arms.
or spines, and there they are held in small hollows between the armoring plates until they are so far developed that they push themselves loose of their own accord and swim off independently. The egg production of the crinoids is similar, the eggs being retained within the body cavity until they have reached the larval form, when they are released. The ophiuroids carry their eggs about with them in a pouch, where the young develop. In the sponge the egg forms in a cell within the body and undergoes considerable development, so that at the time when it is thrown off by the parent body it has become a larva capable of independent existence.

EGG INDUSTRY. From an economic point of view eggs constitute one of the most important commodities in commerce, and the egg industry, both in the production and distribution, is of notable proportions. Although eggs are used in some extent in the arts, it is as an esteemed food product that they maintain their importance.

In the United States the egg industry is continually growing. Formerly this country relied largely upon importation for its supply of eggs, but now it exports far more of them than it obtains from foreign ports. The increasing use of incubators has led to a large increase in the number of eggs laid by native fowls, which need no longer waste their time in hatching them, but may devote it to the more profitable labours of producing them. Eggs are among the products in this branch of American industry that although the number of fowls kept in this country is now relatively smaller than formerly, yet by the adoption of labor- and time-saving machines there has been a constantly increasing output of eggs.

The production of poultry and eggs is one of the most profitable industries. A statistician of authority estimates that a hen may realize 400 per cent of profit for her owner. In 33 States and Territories the value of eggs exceeds the value of the poultry product. The egg product in the United States amounts to more, when measured by dollars and cents, than the combined gold and silver production.

According to the figures of the 1910 census, taking for the year 1900 (the year so far compiled for this industry), the total production of eggs for that year as reported from 4,883,507 farms (out of the 6,361,502 farms at that time in the United States) amounted to 1,457,865,772 dozen, valued at $281,157,980. Of the entire production only 926,465,767 dozen (65 per cent) were sold on the market, the remainder being consumed on the farms or used in hatching. Among the several States, Missouri held the lead in market production, selling a total of 71,886,145 dozen. Iowa was second, with a market production of 70,835,349 dozen. Then followed in the order of their contributions to the grand total: Ohio, 69,575,637 dozen; Illinois, 62,036,857 dozen; Indiana, 53,899,416 dozen; Kansas, 52,833,155 dozen; Pennsylvania, 52,446,077 dozen; New York, 48,074,681 dozen; Michigan, 38,568,386 dozen; Minnesota, 34,347,776 dozen; Wisconsin, 32,268,836 dozen. These 10 States produced nearly three-fifths of the entire output of the country.

The average value per dozen of the 1909 egg production was 19.3 cents. They were cheapest in Texas (15 cents); Oklahoma and Arkansas (16 cents); Louisiana, Kentucky, Tennessee, Nebraska, Kansas and South Dakota (17 cents), and dearest in Arizona, Nevada and Massachusetts (30 cents), and Rhode Island and Connecticut (20 cents). The average prices in 1917 ranged from 28½ cents in March to 56 cents in December in the New York market, and from 24½ cents to 43 cents in the Saint Louis market.

Eggs are an article of food eaten all over the country in 1917 varied from the high of 14 cents in Alabama, Arkansas and Texas, and of 28 cents in Massachusetts, Connecticut and New Jersey for April to the high of 30 cents in Alabama and 63 cents in Rhode Island for December.

By far the larger percentage of eggs used for food are those of the hen. There are, however, a considerable and constantly increasing proportion of duck eggs on the market and a few goose eggs. The average hen's eggs weigh 24 ounces to the dozen, and as food it is customary to regard a dozen eggs as equivalent to a pound of lean beef. This is a very close approximation with the balance somewhat in favor of the eggs. A dozen duck eggs weigh 30 to 42 ounces, and a dozen goose eggs about 80 ounces. Pound for pound, eggs contain the same amount of fat as beef, and about half as much protein but being more digestible when properly cooked, their food value cannot be gauged exclusively by their chemical constitution. The yolk of the egg contains a large portion, containing all the fat of the egg and the important phospho-protein lecitho-vitellin. The white is chiefly albumen and water. In the general make-up of the egg the shell constitutes about one-tenth, the yolk about three-tenths and the white six-tenths. The yolk and white taken together, as ordinarily eaten, show a composition of proteins, 13.5 per cent; fat, 10.8 per cent; water, 73.8 per cent, and mineral salts, 1.6 per cent. The eggs of ducks and geese have a higher fat content, reaching 14.5 per cent, with a correspondingly smaller percentage of water. When fresh, eggs have a specific gravity between 1.08 and 1.09, growing slightly less day by day when kept in the open air; so if an egg sinks in a salt solution of 1.07 specific gravity the egg is fresh; otherwise, it is bad. Preservation.—Eggs freshly laid will retain their fine qualities for several days if kept in a cool place. The nearer this temperature approaches 40° F the better, for eggs which have been fermented develop a certain amount of internal heat due to the vital processes which are beginning, and a low temperature is necessary to halt these changes. For this reason unfertilized eggs, if they can be had, are
much easier to keep in perfect condition. Where eggs are to be preserved for long periods cold-weather air cannot enter and set up fermentations. They are usually rubbed over with butter, lard, gum-water, etc., or, which is still better, they are placed in layers, small end down, in very dry ashes or fine dry salt, packed in tubs and boxes and put in dry, cool place, protected from severe cold in winter. This is, however, more expensive but a highly recommended plan is to dip the eggs into a solution of silicate of soda, or water glass, allowing them to drain until dry, before packing in salt. If the dipping is too thoroughly done, egg salt packing may be dispensed with. An alternate method is to pack the eggs closely in an earthen jar or crock and pour over them the silicate solution, allowing them to remain in the solution until used. The process by which the eggs are made up is to add one part of the water glass as obtained from the druggist to 10 parts of water for the dipping process or to 12 parts of water where the eggs are kept in the solution.

Marketing.—It is estimated that the losses in marketing eggs in the United States amount to not less than $50,000,000 a year. This enormous loss is nearly all due to carelessness in the first handling—that by the producer. In a lot of 700,000 eggs bought recently in Kansas, more than 60,000 eggs were what are called in the egg trade "rots"; that is, they were bad when sold by the farmer—carelessly gathered, perhaps from long abandoned nests, or improperly kept after gathering, or kept too long before selling. Further losses on this one purchase of eggs, mostly through thin shells, which broke in transport, brought the total loss up to 14.3 per cent of the amount paid for the lot. Obviously nine-tenths of this loss could have been avoided with proper care. Such experiences have led to the establishment of a trade rule among merchants who buy eggs in quantities for shipment that they are to be paid for "loss off"; meaning that no eggs which come under the classifications of "rots," "spots," "blood rings," or "leakers,"—terms which explain themselves—shall be paid for. This rule, where enforced, has already operated to reduce materially the number of bad eggs in consigned shipments.

The considerably larger price commanded by fresh, freshly-picked eggs in salt packing has stimulated marketing in several channels outside of the regular commercial routine. One of the most successful of these plans has been the marketing through creameries. The farmer who delivers milk or cream daily or semi-weekly, as the case may be, may without any extra labor deliver the surplus eggs raised on his farm within a day or so of their laying. The creamery, gathering from many farms, can ship daily an egg product of the highest market value. The cost of such handling in connection with the regular business of the creamery has been proved to be not above one cent per dozen eggs shipped. In other localities where creameries do not exist, associations known as "Community Egg Circles" have been formed, especially for this co-operative shipping of strictly fresh eggs, bringing their members from five to eight cents per dozen above the current prices for ordinary trade eggs.

Another avenue open to the individual producer is the parcel post. Eggs packed in containers approved by the Post Office Department can be sent direct to the individual consumer and the highest prices realized. Some of these approved containers are substantial, and may be returned empty at a nominal cost and so used many times, distributing their first cost over several shipments. However, the special packaging need not be used if the eggs are securely packed with excelsior, or other similar material, in strong baskets or boxes.

Eggs are also marketed in bulk after being broken, either in the liquid form or in a powder after drying. These methods are in use where very large supplies of eggs are produced at a long distance from the point where they can be sold at a reasonable profit, and where the probability is that they would suffer a serious loss through breakage during transport. In the preparation of eggs for powdering, much the utmost care must be taken that they are not contaminated by any dirt in the process of breaking. When the cans are full they are frozen, and in this condition are transported and delivered to the consumer—generally some large wholesale cake-baking establishment. In some instances borax is added to the liquid eggs as a preservative, but this is highly objectionable where they are to be used as food. These liquid eggs are also used in certain leather dressing processes. The drying or powdering of eggs is done by forcing the liquid eggs through tiny apertures in a plate into a drying chamber at such temperature that the egg spray is dried to the condition of meal before it reaches the collecting tray at the bottom.

Cooking.—The cooking of eggs has the effect of rendering their valuable proteins more or less indigestible, according to the degree of the cooking. While this is largely a matter of indifference to the person in good health, it is often of some importance to an invalid or convalescent. In the latter event the less cooking the better. Many times the egg is simply beaten up, perhaps with the addition of wine, and eaten raw. Another approved method of preparing eggs for persons of delicate digestion is to "jelly" them by pouring a quart of boiling water upon an egg or two and letting the vessel stand on the back of the stove where it will keep hot but not boil. In about 10 minutes the egg will be turned into a soft semi-transparent jelly, in which condition all its protein is readily assimilable.

Poisoning by Eggs.—In some persons eggs when eaten produce symptoms of poisoning. This is to be considered an abnormal condition. But in several instances unmistakable indications of poisoning from eggs have been observed in persons who are not usually affected by such diet. This kind of poisoning is attributed to the presence of toxic bacteria, and is considered to be of the same nature as poinaine poisoning and to be treated in the same manner. Fortunately such cases are rare. See Pouzarov.

Foreign Trade in Eggs.—Notwithstanding the very large domestic production, the United States imports a very large quantity of dried and frozen eggs annually. In 1917 this im-
portation amounted to 17,268,379 pounds, valued at $3,589,504. During the year the exports were also 1,012,398 dozen eggs, valued at $7,270,543, and canned eggs valued at $171,112.

EGG, or EGGG, £g, one of the Hebrides Islands, belonging to Inverness-shire, Scotland. It is south of Skye. Its length is a little less than seven miles.

EGG-BIRD, or SOOTY TERN (Sterna fuscata), a member of the gull family (Laridae) famous for its edible eggs and breeding societies for "wide-awake fairs." It is found about warm seas throughout the world and abounds in the West Indies. Ascension Island is one of its most frequent breeding places. Occasionally it wanders as far as New England. The adults have beautiful black and white plumage, but the young are of a light, sooty color. The nests are rough excavations in the sand, in which three eggs are usually deposited. They are much valued and the gathering of them in the spring months forms an important West Indian industry. The name egg-bird is also commonly applied to other marine birds of the gull family, as guillemots, murrets, etc., whose eggs are of economic value.

EGG DANCE, a once popular diversion in England, Scotland, Holland and some other parts of Europe; now confined chiefly to Spain; among the people of Valencia. A number of eggs, placed in a prescribed form upon the dancing floor, and among them a blindfolded dancer moved as best he might, to music; the object being to execute an intricate dance without breaking the eggs. The music, like the arrangement of the eggs, was also prescribed.

EGG-EATING SNAKE, the Dasyelis scabra, a tree-climbing species of coluber found in Central and South Africa. It is about two feet in length and is unique in its adaptation to the diet from which it derives its name. While the jaws are almost destitute of teeth and capable of great distension, a substitute for the teeth is found in the elongated hypophyses or vertical processes of several of the cervical vertebrae, which project into the interior of the oesophagus as a series of saw-like teeth tipped with very hard cement substance. This mechanism enables the snake to secure the entire contents of an egg as large as a hen's without losing a drop. At all events the egg shell is only broken by contact with the oesophageal teeth when safely within the throat, when the contents are swallowed and the shell regurgitated. Consult Fitzsimmons, 'Snakes of South Africa' (Cape Town 1912).

EGG-FISH, any of various plectognath "globe-fishes," which swim themselves into the shells of other eggs. See GLOBE-FISH.

EGG-PLANT, GUINEA-QUASH, or aUBERGINE (Solanum melongena), a plant of the family Solanaceae. Its original home is supposed to be the East Indies, where it has long been cultivated and from whence it has been introduced into all tropical countries and many temperate ones for the sake of its large fleshly egg-like fruit, yellow or purple fruits, which are used as a vegetable. In the United States it is cultivated as far north as Long Island and southern Michigan. In the North the plants must be started under glass and transplanted to the field or garden after danger of frost has passed. They do best upon rich deep loams well exposed to the sun. Their principal insect enemies are practically the same as those of the potato and are combated similarly. (See INSECTICIDE.) Their fungus diseases are few and rarely devastating. The principal ones are a bacterial disease caused by Bacillus solanacearum, for which there seems to be no satisfactory remedy; anthracnose (Glascosporium melongena), which appears as pink-spotted sunken areas upon the fruits; leaf spot (Botrytis allasticae fasicularis), which turns the affected leaves brown and produces holes in them, and a mild Latorites fascicularis), which produces soft spots with gray moldy surfaces upon the fruits. Each of these parasites may appear upon any of the green parts, but the parts mentioned are the usual ones. They may all be controlled by timely applications of any standard fungicide.

EGG-TOOTH, the hard calcareous protuberance at the tip of the beak or snout of a chick or young reptile which is born within an egg having a tough shell, designed to assist the embryo in escaping. It wears a hole through the lining membrane of the egg, and then acts as a file to bore through the outer shell or wedge apart any crack. It is possessed by all birds and by such reptiles (turtles, lizards and snakes) as develop in eggs with hard shells. Soon after the embryo goes free this excescence falls of, and in this special temporary provision for a special non-recurring exigency, Darwin found an example, in his view, of the results of natural selection.

EGG-URCHIN, or SEA-EGG, any of the typical globose sea-urchins, especially those of the genus Echinos. Similarly, the flat, bun-shaped echinoderms are called 'cake-urchins,' the cockle-shaped (spatangoids) 'heart-urchins,' and so on. See ECHINODERMATA; SEA-URCHIN.

EGGA, £g, East Africa, town of Gando, in the Niger territories on the Niger. Pottery, iron, gold and wooden-wares, thick cloth, generally dyed blue, and leather are manufactured, and an active river trade is carried on, especially in ivory. Pop. 12,000.

EGGAR-MOTH. See EGGER-MOTH.

EGGELING, Julius, English philologist: b. Hecklingen, Germany, 12 July 1842. After studying at Breslau and Berlin, he went to England and in 1867, and on account of his knowledge of Sanskrit was appointed secretary and librarian of the Royal Asiatic Society 1869, becoming professor of Sanskrit at University College 1872 and filling the same chair at the University of Edinburgh three years later. Among his publi-

EGHAM, England, an urban district in the county of Surrey, on the Thames, about 21 miles west of London. It contains the Royal Indian Engineering College, the Royal HOLLOW College for Women, and the HOLLOW Sanatorium. Runnymede, where King John signed Magna Charta, is in Egham parish. Pop. 12,551.

EGHERT, ég-ért, Saint, an English saint: b. Northumbria; d. Iona, 24 April 729. While studying in Ireland at the convent of Rathmelsing he was afflicted by the plague prevalent in 664. He vowed that if he recovered he would leave his country and preach to the German pagans, recite his psalter daily and fast a day and a night in every week. In 686 he started out but was compelled to return by a storm. He then took up his residence on the Island Hy from which he sent Wibird, an Englishman, to the Frisians in 690. In 692 he sent forth Willibrord and his companions. He introduced the Roman method of celebrating Easter and the Roman tunsire. In 716 he went to Iona and persuaded the monks to follow the same customs.

EGIL SKALLAGRIMSSON, ágil skál-la-grím'sön, Icelandic bard or skald of the 10th century. He distinguished himself by his war-like exploits and adventures in Norway, Denmark and England. Having killed in combat the son of Erik Blóðóx, King of Norway, he was doomed to death on being subsequently taken prisoner by that prince in Northumbria, but was allowed to redeem his life by giving a specimen of his powers as an improvisatore. He immediately composed and recited a poem in praise of Erik, known as 'Hvíðfæðhús') ('The Redemption of the Head'), which procured him his life and liberty. Other works by him are 'Sonatorrek,' composed on the death of his favorite son; 'Arinbjarnardrápa' concerning the life and deeds of his friend Arinbjörn, and the 'Skjalaldarmál.' The Icelandic poem 'Egill's Saga' tells his story and contains his poems. The 'Saga' was edited by Jónsson (1884-86 and 1894) and translated by N. M. Petersen (1862). The latest edition is by Dahlérup and Jónsson (1901).

EGINHARD, ágin'hard, or EINHARD, in'hard, German historian: b. East Franconia, now the grand duchy of Hesse-Darmstadt, about 770; d. Sehingenstadt, 14 March 840. He was educated in the school of the abbot of Fulda. When about 25 he entered the service of Charlemagne and thereafter was in all things.
the confidant of the emperor and one of the principal ministers. One of his great charges was the construction and repair of the public buildings. He was inseparable from the emperor, residing in the palace and accompanying him in all his journeys and expeditions: the only time when they were temporarily separated was when, in 806, the secretary — for such he has always been called — went to Rome to obtain the approval of the Pope of a provision of Charlemagne's testament or will for a division of the empire among his sons after his death. That Egernhard possessed considerable learning appears from his extant writings. During his many years of study at Fulda he acquired all the secular knowledge obtainable in his time, and in the palace of Charlemagne enjoyed the advantage of converse with the celebrated Alcuin. It was on the advice of the secretary that Charlemagne in 813 made his eldest son, Louis, his partner in the empire; and when Louis, on his father's death, became sole emperor, he retained Egernhard in all his high offices. Egernhard remained his tutor of his sons the Lothair. In 830 he withdrew from the court and retired to his large estates at Mulheim, where he had erected a splendid basilica and founded various religious institutes, and there passed the remainder of his life. He changed the name of the place to Seligenstadt (City of the Saints, namely, of Saints Marcellinus and Petrus). In this basilica he was entombed, beside his wife, Emma, who died four years before him. According to an old legend Emma was the daughter of Charlemagne, and as this went on the story of their love adventures was added to from the fount of romantic imagination: in fact, Charlemagne had no daughter named Emma, and the lady Emma who was Egernhard's wife was the sister of Bernhartius, bishop of Worms. Egernhard's 'Life of Charlemagne (Vita Caroli Magni), written in Latin in a style and imitative of Suetonius 'Lives of the Caesars,' is one of the most notable literary monuments of the Middle Ages; it was long used as a manual of school instruction and hence has survived in a multitude of manuscript copies. Another work of his is a history of the Franks, 'Annales Regum Francorum, Pippini Caroli Magni et Hludovici Imperatoris' (Annals of the Frankish Kings Pippin, Charlemagne, and Louis the Emperor). There are extant 62 of his 'Letters' (Epistolae), and a narrative of the translation from Rome to Seligenstadt of the relics of Saints Marcellinus and Petrus ('Historia Translatiorum Beatorum Christi Martyrum Marcellini et Petri'). To the narrative he appends a poem on the same subject.

EGLANTINE, eg'lán-tín or -tīn, the name of the sweet-brier rose (Rosa rubiginosa), in the poetry of Chaucer, Spenser and Shakespeare. The name is common among the English poets; the earlier ones applied it to any wild rose, and Milton seems to confound several different species, among them the honesuckle, etc. The flower is a native of Europe and Asia, but was easily naturalized in America and being hardy, it withstand the severe winters. It is now wild in the territory from Nova Scotia to Ontario, extending to Tennessee, and east to the shores of Virginia. It is from four to six feet high, sometimes growing as a long spike-covered wand. The pink or white flowers are a marked feature of the flora of this region, during the months of June and July. A climbing-shrub, native of Asia (Rosa eglanteria), with yellow, ill-smelling flowers, is also sometimes called eglantine.

EGLESTON, Thomas, American mineralogist: b. New York, 9 Dec. 1832; d. 15 Jan. 1900. He was graduated at Yale College in 1854, and at the School of Mines in Paris in 1860. He returned to the United States in 1861; and soon afterward was appointed director of the mineralogical collection and laboratory of the Smithsonian Institution in Washington. He established the School of Mines as a department of Columbia College, New York; and was professor of mineralogy and metallurgy there 1864-97. He was a United States commissioner to examine the fortifications of the Atlantic coast in 1869; and one of the jurors of the International Exposition at Vienna in 1873. He became a member of the Legion of Honor (1890); president of the American Institute of Mining Engineers, of which he was also a founder, and vice-president of the New York Academy of Sciences 1896-98. He wrote 'The Metallurgy of Gold and Silver in the United States'; 'A Catalogue of Minerals and Their Synonyms'; 'Life of Major-General Paterson, of the Revolutionary army.

EGLI, Ņg'lē, Johann Jakob, Swiss geographer: b. Uhwiessen-Laufen, canton of Zurich, 17 May 1825; d. 1896. He was made professor of geography at the University of Zurich 1883, after teaching in several schools, and did much for the accuracy, precision and uniformity of the nomenclature of geography. Among his earlier works are a thesis on the 'Discovery of the Sources of the Nile'; and a 'Geography of Switzerland.' Later works include 'Nomina Geographica: Versuch einer allgemeinen geographischen Onomatologie'; 'Geschichte der geographischen Namenkunde'; 'Neue Erdkunde'; 'Neue Handelsgeographie'; and 'Der Völkergeist in den geographischen Namen.'

EGLON, A king of Moab mentioned in the book of Judges (iii, 13, iv, 20). He formed a confederation with the Amalekites and Amorites ruling over them for 18 years until assassinated by Ehud, the Benjamite, who defeated his leaderless peoples and gave them deliverance and a peace which lasted for 80 years. Eglon is also the name of a place mentioned in the book of Joshua (x, 1-27, xii, 12) located not far from Lachish. Its king Dehir joined the Confederation opposed to Joshua's advance into Canaan. After the battle of Ajalon it was destroyed. It is located in the plain of the Jordan Valley, situated on the western coast of the Dead Sea. Eglon was founded by leading archaeologists with T. Nejleh.

EGMONT, Justus van, Flemish painter: b. Leyden 1602; d. Antwerp, 8 Jan. 1674. He was a pupil of Caspar Van den Hoeck (1651) and later of Rubens. He established himself at Paris where he became court painter to Louis XIII and Louis XIV, and was also one of the founders of the Royal Academy of Painting and Sculpture 1648. Among his works are 'Portrait of Archduke Leopold William'; two 'Portraits of Philip IV. of Spain' (Vienna,
EGMONT - EGOIST

Schiller rightly defined 'Egmont' as a tragedy of character. There is no development of qualities in the hero, there is no dramatic conflict; there is merely a stratagem in which he allows himself to be ensnared. Egmont's very being is fatal, not his conduct; for he does not act. The whole piece is rather potentially than actually dynamic. There are clear-cut figures and popular scenes of truly Shakespearean vividness, but the prevailing quality is picturesqueness — else, perhaps, Beethoven's incidental music would not be so appropriate. Completed in Italy, the play reveals Goethe's later classical tendencies chiefly in the scrupulous finish of its prose style. Translated by F. Boott (Boston 1871), and by Sir Walter Scott (London 1850). Edited by Max Winkler (Boston 1896).

WILLIAM G. HOWARD.

EGOISM, eg-o-lsm (Fr. egoïsme; Lat. ego- *), an ethical term used in the sense of selfishness; it is specially opposed to altruism. The word is sometimes used to denote a meta-physical system of subjective idealism, in which the Ego is the sole reality. See ALTRUISM; ETHICS.

EGOIST. The (originally published in 1879), may be described as the quintessence of Meredithism. That "acute and honorable minoritv," which in the eighteen-nineties made it their business to "discover" the great obscure novelist, with James Thomson, Stevenson and Henley, as their earliest proselytizers, proclaimed 'The Egoist' as the supreme and occult masterpiece of its author. Appreciation of it was made the touchstone of literary intelligence, much as the later novels of Henry James, a decade or so afterward, were regarded by "the precious" of the day. When one says that in those novels of Henry James we have the method and manner of 'The Egoist' run to seed, we go far toward characterizing the book from which James learned not wisely but too well. 'The Egoist' is an exceedingly elaborate, and so to say microscopic, study of a sort of sophisticated modern Lovelace, Sir Willoughby Patterne of Patterne Hall, handsome, cultivated, rich, charming. and fit model for the pitiless eye of that "Comic Spirit," which Meredith invokes as his muse, a muse that loves "to uncover ridiculousness in imposing figures," supremely and mathematically absurd in his very perfection and complacency. *Comedy," says Meredith by way of prelude, "is a game played to throw reflections upon social life, and it deals with human nature in the drawing-room of civilized men and women, where we have no dust of the struggling outer world, no mire, no violent crashes, to make the correctness of the representation convincing. In other words, the atmosphere of 'The Egoist' is one of intense social rarefaction, and the drama, such as it is, that of 'Fire Shades,' only perceptible by the highly specialized beings accustomed to draw health in that social ether. The hard brilliancy of 'The Egoist' is but a shadow. It is more like one of Congreve's comedies than anything else in English, but it is Congreve psychologized; for instead of human beings for *dramatis persona*, we have highly attenuated states of mind, and the philosopher takes the place of the man of the world. The style and mood also too frequently remind one of John
Donne, fantastically metaphysical and perversely obscure. While we admit that it is an amazing tour de force, one cannot but ask whether it was worth doing, after all? That such great powers should have expended themselves, with such an array and exuberance, upon so slight a theme—a theme, of course, so essentially human, but in the case of ‘The Egoist,’ attacked in so frivolous a manifestation. It is probable, as time goes on, that ‘The Egoist’ will be regarded chiefly as a "curiosity of literature," one of those cryptic great books such as the ‘Titan’ of Jean Paul Richter—a writer who, with Carlyle, exercised great influence for the bad on Meredith’s style. Book-lovers here and there may pick out this and that fine thing and passage, but posterity, on the whole, will scarcely have time or patience to read ‘The Egoist.’

RICHARD LE GALLJENNE

EGRET, ेegrêt, a name given to those species of white herons which have the feathers of the lower part of the back elongated and their webs disunited owing to the absence of barbules at certain seasons of the year, so that they form a soft and flowing train reaching to the tail or beyond it. Their forms are more graceful than those of the common herons. The name is properly applied to two American and two European species. The American egret (Ardea egretta) has the plumage white, or partly of a creamy color. The bird is found breeding from Florida to New York and along the shores of the Mexican Gulf to Texas, but ranges much beyond these limits at other seasons. Its food consists of the smaller quadrupeds, small fishes, frogs, lizards, snakes and insects, and it breeds like other herons. The long silky filaments of the back are hardly to be seen, except about the love season, which varies from early spring to midsummer according to climate; both sexes possess this train and many are shot to obtain these feathers for ornamental purposes. The little white egret or snowy heron of America (A. candidissima) is much smaller and has a crest on the head which the large species lacks. In habits and distribution it is similar. The European egret (A. alba) is about 40 inches long, of a pure white plumage. It is common in southern Europe, but comparatively rare in the northern and central parts. The little egret (A. garretta) is about 22 inches long from bill to end of tail; the plumage is white; from the hinder part of the head spring two narrow feathers four inches long. This species is most abundant in southern Europe and northern Africa; it occasionally wanders as far as England. The Louisiana heron (A. tricolor) and the reddish egret (A. rubescens) are often given the name, but the latter is white in winter only, and the former is partly colored at all seasons. Both are maritime birds, chiefly of the Gulf States.
